MySQL 8.0 Reference Manual
Including MySQL NDB Cluster 8.0
Abstract

This is the MySQL™ Reference Manual. It documents MySQL 8.0 through 8.0.18, as well as NDB Cluster releases based on version 8.0 of NDB through 8.0.18-ndb-8.0.18, respectively. It may include documentation of features of MySQL versions that have not yet been released. For information about which versions have been released, see the MySQL 8.0 Release Notes.

MySQL 8.0 features. This manual describes features that are not included in every edition of MySQL 8.0; such features may not be included in the edition of MySQL 8.0 licensed to you. If you have any questions about the features included in your edition of MySQL 8.0, refer to your MySQL 8.0 license agreement or contact your Oracle sales representative.

For notes detailing the changes in each release, see the MySQL 8.0 Release Notes.

For legal information, including licensing information, see the Preface and Legal Notices.

For help with using MySQL, please visit the MySQL Forums, where you can discuss your issues with other MySQL users.

2.11 Upgrading MySQL .......................................................... 231
  2.11.1 Before You Begin ...................................................... 231
  2.11.2 Upgrade Paths .......................................................... 232
  2.11.3 What the MySQL Upgrade Process Upgrades ...................... 233
  2.11.4 Changes in MySQL 8.0 ................................................. 236
  2.11.5 Preparing Your Installation for Upgrade ......................... 246
  2.11.6 Upgrading MySQL Binary or Package-based Installations on Unix/Linux .................. 249
  2.11.7 Upgrading MySQL with the MySQL Yum Repository .............. 254
  2.11.8 Upgrading MySQL with the MySQL APT Repository .............. 255
  2.11.9 Upgrading MySQL with the MySQL SLES Repository .......... 255
  2.11.10 Upgrading MySQL on Windows .................................... 255
  2.11.11 Upgrading a Docker Installation of MySQL ..................... 257
  2.11.12 Upgrade Troubleshooting ......................................... 257
  2.11.13 Rebuilding or Repairing Tables or Indexes ................... 258
  2.11.14 Copying MySQL Databases to Another Machine ................ 259

2.12 Downgrading MySQL ..................................................... 260

2.13 Perl Installation Notes ................................................ 260
  2.13.1 Installing Perl on Unix .......................................... 261
  2.13.2 Installing ActiveState Perl on Windows ......................... 261
  2.13.3 Problems Using the Perl DBI/DBD Interface ..................... 262

3 Tutorial ............................................................................. 265
  3.1 Connecting to and Disconnecting from the Server ................. 265
  3.2 Entering Queries ............................................................... 266
  3.3 Creating and Using a Database ........................................... 269
    3.3.1 Creating and Selecting a Database ................................ 270
    3.3.2 Creating a Table ...................................................... 271
    3.3.3 Loading Data into a Table .......................................... 272
    3.3.4 Retrieving Information from a Table ............................ 274
  3.4 Getting Information About Databases and Tables .................. 287
  3.5 Using mysql in Batch Mode ............................................. 288
  3.6 Examples of Common Queries ............................................ 289
    3.6.1 The Maximum Value for a Column ................................. 290
    3.6.2 The Row Holding the Maximum of a Certain Column .......... 290
    3.6.3 Maximum of Column per Group .................................... 291
    3.6.4 The Rows Holding the Group-wise Maximum of a Certain Column ........................................... 291
    3.6.5 Using User-Defined Variables .................................... 292
    3.6.6 Using Foreign Keys .................................................. 292
    3.6.7 Searching on Two Keys ............................................. 294

22.2.6 NDB Cluster Example with Tables and Data .................................................. 3438
22.2.7 Safe Shutdown and Restart of NDB Cluster .................................................. 3441
22.2.8 Upgrading and Downgrading NDB Cluster .................................................. 3442
22.3 Configuration of NDB Cluster ............................................................... 3443
  22.3.1 Quick Test Setup of NDB Cluster .......................................................... 3443
  22.3.2 Overview of NDB Cluster Configuration Parameters, Options, and Variables .... 3445
  22.3.3 NDB Cluster Configuration Files ............................................................. 3464
  22.3.4 Using High-Speed Interconnects with NDB Cluster ................................. 3643
22.4 NDB Cluster Programs ............................................................... 3643
  22.4.1 ndb — The NDB Cluster Data Node Daemon ........................................... 3644
  22.4.2 ndbinfo_select_all — Select From ndbinfo Tables ................................. 3651
  22.4.3 ndbmtl — The NDB Cluster Data Node Daemon (Multi-Threaded) ............... 3653
  22.4.4 ndb_mgm — The NDB Cluster Management Server Daemon ....................... 3654
  22.4.5 ndb_mgm — The NDB Cluster Management Client ................................... 3662
  22.4.6 ndb_blob_tool — Check and Repair BLOB and TEXT columns of NDB Cluster Tables ................................................................. 3664
  22.4.7 ndb_config — Extract NDB Cluster Configuration Information .................. 3666
  22.4.8 ndb_delete_all — Delete All Rows from an NDB Table ............................ 3675
  22.4.9 ndb_desc — Describe NDB Tables .......................................................... 3676
  22.4.10 ndb_drop_index — Drop Index from an NDB Table ................................ 3682
  22.4.11 ndb_drop_table — Drop an NDB Table ................................................ 3683
  22.4.12 ndb_error_reporter — NDB Error-Reporting Utility ............................... 3683
  22.4.13 ndb_import — Import CSV Data Into NDB ............................................ 3685
  22.4.14 ndb_index_stat — NDB Index Statistics Utility ..................................... 3698
  22.4.15 ndb_move_data — NDB Data Copy Utility ............................................. 3703
  22.4.16 ndb_perror — Obtain NDB Error Message Information ............................ 3706
  22.4.17 ndb_print_backup_file — Print NDB Backup File Contents ....................... 3708
  22.4.18 ndb_print_file — Print NDB Disk Data File Contents ............................ 3708
  22.4.19 ndb_print_frag_file — Print NDB Fragment List File Contents ................ 3709
  22.4.20 ndb_print_schema_file — Print NDB Schema File Contents ..................... 3709
  22.4.21 ndb_print_sys_file — Print NDB System File Contents .......................... 3710
  22.4.22 ndb_redo_log_reader — Check and Print Content of Cluster Redo Log .......... 3713
  22.4.23 ndb_restore — Restore an NDB Cluster Backup ..................................... 3734
  22.4.24 ndb_select_all — Print Rows from an NDB Table .................................. 3743
  22.4.25 ndb_select_count — Print Row Counts for NDB Tables ........................... 3737
  22.4.26 ndb_setup.py — Start browser-based Auto-Installer for NDB Cluster .......... 3738
  22.4.27 ndb_show_tables — Display List of NDB Tables ................................... 3742
  22.4.28 ndb_size.pl — NDBCLUSTER Size Requirement Estimator ......................... 3743
  22.4.29 ndb_top — View CPU usage information for NDB threads ......................... 3746
  22.4.30 ndb_watcher — Wait for NDB Cluster to Reach a Given Status ................. 3751
  22.4.31 Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs ................................................................. 3754
  22.5 Management of NDB Cluster ....................................................... 3759
    22.5.1 Summary of NDB Cluster Start Phases ............................................... 3760
    22.5.2 Commands in the NDB Cluster Management Client .................................. 3761
    22.5.3 Online Backup of NDB Cluster .......................................................... 3766
    22.5.4 MySQL Server Usage for NDB Cluster .............................................. 3771
    22.5.5 Performing a Rolling Restart of an NDB Cluster .................................. 3773
    22.5.6 Event Reports Generated in NDB Cluster ............................................ 3775
    22.5.7 NDB Cluster Log Messages ............................................................... 3785
    22.5.8 NDB Cluster Single User Mode .......................................................... 3800
    22.5.9 Quick Reference: NDB Cluster SQL Statements ..................................... 3801
    22.5.10 ndbinfo: The NDB Cluster Information Database ................................. 3804
    22.5.11 INFORMATION_SCHEMA Tables for NDB Cluster .................................. 3851
    22.5.12 NDB Cluster Security Issues ........................................................... 3852
    22.5.13 NDB Cluster Disk Data Tables .......................................................... 3858
    22.5.14 Online Operations with ALTER TABLE in NDB Cluster ......................... 3866
    22.5.15 Adding NDB Cluster Data Nodes Online ............................................. 3869
24.5.4 The View WITH CHECK OPTION Clause .................................................. 4024

Preface and Legal Notices

This is the Reference Manual for the MySQL Database System, version 8.0, through release 8.0.18. Differences between minor versions of MySQL 8.0 are noted in the present text with reference to release numbers (8.0.x). For license information, see the Legal Notices.

This manual is not intended for use with older versions of the MySQL software due to the many functional and other differences between MySQL 8.0 and previous versions. If you are using an earlier release of the MySQL software, please refer to the appropriate manual. For example, MySQL 5.7 Reference Manual covers the 5.7 series of MySQL software releases.

Licensing information—MySQL 8.0. This product may include third-party software, used under license. If you are using a Commercial release of MySQL 8.0, see the MySQL 8.0 Commercial Release License Information User Manual for licensing information, including licensing information relating to third-party software that may be included in this Commercial release. If you are using a Community release of MySQL 8.0, see the MySQL 8.0 Community Release License Information User Manual for licensing information, including licensing information relating to third-party software that may be included in this Community release.

Licensing information—MySQL NDB Cluster 8.0. If you are using a Community release of MySQL NDB Cluster 8.0, see the MySQL NDB Cluster 8.0 Community Release License Information User Manual for licensing information, including licensing information relating to third-party software that may be included in this Community release.

Legal Notices

Copyright © 1997, 2019, Oracle and/or its affiliates. All rights reserved.

This software and related documentation are provided under a license agreement containing restrictions on use and disclosure and are protected by intellectual property laws. Except as expressly permitted in your license agreement or allowed by law, you may not use, copy, reproduce, translate, broadcast, modify, license, transmit, distribute, exhibit, perform, publish, or display any part, in any form, or by any means. Reverse engineering, disassembly, or decompilation of this software, unless required by law for interoperability, is prohibited.

The information contained herein is subject to change without notice and is not warranted to be error-free. If you find any errors, please report them to us in writing.

If this is software or related documentation that is delivered to the U.S. Government or anyone licensing it on behalf of the U.S. Government, then the following notice is applicable:

U.S. GOVERNMENT END USERS: Oracle programs, including any operating system, integrated software, any programs installed on the hardware, and/or documentation, delivered to U.S. Government end users are "commercial computer software" pursuant to the applicable Federal Acquisition Regulation and agency-specific supplemental regulations. As such, use, duplication, disclosure, modification, and adaptation of the programs, including any operating system, integrated software, any programs installed on the hardware, and/or documentation, shall be subject to license terms and license restrictions applicable to the programs. No other rights are granted to the U.S. Government.

This software or hardware is developed for general use in a variety of information management applications. It is not developed or intended for use in any inherently dangerous applications, including applications that may create a risk of personal injury. If you use this software or hardware in dangerous applications, then you shall be responsible to take all appropriate fail-safe, backup, redundancy, and other measures to ensure its safe use. Oracle Corporation and its affiliates disclaim any liability for any damages caused by use of this software or hardware in dangerous applications.

Oracle and Java are registered trademarks of Oracle and/or its affiliates. Other names may be trademarks of their respective owners.
Intel and Intel Xeon are trademarks or registered trademarks of Intel Corporation. All SPARC trademarks are used under license and are trademarks or registered trademarks of SPARC International, Inc. AMD, Opteron, the AMD logo, and the AMD Opteron logo are trademarks or registered trademarks of Advanced Micro Devices. UNIX is a registered trademark of The Open Group.

This software or hardware and documentation may provide access to or information about content, products, and services from third parties. Oracle Corporation and its affiliates are not responsible for and expressly disclaim all warranties of any kind with respect to third-party content, products, and services unless otherwise set forth in an applicable agreement between you and Oracle. Oracle Corporation and its affiliates will not be responsible for any loss, costs, or damages incurred due to your access to or use of third-party content, products, or services, except as set forth in an applicable agreement between you and Oracle.

This documentation is NOT distributed under a GPL license. Use of this documentation is subject to the following terms:

You may create a printed copy of this documentation solely for your own personal use. Conversion to other formats is allowed as long as the actual content is not altered or edited in any way. You shall not publish or distribute this documentation in any form or on any media, except if you distribute the documentation in a manner similar to how Oracle disseminates it (that is, electronically for download on a Web site with the software) or on a CD-ROM or similar medium, provided however that the documentation is disseminated together with the software on the same medium. Any other use, such as any dissemination of printed copies or use of this documentation, in whole or in part, in another publication, requires the prior written consent from an authorized representative of Oracle. Oracle and/or its affiliates reserve any and all rights to this documentation not expressly granted above.

**Documentation Accessibility**

For information about Oracle’s commitment to accessibility, visit the Oracle Accessibility Program website at http://www.oracle.com/pls/topic/lookup?ctx=acc&id=docacc.

**Access to Oracle Support**

Oracle customers that have purchased support have access to electronic support through My Oracle Support. For information, visit http://www.oracle.com/pls/topic/lookup?ctx=acc&id=info or visit http://www.oracle.com/pls/topic/lookup?ctx=acc&id=trs if you are hearing impaired.

The MySQL™ software delivers a very fast, multithreaded, multi-user, and robust SQL (Structured Query Language) database server. MySQL Server is intended for mission-critical, heavy-load production systems as well as for embedding into mass-deployed software. Oracle is a registered trademark of Oracle Corporation and/or its affiliates. MySQL is a trademark of Oracle Corporation and/or its affiliates, and shall not be used by Customer without Oracle’s express written authorization. Other names may be trademarks of their respective owners.

The MySQL software is Dual Licensed. Users can choose to use the MySQL software as an Open Source product under the terms of the GNU General Public License (http://www.fsf.org/licenses/) or can purchase a standard commercial license from Oracle. See http://www.mysql.com/company/legal/licensing/ for more information on our licensing policies.

The following list describes some sections of particular interest in this manual:

- For a discussion of MySQL Database Server capabilities, see Section 1.3.2, “The Main Features of MySQL”.

- For an overview of new MySQL features, see Section 1.4, “What Is New in MySQL 8.0”. For information about the changes in each version, see the Release Notes.

- For installation instructions, see Chapter 2, *Installing and Upgrading MySQL*. For information about upgrading MySQL, see Section 2.11, “Upgrading MySQL”.

- For a tutorial introduction to the MySQL Database Server, see Chapter 3, *Tutorial*.

- For information about configuring and administering MySQL Server, see Chapter 5, *MySQL Server Administration*.

- For information about security in MySQL, see Chapter 6, *Security*.

- For information about setting up replication servers, see Chapter 17, *Replication*.
• For information about MySQL Enterprise, the commercial MySQL release with advanced features and management tools, see Chapter 30, MySQL Enterprise Edition.

• For answers to a number of questions that are often asked concerning the MySQL Database Server and its capabilities, see Appendix A, MySQL 8.0 Frequently Asked Questions.

• For a history of new features and bug fixes, see the Release Notes.

Important

To report problems or bugs, please use the instructions at Section 1.7, “How to Report Bugs or Problems”. If you find a sensitive security bug in MySQL Server, please let us know immediately by sending an email message to <secalert_us@oracle.com>. Exception: Support customers should report all problems, including security bugs, to Oracle Support.

1.1 About This Manual

This is the Reference Manual for the MySQL Database System, version 8.0, through release 8.0.18. Differences between minor versions of MySQL 8.0 are noted in the present text with reference to release numbers (8.0.<x>). For license information, see the Legal Notices.

This manual is not intended for use with older versions of the MySQL software due to the many functional and other differences between MySQL 8.0 and previous versions. If you are using an earlier release of the MySQL software, please refer to the appropriate manual. For example, MySQL 5.7 Reference Manual covers the 5.7 series of MySQL software releases.

Because this manual serves as a reference, it does not provide general instruction on SQL or relational database concepts. It also does not teach you how to use your operating system or command-line interpreter.

The MySQL Database Software is under constant development, and the Reference Manual is updated frequently as well. The most recent version of the manual is available online in searchable form at https://dev.mysql.com/doc/. Other formats also are available there, including HTML, PDF, and EPUB versions.

The Reference Manual source files are written in DocBook XML format. The HTML version and other formats are produced automatically, primarily using the DocBook XSL stylesheets. For information about DocBook, see http://docbook.org/

The source code for MySQL itself contains internal documentation written using Doxygen. The generated Doxygen content is available https://dev.mysql.com/doc/index-other.html. It is also possible to generate this content locally from a MySQL source distribution using the instructions at Section 2.9.7, “Generating MySQL Doxygen Documentation Content”.

If you have questions about using MySQL, join the MySQL Community Slack, or ask in our forums; see Section 1.6.2, “MySQL Community Support at the MySQL Forums”. If you have suggestions concerning additions or corrections to the manual itself, please send them to the http://www.mysql.com/company/contact/.

This manual was originally written by David Axmark and Michael “Monty” Widenius. It is maintained by the MySQL Documentation Team, consisting of Chris Cole, Paul DuBois, Margaret Fisher, Edward Gilmore, Stefan Hinz, David Moss, Philip Olson, Daniel Price, Daniel So, and Jon Stephens.

1.2 Typographical and Syntax Conventions

This manual uses certain typographical conventions:

• Text in this style is used for SQL statements; database, table, and column names; program listings and source code; and environment variables. Example: “To reload the grant tables, use the FLUSH PRIVILEGES statement.”
Typographical and Syntax Conventions

- **Text in this style** indicates input that you type in examples.
- **Text in this style** indicates the names of executable programs and scripts, examples being `mysql` (the MySQL command-line client program) and `mysqld` (the MySQL server executable).
- **Text in this style** is used for variable input for which you should substitute a value of your own choosing.
- **Text in this style** is used for emphasis.
- **Text in this style** is used in table headings and to convey especially strong emphasis.
- **Text in this style** is used to indicate a program option that affects how the program is executed, or that supplies information that is needed for the program to function in a certain way. *Example*: “The `--host` option (short form `-h`) tells the `mysql` client program the hostname or IP address of the MySQL server that it should connect to”.
- File names and directory names are written like this: “The global `my.cnf` file is located in the `/etc` directory.”
- Character sequences are written like this: “To specify a wildcard, use the `'%'` character.”

When commands are shown that are meant to be executed from within a particular program, the prompt shown preceding the command indicates which command to use. For example, `shell>` indicates a command that you execute from your login shell, `root-shell>` is similar but should be executed as `root`, and `mysql>` indicates a statement that you execute from the `mysql` client program:

```
shell> type a shell command here
root-shell> type a shell command as root here
mysql> type a mysql statement here
```

In some areas different systems may be distinguished from each other to show that commands should be executed in two different environments. For example, while working with replication the commands might be prefixed with `master` and `slave`:

```
master> type a mysql command on the replication master here
slave> type a mysql command on the replication slave here
```

The “shell” is your command interpreter. On Unix, this is typically a program such as `sh`, `csh`, or `bash`. On Windows, the equivalent program is `command.com` or `cmd.exe`, typically run in a console window.

When you enter a command or statement shown in an example, do not type the prompt shown in the example.

Database, table, and column names must often be substituted into statements. To indicate that such substitution is necessary, this manual uses `db_name`, `tbl_name`, and `col_name`. For example, you might see a statement like this:

```
mysql> SELECT col_name FROM db_name.tbl_name;
```

This means that if you were to enter a similar statement, you would supply your own database, table, and column names, perhaps like this:

```
mysql> SELECT author_name FROM biblio_db.author_list;
```

SQL keywords are not case-sensitive and may be written in any lettercase. This manual uses uppercase.

In syntax descriptions, square brackets ("[" and "]") indicate optional words or clauses. For example, in the following statement, `IF EXISTS` is optional:

```
DROP TABLE [IF EXISTS] tbl_name
```
When a syntax element consists of a number of alternatives, the alternatives are separated by vertical bars ("|"). When one member from a set of choices may be chosen, the alternatives are listed within square brackets (“[” and “]”):

```
TRIM([BOTH | LEADING | TRAILING] [remstr] FROM) str
```

When one member from a set of choices must be chosen, the alternatives are listed within braces (“{” and “}”):

```
{DESCRIBE | DESC} tbl_name [col_name | wild]
```

An ellipsis (…) indicates the omission of a section of a statement, typically to provide a shorter version of more complex syntax. For example, SELECT ... INTO OUTFILE is shorthand for the form of SELECT statement that has an INTO OUTFILE clause following other parts of the statement.

An ellipsis can also indicate that the preceding syntax element of a statement may be repeated. In the following example, multiple reset_option values may be given, with each of those after the first preceded by commas:

```
RESET reset_option [, reset_option] ...
```

Commands for setting shell variables are shown using Bourne shell syntax. For example, the sequence to set the CC environment variable and run the configure command looks like this in Bourne shell syntax:

```
shell> CC=gcc ./configure
```

If you are using csh or tcsh, you must issue commands somewhat differently:

```
shell> setenv CC gcc
shell> ./configure
```

### 1.3 Overview of the MySQL Database Management System

#### 1.3.1 What is MySQL?

MySQL, the most popular Open Source SQL database management system, is developed, distributed, and supported by Oracle Corporation.

- **MySQL is a database management system.**

  A database is a structured collection of data. It may be anything from a simple shopping list to a picture gallery or the vast amounts of information in a corporate network. To add, access, and process data stored in a computer database, you need a database management system such as MySQL Server. Since computers are very good at handling large amounts of data, database management systems play a central role in computing, as standalone utilities, or as parts of other applications.

- **MySQL databases are relational.**

  A relational database stores data in separate tables rather than putting all the data in one big storeroom. The database structures are organized into physical files optimized for speed. The logical model, with objects such as databases, tables, views, rows, and columns, offers a flexible programming environment. You set up rules governing the relationships between different data fields, such as one-to-one, one-to-many, unique, required or optional, and “pointers” between different tables. The database enforces these rules, so that with a well-designed database, your application never sees inconsistent, duplicate, orphan, out-of-date, or missing data.
The SQL part of “MySQL” stands for “Structured Query Language”. SQL is the most common standardized language used to access databases. Depending on your programming environment, you might enter SQL directly (for example, to generate reports), embed SQL statements into code written in another language, or use a language-specific API that hides the SQL syntax.

SQL is defined by the ANSI/ISO SQL Standard. The SQL standard has been evolving since 1986 and several versions exist. In this manual, “SQL-92” refers to the standard released in 1992, “SQL:1999” refers to the standard released in 1999, and “SQL:2003” refers to the current version of the standard. We use the phrase “the SQL standard” to mean the current version of the SQL Standard at any time.

- **MySQL software is Open Source.**
  
  Open Source means that it is possible for anyone to use and modify the software. Anybody can download the MySQL software from the Internet and use it without paying anything. If you wish, you may study the source code and change it to suit your needs. The MySQL software uses the GPL (GNU General Public License), http://www.fsf.org/licenses/, to define what you may and may not do with the software in different situations. If you feel uncomfortable with the GPL or need to embed MySQL code into a commercial application, you can buy a commercially licensed version from us. See the MySQL Licensing Overview for more information (http://www.mysql.com/company/legal/licensing/).

- **The MySQL Database Server is very fast, reliable, scalable, and easy to use.**
  
  If that is what you are looking for, you should give it a try. MySQL Server can run comfortably on a desktop or laptop, alongside your other applications, web servers, and so on, requiring little or no attention. If you dedicate an entire machine to MySQL, you can adjust the settings to take advantage of all the memory, CPU power, and I/O capacity available. MySQL can also scale up to clusters of machines, networked together.

  MySQL Server was originally developed to handle large databases much faster than existing solutions and has been successfully used in highly demanding production environments for several years. Although under constant development, MySQL Server today offers a rich and useful set of functions. Its connectivity, speed, and security make MySQL Server highly suited for accessing databases on the Internet.

- **MySQL Server works in client/server or embedded systems.**
  
  The MySQL Database Software is a client/server system that consists of a multithreaded SQL server that supports different back ends, several different client programs and libraries, administrative tools, and a wide range of application programming interfaces (APIs).

  We also provide MySQL Server as an embedded multithreaded library that you can link into your application to get a smaller, faster, easier-to-manage standalone product.

- **A large amount of contributed MySQL software is available.**
  
  MySQL Server has a practical set of features developed in close cooperation with our users. It is very likely that your favorite application or language supports the MySQL Database Server.

  The official way to pronounce “MySQL” is “My Ess Que Ell” (not “my sequel”), but we do not mind if you pronounce it as “my sequel” or in some other localized way.

### 1.3.2 The Main Features of MySQL

This section describes some of the important characteristics of the MySQL Database Software. In most respects, the roadmap applies to all versions of MySQL. For information about features as they are introduced into MySQL on a series-specific basis, see the “In a Nutshell” section of the appropriate Manual:
• MySQL 8.0: Section 1.4, “What Is New in MySQL 8.0”
• MySQL 5.7: What Is New in MySQL 5.7
• MySQL 5.6: What Is New in MySQL 5.6
• MySQL 5.5: What Is New in MySQL 5.5

Internals and Portability

• Written in C and C++.
• Tested with a broad range of different compilers.
• Works on many different platforms. See https://www.mysql.com/support/supportedplatforms/database.html.
• For portability, uses CMake in MySQL 5.5 and up. Previous series use GNU Automake, Autoconf, and Libtool.
• Tested with Purify (a commercial memory leakage detector) as well as with Valgrind, a GPL tool (http://developer.kde.org/~sewardj/).
• Uses multi-layered server design with independent modules.
• Designed to be fully multithreaded using kernel threads, to easily use multiple CPUs if they are available.
• Provides transactional and nontransactional storage engines.
• Uses very fast B-tree disk tables (MyISAM) with index compression.
• Designed to make it relatively easy to add other storage engines. This is useful if you want to provide an SQL interface for an in-house database.
• Uses a very fast thread-based memory allocation system.
• Executes very fast joins using an optimized nested-loop join.
• Implements in-memory hash tables, which are used as temporary tables.
• Implements SQL functions using a highly optimized class library that should be as fast as possible. Usually there is no memory allocation at all after query initialization.
• Provides the server as a separate program for use in a client/server networked environment, and as a library that can be embedded (linked) into standalone applications. Such applications can be used in isolation or in environments where no network is available.

Data Types

• Many data types: signed/unsigned integers 1, 2, 3, 4, and 8 bytes long, FLOAT, DOUBLE, CHAR, VARCHAR, BINARY, VARBINARY, TEXT, BLOB, DATE, TIME, DATETIME, TIMESTAMP, YEAR, SET, ENUM, and OpenGIS spatial types. See Chapter 11, Data Types.
• Fixed-length and variable-length string types.

Statements and Functions

• Full operator and function support in the SELECT list and WHERE clause of queries. For example:

```sql
mysql> SELECT CONCAT(first_name, ' ', last_name) -> FROM citizen -> WHERE income/dependents > 10000 AND age > 30;
```
The Main Features of MySQL

• Full support for SQL GROUP BY and ORDER BY clauses. Support for group functions (COUNT(), AVG(), STD(), SUM(), MAX(), MIN(), and GROUP_CONCAT()).

• Support for LEFT OUTER JOIN and RIGHT OUTER JOIN with both standard SQL and ODBC syntax.

• Support for aliases on tables and columns as required by standard SQL.

• Support for DELETE, INSERT, REPLACE, and UPDATE to return the number of rows that were changed (affected), or to return the number of rows matched instead by setting a flag when connecting to the server.

• Support for MySQL-specific SHOW statements that retrieve information about databases, storage engines, tables, and indexes. Support for the INFORMATION_SCHEMA database, implemented according to standard SQL.

• An EXPLAIN statement to show how the optimizer resolves a query.

• Independence of function names from table or column names. For example, ABS is a valid column name. The only restriction is that for a function call, no spaces are permitted between the function name and the "()" that follows it. See Section 9.3, “Keywords and Reserved Words”.

• You can refer to tables from different databases in the same statement.

Security

• A privilege and password system that is very flexible and secure, and that enables host-based verification.

• Password security by encryption of all password traffic when you connect to a server.

Scalability and Limits

• Support for large databases. We use MySQL Server with databases that contain 50 million records. We also know of users who use MySQL Server with 200,000 tables and about 5,000,000,000 rows.

• Support for up to 64 indexes per table. Each index may consist of 1 to 16 columns or parts of columns. The maximum index width for InnoDB tables is either 767 bytes or 3072 bytes. See Section 15.6.1.6, “Limits on InnoDB Tables”. The maximum index width for MyISAM tables is 1000 bytes. See Section 16.2, “The MyISAM Storage Engine”. An index may use a prefix of a column for CHAR, VARCHAR, BLOB, or TEXT column types.

Connectivity

• Clients can connect to MySQL Server using several protocols:

  • Clients can connect using TCP/IP sockets on any platform.

  • On Windows systems, clients can connect using named pipes if the server is started with the named_pipe system variable enabled. Windows servers also support shared-memory connections if started with the shared_memory system variable enabled. Clients can connect through shared memory by using the --protocol=memory option.

  • On Unix systems, clients can connect using Unix domain socket files.

• MySQL client programs can be written in many languages. A client library written in C is available for clients written in C or C++, or for any language that provides C bindings.

• APIs for C, C++, Eiffel, Java, Perl, PHP, Python, Ruby, and Tcl are available, enabling MySQL clients to be written in many languages. See Chapter 28, Connectors and APIs.

• The Connector/ODBC (MyODBC) interface provides MySQL support for client programs that use ODBC (Open Database Connectivity) connections. For example, you can use MS Access to connect
to your MySQL server. Clients can be run on Windows or Unix. Connector/ODBC source is available. All ODBC 2.5 functions are supported, as are many others. See MySQL Connector/ODBC Developer Guide.

- The Connector/J interface provides MySQL support for Java client programs that use JDBC connections. Clients can be run on Windows or Unix. Connector/J source is available. See MySQL Connector/J 5.1 Developer Guide.

- MySQL Connector/NET enables developers to easily create .NET applications that require secure, high-performance data connectivity with MySQL. It implements the required ADO.NET interfaces and integrates into ADO.NET aware tools. Developers can build applications using their choice of .NET languages. MySQL Connector/NET is a fully managed ADO.NET driver written in 100% pure C#. See MySQL Connector/NET Developer Guide.

Localization

- The server can provide error messages to clients in many languages. See Section 10.11, “Setting the Error Message Language”.

- Full support for several different character sets, including latin1 (cp1252), german, big5, ujis, several Unicode character sets, and more. For example, the Scandinavian characters “å”, “ä” and “ö” are permitted in table and column names.

- All data is saved in the chosen character set.

- Sorting and comparisons are done according to the default character set and collation. is possible to change this when the MySQL server is started (see Section 10.3.2, “Server Character Set and Collation”). To see an example of very advanced sorting, look at the Czech sorting code. MySQL Server supports many different character sets that can be specified at compile time and runtime.

- The server time zone can be changed dynamically, and individual clients can specify their own time zone. See Section 5.1.13, “MySQL Server Time Zone Support”.

Clients and Tools

- MySQL includes several client and utility programs. These include both command-line programs such as mysqldump and mysqladmin, and graphical programs such as MySQL Workbench.

- MySQL Server has built-in support for SQL statements to check, optimize, and repair tables. These statements are available from the command line through the mysqlcheck client. MySQL also includes myisamchk, a very fast command-line utility for performing these operations on MyISAM tables. See Chapter 4, MySQL Programs.

- MySQL programs can be invoked with the --help or -? option to obtain online assistance.

1.3.3 History of MySQL

We started out with the intention of using the mSQL database system to connect to our tables using our own fast low-level (ISAM) routines. However, after some testing, we came to the conclusion that mSQL was not fast enough or flexible enough for our needs. This resulted in a new SQL interface to our database but with almost the same API interface as mSQL. This API was designed to enable third-party code that was written for use with mSQL to be ported easily for use with MySQL.

MySQL is named after co-founder Monty Widenius's daughter, My. The name of the MySQL Dolphin (our logo) is “Sakila,” which was chosen from a huge list of names suggested by users in our “Name the Dolphin” contest. The winning name was submitted by Ambrose Twbez, an Open Source software developer from Swaziland, Africa. According to Ambrose, the feminine name Sakila has its roots in SiSwati, the local language of Swaziland. Sakila is also the name of a town in Arusha, Tanzania, near Ambrose's country of origin, Uganda.

1.4 What Is New in MySQL 8.0
This section summarizes what has been added to, deprecated in, and removed from MySQL 8.0. A companion section lists MySQL server options and variables that have been added, deprecated, or removed in MySQL 8.0. See Section 1.5, “Server and Status Variables and Options Added, Deprecated, or Removed in MySQL 8.0”:

• Features Added in MySQL 8.0
• Features Deprecated in MySQL 8.0
• Features Removed in MySQL 8.0

Features Added in MySQL 8.0

The following features have been added to MySQL 8.0:

• **Data dictionary.** MySQL now incorporates a transactional data dictionary that stores information about database objects. In previous MySQL releases, dictionary data was stored in metadata files and nontransactional tables. For more information, see Chapter 14, *MySQL Data Dictionary*.

• **Atomic data definition statements (Atomic DDL).** An atomic DDL statement combines the data dictionary updates, storage engine operations, and binary log writes associated with a DDL operation into a single, atomic transaction. For more information, see Section 13.1.1, “Atomic Data Definition Statement Support”.

• **Upgrade procedure.** Previously, after installation of a new version of MySQL, the MySQL server automatically upgrades the data dictionary tables at the next startup, after which the DBA is expected to invoke `mysql_upgrade` manually to upgrade the system tables in the `mysql` schema, as well as objects in other schemas such as the `sys` schema and user schemas.

As of MySQL 8.0.16, the server performs the tasks previously handled by `mysql_upgrade`. After installation of a new MySQL version, the server now automatically performs all necessary upgrade tasks at the next startup and is not dependent on the DBA invoking `mysql_upgrade`. In addition, the server updates the contents of the help tables (something `mysql_upgrade` did not do). A new `--upgrade` server option provides control over how the server performs automatic data dictionary and server upgrade operations. For more information, see Section 2.11.3, “What the MySQL Upgrade Process Upgrades”.

• **Security and account management.** These enhancements were added to improve security and enable greater DBA flexibility in account management:

  • The grant tables in the `mysql` system database are now InnoDB (transactional) tables. Previously, these were MyISAM (nontransactional) tables. The change of grant table storage engine underlies an accompanying change to the behavior of account-management statements. Previously, an account-management statement (such as `CREATE USER` or `DROP USER`) that named multiple users could succeed for some users and fail for others. Now, each statement is transactional and either succeeds for all named users or rolls back and has no effect if any error occurs. The statement is written to the binary log if it succeeds, but not if it fails; in that case, rollback occurs and no changes are made. For more information, see Section 13.1.1, “Atomic Data Definition Statement Support”.

  • A new `caching_sha2_password` authentication plugin is available. Like the `sha256_password` plugin, `caching_sha2_password` implements SHA-256 password hashing, but uses caching to address latency issues at connect time. It also supports more connection protocols and does not require linking against OpenSSL for RSA key pair-based password-exchange capabilities. See Section 6.4.1.3, “Caching SHA-2 Pluggable Authentication”.

    The `caching_sha2_password` and `sha256_password` authentication plugins provide more secure password encryption than the `mysql_native_password` plugin, and `caching_sha2_password` provides better performance than `sha256_password`. Due to these superior security and performance characteristics of `caching_sha2_password`, it is now the preferred authentication plugin, and is also the default authentication plugin rather than...
mysql_native_password. For information about the implications of this change of default plugin for server operation and compatibility of the server with clients and connectors, see caching_sha2_password as the Preferred Authentication Plugin.

- MySQL now supports roles, which are named collections of privileges. Roles can be created and dropped. Roles can have privileges granted to and revoked from them. Roles can be granted to and revoked from user accounts. The active applicable roles for an account can be selected from among those granted to the account, and can be changed during sessions for that account. For more information, see Section 6.2.10, “Using Roles”.

- MySQL now incorporates the concept of user account categories, with system and regular users distinguished according to whether they have the SYSTEM_USER privilege. See Section 6.2.11, “Account Categories”.

- Previously, it was not possible to grant privileges that apply globally except for certain schemas. This is now possible if the partial_revokes system variable is enabled. See Section 6.2.12, “Privilege Restriction Using Partial Revokes”.

- The GRANT statement has an AS user [WITH ROLE] clause that specifies additional information about the privilege context to use for statement execution. This syntax is visible at the SQL level, although its primary purpose is to enable uniform replication across all nodes of grantor privilege restrictions imposed by partial revokes, by causing those restrictions to appear in the binary log. See Section 13.7.1.6, “GRANT Syntax”.

- MySQL now maintains information about password history, enabling restrictions on reuse of previous passwords. DBAs can require that new passwords not be selected from previous passwords for some number of password changes or period of time. It is possible to establish password-reuse policy globally as well as on a per-account basis.

It is now possible to require that attempts to change account passwords be verified by specifying the current password to be replaced. This enables DBAs to prevent users from changing password without proving that they know the current password. It is possible to establish password-verification policy globally as well as on a per-account basis.

Accounts are now permitted to have dual passwords, which enables phased password changes to be performed seamlessly in complex multiple-server systems, without downtime.

These new capabilities provide DBAs more complete control over password management. For more information, see Section 6.2.15, “Password Management”.

- MySQL now supports FIPS mode, if compiled using OpenSSL, and an OpenSSL library and FIPS Object Module are available at runtime. FIPS mode imposes conditions on cryptographic operations such as restrictions on acceptable encryption algorithms or requirements for longer key lengths. See Section 6.5, “FIPS Support”.

- The SSL context the server uses for new connections now is reconfigurable at runtime. This capability may be useful, for example, to avoid restarting a MySQL server that has been running so long that its SSL certificate has expired. See Server-Side Runtime Configuration for Encrypted Connections.

- OpenSSL 1.1.1 supports the TLS v1.3 protocol for encrypted connections, and MySQL now supports TLS v1.3 as well, if compiled using OpenSSL 1.1.1 or higher. See Section 6.3.5, “Encrypted Connection Protocols and Ciphers”.

- MySQL now sets the access control granted to clients on the named pipe to the minimum necessary for successful communication on Windows. Newer MySQL client software can open named pipe connections without any additional configuration. If older client software cannot be upgraded immediately, the new named_pipe_full_access_group system variable can be used to give a Windows group the necessary permissions to open a named pipe connection. Membership in the full-access group should be restricted and temporary.
• **Resource management.** MySQL now supports creation and management of resource groups, and permits assigning threads running within the server to particular groups so that threads execute according to the resources available to the group. Group attributes enable control over its resources, to enable or restrict resource consumption by threads in the group. DBAs can modify these attributes as appropriate for different workloads. Currently, CPU time is a manageable resource, represented by the concept of “virtual CPU” as a term that includes CPU cores, hyperthreads, hardware threads, and so forth. The server determines at startup how many virtual CPUs are available, and database administrators with appropriate privileges can associate these CPUs with resource groups and assign threads to groups. For more information, see Section 8.12.5, “Resource Groups”.

• **Table encryption management.** Table encryption can now be managed globally by defining and enforcing encryption defaults. The `default_table_encryption` variable defines an encryption default for newly created schemas and general tablespace. The encryption default for a schema can also be defined using the `DEFAULT ENCRYPTION` clause when creating a schema. By default, a table inherits the encryption of the schema or general tablespace it is created in. Encryption defaults are enforced by enabling the `table_encryption_privilege_check` variable. The privilege check occurs when creating or altering a schema or general tablespace with an encryption setting that differs from the `default_table_encryption` setting, or when creating or altering a table with an encryption setting that differs from the default schema encryption. The `TABLE_ENCRYPTION_ADMIN` privilege permits overriding default encryption settings when `table_encryption_privilege_check` is enabled. For more information, see Defining an Encryption Default for Schemas and General Tablespaces.

• **InnoDB enhancements.** These InnoDB enhancements were added:
  
  - The current maximum auto-increment counter value is written to the redo log each time the value changes, and saved to an engine-private system table on each checkpoint. These changes make the current maximum auto-increment counter value persistent across server restarts. Additionally:
    - A server restart no longer cancels the effect of the `AUTO_INCREMENT = N` table option. If you initialize the auto-increment counter to a specific value, or if you alter the auto-increment counter value to a larger value, the new value is persisted across server restarts.
    - A server restart immediately following a `ROLLBACK` operation no longer results in the reuse of auto-increment values that were allocated to the rolled-back transaction.
    - If you modify an `AUTO_INCREMENT` column value to a value larger than the current maximum auto-increment value (in an `UPDATE` operation, for example), the new value is persisted, and subsequent `INSERT` operations allocate auto-increment values starting from the new, larger value.
  
  For more information, see Section 15.6.1.4, “AUTO_INCREMENT Handling in InnoDB”, and InnoDB AUTO_INCREMENT Counter Initialization.

  - When encountering index tree corruption, InnoDB writes a corruption flag to the redo log, which makes the corruption flag crash safe. InnoDB also writes in-memory corruption flag data to an engine-private system table on each checkpoint. During recovery, InnoDB reads corruption flags from both locations and merges results before marking in-memory table and index objects as corrupt.

  - The InnoDB memcached plugin supports multiple `get` operations (fetching multiple key-value pairs in a single memcached query) and range queries. See Section 15.19.4, “InnoDB memcached Multiple get and Range Query Support”.

  - A new dynamic variables, `innodb_deadlock_detect`, may be used to disable deadlock detection. On high concurrency systems, deadlock detection can cause a slowdown when numerous threads wait for the same lock. At times, it may be more efficient to disable deadlock detection and rely on the `innodb_lock_wait_timeout` setting for transaction rollback when a deadlock occurs.
• The new `INFORMATION_SCHEMA.INNODB_CACHED_INDEXES` table reports the number of index pages cached in the InnoDB buffer pool for each index.

• InnoDB temporary tables are now created in the shared temporary tablespace, `ibtmp1`.

• The InnoDB tablespace encryption feature supports encryption of redo log and undo log data. See Redo Log Encryption, and Undo Log Encryption.

• InnoDB supports `NOWAIT` and `SKIP LOCKED` options with `SELECT ... FOR SHARE` and `SELECT ... FOR UPDATE` locking read statements. `NOWAIT` causes the statement to return immediately if a requested row is locked by another transaction. `SKIP LOCKED` removes locked rows from the result set. See Locking Read Concurrency with NOWAIT and SKIP LOCKED.

  `SELECT ... FOR SHARE` replaces `SELECT ... LOCK IN SHARE MODE`, but `LOCK IN SHARE MODE` remains available for backward compatibility. The statements are equivalent. However, `FOR UPDATE` and `FOR SHARE` support `NOWAIT`, `SKIP LOCKED`, and `OF tbl_name` options. See Section 13.2.10, “SELECT Syntax”.

  `OF tbl_name` applies locking queries to named tables.

• ADD PARTITION, DROP PARTITION, COALESCE PARTITION, REORGANIZE PARTITION, and REBUILD PARTITION ALTER TABLE options are supported by native partitioning in-place APIs and may be used with `ALGORITHM={COPY|INPLACE}` and `LOCK` clauses.

  `DROP PARTITION` with `ALGORITHM=INPLACE` deletes data stored in the partition and drops the partition. However, `DROP PARTITION` with `ALGORITHM=COPY` or `old_alter_table=ON` rebuilds the partitioned table and attempts to move data from the dropped partition to another partition with a compatible `PARTITION ... VALUES` definition. Data that cannot be moved to another partition is deleted.

• The InnoDB storage engine now uses the MySQL data dictionary rather than its own storage engine-specific data dictionary. For information about the data dictionary, see Chapter 14, MySQL Data Dictionary.

• mysql system tables and data dictionary tables are now created in a single InnoDB tablespace file named `mysql.ibd` in the MySQL data directory. Previously, these tables were created in individual InnoDB tablespace files in the `mysql` database directory.

• The following undo tablespace changes are introduced in MySQL 8.0:

  • By default, undo logs now reside in two undo tablespaces that are created when the MySQL instance is initialized. Undo logs are no longer created in the system tablespace.

  • As of MySQL 8.0.14, additional undo tablespaces can be created in a chosen location at runtime using `CREATE UNDO TABLESPACE` syntax.

    ```
    CREATE UNDO TABLESPACE tablespace_name ADD DATAFILE 'file_name.ibu';
    ```

    Undo tablespaces created using `CREATE UNDO TABLESPACE` syntax can be dropped at runtime using `DROP UNDO TABLESPACE` syntax.

    ```
    DROP UNDO TABLESPACE tablespace_name;
    ```

    `ALTER UNDO TABLESPACE` syntax can be used to mark an undo tablespace as active or inactive.

    ```
    ALTER UNDO TABLESPACE tablespace_name SET {ACTIVE|INACTIVE};
    ```
A `STATE` column that shows the state of a tablespace was added to the `INFORMATION_SCHEMA.INNODB_TABLESPACES` table. An undo tablespace must be in an empty state before it can be dropped.

- The `innodb_undo_log_truncate` variable is enabled by default.

- The `innodb_rollback_segments` variable defines the number of rollback segments per undo tablespace. Previously, `innodb_rollback_segments` specified the total number of rollback segments for the MySQL instance. This change increases the number of rollback segments available for concurrent transactions. More rollback segments increases the likelihood that concurrent transactions use separate rollback segments for undo logs, resulting in less resource contention.

- Default values for variables that affect buffer pool preflushing and flushing behavior were modified:
  - The `innodb_max_dirty_pages_pct_lwm` default value is now 10. The previous default value of 0 disables buffer pool preflushing. A value of 10 enables preflushing when the percentage of dirty pages in the buffer pool exceeds 10%. Enabling preflushing improves performance consistency.
  - The `innodb_max_dirty_pages_pct` default value was increased from 75 to 90. InnoDB attempts to flush data from the buffer pool so that the percentage of dirty pages does not exceed this value. The increased default value permits a greater percentage of dirty pages in the buffer pool.
  - The default `innodb_autoinc_lock_mode` setting is now 2 (interleaved). Interleaved lock mode permits the execution of multi-row inserts in parallel, which improves concurrency and scalability. The new `innodb_autoinc_lock_mode` default setting reflects the change from statement-based replication to row based replication as the default replication type in MySQL 5.7. Statement-based replication requires the consecutive auto-increment lock mode (the previous default) to ensure that auto-increment values are assigned in a predictable and repeatable order for a given sequence of SQL statements, whereas row-based replication is not sensitive to the execution order of SQL statements. For more information, see InnoDB AUTO_INCREMENT Lock Modes.

For systems that use statement-based replication, the new `innodb_autoinc_lock_mode` default setting may break applications that depend on sequential auto-increment values. To restore the previous default, set `innodb_autoinc_lock_mode` to 1.

- Renaming a general tablespace is supported by `ALTER TABLESPACE ... RENAME TO` syntax.

- The new `innodb_dedicated_server` variable, which is disabled by default, can be used to have InnoDB automatically configure the following options according to the amount of memory detected on the server:
  - `innodb_buffer_pool_size`
  - `innodb_log_file_size`
  - `innodb_flush_method`

This option is intended for MySQL server instances that run on a dedicated server. For more information, see Section 15.8.12, “Enabling Automatic Configuration for a Dedicated MySQL Server”.

- The new `INFORMATION_SCHEMA.INNODB_TABLESPACES_BRIEF` view provides space, name, path, flag, and space type data for InnoDB tablespaces.

- The `zlib` library version bundled with MySQL was raised from version 1.2.3 to version 1.2.11. MySQL implements compression with the help of the zlib library.
If you use InnoDB compressed tables, see Section 2.11.4, “Changes in MySQL 8.0” for related upgrade implications.

- Serialized dictionary information (SDI) is present in all InnoDB tablespace files except for global temporary tablespace and undo tablespace files. SDI is serialized metadata for table and tablespace objects. The presence of SDI data provides metadata redundancy. For example, dictionary object metadata may be extracted from tablespace files if the data dictionary becomes unavailable. SDI extraction is performed using the ibd2sdi tool. SDI data is stored in JSON format.

  The inclusion of SDI data in tablespace files increases tablespace file size. An SDI record requires a single index page, which is 16KB in size by default. However, SDI data is compressed when it is stored to reduce the storage footprint.

- The InnoDB storage engine now supports atomic DDL, which ensures that DDL operations are either fully committed or rolled back, even if the server halts during the operation. For more information, see Section 13.1.1, “Atomic Data Definition Statement Support”.

- Tablespace files can be moved or restored to a new location while the server is offline using the innodb_directories option. For more information, see Section 15.6.3.8, “Moving Tablespace Files While the Server is Offline”.

- The following redo logging optimizations were implemented:
  - User threads can now write concurrently to the log buffer without synchronizing writes.
  - User threads can now add dirty pages to the flush list in a relaxed order.
  - A dedicated log thread is now responsible for writing the log buffer to the system buffers, flushing system buffers to disk, notifying user threads about written and flushed redo, maintaining the lag required for the relaxed flush list order, and write checkpoints.
  - System variables were added for configuring the use of spin delay by user threads waiting for flushed redo:
    - innodb_log_wait_for_flush_spin_hwm: Defines the maximum average log flush time beyond which user threads no longer spin while waiting for flushed redo.
    - innodb_log_spin_cpu_abs_lwm: Defines the minimum amount of CPU usage below which user threads no longer spin while waiting for flushed redo.
    - innodb_log_spin_cpu_pct_hwm: Defines the maximum amount of CPU usage above which user threads no longer spin while waiting for flushed redo.
  - The innodb_log_buffer_size variable is now dynamic, which permits resizing of the log buffer while the server is running.

  For more information, see Section 8.5.4, “Optimizing InnoDB Redo Logging”.

- As of MySQL 8.0.12, undo logging is supported for small updates to large object (LOB) data, which improves performance of LOB updates that are 100 bytes in size or less. Previously, LOB updates were a minimum of one LOB page in size, which is less than optimal for updates that might only modify a few bytes. This enhancement builds upon support added in MySQL 8.0.4 for partial update of LOB data.

- As of MySQL 8.0.12, ALGORITHM=INSTANT is supported for the following ALTER TABLE operations:
  - Adding a column. This feature is also referred to as “Instant ADD COLUMN”. Limitations apply. See Section 15.12.1, “Online DDL Operations”.
• Adding or dropping a virtual column.

• Adding or dropping a column default value.

• Modifying the definition of an ENUM or SET column.

• Changing the index type.

• Renaming a table.

Operations that support ALGORITHM=INSTANT only modify metadata in the data dictionary. No metadata locks are taken on the table, and table data is unaffected, making the operations instantaneous. If not specified explicitly, ALGORITHM=INSTANT is used by default by operations that support it. If ALGORITHM=INSTANT is specified but not supported, the operation fails immediately with an error.

For more information about operations that support ALGORITHM=INSTANT, see Section 15.12.1, “Online DDL Operations”.

• As of MySQL 8.0.13, the TempTable storage engine supports storage of binary large object (BLOB) type columns. This enhancement improves performance for queries that use temporary tables containing BLOB data. Previously, temporary tables that contained BLOB data were stored in the on-disk storage engine defined by internal_tmp_disk_storage_engine. For more information, see Section 8.4.4, “Internal Temporary Table Use in MySQL”.

• As of MySQL 8.0.13, the InnoDB data-at-rest encryption feature supports general tablespaces. Previously, only file-per-table tablespaces could be encrypted. To support encryption of general tablespaces, CREATE TABLESPACE and ALTER TABLESPACE syntax was extended to include an ENCRYPTION clause.

The INFORMATION_SCHEMA.INNODB_TABLESPACES table now includes an ENCRYPTION column that indicates whether or not a tablespace is encrypted.

The stage/innodb/alter tablespace (encryption) Performance Schema stage instrument was added to permit monitoring of general tablespace encryption operations.

• Disabling the innodb_buffer_pool_in_core_file variable reduces the size of core files by excluding InnoDB buffer pool pages. To use this variable, the core_file variable must be enabled and the operating system must support the MADV_DONTDUMP non-POSIX extension to madvise(), which is supported in Linux 3.4 and later. For more information, see Section 15.8.3.8, “Excluding Buffer Pool Pages from Core Files”.

• As of MySQL 8.0.13, user-created temporary tables and internal temporary tables created by the optimizer are stored in session temporary tablespaces that are allocated to a session from a pool of temporary tablespaces. When a session disconnects, its temporary tablespaces are truncated and released back to the pool. In previous releases, temporary tables were created in the global temporary tablespace (ibtmp1), which did not return disk space to the operating system after temporary tables were dropped.

The innodb_temp_tablespaces_dir variable defines the location where session temporary tablespaces are created. The default location is the #innodb_temp directory in the data directory.

The INNODB_SESSION_TEMP_TABLESPACES table provides metadata about session temporary tablespace.

The global temporary tablespace (ibtmp1) now stores rollback segments for changes made to user-created temporary tables.
Features Added in MySQL 8.0

- As of MySQL 8.0.14, **InnoDB** supports parallel clustered index reads, which can improve **CHECK TABLE** performance. This feature does not apply to secondary index scans. The `innodb_parallel_read_threads` session variable must be set to a value greater than 1 for parallel clustered index reads to occur. The default value is 4. The actual number of threads used to perform a parallel clustered index read is determined by the `innodb_parallel_read_threads` setting or the number of index subtrees to scan, whichever is smaller.

- As of 8.0.14, when the `innodb_dedicated_server` variable is enabled, the size and number of log files are configured according to the automatically configured buffer pool size. Previously, log file size was configured according to the amount of memory detected on the server, and the number of log files was not configured automatically.

- As of 8.0.14, the ADD DATAFILE clause of the CREATE TABLESPACE statement is optional, which permits users without the FILE privilege to create tablespaces. A CREATE TABLESPACE statement executed without an ADD DATAFILE clause implicitly creates a tablespace data file with a unique file name.

- By default, when the amount of memory occupied by the TempTable storage engine exceeds the memory limit defined by the `temptable_max_ram` variable, the TempTable storage engine begins allocating memory-mapped temporary files from disk. As of MySQL 8.0.16, this behavior is controlled by the `temptable_use_mmap` variable. Disabling `temptable_use_mmap` causes the TempTable storage engine to use InnoDB on-disk internal temporary tables instead of memory-mapped files as its overflow mechanism. For more information, see Internal Temporary Table Storage Engine.

- As of MySQL 8.0.16, the **InnoDB** data-at-rest encryption feature supports encryption of the `mysql` system tablespace. The `mysql` system tablespace contains the `mysql` system database and the MySQL data dictionary tables. For more information, see Section 15.6.3.9, “InnoDB Data-at-Rest Encryption”.

- The `innodb_spin_wait_pause_multiplier` variable, introduced in MySQL 8.0.16, provides greater control over the duration of spin-lock polling delays that occur when a thread waits to acquire a mutex or rw-lock. Delays can be tuned more finely to account for differences in PAUSE instruction duration on different processor architectures. For more information, see Section 15.8.8, “Configuring Spin Lock Polling”.

- **Character set support.** The default character set has changed from latin1 to utf8mb4. The utf8mb4 character set has several new collations, including=utf8mb4_ja_0900_as_cs, the first Japanese language-specific collation available for Unicode in MySQL. For more information, see Section 10.10.1, “Unicode Character Sets”.

- **JSON enhancements.** The following enhancements or additions were made to MySQL’s JSON functionality:

  - Added the `->>` (inline path) operator, which is equivalent to calling `JSON_UNQUOTE()` on the result of `JSON_EXTRACT()`.

    This is a refinement of the column path operator `->` introduced in MySQL 5.7; `col->"$.path"` is equivalent to `JSON_UNQUOTE(col->"$.path")`. The inline path operator can be used wherever you can use `JSON_UNQUOTE(JSON_EXTRACT())`, such SELECT column lists, WHERE and HAVING clauses, and ORDER BY and GROUP BY clauses. For more information, see the description of the operator, as well as JSON Path Syntax.

  - Added two JSON aggregation functions `JSON_ARRAYAGG()` and `JSON_OBJECTAGG()`.

    `JSON_ARRAYAGG()` takes a column or expression as its argument, and aggregates the result as a single JSON array. The expression can evaluate to any MySQL data type; this does not have to be a JSON value. `JSON_OBJECTAGG()` takes two columns or expressions which it interprets as a key
Features Added in MySQL 8.0

and a value; it returns the result as a single JSON object. For more information and examples, see Section 12.20, “Aggregate (GROUP BY) Functions”.

• Added the JSON utility function JSON_PRETTY(), which outputs an existing JSON value in an easy-to-read format; each JSON object member or array value is printed on a separate line, and a child object or array is intended 2 spaces with respect to its parent.

This function also works with a string that can be parsed as a JSON value. For more detailed information and examples, see Section 12.17.8, “JSON Utility Functions”.

• When sorting JSON values in a query using ORDER BY, each value is now represented by a variable-length part of the sort key, rather than a part of a fixed 1K in size. In many cases this can reduce excessive usage. For example, a scalar INT or even BIGINT value actually requires very few bytes, so that the remainder of this space (up to 90% or more) was taken up by padding. This change has the following benefits for performance:

  • Sort buffer space is now used more effectively, so that filesorts need not flush to disk as early or often as with fixed-length sort keys. This means that more data can be sorted in memory, avoiding unnecessary disk access.

  • Shorter keys can be compared more quickly than longer ones, providing a noticeable improvement in performance. This is true for sorts performed entirely in memory as well as for sorts that require writing to and reading from disk.

• Added support in MySQL 8.0.2 for partial, in-place updates of JSON column values, which is more efficient than completely removing an existing JSON value and writing a new one in its place, as was done previously when updating any JSON column. For this optimization to be applied, the update must be applied using JSON_SET(), JSON_REPLACE(), or JSON_REMOVE(). New elements cannot be added to the JSON document being updated; values within the document cannot take more space than they did before the update. See Partial Updates of JSON Values, for a detailed discussion of the requirements.

Partial updates of JSON documents can be written to the binary log, taking up less space than logging complete JSON documents. Partial updates are always logged as such when statement-based replication is in use. For this to work with row-based replication, you must first set binlog_row_value_options=PARTIAL_JSON; see this variable’s description for more information.

• Added the JSON utility functions JSON_STORAGE_SIZE() and JSON_STORAGE_FREE(). JSON_STORAGE_SIZE() returns the storage space in bytes used for the binary representation of a JSON document prior to any partial update (see previous item). JSON_STORAGE_FREE() shows the amount of space remaining in a table column of type JSON after it has been partially updated using JSON_SET() or JSON_REPLACE(); this is greater than zero if the binary representation of the new value is less than that of the previous value.

Each of these functions also accepts a valid string representation of a JSON document. For such a value, JSON_STORAGE_SIZE() returns the space used by its binary representation following its conversion to a JSON document. For a variable containing the string representation of a JSON document, JSON_STORAGE_FREE() returns zero. Either function produces an error if its (non-null) argument cannot be parsed as a valid JSON document, and NULL if the argument is NULL.

For more information and examples, see Section 12.17.8, “JSON Utility Functions”.

JSON_STORAGE_SIZE() and JSON_STORAGE_FREE() were implemented in MySQL 8.0.2.

• Added support in MySQL 8.0.2 for ranges such as $[1 to 5] in XPath expressions. Also added support in this version for the last keyword and relative addressing, such that $[last] always selects the last (highest-numbered) element in the array and $[last-1] the next to last element. last and expressions using it can also be included in range definitions. For example, $[last-2
to last-1] returns the last two elements but one from an array. See Searching and Modifying JSON Values, for additional information and examples.

- Added a JSON merge function intended to conform to RFC 7396. JSON_MERGE_PATCH(), when used on 2 JSON objects, merges them into a single JSON object that has as members a union of the following sets:
  - Each member of the first object for which there is no member with the same key in the second object.
  - Each member of the second object for which there is no member having the same key in the first object, and whose value is not the JSON null literal.
  - Each member having a key that exists in both objects, and whose value in the second object is not the JSON null literal.

As part of this work, the JSON_MERGE() function has been renamed JSON_MERGE_PRESERVE(). JSON_MERGE() continues to be recognized as an alias for JSON_MERGE_PRESERVE() in MySQL 8.0, but is now deprecated and is subject to removal in a future version of MySQL.

For more information and examples, see Section 12.17.4, “Functions That Modify JSON Values”.

- Implemented “last duplicate key wins” normalization of duplicate keys, consistent with RFC 7159 and most JavaScript parsers. An example of this behavior is shown here, where only the rightmost member having the key x is preserved:

```sql
mysql> SELECT JSON_OBJECT('x', '32', 'y', '[true, false]', 'x', '"abc"', 'x', '100') AS Result;
+------------------------------------+
| Result                             |
+------------------------------------+
| {"x": "100", "y": [true, false]} |
+------------------------------------+
1 row in set (0.00 sec)
```

Values inserted into MySQL JSON columns are also normalized in this way, as shown in this example:

```sql
mysql> CREATE TABLE t1 (c1 JSON);
mysql> INSERT INTO t1 VALUES ('{"x": 17, "x": "red", "x": [3, 5, 7]}');
mysql> SELECT c1 FROM t1;
+------------------+
| c1               |
+------------------+
| {"x": [3, 5, 7]} |
+------------------+
```

This is an incompatible change from previous versions of MySQL, where a “first duplicate key wins” algorithm was used in such cases.

See Normalization, Merging, and Autowrapping of JSON Values, for more information and examples.

- Added the JSON_TABLE() function in MySQL 8.0.4. This function accepts JSON data and returns it as a relational table having the specified columns.

This function has the syntax JSON_TABLE(expr, path COLUMNS column_list) [AS] alias, where expr is an expression that returns JSON data, path is a JSON path applied to the source, and column_list is a list of column definitions. An example is shown here:
The JSON source expression can be any expression that yields a valid JSON document, including a JSON literal, a table column, or a function call that returns JSON such as `JSON_EXTRACT(t1, data, '%$post.comments')`. For more information, see Section 12.17.6, “JSON Table Functions”.

- **Data type support.** MySQL now supports use of expressions as default values in data type specifications. This includes the use of expressions as default values for the `BLOB`, `TEXT`, `GEOMETRY`, and `JSON` data types, which previously could not be assigned default values at all. For details, see Section 11.7, “Data Type Default Values”.

- **Optimizer.** These optimizer enhancements were added:
  
  - MySQL now supports invisible indexes. An invisible index is not used by the optimizer at all, but is otherwise maintained normally. Indexes are visible by default. Invisible indexes make it possible to test the effect of removing an index on query performance, without making a destructive change that must be undone should the index turn out to be required. See Section 8.3.12, “Invisible Indexes”.
  
  - MySQL now supports descending indexes: `DESC` in an index definition is no longer ignored but causes storage of key values in descending order. Previously, indexes could be scanned in reverse order but at a performance penalty. A descending index can be scanned in forward order, which is more efficient. Descending indexes also make it possible for the optimizer to use multiple-column indexes when the most efficient scan order mixes ascending order for some columns and descending order for others. See Section 8.3.13, “Descending Indexes”.
  
  - MySQL now supports creation of functional index key parts that index expression values rather than column values. Functional key parts enable indexing of values that cannot be indexed otherwise, such as `JSON` values. For details, see Section 13.1.15, “CREATE INDEX Syntax”.
  
  - In MySQL 8.0.14 and later, trivial `WHERE` conditions arising from constant literal expressions are removed during preparation, rather than later on during optimization. Removal of the condition earlier in the process makes it possible to simplify joins for queries with outer joins having trivial conditions, such as this one:

```sql
SELECT * FROM t1 LEFT JOIN t2 ON condition_1 WHERE condition_2 OR 0 = 1
```
The optimizer now sees during preparation that $0 = 1$ is always false, making OR $0 = 1$ redundant, and removes it, leaving this:

```
SELECT * FROM t1 LEFT JOIN t2 ON condition_1 where condition_2
```

Now the optimizer can rewrite the query as an inner join, like this:

```
SELECT * FROM t1 LEFT JOIN t2 WHERE condition_1 AND condition_2
```

For more information, see Section 8.2.1.8, “Outer Join Optimization”.

- In MySQL 8.0.16 and later, MySQL can use constant folding at optimization time to handle comparisons between a column and a constant value where the constant is out of range or on a range boundary with respect to the type of the column, rather than doing so for each row at execution time. For example, given a table `t` with a `TINYINT UNSIGNED` column `c`, the optimizer can rewrite a condition such as `WHERE c < 256` to `WHERE 1` (and optimize the condition away altogether), or `WHERE c >= 255` to `WHERE c = 255`.

See Section 8.2.1.13, “Constant-Folding Optimization”, for more information.

- Beginning with MySQL 8.0.16, the semi-join optimizations used with `IN` subqueries can now be applied to `EXISTS` subqueries as well. In addition, the optimizer now decorrelates trivially-correlated equality predicates in the `WHERE` condition attached to the subquery, so that they can be treated similarly to expressions in `IN` subqueries; this applies to both `EXISTS` and `IN` subqueries.

For more information, see Section 8.2.2.1, “Optimizing IN and EXISTS Subquery predicates with Semi-Join Transformations”.

- **Common table expressions.** MySQL now supports common table expressions, both nonrecursive and recursive. Common table expressions enable use of named temporary result sets, implemented by permitting a `WITH` clause preceding `SELECT` statements and certain other statements. For more information, see Section 13.2.13, “WITH Syntax (Common Table Expressions)”.

- **Window functions.** MySQL now supports window functions that, for each row from a query, perform a calculation using rows related to that row. These include functions such as `RANK()`, `LAG()`, and `NTILE()`. In addition, several existing aggregate functions now can be used as window functions (for example, `SUM()` and `AVG()`). For more information, see Section 12.21, “Window Functions”.

- **Lateral derived tables.** A derived table now may be preceded by the `LATERAL` keyword to specify that it is permitted to refer to (depend on) columns of preceding tables in the same `FROM` clause. Lateral derived tables make possible certain SQL operations that cannot be done with nonlateral derived tables or that require less-efficient workarounds. See Section 13.2.11.9, “Lateral Derived Tables”.

- **Aliases in single-table DELETE statements.** In MySQL 8.0.16 and later, single-table `DELETE` statements support the use of table aliases.

- **Regular expression support.** Previously, MySQL used the Henry Spencer regular expression library to support regular expression operators (`REGEXP`, `RLIKE`). Regular expression support has been reimplemented using International Components for Unicode (ICU), which provides full Unicode support and is multibyte safe. The `REGEXP_LIKE()` function performs regular expression matching in the manner of the `REGEXP` and `RLIKE` operators, which now are synonyms for that function. In addition, the `REGEXP_INSTR()`, `REGEXP_REPLACE()`, and `REGEXP_SUBSTR()` functions are available to find match positions and perform substring substitution and extraction, respectively. The `regexp_stack_limit` and `regexp_time_limit` system variables provide control over resource consumption by the match engine. For more information, see Section 12.5.2, “Regular Expressions”.
Features Added in MySQL 8.0

For information about ways in which applications that use regular expressions may be affected by the implementation change, see Regular Expression Compatibility Considerations.

• Internal temporary tables. The TempTable storage engine replaces the MEMORY storage engine as the default engine for in-memory internal temporary tables. The TempTable storage engine provides efficient storage for VARCHAR and VARBINARY columns. The internal_tmp_mem_storage_engine session variable defines the storage engine for in-memory internal temporary tables. Permitted values are TempTable (the default) and MEMORY. The temptable_max_ram variable defines the maximum amount of memory that the TempTable storage engine can use before data is stored to disk.

• Logging. Error logging was rewritten to use the MySQL component architecture. Traditional error logging is implemented using built-in components, and logging using the system log is implemented as a loadable component. In addition, a loadable JSON log writer is available. To control which log components to enable, use the log_error_services system variable. For more information, see Section 5.4.2, “The Error Log”.

• Backup lock. A new type of backup lock permits DML during an online backup while preventing operations that could result in an inconsistent snapshot. The new backup lock is supported by LOCK INSTANCE FOR BACKUP and UNLOCK INSTANCE syntax. The BACKUP_ADMIN privilege is required to use these statements.

• Replication. The following enhancements have been made to MySQL Replication:
  • MySQL Replication now supports binary logging of partial updates to JSON documents using a compact binary format, saving space in the log over logging complete JSON documents. Such compact logging is done automatically when statement-based logging is in use, and can be enabled by setting the new binlog_row_value_options system variable to PARTIAL_JSON. For more information, see Partial Updates of JSON Values, as well as the description of binlog_row_value_options.
  • Connection management. MySQL Server now permits a TCP/IP port to be configured specifically for administrative connections. This provides an alternative to the single administrative connection that is permitted on the network interfaces used for ordinary connections even when max_connections connections are already established. See Section 8.12.4.1, “How MySQL Handles Client Connections”.

MySQL now provides more control over the use of compression to minimize the number of bytes sent over connections to the server. Previously, a given connection was either uncompressed or used the zlib compression algorithm. Now, it is also possible to use the zstd algorithm, and to select a compression level for zstd connections. The permitted compression algorithms can be configured on the server side, as well as on the connection-origination side for connections by client programs and by servers participating in master/slave replication or Group Replication. For more information, see Section 4.2.6, “Connection Compression Control”.

• Configuration. The maximum permitted length of host names throughout MySQL has been raised to 255 ASCII characters, up from the previous limit of 60 characters. This applies to, for example, host name-related columns in the data dictionary, mysql system schema, Performance Schema, INFORMATION_SCHEMA, and sys schema; the MASTER_HOST value for the CHANGE MASTER TO statement; the Host column in SHOW PROCESSLIST statement output; host names in account names (such as used in account-management statements and in DEFINER attributes); and host name-related command options and system variables.

Caveats:

• The increase in permitted host name length can affect tables with indexes on host name columns. For example, tables in the mysql system schema that index host names now have an explicit ROW_FORMAT attribute of DYNAMIC to accommodate longer index values.
• Some file name-valued configuration settings might be constructed based on the server host name. The permitted values are constrained by the underlying operating system, which may not permit file names long enough to include 255-character host names. This affects the `general_log_file`, `log_error`, `pid_file`, `relay_log`, and `slow_query_log_file` system variables and corresponding options. If host name-based values are too long for the OS, explicit shorter values must be provided.

• Although the server now supports 255-character host names, connections to the server established using the `--ssl-mode=VERIFY_IDENTITY` option are constrained by maximum host name length supported by OpenSSL. Host name matches pertain to two fields of SSL certificates, which have maximum lengths as follows: Common Name: maximum length 64; Subject Alternative Name: maximum length as per RFC#1034.

• **Plugins.** Previously, MySQL plugins could be written in C or C++. MySQL header files used by plugins now contain C++ code, which means that plugins must be written in C++, not C.

• **C API.** The MySQL C API now supports asynchronous functions for nonblocking communication with the MySQL server. Each function is the asynchronous counterpart to an existing synchronous function. The synchronous functions block if reads from or writes to the server connection must wait. The asynchronous functions enable an application to check whether work on the server connection is ready to proceed. If not, the application can perform other work before checking again later. See Section 28.7.12, “C API Asynchronous Interface”.

• **Additional Target Types for Casts.** The functions `CAST()` and `CONVERT()` now support conversions to types `DOUBLE`, `FLOAT`, and `REAL`. Added in MySQL 8.0.17. See Section 12.10, “Cast Functions and Operators”.

• **JSON Schema Validation.** MySQL 8.0.17 adds two functions `JSON_SCHEMA_VALID()` and `JSON_SCHEMA_VALIDATION_REPORT()` for validating JSON documents against JSON schemas. `JSON_SCHEMA_VALID()` returns TRUE (1) if the document validates against the schema and FALSE (0) if it does not. `JSON_SCHEMA_VALIDATION_REPORT()` returns a JSON document containing detailed information about the results of the validation. The following statements apply to both of these functions:

  • The schema must conform to Draft 4 of the JSON Schema specification.
  • `required` attributes are supported.
  • External resources and the `$ref` keyword are not supported.
  • Regular expression patterns are supported; invalid patterns are silently ignored.

See Section 12.17.7, “JSON Schema Validation Functions”, for more information and examples.

• **JSON_OVERLAPS() and MEMBER OF().** MySQL 8.0 also provides additional functionality for obtaining information about the contents of JSON documents. The `JSON_OVERLAPS()` function compares two JSON objects or arrays, returning true (1) if they contain any key-value pairs or array elements in common, and false (0) if they do not. The `MEMBER OF()` operator returns true (1) if a given value exists as an element of a specified array, false (0) if it does not. Both of these are available in MySQL 8.0.17 and later. For more information and examples, see Section 12.17.3, “Functions That Search JSON Values”.

• **hintable time_zone.** As of MySQL 8.0.17, the `time_zone` session variable is hintable using `SET_VAR`.

**Features Deprecated in MySQL 8.0**

The following features are deprecated in MySQL 8.0 and may be or will be removed in a future series. Where alternatives are shown, applications should be updated to use them.

---

**Features Deprecated in MySQL 8.0**

The following features are deprecated in MySQL 8.0 and may be or will be removed in a future series. Where alternatives are shown, applications should be updated to use them.
Features Deprecated in MySQL 8.0

For applications that use features deprecated in MySQL 8.0 that have been removed in a higher MySQL series, statements may fail when replicated from a MySQL 8.0 master to a higher-series slave, or may have different effects on master and slave. To avoid such problems, applications that use features deprecated in 8.0 should be revised to avoid them and use alternatives when possible.

- The `utf8mb3` character set is deprecated. Please use `utf8mb4` instead.

- Because `caching_sha2_password` is the default authentication plugin in MySQL 8.0 and provides a superset of the capabilities of the `sha256_password` authentication plugin, `sha256_password` is deprecated and will be removed in a future MySQL version. MySQL accounts that authenticate using `sha256_password` should be migrated to use `caching_sha2_password` instead.

- The `validate_password` plugin has been reimplemented to use the server component infrastructure. The plugin form of `validate_password` is still available but is deprecated and will be removed in a future version of MySQL. MySQL installations that use the plugin should make the transition to using the component instead. See Section 6.4.3.3, "Transitioning to the Password Validation Component".

- The `ALTER TABLESPACE` and `DROP TABLESPACE ENGINE` clause is deprecated.

- The `PAD_CHAR_TO_FULL_LENGTH` SQL mode is deprecated.

- `AUTO_INCREMENT` support is deprecated for columns of type `FLOAT` and `DOUBLE` (and any synonyms). Consider removing the `AUTO_INCREMENT` attribute from such columns, or convert them to an integer type.

- The `UNSIGNED` attribute is deprecated for columns of type `FLOAT`, `DOUBLE`, and `DECIMAL` (and any synonyms). Consider using a simple `CHECK` constraint instead for such columns.

- `FLOAT(M,D)` and `DOUBLE(M,D)` syntax to specify the number of digits for columns of type `FLOAT` and `DOUBLE` (and any synonyms) is a nonstandard MySQL extension. This syntax is deprecated.

- The `ZEROFILL` attribute is deprecated for numeric data types, as is the display width attribute for integer data types. Consider using an alternative means of producing the effect of these attributes. For example, applications could use the `LPAD()` function to zero-pad numbers up to the desired width, or they could store the formatted numbers in `CHAR` columns.

- For string data types, the `BINARY` attribute is a nonstandard MySQL extension that is shorthand for specifying the binary (_bin) collation of the column character set (or of the table default character set if no column character set is specified). In MySQL 8.0, this nonstandard use of `BINARY` is ambiguous because the `utf8mb4` character set has multiple _bin collations, so the `BINARY` attribute is deprecated and support for it will be removed in a future MySQL version. Applications should be adjusted to use an explicit _bin collation instead.

  The use of `BINARY` to specify a data type or character set remains unchanged.

- The nonstandard C-style `&&`, `||`, and `!` operators that are synonyms for the standard SQL `AND`, `OR`, and `NOT` operators, respectively, are deprecated. Applications that use the nonstandard operators should be adjusted to use the standard operators.

  **Note**
  Use of `||` is deprecated unless the `PIPES_AS_CONCAT` SQL mode is enabled. In that case, `||` signifies the SQL-standard string concatenation operator.

- The `JSON_MERGE()` function is deprecated. Use `JSON_MERGE_PRESERVE()` instead.

- The `SQL_CALC_FOUND_ROWS` query modifier and accompanying `FOUND_ROWS()` function are deprecated. See the `FOUND_ROWS()` description for information about an alternative strategy.

- Support for `TABLESPACE = innodb_file_per_table` and `TABLESPACE = innodb_temporary` clauses with `CREATE TEMPORARY TABLE` is deprecated as of MySQL 8.0.13.
• The `mysql_upgrade` client is deprecated because its capabilities for upgrading the system tables in the `mysql` system schema and objects in other schemas have been moved into the MySQL server. See Section 2.11.3, “What the MySQL Upgrade Process Upgrades”.

• The `--no-dd-upgrade` server option is deprecated. It is superseded by the `--upgrade` option, which provides finer control over data dictionary and server upgrade behavior.

• The `mysql_upgrade_info` file, which is created data directory and used to store the MySQL version number, is deprecated and will be removed in a future MySQL version.

• These legacy parameters for compression of connections to the server are deprecated:
  The `--compress` client command-line option; the `MYSQL_OPT_COMPRESS` option for the `mysql_options()` C API function; the `slave_compressed_protocol` system variable. For information about parameters to use instead, see Section 4.2.6, “Connection Compression Control”.

### Features Removed in MySQL 8.0

The following items are obsolete and have been removed in MySQL 8.0. Where alternatives are shown, applications should be updated to use them.

For MySQL 5.7 applications that use features removed in MySQL 8.0, statements may fail when replicated from a MySQL 5.7 master to a MySQL 8.0 slave, or may have different effects on master and slave. To avoid such problems, applications that use features removed in MySQL 8.0 should be revised to avoid them and use alternatives when possible.

• The `innodb_locks_unsafe_for_binlog` system variable was removed. The `READ COMMITTED` isolation level provides similar functionality.

• The `information_schema_stats` variable, introduced in MySQL 8.0.0, was removed and replaced by `information_schema_stats_expiry` in MySQL 8.0.3.

  `information_schema_stats_expiry` defines an expiration setting for cached `INFORMATION_SCHEMA` table statistics. For more information, see Section 8.2.3, “Optimizing `INFORMATION_SCHEMA` Queries”.

• Code related to obsoleted InnoDB system tables was removed in MySQL 8.0.3.

  `INFORMATION_SCHEMA` views based on InnoDB system tables were replaced by internal system views on data dictionary tables. Affected InnoDB `INFORMATION_SCHEMA` views were renamed:

<table>
<thead>
<tr>
<th>Table 1.1 Renamed InnoDB Information Schema Views</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Old Name</strong></td>
</tr>
<tr>
<td>-----------------------------------------------</td>
</tr>
<tr>
<td><code>INNODB_SYS_COLUMNS</code></td>
</tr>
<tr>
<td><code>INNODB_SYS_DATAFILES</code></td>
</tr>
<tr>
<td><code>INNODB_SYS_FIELDS</code></td>
</tr>
<tr>
<td><code>INNODB_SYS_FOREIGN</code></td>
</tr>
<tr>
<td><code>INNODB_SYS_FOREIGN_COLS</code></td>
</tr>
<tr>
<td><code>INNODB_SYS_INDEXES</code></td>
</tr>
<tr>
<td><code>INNODB_SYS_TABLES</code></td>
</tr>
<tr>
<td><code>INNODB_SYS_TABLESPACES</code></td>
</tr>
<tr>
<td><code>INNODB_SYS_TABLESTATS</code></td>
</tr>
<tr>
<td><code>INNODB_SYS_VIRTUAL</code></td>
</tr>
</tbody>
</table>

  After upgrading to MySQL 8.0.3 or later, update any scripts that reference previous InnoDB `INFORMATION_SCHEMA` view names.

• The following features related to account management are removed:
Features Removed in MySQL 8.0

- Using `GRANT` to create users. Instead, use `CREATE USER`. Following this practice makes the `NO_AUTO_CREATE_USER` SQL mode immaterial for `GRANT` statements, so it too is removed.

- Using `GRANT` to modify account properties other than privilege assignments. This includes authentication, SSL, and resource-limit properties. Instead, establish such properties at account-creation time with `CREATE USER` or modify them afterward with `ALTER USER`.

- `IDENTIFIED BY PASSWORD 'auth_string'` syntax for `CREATE USER` and `GRANT`. Instead, use `IDENTIFIED WITH auth_plugin AS 'auth_string'` for `CREATE USER` and `ALTER USER`, where the 'auth_string' value is in a format compatible with the named plugin.

  Additionally, because `IDENTIFIED BY PASSWORD` syntax was removed, the `log_builtin_as_identified_by_password` system variable is superfluous and was removed.

- The `PASSWORD()` function. Additionally, `PASSWORD()` removal means that `SET PASSWORD ... = PASSWORD('auth_string')` syntax is no longer available.

- The `old_passwords` system variable.

- The query cache was removed. Removal includes these items:

  - The `FLUSH QUERY CACHE` and `RESET QUERY CACHE` statements.
  
  - These system variables: `query_cache_limit`, `query_cache_min_res_unit`, `query_cache_size`, `query_cache_type`, `query_cache_wlock_invalidate`.
  
  - These status variables: `Qcache_free_blocks`, `Qcache_free_memory`, `Qcache_hits`, `Qcache_inserts`, `Qcache_lowmem_prunes`, `Qcache_not_cached`, `Qcache_queries_in_cache`, `Qcache_total_blocks`.
  
  - These thread states: checking privileges on cached query, checking query cache for query, invalidating query cache entries, sending cached result to client, storing result in query cache, waiting for query cache lock.

  - The `SQL_CACHE` SELECT modifier.

  These deprecated query cache items remain deprecated, but have no effect, and will be removed in a future MySQL release:

  - `SQL_NO_CACHE SELECT` modifier.
  
  - The `ndb_cache_check_time` system variable.

  The `have_query_cache` system variable remains deprecated, always has a value of `NO`, and will be removed in a future MySQL release.

  - The data dictionary provides information about database objects, so the server no longer checks directory names in the data directory to find databases. Consequently, the `--ignore-db-dir` option and `ignore_db_dirs` system variables are extraneous and are removed.

  - The `tx_isolation` and `tx_read_only` system variables have been removed. Use `transaction_isolation` and `transaction_read_only` instead.

  - The `sync_frm` system variable has been removed because `.frm` files have become obsolete.

  - The `secure_auth` system variable and `--secure-auth` client option have been removed. The `MYSQL_SECURE_AUTH` option for the `mysql_options()` C API function was removed.

  - The `multi_range_count` system variable is removed.
Features Removed in MySQL 8.0

- The `log_warnings` system variable and `--log-warnings` server option have been removed. Use the `log_error_verbosity` system variable instead.

- The global scope for the `sql_log_bin` system variable was removed. `sql_log_bin` has session scope only, and applications that rely on accessing `@GLOBAL.sql_log_bin` should be adjusted.

- The `metadata_locks_cache_size` and `metadata_locks_hash_instances` system variables are removed.

- The unused `date_format`, `datetime_format`, `time_format`, and `max_tmp_tables` system variables are removed.

- These deprecated compatibility SQL modes are removed: `DB2`, `MAXDB`, `MSSQL`, `MySQL323`, `MySQL40`, `ORACLE`, `POSTGRESQL`, `NO_FIELD_OPTIONS`, `NO_KEY_OPTIONS`, `NO_TABLE_OPTIONS`. They can no longer be assigned to the `sql_mode` system variable or used as permitted values for the `mysqldump --compatible` option.

- Removal of `MAXDB` means that the `TIMESTAMP` data type for `CREATE TABLE` or `ALTER TABLE` is treated as `TIMESTAMP`, and is no longer treated as `DATETIME`.

- The deprecated `ASC` or `DESC` qualifiers for `GROUP BY` clauses are removed. Queries that previously relied on `GROUP BY` sorting may produce results that differ from previous MySQL versions. To produce a given sort order, provide an `ORDER BY` clause.

- The `EXTENDED` and `PARTITIONS` keywords for the `EXPLAIN` statement have been removed. These keywords are unnecessary because their effect is always enabled.

- These encryption-related items are removed:
  - The `ENCODE()` and `DECODE()` functions.
  - The `ENCRYPT()` function.
  - The `DES_ENCRYPT()`, and `DES_DECRYPT()` functions, the `--des-key-file` option, the `have_crypt` system variable, the `DES_KEY_FILE` option for the `FLUSH` statement, and the `HAVE_CRYPT` CMake option.

In place of the removed encryption functions: For `ENCRYPT()`, consider using `SHA2()` instead for one-way hashing. For the others, consider using `AES_ENCRYPT()` and `AES_DECRYPT()` instead.

- In MySQL 5.7, several spatial functions available under multiple names were deprecated to move in the direction of making the spatial function namespace more consistent, the goal being that each spatial function name begin with `ST_` if it performs an exact operation, or with `MBR` if it performs an operation based on minimum bounding rectangles. In MySQL 8.0, the deprecated functions are removed to leave only the corresponding `ST_` and `MBR` functions:
  - These functions are removed in favor of the `MBR` names: `Contains()`, `Disjoint()`, `Equals()`, `Intersects()`, `Overlaps()`, `Within()`.
  - These functions are removed in favor of the `ST_` names: `Area()`, `AsBinary()`, `AsText()`, `AsWKB()`, `AsWK2()`, `Buffer()`, `Centroid()`, `ConvexHull()`, `Crosses()`, `Dimension()`, `Distance()`, `EndPoint()`, `Envelope()`, `ExteriorRing()`, `GeomCollFromText()`, `GeomCollFromWKB()`, `GeomFromText()`, `GeomFromWKB()`, `GeometryCollectionFromText()`, `GeometryCollectionFromWKB()`, `GeometryFromText()`, `GeometryFromWKB()`, `GeometryN()`, `GeometryType()`, `InteriorRingN()`, `IsClosed()`, `IsEmpty()`, `IsSimple()`, `LineFromText()`, `LineFromWKB()`, `LineStringFromText()`, `LineStringFromWKB()`, `MLineFromText()`, `MLineFromWKB()`, `MPointFromText()`, `MPointFromWKB()`, `MPolyFromText()`, `MPolyFromWKB()`, `MultiLineStringFromText()`, `MultiLineStringFromWKB()`, `MultiPointFromText()`, `MultiPointFromWKB()`, `MultiPolygonFromText()`, `MultiPolygonFromWKB()`, `NumGeometries()`, `NumInteriorRings()`, `NumPoints()`,
PointFromText(), PointFromWKB(), PointN(), PolyFromText(), PolyFromWKB(), PolygonFromText(), PolygonFromWKB(), SRID(), StartPoint(), Touches(), X(), Y().

- `GLength()` is removed in favor of `ST_Length()`.

- The functions described in Section 12.16.4, “Functions That Create Geometry Values from WKB Values” previously accepted either WKB strings or geometry arguments. Geometry arguments are no longer permitted and produce an error. See that section for guidelines for migrating queries away from using geometry arguments.

- The parser no longer treats `\N` as a synonym for `NULL` in SQL statements. Use `NULL` instead.

This change does not affect text file import or export operations performed with `LOAD DATA` or `SELECT ... INTO OUTFILE`, for which `NULL` continues to be represented by `\N`. See Section 13.2.7, “LOAD DATA Syntax”.

- `PROCEDURE ANALYSE()` syntax is removed.

- The client-side `--ssl` and `--ssl-verify-server-cert` options have been removed. Use `--ssl-mode=REQUIRED` instead of `--ssl=1` or `--enable-ssl`. Use `--ssl-mode=DISABLED` instead of `--ssl=0`, `--skip-ssl`, or `--disable-ssl`. Use `--ssl-mode=VERIFY_IDENTITY` instead of `--ssl-verify-server-cert` options. (The server-side `--ssl` option remains unchanged.)

For the C API, `MYSQL_OPT_SSL_ENFORCE` and `MYSQL_OPT_SSL_VERIFY_SERVER_CERT` options for `mysql_options()` correspond to the client-side `--ssl` and `--ssl-verify-server-cert` options and are removed. Use `MYSQL_OPT_SSL_MODE` with an option value of `SSL_MODE_REQUIRED` or `SSL_MODE_VERIFY_IDENTITY` instead.

- The `--temp-pool` server option was removed.

- The `--ignore-built-in-innodb` server option and `ignore_builtin_innodb` system variable are removed.

- The server no longer performs conversion of pre-MYSQL 5.1 database names containing special characters to 5.1 format with the addition of a `#mysql50#` prefix. Because these conversions are no longer performed, the `--fix-db-names` and `--fix-table-names` options for `mysqlcheck`, the `UPGRADE DATA DIRECTORY NAME` clause for the `ALTER DATABASE` statement, and the `Com_alter_db_upgrade` status variable are removed.

Upgrades are supported only from one major version to another (for example, 5.0 to 5.1, or 5.1 to 5.5), so there should be little remaining need for conversion of older 5.0 database names to current versions of MySQL. As a workaround, upgrade a MySQL 5.0 installation to MySQL 5.1 before upgrading to a more recent release.

- The `mysql_install_db` program has been removed from MySQL distributions. Data directory initialization should be performed by invoking `mysqld` with the `--initialize` or `--initialize-insecure` option instead. In addition, the `--bootstrap` option for `mysqld` that was used by `mysql_install_db` was removed, and the `INSTALL_SCRIPTDIR` CMake option that controlled the installation location for `mysql_install_db` was removed.

- The generic partitioning handler was removed from the MySQL server. In order to support partitioning of a given table, the storage engine used for the table must now provide its own (“native”) partitioning handler. The `--partition` and `--skip-partition` options are removed from the MySQL Server, and partitioning-related entries are no longer shown in the output of `SHOW PLUGINS` or in the `INFORMATION_SCHEMA.PLUGINS` table.

Two MySQL storage engines currently provide native partitioning support—InnoDB and NDB; of these, only InnoDB is supported in MySQL 8.0. Any attempt to create partitioned tables in MySQL 8.0 using any other storage engine fails.
**Features Removed in MySQL 8.0**

**Ramifications for upgrades.** The direct upgrade of a partitioned table using a storage engine other than **InnoDB** (such as **MyISAM**) from MySQL 5.7 (or earlier) to MySQL 8.0 is not supported. There are two options for handling such a table:

- Remove the table’s partitioning, using `ALTER TABLE ... REMOVE PARTITIONING`.
- Change the storage engine used for the table to **InnoDB**, with `ALTER TABLE ... ENGINE=INNODB`.

At least one of the two operations just listed must be performed for each partitioned non-**InnoDB** table prior to upgrading the server to MySQL 8.0. Otherwise, such a table cannot be used following the upgrade.

Due to the fact that table creation statements that would result in a partitioned table using a storage engine without partitioning support now fail with an error (**ER_CHECK_NOT_IMPLEMENTED**), you must make sure that any statements in a dump file (such as that written by `mysqldump`) from an older version of MySQL that you wish to import into a MySQL 8.0 server that create partitioned tables do not also specify a storage engine such as **MyISAM** that has no native partitioning handler. You can do this by performing either of the following:

- Remove any references to partitioning from `CREATE TABLE` statements that use a value for the `STORAGE ENGINE` option other than **InnoDB**.
- Specifying the storage engine as **InnoDB**, or allow **InnoDB** to be used as the table’s storage engine by default.

For more information, see Section 23.6.2, “Partitioning Limitations Relating to Storage Engines”.

- System and status variable information is no longer maintained in the **INFORMATION_SCHEMA**. These tables are removed: `GLOBAL_VARIABLES`, `SESSION_VARIABLES`, `GLOBAL_STATUS`, `SESSION_STATUS`. Use the corresponding Performance Schema tables instead. See Section 26.12.13, “Performance Schema System Variable Tables”, and Section 26.12.14, “Performance Schema Status Variable Tables”. In addition, the `show_compatibility_56` system variable was removed. It was used in the transition period during which system and status variable information in **INFORMATION_SCHEMA** tables was moved to Performance Schema tables, and is no longer needed. These status variables are removed: `Slave_heartbeat_period`, `Slave_last_heartbeat`, `Slave_received_heartbeats`, `Slave_retried_transactions`, `Slave_running`. The information they provided is available in Performance Schema tables; see Migrating to Performance Schema System and Status Variable Tables.

- The Performance Schema `setup_timers` table was removed, as was the `TICK` row in the `performance_timers` table.

- The `libmysqld` embedded server library is removed, along with:
  - The `mysql_options()` `MYSQL_OPT_GUESS_CONNECTION`, `MYSQL_OPT_USE_EMBEDDED_CONNECTION`, `MYSQL_OPT_USE_REMOTE_CONNECTION`, and `MYSQL_SET_CLIENT_IP` options
  - The `mysql_config` `--libmysqld-libs`, `--embedded-libs`, and `--embedded` options
  - The `Cmake` `WITH_EMBEDDED_SERVER`, `WITH_EMBEDDED_SHARED_LIBRARY`, and `INSTALL_SECURE_FILE_PRIV_EMBEDDEDDIR` options
  - The (undocumented) `mysql` `--server-arg` option
  - The `mysqltest` `--embedded-server`, `--server-arg`, and `--server-file` options
  - The `mysqltest_embedded` and `mysql_client_test_embedded` test programs
The `mysql_plugin` utility was removed. Alternatives include loading plugins at server startup using the `--plugin-load` or `--plugin-load-add` option, or at runtime using the `INSTALL PLUGIN` statement.

The `resolveip` utility is removed. `nslookup`, `host`, or `dig` can be used instead.

The `resolve_stack_dump` utility is removed. Stack traces from official MySQL builds are always symbolized, so there is no need to use `resolve_stack_dump`.

The following server error codes are not used and have been removed. Applications that test specifically for any of these errors should be updated.

</tbody>
</table>
• The deprecated INFORMATION_SCHEMA INNODB_LOCKS and INNODB_LOCK_WAITS tables are removed. Use the Performance Schema data_locks and data_lock_waits tables instead.

Note

In MySQL 5.7, the LOCK_TABLE column in the INNODB_LOCKS table and the locked_table column in the sys schema innodb_lock_waits and x$innodb_lock_waits views contain combined schema/table name values. In MySQL 8.0, the data_locks table and the sys schema views contain separate schema name and table name columns. See Section 27.4.3.9, “The innodb_lock_waits and x$innodb_lock_waits Views”.

• InnoDB no longer supports compressed temporary tables. When innodb_strict_mode is enabled (the default), CREATE TEMPORARY TABLE returns an error if ROW_FORMAT=COMPRESSED or KEY_BLOCK_SIZE is specified. If innodb_strict_mode is disabled, warnings are issued and the temporary table is created using a non-compressed row format.

• InnoDB no longer creates .isl files (InnoDB Symbolic Link files) when creating tablespace data files outside of the MySQL data directory. The innodb_directories option now supports locating tablespace files created outside of the data directory.

With this change, moving a remote tablespace while the server is offline by manually modifying an .isl file is no longer supported. Moving remote tablespace files is now supported by the innodb_directories option. See Section 15.6.3.8, “Moving Tablespace Files While the Server is Offline”.

• The following InnoDB file format variables were removed:
  • innodb_file_format
  • innodb_file_format_check
Server and Status Variables and Options Added, Deprecated, or Removed in MySQL 8.0

1.5 Server and Status Variables and Options Added, Deprecated, or Removed in MySQL 8.0

This section lists server variables, status variables, and options that were added for the first time, have been deprecated, or have been removed in MySQL 8.0.

- **Options and Variables Introduced in MySQL 8.0**
- **Options and Variables Deprecated in MySQL 8.0**
- **Options and Variables Removed in MySQL 8.0**

**Options and Variables Introduced in MySQL 8.0**

The following system variables, status variables, and options are new in MySQL 8.0, and have not been included in any previous release series.

- `innodb_file_format_max`
- `innodb_large_prefix`

File format variables were necessary for creating tables compatible with earlier versions of InnoDB in MySQL 5.1. Now that MySQL 5.1 has reached the end of its product lifecycle, these options are no longer required.

The `FILE_FORMAT` column was removed from the `INNODB_TABLES` and `INNODB_TABLESPACES` Information Schema tables.

- The `innodb_support_xa` system variable, which enables support for two-phase commit in XA transactions, was removed. InnoDB support for two-phase commit in XA transactions is always enabled.

- Support for DTrace was removed.

- The `JSON_APPEND()` function was removed. Use `JSON_ARRAY_APPEND()` instead.

- Support for placing table partitions in shared InnoDB tablespaces was removed in MySQL 8.0.13. Shared tablespaces include the InnoDB system tablespace and general tablespaces. For information about identifying partitions in shared tablespaces and moving them to file-per-table tablespaces, see Section 2.11.5, "Preparing Your Installation for Upgrade".

- Support for setting user variables in statements other than `SET` was deprecated in MySQL 8.0.13. This functionality is subject to removal in MySQL 9.0.

- The `--ndb_perror` option was removed. Use the `ndb_perror` utility instead.

- The `innodb_undo_logs` variable was removed. The `innodb_rollback_segments` variables perform the same function and should be used instead.

- The `Innodb_available_undo_logs` status variable was removed. The number of available rollback segments per tablespace may be retrieved using `SHOW VARIABLES LIKE 'innodb_rollback_segments';`

- As of MySQL 8.0.14, the previously deprecated `innodb_undo_tablespaces` variable is no longer configurable. For more information, see Section 15.6.3.4, "Undo Tablespaces".

- Support for the `ALTER TABLE ... UPGRADE PARTITIONING` statement has been removed.

- As of MySQL 8.0.16, support for the `internal_tmp_disk_storage_engine` system variable has been removed; internal temporary tables on disk now always use the InnoDB storage engine. See Storage Engine for On-Disk Internal Temporary Tables for more information.
• **Acl_cache_items_count**: Number of cached privilege objects. Added in MySQL 8.0.0.

• **Audit_log_current_size**: Audit log file current size. Added in MySQL 8.0.11.

• **Audit_log_event_max_drop_size**: Size of largest dropped audited event. Added in MySQL 8.0.11.

• **Audit_log_events**: Number of handled audited events. Added in MySQL 8.0.11.

• **Audit_log_events_filtered**: Number of filtered audited events. Added in MySQL 8.0.11.

• **Audit_log_events_lost**: Number of dropped audited events. Added in MySQL 8.0.11.

• **Audit_log_events_written**: Number of written audited events. Added in MySQL 8.0.11.

• **Audit_log_total_size**: Combined size of written audited events. Added in MySQL 8.0.11.

• **Audit_log_write_waits**: Number of write-delayed audited events. Added in MySQL 8.0.11.

• **Caching_sha2_password_rsa_public_key**: caching_sha2_password authentication plugin RSA public key value. Added in MySQL 8.0.4.

• **Com_alter_resource_group**: Count of ALTER RESOURCE GROUP statements. Added in MySQL 8.0.3.

• **Com_alter_user_default_role**: Count of ALTER USER ... DEFAULT ROLE statements. Added in MySQL 8.0.0.

• **Com_clone**: Count of CLONE statements. Added in MySQL 8.0.2.

• **Com_create_resource_group**: Count of CREATE RESOURCE GROUP statements. Added in MySQL 8.0.3.

• **Com_create_role**: Count of CREATE ROLE statements. Added in MySQL 8.0.0.

• **Com_drop_resource_group**: Count of DROP RESOURCE GROUP statements. Added in MySQL 8.0.3.

• **Com_drop_role**: Count of DROP ROLE statements. Added in MySQL 8.0.0.

• **Com_grant_roles**: Count of GRANT ROLE statements. Added in MySQL 8.0.0.

• **Com_install_component**: Count of INSTALL COMPONENT statements. Added in MySQL 8.0.0.

• **Com_revoke_roles**: Count of REVOKE ROLES statements. Added in MySQL 8.0.0.

• **Com_set_resource_group**: Count of SET RESOURCE GROUP statements. Added in MySQL 8.0.3.

• **Com_set_role**: Count of SET ROLE statements. Added in MySQL 8.0.0.

• **Com_uninstall_component**: Count of UINSTALL COMPONENT statements. Added in MySQL 8.0.0.

• **Compression_algorithm**: Compression algorithm for current connection. Added in MySQL 8.0.18.

• **Compression_level**: Compression level for current connection. Added in MySQL 8.0.18.

• **Connection_control_delay_generated**: How many times the server delayed a connection request. Added in MySQL 8.0.1.

• **Current_tls_ca**: Current value of ssl_ca system variable. Added in MySQL 8.0.16.
• **Current_tls_capath**: Current value of ssl_capath system variable. Added in MySQL 8.0.16.

• **Current_tls_cert**: Current value of ssl_cert system variable. Added in MySQL 8.0.16.

• **Current_tls_cipher**: Current value of ssl_cipher system variable. Added in MySQL 8.0.16.

• **Current_tls_ciphersuites**: Current value of ssl_ciphersuites system variable. Added in MySQL 8.0.16.

• **Current_tls_crl**: Current value of ssl_crl system variable. Added in MySQL 8.0.16.

• **Current_tls_crlpath**: Current value of ssl_crlpath system variable. Added in MySQL 8.0.16.

• **Current_tls_key**: Current value of ssl_key system variable. Added in MySQL 8.0.16.

• **Current_tls_version**: Current value of ssl_version system variable. Added in MySQL 8.0.16.

• **Firewall_access_denied**: Number of statements rejected by MySQL Enterprise Firewall. Added in MySQL 8.0.11.

• **Firewall_access_granted**: Number of statements accepted by MySQL Enterprise Firewall. Added in MySQL 8.0.11.

• **Firewall_cached_entries**: Number of statements recorded by MySQL Enterprise Firewall. Added in MySQL 8.0.11.

• **Secondary_engine_execution_count**: For future use. Added in MySQL 8.0.13.

• **activate_all_roles_on_login**: Whether to activate all user roles at connect time. Added in MySQL 8.0.2.

• **admin_address**: IP address to bind to for connections on administrative interface. Added in MySQL 8.0.14.

• **admin_port**: TCP/IP number to use for connections on administrative interface. Added in MySQL 8.0.14.

• **audit-log**: Whether to activate the audit log plugin. Added in MySQL 8.0.11.

• **audit_log_buffer_size**: The size of the audit log buffer. Added in MySQL 8.0.11.

• **audit_log_compression**: Audit log file compression method. Added in MySQL 8.0.11.

• **audit_log_connection_policy**: Audit logging policy for connection-related events. Added in MySQL 8.0.11.

• **audit_log_current_session**: Whether to audit current session. Added in MySQL 8.0.11.

• **audit_log_encryption**: Audit log file encryption method. Added in MySQL 8.0.11.

• **audit_log_exclude_accounts**: Accounts not to audit. Added in MySQL 8.0.11.

• **audit_log_file**: The name of the audit log file. Added in MySQL 8.0.11.

• **audit_log_filter_id**: ID of current audit log filter. Added in MySQL 8.0.11.

• **audit_log_flush**: Close and reopen the audit log file. Added in MySQL 8.0.11.

• **audit_log_format**: The audit log file format. Added in MySQL 8.0.11.

• **audit_log_include_accounts**: Accounts to audit. Added in MySQL 8.0.11.

• **audit_log_policy**: Audit logging policy. Added in MySQL 8.0.11.

• **audit_log_read_buffer_size**: Audit log file read buffer size. Added in MySQL 8.0.11.
• **audit_log_rotate_on_size**: Close and reopen the audit log file at a certain size. Added in MySQL 8.0.11.

• **audit_log_statement_policy**: Audit logging policy for statement-related events. Added in MySQL 8.0.11.

• **audit_log_strategy**: The audit logging strategy. Added in MySQL 8.0.11.

• **authentication_ldap_sasl_auth_method_name**: Authentication method name. Added in MySQL 8.0.11.

• **authentication_ldap_sasl_bind_base_dn**: LDAP server base distinguished name. Added in MySQL 8.0.11.

• **authentication_ldap_sasl_bind_root_dn**: LDAP server root distinguished name. Added in MySQL 8.0.11.

• **authentication_ldap_sasl_bind_root_pwd**: LDAP server root bind password. Added in MySQL 8.0.11.

• **authentication_ldap_sasl_ca_path**: LDAP server certificate authority file name. Added in MySQL 8.0.11.

• **authentication_ldap_sasl_group_search_attr**: LDAP server group search attribute. Added in MySQL 8.0.11.

• **authentication_ldap_sasl_group_search_filter**: LDAP custom group search filter. Added in MySQL 8.0.11.

• **authentication_ldap_sasl_init_pool_size**: LDAP server initial connection pool size. Added in MySQL 8.0.11.

• **authentication_ldap_sasl_log_status**: LDAP server log level. Added in MySQL 8.0.11.

• **authentication_ldap_sasl_max_pool_size**: LDAP server maximum connection pool size. Added in MySQL 8.0.11.

• **authentication_ldap_sasl_server_host**: LDAP server host name or IP address. Added in MySQL 8.0.11.

• **authentication_ldap_sasl_server_port**: LDAP server port number. Added in MySQL 8.0.11.

• **authentication_ldap_sasl_tls**: Whether to use encrypted connections to LDAP server. Added in MySQL 8.0.11.

• **authentication_ldap_sasl_user_search_attr**: LDAP server user search attribute. Added in MySQL 8.0.11.

• **authentication_ldap_simple_auth_method_name**: Authentication method name. Added in MySQL 8.0.11.

• **authentication_ldap_simple_bind_base_dn**: LDAP server base distinguished name. Added in MySQL 8.0.11.

• **authentication_ldap_simple_bind_root_dn**: LDAP server root distinguished name. Added in MySQL 8.0.11.

• **authentication_ldap_simple_bind_root_pwd**: LDAP server root bind password. Added in MySQL 8.0.11.

• **authentication_ldap_simple_ca_path**: LDAP server certificate authority file name. Added in MySQL 8.0.11.
Options and Variables Introduced in MySQL 8.0

- `authentication_ldap_simple_group_search_attr`: LDAP server group search attribute. Added in MySQL 8.0.11.
- `authentication_ldap_simple_group_search_filter`: LDAP custom group search filter. Added in MySQL 8.0.11.
- `authentication_ldap_simple_init_pool_size`: LDAP server initial connection pool size. Added in MySQL 8.0.11.
- `authentication_ldap_simple_log_status`: LDAP server log level. Added in MySQL 8.0.11.
- `authentication_ldap_simple_max_pool_size`: LDAP server maximum connection pool size. Added in MySQL 8.0.11.
- `authentication_ldap_simple_server_host`: LDAP server host name or IP address. Added in MySQL 8.0.11.
- `authentication_ldap_simple_server_port`: LDAP server port number. Added in MySQL 8.0.11.
- `authentication_ldap_simple_tls`: Whether to use encrypted connections to LDAP server. Added in MySQL 8.0.11.
- `authentication_ldap_simple_user_search_attr`: LDAP server user search attribute. Added in MySQL 8.0.11.
- `authentication_windows_log_level`: Windows authentication plugin logging level. Added in MySQL 8.0.11.
- `authentication_windows_use_principal_name`: Whether to use Windows authentication plugin principal name. Added in MySQL 8.0.11.
- `binlog_encryption`: Enable encryption for binary log files and relay log files on this server. Added in MySQL 8.0.14.
- `binlog_expire_logs_seconds`: Purge binary logs after this many seconds. Added in MySQL 8.0.1.
- `binlog_rotate_encryption_master_key_at_startup`: Rotate the binary log master key at server startup. Added in MySQL 8.0.14.
- `binlog_row_metadata`: Configures the amount of table related metadata binary logged when using row-based logging. Added in MySQL 8.0.1.
- `binlog_row_value_options`: Enables binary logging of partial JSON updates for row-based replication. Added in MySQL 8.0.3.
- `binlog_transaction_dependency_history_size`: Number of row hashes kept for looking up transaction that last updated some row. Added in MySQL 8.0.1.
- `binlog_transaction_dependency_tracking`: Source of dependency information (commit timestamps or transaction write sets) from which to assess which transactions can be executed in parallel by slave's multithreaded applier. Added in MySQL 8.0.1.
- `caching_sha2_password_auto_generate_rsa_keys`: Whether to autogenerate RSA key-pair files. Added in MySQL 8.0.4.
- `caching_sha2_password_private_key_path`: SHA2 authentication plugin private key path name. Added in MySQL 8.0.3.
- `caching_sha2_password_public_key_path`: SHA2 authentication plugin public key path name. Added in MySQL 8.0.3.
- `connection_control_failed_connections_threshold`: Consecutive failed connection attempts before delays occur. Added in MySQL 8.0.1.

- `connection_control_max_connection_delay`: Maximum delay (milliseconds) for server response to failed connection attempts. Added in MySQL 8.0.1.

- `connection_control_min_connection_delay`: Minimum delay (milliseconds) for server response to failed connection attempts. Added in MySQL 8.0.1.

- `create_admin_listener_thread`: Whether to use dedicated listening thread for connections on administrative interface. Added in MySQL 8.0.14.

- `cte_max_recursion_depth`: Common table expression maximum recursion depth. Added in MySQL 8.0.3.

- `ddl-rewriter`: Whether to activate the `ddl_rewriter` plugin. Added in MySQL 8.0.16.

- `default_collation_for_utf8mb4`: Default collation for `utf8mb4` character set. Added in MySQL 8.0.11.

- `default_table_encryption`: The default schema and tablespace encryption setting. Added in MySQL 8.0.16.

- `dragnet.Status`: Result of most recent assignment to `dragnet.log_error_filter_rules`. Added in MySQL 8.0.12.

- `early-plugin-load`: Specify plugins to load before loading mandatory built-in plugins and before storage engine initialization. Added in MySQL 8.0.0.

- `group_replication_autorejoin_tries`: Number of tries that a member makes to automatically rejoin the group. Added in MySQL 8.0.16.

- `group_replication_communication_debug_options`: The level of debugging messages for Group Replication components. Added in MySQL 8.0.3.

- `group_replication_communication_max_message_size`: Maximum message size for Group Replication communications, larger messages are fragmented. Added in MySQL 8.0.16.

- `group_replication_consistency`: The type of transaction consistency guarantee which the group provides. Added in MySQL 8.0.14.

- `group_replication_exit_state_action`: How the instance behaves when it leaves the group involuntarily. Added in MySQL 8.0.12.

- `group_replication_flow_control_hold_percent`: Defines what percentage of the group quota remains unused. Added in MySQL 8.0.2.

- `group_replication_flow_control_max_commit_quota`: Defines the maximum flow control quota of the group. Added in MySQL 8.0.2.

- `group_replication_flow_control_member_quota_percent`: Defines the percentage of the quota that a member should assume is available for itself when calculating the quotas. Added in MySQL 8.0.2.

- `group_replication_flow_control_min_quota`: Controls the lowest flow control quota that can be assigned to a member. Added in MySQL 8.0.2.

- `group_replication_flow_control_min_recovery_quota`: Controls the lowest quota that can be assigned to a member because of another recovering member in the group. Added in MySQL 8.0.2.
Options and Variables Introduced in MySQL 8.0

- `group_replication_flow_control_period`: Defines how many seconds to wait between flow control iterations. Added in MySQL 8.0.2.

- `group_replication_flow_control_release_percent`: Defines how the group quota should be released when flow control no longer needs to throttle the writer members. Added in MySQL 8.0.2.

- `group_replication_member_expel_timeout`: The time between a suspected failure of a group member and it being expelled from the group, causing a group membership reconfiguration. Added in MySQL 8.0.13.

- `group_replication_member_weight`: Chance of this member being elected as primary. Added in MySQL 8.0.2.

- `group_replication_message_cache_size`: Maximum memory for the message cache in the group communication engine (XCom). Added in MySQL 8.0.16.

- `group_replication_recovery_compression_algorithm`: Permitted compression algorithms for outgoing recovery connections. Added in MySQL 8.0.18.

- `group_replication_recovery_get_public_key`: Whether to accept preference about fetching public key from master. Added in MySQL 8.0.4.

- `group_replication_recovery_public_key_path`: To accept public key information. Added in MySQL 8.0.4.

- `group_replication_recovery_zstd_compression_level`: Compression level for recovery connections that use zstd compression. Added in MySQL 8.0.18.

- `group_replication_unreachable_majority_timeout`: How long to wait for network partitions that result in a minority to leave the group. Added in MySQL 8.0.2.

- `histogram_generation_max_mem_size`: Maximum memory for creating histogram statistics. Added in MySQL 8.0.2.

- `immediate_server_version`: The MySQL Server release number of the server that is the immediate master in a replication topology. Added in MySQL 8.0.14.

- `information_schema_stats_expiry`: Expiration setting for cached table statistics. Added in MySQL 8.0.3.

- `innodb_buffer_pool_debug`: Permits multiple buffer pool instances when the buffer pool is less than 1GB in size. Added in MySQL 8.0.0.

- `innodb_buffer_pool_in_core_file`: Controls writing of buffer pool pages to core files. Added in MySQL 8.0.14.

- `innodb_checkpoint_disabled`: Disables checkpoints so that a deliberate server exit always initiates recovery. Added in MySQL 8.0.2.

- `innodb_ddl_log_crash_reset_debug`: A debug option that resets DDL log crash injection counters. Added in MySQL 8.0.3.

- `innodb_deadlock_detect`: Enables or disables deadlock detection. Added in MySQL 8.0.0.

- `innodb_dedicated_server`: Enables automatic configuration of buffer pool size, log file size, and flush method. Added in MySQL 8.0.3.

- `innodb_directories`: Defines directories to scan at startup for tablespace data files. Added in MySQL 8.0.4.

- `innodb_fsync_threshold`: Controls how often InnoDB calls fsync when creating a new file. Added in MySQL 8.0.13.
• **innodb_log_checkpoint_fuzzy_now**: A debug option that forces InnoDB to write a fuzzy checkpoint. Added in MySQL 8.0.13.

• **innodb_log_spin_cpu_abs_lwm**: Minimum amount of CPU usage below which user threads no longer spin while waiting for flushed redo. Added in MySQL 8.0.11.

• **innodb_log_spin_cpu_pct_hwm**: Maximum amount of CPU usage above which user threads no longer spin while waiting for flushed redo. Added in MySQL 8.0.11.

• **innodb_log_wait_for_flush_spin_hwm**: The maximum average log flush time beyond which user threads no longer spin while waiting for flushed redo. Added in MySQL 8.0.11.

• **innodb_parallel_read_threads**: Defines the number of threads for parallel index reads. Added in MySQL 8.0.14.

• **innodb_print_ddl_logs**: Whether or not to print DDL logs to the error log. Added in MySQL 8.0.3.

• **innodb_redo_log_archive_dirs**: Labeled redo log archive directories. Added in MySQL 8.0.17.

• **innodb_redo_log_encrypt**: Controls encryption of redo log data for encrypted tablespaces. Added in MySQL 8.0.1.

• **innodb_scan_directories**: Defines directories to scan for tablespace files during InnoDB recovery. Added in MySQL 8.0.2.

• **innodb_spin_wait_pause_multiplier**: Defines a multiplier value used to determine the number of PAUSE instructions in spin-wait loops. Added in MySQL 8.0.16.

• **innodb_stats_include_delete_marked**: Include delete-marked records when calculating persistent InnoDB statistics. Added in MySQL 8.0.1.

• **innodb_temp_tablespaces_dir**: Session temporary tablespaces path. Added in MySQL 8.0.13.

• **innodb_tmpdir**: The directory location for the temporary table files created during online ALTER TABLE operations. Added in MySQL 8.0.0.

• **innodb_undo_log_encrypt**: Controls encryption of undo log data for encrypted tablespaces. Added in MySQL 8.0.1.

• **internal_tmp_mem_storage_engine**: Defines the storage to use for internal in-memory temporary tables. Added in MySQL 8.0.2.

• **keyring-migration-destination**: Key migration destination keyring plugin. Added in MySQL 8.0.4.

• **keyring-migration-host**: Host name for connecting to running server for key migration. Added in MySQL 8.0.4.

• **keyring-migration-password**: Password for connecting to running server for key migration. Added in MySQL 8.0.4.

• **keyring-migration-port**: TCP/IP port number for connecting to running server for key migration. Added in MySQL 8.0.4.

• **keyring-migration-socket**: Unix socket file or Windows named pipe for connecting to running server for key migration. Added in MySQL 8.0.4.

• **keyring-migration-source**: Key migration source keyring plugin. Added in MySQL 8.0.4.

• **keyring-migration-user**: User name for connecting to running server for key migration. Added in MySQL 8.0.4.
Options and Variables Introduced in MySQL 8.0

- **keyring_aws_cmk_id**: AWS keyring plugin customer master key ID value. Added in MySQL 8.0.11.
- **keyring_aws_conf_file**: AWS keyring plugin configuration file location. Added in MySQL 8.0.11.
- **keyring_aws_data_file**: AWS keyring plugin storage file location. Added in MySQL 8.0.11.
- **keyring_aws_region**: AWS keyring plugin region. Added in MySQL 8.0.11.
- **keyring_encrypted_file_data**: keyring_encrypted_file plugin data file. Added in MySQL 8.0.11.
- **keyring_encrypted_file_password**: keyring_encrypted_file plugin password. Added in MySQL 8.0.11.
- **keyring_okv_conf_dir**: Oracle Key Vault keyring plugin configuration directory. Added in MySQL 8.0.11.
- **keyring_operations**: Whether keyring operations are enabled. Added in MySQL 8.0.4.
- **lock_order**: Whether to enable LOCK_ORDER tool at runtime. Added in MySQL 8.0.17.
- **lock_order_debug_loop**: Whether to cause debug assert when LOCK_ORDER tool encounters dependency flagged as a loop. Added in MySQL 8.0.17.
- **lock_order_debug_missing_arc**: Whether to cause debug assert when LOCK_ORDER tool encounters undeclared dependency. Added in MySQL 8.0.17.
- **lock_order_debug_missing_key**: Whether to cause debug assert when LOCK_ORDER tool encounters object not properly instrumented with the Performance Schema. Added in MySQL 8.0.17.
- **lock_order_debug_missing_unlock**: Whether to cause debug assert when LOCK_ORDER tool encounters lock that is destroyed while still held. Added in MySQL 8.0.17.
- **lock_order_dependencies**: Path to the lock_order_dependencies.txt file. Added in MySQL 8.0.17.
- **lock_order_extra_dependencies**: Path to a second dependency file. Added in MySQL 8.0.17.
- **lock_order_output_directory**: Directory where LOCK_ORDER tool writes logs. Added in MySQL 8.0.17.
- **lock_order_print_txt**: Whether to perform lock-order graph analysis and print textual report. Added in MySQL 8.0.17.
- **lock_order_trace_loop**: Whether to print log file trace when LOCK_ORDER tool encounters dependency flagged as a loop. Added in MySQL 8.0.17.
- **lock_order_trace_missing_arc**: Whether to print log file trace when LOCK_ORDER tool encounters undeclared dependency. Added in MySQL 8.0.17.
- **lock_order_trace_missing_key**: Whether to print log file trace when LOCK_ORDER tool encounters object not properly instrumented with the Performance Schema. Added in MySQL 8.0.17.
- **lock_order_trace_missing_unlock**: Whether to print log file trace when LOCK_ORDER tool encounters lock that is destroyed while still held. Added in MySQL 8.0.17.
- **log_error_filter_rules**: Filter rules for error logging. Added in MySQL 8.0.2.
- **log_error_services**: Components to use for error logging. Added in MySQL 8.0.2.
- **log_error_suppression_list**: Warning/information error log messages to suppress. Added in MySQL 8.0.13.
• **log_slow_extra**: Whether to write extra information to the slow query log file. Added in MySQL 8.0.14.

• **mandatory_roles**: Automatically granted roles for all users. Added in MySQL 8.0.2.

• **mysql_firewall_mode**: Whether MySQL Enterprise Firewall is operational. Added in MySQL 8.0.11.

• **mysql_firewall_trace**: Whether to enable firewall trace. Added in MySQL 8.0.11.

• **mysqlx**: Whether X Plugin is initialized. Added in MySQL 8.0.11.

• **mysqlx_interactive_timeout**: Number of seconds to wait for interactive clients to timeout. Added in MySQL 8.0.4.

• **mysqlx_read_timeout**: Number of seconds to wait for blocking read operations to complete. Added in MySQL 8.0.4.

• **mysqlx_wait_timeout**: Number of seconds to wait for activity on a connection. Added in MySQL 8.0.4.

• **mysqlx_write_timeout**: Number of seconds to wait for blocking write operations to complete. Added in MySQL 8.0.4.

• **named_pipe_full_access_group**: Name of Windows group granted full access to the named pipe. Added in MySQL 8.0.14.

• **no-dd-upgrade**: Prevent automatic upgrade of data dictionary tables at startup. Added in MySQL 8.0.4.

• **no-monitor**: Do not fork monitor process required for RESTART. Added in MySQL 8.0.12.

• **original_commit_timestamp**: The time when a transaction was committed on the original master. Added in MySQL 8.0.1.

• **original_server_version**: The MySQL Server release number of the server where a transaction was originally committed. Added in MySQL 8.0.14.

• **partial_revokes**: Whether partial revocation is enabled. Added in MySQL 8.0.16.

• **password_history**: Number of password changes required before password reuse. Added in MySQL 8.0.3.

• **password_require_current**: Whether password changes require current password verification. Added in MySQL 8.0.13.

• **passwordReuse_interval**: Number of days elapsed required before password reuse. Added in MySQL 8.0.3.

• **performance_schema_max_digest_sample_age**: The query resample age in seconds. Added in MySQL 8.0.3.

• **persist_only_admin_x509_subject**: SSL certificate X.509 Subject that enables persisting persist-restricted system variables. Added in MySQL 8.0.14.

• **persisted_globals_load**: Whether to load persisted configuration settings. Added in MySQL 8.0.0.

• **print_identified_with_as_hex**: For SHOW CREATE USER, print hash values containing unprintable characters in hex. Added in MySQL 8.0.17.

• **protocol_compression_algorithms**: Permitted compression algorithms for incoming connections. Added in MySQL 8.0.18.
- `regexp_stack_limit`: Regular expression match stack size limit. Added in MySQL 8.0.4.
- `regexp_time_limit`: Regular expression match timeout. Added in MySQL 8.0.4.
- `resultset_metadata`: Whether the server returns result set metadata. Added in MySQL 8.0.3.
- `rpl_read_size`: Set the minimum amount of data in bytes that is read from the binary log files and relay log files. Added in MySQL 8.0.11.
- `secondary_engine_cost_threshold`: For future use. Added in MySQL 8.0.16.
- `show_create_table_verbosity`: Whether to display ROW_FORMAT in SHOW CREATE TABLE even if it has the default value. Added in MySQL 8.0.11.
- `sql_require_primary_key`: Whether tables must have a primary key. Added in MySQL 8.0.13.
- `ssl_fips_mode`: Whether to enable FIPS mode on server side. Added in MySQL 8.0.11.
- `syseventlog.facility`: Facility for syslog messages. Added in MySQL 8.0.13.
- `syseventlog.include_pid`: Whether to include server PID in syslog messages. Added in MySQL 8.0.13.
- `syseventlog.tag`: Tag for server identifier in syslog messages. Added in MySQL 8.0.13.
- `table_encryption_privilege_check`: Enables the TABLE_ENCRYPTION_ADMIN privilege check. Added in MySQL 8.0.16.
- `temptable_max_ram`: Defines the maximum amount of memory that can occupied by the TempTable storage engine before data is stored on disk. Added in MySQL 8.0.2.
- `temptable_use_mmap`: Defines whether the TempTable storage engine allocates memory-mapped files when the temptable_max_ram threshold is reached. Added in MySQL 8.0.16.
- `thread_pool_algorithm`: The thread pool algorithm. Added in MySQL 8.0.11.
- `thread_pool_high_priority_connection`: Whether the current session is high priority. Added in MySQL 8.0.11.
- `thread_pool_max_unused_threads`: The maximum permissible number of unused threads. Added in MySQL 8.0.11.
- `thread_pool_prio_kickup_timer`: How long before a statement is moved to high-priority execution. Added in MySQL 8.0.11.
- `thread_pool_size`: Number of thread groups in the thread pool. Added in MySQL 8.0.11.
- `thread_pool_stall_limit`: How long before a statement is defined as stalled. Added in MySQL 8.0.11.
- `tls_ciphersuites`: Permissible TLSv1.3 ciphersuites for encrypted connections. Added in MySQL 8.0.16.
- `upgrade`: Control automatic upgrade at startup. Added in MySQL 8.0.16.
- `use_secondary_engine`: For future use. Added in MySQL 8.0.13.
- `validate-config`: Validate server configuration. Added in MySQL 8.0.16.
- `validate_password.check_user_name`: Whether to check passwords against user name. Added in MySQL 8.0.4.
Options and Variables Deprecated in MySQL 8.0

The following system variables, status variables, and options have been deprecated in MySQL 8.0.

- **Compression**: Whether the client connection uses compression in the client/server protocol. Deprecated as of MySQL 8.0.18.
- **expire_logs_days**: Purge binary logs after this many days. Deprecated as of MySQL 8.0.3.
- **innodb_undo_tablespaces**: Number of tablespace files that rollback segments are divided between. Deprecated as of MySQL 8.0.4.
- **log_syslog**: Whether to write error log to syslog. Deprecated as of MySQL 8.0.2.
- **no-dd-upgrade**: Prevent automatic upgrade of data dictionary tables at startup. Deprecated as of MySQL 8.0.16.
- **slave_compressed_protocol**: Use compression of master/slave protocol. Deprecated as of MySQL 8.0.18.
- **symbolic-links**: Permit symbolic links for MyISAM tables. Deprecated as of MySQL 8.0.2.

Options and Variables Removed in MySQL 8.0

The following system variables, status variables, and options have been removed in MySQL 8.0.

- **Com_alter_db_upgrade**: Count of ALTER DATABASE ... UPGRADE DATA DIRECTORY NAME statements. Removed in MySQL 8.0.0.
- **Innodb_available_undo_logs**: Display the total number of InnoDB rollback segments; different from innodb_rollback_segments, which displays the number of active rollback segments. Removed in MySQL 8.0.2.
- **Qcache_free_blocks**: Number of free memory blocks in the query cache. Removed in MySQL 8.0.3.
- **Qcache_free_memory**: The amount of free memory for the query cache. Removed in MySQL 8.0.3.
Options and Variables Removed in MySQL 8.0

- **Qcache_hits**: Number of query cache hits. Removed in MySQL 8.0.3.
- **Qcache_inserts**: Number of query cache inserts. Removed in MySQL 8.0.3.
- **Qcache_lowmem_prunes**: Number of queries that were deleted from the query cache due to lack of free memory in the cache. Removed in MySQL 8.0.3.
- **Qcache_not_cached**: Number of noncached queries (not cacheable, or not cached due to the query_cache_type setting). Removed in MySQL 8.0.3.
- **Qcache_queries_in_cache**: Number of queries registered in the query cache. Removed in MySQL 8.0.3.
- **Qcache_total_blocks**: The total number of blocks in the query cache. Removed in MySQL 8.0.3.
- **Slave_heartbeat_period**: The slave's replication heartbeat interval, in seconds. Removed in MySQL 8.0.1.
- **Slave_last_heartbeat**: Shows when the latest heartbeat signal was received, in TIMESTAMP format. Removed in MySQL 8.0.1.
- **Slave_received_heartbeats**: Number of heartbeats received by a replication slave since previous reset. Removed in MySQL 8.0.1.
- **Slave_retried_transactions**: The total number of times since startup that the replication slave SQL thread has retried transactions. Removed in MySQL 8.0.1.
- **Slave_running**: The state of this server as a replication slave (slave I/O thread status). Removed in MySQL 8.0.1.
- **bootstrap**: Used by mysql installation scripts. Removed in MySQL 8.0.0.
- **date_format**: The DATE format (unused). Removed in MySQL 8.0.3.
- **datetime_format**: The DATETIME/TIMESTAMP format (unused). Removed in MySQL 8.0.3.
- **des-key-file**: Load keys for des_encrypt() and des_encrypt from given file. Removed in MySQL 8.0.3.
- **group_replication_allow_local_disjoint_gtids_join**: Allow the current server to join the group even if it has transactions not present in the group. Removed in MySQL 8.0.4.
- **have_crypt**: Availability of the crypt() system call. Removed in MySQL 8.0.3.
- **ignore-built-in-innodb**: Ignore the built-in InnoDB. Removed in MySQL 8.0.3.
- **ignore-db-dir**: Treat directory as nondatabase directory. Removed in MySQL 8.0.0.
- **ignore_db_dirs**: Directories treated as nondatabase directories. Removed in MySQL 8.0.0.
- **innodb_checksums**: Enable InnoDB checksums validation. Removed in MySQL 8.0.0.
- **innodb_disable_resize_buffer_pool_debug**: Disables resizing of the InnoDB buffer pool. Removed in MySQL 8.0.0.
- **innodb_file_format**: The format for new InnoDB tables. Removed in MySQL 8.0.0.
- **innodb_file_format_check**: Whether InnoDB performs file format compatibility checking. Removed in MySQL 8.0.0.
- **innodb_file_format_max**: The file format tag in the shared tablespace. Removed in MySQL 8.0.0.
- **innodb_large_prefix**: Enables longer keys for column prefix indexes. Removed in MySQL 8.0.0.
• **innodb_locks_unsafe_for_binlog**: Force InnoDB not to use next-key locking. Instead use only row-level locking. Removed in MySQL 8.0.0.

• **innodb_scan_directories**: Defines directories to scan for tablespace files during InnoDB recovery. Removed in MySQL 8.0.4.

• **innodb_stats_sample_pages**: Number of index pages to sample for index distribution statistics. Removed in MySQL 8.0.0.

• **innodb_support_xa**: Enable InnoDB support for the XA two-phase commit. Removed in MySQL 8.0.0.

• **innodb_undo_logs**: Defines the number of undo logs (rollback segments) used by InnoDB; an alias for innodb_rollback_segments. Removed in MySQL 8.0.2.

• **internal_tmp_disk_storage_engine**: Storage engine for internal temporary tables. Removed in MySQL 8.0.16.

• **log-warnings**: Log some noncritical warnings to the log file. Removed in MySQL 8.0.3.

• **log_builtin_as_identified_by_password**: Whether to log CREATE/ALTER USER, GRANT in backward-compatible fashion. Removed in MySQL 8.0.11.

• **log_error_filter_rules**: Filter rules for error logging. Removed in MySQL 8.0.4.

• **log_syslog**: Whether to write error log to syslog. Removed in MySQL 8.0.13.

• **log_syslog_facility**: Facility for syslog messages. Removed in MySQL 8.0.13.

• **log_syslog_include_pid**: Whether to include server PID in syslog messages. Removed in MySQL 8.0.13.

• **log_syslog_tag**: Tag for server identifier in syslog messages. Removed in MySQL 8.0.13.

• **max_tmp_tables**: Unused. Removed in MySQL 8.0.3.

• **metadata_locks_cache_size**: Size of the metadata locks cache. Removed in MySQL 8.0.13.

• **metadata_locks_hash_instances**: Number of metadata lock hashes. Removed in MySQL 8.0.13.

• **multi_range_count**: The maximum number of ranges to send to a table handler at once during range selects. Removed in MySQL 8.0.3.

• **old_passwords**: Selects password hashing method for PASSWORD(). Removed in MySQL 8.0.11.

• **partition**: Enable (or disable) partitioning support. Removed in MySQL 8.0.0.

• **query_cache_limit**: Do not cache results that are bigger than this. Removed in MySQL 8.0.3.

• **query_cache_min_res_unit**: Minimal size of unit in which space for results is allocated (last unit will be trimmed after writing all result data). Removed in MySQL 8.0.3.

• **query_cache_size**: The memory allocated to store results from old queries. Removed in MySQL 8.0.3.

• **query_cache_type**: Query cache type. Removed in MySQL 8.0.3.

• **query_cache_wlock_invalidate**: Invalidate queries in query cache on LOCK for write. Removed in MySQL 8.0.3.

• **secure-auth**: Disallow authentication for accounts that have old (pre-4.1) passwords. Removed in MySQL 8.0.3.
• **show_compatibility_56**: Compatibility for SHOW STATUS/VARIABLES. Removed in MySQL 8.0.1.

• **skip-partition**: Do not enable user-defined partitioning. Removed in MySQL 8.0.0.

• **sync_frm**: Sync .frm to disk on create. Enabled by default. Removed in MySQL 8.0.0.

• **temp_pool**: Using this option will cause most temporary files created to use a small set of names, rather than a unique name for each new file. Removed in MySQL 8.0.1.

• **time_format**: The TIME format (unused). Removed in MySQL 8.0.3.

• **tx_isolation**: The default transaction isolation level. Removed in MySQL 8.0.3.

• **tx_read_only**: Default transaction access mode. Removed in MySQL 8.0.3.

### 1.6 MySQL Information Sources

This section lists sources of additional information that you may find helpful, such as MySQL websites, mailing lists, user forums, and Internet Relay Chat.

#### 1.6.1 MySQL Websites

The primary website for MySQL documentation is [https://dev.mysql.com/doc/](https://dev.mysql.com/doc/). Online and downloadable documentation formats are available for the MySQL Reference Manual, MySQL Connectors, and more.

The MySQL developers provide information about new and upcoming features as the [MySQL Server Blog](https://dev.mysql.com/mysql-server-blog/).

#### 1.6.2 MySQL Community Support at the MySQL Forums

The forums at [http://forums.mysql.com](http://forums.mysql.com) are an important community resource. Many forums are available, grouped into these general categories:

- Migration
- MySQL Usage
- MySQL Connectors
- Programming Languages
- Tools
- 3rd-Party Applications
- Storage Engines
- MySQL Technology
- SQL Standards
- Business

#### 1.6.3 MySQL Enterprise

Oracle offers technical support in the form of MySQL Enterprise. For organizations that rely on the MySQL DBMS for business-critical production applications, MySQL Enterprise is a commercial subscription offering which includes:
How to Report Bugs or Problems

Before posting a bug report about a problem, please try to verify that it is a bug and that it has not been reported already:

• Start by searching the MySQL online manual at https://dev.mysql.com/doc/. We try to keep the manual up to date by updating it frequently with solutions to newly found problems. In addition, the release notes accompanying the manual can be particularly useful since it is quite possible that a newer version contains a solution to your problem. The release notes are available at the location just given for the manual.

• If you get a parse error for an SQL statement, please check your syntax closely. If you cannot find something wrong with it, it is extremely likely that your current version of MySQL Server doesn't support the syntax you are using. If you are using the current version and the manual doesn't cover the syntax that you are using, MySQL Server doesn't support your statement.

    If the manual covers the syntax you are using, but you have an older version of MySQL Server, you should check the MySQL change history to see when the syntax was implemented. In this case, you have the option of upgrading to a newer version of MySQL Server.

• For solutions to some common problems, see Section B.4, “Problems and Common Errors”.

• Search the bugs database at http://bugs.mysql.com/ to see whether the bug has been reported and fixed.

• You can also use http://www.mysql.com/search/ to search all the Web pages (including the manual) that are located at the MySQL website.

If you cannot find an answer in the manual, the bugs database, or the mailing list archives, check with your local MySQL expert. If you still cannot find an answer to your question, please use the following guidelines for reporting the bug.

The normal way to report bugs is to visit http://bugs.mysql.com/, which is the address for our bugs database. This database is public and can be browsed and searched by anyone. If you log in to the system, you can enter new reports.

Bugs posted in the bugs database at http://bugs.mysql.com/ that are corrected for a given release are noted in the release notes.

If you find a sensitive security bug in MySQL Server, please let us know immediately by sending an email message to <secalert_us@oracle.com>. Exception: Support customers should report all problems, including security bugs, to Oracle Support at http://support.oracle.com/.

To discuss problems with other users, you can use the MySQL Community Slack.

Writing a good bug report takes patience, but doing it right the first time saves time both for us and for yourself. A good bug report, containing a full test case for the bug, makes it very likely that we will fix the bug in the next release. This section helps you write your report correctly so that you do not waste
How to Report Bugs or Problems

your time doing things that may not help us much or at all. Please read this section carefully and make sure that all the information described here is included in your report.

Preferably, you should test the problem using the latest production or development version of MySQL Server before posting. Anyone should be able to repeat the bug by just using `mysql test < script_file` on your test case or by running the shell or Perl script that you include in the bug report. Any bug that we are able to repeat has a high chance of being fixed in the next MySQL release.

It is most helpful when a good description of the problem is included in the bug report. That is, give a good example of everything you did that led to the problem and describe, in exact detail, the problem itself. The best reports are those that include a full example showing how to reproduce the bug or problem. See Section 29.5, “Debugging and Porting MySQL”.

Remember that it is possible for us to respond to a report containing too much information, but not to one containing too little. People often omit facts because they think they know the cause of a problem and assume that some details do not matter. A good principle to follow is that if you are in doubt about stating something, state it. It is faster and less troublesome to write a couple more lines in your report than to wait longer for the answer if we must ask you to provide information that was missing from the initial report.

The most common errors made in bug reports are (a) not including the version number of the MySQL distribution that you use, and (b) not fully describing the platform on which the MySQL server is installed (including the platform type and version number). These are highly relevant pieces of information, and in 99 cases out of 100, the bug report is useless without them. Very often we get questions like, “Why doesn't this work for me?” Then we find that the feature requested wasn't implemented in that MySQL version, or that a bug described in a report has been fixed in newer MySQL versions. Errors often are platform-dependent. In such cases, it is next to impossible for us to fix anything without knowing the operating system and the version number of the platform.

If you compiled MySQL from source, remember also to provide information about your compiler if it is related to the problem. Often people find bugs in compilers and think the problem is MySQL-related. Most compilers are under development all the time and become better version by version. To determine whether your problem depends on your compiler, we need to know what compiler you used. Note that every compiling problem should be regarded as a bug and reported accordingly.

If a program produces an error message, it is very important to include the message in your report. If we try to search for something from the archives, it is better that the error message reported exactly matches the one that the program produces. (Even the lettercase should be observed.) It is best to copy and paste the entire error message into your report. You should never try to reproduce the message from memory.

If you have a problem with Connector/ODBC (MyODBC), please try to generate a trace file and send it with your report. See How to Report Connector/ODBC Problems or Bugs.

If your report includes long query output lines from test cases that you run with the `mysql` command-line tool, you can make the output more readable by using the `--vertical` option or the `\G` statement terminator. The `EXPLAIN SELECT` example later in this section demonstrates the use of `\G`.

Please include the following information in your report:

- The version number of the MySQL distribution you are using (for example, MySQL 5.7.10). You can find out which version you are running by executing `mysqladmin version`. The `mysqladmin` program can be found in the `bin` directory under your MySQL installation directory.

- The manufacturer and model of the machine on which you experience the problem.

- The operating system name and version. If you work with Windows, you can usually get the name and version number by double-clicking your My Computer icon and pulling down the “Help/About Windows” menu. For most Unix-like operating systems, you can get this information by executing the command `uname -a`.

- Sometimes the amount of memory (real and virtual) is relevant. If in doubt, include these values.
• The contents of the `docs/INFO_BIN` file from your MySQL installation. This file contains information about how MySQL was configured and compiled.

• If you are using a source distribution of the MySQL software, include the name and version number of the compiler that you used. If you have a binary distribution, include the distribution name.

• If the problem occurs during compilation, include the exact error messages and also a few lines of context around the offending code in the file where the error occurs.

• If `mysqld` died, you should also report the statement that crashed `mysqld`. You can usually get this information by running `mysqld` with query logging enabled, and then looking in the log after `mysqld` crashes. See Section 29.5, "Debugging and Porting MySQL".

• If a database table is related to the problem, include the output from the `SHOW CREATE TABLE db_name.tbl_name` statement in the bug report. This is a very easy way to get the definition of any table in a database. The information helps us create a situation matching the one that you have experienced.

• The SQL mode in effect when the problem occurred can be significant, so please report the value of the `sql_mode` system variable. For stored procedure, stored function, and trigger objects, the relevant `sql_mode` value is the one in effect when the object was created. For a stored procedure or function, the `SHOW CREATE PROCEDURE` or `SHOW CREATE FUNCTION` statement shows the relevant SQL mode, or you can query `INFORMATION_SCHEMA` for the information:

```
SELECT ROUTINE_SCHEMA, ROUTINE_NAME, SQL_MODE
FROM INFORMATION_SCHEMA.ROUTINES;
```

For triggers, you can use this statement:

```
SELECT EVENT_OBJECT_SCHEMA, EVENT_OBJECT_TABLE, TRIGGER_NAME, SQL_MODE
FROM INFORMATION_SCHEMA.TRIGGERS;
```

• For performance-related bugs or problems with `SELECT` statements, you should always include the output of `EXPLAIN SELECT ...`, and at least the number of rows that the `SELECT` statement produces. You should also include the output from `SHOW CREATE TABLE tbl_name` for each table that is involved. The more information you provide about your situation, the more likely it is that someone can help you.

The following is an example of a very good bug report. The statements are run using the `mysql` command-line tool. Note the use of the `\G` statement terminator for statements that would otherwise provide very long output lines that are difficult to read.

```
mysql> SHOW VARIABLES;
mysql> SHOW COLUMNS FROM ...
<output from SHOW COLUMNS>
mysql> EXPLAIN SELECT ...
<output from EXPLAIN>
mysql> FLUSH STATUS;
mysql> SELECT ...
<output from SELECT, including the time taken to run the query>
mysql> SHOW STATUS;
<output from SHOW STATUS>
```

• If a bug or problem occurs while running `mysqld`, try to provide an input script that reproduces the anomaly. This script should include any necessary source files. The more closely the script can reproduce your situation, the better. If you can make a reproducible test case, you should upload it to be attached to the bug report.

If you cannot provide a script, you should at least include the output from `mysqladmin variables extended-status processlist` in your report to provide some information on how your system is performing.
• If you cannot produce a test case with only a few rows, or if the test table is too big to be included in the bug report (more than 10 rows), you should dump your tables using `mysqldump` and create a `README` file that describes your problem. Create a compressed archive of your files using `tar` and `gzip` or `zip`. After you initiate a bug report for our bugs database at [http://bugs.mysql.com/](http://bugs.mysql.com/), click the Files tab in the bug report for instructions on uploading the archive to the bugs database.

• If you believe that the MySQL server produces a strange result from a statement, include not only the result, but also your opinion of what the result should be, and an explanation describing the basis for your opinion.

• When you provide an example of the problem, it is better to use the table names, variable names, and so forth that exist in your actual situation than to come up with new names. The problem could be related to the name of a table or variable. These cases are rare, perhaps, but it is better to be safe than sorry. After all, it should be easier for you to provide an example that uses your actual situation, and it is by all means better for us. If you have data that you do not want to be visible to others in the bug report, you can upload it using the Files tab as previously described. If the information is really top secret and you do not want to show it even to us, go ahead and provide an example using other names, but please regard this as the last choice.

• Include all the options given to the relevant programs, if possible. For example, indicate the options that you use when you start the `mysqld` server, as well as the options that you use to run any MySQL client programs. The options to programs such as `mysqld` and `mysql`, and to the `configure` script, are often key to resolving problems and are very relevant. It is never a bad idea to include them. If your problem involves a program written in a language such as Perl or PHP, please include the language processor's version number, as well as the version for any modules that the program uses. For example, if you have a Perl script that uses the `DBI` and `DBD::mysql` modules, include the version numbers for Perl, `DBI`, and `DBD::mysql`.

• If your question is related to the privilege system, please include the output of `mysqladmin reload`, and all the error messages you get when trying to connect. When you test your privileges, you should execute `mysqladmin reload version` and try to connect with the program that gives you trouble.

• If you have a patch for a bug, do include it. But do not assume that the patch is all we need, or that we can use it, if you do not provide some necessary information such as test cases showing the bug that your patch fixes. We might find problems with your patch or we might not understand it at all. If so, we cannot use it.

If we cannot verify the exact purpose of the patch, we will not use it. Test cases help us here. Show that the patch handles all the situations that may occur. If we find a borderline case (even a rare one) where the patch will not work, it may be useless.

• Guesses about what the bug is, why it occurs, or what it depends on are usually wrong. Even the MySQL team cannot guess such things without first using a debugger to determine the real cause of a bug.

• Indicate in your bug report that you have checked the reference manual and mail archive so that others know you have tried to solve the problem yourself.

• If your data appears corrupt or you get errors when you access a particular table, first check your tables with `CHECK TABLE`. If that statement reports any errors:

  • The InnoDB crash recovery mechanism handles cleanup when the server is restarted after being killed, so in typical operation there is no need to “repair” tables. If you encounter an error with InnoDB tables, restart the server and see whether the problem persists, or whether the error affected only cached data in memory. If data is corrupted on disk, consider restarting with the `innodb_force_recovery` option enabled so that you can dump the affected tables.

  • For non-transactional tables, try to repair them with `REPAIR TABLE` or with `myisamchk`. See Chapter 5, MySQL Server Administration.
If you are running Windows, please verify the value of `lower_case_table_names` using the `SHOW VARIABLES LIKE 'lower_case_table_names'` statement. This variable affects how the server handles lettercase of database and table names. Its effect for a given value should be as described in Section 9.2.2, “Identifier Case Sensitivity”.

- If you often get corrupted tables, you should try to find out when and why this happens. In this case, the error log in the MySQL data directory may contain some information about what happened. (This is the file with the `.err` suffix in the name.) See Section 5.4.2, “The Error Log”. Please include any relevant information from this file in your bug report. Normally `mysqld` should never crash a table if nothing killed it in the middle of an update. If you can find the cause of `mysqld` dying, it is much easier for us to provide you with a fix for the problem. See Section B.4.1, “How to Determine What Is Causing a Problem”.

- If possible, download and install the most recent version of MySQL Server and check whether it solves your problem. All versions of the MySQL software are thoroughly tested and should work without problems. We believe in making everything as backward-compatible as possible, and you should be able to switch MySQL versions without difficulty. See Section 2.1.1, “Which MySQL Version and Distribution to Install”.

### 1.8 MySQL Standards Compliance

This section describes how MySQL relates to the ANSI/ISO SQL standards. MySQL Server has many extensions to the SQL standard, and here you can find out what they are and how to use them. You can also find information about functionality missing from MySQL Server, and how to work around some of the differences.

The SQL standard has been evolving since 1986 and several versions exist. In this manual, “SQL-92” refers to the standard released in 1992. “SQL:1999”, “SQL:2003”, “SQL:2008”, and “SQL:2011” refer to the versions of the standard released in the corresponding years, with the last being the most recent version. We use the phrase “the SQL standard” or “standard SQL” to mean the current version of the SQL Standard at any time.

One of our main goals with the product is to continue to work toward compliance with the SQL standard, but without sacrificing speed or reliability. We are not afraid to add extensions to SQL or support for non-SQL features if this greatly increases the usability of MySQL Server for a large segment of our user base. The `HANDLER` interface is an example of this strategy. See Section 13.2.4, “HANDLER Syntax”.

We continue to support transactional and nontransactional databases to satisfy both mission-critical 24/7 usage and heavy Web or logging usage.

MySQL Server was originally designed to work with medium-sized databases (10-100 million rows, or about 100MB per table) on small computer systems. Today MySQL Server handles terabyte-sized databases.

We are not targeting real-time support, although MySQL replication capabilities offer significant functionality.

MySQL supports ODBC levels 0 to 3.51.

MySQL supports high-availability database clustering using the `NDBCLUSTER` storage engine. See Chapter 22, MySQL NDB Cluster 8.0.

We implement XML functionality which supports most of the W3C XPath standard. See Section 12.11, “XML Functions”.

MySQL supports a native JSON data type as defined by RFC 7159, and based on the ECMAScript standard (ECMA-262). See Section 11.6, “The JSON Data Type”. MySQL also implements a subset of the SQL/JSON functions specified by a pre-publication draft of the SQL:2016 standard; see Section 12.17, “JSON Functions”, for more information.
Selecting SQL Modes

The MySQL server can operate in different SQL modes, and can apply these modes differently for different clients, depending on the value of the `sql_mode` system variable. DBAs can set the global SQL mode to match site server operating requirements, and each application can set its session SQL mode to its own requirements.

Modes affect the SQL syntax MySQL supports and the data validation checks it performs. This makes it easier to use MySQL in different environments and to use MySQL together with other database servers.

For more information on setting the SQL mode, see Section 5.1.11, “Server SQL Modes”.

Running MySQL in ANSI Mode

To run MySQL Server in ANSI mode, start `mysqld` with the `--ansi` option. Running the server in ANSI mode is the same as starting it with the following options:

```
--transaction-isolation=SERIALIZABLE --sql-mode=ANSI
```

To achieve the same effect at runtime, execute these two statements:

```
SET GLOBAL TRANSACTION ISOLATION LEVEL SERIALIZABLE;
SET GLOBAL sql_mode = 'ANSI';
```

You can see that setting the `sql_mode` system variable to 'ANSI' enables all SQL mode options that are relevant for ANSI mode as follows:

```
mysql> SET GLOBAL sql_mode='ANSI';
```

```
mysql> SELECT @@GLOBAL.sql_mode;
```

```
-> 'REAL_AS_FLOAT,PIPES_AS_CONCAT,ANSI_QUOTES,IGNORE_SPACE,ANSI'
```

Running the server in ANSI mode with `--ansi` is not quite the same as setting the SQL mode to 'ANSI' because the `--ansi` option also sets the transaction isolation level.

See Section 5.1.7, “Server Command Options”.

1.8.1 MySQL Extensions to Standard SQL

MySQL Server supports some extensions that you probably will not find in other SQL DBMSs. Be warned that if you use them, your code will not be portable to other SQL servers. In some cases, you can write code that includes MySQL extensions, but is still portable, by using comments of the following form:

```
/*! MySQL-specific code */
```

In this case, MySQL Server parses and executes the code within the comment as it would any other SQL statement, but other SQL servers will ignore the extensions. For example, MySQL Server recognizes the `STRAIGHT_JOIN` keyword in the following statement, but other servers will not:

```
SELECT /*! STRAIGHT_JOIN */ col1 FROM table1,table2 WHERE ...
```

If you add a version number after the `!` character, the syntax within the comment is executed only if the MySQL version is greater than or equal to the specified version number. The `KEY_BLOCK_SIZE` clause in the following comment is executed only by servers from MySQL 5.1.10 or higher:

```
CREATE TABLE t1(a INT, KEY (a)) /*!50110 KEY_BLOCK_SIZE=1024 */;
```

The following descriptions list MySQL extensions, organized by category.
MySQL Extensions to Standard SQL

- Organization of data on disk

MySQL Server maps each database to a directory under the MySQL data directory, and maps tables within a database to file names in the database directory. Consequently, database and table names are case-sensitive in MySQL Server on operating systems that have case-sensitive file names (such as most Unix systems). See Section 9.2.2, “Identifier Case Sensitivity”.

- General language syntax

  - By default, strings can be enclosed by " as well as '. If the ANSI_QUOTES SQL mode is enabled, strings can be enclosed only by ' and the server interprets strings enclosed by " as identifiers.

  - \ is the escape character in strings.

  - In SQL statements, you can access tables from different databases with the db_name.tbl_name syntax. Some SQL servers provide the same functionality but call this User space. MySQL Server doesn’t support tablespaces such as used in statements like this: CREATE TABLE ralph.my_table ... IN my_tablespace.

- SQL statement syntax

  - The ANALYZE TABLE, CHECK TABLE, OPTIMIZE TABLE, and REPAIR TABLE statements.

  - The DO statement.

  - EXPLAIN SELECT to obtain a description of how tables are processed by the query optimizer.

  - The FLUSH and RESET statements.

  - The SET statement. See Section 13.7.5.1, “SET Syntax for Variable Assignment”.

  - The SHOW statement. See Section 13.7.6, “SHOW Syntax”. The information produced by many of the MySQL-specific SHOW statements can be obtained in more standard fashion by using SELECT to query INFORMATION_SCHEMA. See Chapter 25, INFORMATION_SCHEMA Tables.

  - Use of LOAD DATA. In many cases, this syntax is compatible with Oracle LOAD DATA. See Section 13.2.7, “LOAD DATA Syntax”.

  - Use of RENAME TABLE. See Section 13.1.36, “RENAME TABLE Syntax”.

  - Use of REPLACE instead of DELETE plus INSERT. See Section 13.2.9, “REPLACE Syntax”.

  - Use of CHANGE col_name, DROP col_name, or DROP INDEX, IGNORE or RENAME in ALTER TABLE statements. Use of multiple ADD, ALTER, DROP, or CHANGE clauses in an ALTER TABLE statement. See Section 13.1.9, “ALTER TABLE Syntax”.

  - Use of index names, indexes on a prefix of a column, and use of INDEX or KEY in CREATE TABLE statements. See Section 13.1.20, “CREATE TABLE Syntax”.

  - Use of TEMPORARY or IF NOT EXISTS with CREATE TABLE.

  - Use of IF EXISTS with DROP TABLE and DROP DATABASE.

  - The capability of dropping multiple tables with a single DROP TABLE statement.

  - The ORDER BY and LIMIT clauses of the UPDATE and DELETE statements.

  - INSERT INTO tbl_name SET col_name = ... syntax.
MySQL Extensions to Standard SQL

- The **DELAYED** clause of the **INSERT** and **REPLACE** statements.
- The **LOW_PRIORITY** clause of the **INSERT**, **REPLACE**, **DELETE**, and **UPDATE** statements.
- Use of **INTO OUTFILE** or **INTO DUMPFILE** in **SELECT** statements. See Section 13.2.10, “SELECT Syntax”.
- Options such as **STRAIGHT_JOIN** or **SQL_SMALL_RESULT** in **SELECT** statements.
- You don’t need to name all selected columns in the **GROUP BY** clause. This gives better performance for some very specific, but quite normal queries. See Section 12.20, “Aggregate (GROUP BY) Functions”.
- You can specify **ASC** and **DESC** with **GROUP BY**, not just with **ORDER BY**.
- The ability to set variables in a statement with the := assignment operator. See Section 9.4, “User-Defined Variables”.

**Data types**

- The **MEDIUMINT**, **SET**, and **ENUM** data types, and the various **BLOB** and **TEXT** data types.
- The **AUTO_INCREMENT**, **BINARY**, **NULL**, **UNSIGNED**, and **ZEROFILL** data type attributes.

**Functions and operators**

- To make it easier for users who migrate from other SQL environments, MySQL Server supports aliases for many functions. For example, all string functions support both standard SQL syntax and ODBC syntax.
- MySQL Server understands the || and && operators to mean logical OR and AND, as in the C programming language. In MySQL Server, || and OR are synonyms, as are && and AND. Because of this nice syntax, MySQL Server doesn't support the standard SQL || operator for string concatenation; use CONCAT() instead. Because CONCAT() takes any number of arguments, it is easy to convert use of the || operator to MySQL Server.
- Use of **COUNT(DISTINCT value_list)** where **value_list** has more than one element.
- String comparisons are case insensitive by default, with sort ordering determined by the collation of the current character set, which is **utf8mb4** by default. To perform case-sensitive comparisons instead, you should declare your columns with the **BINARY** attribute or use the **BINARY** cast, which causes comparisons to be done using the underlying character code values rather than a lexical ordering.
- The % operator is a synonym for **MOD()**. That is, \( N \% M \) is equivalent to **MOD(N, M)**. % is supported for C programmers and for compatibility with PostgreSQL.
- The =, <>, <=, <, >=, >, <<, >>, <=>, AND, OR, or LIKE operators may be used in expressions in the output column list (to the left of the **FROM**) in **SELECT** operators. For example:

```sql
mysql> SELECT col1=1 AND col2=2 FROM my_table;
```
- The **LAST_INSERT_ID()** function returns the most recent **AUTO_INCREMENT** value. See Section 12.15, “Information Functions”.
- **LIKE** is permitted on numeric values.
- The **REGEXP** and **NOT REGEXP** extended regular expression operators.
MySQL Differences from Standard SQL

- **CONCAT()** or **CHAR()** with one argument or more than two arguments. (In MySQL Server, these functions can take a variable number of arguments.)
- The **BIT_COUNT(), CASE, ELT(), FROM_DAYS(), FORMAT(), IF(), MD5(), PERIOD_ADD(), PERIOD_DIFF(), TO_DAYS(),** and **WEEKDAY()** functions.
- Use of **TRIM()** to trim substrings. Standard SQL supports removal of single characters only.
- The **GROUP BY** functions **STD(), BIT_OR(), BIT_AND(), BIT_XOR(),** and **GROUP_CONCAT().** See Section 12.20, “Aggregate (GROUP BY) Functions”.

1.8.2 MySQL Differences from Standard SQL

We try to make MySQL Server follow the ANSI SQL standard and the ODBC SQL standard, but MySQL Server performs operations differently in some cases:

- There are several differences between the MySQL and standard SQL privilege systems. For example, in MySQL, privileges for a table are not automatically revoked when you delete a table. You must explicitly issue a **REVOKE** statement to revoke privileges for a table. For more information, see Section 13.7.1.8, “REVOKE Syntax”.
- The **CAST()** function does not support cast to **REAL** or **BIGINT**. See Section 12.10, “Cast Functions and Operators”.

1.8.2.1 SELECT INTO TABLE Differences

MySQL Server doesn’t support the **SELECT ... INTO TABLE** Sybase SQL extension. Instead, MySQL Server supports the **INSERT INTO ... SELECT** standard SQL syntax, which is basically the same thing. See Section 13.2.6.1, “INSERT ... SELECT Syntax”. For example:

```sql
INSERT INTO tbl_temp2 (fld_id)
SELECT tbl_temp1.fld_order_id
FROM tbl_temp1 WHERE tbl_temp1.fld_order_id > 100;
```

Alternatively, you can use **SELECT ... INTO OUTFILE** or **CREATE TABLE ... SELECT**.

You can use **SELECT ... INTO** with user-defined variables. The same syntax can also be used inside stored routines using cursors and local variables. See Section 13.2.10.1, “SELECT ... INTO Syntax”.

1.8.2.2 UPDATE Differences

If you access a column from the table to be updated in an expression, **UPDATE** uses the current value of the column. The second assignment in the following statement sets **col2** to the current (updated) **col1** value, not the original **col1** value. The result is that **col1** and **col2** have the same value. This behavior differs from standard SQL.

```sql
UPDATE t1 SET col1 = col1 + 1, col2 = col1;
```

1.8.2.3 Foreign Key Differences

The MySQL implementation of foreign keys differs from the SQL standard in the following key respects:

- If there are several rows in the parent table that have the same referenced key value, **InnoDB** acts in foreign key checks as if the other parent rows with the same key value do not exist. For example, if you have defined a **RESTRICT** type constraint, and there is a child row with several parent rows, **InnoDB** does not permit the deletion of any of those parent rows.

**InnoDB** performs cascading operations through a depth-first algorithm, based on records in the indexes corresponding to the foreign key constraints.
How MySQL Deals with Constraints

- A FOREIGN KEY constraint that references a non-UNIQUE key is not standard SQL but rather an InnoDB extension.

- If ON UPDATE CASCADE or ON UPDATE SET NULL recurses to update the same table it has previously updated during the same cascade, it acts like RESTRICT. This means that you cannot use self-referential ON UPDATE CASCADE or ON UPDATE SET NULL operations. This is to prevent infinite loops resulting from cascaded updates. A self-referential ON DELETE SET NULL, on the other hand, is possible, as is a self-referential ON DELETE CASCADE. Cascading operations may not be nested more than 15 levels deep.

- In an SQL statement that inserts, deletes, or updates many rows, foreign key constraints (like unique constraints) are checked row-by-row. When performing foreign key checks, InnoDB sets shared row-level locks on child or parent records that it must examine. MySQL checks foreign key constraints immediately; the check is not deferred to transaction commit. According to the SQL standard, the default behavior should be deferred checking. That is, constraints are only checked after the entire SQL statement has been processed. This means that it is not possible to delete a row that refers to itself using a foreign key.

For information about how the InnoDB storage engine handles foreign keys, see Section 15.6.1.5, “InnoDB and FOREIGN KEY Constraints”.

### 1.8.2.4 '--' as the Start of a Comment

Standard SQL uses the C syntax /* this is a comment */ for comments, and MySQL Server supports this syntax as well. MySQL also support extensions to this syntax that enable MySQL-specific SQL to be embedded in the comment, as described in Section 9.6, “Comment Syntax”.

Standard SQL uses “--” as a start-comment sequence. MySQL Server uses # as the start comment character. MySQL Server also supports a variant of the -- comment style. That is, the -- start-comment sequence must be followed by a space (or by a control character such as a newline). The space is required to prevent problems with automatically generated SQL queries that use constructs such as the following, where we automatically insert the value of the payment for payment:

```sql
UPDATE account SET credit=credit-payment
```

Consider about what happens if payment has a negative value such as -1:

```sql
UPDATE account SET credit=credit--1
```

credit--1 is a valid expression in SQL, but -- is interpreted as the start of a comment, part of the expression is discarded. The result is a statement that has a completely different meaning than intended:

```sql
UPDATE account SET credit=credit
```

The statement produces no change in value at all. This illustrates that permitting comments to start with -- can have serious consequences.

Using our implementation requires a space following the -- for it to be recognized as a start-comment sequence in MySQL Server. Therefore, credit--1 is safe to use.

Another safe feature is that the mysql command-line client ignores lines that start with --.

### 1.8.3 How MySQL Deals with Constraints

MySQL enables you to work both with transactional tables that permit rollback and with nontransactional tables that do not. Because of this, constraint handling is a bit different in MySQL than in other DBMSs. We must handle the case when you have inserted or updated a lot of rows in a nontransactional table for which changes cannot be rolled back when an error occurs.
How MySQL Deals with Constraints

The basic philosophy is that MySQL Server tries to produce an error for anything that it can detect while parsing a statement to be executed, and tries to recover from any errors that occur while executing the statement. We do this in most cases, but not yet for all.

The options MySQL has when an error occurs are to stop the statement in the middle or to recover as well as possible from the problem and continue. By default, the server follows the latter course. This means, for example, that the server may coerce invalid values to the closest valid values.

Several SQL mode options are available to provide greater control over handling of bad data values and whether to continue statement execution or abort when errors occur. Using these options, you can configure MySQL Server to act in a more traditional fashion that is like other DBMSs that reject improper input. The SQL mode can be set globally at server startup to affect all clients. Individual clients can set the SQL mode at runtime, which enables each client to select the behavior most appropriate for its requirements. See Section 5.1.11, "Server SQL Modes".

The following sections describe how MySQL Server handles different types of constraints.

1.8.3.1 PRIMARY KEY and UNIQUE Index Constraints

Normally, errors occur for data-change statements (such as INSERT or UPDATE) that would violate primary-key, unique-key, or foreign-key constraints. If you are using a transactional storage engine such as InnoDB, MySQL automatically rolls back the statement. If you are using a nontransactional storage engine, MySQL stops processing the statement at the row for which the error occurred and leaves any remaining rows unprocessed.

MySQL supports an IGNORE keyword for INSERT, UPDATE, and so forth. If you use it, MySQL ignores primary-key or unique-key violations and continues processing with the next row. See the section for the statement that you are using (Section 13.2.6, “INSERT Syntax”, Section 13.2.12, “UPDATE Syntax”, and so forth).

You can get information about the number of rows actually inserted or updated with the mysql_info() C API function. You can also use the SHOW WARNINGS statement. See Section 28.7.7.36, “mysql_info()”, and Section 13.7.6.40, “SHOW WARNINGS Syntax”.

InnoDB and NDB tables support foreign keys. See Section 1.8.3.2, “FOREIGN KEY Constraints”.

1.8.3.2 FOREIGN KEY Constraints

Foreign keys let you cross-reference related data across tables, and foreign key constraints help keep this spread-out data consistent.

MySQL supports ON UPDATE and ON DELETE foreign key references in CREATE TABLE and ALTER TABLE statements. The available referential actions are RESTRICT (the default), CASCADE, SET NULL, and NO ACTION.

SET DEFAULT is also supported by the MySQL Server but is currently rejected as invalid by InnoDB. Since MySQL does not support deferred constraint checking, NO ACTION is treated as RESTRICT. For the exact syntax supported by MySQL for foreign keys, see Section 13.1.20.6, “Using FOREIGN KEY Constraints”.

MATCH FULL, MATCH PARTIAL, and MATCH SIMPLE are allowed, but their use should be avoided, as they cause the MySQL Server to ignore any ON DELETE or ON UPDATE clause used in the same statement. MATCH options do not have any other effect in MySQL, which in effect enforces MATCH SIMPLE semantics full-time.

MySQL requires that foreign key columns be indexed; if you create a table with a foreign key constraint but no index on a given column, an index is created.

You can obtain information about foreign keys from the INFORMATION_SCHEMA.KEY_COLUMN_USAGE table. An example of a query against this table is shown here:
Information about foreign keys on InnoDB tables can also be found in the INNODB_FOREIGN and INNODB_FOREIGN_COLS tables, in the INFORMATION_SCHEMA database.

InnoDB and NDB tables support foreign keys. See Section 15.6.1.5, “InnoDB and FOREIGN KEY Constraints”, for information specific to foreign key support in InnoDB.

1.8.3.3 Constraints on Invalid Data

By default, MySQL is forgiving of invalid or improper data values and coerces them to valid values for data entry. However, you can enable strict SQL mode to select more traditional treatment of bad values such that the server rejects them and aborts the statement in which they occur. See Section 5.1.11, “Server SQL Modes”.

This section describes the default (forgiving) behavior of MySQL, as well as the strict SQL mode and how it differs.

If you are not using strict mode, then whenever you insert an “incorrect” value into a column, such as a NULL into a NOT NULL column or a too-large numeric value into a numeric column, MySQL sets the column to the “best possible value” instead of producing an error: The following rules describe in more detail how this works:

- If you try to store an out of range value into a numeric column, MySQL Server instead stores zero, the smallest possible value, or the largest possible value, whichever is closest to the invalid value.

- For strings, MySQL stores either the empty string or as much of the string as can be stored in the column.

- If you try to store a string that does not start with a number into a numeric column, MySQL Server stores 0.

- Invalid values for ENUM and SET columns are handled as described in Section 1.8.3.4, “ENUM and SET Constraints”.

- MySQL permits you to store certain incorrect date values into DATE and DATETIME columns (such as '2000-02-31' or '2000-02-00'). In this case, when an application has not enabled strict SQL mode, it up to the application to validate the dates before storing them. If MySQL can store a date value and retrieve exactly the same value, MySQL stores it as given. If the date is totally wrong (outside the server’s ability to store it), the special “zero” date value '0000-00-00' is stored in the column instead.

- If you try to store NULL into a column that doesn’t take NULL values, an error occurs for single-row INSERT statements. For multiple-row INSERT statements or for INSERT INTO ... SELECT statements, MySQL Server stores the implicit default value for the column data type. In general, this is 0 for numeric types, the empty string (" ") for string types, and the “zero” value for date and time types. Implicit default values are discussed in Section 11.7, “Data Type Default Values”.

- If an INSERT statement specifies no value for a column, MySQL inserts its default value if the column definition includes an explicit DEFAULT clause. If the definition has no such DEFAULT clause, MySQL inserts the implicit default value for the column data type.
How MySQL Deals with Constraints

The reason for using the preceding rules in nonstrict mode is that we can't check these conditions until the statement has begun executing. We can't just roll back if we encounter a problem after updating a few rows, because the storage engine may not support rollback. The option of terminating the statement is not that good; in this case, the update would be "half done," which is probably the worst possible scenario. In this case, it is better to "do the best you can" and then continue as if nothing happened.

You can select stricter treatment of input values by using the `STRICT_TRANS_TABLES` or `STRICT_ALL_TABLES` SQL modes:

```sql
SET sql_mode = 'STRICT_TRANS_TABLES';
SET sql_mode = 'STRICT_ALL_TABLES';
```

`STRICT_TRANS_TABLES` enables strict mode for transactional storage engines, and also to some extent for nontransactional engines. It works like this:

- For transactional storage engines, bad data values occurring anywhere in a statement cause the statement to abort and roll back.
- For nontransactional storage engines, a statement aborts if the error occurs in the first row to be inserted or updated. (When the error occurs in the first row, the statement can be aborted to leave the table unchanged, just as for a transactional table.) Errors in rows after the first do not abort the statement, because the table has already been changed by the first row. Instead, bad data values are adjusted and result in warnings rather than errors. In other words, with `STRICT_TRANS_TABLES`, a wrong value causes MySQL to roll back all updates done so far, if that can be done without changing the table. But once the table has been changed, further errors result in adjustments and warnings.

For even stricter checking, enable `STRICT_ALL_TABLES`. This is the same as `STRICT_TRANS_TABLES` except that for nontransactional storage engines, errors abort the statement even for bad data in rows following the first row. This means that if an error occurs partway through a multiple-row insert or update for a nontransactional table, a partial update results. Earlier rows are inserted or updated, but those from the point of the error on are not. To avoid this for nontransactional tables, either use single-row statements or else use `STRICT_TRANS_TABLES` if conversion warnings rather than errors are acceptable. To avoid problems in the first place, do not use MySQL to check column content. It is safest (and often faster) to let the application ensure that it passes only valid values to the database.

With either of the strict mode options, you can cause errors to be treated as warnings by using `INSERT IGNORE` or `UPDATE IGNORE` rather than `INSERT` or `UPDATE` without `IGNORE`.

### 1.8.3.4 ENUM and SET Constraints

**ENUM** and **SET** columns provide an efficient way to define columns that can contain only a given set of values. See [Section 11.4.4, “The ENUM Type”](#), and [Section 11.4.5, “The SET Type”](#).

With strict mode enabled (see [Section 5.1.11, “Server SQL Modes”](#)), the definition of a **ENUM** or **SET** column acts as a constraint on values entered into the column. An error occurs for values that do not satisfy these conditions:

- An **ENUM** value must be one of those listed in the column definition, or the internal numeric equivalent thereof. The value cannot be the error value (that is, 0 or the empty string). For a column defined as `ENUM('a', 'b', 'c')`, values such as `''`, `'d'`, or `'ax'` are invalid and are rejected.

- A **SET** value must be the empty string or a value consisting only of the values listed in the column definition separated by commas. For a column defined as `SET('a', 'b', 'c')`, values such as `'d'` or `'a,b,c,d'` are invalid and are rejected.

Errors for invalid values can be suppressed in strict mode if you use `INSERT IGNORE` or `UPDATE IGNORE`. In this case, a warning is generated rather than an error. For **ENUM**, the value is inserted as
the error member (0). For SET, the value is inserted as given except that any invalid substrings are deleted. For example, 'a,x,b,y' results in a value of 'a,b'.

1.9 Credits

The following sections list developers, contributors, and supporters that have helped to make MySQL what it is today.

1.9.1 Contributors to MySQL

Although Oracle Corporation and/or its affiliates own all copyrights in the MySQL server and the MySQL manual, we wish to recognize those who have made contributions of one kind or another to the MySQL distribution. Contributors are listed here, in somewhat random order:

• Gianmassimo Vigazzola <qwerg@mbox.vol.it> or <qwerg@tin.it>
  The initial port to Win32/NT.

• Per Eric Olsson
  For constructive criticism and real testing of the dynamic record format.

• Irena Pancirov <irena@mail.yacc.it>
  Win32 port with Borland compiler. mysqlshutdown.exe and mysqlwatch.exe.

• David J. Hughes
  For the effort to make a shareware SQL database. At TcX, the predecessor of MySQL AB, we started with mSQL, but found that it couldn’t satisfy our purposes so instead we wrote an SQL interface to our application builder Unireg. mysqladmin and mysql client are programs that were largely influenced by their mSQL counterparts. We have put a lot of effort into making the MySQL syntax a superset of mSQL. Many of the API’s ideas are borrowed from mSQL to make it easy to port free mSQL programs to the MySQL API. The MySQL software doesn’t contain any code from mSQL. Two files in the distribution (client/insert_test.c and client/select_test.c) are based on the corresponding (noncopyrighted) files in the mSQL distribution, but are modified as examples showing the changes necessary to convert code from mSQL to MySQL Server. (mSQL is copyrighted David J. Hughes.)

• Patrick Lynch
  For helping us acquire http://www.mysql.com/.

• Fred Lindberg
  For setting up qmail to handle the MySQL mailing list and for the incredible help we got in managing the MySQL mailing lists.

• Igor Romanenko <igor@frog.kiev.ua>
  mysqldump (previously msqldump, but ported and enhanced by Monty).

• Yuri Dario
  For keeping up and extending the MySQL OS/2 port.

• Tim Bunce
  Author of mysqlhotcopy.

• Zarko Mocnik <zarko.mocnik@dem.si>
Sorting for Slovenian language.

- "TAMITO" <tommy@valley.ne.jp>
  The \_MB character set macros and the ujis and sjis character sets.

- Joshua Chamas <joshua@chamas.com>
  Base for concurrent insert, extended date syntax, debugging on NT, and answering on the MySQL mailing list.

- Yves Carlier <Yves.Carlier@rug.ac.be>
  mysqlaccess, a program to show the access rights for a user.

- Rhys Jones <rhys@wales.com> (And GWE Technologies Limited)
  For one of the early JDBC drivers.

- Dr Xiaokun Kelvin ZHU <X.Zhu@brad.ac.uk>
  Further development of one of the early JDBC drivers and other MySQL-related Java tools.

- James Cooper <pixel@organic.com>
  For setting up a searchable mailing list archive at his site.

- Rick Mehalick <Rick_Mehalick@i-o.com>
  For xmysql, a graphical X client for MySQL Server.

- Doug Sisk <sisk@wix.com>
  For providing RPM packages of MySQL for Red Hat Linux.

- Diemand Alexander V. <axeld@vial.ethz.ch>
  For providing RPM packages of MySQL for Red Hat Linux-Alpha.

- Antoni Pamies Olive <toni@readysoft.es>
  For providing RPM versions of a lot of MySQL clients for Intel and SPARC.

- Jay Bloodworth <jay@pathways.sde.state.sc.us>
  For providing RPM versions for MySQL 3.21.

- David Sacerdote <davids@secnet.com>
  Ideas for secure checking of DNS host names.

- Wei-Jou Chen <jou@nematic.ieo.nctu.edu.tw>
  Some support for Chinese(BIG5) characters.

- Wei He <hewei@mail.ied.ac.cn>
  A lot of functionality for the Chinese(GBK) character set.

- Jan Pazdziora <adelton@fi.muni.cz>
  Czech sorting order.

- Zeev Suraski <bourbon@netvision.net.il>
FROM_UNIXTIME() time formatting, ENCRYPT() functions, and bison advisor. Active mailing list member.

- **Luuk de Boer <luuk@wxs.nl>**
  Ported (and extended) the benchmark suite to DBI/DBD. Have been of great help with crash-me and running benchmarks. Some new date functions. The mysql_setpermission script.

- **Alexis Mikhailov <root@medinf.chuvashia.su>**
  User-defined functions (UDFs); CREATE FUNCTION and DROP FUNCTION.

- **Andreas F. Bobak <bobak@relog.ch>**
  The AGGREGATE extension to user-defined functions.

- **Ross Wakelin <R.Wakelin@march.co.uk>**
  Help to set up InstallShield for MySQL-Win32.

- **Jethro Wright III <jetman@li.net>**
  The libmysql.dll library.

- **James Pereria <jpereira@iafrica.com>**
  Mysqlmanager, a Win32 GUI tool for administering MySQL Servers.

- **Curt Sampson <cjs@portal.ca>**
  Porting of MIT-pthreads to NetBSD/Alpha and NetBSD 1.3/i386.

- **Martin Ramsch <m.ramsch@computer.org>**
  Examples in the MySQL Tutorial.

- **Steve Harvey**
  For making mysqlaccess more secure.

- **Konark IA-64 Centre of Persistent Systems Private Limited**
  Help with the Win64 port of the MySQL server.

- **Albert Chin-A-Young.**
  Configure updates for Tru64, large file support and better TCP wrappers support.

- **John Birrell**
  Emulation of pthread_mutex() for OS/2.

- **Benjamin Pflugmann**
  Extended MERGE tables to handle INSERTS. Active member on the MySQL mailing lists.

- **Jocelyn Fournier**
  Excellent spotting and reporting innumerable bugs (especially in the MySQL 4.1 subquery code).

- **Marc Liyanage**
  Maintaining the OS X packages and providing invaluable feedback on how to create OS X packages.
Contributors to MySQL

- Robert Rutherford
  Providing invaluable information and feedback about the QNX port.

- Previous developers of NDB Cluster

  Lots of people were involved in various ways summer students, master thesis students, employees. In total more than 100 people so too many to mention here. Notable name is Ataullah Dabaghi who up until 1999 contributed around a third of the code base. A special thanks also to developers of the AXE system which provided much of the architectural foundations for NDB Cluster with blocks, signals and crash tracing functionality. Also credit should be given to those who believed in the ideas enough to allocate of their budgets for its development from 1992 to present time.

- Google Inc.

  We wish to recognize Google Inc. for contributions to the MySQL distribution: Mark Callaghan’s SMP Performance patches and other patches.

Other contributors, bugfinders, and testers: James H. Thompson, Maurizio Menghini, Wojciech Tryc, Luca Berra, Zarko Mocnik, Wim Bonis, Elmar Haneke, <jehamby@lightside>, <psmith@BayNetworks.com>, <duane@connect.com.au>, Ted Deppner <ted@psyber.com>, Mike Simons, Jaakko Hyvatti.

And lots of bug report/patches from the folks on the mailing list.

A big tribute goes to those that help us answer questions on the MySQL mailing lists:

- Daniel Koch <dkoch@amcity.com>
  Irix setup.

- Luuk de Boer <luuk@wxs.nl>
  Benchmark questions.

- Tim Sailer <tps@users.buoy.com>
  DBD::mysql questions.

- Boyd Lynn Gerber <gerberb@zenez.com>
  SCO-related questions.

- Richard Mehalick <RM186061@shellus.com>
  xmysql-related questions and basic installation questions.

- Zeev Suraski <bourbon@netvision.net.il>
  Apache module configuration questions (log & auth), PHP-related questions, SQL syntax-related questions and other general questions.

- Francesc Guasch <frankie@citel.upc.es>
  General questions.

- Jonathan J Smith <jsmith@wtp.net>
  Questions pertaining to OS-specifics with Linux, SQL syntax, and other things that might need some work.

- David Sklar <sklar@student.net>
Using MySQL from PHP and Perl.

- Alistair MacDonald <A.MacDonald@uel.ac.uk>
  Is flexible and can handle Linux and perhaps HP-UX.
- John Lyon <jlyon@imag.net>
  Questions about installing MySQL on Linux systems, using either .rpm files or compiling from source.
- Lorvid Ltd. <lorvid@WOLFENET.com>
  Simple billing/license/support/copyright issues.
- Patrick Sherrill <patrick@coconet.com>
  ODBC and VisualC++ interface questions.
- Randy Harmon <rjharmon@uptimecomputers.com>
  DBD, Linux, some SQL syntax questions.

1.9.2 Documenters and translators

The following people have helped us with writing the MySQL documentation and translating the documentation or error messages in MySQL.

- Paul DuBois
  Ongoing help with making this manual correct and understandable. That includes rewriting Monty’s and David’s attempts at English into English as other people know it.
- Kim Aldale
  Helped to rewrite Monty’s and David’s early attempts at English into English.
- Michael J. Miller Jr. <mke@terrapin.turbolift.com>
  For the first MySQL manual. And a lot of spelling/language fixes for the FAQ (that turned into the MySQL manual a long time ago).
- Yan Cailin
  First translator of the MySQL Reference Manual into simplified Chinese in early 2000 on which the Big5 and HK coded versions were based.
- Jay Flaherty <fty@mediapulse.com>
  Big parts of the Perl DBI/DBD section in the manual.
- Paul Southworth <pauls@etext.org>, Ray Loyzaga <yar@cs.su.oz.au>
- Therrien Gilbert <gilbert@ican.net>, Jean-Marc Pouyot <jmp@scalaire.fr>
  French error messages.
- Petr Snajdr, <snajdr@pvt.net>
  Czech error messages.
Packages that support MySQL

1.9.3 Packages that support MySQL

The following is a list of creators/maintainers of some of the most important API/packages/applications that a lot of people use with MySQL.

We cannot list every possible package here because the list would then be way too hard to maintain. For other packages, please refer to the software portal at http://solutions.mysql.com/software/.

- **Tim Bunce, Alligator Descartes**
  For the **DBD** (Perl) interface.

- **Andreas Koenig <a.koenig@mind.de>**
  For the Perl interface for MySQL Server.
The following is a list of some of the tools we have used to create MySQL. We use this to express our thanks to those that has created them as without these we could not have made MySQL what it is today.

- **Free Software Foundation**
  From whom we got an excellent compiler (**gcc**), an excellent debugger (**gdb** and the **libc** library (from which we have borrowed **strto.c** to get some code working in Linux).

- **Free Software Foundation & The XEmacs development team**
  For a really great editor/environment.

- **Julian Seward**
  Author of **valgrind**, an excellent memory checker tool that has helped us find a lot of otherwise hard to find bugs in MySQL.

- **Dorothea Lütkehaus and Andreas Zeller**
  For **DDD** (The Data Display Debugger) which is an excellent graphical front end to **gdb**.

### 1.9.4 Tools that were used to create MySQL

The following is a list of some of the tools we have used to create MySQL. We use this to express our thanks to those that has created them as without these we could not have made MySQL what it is today.

- **Free Software Foundation**
  From whom we got an excellent compiler (**gcc**), an excellent debugger (**gdb** and the **libc** library (from which we have borrowed **strto.c** to get some code working in Linux).

- **Free Software Foundation & The XEmacs development team**
  For a really great editor/environment.

- **Julian Seward**
  Author of **valgrind**, an excellent memory checker tool that has helped us find a lot of otherwise hard to find bugs in MySQL.

- **Dorothea Lütkehaus and Andreas Zeller**
  For **DDD** (The Data Display Debugger) which is an excellent graphical front end to **gdb**.

### 1.9.5 Supporters of MySQL

Although Oracle Corporation and/or its affiliates own all copyrights in the MySQL server and the MySQL manual, we wish to recognize the following companies, which helped us finance the development of the MySQL server, such as by paying us for developing a new feature or giving us hardware for development of the MySQL server.

- **VA Linux / Andover.net**
  Funded replication.

- **NuSphere**
  Editing of the MySQL manual.

- **Stork Design studio**
Supporters of MySQL

- Intel
  Contributed to development on Windows and Linux platforms.

- Compaq
  Contributed to Development on Linux/Alpha.

- SWSoft
  Development on the embedded mysql version.

- FutureQuest
  The \texttt{--skip-show-database} option.
Chapter 2 Installing and Upgrading MySQL

  2.11.1 Before You Begin .............................................................................. 231
  2.11.2 Upgrade Paths .................................................................................... 232
  2.11.3 What the MySQL Upgrade Process Upgrades ...................................... 233
This chapter describes how to obtain and install MySQL. A summary of the procedure follows and later sections provide the details. If you plan to upgrade an existing version of MySQL to a newer version rather than install MySQL for the first time, see Section 2.11, "Upgrading MySQL", for information about upgrade procedures and about issues that you should consider before upgrading.

If you are interested in migrating to MySQL from another database system, see Section A.8, "MySQL 8.0 FAQ: Migration", which contains answers to some common questions concerning migration issues.

Installation of MySQL generally follows the steps outlined here:

1. **Determine whether MySQL runs and is supported on your platform.**
   
   Please note that not all platforms are equally suitable for running MySQL, and that not all platforms on which MySQL is known to run are officially supported by Oracle Corporation. For information about those platforms that are officially supported, see [https://www.mysql.com/support/supportedplatforms/database.html](https://www.mysql.com/support/supportedplatforms/database.html) on the MySQL website.

2. **Choose which distribution to install.**
   
   Several versions of MySQL are available, and most are available in several distribution formats. You can choose from pre-packaged distributions containing binary (precompiled) programs or source code. When in doubt, use a binary distribution. Oracle also provides access to the MySQL source code for those who want to see recent developments and test new code. To determine which version and type of distribution you should use, see Section 2.1.1, "Which MySQL Version and Distribution to Install".

3. **Download the distribution that you want to install.**
   
   For instructions, see Section 2.1.2, "How to Get MySQL". To verify the integrity of the distribution, use the instructions in Section 2.1.3, "Verifying Package Integrity Using MD5 Checksums or GnuPG".

4. **Install the distribution.**
   
   To install MySQL from a binary distribution, use the instructions in Section 2.2, "Installing MySQL on Unix/Linux Using Generic Binaries".

   To install MySQL from a source distribution or from the current development source tree, use the instructions in Section 2.9, "Installing MySQL from Source".

5. **Perform any necessary postinstallation setup.**
   
   After installing MySQL, see Section 2.10, "Postinstallation Setup and Testing" for information about making sure the MySQL server is working properly. Also refer to the information provided
in Section 2.10.4, “Securing the Initial MySQL Account”. This section describes how to secure the initial MySQL root user account, which has no password until you assign one. The section applies whether you install MySQL using a binary or source distribution.

If you want to run the MySQL benchmark scripts, Perl support for MySQL must be available. See Section 2.13, “Perl Installation Notes”.

Instructions for installing MySQL on different platforms and environments is available on a platform by platform basis:

- **Unix, Linux, FreeBSD**

  For instructions on installing MySQL on most Linux and Unix platforms using a generic binary (for example, a .tar.gz package), see Section 2.2, “Installing MySQL on Unix/Linux Using Generic Binaries”.

  For information on building MySQL entirely from the source code distributions or the source code repositories, see Section 2.9, “Installing MySQL from Source”.

  For specific platform help on installation, configuration, and building from source see the corresponding platform section:

  - Linux, including notes on distribution specific methods, see Section 2.5, “Installing MySQL on Linux”.

  - IBM AIX, see Section 2.7, “Installing MySQL on Solaris”.

  - FreeBSD, see Section 2.8, “Installing MySQL on FreeBSD”.

- **Microsoft Windows**

  For instructions on installing MySQL on Microsoft Windows, using either the MySQL Installer or Zipped binary, see Section 2.3, “Installing MySQL on Microsoft Windows”.

  For information about managing MySQL instances, see Section 2.3.4, “MySQL Notifier”.

  For details and instructions on building MySQL from source code using Microsoft Visual Studio, see Section 2.9, “Installing MySQL from Source”.

- **OS X**

  For installation on OS X, including using both the binary package and native PKG formats, see Section 2.4, “Installing MySQL on macOS”.

  For information on making use of an OS X Launch Daemon to automatically start and stop MySQL, see Section 2.4.3, “Installing and Using the MySQL Launch Daemon”.

  For information on the MySQL Preference Pane, see Section 2.4.4, “Installing and Using the MySQL Preference Pane”.

### 2.1 General Installation Guidance

The immediately following sections contain the information necessary to choose, download, and verify your distribution. The instructions in later sections of the chapter describe how to install the distribution that you choose. For binary distributions, see the instructions at Section 2.2, “Installing MySQL on Unix/Linux Using Generic Binaries” or the corresponding section for your platform if available. To build MySQL from source, use the instructions in Section 2.9, “Installing MySQL from Source”.

#### 2.1.1 Which MySQL Version and Distribution to Install
MySQL is available on a number of operating systems and platforms. For information about those platforms that are officially supported, see https://www.mysql.com/support/supportedplatforms/database.html on the MySQL website.

When preparing to install MySQL, decide which version and distribution format (binary or source) to use.

First, decide whether to install a development release or a General Availability (GA) release. Development releases have the newest features, but are not recommended for production use. GA releases, also called production or stable releases, are meant for production use. We recommend using the most recent GA release.

The naming scheme in MySQL 8.0 uses release names that consist of three numbers and an optional suffix (for example, mysql-8.0.1-dmr). The numbers within the release name are interpreted as follows:

- The first number (8) is the major version number.
- The second number (0) is the minor version number. Taken together, the major and minor numbers constitute the release series number. The series number describes the stable feature set.
- The third number (1) is the version number within the release series. This is incremented for each new bugfix release. In most cases, the most recent version within a series is the best choice.

Release names can also include a suffix to indicate the stability level of the release. Releases within a series progress through a set of suffixes to indicate how the stability level improves. The possible suffixes are:

- **dmr** indicates a development milestone release (DMR). MySQL development uses a milestone model, in which each milestone introduces a small subset of thoroughly tested features. From one milestone to the next, feature interfaces may change or features may even be removed, based on feedback provided by community members who try these early releases. Features within milestone releases may be considered to be of pre-production quality.
- **rc** indicates a Release Candidate (RC). Release candidates are believed to be stable, having passed all of MySQL’s internal testing. New features may still be introduced in RC releases, but the focus shifts to fixing bugs to stabilize features introduced earlier within the series.
- Absence of a suffix indicates a General Availability (GA) or Production release. GA releases are stable, having successfully passed through the earlier release stages, and are believed to be reliable, free of serious bugs, and suitable for use in production systems.

Development within a series begins with DMR releases, followed by RC releases, and finally reaches GA status releases.

After choosing which MySQL version to install, decide which distribution format to install for your operating system. For most use cases, a binary distribution is the right choice. Binary distributions are available in native format for many platforms, such as RPM packages for Linux or DMG packages for OS X. Distributions are also available in more generic formats such as Zip archives or compressed tar files. On Windows, you can use the MySQL Installer to install a binary distribution.

Under some circumstances, it may be preferable to install MySQL from a source distribution:

- You want to install MySQL at some explicit location. The standard binary distributions are ready to run at any installation location, but you might require even more flexibility to place MySQL components where you want.
- You want to configure mysqld with features that might not be included in the standard binary distributions. Here is a list of the most common extra options used to ensure feature availability:
  - `-DWITH_LIBWRAP=1` for TCP wrappers support.
  - `-DWITH_ZLIB=(system|bundled)` for features that depend on compression.
2.1.2 How to Get MySQL

Check our downloads page at https://dev.mysql.com/downloads/ for information about the current version of MySQL and for downloading instructions. For a complete up-to-date list of MySQL download mirror sites, see https://dev.mysql.com/downloads/mirrors.html. You can also find information there about becoming a MySQL mirror site and how to report a bad or out-of-date mirror.

For RPM-based Linux platforms that use Yum as their package management system, MySQL can be installed using the MySQL Yum Repository. See Section 2.5.1, “Installing MySQL on Linux Using the MySQL Yum Repository” for details.

For Debian-based Linux platforms, MySQL can be installed using the MySQL APT Repository. See Section 2.5.2, “Installing MySQL on Linux Using the MySQL APT Repository” for details.

For SUSE Linux Enterprise Server (SLES) platforms, MySQL can be installed using the MySQL SLES Repository. See Section 2.5.3, “Installing MySQL on Linux Using the MySQL SLES Repository” for details.

To obtain the latest development source, see Section 2.9.3, “Installing MySQL Using a Development Source Tree”.

2.1.3 Verifying Package Integrity Using MD5 Checksums or GnuPG

After downloading the MySQL package that suits your needs and before attempting to install it, make sure that it is intact and has not been tampered with. There are three means of integrity checking:

• MD5 checksums

• Cryptographic signatures using GnuPG, the GNU Privacy Guard

• For RPM packages, the built-in RPM integrity verification mechanism

The following sections describe how to use these methods.

If you notice that the MD5 checksum or GPG signatures do not match, first try to download the respective package one more time, perhaps from another mirror site.

2.1.3.1 Verifying the MD5 Checksum

After you have downloaded a MySQL package, you should make sure that its MD5 checksum matches the one provided on the MySQL download pages. Each package has an individual checksum that you can verify against the package that you downloaded. The correct MD5 checksum is listed on the downloads page for each MySQL product, and you will compare it against the MD5 checksum of the file (product) that you download.

Each operating system and setup offers its own version of tools for checking the MD5 checksum. Typically the command is named md5sum, or it may be named md5, and some operating systems do not ship it at all. On Linux, it is part of the GNU Text Utilities package, which is available for a wide range of platforms. You can also download the source code from http://www.gnu.org/software/textutils/. If you have OpenSSL installed, you can use the command openssl md5 package_name instead.
Verifying Package Integrity Using MD5 Checksums or GnuPG

A Windows implementation of the `md5` command line utility is available from http://www.fourmilab.ch/md5/. `winMd5Sum` is a graphical MD5 checking tool that can be obtained from http://www.nullriver.com/index/products/winmd5sum. Our Microsoft Windows examples will assume the name `md5.exe`.

Linux and Microsoft Windows examples:

```
shell> md5sum mysql-standard-8.0.18-linux-i686.tar.gz
aaab65abbec64d5e907dcd41b8699945  mysql-standard-8.0.18-linux-i686.tar.gz
```

```
shell> md5.exe mysql-installer-community-8.0.18.msi
aaab65abbec64d5e907dcd41b8699945  mysql-installer-community-8.0.18.msi
```

You should verify that the resulting checksum (the string of hexadecimal digits) matches the one displayed on the download page immediately below the respective package.

**Note**

Make sure to verify the checksum of the archive file (for example, the `.zip`, `.tar.gz`, or `.msi` file) and not of the files that are contained inside of the archive. In other words, verify the file before extracting its contents.

### 2.1.3.2 Signature Checking Using GnuPG

Another method of verifying the integrity and authenticity of a package is to use cryptographic signatures. This is more reliable than using MD5 checksums, but requires more work.

We sign MySQL downloadable packages with GnuPG (GNU Privacy Guard). GnuPG is an Open Source alternative to the well-known Pretty Good Privacy (PGP) by Phil Zimmermann. Most Linux distributions ship with GnuPG installed by default. Otherwise, see http://www.gnupg.org/ for more information about GnuPG and how to obtain and install it.

To verify the signature for a specific package, you first need to obtain a copy of our public GPG build key, which you can download from http://pgp.mit.edu/. The key that you want to obtain is named `mysql-build@oss.oracle.com`.

Verifying Package Integrity Using MD5 Checksums or GnuPG

To import the build key into your personal public GPG keyring, use gpg --import. For example, if you have saved the key in a file named mysql_pubkey.asc, the import command looks like this:

```
shell> gpg --import mysql_pubkey.asc
```

You can also download the key from the public keyserver using the public key id, 5072E1F5:

```
shell> gpg --recv-keys 5072E1F5
```

If you want to import the key into your RPM configuration to validate RPM install packages, you should be able to import the key directly:

```
shell> gpg --import mysql_pubkey.asc
```

To import the build key into your personal public GPG keyring, use gpg --import. For example, if you have saved the key in a file named mysql_pubkey.asc, the import command looks like this:

```
shell> gpg --import mysql_pubkey.asc
```

gpg: key 5072E1F5: public key "MySQL Release Engineering <mysql-build@oss.oracle.com>" imported

gpg: Total number processed: 1

gpg:               imported: 1

gpg: no ultimately trusted keys found

You can also download the key from the public keyserver using the public key id, 5072E1F5:

```
shell> gpg --recv-keys 5072E1F5
```

You can also obtain the key from the RPM configuration to validate RPM install packages, you should be able to import the key directly:

```
shell> gpg --import mysql_pubkey.asc
```

You can also obtain the key from the RPM configuration to validate RPM install packages, you should be able to import the key directly:

```
shell> gpg --recv-keys 5072E1F5
```

If you want to import the key into your RPM configuration to validate RPM install packages, you should be able to import the key directly:

```

```
new signatures: 53
```
Verifying Package Integrity Using MD5 Checksums or GnuPG

shell> rpm --import mysql_pubkey.asc

If you experience problems or require RPM specific information, see Section 2.1.3.4, “Signature Checking Using RPM”.

After you have downloaded and imported the public build key, download your desired MySQL package and the corresponding signature, which also is available from the download page. The signature file has the same name as the distribution file with an `.asc` extension, as shown by the examples in the following table.

### Table 2.1 MySQL Package and Signature Files for Source files

<table>
<thead>
<tr>
<th>File Type</th>
<th>File Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Distribution file</td>
<td>mysql-standard-8.0.18-linux-i686.tar.gz</td>
</tr>
<tr>
<td>Signature file</td>
<td>mysql-standard-8.0.18-linux-i686.tar.gz.asc</td>
</tr>
</tbody>
</table>

Make sure that both files are stored in the same directory and then run the following command to verify the signature for the distribution file:

shell> gpg --verify package_name.asc

If the downloaded package is valid, you will see a “Good signature” similar to:

shell> gpg --verify mysql-standard-8.0.18-linux-i686.tar.gz.asc

gpg: Signature made Tue 01 Feb 2011 02:38:30 AM CST using DSA key ID 5072E1F5

gpg: Good signature from "MySQL Release Engineering <mysql-build@oss.oracle.com>"

The **Good signature** message indicates that the file signature is valid, when compared to the signature listed on our site. But you might also see warnings, like so:

shell> gpg --verify mysql-standard-8.0.18-linux-i686.tar.gz.asc

gpg: Signature made Wed 23 Jan 2013 02:25:45 AM PST using DSA key ID 5072E1F5

gpg: checking the trustdb

gpg: no ultimately trusted keys found

gpg: Good signature from "MySQL Release Engineering <mysql-build@oss.oracle.com>"

gpg: WARNING: This key is not certified with a trusted signature!

gpg: There is no indication that the signature belongs to the owner.

That is normal, as they depend on your setup and configuration. Here are explanations for these warnings:

- **gpg: no ultimately trusted keys found**: This means that the specific key is not “ultimately trusted” by you or your web of trust, which is okay for the purposes of verifying file signatures.

- **WARNING: This key is not certified with a trusted signature! There is no indication that the signature belongs to the owner.**: This refers to your level of trust in your belief that you possess our real public key. This is a personal decision. Ideally, a MySQL developer would hand you the key in person, but more commonly, you downloaded it. Was the download tampered with? Probably not, but this decision is up to you. Setting up a web of trust is one method for trusting them.

See the GPG documentation for more information on how to work with public keys.

### 2.1.3.3 Signature Checking Using Gpg4win for Windows

The Section 2.1.3.2, “Signature Checking Using GnuPG” section describes how to verify MySQL downloads using GPG. That guide also applies to Microsoft Windows, but another option is to use a GUI tool like **Gpg4win**. You may use a different tool but our examples are based on Gpg4win, and utilize its bundled **Kleopatra GUI**.
Download and install Gpg4win, and then load Kleopatra. The dialog should look similar to:

**Figure 2.1 Kleopatra: Initial Screen**

![Kleopatra: Initial Screen](image)

Next, add the MySQL Release Engineering certificate. Do this by clicking **File, Lookup Certificates on Server**. Type "Mysql Release Engineering" into the search box and press **Search**.

**Figure 2.2 Kleopatra: Lookup Certificates on Server Wizard: Finding a Certificate**

![Lookup Certificates on Server Wizard: Finding a Certificate](image)

Select the "MySQL Release Engineering" certificate. The Fingerprint and Key-ID must be "5072E1F5", or choose **Details...** to confirm the certificate is valid. Now, import it by clicking **Import**. An import dialog will be displayed, choose **Okay**, and this certificate will now be listed under the **Imported Certificates** tab.

Next, configure the trust level for our certificate. Select our certificate, then from the main menu select **Certificates, Change Owner Trust...**. We suggest choosing **I believe checks are very accurate** for our certificate, as otherwise you might not be able to verify our signature. Select **I believe checks are very accurate** to enable "full trust" and then press **OK**.
Next, verify the downloaded MySQL package file. This requires files for both the packaged file, and the signature. The signature file must have the same name as the packaged file but with an appended `.asc` extension, as shown by the example in the following table. The signature is linked to on the downloads page for each MySQL product. You must create the `.asc` file with this signature.

**Table 2.2 MySQL Package and Signature Files for MySQL Installer for Microsoft Windows**

<table>
<thead>
<tr>
<th>File Type</th>
<th>File Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Distribution file</td>
<td>mysql-installer-community-8.0.18.msi</td>
</tr>
<tr>
<td>Signature file</td>
<td>mysql-installer-community-8.0.18.msi.asc</td>
</tr>
</tbody>
</table>

Make sure that both files are stored in the same directory and then run the following command to verify the signature for the distribution file. Either drag and drop the signature (.asc) file into Kleopatra, or load the dialog from File, Decrypt/Verify Files..., and then choose either the `.msi` or `.asc` file.
Click **Decrypt/Verify** to check the file. The two most common results will look like the following, and although the yellow warning looks problematic, the following means that the file check passed with success. You may now run this installer.

Seeing a red "The signature is bad" error means the file is invalid. Do not execute the MSI file if you see this error.
Section 2.1.3.2, “Signature Checking Using GnuPG” section explains why you probably don’t see a green Good signature result.

2.1.3.4 Signature Checking Using RPM

For RPM packages, there is no separate signature. RPM packages have a built-in GPG signature and MD5 checksum. You can verify a package by running the following command:

```
shell> rpm --checksig package_name.rpm
```

Example:

```
shell> rpm --checksig MySQL-server-8.0.18-0.linux_glibc2.5.i386.rpm
MySQL-server-8.0.18-0.linux_glibc2.5.i386.rpm: md5 gpg OK
```

Note

If you are using RPM 4.1 and it complains about (GPG) NOT OK (MISSING KEYS: GPG#5072e1f5), even though you have imported the MySQL public build key into your own GPG keyring, you need to import the key into the RPM keyring first. RPM 4.1 no longer uses your personal GPG keyring (or GPG itself). Rather, RPM maintains a separate keyring because it is a system-wide application and a user’s GPG public keyring is a user-specific file. To import the MySQL public key into the RPM keyring, first obtain the key, then use rpm --import to import the key. For example:

```
shell> gpg --export -a 5072e1f5 > 5072e1f5.asc
shell> rpm --import 5072e1f5.asc
```

Alternatively, rpm also supports loading the key directly from a URL, and you can use this manual page:
If you need to obtain the MySQL public key, see Section 2.1.3.2, “Signature Checking Using GnuPG”.

2.1.4 Installation Layouts

The installation layout differs for different installation types (for example, native packages, binary tarballs, and source tarballs), which can lead to confusion when managing different systems or using different installation sources. The individual layouts are given in the corresponding installation type or platform chapter, as described following. Note that the layout of installations from vendors other than Oracle may differ from these layouts.

• Section 2.3.1, “MySQL Installation Layout on Microsoft Windows”
• Section 2.9.1, “MySQL Layout for Source Installation”
• Table 2.3, “MySQL Installation Layout for Generic Unix/Linux Binary Package”
• Table 2.11, “MySQL Installation Layout for Linux RPM Packages from the MySQL Developer Zone”
• Table 2.6, “MySQL Installation Layout on macOS”

2.1.5 Compiler-Specific Build Characteristics

In some cases, the compiler used to build MySQL affects the features available for use. The notes in this section apply for binary distributions provided by Oracle Corporation or that you compile yourself from source.

icc (Intel C++ Compiler) Builds

A server built with icc has these characteristics:

• SSL support is not included.

2.2 Installing MySQL on Unix/Linux Using Generic Binaries

Oracle provides a set of binary distributions of MySQL. These include generic binary distributions in the form of compressed tar files (files with a .tar.xz extension) for a number of platforms, and binaries in platform-specific package formats for selected platforms.

This section covers the installation of MySQL from a compressed tar file binary distribution on Unix/Linux platforms. For other platform-specific binary package formats, see the other platform-specific sections in this manual. For example, for Windows distributions, see Section 2.3, “Installing MySQL on Microsoft Windows”. See Section 2.1.2, “How to Get MySQL” on how to obtain MySQL in different distribution formats.

MySQL compressed tar file binary distributions have names of the form mysql-VERSION-OS.tar.xz, where VERSION is a number (for example, 8.0.18), and OS indicates the type of operating system for which the distribution is intended (for example, pc-linux-i686 or winx64).

There is also a “minimal install” version of the MySQL compressed tar file for the Linux generic binary distribution, which has a name of the form mysql-VERSION-OS-minimal.tar.xz. The minimal install distribution excludes debug binaries and is stripped of debug symbols, making it significantly smaller than the regular binary distribution. If you choose to install the minimal install distribution, remember to adjust for the difference in file name format in the instructions that follow.

Warnings

• If you have previously installed MySQL using your operating system native package management system, such as Yum or APT, you may experience
problems installing using a native binary. Make sure your previous MySQL installation has been removed entirely (using your package management system), and that any additional files, such as old versions of your data files, have also been removed. You should also check for configuration files such as /etc/my.cnf or the /etc/mysql directory and delete them.

For information about replacing third-party packages with official MySQL packages, see the related APT guide or Yum guide.

MySQL has a dependency on the libaio library. Data directory initialization and subsequent server startup steps will fail if this library is not installed locally. If necessary, install it using the appropriate package manager. For example, on Yum-based systems:

```shell
shell> yum search libaio  # search for info
shell> yum install libaio  # install library
```

Or, on APT-based systems:

```shell
shell> apt-cache search libaio  # search for info
shell> apt-get install libaio1  # install library
```

To install a compressed tar file binary distribution, unpack it at the installation location you choose (typically /usr/local/mysql). This creates the directories shown in the following table.

**Table 2.3 MySQL Installation Layout for Generic Unix/Linux Binary Package**

<table>
<thead>
<tr>
<th>Directory</th>
<th>Contents of Directory</th>
</tr>
</thead>
<tbody>
<tr>
<td>bin</td>
<td>mysql server, client and utility programs</td>
</tr>
<tr>
<td>docs</td>
<td>MySQL manual in Info format</td>
</tr>
<tr>
<td>man</td>
<td>Unix manual pages</td>
</tr>
<tr>
<td>include</td>
<td>Include (header) files</td>
</tr>
<tr>
<td>lib</td>
<td>Libraries</td>
</tr>
<tr>
<td>share</td>
<td>Error messages, dictionary, and SQL for database installation</td>
</tr>
<tr>
<td>support-files</td>
<td>Miscellaneous support files</td>
</tr>
</tbody>
</table>

Debug versions of the mysql server binary are available as mysql-debug. To compile your own debug version of MySQL from a source distribution, use the appropriate configuration options to enable debugging support. See Section 2.9, “Installing MySQL from Source”.

To install and use a MySQL binary distribution, the command sequence looks like this:

```shell
shell> groupadd mysql
shell> useradd -r -g mysql -s /bin/false mysql
shell> cd /usr/local
shell> tar xvf /path/to/mysql-VERSION-OS.tar.xz
shell> ln -s full-path-to-mysql-VERSION-OS mysql
shell> cd mysql
shell> mkdir mysql-files
shell> chown mysql:mysql mysql-files
shell> chmod 750 mysql-files
shell> bin/mysql --initialize --user=mysql
shell> bin/mysql --safe --user=mysql &  # Next command is optional
shell> cp support-files/mysql.server /etc/init.d/mysql.server
```
Create a mysql User and Group

This procedure assumes that you have root (administrator) access to your system. Alternatively, you can prefix each command using the sudo (Linux) or pfexec (Solaris) command.

The mysql-files directory provides a convenient location to use as the value for the secure_file_priv system variable, which limits import and export operations to a specific directory. See Section 5.1.8, "Server System Variables".

A more detailed version of the preceding description for installing a binary distribution follows.

Create a mysql User and Group

If your system does not already have a user and group to use for running mysqld, you may need to create them. The following commands add the mysql group and the mysql user. You might want to call the user and group something else instead of mysql. If so, substitute the appropriate name in the following instructions. The syntax for useradd and groupadd may differ slightly on different versions of Unix/Linux, or they may have different names such as adduser and addgroup.

```
shell> groupadd mysql
shell> useradd -r -g mysql -s /bin/false mysql
```

Because the user is required only for ownership purposes, not login purposes, the useradd command uses the -r and -s /bin/false options to create a user that does not have login permissions to your server host. Omit these options if your useradd does not support them.

Obtain and Unpack the Distribution

Pick the directory under which you want to unpack the distribution and change location into it. The example here unpacks the distribution under /usr/local. The instructions, therefore, assume that you have permission to create files and directories in /usr/local. If that directory is protected, you must perform the installation as root.

```
shell> cd /usr/local
```

Obtain a distribution file using the instructions in Section 2.1.2, “How to Get MySQL”. For a given release, binary distributions for all platforms are built from the same MySQL source distribution.

Unpack the distribution, which creates the installation directory. tar can uncompress and unpack the distribution if it has z option support:

```
shell> tar xvf /path/to/mysql-VERSION-OS.tar.xz
```

The tar command creates a directory named mysql-VERSION-OS.

To install MySQL from a compressed tar file binary distribution, your system must have GNU XZ Utils to uncompress the distribution and a reasonable tar to unpack it.

```
shell> tar xvf /path/to/mysql-VERSION-OS.tar.xz
```

The compression algorithm changed from Gzip to XZ in MySQL Server 8.0.12; and the generic binary's file extension changed from .tar.gz to .tar.xz.

GNU tar is known to work. The standard tar provided with some operating systems is not able to unpack the long file names in the MySQL distribution. You should download and install GNU tar, or if
available, use a preinstalled version of GNU tar. Usually this is available as gnutar, gtar, or as tar within a GNU or Free Software directory, such as /usr/sfw/bin or /usr/local/bin. GNU tar is available from http://www.gnu.org/software/tar/.

If your tar does not support the xz format then use the xz command to unpack the distribution and tar to unpack it. Replace the preceding tar command with the following alternative command to unpack and extract the distribution:

```
shell> xz -dc /path/to/mysql-VERSION-OS.tar.xz | tar x
```

Next, create a symbolic link to the installation directory created by tar:

```
shell> ln -s full-path-to-mysql-VERSION-OS mysql
```

The ln command makes a symbolic link to the installation directory. This enables you to refer more easily to it as /usr/local/mysql. To avoid having to type the path name of client programs always when you are working with MySQL, you can add the /usr/local/mysql/bin directory to your PATH variable:

```
shell> export PATH=$PATH:/usr/local/mysql/bin
```

## Perform Postinstallation Setup

The remainder of the installation process involves setting distribution ownership and access permissions, initializing the data directory, starting the MySQL server, and setting up the configuration file. For instructions, see Section 2.10, "Postinstallation Setup and Testing".

### 2.3 Installing MySQL on Microsoft Windows

**Important**

MySQL 8.0 Server requires the Microsoft Visual C++ 2015 Redistributable Package to run on Windows platforms. Users should make sure the package has been installed on the system before installing the server. The package is available at the Microsoft Download Center. Additionally, MySQL debug binaries require Visual Studio 2015 to be installed.

MySQL is available for Microsoft Windows 64-bit operating systems only. For supported Windows platform information, see https://www.mysql.com/support/supportedplatforms/database.html.

There are different methods to install MySQL on Microsoft Windows.

**MySQL Installer Method**

The simplest and recommended method is to download MySQL Installer (for Windows) and let it install and configure a specific version of MySQL Server as follows:

**Note**

Unlike the standard MySQL Installer, the smaller "web-community" version does not bundle any MySQL applications but it will download the MySQL products you choose to install.

2. Determine the setup type to use for the initial installation of MySQL products. For example:
• **Developer Default**: Provides a setup type that includes the selected version of MySQL Server and other MySQL tools related to MySQL development, such as MySQL Workbench.

• **Server Only**: Provides a setup for the selected version of MySQL Server without other products.

• **Custom**: Enables you to select any version of MySQL Server and other MySQL products.

3. Install the server instance (and products) and then begin the server configuration by first selecting one of the following levels of availability for the server instance:

• **Standalone MySQL Server / Classic MySQL Replication (default)**
  
  Configures a server instance to run without high availability.

• **InnoDB cluster**
  
  Provides two configuration options based on MySQL Group Replication to:
  
  • Configure multiple server instances in a sandbox InnoDB cluster on the local host (for testing only).
  
  • Create a new InnoDB cluster and configure one seed instance or add a new server instance to an existing InnoDB cluster.

4. Complete the configuration process by following the onscreen instructions. For more information about each individual step, see *MySQL Server Configuration with MySQL Installer*.

MySQL is now installed. If you configured MySQL as a service, then Windows will automatically start MySQL server every time you restart your system. Also, this process installs the MySQL Installer application on the local host, which you can use later to upgrade or reconfigure MySQL server.

**Note**

If you installed MySQL Workbench on your system, consider using it to check your new MySQL server connection. By default, the program automatically start after installing MySQL.

### Additional Installation Information

It is possible to run MySQL as a standard application or as a Windows service. By using a service, you can monitor and control the operation of the server through the standard Windows service management tools. For more information, see Section 2.3.5.8, “Starting MySQL as a Windows Service”.

To accommodate the `RESTART` statement, the MySQL server forks when run as a service or standalone, to enable a monitor process to supervise the server process. In this case, you will observe two `mysqld` processes. If `RESTART` capability is not required, the server can be started with the `--no-monitor` option. See Section 13.7.7.8, “RESTART Syntax”.

Generally, you should install MySQL on Windows using an account that has administrator rights. Otherwise, you may encounter problems with certain operations such as editing the `PATH` environment variable or accessing the Service Control Manager. When installed, MySQL does not need to be executed using a user with Administrator privileges.

For a list of limitations on the use of MySQL on the Windows platform, see Section C.10.5, “Windows Platform Limitations”.

In addition to the MySQL Server package, you may need or want additional components to use MySQL with your application or development environment. These include, but are not limited to:
MySQL on Windows Considerations

- To connect to the MySQL server using ODBC, you must have a Connector/ODBC driver. For more information, including installation and configuration instructions, see MySQL Connector/ODBC Developer Guide.

  ![Note]
  MySQL Installer will install and configure Connector/ODBC for you.

- To use MySQL server with .NET applications, you must have the Connector/NET driver. For more information, including installation and configuration instructions, see MySQL Connector/NET Developer Guide.

  ![Note]
  MySQL Installer will install and configure MySQL Connector/NET for you.

MySQL distributions for Windows can be downloaded from https://dev.mysql.com/downloads/. See Section 2.1.2, “How to Get MySQL”.

MySQL for Windows is available in several distribution formats, detailed here. Generally speaking, you should use MySQL Installer. It contains more features and MySQL products than the older MSI, is simpler to use than the compressed file, and you need no additional tools to get MySQL up and running. MySQL Installer automatically installs MySQL Server and additional MySQL products, creates an options file, starts the server, and enables you to create default user accounts. For more information on choosing a package, see Section 2.3.2, “Choosing an Installation Package”.

- A MySQL Installer distribution includes MySQL Server and additional MySQL products including MySQL Workbench, MySQL for Visual Studio, and MySQL for Excel. MySQL Installer can also be used to upgrade these products in the future (see https://dev.mysql.com/doc/mysql-compat-matrix/en/).

  For instructions on installing MySQL using MySQL Installer, see Section 2.3.3, “MySQL Installer for Windows”.

- The standard binary distribution (packaged as a compressed file) contains all of the necessary files that you unpack into your chosen location. This package contains all of the files in the full Windows MSI Installer package, but does not include an installation program.

  For instructions on installing MySQL using the compressed file, see Section 2.3.5, “Installing MySQL on Microsoft Windows Using a noinstall ZIP Archive”.

- The source distribution format contains all the code and support files for building the executables using the Visual Studio compiler system.

  For instructions on building MySQL from source on Windows, see Section 2.9, “Installing MySQL from Source”.

MySQL on Windows Considerations

- Large Table Support

  If you need tables with a size larger than 4GB, install MySQL on an NTFS or newer file system. Do not forget to use MAX_ROWS and AVG_ROW_LENGTH when you create tables. See Section 13.1.20, “CREATE TABLE Syntax”.

- MySQL and Virus Checking Software

  Virus-scanning software such as Norton/Symantec Anti-Virus on directories containing MySQL data and temporary tables can cause issues, both in terms of the performance of MySQL and the virus-scanning software misidentifying the contents of the files as containing spam. This is due to the
fingerprinting mechanism used by the virus-scanning software, and the way in which MySQL rapidly updates different files, which may be identified as a potential security risk.

After installing MySQL Server, it is recommended that you disable virus scanning on the main directory (datadir) used to store your MySQL table data. There is usually a system built into the virus-scanning software to enable specific directories to be ignored.

In addition, by default, MySQL creates temporary files in the standard Windows temporary directory. To prevent the temporary files also being scanned, configure a separate temporary directory for MySQL temporary files and add this directory to the virus scanning exclusion list. To do this, add a configuration option for the `tmpdir` parameter to your `my.ini` configuration file. For more information, see Section 2.3.5.2, “Creating an Option File”.

### 2.3.1 MySQL Installation Layout on Microsoft Windows

For MySQL 8.0 on Windows, the default installation directory is `C:\Program Files\MySQL\MySQL Server 8.0` for installations performed with MySQL Installer. If you use the ZIP archive method to install MySQL, you may prefer to install in `C:\mysql`. However, the layout of the subdirectories remains the same.

All of the files are located within this parent directory, using the structure shown in the following table.

<table>
<thead>
<tr>
<th>Directory</th>
<th>Contents of Directory</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>bin</td>
<td>mysql server, client and utility programs</td>
<td></td>
</tr>
<tr>
<td><code>%PROGRAMDATA%\MySQL\MySQL Server 8.0\</code></td>
<td>Log files, databases</td>
<td>The Windows system variable <code>%PROGRAMDATA</code> defaults to <code>C:\ProgramFiles\ProgramData</code>.</td>
</tr>
<tr>
<td>docs</td>
<td>Release documentation</td>
<td>With MySQL Installer, use the Modify operation to select this optional folder.</td>
</tr>
<tr>
<td>include</td>
<td>Include (header) files</td>
<td></td>
</tr>
<tr>
<td>lib</td>
<td>Libraries</td>
<td></td>
</tr>
<tr>
<td>share</td>
<td>Miscellaneous support files, including error messages, character set files, sample configuration files, SQL for database installation</td>
<td></td>
</tr>
</tbody>
</table>

### 2.3.2 Choosing an Installation Package

For MySQL 8.0, there are multiple installation package formats to choose from when installing MySQL on Windows. The package formats described in this section are:

- MySQL Installer
- MySQL noinstall ZIP Archives
- MySQL Docker Images

Program Database (PDB) files (with file name extension `pdb`) provide information for debugging your MySQL installation in the event of a problem. These files are included in ZIP Archive distributions (but not MSI distributions) of MySQL.
MySQL Installer

This package has a file name similar to `mysql-installer-community-8.0.18.0.msi` or `mysql-installer-commercial-8.0.18.0.msi`, and utilizes MSIs to automatically install MySQL server and other products. MySQL Installer will download and apply updates to itself, and for each of the installed products. It also configures the installed MySQL server (including a sandbox InnoDB cluster test setup) and MySQL Router. MySQL Installer is recommended for most users.

MySQL Installer can install and manage (add, modify, upgrade, and remove) many other MySQL products, including:

- Connectors – MySQL Connector/C, MySQL Connector/C++, MySQL Connector/NET, Connector/ODBC, MySQL Connector/Python, MySQL Connector/J, MySQL Connector/Node.js
- Documentation – MySQL Manual (PDF format), samples and examples

MySQL Installer operates on all MySQL supported versions of Windows (see [https://www.mysql.com/support/supportedplatforms/database.html](https://www.mysql.com/support/supportedplatforms/database.html)).

**Note**

Because MySQL Installer is not a native component of Microsoft Windows and depends on .NET, it will not work on minimal installation options like the Server Core version of Windows Server.

For instructions on how to install MySQL using MySQL Installer, see Section 2.3.3, “MySQL Installer for Windows”.

MySQL noinstall ZIP Archives

These packages contain the files found in the complete MySQL Server installation package, with the exception of the GUI. This format does not include an automated installer, and must be manually installed and configured.

The noinstall ZIP archives are split into two separate compressed files. The main package is named `mysql-VERSION-winx64.zip`. This contains the components needed to use MySQL on your system. The optional MySQL test suite, MySQL benchmark suite, and debugging binaries/information components (including PDB files) are in a separate compressed file named `mysql-VERSION-winx64-debug-test.zip`.

If you choose to install a noinstall ZIP archive, see Section 2.3.5, “Installing MySQL on Microsoft Windows Using a noinstall ZIP Archive”.

MySQL Docker Images

For information on using the MySQL Docker images provided by Oracle on Windows platform, see Section 2.5.6.3, “Deploying MySQL on Windows and Other Non-Linux Platforms with Docker”.

**Warning**

The MySQL Docker images provided by Oracle are built specifically for Linux platforms. Other platforms are not supported, and users running the MySQL Docker images from Oracle on them are doing so at their own risk.

2.3.3 MySQL Installer for Windows

MySQL Installer is a standalone application designed to ease the complexity of installing and configuring MySQL products that run on Microsoft Windows. It supports the following MySQL products:
MySQL Installer for Windows

• MySQL Servers

MySQL Installer can install and manage multiple, separate MySQL server instances on the same host at the same time. For example, MySQL Installer can install, configure, and upgrade a separate instance of MySQL 5.6, MySQL 5.7, and MySQL 8.0 on the same host. MySQL Installer does not permit server upgrades between major and minor version numbers, but does permit upgrades within a release series (such as 5.7.18 to 5.7.19).

Note
MySQL Installer cannot install both Community and Commercial (Standard Edition and Enterprise Edition) releases of MySQL server on the same host. If you require both releases on the same host, consider using the ZIP archive distribution to install one of the releases.

• MySQL Applications

MySQL Workbench, MySQL Shell, MySQL Router, MySQL for Visual Studio, MySQL for Excel, MySQL Notifier, and MySQL Utilities.

• MySQL Connectors

MySQL Connector/NET, MySQL Connector/Python, MySQL Connector/ODBC, MySQL Connector/J, MySQL Connector/C, and MySQL Connector/C++.

Note
To install MySQL Connector/Node.js, see https://dev.mysql.com/downloads/connector/nodejs/. Connector/Node.js does not provide an .msi file for use with MySQL Installer.

• Documentation and Samples

MySQL Reference Manuals (by version) in PDF format and MySQL database samples (by version).

Installation Requirements

MySQL Installer requires Microsoft .NET Framework 4.5.2 or later. If this version is not installed on the host computer, you can download it by visiting the Microsoft website.

MySQL Installer Community Release

Download software from https://dev.mysql.com/downloads/installer/ to install the Community release of all MySQL products for Windows. Select one of the following MySQL Installer package options:

• Web: Contains MySQL Installer and configuration files only. The web package downloads only the MySQL products you select to install, but it requires an internet connection for each download. The size of this file is approximately 2 MB; the name of the file has the form mysql-installer-community-web-VERSION.N.msi, where VERSION is the MySQL server version number such as 8.0 and N is the package number, which begins at 0.

• Full or Current Bundle: Bundles all of the MySQL products for Windows (including the MySQL server). The file size is over 300 MB, and the name has the form mysql-installer-community-VERSION.N.msi, where VERSION is the MySQL Server version number such as 8.0 and N is the package number, which begins at 0.

MySQL Installer Commercial Release

Download software from https://edelivery.oracle.com/ to install the Commercial (Standard Edition or Enterprise Edition) release of MySQL products for Windows. The Commercial release includes all of the current and previous GA versions in the Community release (excludes development-milestone versions) and also includes the following products:
• Workbench SE/EE
• MySQL Enterprise Backup
• MySQL Enterprise Firewall

The Commercial release integrates with your My Oracle Support (MOS) account. For knowledge-base content and patches, see My Oracle Support.

2.3.3.1 MySQL Installer Initial Setup

• MySQL Installer Licensing and Support Authentication
• Choosing a Setup Type
• Path Conflicts
• Check Requirements
• MySQL Installer Configuration Files

When you download MySQL Installer for the first time, a setup wizard guides you through the initial installation of MySQL products. As the following figure shows, the initial setup is a one-time activity in the overall process. MySQL Installer detects existing MySQL products installed on the host during its initial setup and adds them to the list of products to be managed.

Figure 2.7 MySQL Installer Process Overview

MySQL Installer extracts configuration files (described later) to the hard drive of the host during the initial setup. Although MySQL Installer is a 32-bit application, it can install both 32-bit and 64-bit binaries.

The initial setup adds a link to the Start menu under the MySQL group. Click Start, All Programs, MySQL, MySQL Installer to open MySQL Installer.

MySQL Installer Licensing and Support Authentication

MySQL Installer requires you to accept the license agreement before it will install new MySQL packages. After you accept the terms of the agreement, you can add, update, reconfigure, and remove all of the products and features provided by the MySQL Installer release you downloaded.

For the Commercial release, entering your My Oracle Support (MOS) credentials is optional when installing bundled MySQL products, but your credentials are required when choosing unbundled MySQL products that MySQL Installer must download. An unbundled product is any .msi file that you download using MySQL Installer after the initial setup. Your credentials must match the user name and password that you have registered with Oracle for access to the support site.

Choosing a Setup Type

During the initial setup, you are prompted to select the MySQL products to be installed on the host. One alternative is to use a predetermined setup type that matches your setup requirements. By default, both GA and pre-release products are included in the download and installation with the Developer Default, Client only, and Full setup types. Select the Only install GA products option to restrict the product set to include GA products only when using these setup types.
Choosing one of the following setup types determines the initial installation only and does not limit your ability to install or update MySQL products for Windows later:

- **Developer Default**: Install the following products that compliment application development with MySQL:
  - **MySQL Server** (Installs the version that you selected when you downloaded MySQL Installer.)
  - MySQL Shell
  - MySQL Router
  - MySQL Workbench
  - MySQL for Visual Studio
  - MySQL for Excel
  - MySQL Notifier
  - **MySQL Connectors** (.NET / Python / ODBC / Java / C / C++)
  - MySQL Utilities
  - MySQL Documentation
  - MySQL Samples and Examples

- **Server only**: Only install the MySQL server. This setup type installs the general availability (GA) or development release server that you selected when you downloaded MySQL Installer. It uses the default installation and data paths.

- **Client only**: Only install the most recent MySQL applications and MySQL connectors. This setup type is similar to the **Developer Default** type, except that it does not include MySQL server or the client programs typically bundled with the server, such as `mysql` or `mysqladmin`.

- **Full**: Install all available MySQL products.

- **Custom** The custom setup type enables you to filter and select individual MySQL products from the MySQL Installer catalog.

  Use the **Custom** setup type to install:

  - A product or product version that is not available from the usual download locations. The catalog contains all product releases, including the other releases between pre-release (or development) and GA.

  - An instance of MySQL server using an alternative installation path, data path, or both. For instructions on how to adjust the paths, see Section 2.3.3.2, “Setting Alternative Server Paths with MySQL Installer”.

  - Two or more MySQL server versions on the same host at the same time (for example, 5.6, 5.7, and 8.0).

  - A specific combination of products and features not offered as a predetermine setup type. For example, you can install a single product, such as MySQL Workbench, instead of installing all client applications for Windows.

**Path Conflicts**

When the default installation or data folder (required by MySQL server) for a product to be installed already exists on the host, the wizard displays the **Path Conflict** step to identify each conflict and
enable you to take action to avoid having files in the existing folder overwritten by the new installation. You see this step in the initial setup only when MySQL Installer detects a conflict.

To resolve the path conflict, do one of the following:

• Select a product from the list to display the conflict options. A warning symbol indicates which path is in conflict. Use the browse button to choose a new path and then click Next.

• Click Back to choose a different setup type or product version, if applicable. The Custom setup type enables you to select individual product versions.

• Click Next to ignore the conflict and overwrite files in the existing folder.

• Delete the existing product. Click Cancel to stop the initial setup and close MySQL Installer. Open MySQL Installer again from the Start menu and delete the installed product from the host using the Delete operation from the dashboard.

Check Requirements

MySQL Installer uses entries in the package-rules.xml file to determine whether the prerequisite software for each product is installed on the host. When the requirements check fails, MySQL Installer displays the Check Requirements step to help you update the host. The following figure identifies and describes the key areas of this step.

Figure 2.8 Check Requirements

Description of Check Requirements Elements

1. Shows the current step in the initial setup. Steps in this list may change slightly depending on the products already installed on the host, the availability of prerequisite software, and the products to be installed on the host.

2. Lists all pending installation requirements by product and indicates the status as follows:

   • A blank space in the Status column means that MySQL Installer can attempt to download and install the required software for you.
• The word Manual in the Status column means that you must satisfy the requirement manually. Select each product in the list to see its requirement details.

3. Describes the requirement in detail to assist you with each manual resolution. When possible, a download URL is provided. After you download and install the required software, click Check to verify that the requirement has been met.

4. Provides the following set operations to proceed:

• Back – Return to the previous step. This action enables you to select a different the setup type.

• Execute – Have MySQL Installer attempt to download and install the required software for all items without a manual status. Manual requirements are resolved by you and verified by clicking Check.

• Next – Do not execute the request to apply the requirements automatically and proceed to the installation without including the products that fail the check requirements step.

• Cancel – Stop the installation of MySQL products. Because MySQL Installer is already installed, the initial setup begins again when you open MySQL Installer from the Start menu and click Add from the dashboard. For a description of the available management operations, see Product Catalog.

MySQL Installer Configuration Files

All MySQL Installer files are located within the C:\Program Files (x86) and C:\ProgramData folders. The following table describes the files and folders that define MySQL Installer as a standalone application.

Note
 Installed MySQL products are neither altered nor removed when you update or uninstall MySQL Installer.

Table 2.5 MySQL Installer Configuration Files

<table>
<thead>
<tr>
<th>File or Folder</th>
<th>Description</th>
<th>Folder Hierarchy</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL Installer for Windows</td>
<td>This folder contains all of the files needed to run MySQL Installer and MySQLInstallerConsole.exe, a command-line program with similar functionality.</td>
<td>C:\Program Files (x86)</td>
</tr>
<tr>
<td>Templates</td>
<td>The Templates folder has one file for each version of MySQL server. Template files contain keys and formulas to calculate some values dynamically.</td>
<td>C:\ProgramData\MySQL\MySQL Installer for Windows\Manifest</td>
</tr>
<tr>
<td>package-rules.xml</td>
<td>This file contains the prerequisites for every product to be installed.</td>
<td>C:\ProgramData\MySQL\MySQL Installer for Windows\Manifest</td>
</tr>
<tr>
<td>products.xml</td>
<td>The products file (or product catalog) contains a list of all products available for download.</td>
<td>C:\ProgramData\MySQL\MySQL Installer for Windows\Manifest</td>
</tr>
<tr>
<td>Product Cache</td>
<td>The Product Cache folder contains all standalone .msi files bundled with the full package or downloaded afterward.</td>
<td>C:\ProgramData\MySQL\MySQL Installer for Windows</td>
</tr>
</tbody>
</table>
2.3.3.2 Setting Alternative Server Paths with MySQL Installer

You can change the default installation path, the data path, or both when you install MySQL server. After you have installed the server, the paths cannot be altered without removing and reinstalling the server instance.

To change paths for MySQL server

1. Identify the MySQL server to change and display the Advanced Options link.
   a. Navigate to the Select Products and Features step by doing one of the following:
      i. If this is an initial setup of MySQL Installer, select the Custom setup type and click Next.
      ii. If MySQL Installer is installed already, launch it from the Start menu and then click Add from the dashboard.
   b. Click Edit to apply a filter on the product list shown in Available Products (see Locating Products to Install).
   c. With the server instance selected, use the arrow to move the selected server to the Products/Features To Be Installed list.
   d. Click the server to select it. When you select the server, the Advanced Options link appears. For details, see the figure that follows.

2. Click Advanced Options to open a dialog box where you can enter alternative path names. After the path names are validated, click Next to continue with the configuration steps.

Figure 2.9 Change MySQL Server Path

2.3.3.3 Installation Workflow with MySQL Installer

MySQL Installer provides a wizard-like tool to install and configure new MySQL products for Windows. Unlike the initial setup, which runs only once, MySQL Installer invokes the wizard each time you download or install a new product. For first-time installations, the steps of the initial setup proceed directly into the steps of the installation.
Note
Full permissions are granted to the user executing MySQL Installer to all generated files, such as my.ini. This does not apply to files and directories for specific products, such as the MySQL server data directory in %ProgramData% that is owned by SYSTEM.

Products installed and configured on a host follow a general pattern that might require your input during the various steps. MySQL Installer loads all selected products together using the following workflow:

- **Product download.** If you installed the full (not web) MySQL Installer package, all .msi files were loaded to the Product Cache folder during the initial setup and are not downloaded again. Otherwise, click Execute to begin the download. The status of each product changes from Downloading to Downloaded.

- **Product installation.** The status of each product in the list changes from Ready to Install, to Installing, and lastly to Complete. During the process, click Show Details to view the installation actions.

If you cancel the installation at this point, the products are installed, but the server (if installed) is not yet configured. To restart the server configuration, open MySQL Installer from the Start menu and click the Reconfigure link next to the appropriate server in the dashboard.

- **Product configuration.** This step applies to MySQL Server, MySQL Router, and samples only. The status for each item in the list should indicate Ready to Configure.

Click Next to start the configuration wizard for all items in the list. The configuration options presented during this step are specific to the version of database or router that you selected to install.

Click Execute to begin applying the configuration options or click Back (repeatedly) to return to each configuration page. Click Finish to open the MySQL Installer dashboard.

- **Installation complete.** This step finalizes the installation for products that do not require configuration. It enables you to copy the log to a clipboard and to start certain applications, such as MySQL Workbench and MySQL Shell. Click Finish to open the MySQL Installer dashboard.

**MySQL Server Configuration with MySQL Installer**

MySQL Installer performs the initial configuration of the MySQL server. For example:

- For the MySQL 8.0 release series, a server can be configured to run as a standalone database, as a sandbox InnoDB cluster on a single host, or to create a production InnoDB cluster inside a local network (see High Availability).

- It creates the configuration file (my.ini) that is used to configure the MySQL server. The values written to this file are influenced by choices you make during the installation process. Some definitions are host dependent. For example, query_cache is enabled if the host has fewer than three cores.

  **Note**
  Query cache was deprecated in MySQL 5.7 and removed in MySQL 8.0 (and later).

- By default, a Windows service for the MySQL server is added.

- Provides default installation and data paths for MySQL server. For instructions on how to change the default paths, see Section 2.3.3.2, “Setting Alternative Server Paths with MySQL Installer”.

- It can optionally create MySQL server user accounts with configurable permissions based on general roles, such as DB Administrator, DB Designer, and Backup Admin. It optionally creates a Windows user named MysqlSys with limited privileges, which would then run the MySQL Server.
User accounts may also be added and configured in MySQL Workbench.

- Checking **Show Advanced Options** enables additional **Logging Options** to be set. This includes defining custom file paths for the error log, general log, slow query log (including the configuration of seconds it requires to execute a query), and the binary log.

During the configuration process, click **Next** to proceed to the next step or **Back** to return to the previous step. Click **Execute** at the final step to apply the server configuration.

The sections that follow describe the server configuration options that apply to MySQL server on Windows. The server version you installed will determine which steps and options you can configure. Configuring MySQL server may include some or all of the steps.

**High Availability**

MySQL Installer enables you to install, configure, and deploy MySQL Server as a standalone instance or as a member of a highly available cluster using MySQL Group Replication. In either case, MySQL Installer restricts the installation and configuration of the server (or servers) to the local Windows host computer.

- **Standalone MySQL Server / Classic MySQL Replication (default)**

  Select this option to configure one MySQL instance to run as a standalone database server. This option is ideal if you intend to set up classic replication later and then to include this server in your custom solution. The remaining configuration steps are described in the sections that follow, starting with Type and Networking.

- **InnoDB cluster**

  Select this option to create or extend an InnoDB cluster solution that is based on MySQL Group Replication (see Section 21.1, “Introducing InnoDB Cluster”). You can configure (or reconfigure) a minimum of three server instances to perform a basic setup as a test-only sandbox cluster on a single computer or to create a production cluster inside a local network.

  **InnoDB Cluster Log Verbosity Level.** This configuration step includes an adjustable log that captures information during the configuration of each server instance in the production or sandbox cluster. The values are: **MINIMAL**, **MEDIUM** (default), and **DEBUG**. If the cluster configuration fails, use the **Reconfigure** action from the MySQL Installer dashboard to restart the configuration and then set the verbosity level to **DEBUG** to gather additional information during your next attempt.

MySQL Installer provides the following configuration variations to deploy an InnoDB cluster:

- **Set Up a Local Server Cluster for Testing Only**

  Select **Create a Sandbox InnoDB cluster for Testing** to enable this option. When prompted, define the number of server sandbox instances in the cluster, set a password for the root user, and adjust the InnoDB cluster log verbosity level as needed. For a more detailed description of the configuration, see Deploying a Sandbox InnoDB Cluster with MySQL Installer. This setup requires MySQL 5.7.17 or higher.

- **Create or Join an InnoDB cluster**

  To set up a highly available InnoDB cluster using MySQL Installer, you must have a minimum of three computers on a local network. If you require a more advanced setup, use MySQL Shell to configure some or all of the server instances in the cluster. For details about how to perform a local-network cluster setup, see Setting up an InnoDB cluster with MySQL Installer. This setup requires MySQL 8.0.0 or higher.

InnoDB cluster was designed to operate with MySQL Shell, which enables you to perform advanced cluster administration, and MySQL Router to automate the connections made between client
applications and server instances. Neither MySQL Shell nor MySQL Router are required to deploy a cluster on Windows using MySQL Installer.

Deploying a Sandbox InnoDB Cluster with MySQL Installer

A sandbox deployment includes multiple server sandbox instances that run together on the same computer. Because all server instances reside on the same computer, a sandbox cluster does not meet the requirements of a highly available solution. Instead, this deployment option simulates an environment from which you can explore the techniques associated with InnoDB cluster administration.

When you select **Create a Sandbox InnoDB cluster for Testing**, a follow-on step prompts you to select a cluster consisting of three, five, seven, or nine MySQL server instances. Unlike the other server setups provided by MySQL Installer, the sandbox deployment skips the usual server configuration steps (except Authentication Method). The resulting cluster, named `sandboxCluster`, is available on selected ports that are configured for you.

![Note]

MySQL Installer deletes ports 3310 to 3390 during the configuration, if those ports were set for the sandbox InnoDB cluster manually using MySQL Shell.

Each sandbox instance is configured to run as a process (not a Windows service). You must start each instance in the sandbox cluster manually after restarting the computer.

After you create the test cluster, click the **Summary** tab to view the specific ports that apply to your cluster. To modify the number of server instances within the existing cluster or to adjust the logging level, use the **Reconfigure** quick action from the MySQL Installer dashboard.

![Warning]

MySQL Installer deletes all existing sandbox cluster data when the cluster is reconfigured or when the server instances within the sandbox cluster are upgraded.

MySQL Installer stores all sandbox InnoDB cluster configuration entries in the `installer_config.xml` file. By default, MySQL Installer creates the sandbox instances in `%userprofile%\MySQL\mysql-sandboxes` on the local host.

Setting up InnoDB Cluster with MySQL Installer

To create a single InnoDB cluster, select **InnoDB Cluster** as the High Availability option and then select **Create a New InnoDB Cluster**. Adjust the log verbosity level (as needed), and click **Next** to configure the first server instance. This setup process involves installing and running MySQL Installer on multiple computers.

Define the first server instance (or seed) by providing the following configuration information:

- **InnoDB Cluster Name:**

  The default cluster name is `myCluster`. If you intend to configure multiple clusters, replace the default name with one that is meaningful within your solution. Alphanumeric characters, spaces, and underscore (_) characters are valid for this field. The limit is 40 characters.

- **Cluster Admin User Name:**

  The default cluster administrator name is `ic`. You can reuse the same MySQL administrative account across multiple clusters. You will be prompted for this account name (and password) later when you configure other server instances to join the cluster. The limit is 32 characters.

- **Cluster Admin Password:**
Enter a password for the cluster administrator account (minimum length is four characters). MySQL Installer will evaluate the strength of the MySQL password as you type. Use the Repeat Password field to confirm the password.

- **Host Address:**

Select the host name or IP address of the local host from the list. When joining additional server instances to the cluster, you will be prompted to identify the seed instance by the host name or IP address.

- **Server ID:**

The default value is 1. This identifier is required to record the events of a server instance in the binary log. The ID of each server instance within a cluster must be unique; however, you can reuse the same number in a different cluster. The server ID you specify in this field also appears later in Advanced Options step. If you change the value in Advanced Option, the number is changed for the InnoDB cluster Setup too.

Click **Next** and then complete the remaining configuration steps, which are described in the sections that follow, starting with Type and Networking. After the seed instance is added and the cluster is created, it requires more instances for full tolerance. At this point, the status is **OK_NO_TOLERANCE**.

To add the second and third server instances to the cluster, you must use a separate computer inside the local network for each. Some of the configuration details of the seed instance are required to complete the join operation.

After you start MySQL Installer and install the server instance on the next computer, begin the configuration by selecting **InnoDB Cluster** as the High Availability option and then select **Add Local MySQL Server Instance to an InnoDB Cluster**. Adjust the **InnoDB Cluster Log Verbosity Level** (as needed) and then click **Next**.

Define the joining server instance by providing the following configuration information:

- **Seed Instance Address:**

Enter the host name or IP address of the computer that hosts the seed instance.

- **Seed Instance Port:**

The default value is 3306, which is the port for classic MySQL. Use the same TCP port that you configured for the seed instance.

- **Cluster Admin User Name:**

The default cluster administrator name is ic. If you assigned a different name when you configured the seed instance, enter the alternative cluster administrator name.

- **Cluster Admin Password:**

Enter the password assigned to the cluster administrator account.

- **Host Address:**

Select the host name or IP address of the local host from the list.

- **Server ID:**

The default value is 1. This identifier is required to record the events of a server instance in the binary log. The ID of each server instance within a cluster must be unique; however, you can reuse the same number in a different cluster. The server ID you specify in this field also appears later in
Advanced Options step. If you change the value in Advanced Option, the number is changed for the InnoDB cluster Setup too.

- **Test Connection**

Use this button to verify the connection between the local server instance and the seed instance defined for the cluster. A valid connection is required to proceed.

Click **Next** and then complete the remaining configuration steps, which are described in the sections that follow, starting with **Type and Networking**.

With one seed instance and a second server instance in the cluster, the status is **OK_NO_TOLERANCE**. After you add the third server instance, the status is **OK**, which indicates that the cluster now is tolerant to the failure of one instance.

**Type and Networking**

- **Server Configuration Type**

Choose the MySQL server configuration type that describes your setup. This setting defines the amount of system resources (memory) that will be assigned to your MySQL server instance.

  - **Development**: A machine that will host many other applications, and typically this is your personal workstation. This option configures MySQL to use the least amount of memory.
  
  - **Server**: Several other applications will be running on this machine, such as a web server. This option configures MySQL to use a medium amount of memory.
  
  - **Dedicated**: A machine that is dedicated to running the MySQL server. Because no other major applications will run on this server, such as a web server, this option configures MySQL to use the majority of available memory.

- **Connectivity**

Connectivity options control how the connection to MySQL is made. Options include:

  - **TCP/IP**: You may enable TCP/IP Networking here as otherwise only local host connections are permitted. Also define the **Port** (for the classic MySQL protocol), **X Protocol Port** (for MySQL as a document store), and whether to open the firewall port for network access. If the port number is in use already, you will see the information icon (⚠️) next to the default value and **Next** is disabled until you provide a new port number.

  - **Named Pipe**: Enable and define the pipe name, similar to setting the **named_pipe** system variable. The default name is **MySQL**.

  - **Shared Memory**: Enable and then define the memory name, similar to setting the **shared_memory** system variable. The default name is **MySQL**.

- **Advanced Configuration**

Check **Show Advanced and Logging Options** to set custom logging and advanced options in later steps. The Logging Options step enables you to define custom file paths for the error log, general log, slow query log (including the configuration of seconds it requires to execute a query), and the binary log. The Advanced Options step enables you to set the unique server ID required when binary logging is enabled in a replication topology.

- **MySQL Enterprise Firewall** (Enterprise Edition only)

The **Enable Enterprise Firewall** check box is selected by default. For post-installation instructions, see Section 6.4.7, “MySQL Enterprise Firewall”.

---
Authentication Method

The **Authentication Method** step is visible only during the installation or upgrade of MySQL 8.0.4 or higher. It introduces a choice between two server-side authentication options. The MySQL user accounts that you create in the next step will use the authentication method that you select in this step.

MySQL 8.0 connectors and community drivers that use `libmysqlclient` 8.0 now support the `mysql_native_password` default authentication plugin. However, if you are unable to update your clients and applications to support this new authentication method, you can configure the MySQL server to use `mysql_native_password` for legacy authentication. For more information about the implications of this change, see caching_sha2_password as the Preferred Authentication Plugin.

If you are installing or upgrading to MySQL 8.0.4 or higher, select one of the following authentication methods:

- **Use Strong Password Encryption for Authentication (RECOMMENDED)**

  MySQL 8.0 supports a new authentication based on improved, stronger SHA256-based password methods. It is recommended that all new MySQL server installations use this method going forward.

  **Important**
  The caching_sha2_password authentication plugin on the server requires new versions of connectors and clients, which add support for the new MySQL 8.0 default authentication.

- **Use Legacy Authentication Method (Retain MySQL 5.x Compatibility)**

  Using the old MySQL 5.x legacy authentication method should be considered only in the following cases:
  - Applications cannot be updated to use MySQL 8.0 connectors and drivers.
  - Recompilation of an existing application is not feasible.
  - An updated, language-specific connector or driver is not available yet.

Accounts and Roles

- **Root Account Password**

  Assigning a root password is required and you will be asked for it when performing other MySQL Installer operations. Password strength is evaluated when you repeat the password in the box provided. For descriptive information regarding password requirements or status, move your mouse pointer over the information icon (⚠️) when it appears.

- **MySQL User Accounts (Optional)**

  Click **Add User** or **Edit User** to create or modify MySQL user accounts with predefined roles. Next, enter the required account credentials:
  - **User Name**: MySQL user names can be up to 32 characters long.
  - **Host**: Select `localhost` for local connections only or `<All Hosts (%)>` when remote connections to the server are required.
  - **Role**: Each predefined role, such as `DB Admin`, is configured with its own set of privileges. For example, the `DB Admin` role has more privileges than the `DB Designer` role. The **Role** drop-down list contains a description of each role.
• **Password**: Password strength assessment is performed while you type the password. Passwords must be confirmed. MySQL permits a blank or empty password (considered to be insecure).

**MySQL Installer Commercial Release Only**: MySQL Enterprise Edition for Windows, a commercial product, also supports an authentication method that performs external authentication on Windows. Accounts authenticated by the Windows operating system can access the MySQL server without providing an additional password.

To create a new MySQL account that uses Windows authentication, enter the user name and then select a value for **Host** and **Role**. Click **Windows** authentication to enable the `authentication_windows` plugin. In the Windows Security Tokens area, enter a token for each Windows user (or group) who can authenticate with the MySQL user name. MySQL accounts can include security tokens for both local Windows users and Windows users that belong to a domain. Multiple security tokens are separated by the semicolon character (;) and use the following format for local and domain accounts:

- **Local account**
  
  Enter the simple Windows user name as the security token for each local user or group; for example, `finley;jeffrey;admin`.

- **Domain account**
  
  Use standard Windows syntax (`domain\domainuser`) or MySQL syntax (`domain\domainuser`) to enter Windows domain users and groups.

For domain accounts, you may need to use the credentials of an administrator within the domain if the account running MySQL Installer lacks the permissions to query the Active Directory. If this is the case, select **Validate Active Directory users with** to activate the domain administrator credentials.

Windows authentication permits you to test all of the security tokens each time you add or modify a token. Click **Test Security Tokens** to validate (or revalidate) each token. Invalid tokens generate a descriptive error message along with a red X icon and red token text. When all tokens resolve as valid (green text without an X icon), you can click **OK** to save the changes.

**Windows Service**

On the Windows platform, MySQL server can run as a named service managed by the operating system and be configured to start up automatically when Windows starts. Alternatively, you can configure MySQL server to run as an executable program that requires manual configuration.

- **Configure MySQL server as a Windows service** (Selected by default.)

  When the default configuration option is selected, you can also select the following:

  - **Start the MySQL Server at System Startup**
    
    When selected (default), the service startup type is set to Automatic; otherwise, the startup type is set to Manual.

  - **Run Windows Service as**
    
    When **Standard System Account** is selected (default), the service logs on as Network Service.

    The **Custom User** option must have privileges to log on to Microsoft Windows as a service. The **Next** button will be disabled until this user is configured with the required privileges.

A custom user account is configured in Windows by searching for "local security policy" in the Start menu. In the Local Security Policy window, select **Local Policies, User Rights Assignment**, ...
and then **Log On As A Service** to open the property dialog. Click **Add User or Group** to add the custom user and then click **OK** in each dialog to save the changes.

- Deselect the Windows Service option

### Logging Options

This step is available if the **Show Advanced Configuration** check box was selected during the **Type and Networking** step. To enable this step now, click **Back** to return to the **Type and Networking** step and select the check box.

Advanced configuration options are related to the following MySQL log files:

- Error Log
- General Log
- Slow Query Log
- Bin Log

**Note**
The binary log is enabled by default for MySQL 5.7 and higher.

### Advanced Options

This step is available if the **Show Advanced Configuration** check box was selected during the **Type and Networking** step. To enable this step now, click **Back** to return to the **Type and Networking** step and select the check box.

The advanced-configuration options include:

- **Server ID**

  Set the unique identifier used in a replication topology. If binary logging is enabled, you must specify a server ID. The default ID value depends on the server version. For more information, see the description of the **--server-id** option.

  **Tip**
  If you specified an ID for a server instance of an InnoDB cluster, then MySQL Installer adjusts the ID (shown on this page) to match the previous identifier.

- **Table Names Case**

  You can set the following options during the initial and subsequent configuration the server. For the MySQL 8.0 release series, these options apply only to the initial configuration of the server.

  - **Lower Case**
    
    Sets the **lower_case_table_names** option value to 1 (default), in which table names are stored in lowercase on disk and comparisons are not case sensitive.

  - **Preserve Given Case**
    
    Sets the **lower_case_table_names** option value to 2, in which table names are stored as given but compared in lowercase.

### Apply Server Configuration

All configuration settings are applied to the MySQL server when you click **Execute**. Use the **Configuration Steps** tab to follow the progress of each action; the icon for each toggles from white to
green (with a check mark) on success. Otherwise, the process stops and displays an error message if an individual action times out. Click the Log tab to view the log.

When the installation completes successfully and you click Finish, MySQL Installer and the installed MySQL products are added to the Microsoft Windows Start menu under the MySQL group. Opening MySQL Installer loads the dashboard where installed MySQL products are listed and other MySQL Installer operations are available.

MySQL Router Configuration with MySQL Installer

MySQL Installer downloads and installs a suite of tools for developing and managing business-critical applications on Windows. The suite consist of applications, connectors, documentation, and samples.

During the initial setup, choose any predetermined setup type, except Server only, to install the latest GA version of the tools. Use the Custom setup type to install an individual tool or specific version. If MySQL Installer is installed on the host already, use the Add operation to select and install tools from the MySQL Installer dashboard.

MySQL Router Configuration

MySQL Installer provides a configuration wizard that can bootstrap an installed instance of MySQL Router 8.0 or later to route traffic between MySQL applications and an InnoDB cluster. When configured, MySQL Router runs as a local Windows service. For detailed information about using MySQL Router with an InnoDB cluster, see Routing for MySQL InnoDB cluster.

Note

You are prompted to configure MySQL Router after the initial installation and when you reconfigure an installed router explicitly. In contrast, the upgrade operation does not require or prompt you to configure the upgraded product.

To configure MySQL Router, do the following:

1. Set up InnoDB cluster. For instructions on how to configure a sandbox InnoDB cluster on the local host using MySQL Installer, see High Availability.

   For general InnoDB cluster information, see Chapter 21, InnoDB Cluster.

2. Using MySQL Installer, download and install the MySQL Router application. After the installation finishes, the configuration wizard prompts you for information. Select the Configure MySQL Router for InnoDB cluster check box to begin the configuration and provide the following configuration values:

   • Hostname: Host name of the primary (seed) server in the InnoDB cluster (localhost by default).
   • Port: The port number of the primary (seed) server in the InnoDB cluster (3310 by default).
   • Management User: An administrative user with root-level privileges.
   • Password: The password for the management user.
   • Classic MySQL protocol connections to InnoDB cluster

   Read/Write: Set the first base port number to one that is unused (between 80 and 65532) and the wizard will select the remaining ports for you.

The figure that follows shows an example of the MySQL Router configuration page, with the first base port number specified as 6446 and the remaining ports set by the wizard as 6447, 6448, and 6449.
3. Click **Next** and then **Execute** to apply the configuration. Click **Finish** to close MySQL Installer or return to the MySQL Installer dashboard.

After installing a production cluster with MySQL Router, the root account only exists in the user table as `root@localhost` (local), instead of `root@%` (remote). Regardless of where the router or client are located, even if both are located on the same host as the seed server, any connection that passes through the router is viewed by server as being remote, not local. As a result, a connection made to the server using the local host (see the example that follows), does not authenticate.

| Shell> \c root@localhost:6446 |

### 2.3.3.4 MySQL Installer Product Catalog and Dashboard

- **Product Catalog**
- **MySQL Installer Dashboard**
- **Locating Products to Install**

This section describes the MySQL Installer product catalog and the dashboard.

**Product Catalog**

The product catalog stores the complete list of released MySQL products for Microsoft Windows that are available to download from MySQL Downloads. By default, and when an Internet connection is present, MySQL Installer updates the catalog daily. You can also update the catalog manually from the dashboard (described later).

An up-to-date catalog performs the following actions:
- Populates the **Available Products** pane of the Select Products and Features step. This step appears when you select:
  - The **Custom** setup type during the **initial setup**.
  - The **Add** operation from the dashboard.
MySQL Installer for Windows

- Identifies when product updates are available for the installed products listed in the dashboard.

The catalog includes all development releases (Pre-Release), general releases (Current GA), and minor releases (Other Releases). Products in the catalog will vary somewhat, depending on the MySQL Installer release that you download.

MySQL Installer Dashboard

The MySQL Installer dashboard is the default view that you see when you start MySQL Installer after the initial setup finishes. If you closed MySQL Installer before the setup was finished, MySQL Installer resumes the initial setup before it displays the dashboard.

Figure 2.11 MySQL Installer Dashboard Elements

Description of MySQL Installer Dashboard Elements

1. MySQL Installer dashboard operations provide a variety of actions that apply to installed products or products listed in the catalog. To initiate the following operations, first click the operation link and then select the product or products to manage:

   - **Add**: This operation opens the Select Products and Features page. From there, you can filter the product in the product catalog, select one or more products to download (as needed), and begin the installation. For hints about using the filter, see Locating Products to Install.

   - **Modify**: Use this operation to add or remove the features associated with installed products. Features that you can modify vary in complexity by product. When the Program Shortcut check box is selected, the product appears in the Start menu under the MySQL group.

   - **Upgrade**: This operation loads the Select Products to Upgrade page and populates it with all the upgrade candidates. An installed product can have more than one upgrade version and requires a current product catalog.

Important server upgrade conditions:
MySQL Installer does not permit server upgrades between major release versions or minor release versions, but does permit upgrades within a release series, such as an upgrade from 5.7.18 to 5.7.19.

Upgrades between milestone releases (or from a milestone release to a GA release) are not supported. Significant development changes take place in milestone releases and you may encounter compatibility issues or problems starting the server.

For upgrades to MySQL 8.0.16 server and higher, a check box enables you to skip the upgrade check and process for system tables, while checking and processing data dictionary tables normally. MySQL Installer does not prompt you with the check box when the previous server upgrade was skipped or when the server was configured as a sandbox InnoDB cluster. This behavior represents a change in how MySQL Server performs an upgrade (see Section 2.11.3, “What the MySQL Upgrade Process Upgrades”) and it alters the sequence of steps that MySQL Installer applies to the configuration process.

If you select Skip system tables upgrade check and process. (Not recommended), MySQL Installer starts the upgraded server with the --upgrade=MINIMAL server option, which upgrades the data dictionary only. If you stop and then restart the server without the --upgrade=MINIMAL option, the server upgrades the system tables automatically, if needed.

The following information appears in the Log tab and log file after the upgrade configuration (with system tables skipped) is complete:

```
WARNING: The system tables upgrade was skipped after upgrading MySQL Server. The server will be started now with the --upgrade=MINIMAL option, but then each time the server is started it will attempt to upgrade the system tables, unless you modify the Windows service (command line) to add --upgrade=MINIMAL to bypass the upgrade.

FOR THE BEST RESULTS: Run mysqld.exe --upgrade=FORCE on the command line to upgrade the system tables manually.
```

To choose a new product version:

a. Click Upgrade. Confirm that the check box next to product name in the Upgradeable Products pane has a check mark. Deselect the products that you do not intend to upgrade at this time.

b. Click a product in the list to highlight it. This action populates the Upgradeable Versions pane with the details of each available version for the selected product: version number, published date, and a Changes link to open the release notes for that version.

MySQL Installer upgrades all of the selected products in one action. Click Show Details to view the actions performed by MySQL Installer.

Remove This operation opens the Remove Products page and populates it with the MySQL products installed on the host. Select the MySQL products you want to remove (uninstall) and then click Execute to begin the removal process.
To select products to remove, do one of the following:

- Select the check box for one or more products.
- Select the Product check box to select all products.

2. The Reconfigure link in the Quick Action column next to each installed server loads the current configuration values for the server and then cycles through all configuration steps enabling you to change the options and values. On completion, MySQL Installer stops the server, applies the configuration changes, and restarts the server for you. For a description of each configuration option, see MySQL Server Configuration with MySQL Installer.

Installed Samples and Examples associated with a specific MySQL server version can be also be reconfigured to apply feature-configuration changes, if any. You must provide credentials with root privileges to reconfigure these items.

3. The Catalog link enables you to download the latest catalog of MySQL products manually and then to integrate those product changes with MySQL Installer. The catalog-download action does not perform an upgrade of the products already installed on the host. Instead, it returns to the dashboard and displays an arrow icon in the Version column for each installed product that has a newer version. Use the Upgrade operation to install the newer product version.

You can also use the Catalog link to display the current change history of each product without downloading the new catalog. Select the Do not update at this time check box to view the change history only.

4. The MySQL Installer About icon shows the current version of MySQL Installer and general information about MySQL. The version number is located above the Back button.

   Tip
   Always include this version number when reporting a problem with MySQL Installer.

Click the double arrow to show a list of links to the latest MySQL product documentation, blogs, webinars, and more.

5. The MySQL Installer Options icon includes the following tabs:

- **Product Catalog**: Manages the daily automatic catalog updates. By default, catalog updates are scheduled at a fixed hour. When new products or product versions are available, MySQL Installer adds them to the catalog and then displays an arrow icon next to the version number of installed products listed in the dashboard.

Use this option to enable or disable automatic catalog updates and to reset the time of day when the MySQL Installer updates the catalog automatically. For specific settings, see the task named ManifestUpdate in the Windows Task Scheduler.

- **Connectivity Settings**: Several operations performed by MySQL Installer require internet access. This option enables you to use a default value to validate the connection or to use a different URL, one selected from a list or added by you manually. With the Manual option selected, new URLs can be added and all URLs in the list can be moved or deleted. When the Automatic option is selected, MySQL Installer attempts to connect to each default URL in the list (in order) until a connection is made. If no connection can be made, it raises an error.
Locating Products to Install

MySQL products in the catalog are listed by category: MySQL Servers, Applications, MySQL Connectors, and Documentation. Only the latest GA versions appear in the Available Products pane by default. If you are looking for a pre-release or older version of a product, it may not be visible in the default list.

To change the default product list, click Add on the dashboard to open the Select Products and Features page, and then click Edit to open the filter dialog box (see the figure that follows). Modify the product values and then click Filter.

Figure 2.12 Filter Available Products

Reset one or more of the following values to filter the list of available products:

- **Text**: Filter by text.
- **Category**: All Software (default), MySQL Servers, Applications, MySQL Connectors, or Documentation (for samples and documentation).
- **Maturity**: Current Bundle (appears initially with the full package only), Pre-Release, Current GA, or Other Releases.

**Note**
The Commercial release of MySQL Installer does not display any MySQL products when you select the Pre-Release age filter. Products in development are available from the Community release of MySQL Installer only.

- **Already Downloaded** (the check box is deselected by default).
- **Architecture**: Any (default), 32-bit, or 64-bit.

2.3.3.5 MySQLInstallerConsole Reference

MySQLInstallerConsole.exe provides command-line functionality that is similar to MySQL Installer. It is installed when MySQL Installer is initially executed and then available within the MySQL Installer directory. Typically, that is in C:\Program Files (x86)\MySQL\MySQL Installer\, and the console must be executed with administrative privileges.

To use, invoke the command prompt with administrative privileges by choosing Start, Accessories, then right-click on Command Prompt and choose Run as administrator. And from the command line, optionally change the directory to where MySQLInstallerConsole.exe is located:

```bash
C:\> cd Program Files (x86)\MySQL\MySQL Installer for Windows
C:\Program Files (x86)\MySQL\MySQL Installer for Windows> MySQLInstallerConsole.exe help
================== Start Initialization ===================
MySQL Installer is running in Community mode
```
Attempting to update manifest.
Initializing product requirements
Loading product catalog
Checking for product catalog snippets
Checking for product packages in the bundle
Categorizing product catalog
Finding all installed packages.
Your product catalog was last updated at 11/1/2016 4:10:38 PM
================================ End Initialization ===================

The following commands are available:

Configure - Configures one or more of your installed programs.
Help - Provides list of available commands.
Install - Install and configure one or more available MySQL programs.
List - Provides an interactive way to list all products available.
Modify - Modifies the features of installed products.
Remove - Removes one or more products from your system.
Status - Shows the status of all installed products.
Update - Update the current product catalog.
Upgrade - Upgrades one or more of your installed programs.

MySQLInstallerConsole.exe supports the following commands:

**Note**
Configuration block values that contain a colon (";") must be wrapped in double quotes. For example, installdir="C:\MySQL\MySQL Server 8.0".

- **configure** [product1]:[setting]=[value]; [product2]:[setting]=[value]; [...]
  Configure one or more MySQL products on your system. Multiple setting=value pairs can be configured for each product.

  **Switches include:**
  
  - **-showsettings**: Displays the available options for the selected product, by passing in the product name after **-showsettings**.
  
  - **-silent**: Disable confirmation prompts.

```c:\> MySQLInstallerConsole configure -showsettings server```
```c:\> MySQLInstallerConsole configure server:port=3307```

- **help** [command]
  Displays a help message with usage examples, and then exits. Pass in an additional command to receive help specific to that command.

```c:\> MySQLInstallerConsole help```
```c:\> MySQLInstallerConsole help install```

- **install** [product]:[features]:[config block]:[config block]:[config block]; [...]
  Install one or more MySQL products on your system. If pre-release products are available, both GA and pre-release products are installed when the value of the **-type** switch is Developer, Client, or Full. Use the **-only_ga_products** switch to restrict the product set to GA products only when using these setup types.

  **Switches and syntax options include:**
  
  - **-only_ga_products**: Restricts the product set to include GA products only.
MySQL Installer for Windows

- **-type=[SetupType]**: Installs a predefined set of software. The "SetupType" can be one of the following:
  
  **Note**
  
  Non-custom setup types can only be chosen if no other MySQL products are installed.

  - **Developer**: Installs a complete development environment.
  - **Server**: Installs a single MySQL server
  - **Client**: Installs client programs and libraries
  - **Full**: Installs everything
  - **Custom**: Installs user selected products. This is the default option.

- **-showsettings**: Displays the available options for the selected product, by passing in the product name after **-showsettings**.

- **-silent**: Disable confirmation prompts.

- **[config block]**: One or more configuration blocks can be specified. Each configuration block is a semicolon separated list of key value pairs. A block can include either a "config" or "user" type key, where "config" is the default type if one is not defined.

  Configuration block values that contain a colon character (:) must be wrapped in double quotes. For example, `installdir="C:\MySQL\MySQL Server 8.0"`.

  Only one "config" type block can be defined per product. A "user" block should be defined for each user that should be created during the product’s installation.

  **Note**
  
  Adding users is not supported when a product is being reconfigured.

- **[feature]**: The feature block is a semicolon separated list of features, or an asterisk character (*) to select all features.

  ```
  C:\> MySQLInstallerConsole install server;5.6.25:*:port=3307;serverid=2:type=user;username=foo;password=bar;role=DBManager
  ```

- **list**

  Lists an interactive console where all of the available MySQL products can be searched. Execute **MySQLInstallerConsole list** to launch the console, and enter in a substring to search.

  ```
  C:\> MySQLInstallerConsole list
  ```

- **modify [product1:-removelist|+addlist] [product2:-removelist|+addlist] [...]**
MySQL Notifier

Modifies or displays features of a previously installed MySQL product.

- `-silent` : Disable confirmation prompts.

```
C:\> MySQLInstallerConsole modify server
C:\> MySQLInstallerConsole modify server:+documentation
C:\> MySQLInstallerConsole modify server:-debug
```

- `remove [product1] [product2] [...]

Removes one or more products from your system.

- `*` : Pass in `*` to remove all of the MySQL products.
- `-continue` : Continue the operation even if an error occurs.
- `-silent` : Disable confirmation prompts.

```
C:\> MySQLInstallerConsole remove *
C:\> MySQLInstallerConsole remove server
```

- `status`

Provides a quick overview of the MySQL products that are installed on the system. Information includes product name and version, architecture, date installed, and install location.

```
C:\> MySQLInstallerConsole status
```

- `update`

Downloads the latest MySQL product catalog to your system. On success, the download catalog will be applied the next time either MySQLInstaller or MySQLInstallerConsole is executed.

```
C:\> MySQLInstallerConsole update
```

Note

The **Automatic Catalog Update** GUI option executes this command from the Windows Task Scheduler.

- `upgrade [product1:version] [product2:version] [...]

Upgrades one or more products on your system. Syntax options include:

- `*` : Pass in `*` to upgrade all products to the latest version, or pass in specific products.
- `!` : Pass in `!` as a version number to upgrade the MySQL product to its latest version.
- `-silent` : Disable confirmation prompts.

```
C:\> MySQLInstallerConsole upgrade *
C:\> MySQLInstallerConsole upgrade workbench:6.3.5
C:\> MySQLInstallerConsole upgrade workbench:!
C:\> MySQLInstallerConsole upgrade workbench:6.3.5 excel:1.3.2
```

2.3.4 MySQL Notifier

MySQL Notifier is a tool that enables you to monitor and adjust the status of your local and remote MySQL server instances through an indicator that resides in the Microsoft Windows taskbar. MySQL Notifier also gives quick access to MySQL Workbench through its context menu.
MySQL Notifier is installed by using MySQL Installer. It can be loaded automatically when Microsoft Windows is started.

To install, download and execute the MySQL Installer. With MySQL Notifier selected from Applications, proceed with the installation. See the MySQL Installer manual for additional details.

For notes detailing the changes in each release of MySQL Notifier, see the MySQL Notifier Release Notes.

Visit the MySQL Notifier forum for additional MySQL Notifier help and support.

Features include:

- Start, stop, and restart instances of the MySQL server.
- Automatically detects (and adds) new MySQL server services. These are listed under Manage Monitored Items, and may also be configured.
- The Tray icon changes, depending on the status. It is a right-pointing green triangle if all monitored MySQL server instances are running or a red square if at least one service is stopped. The Update MySQL Notifier tray icon based on service status option, which dictates this behavior, is enabled by default for each service.
- Links to other applications like MySQL Workbench, MySQL Installer, and the MySQL Utilities. For example, choosing Manage Instance will load the MySQL Workbench Server Administration window for that particular instance.
- If MySQL Workbench is also installed, then the Manage Instance and SQL Editor options are available for local (but not remote) MySQL instances.
- Monitors both local and remote MySQL instances.

2.3.4.1 MySQL Notifier Usage

MySQL Notifier provides visual status information for the MySQL servers that are monitored on both local or remote computers. The MySQL Notifier icon in the taskbar changes color to indicate the current status: Running or Stopped.

MySQL Notifier automatically adds discovered MySQL services on the local computer. By default, the Automatically add new services whose name contains option is enabled and set to mysql. Related notification options include being notified when new services are either discovered or experience status changes, and are also enabled by default. Uninstalling a service removes the service from MySQL Notifier.

Clicking the MySQL Notifier icon from the Windows taskbar reveals the MySQL Notifier main menu, which lists each MySQL server separately and displays its current status. You can start, stop, or restart each MySQL server from the menu as the following figure shows. When MySQL Workbench is installed locally, the Manage Instance and SQL Editor menu items start the application.

Figure 2.13 MySQL Notifier Service Instance Menu

The Actions menu includes the following items:
MySQL Notifier

- Manage Monitored Items
- Launch MySQL Installer (Only when the product is installed.)
- Check for Updates (Only when MySQL Installer is installed.)
- MySQL Utilities Shell (Only when the product is installed.)
- Refresh Status
- Options
- About
- Close MySQL Notifier

The main menu does not show the Actions menu when there are no services being monitored by MySQL Notifier.

MySQL Notifier Options

The Actions, Options menu provides a set of options that configure MySQL Notifier operations. Options are grouped into the following categories: General Options, Notification Options, and MySQL Server Connections Options.

Click Accept to enable the selected options or Cancel to ignore all changes. Click Reset to Defaults and then Accept to apply default option values.

General Options. This group includes:

- Use colorful status icons: Enables a colorful style of icons for the tray of MySQL Notifier. Selected by default.
- Run at Windows Startup: Allows the application to be loaded when Microsoft Windows starts. Deselected by default.
- Automatically Check For Updates Every # Weeks: Checks for a new version of MySQL Notifier, and runs this check every # weeks. Selected by default with the updates every four weeks.
- Automatically add new services whose name contains: The text used to filter services and add them automatically to the monitored list of the local computer running MySQL Notifier and on remote computers already monitoring Windows services. Selected by default for names containing mysql.
- Ping monitored MySQL Server instances every # seconds: The interval (in seconds) to ping monitored MySQL Server instances for status changes. Longer intervals might be necessary if the list of monitored remote instances is large. 30 seconds by default.

Notification Options. This group includes:

- Notify me when a service is automatically added: Display a balloon notification from the taskbar when a newly discovered service is added to the monitored services list. Selected by default.
- Notify me when a service changes status: Displays a balloon notification from the taskbar when a monitored service changes its status. Selected by default.

MySQL Server Connections Options. This group includes:

- Automatic connections migration delayed until: When there are connections to migrate to MySQL Workbench (if installed), this option postpones the migration by one hour, one day, one week, one month, or indefinitely.
Managing Monitored Items

The Actions, Manage Monitored Items menu enables you to add, configure, and delete the services and MySQL instances you intend to monitor. The Manage Items window has two tabs: Services and Instances.

Services Tab. When MySQL is configured as a local service, MySQL Notifier adds the service to the Services tab automatically. With the Services tab open, you can select the following options that apply to all services being monitored:

- Notify me when status changes
- Update MySQL Notifier tray icon based on service status

The next figure shows the Services tab open and both options selected. This tab shows the service name, the computer where the service is hosted, and the current status of the service.

Figure 2.14 MySQL Notifier: Manage Services

To stop monitoring a service, select it from the list of monitored services and click Delete.

Click Add and then Windows Service to open the Add Service window. To add a new service, select a computer from the drop-down list, choose a service from the list, and then click OK to accept. Use the Filter field to reduce the set of services in the list or select Only show services that match auto-add filter? to reuse the general-options filter from the Options menu.

A variety of Windows services (including MySQL) may be selected as the following figure shows. In addition to the service name, the list shows the current status of each Windows services for the selected computer.
Instances Tab. When MySQL is configured as a MySQL instance, MySQL Notifier adds the instance to the Instances tab automatically. With the Instances tab open, you can select the following options that apply to each instance being monitored:

- Notify me when status changes
- Update MySQL Notifier tray icon based on service status
- Monitor MySQL Instance status every [ # ] [ seconds | minutes | hours | days ]

The next figure shows the Instances tab open and both options selected. Monitoring the instance status is set to every two minutes in this example. This tab shows the instance name, the database driver, and the current status of the instance.
To stop monitoring an instance, select it from the list of monitored MySQL instances and click **Delete**.

Click **Add** and then **MySQL Instances** to open the **Monitor MySQL Server Instance** window. Use the **Filter** field to reduce the set of instances in the list or select **Show MySQL instances already being monitored?** to show monitored items only.

Optionally, you can select a connection from MySQL Workbench to monitor. Click **Add New Connection**, shown in the next figure, to create a new connection.
Troubleshooting

For issues that are not documented here, visit the MySQL Notifier Support Forum for MySQL Notifier help and support.

- **Problem**: attempting to start/stop/restart a MySQL service might generate an error similar to "The Service MySQL VERSION failed the most recent status change request with the message "The service mysql VERSION was not found in the Windows Services".

  **Explanation**: this is a case-sensitivity issue, in that the service name is `MySQL VERSION` compared to having `mysql VERSION` in the configuration file.

  **Solution**: either update your MySQL Notifier configuration file with the correct information, or stop MySQL Notifier and delete this configuration file. The MySQL Notifier configuration file is located at `%APPDATA%\Oracle\MySQL Notifier\settings.config` where `%APPDATA%` is a variable and depends on your system. A typical location is "C:\Users\YourUsername\AppData\Roaming\Oracle\MySQL Notifier\settings.config" where `YourUsername` is your system user name. In this file, and within the ServerList section, change the `ServerName` values from lowercase to the actual service names. For example, change `mysql VERSION` to `MySQL VERSION`, save, and then restart MySQL Notifier. Alternatively, stop MySQL Notifier, delete this file, then restart MySQL Notifier.

- **Problem**: when connecting to a remote computer for the purpose of monitoring a remote Windows service, the Add Service dialog does not always show all the services shown in the Windows Services console.

  **Explanation**: this behavior is governed by the operating system and the outcome is expected when working with nondomain user accounts. For a complete description of the behavior, see the User Account Control and WMI article from Microsoft.
Solution: when the remote computer is in a compatible domain, it is recommended that domain user accounts are used to connect through WMI to a remote computer. For detailed setup instructions using WMI, see Section 2.3.4.2, “Setting Up Remote Monitoring in MySQL Notifier”.

Alternatively, when domain user accounts are not available, Microsoft provides a less secure workaround that should only be implemented with caution. For more information, see the Description of User Account Control and remote restrictions in Windows Vista KB article from Microsoft.

### 2.3.4.2 Setting Up Remote Monitoring in MySQL Notifier

MySQL Notifier uses Windows Management Instrumentation (WMI) to manage and monitor services on remote computers. This section explains how it works and how to set up your system to monitor remote MySQL instances.

In order to configure WMI, it is important to understand that the underlying Distributed Component Object Model (DCOM) architecture is doing the WMI work. Specifically, MySQL Notifier is using asynchronous notification queries on remote Microsoft Windows hosts as .NET events. These events send an asynchronous callback to the computer running MySQL Notifier so it knows when a service status has changed on the remote computer. Asynchronous notifications offer the best performance compared to semisynchronous notifications or synchronous notifications that use timers.

As the following figure shows, asynchronous notification requires the remote computer to send a callback to the client computer (thus opening a reverse connection), so the Windows Firewall and DCOM settings must be properly configured for the communication to function properly. The client (Computer A), which includes an unsecured application (unsecapp.exe in this example), makes an asynchronous call to a remote computer (Computer B) and receives a call back with data.

![MySQL Notifier Distributed Component Object Model (DCOM)](image_url)

Most of the common errors thrown by asynchronous WMI notifications are related to Windows Firewall blocking the communication, or to DCOM / WMI settings not being set up properly. For a list of common errors with solutions, see Common Errors.

The following steps are required to make WMI function. These steps are divided between two machines. A single host computer that runs MySQL Notifier (Computer A), and multiple remote machines that are being monitored (Computer B).

**Computer running MySQL Notifier (Computer A)**

1. Enable remote administration by either editing the Group Policy Editor, or using NETSH:

   Using the **Group Policy Editor**:
   - Click **Start**, click **Run**, type **GPEDIT.MSC**, and then click **OK**.
   - Under the **Local Computer Policy** heading, expand Computer Configuration.
   - Expand Administrative Templates, then Network, Network Connections, and then Windows Firewall.
d. If the computer is in the domain, then double-click **Domain Profile**; otherwise, double-click **Standard Profile**.

e. Double-click **Windows Firewall: Allow inbound remote administration exception** to open a configuration window.

f. Check the **Enabled** option button and then click **OK**.

Using the **NETSH** command:

>Note

The "netsh firewall" command is deprecated as of Microsoft Server 2008 and Vista, and replaced with "netsh advfirewall firewall".

a. Open a command prompt window with Administrative rights (you can right-click the Command Prompt icon and select **Run as Administrator**).

b. Execute the following command:

```
NETSH advfirewall firewall set service RemoteAdmin enable
```

2. Open the DCOM port TCP 135:

a. Open a command prompt window with Administrative rights (you can right-click the Command Prompt icon and select **Run as Administrator**).

b. Execute the following command:

```
NETSH advfirewall firewall add rule name=DCOM_TCP135 protocol=TCP localport=135 dir=in action=allow
```

3. Add the client application that contains the sink for the callback (**MySqlNotifier.exe**) to the Windows Firewall Exceptions List (use either the Windows Firewall configuration or **NETSH**):

Using the Windows Firewall configuration:

a. In the Control Panel, double-click **Windows Firewall**.

b. In the Windows Firewall window, click **Allow a program or feature through Windows Firewall**.

c. In the Allowed Programs window, click **Change Settings** and do one of the following:

- If **MySqlNotifier.exe** is in the Allowed programs and features list, make sure it is checked for the type of networks the computer connects to (Private, Public or both).

- If **MySqlNotifier.exe** is not in the list, click **Allow another program**.

  i. In the **Add a Program** window, select the **MySqlNotifier.exe** if it exists in the Programs list, otherwise click **Browse** and go to the directory where **MySqlNotifier.exe** was installed to select it, then click **Add**.

  ii. Make sure **MySqlNotifier.exe** is checked for the type of networks the computer connects to (Private, Public or both).

Using the **NETSH** command:

a. Open a command prompt window with Administrative rights (you can right-click the Command Prompt icon and click **Run as Administrator**).
MySQL Notifier

b. Execute the following command, where you change "[YOUR_INSTALL_DIRECTORY]":

```
NETSH advfirewall firewall add rule name=MySqlNotifier program=[YOUR_INSTALL_DIRECTORY]\MySqlNotifier.exe action=allow dir=in
```

4. If Computer B is either a member of WORKGROUP or is in a different domain that is untrusted by Computer A, then the callback connection (Connection 2) is created as an Anonymous connection. To grant Anonymous connections DCOM Remote Access permissions:

   a. Click Start, click Run, type DCOMCNFG, and then click OK.

   b. In the Component Services dialog box, expand Component Services, expand Computers, and then right-click My Computer and click Properties.

   c. In the My Computer Properties dialog box, click the COM Security tab.

   d. Under Access Permissions, click Edit Limits.

   e. In the Access Permission dialog box, select ANONYMOUS LOGON name in the Group or user names box. In the Allow column under Permissions for User, select Remote Access, and then click OK.

Monitored Remote Computer (Computer B)

If the user account that is logged on to the computer running the MySQL Notifier (Computer A) is a local administrator on the remote computer (Computer B), such that the same account is an administrator on Computer B, you can skip to the "Allow for remote administration" step.

Setting DCOM security to allow a non-administrator user to access a computer remotely:

1. Grant "DCOM remote launch" and activation permissions for a user or group:

   a. Click Start, click Run, type DCOMCNFG, and then click OK.

   b. In the Component Services dialog box, expand Component Services, expand Computers, and then right-click My Computer and click Properties.

   c. In the My Computer Properties dialog box, click the COM Security tab.

   d. Under Launch and Activation Permission, click Edit Limits.

   e. In the Launch and Activation Permission dialog box, follow these steps if your name or your group does not appear in the Groups or user names list:

      i. In the Launch and Activation Permission dialog box, click Add.

      ii. In the Select Users or Groups dialog box, add your name and the group in the Enter the object names to select box, and then click OK.

   f. In the Launch and Activation Permission dialog box, select your user and group in the Group or user names box. In the Allow column under Permissions for User, select Remote Launch, select Remote Activation, and then click OK.

Grant DCOM remote access permissions:

   a. Click Start, click Run, type DCOMCNFG, and then click OK.

   b. In the Component Services dialog box, expand Component Services, expand Computers, and then right-click My Computer and click Properties.

   c. In the My Computer Properties dialog box, click the COM Security tab.
d. Under Access Permissions, click **Edit Limits**.

e. In the Access Permission dialog box, select **ANONYMOUS LOGON name** in the Group or user names box. In the Allow column under Permissions for User, select **Remote Access**, and then click **OK**.

2. Allowing non-administrator users access to a specific WMI namespace:

a. In the Control Panel, double-click **Administrative Tools**.

b. In the Administrative Tools window, double-click **Computer Management**.

c. In the Computer Management window, expand the **Services and Applications** tree.

d. Right-click the WMI Control icon and select **Properties**.

e. In the WMI Control Properties window, click the **Security** tab.

f. In the Security tab, select the namespace and click **Security**. Root/CIMV2 is a commonly used namespace.

g. Locate the appropriate account and check **Remote Enable** in the Permissions list.

3. Allow for remote administration by either editing the **Group Policy Editor** or using **NETSH**:

Using the **Group Policy Editor**:

a. Click **Start**, click **Run**, type **GPEDIT.MSC**, and then click **OK**.

b. Under the Local Computer Policy heading, double-click **Computer Configuration**.

c. Double-click **Administrative Templates**, then **Network, Network Connections**, and then **Windows Firewall**.

d. If the computer is in the domain, then double-click **Domain Profile**; otherwise, double-click **Standard Profile**.

e. Click **Windows Firewall: Allow inbound remote administration exception**.

f. On the Action menu either select **Edit**, or double-click the selection from the previous step.

  g. Check the **Enabled** radio button, and then click **OK**.

Using the **NETSH** command:

a. Open a command prompt window with Administrative rights (you can right-click the Command Prompt icon and click **Run as Administrator**).

b. Execute the following command:

```
NETSH advfirewall firewall set service RemoteAdmin enable
```

4. Confirm that the user account you are logging in with uses the **Name** value and not the **Full Name** value:

a. In the **Control Panel**, double-click **Administrative Tools**.

b. In the **Administrative Tools** window, double-click **Computer Management**.

c. In the **Computer Management** window, expand the **System Tools** then **Local Users and Groups**.
d. Click the **Users** node, and on the right side panel locate your user and make sure it uses the **Name** value to connect, and not the **Full Name** value.

**Common Errors**

- **0x80070005**
  - DCOM Security was not configured properly (see Computer B, the *Setting DCOM security...* step).
  - The remote computer (Computer B) is a member of WORKGROUP or is in a domain that is untrusted by the client computer (Computer A) (see Computer A, the *Grant Anonymous connections DCOM Remote Access permissions* step).

- **0x8007000E**
  - The remote computer (Computer B) is a member of WORKGROUP or is in a domain that is untrusted by the client computer (Computer A) (see Computer A, the *Grant Anonymous connections DCOM Remote Access permissions* step).

- **0x80041003**
  - Access to the remote WMI namespace was not configured properly (see Computer B, the *Allowing non-administrator users access to a specific WMI namespace* step).

- **0x800706BA**
  - The DCOM port is not open on the client computers (Computer A) firewall. See the *Open the DCOM port TCP 135* step for Computer A.
  - The remote computer (Computer B) is inaccessible because its network location is set to Public. Make sure you can access it through the Windows Explorer.

### 2.3.5 Installing MySQL on Microsoft Windows Using a **noinstall** ZIP Archive

Users who are installing from the **noinstall** package can use the instructions in this section to manually install MySQL. The process for installing MySQL from a ZIP Archive package is as follows:

1. Extract the main archive to the desired install directory

   *Optional:* also extract the debug-test archive if you plan to execute the MySQL benchmark and test suite

2. Create an option file

3. Choose a MySQL server type

4. Initialize MySQL

5. Start the MySQL server

6. Secure the default user accounts

This process is described in the sections that follow.

#### 2.3.5.1 Extracting the Install Archive

To install MySQL manually, do the following:

1. If you are upgrading from a previous version please refer to Section 2.11.10, “Upgrading MySQL on Windows”, before beginning the upgrade process.
2. Make sure that you are logged in as a user with administrator privileges.

3. Choose an installation location. Traditionally, the MySQL server is installed in `C:\mysql`. If you do not install MySQL at `C:\mysql`, you must specify the path to the install directory during startup or in an option file. See Section 2.3.5.2, “Creating an Option File”.

   **Note**
   The MySQL Installer installs MySQL under `C:\Program Files\MySQL`.

4. Extract the install archive to the chosen installation location using your preferred file-compression tool. Some tools may extract the archive to a folder within your chosen installation location. If this occurs, you can move the contents of the subfolder into the chosen installation location.

2.3.5.2 Creating an Option File

If you need to specify startup options when you run the server, you can indicate them on the command line or place them in an option file. For options that are used every time the server starts, you may find it most convenient to use an option file to specify your MySQL configuration. This is particularly true under the following circumstances:

- The installation or data directory locations are different from the default locations (`C:\Program Files\MySQL\MySQL Server 8.0` and `C:\Program Files\MySQL\MySQL Server 8.0\data`).

- You need to tune the server settings, such as memory, cache, or InnoDB configuration information.

When the MySQL server starts on Windows, it looks for option files in several locations, such as the Windows directory, `C:\`, and the MySQL installation directory (for the full list of locations, see Section 4.2.2.2, “Using Option Files”). The Windows directory typically is named something like `C:\WINDOWS`. You can determine its exact location from the value of the `WINDIR` environment variable using the following command:

```
C:\> echo %WINDIR%
```

MySQL looks for options in each location first in the `my.ini` file, and then in the `my.cnf` file. However, to avoid confusion, it is best if you use only one file. If your PC uses a boot loader where `C:` is not the boot drive, your only option is to use the `my.ini` file. Whichever option file you use, it must be a plain text file.

   **Note**
   When using the MySQL Installer to install MySQL Server, it will create the `my.ini` at the default location, and the user executing MySQL Installer is granted full permissions to this new `my.ini` file.

   In other words, be sure that the MySQL Server user has permission to read the `my.ini` file.

You can also make use of the example option files included with your MySQL distribution; see Section 5.1.2, “Server Configuration Defaults”.

An option file can be created and modified with any text editor, such as Notepad. For example, if MySQL is installed in `E:\mysql` and the data directory is in `E:\mydata\data`, you can create an option file containing a `[mysqld]` section to specify values for the `basedir` and `datadir` options:

```
[mysqld]
# set basedir to your installation path
basedir=E:/mysql
# set datadir to the location of your data directory
```
datadir=E:/mydata/data

Microsoft Windows path names are specified in option files using (forward) slashes rather than backslashes. If you do use backslashes, double them:

```
[mysqld]
# set basedir to your installation path
basedir=E:\mysql
# set datadir to the location of your data directory
datadir=E:\mydata\data
```

The rules for use of backslash in option file values are given in Section 4.2.2.2, “Using Option Files”.

The ZIP archive does not include a `data` directory. To initialize a MySQL installation by creating the data directory and populating the tables in the mysql system database, initialize MySQL using either `--initialize` or `--initialize-insecure`. For additional information, see Section 2.10.1, “Initializing the Data Directory”.

If you would like to use a data directory in a different location, you should copy the entire contents of the `data` directory to the new location. For example, if you want to use `E:\mydata` as the data directory instead, you must do two things:

1. Move the entire `data` directory and all of its contents from the default location (for example `C:\Program Files\MySQL\MySQL Server 8.0\data`) to `E:\mydata`.
2. Use a `--datadir` option to specify the new data directory location each time you start the server.

### 2.3.5.3 Selecting a MySQL Server Type

The following table shows the available servers for Windows in MySQL 8.0.

<table>
<thead>
<tr>
<th>Binary</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mysqld</td>
<td>Optimized binary with named-pipe support</td>
</tr>
<tr>
<td>mysqld-debug</td>
<td>Like <code>mysql</code>, but compiled with full debugging and automatic memory allocation checking</td>
</tr>
</tbody>
</table>

All of the preceding binaries are optimized for modern Intel processors, but should work on any Intel i386-class or higher processor.

Each of the servers in a distribution support the same set of storage engines. The `SHOW ENGINES` statement displays which engines a given server supports.

All Windows MySQL 8.0 servers have support for symbolic linking of database directories.

MySQL supports TCP/IP on all Windows platforms. MySQL servers on Windows also support named pipes, if you start the server with the `named_pipe` system variable enabled. It is necessary to enable this variable explicitly because some users have experienced problems with shutting down the MySQL server when named pipes were used. The default is to use TCP/IP regardless of platform because named pipes are slower than TCP/IP in many Windows configurations.

### 2.3.5.4 Initializing the Data Directory

If you installed MySQL using the `noinstall` package, no data directory is included. To initialize the data directory, use the instructions at Section 2.10.1, “Initializing the Data Directory”.

### 2.3.5.5 Starting the Server for the First Time

This section gives a general overview of starting the MySQL server. The following sections provide more specific information for starting the MySQL server from the command line or as a Windows service.
The information here applies primarily if you installed MySQL using the \texttt{noinstall} version, or if you wish to configure and test MySQL manually rather than with the MySQL Installer.

The examples in these sections assume that MySQL is installed under the default location of \texttt{C: \Program Files\MySQL\MySQL Server 8.0}. Adjust the path names shown in the examples if you have MySQL installed in a different location.

Clients have two options. They can use TCP/IP, or they can use a named pipe if the server supports named-pipe connections.

MySQL for Windows also supports shared-memory connections if the server is started with the \texttt{shared\_memory} system variable enabled. Clients can connect through shared memory by using the \texttt{--protocol=MEMORY} option.

For information about which server binary to run, see Section 2.3.5.3, “Selecting a MySQL Server Type”.

Testing is best done from a command prompt in a console window (or “DOS window”). In this way you can have the server display status messages in the window where they are easy to see. If something is wrong with your configuration, these messages make it easier for you to identify and fix any problems.

\textbf{Note}

The database must be initialized before MySQL can be started. For additional information about the initialization process, see Section 2.10.1, “Initializing the Data Directory”.

To start the server, enter this command:

```
C:\> "C:\Program Files\MySQL\MySQL Server 8.0\bin\mysqld" --console
```

For a server that includes InnoDB support, you should see the messages similar to those following as it starts (the path names and sizes may differ):

```
InnoDB: The first specified datafile c:\ibdata\ibdata1 did not exist:
InnoDB: a new database to be created:
InnoDB: Setting file c:\ibdata\ibdata1 size to 209715200
InnoDB: Database physically writes the file full: wait...
InnoDB: Log file c:\iblogs\ib_logfile0 did not exist: new to be created
InnoDB: Setting log file c:\iblogs\ib_logfile0 size to 31457280
InnoDB: Log file c:\iblogs\ib_logfile1 did not exist: new to be created
InnoDB: Setting log file c:\iblogs\ib_logfile1 size to 31457280
InnoDB: Log file c:\iblogs\ib_logfile2 did not exist: new to be created
InnoDB: Setting log file c:\iblogs\ib_logfile2 size to 31457280
InnoDB: Doublewrite buffer not found: creating new
InnoDB: Doublewrite buffer created
InnoDB: creating foreign key constraint system tables
InnoDB: foreign key constraint system tables created
011024 10:58:25  InnoDB: Started
```

When the server finishes its startup sequence, you should see something like this, which indicates that the server is ready to service client connections:

```
mysqld: ready for connections
Version: '8.0.18' socket: '' port: 3306
```

The server continues to write to the console any further diagnostic output it produces. You can open a new console window in which to run client programs.

If you omit the \texttt{--console} option, the server writes diagnostic output to the error log in the data directory (\texttt{C:\Program Files\MySQL\MySQL Server 8.0\data} by default). The error log is the file with the \texttt{.err} extension, and may be set using the \texttt{--log-error} option.
2.3.5.6 Starting MySQL from the Windows Command Line

The MySQL server can be started manually from the command line. This can be done on any version of Windows.

To start the mysql server from the command line, you should start a console window (or “DOS window”) and enter this command:

```
C:\> "C:\Program Files\MySQL\MySQL Server 8.0\bin\mysqld"
```

The path to mysqld may vary depending on the install location of MySQL on your system.

You can stop the MySQL server by executing this command:

```
C:\> "C:\Program Files\MySQL\MySQL Server 8.0\bin\mysqladmin" -u root shutdown
```

If the MySQL root user account has a password, you need to invoke mysqladmin with the -p option and supply the password when prompted.

This command invokes the MySQL administrative utility mysqladmin to connect to the server and tell it to shut down. The command connects as the MySQL root user, which is the default administrative account in the MySQL grant system.

Note

Users in the MySQL grant system are wholly independent from any operating system users under Microsoft Windows.

If mysqld doesn’t start, check the error log to see whether the server wrote any messages there to indicate the cause of the problem. By default, the error log is located in the C:\Program Files\MySQL\MySQL Server 8.0\data directory. It is the file with a suffix of .err, or may be specified by passing in the --log-error option. Alternatively, you can try to start the server with the --console option; in this case, the server may display some useful information on the screen that will help solve the problem.

The last option is to start mysqld with the --standalone and --debug options. In this case, mysqld writes a log file C:\mysqld.trace that should contain the reason why mysqld doesn’t start. See Section 29.5.4, “The DBUG Package”.

Use mysqld --verbose --help to display all the options that mysqld supports.

2.3.5.7 Customizing the PATH for MySQL Tools

Warning

You must exercise great care when editing your system PATH by hand; accidental deletion or modification of any portion of the existing PATH value can leave you with a malfunctioning or even unusable system.

To make it easier to invoke MySQL programs, you can add the path name of the MySQL bin directory to your Windows system PATH environment variable:
Installing MySQL on Microsoft Windows Using a noinstall ZIP Archive

• On the Windows desktop, right-click the My Computer icon, and select Properties.

• Next select the Advanced tab from the System Properties menu that appears, and click the Environment Variables button.

• Under System Variables, select Path, and then click the Edit button. The Edit System Variable dialogue should appear.

• Place your cursor at the end of the text appearing in the space marked Variable Value. (Use the End key to ensure that your cursor is positioned at the very end of the text in this space.) Then enter the complete path name of your MySQL bin directory (for example, C:\Program Files\MySQL \MySQL Server 8.0\bin)

   Note
   There must be a semicolon separating this path from any values present in this field.

Dismiss this dialogue, and each dialogue in turn, by clicking OK until all of the dialogues that were opened have been dismissed. The new PATH value should now be available to any new command shell you open, allowing you to invoke any MySQL executable program by typing its name at the DOS prompt from any directory on the system, without having to supply the path. This includes the servers, the mysql client, and all MySQL command-line utilities such as mysqladmin and mysqldump.

You should not add the MySQL bin directory to your Windows PATH if you are running multiple MySQL servers on the same machine.

2.3.5.8 Starting MySQL as a Windows Service

On Windows, the recommended way to run MySQL is to install it as a Windows service, so that MySQL starts and stops automatically when Windows starts and stops. A MySQL server installed as a service can also be controlled from the command line using NET commands, or with the graphical Services utility. Generally, to install MySQL as a Windows service you should be logged in using an account that has administrator rights.

The Services utility (the Windows Service Control Manager) can be found in the Windows Control Panel. To avoid conflicts, it is advisable to close the Services utility while performing server installation or removal operations from the command line.

Installing the service

Before installing MySQL as a Windows service, you should first stop the current server if it is running by using the following command:

C:\> "C:\Program Files\MySQL\MySQL Server 8.0\bin\mysqladmin" -u root shutdown

   Note
   If the MySQL root user account has a password, you need to invoke mysqladmin with the -p option and supply the password when prompted.

This command invokes the MySQL administrative utility mysqladmin to connect to the server and tell it to shut down. The command connects as the MySQL root user, which is the default administrative account in the MySQL grant system.

   Note
   Users in the MySQL grant system are wholly independent from any operating system users under Windows.
Install the server as a service using this command:

```
C:\> "C:\Program Files\MySQL\MySQL Server 8.0\bin\mysqld" --install
```

The service-installation command does not start the server. Instructions for that are given later in this section.

To make it easier to invoke MySQL programs, you can add the path name of the MySQL bin directory to your Windows system PATH environment variable:

• On the Windows desktop, right-click the My Computer icon, and select Properties.

• Next select the Advanced tab from the System Properties menu that appears, and click the Environment Variables button.

• Under System Variables, select Path, and then click the Edit button. The Edit System Variable dialogue should appear.

• Place your cursor at the end of the text appearing in the space marked Variable Value. (Use the End key to ensure that your cursor is positioned at the very end of the text in this space.) Then enter the complete path name of your MySQL bin directory (for example, `C:\Program Files\MySQL\MySQL Server 8.0\bin`), and there should be a semicolon separating this path from any values present in this field. Dismiss this dialogue, and each dialogue in turn, by clicking OK until all of the dialogues that were opened have been dismissed. You should now be able to invoke any MySQL executable program by typing its name at the DOS prompt from any directory on the system, without having to supply the path. This includes the servers, the mysql client, and all MySQL command-line utilities such as mysqladmin and mysqldump.

You should not add the MySQL bin directory to your Windows PATH if you are running multiple MySQL servers on the same machine.

**Warning**

You must exercise great care when editing your system PATH by hand; accidental deletion or modification of any portion of the existing PATH value can leave you with a malfunctioning or even unusable system.

The following additional arguments can be used when installing the service:

• You can specify a service name immediately following the --install option. The default service name is MySQL.

• If a service name is given, it can be followed by a single option. By convention, this should be --defaults-file=file_name to specify the name of an option file from which the server should read options when it starts.

    The use of a single option other than --defaults-file is possible but discouraged. --defaults-file is more flexible because it enables you to specify multiple startup options for the server by placing them in the named option file.

• You can also specify a --local-service option following the service name. This causes the server to run using the LocalService Windows account that has limited system privileges. If both --defaults-file and --local-service are given following the service name, they can be in any order.

For a MySQL server that is installed as a Windows service, the following rules determine the service name and option files that the server uses:

• If the service-installation command specifies no service name or the default service name (MySQL) following the --install option, the server uses the service name of MySQL and reads options from the [mysqld] group in the standard option files.
Installing MySQL on Microsoft Windows Using a noinstall ZIP Archive

- If the service-installation command specifies a service name other than MySQL following the --install option, the server uses that service name. It reads options from the [mysqld] group and the group that has the same name as the service in the standard option files. This enables you to use the [mysqld] group for options that should be used by all MySQL services, and an option group with the service name for use by the server installed with that service name.

- If the service-installation command specifies a --defaults-file option after the service name, the server reads options the same way as described in the previous item, except that it reads options only from the named file and ignores the standard option files.

As a more complex example, consider the following command:

```
C:\> "C:\Program Files\MySQL\MySQL Server 8.0\bin\mysqld" --install MySQL --defaults-file=C:\my-opts.cnf
```

Here, the default service name (MySQL) is given after the --install option. If no --defaults-file option had been given, this command would have the effect of causing the server to read the [mysqld] group from the standard option files. However, because the --defaults-file option is present, the server reads options from the [mysqld] option group, and only from the named file.

Note

On Windows, if the server is started with the --defaults-file and --install options, --install must be first. Otherwise, mysqld.exe will attempt to start the MySQL server.

You can also specify options as Start parameters in the Windows Services utility before you start the MySQL service.

Finally, before trying to start the MySQL service, make sure the user variables %TEMP% and %TMP% (and also %TMPDIR%, if it has ever been set) for the operating system user who is to run the service are pointing to a folder to which the user has write access. The default user for running the MySQL service is LocalSystem, and the default value for its %TEMP% and %TMP% is C:\Windows\Temp, a directory LocalSystem has write access to by default. However, if there are any changes to that default setup (for example, changes to the user who runs the service or to the mentioned user variables, or the --tmpdir option has been used to put the temporary directory somewhere else), the MySQL service might fail to run because write access to the temporary directory has not been granted to the proper user.

Starting the service

After a MySQL server instance has been installed as a service, Windows starts the service automatically whenever Windows starts. The service also can be started immediately from the Services utility, or by using an sc start mysqld_service_name or NET START mysqld_service_name command. SC and NET commands are not case-sensitive.

When run as a service, mysqld has no access to a console window, so no messages can be seen there. If mysqld does not start, check the error log to see whether the server wrote any messages there to indicate the cause of the problem. The error log is located in the MySQL data directory (for example, C:\Program Files\MySQL\MySQL Server 8.0\data). It is the file with a suffix of .err.

When a MySQL server has been installed as a service, and the service is running, Windows stops the service automatically when Windows shuts down. The server also can be stopped manually using the Services utility, the sc stop mysqld_service_name command, the NET START mysqld_service_name command, or the mysqladmin shutdown command.

You also have the choice of installing the server as a manual service if you do not wish for the service to be started automatically during the boot process. To do this, use the --install-manual option rather than the --install option:
Removing the service

To remove a server that is installed as a service, first stop it if it is running by executing `SC STOP mysql_service_name` or `NET STOP mysql_service_name`. Then use `SC DELETE mysql_service_name` to remove it:

```bash
C:\> SC DELETE mysql
```

Alternatively, use the `mysqld --remove` option to remove the service.

```bash
C:\> "C:\Program Files\MySQL\MySQL Server 8.0\bin\mysqld" --remove
```

If `mysqld` is not running as a service, you can start it from the command line. For instructions, see Section 2.3.5.6, “Starting MySQL from the Windows Command Line”.

If you encounter difficulties during installation, see Section 2.3.6, “Troubleshooting a Microsoft Windows MySQL Server Installation”.

For more information about stopping or removing a Windows service, see Section 5.8.2.2, “Starting Multiple MySQL Instances as Windows Services”.

### 2.3.5.9 Testing The MySQL Installation

You can test whether the MySQL server is working by executing any of the following commands:

```bash
C:\> "C:\Program Files\MySQL\MySQL Server 8.0\bin\mysqlshow"
C:\> "C:\Program Files\MySQL\MySQL Server 8.0\bin\mysqlshow" -u root mysql
C:\> "C:\Program Files\MySQL\MySQL Server 8.0\bin\mysqladmin" version status proc
C:\> "C:\Program Files\MySQL\MySQL Server 8.0\bin\mysql" test
```

If `mysqld` is slow to respond to TCP/IP connections from client programs, there is probably a problem with your DNS. In this case, start `mysqld` with the `--skip-name-resolve` option and use only `localhost` and IP addresses in the `Host` column of the MySQL grant tables. (Be sure that an account exists that specifies an IP address or you may not be able to connect.)

You can force a MySQL client to use a named-pipe connection rather than TCP/IP by specifying the `--pipe` or `--protocol=PIPE` option, or by specifying `. (period)` as the host name. Use the `--socket` option to specify the name of the pipe if you do not want to use the default pipe name.

If you have set a password for the `root` account, deleted the anonymous account, or created a new user account, then to connect to the MySQL server you must use the appropriate `--u` and `--p` options with the commands shown previously. See Section 4.2.4, “Connecting to the MySQL Server Using Command Options”.

For more information about `mysqlshow`, see Section 4.5.7, “`mysqlshow` — Display Database, Table, and Column Information”.

### 2.3.6 Troubleshooting a Microsoft Windows MySQL Server Installation

When installing and running MySQL for the first time, you may encounter certain errors that prevent the MySQL server from starting. This section helps you diagnose and correct some of these errors.

Your first resource when troubleshooting server issues is the `error log`. The MySQL server uses the error log to record information relevant to the error that prevents the server from starting. The error log is located in the `data directory` specified in your `my.ini` file. The default data directory location is `C:`
Troubleshooting a Microsoft Windows MySQL Server Installation

The following examples show other common error messages you might encounter when installing MySQL and starting the server for the first time:

- If the MySQL server cannot find the *mysql* privileges database or other critical files, it displays these messages:

  ```
  System error 1067 has occurred.
  Fatal error: Can't open and lock privilege tables:
  Table 'mysql.user' doesn't exist
  ```

  These messages often occur when the MySQL base or data directories are installed in different locations than the default locations (`C:\Program Files\MySQL\MySQL Server 8.0` and `C:\Program Files\MySQL\MySQL Server 8.0\data`, respectively).

  This situation can occur when MySQL is upgraded and installed to a new location, but the configuration file is not updated to reflect the new location. In addition, old and new configuration files might conflict. Be sure to delete or rename any old configuration files when upgrading MySQL.

  If you have installed MySQL to a directory other than `C:\Program Files\MySQL\MySQL Server 8.0`, ensure that the MySQL server is aware of this through the use of a configuration (`my.ini`) file. Put the `my.ini` file in your Windows directory, typically `C:\WINDOWS`. To determine its exact location from the value of the `WINDIR` environment variable, issue the following command from the command prompt:

  ```
  C:\> echo %WINDIR%
  ```

  You can create or modify an option file with any text editor, such as Notepad. For example, if MySQL is installed in `E:\mysql` and the data directory is `D:\MySQLdata`, you can create the option file and set up a `[mysqld]` section to specify values for the `basedir` and `datadir` options:

  ```
  [mysqld]
  # set basedir to your installation path
  basedir=E:/mysql
  # set datadir to the location of your data directory
  datadir=D:/MySQLdata
  ```

  Microsoft Windows path names are specified in option files using (forward) slashes rather than backslashes. If you do use backslashes, double them:

  ```
  [mysqld]
  # set basedir to your installation path
  basedir=C:\Program Files\MySQL\MySQL Server 8.0
  # set datadir to the location of your data directory
  datadir=D:\MySQLdata
  ```

  The rules for use of backslash in option file values are given in Section 4.2.2.2, “Using Option Files”.

  If you change the `datadir` value in your MySQL configuration file, you must move the contents of the existing MySQL data directory before restarting the MySQL server.
See Section 2.3.5.2, "Creating an Option File".

- If you reinstall or upgrade MySQL without first stopping and removing the existing MySQL service and install MySQL using the MySQL Installer, you might see this error:

```
Error: Cannot create Windows service for MySql. Error: 0
```

This occurs when the Configuration Wizard tries to install the service and finds an existing service with the same name.

One solution to this problem is to choose a service name other than `mysql` when using the configuration wizard. This enables the new service to be installed correctly, but leaves the outdated service in place. Although this is harmless, it is best to remove old services that are no longer in use.

To permanently remove the old `mysql` service, execute the following command as a user with administrative privileges, on the command line:

```
C:\> SC DELETE mysql
[SC] DeleteService SUCCESS
```

If the `SC` utility is not available for your version of Windows, download the `delsrv` utility from [http://www.microsoft.com/windows2000/techinfo/reskit/tools/existing/delsrv-o.asp](http://www.microsoft.com/windows2000/techinfo/reskit/tools/existing/delsrv-o.asp) and use the `delsrv mysql` syntax.

### 2.3.7 Windows Postinstallation Procedures

GUI tools exist that perform most of the tasks described in this section, including:

- **MySQL Installer**: Used to install and upgrade MySQL products.
- **MySQL Workbench**: Manages the MySQL server and edits SQL statements.

If necessary, initialize the data directory and create the MySQL grant tables. Windows installation operations performed by MySQL Installer initialize the data directory automatically. For installation from a ZIP Archive package, initialize the data directory as described at Section 2.10.1, "Initializing the Data Directory".

Regarding passwords, if you installed MySQL using the MySQL Installer, you may have already assigned a password to the initial `root` account. (See Section 2.3.3, "MySQL Installer for Windows"). Otherwise, use the password-assignment procedure given in Section 2.10.4, "Securing the Initial MySQL Account".

Before assigning a password, you might want to try running some client programs to make sure that you can connect to the server and that it is operating properly. Make sure that the server is running (see Section 2.3.5.5, "Starting the Server for the First Time"). You can also set up a MySQL service that runs automatically when Windows starts (see Section 2.3.5.8, "Starting MySQL as a Windows Service").

These instructions assume that your current location is the MySQL installation directory and that it has a `bin` subdirectory containing the MySQL programs used here. If that is not true, adjust the command path names accordingly.

If you installed MySQL using MySQL Installer (see Section 2.3.3, "MySQL Installer for Windows"), the default installation directory is `C:\Program Files\MySQL\MySQL Server 8.0`:

```
C:\> cd "C:\Program Files\MySQL\MySQL Server 8.0"
```

A common installation location for installation from a ZIP archive is `C:\mysql`:
C:\> cd C:\mysql

Alternatively, add the bin directory to your PATH environment variable setting. That enables your command interpreter to find MySQL programs properly, so that you can run a program by typing only its name, not its path name. See Section 2.3.5.7, “Customizing the PATH for MySQL Tools”.

With the server running, issue the following commands to verify that you can retrieve information from the server. The output should be similar to that shown here.

Use mysqlshow to see what databases exist:

C:\> bin\mysqlshow

<table>
<thead>
<tr>
<th>Databases</th>
</tr>
</thead>
<tbody>
<tr>
<td>information_schema</td>
</tr>
<tr>
<td>mysql</td>
</tr>
<tr>
<td>performance_schema</td>
</tr>
<tr>
<td>sys</td>
</tr>
</tbody>
</table>

The list of installed databases may vary, but always includes at least mysql and information_schema.

The preceding command (and commands for other MySQL programs such as mysql) may not work if the correct MySQL account does not exist. For example, the program may fail with an error, or you may not be able to view all databases. If you install MySQL using MySQL Installer, the root user is created automatically with the password you supplied. In this case, you should use the -u root and -p options. (You must use those options if you have already secured the initial MySQL accounts.) With -p, the client program prompts for the root password. For example:

C:\> bin\mysqlshow -u root -p
Enter password: (enter root password here)

<table>
<thead>
<tr>
<th>Databases</th>
</tr>
</thead>
<tbody>
<tr>
<td>information_schema</td>
</tr>
<tr>
<td>mysql</td>
</tr>
<tr>
<td>performance_schema</td>
</tr>
<tr>
<td>sys</td>
</tr>
</tbody>
</table>

If you specify a database name, mysqlshow displays a list of the tables within the database:

C:\> bin\mysqlshow mysql
Database: mysql
<table>
<thead>
<tr>
<th>Tables</th>
</tr>
</thead>
<tbody>
<tr>
<td>columns_priv</td>
</tr>
<tr>
<td>component</td>
</tr>
<tr>
<td>db</td>
</tr>
<tr>
<td>default_roles</td>
</tr>
<tr>
<td>engine_cost</td>
</tr>
<tr>
<td>func</td>
</tr>
<tr>
<td>general_log</td>
</tr>
<tr>
<td>global_grants</td>
</tr>
<tr>
<td>gtid_executed</td>
</tr>
<tr>
<td>help_category</td>
</tr>
<tr>
<td>help_keyword</td>
</tr>
<tr>
<td>help_relation</td>
</tr>
<tr>
<td>help_topic</td>
</tr>
<tr>
<td>innodb_index_stats</td>
</tr>
</tbody>
</table>
Use the `mysql` program to select information from a table in the `mysql` database:

```
C:\> bin\mysql -e "SELECT User, Host, plugin FROM mysql.user" mysql
+------+-----------+-----------------------+
| User | Host      | plugin                |
| root | localhost | caching_sha2_password |
+------+-----------+-----------------------+
```

For more information about `mysql` and `mysqlshow`, see Section 4.5.1, "`mysql` — The MySQL Command-Line Client", and Section 4.5.7, "`mysqlshow` — Display Database, Table, and Column Information".

### 2.4 Installing MySQL on macOS

For a list of macOS versions that the MySQL server supports, see [https://www.mysql.com/support/supportedplatforms/database.html](https://www.mysql.com/support/supportedplatforms/database.html).

MySQL for macOS is available in a number of different forms:

- **Native Package Installer**, which uses the native macOS installer (DMG) to walk you through the installation of MySQL. For more information, see Section 2.4.2, "Installing MySQL on macOS Using Native Packages". You can use the package installer with macOS. The user you use to perform the installation must have administrator privileges.

- **Compressed TAR archive**, which uses a file packaged using the Unix `tar` and `gzip` commands. To use this method, you will need to open a `Terminal` window. You do not need administrator privileges using this method, as you can install the MySQL server anywhere using this method. For more information on using this method, you can use the generic instructions for using a tarball, Section 2.2, "Installing MySQL on Unix/Linux Using Generic Binaries".

In addition to the core installation, the Package Installer also includes Section 2.4.3, "Installing and Using the MySQL Launch Daemon" and Section 2.4.4, "Installing and Using the MySQL Preference Pane" to simplify the management of your installation.

For additional information on using MySQL on macOS, see Section 2.4.1, "General Notes on Installing MySQL on macOS".

### 2.4.1 General Notes on Installing MySQL on macOS

You should keep the following issues and notes in mind:
Installing MySQL on macOS Using Native Packages

- **Other MySQL installations**: The installation procedure does not recognize MySQL installations by package managers such as Homebrew. The installation and upgrade process is for MySQL packages provided by us. If other installations are present, then consider stopping them before executing this installer to avoid port conflicts.

  **Homebrew**: For example, if you installed MySQL Server using Homebrew to its default location then the MySQL installer installs to a different location and won't upgrade the version from Homebrew. In this scenario you would end up with multiple MySQL installations that, by default, attempt to use the same ports. Stop the other MySQL Server instances before running this installer, such as executing `brew services stop mysql` to stop the Homebrew's MySQL service.

- **Launchd**: A launchd daemon is installed that alters MySQL configuration options. Consider editing it if needed, see the documentation below for additional information. Also, macOS 10.10 removed startup item support in favor of launchd daemons. The optional MySQL preference pane under macOS **System Preferences** uses the launchd daemon.

- **Users**: You may need (or want) to create a specific `mysql` user to own the MySQL directory and data. You can do this through the `Directory Utility`, and the `mysql` user should already exist. For use in single user mode, an entry for `_mysql` (note the underscore prefix) should already exist within the system `/etc/passwd` file.

- **Data**: Because the MySQL package installer installs the MySQL contents into a version and platform specific directory, you can use this to upgrade and migrate your database between versions. You will need to either copy the `data` directory from the old version to the new version, or alternatively specify an alternative `datadir` value to set location of the data directory. By default, the MySQL directories are installed under `/usr/local/`.

- **Aliases**: You might want to add aliases to your shell's resource file to make it easier to access commonly used programs such as `mysql` and `mysqladmin` from the command line. The syntax for `bash` is:

  ```
  alias mysql=/usr/local/mysql/bin/mysql
  alias mysqladmin=/usr/local/mysql/bin/mysqladmin
  ```

  For `tcsh`, use:

  ```
  alias mysql /usr/local/mysql/bin/mysql
  alias mysqladmin /usr/local/mysql/bin/mysqladmin
  ```

  Even better, add `/usr/local/mysql/bin` to your `PATH` environment variable. You can do this by modifying the appropriate startup file for your shell. For more information, see Section 4.2.1, “Invoking MySQL Programs”.

- **Removing**: After you have copied over the MySQL database files from the previous installation and have successfully started the new server, you should consider removing the old installation files to save disk space. Additionally, you should also remove older versions of the Package Receipt directories located in `/Library/Receipts/mysql-VERSION.pkg`.

- **Legacy**: Prior to OS X 10.7, MySQL server was bundled with OS X Server.

## 2.4.2 Installing MySQL on macOS Using Native Packages

The package is located inside a disk image (.dmg) file that you first need to mount by double-clicking its icon in the Finder. It should then mount the image and display its contents.

**Note**

Before proceeding with the installation, be sure to stop all running MySQL server instances by using either the MySQL Manager Application (on macOS
To install MySQL using the package installer:

1. Download the disk image (.dmg) file (the community version is available [here](https://dev.mysql.com/downloads/mysql/)) that contains the MySQL package installer. Double-click the file to mount the disk image and see its contents.

   Double-click the MySQL installer package from the disk. It is named according to the version of MySQL you have downloaded. For example, for MySQL server 8.0.18 it might be named `mysql-8.0.18-osx-10.13-x86_64.pkg`.

2. The initial wizard introduction screen references the MySQL server version to install. Click **Continue** to begin the installation.

   The MySQL community edition shows a copy of the relevant GNU General Public License. Click **Continue** and then **Agree** to continue.

3. From the **Installation Type** page you can either click **Install** to execute the installation wizard using all defaults, click **Customize** to alter which components to install (MySQL server, MySQL Test, Preference Pane, Launchd Support -- all but MySQL Test are enabled by default).

   **Note**

   Although the **Change Install Location** option is visible, the installation location cannot be changed.

---

**Figure 2.19 MySQL Package Installer Wizard: Installation Type**

![MySQL Package Installer Wizard](image-url)
4. Click **Install** to install MySQL Server. The installation process ends here if upgrading a current MySQL Server installation, otherwise follow the wizard's additional configuration steps for your new MySQL Server installation.

5. After a successful new MySQL Server installation, complete the configuration steps by choosing the default encryption type for passwords, define the root password, and also enable (or disable) MySQL server at startup.

6. The default MySQL 8.0 password mechanism is **caching_sha2_password** (Strong), and this step allows you to change it to **mysql_native_password** (Legacy).
Choosing the legacy password mechanism alters the generated launchd file to set `--default_authentication_plugin=mysql_native_password` under `ProgramArguments`. Choosing strong password encryption does not set `--default_authentication_plugin` because the default MySQL Server value is used, which is `caching_sha2_password`.

7. Define a password for the root user, and also toggle whether MySQL Server should start after the configuration step is complete.

**Figure 2.22 MySQL Package Installer Wizard: Define Root Password**

8. **Summary** is the final step and references a successful and complete MySQL Server installation. Close the wizard.

**Figure 2.23 MySQL Package Installer Wizard: Summary**
MySQL server is now installed. If you chose to not start MySQL, then use either launchctl from the command line or start MySQL by clicking "Start" using the MySQL preference pane. For additional information, see Section 2.4.3, “Installing and Using the MySQL Launch Daemon”, and Section 2.4.4, “Installing and Using the MySQL Preference Pane”. Use the MySQL Preference Pane or launchctl to configure MySQL to automatically start at bootup.

When installing using the package installer, the files are installed into a directory within `/usr/local` matching the name of the installation version and platform. For example, the installer file `mysql-8.0.18-osx10.13-x86_64.dmg` installs MySQL into `/usr/local/mysql-8.0.18-osx10.13-x86_64/` with a symlink to `/usr/local/mysql`. The following table shows the layout of this MySQL installation directory.

### Table 2.6 MySQL Installation Layout on macOS

<table>
<thead>
<tr>
<th>Directory</th>
<th>Contents of Directory</th>
</tr>
</thead>
<tbody>
<tr>
<td>bin</td>
<td>mysqld server, client and utility programs</td>
</tr>
<tr>
<td>data</td>
<td>Log files, databases, where <code>/usr/local/mysql/data/mysqld.local.err</code> is the default error log</td>
</tr>
<tr>
<td>docs</td>
<td>Helper documents, like the Release Notes and build information</td>
</tr>
<tr>
<td>include</td>
<td>Include (header) files</td>

</tr>
<tr>
<td>support-files</td>
<td>Scripts and sample configuration files</td>
</tr>
<tr>
<td>/tmp/mysql.sock</td>
<td>Location of the MySQL Unix socket</td>
</tr>
</tbody>
</table>

### 2.4.3 Installing and Using the MySQL Launch Daemon

macOS uses launch daemons to automatically start, stop, and manage processes and applications such as MySQL.

By default, the installation package (DMG) on macOS installs a launchd file named `/Library/LaunchDaemons/com.oracle.oss.mysql.mysqld.plist` that contains a plist definition similar to:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE plist PUBLIC "-//Apple Computer//DTD PLIST 1.0//EN" "http://www.apple.com/DTDs/PropertyList-1.0.dtd">
<plist version="1.0">
  <dict>
    <key>Label</key>             <string>com.oracle.oss.mysql.mysqld</string>
    <key>ProcessType</key>       <string>Interactive</string>
    <key>Disabled</key>          <false/>
    <key>RunAtLoad</key>         <true/>
    <key>KeepAlive</key>         <true/>
    <key>SessionCreate</key>     <true/>
    <key>LaunchOnlyOnce</key>    <false/>
    <key>UserName</key>          <string>_mysql</string>
    <key>GroupName</key>         <string>_mysql</string>
    <key>ExitTimeOut</key>       <integer>600</integer>
    <key>Program</key>           <string>/usr/local/mysql/bin/mysqld</string>
    <key>ProgramArguments</key>  <array>
```
Installing and Using the MySQL Launch Daemon

Note

Some users report that adding a plist DOCTYPE declaration causes the launchd operation to fail, despite it passing the lint check. We suspect it's a copy-n-paste error. The md5 checksum of a file containing the above snippet is d925f05f6d1b6ee5ce5451b596d6baed.

To enable the launchd service, you can either:

- Open macOS system preferences and select the MySQL preference panel, and then execute Start MySQL Server.

Figure 2.24 MySQL Preference Pane: Location

The Instances page includes an option to start or stop MySQL, and Initialize Database recreates the data/ directory. Uninstall uninstalls MySQL Server and optionally the MySQL preference panel and launchd information.
Or, manually load the launchd file.

```
shell> cd /Library/LaunchDaemons
shell> sudo launchctl load -F com.oracle.oss.mysql.mysqld.plist
```

To configure MySQL to automatically start at bootup, you can:

```
shell> sudo launchctl load -w com.oracle.oss.mysql.mysqld.plist
```

**Note**

When upgrading MySQL server, the launchd installation process will remove the old startup items that were installed with MySQL server 5.7.7 and below.

Also, upgrading will replace your existing launchd file named `com.oracle.oss.mysql.mysqld.plist`.

Additional launchd related information:

- The plist entries override `my.cnf` entries, because they are passed in as command line arguments. For additional information about passing in program options, see Section 4.2.2, "Specifying Program Options".

- The **ProgramArguments** section defines the command line options that are passed into the program, which is the `mysqld` binary in this case.

- The default plist definition is written with less sophisticated use cases in mind. For more complicated setups, you may want to remove some of the arguments and instead rely on a MySQL configuration file, such as `my.cnf`. 

![Figure 2.25 MySQL Preference Pane: Instances](image)
• If you edit the plist file, then uncheck the installer option when reinstalling or upgrading MySQL. Otherwise, your edited plist file will be overwritten, and all edits will be lost.

Because the default plist definition defines several **ProgramArguments**, you might remove most of these arguments and instead rely upon your **my.cnf** MySQL configuration file to define them. For example:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE plist PUBLIC "-//Apple Computer//DTD PLIST 1.0//EN" "http://www.apple.com/DTDs/PropertyList-1.0.dtd">
<plist version="1.0">
  <dict>
    <key>Label</key>             <string>com.oracle.oss.mysql.mysqld</string>
    <key>ProcessType</key>       <string>Interactive</string>
    <key>Disabled</key>          <false/>
    <key>RunAtLoad</key>         <true/>
    <key>KeepAlive</key>         <true/>
    <key>SessionCreate</key>     <true/>
    <key>LaunchOnlyOnce</key>    <false/>
    <key>UserName</key>          <string>_mysql</string>
    <key>GroupName</key>         <string>_mysql</string>
    <key>ExitTimeOut</key>       <integer>600</integer>
    <key>Program</key>           <string>/usr/local/mysql/bin/mysqld</string>
    <key>ProgramArguments</key>
      <array>
        <string>/usr/local/mysql/bin/mysqld</string>
        <string>--user=_mysql</string>
        <string>--basedir=/usr/local/mysql</string>
        <string>--datadir=/usr/local/mysql/data</string>
        <string>--plugin-dir=/usr/local/mysql/lib/plugin</string>
        <string>--log-error=/usr/local/mysql/data/mysqld.local.err</string>
        <string>--pid-file=/usr/local/mysql/data/mysqld.local.pid</string>
        <string>--keyring-file-data=/usr/local/mysql/keyring/keyring</string>
        <string>--early-plugin-load=keyring_file=keyring_file.so</string>
      </array>
    <key>WorkingDirectory</key>  <string>/usr/local/mysql</string>
  </dict>
</plist>
```

In this case, the **basedir, datadir, plugin_dir, log_error, pid_file, keyring_file_data, and --early-plugin-load** options were removed from the default plist **ProgramArguments** definition, which you might have defined in **my.cnf** instead.

### 2.4.4 Installing and Using the MySQL Preference Pane

The MySQL Installation Package includes a MySQL preference pane that enables you to start, stop, and control automated startup during boot of your MySQL installation.

This preference pane is installed by default, and is listed under your system’s **System Preferences** window.
The MySQL preference pane is installed with the same DMG file that installs MySQL Server. Typically it is installed with MySQL Server but it can be installed by itself too.

To install the MySQL preference pane:

1. Go through the process of installing the MySQL server, as described in the documentation at Section 2.4.2, “Installing MySQL on macOS Using Native Packages”.

2. Click **Customize** at the **Installation Type** step. The "Preference Pane" option is listed there and enabled by default; make sure it is not deselected. The other options, such as MySQL Server, can be selected or deselected.
3. Complete the installation process.

**Note**

The MySQL preference pane only starts and stops MySQL installation installed from the MySQL package installation that have been installed in the default location.

Once the MySQL preference pane has been installed, you can control your MySQL server instance using this preference pane.

The **Instances** page includes an option to start and stop MySQL, and **Initialize Database** recreates the `data/` directory. **Uninstall** uninstalls MySQL Server and optionally the pain and launchd information.

The **Instances** page includes an option to start or stop MySQL, and **Initialize Database** recreates the `data/` directory. **Uninstall** uninstalls MySQL Server and optionally the MySQL preference panel and launchd information.
The **Configuration** page shows MySQL Server options including the path to the MySQL configuration file.
The MySQL Preference Pane shows the current status of the MySQL server, showing **stopped** (in red) if the server is not running and **running** (in green) if the server has already been started. The preference pane also shows the current setting for whether the MySQL server has been set to start automatically.

### 2.5 Installing MySQL on Linux

Linux supports a number of different solutions for installing MySQL. We recommend that you use one of the distributions from Oracle, for which several methods for installation are available:

<table>
<thead>
<tr>
<th>Type</th>
<th>Setup Method</th>
<th>Additional Information</th>
</tr>
</thead>
<tbody>
<tr>
<td>Apt</td>
<td>Enable the MySQL Apt repository</td>
<td>Documentation</td>

</tbody>
</table>

As an alternative, you can use the package manager on your system to automatically download and install MySQL with packages from the native software repositories of your Linux distribution. These native packages are often several versions behind the currently available release. You will also normally be unable to install development milestone releases (DMRs), as these are not usually made available in the native repositories. For more information on using the native package installers, see Section 2.5.7, “Installing MySQL on Linux from the Native Software Repositories”.

**Note**
For many Linux installations, you will want to set up MySQL to be started automatically when your machine starts. Many of the native package installations perform this operation for you, but for source, binary and RPM solutions you may need to set this up separately. The required script, `mysql.server`, can be found in the `support-files` directory under the MySQL installation directory or in a MySQL source tree. You can install it as `/etc/init.d/mysql` for automatic MySQL startup and shutdown. See Section 4.3.3, "mysql.server — MySQL Server Startup Script".

### 2.5.1 Installing MySQL on Linux Using the MySQL Yum Repository

The MySQL Yum repository for Oracle Linux, Red Hat Enterprise Linux, CentOS, and Fedora provides RPM packages for installing the MySQL server, client, MySQL Workbench, MySQL Utilities, MySQL Router, MySQL Shell, Connector/ODBC, Connector/Python and so on (not all packages are available for all the distributions; see Installing Additional MySQL Products and Components with Yum for details).

**Before You Start**

As a popular, open-source software, MySQL, in its original or re-packaged form, is widely installed on many systems from various sources, including different software download sites, software repositories, and so on. The following instructions assume that MySQL is not already installed on your system using a third-party-distributed RPM package; if that is not the case, follow the instructions given in Section 2.11.7, “Upgrading MySQL with the MySQL Yum Repository” or Replacing a Third-Party Distribution of MySQL Using the MySQL Yum Repository.

**Steps for a Fresh Installation of MySQL**

Follow the steps below to install the latest GA version of MySQL with the MySQL Yum repository:

**Adding the MySQL Yum Repository**

First, add the MySQL Yum repository to your system’s repository list. This is a one-time operation, which can be performed by installing an RPM provided by MySQL. Follow these steps:

2. Select and download the release package for your platform.
3. Install the downloaded release package with the following command, replacing `platform-and-version-specific-package-name` with the name of the downloaded RPM package:

```
shell> sudo yum localinstall platform-and-version-specific-package-name.rpm
```
Installing MySQL on Linux Using the MySQL Yum Repository

For an EL6-based system, the command is in the form of:

```
shell> sudo yum localinstall mysql80-community-release-el6-\{version-number\}.noarch.rpm
```

For an EL7-based system:

```
shell> sudo yum localinstall mysql80-community-release-el7-\{version-number\}.noarch.rpm
```

For Fedora 30:

```
shell> sudo dnf localinstall mysql80-community-release-fc30-\{version-number\}.noarch.rpm
```

For Fedora 29:

```
shell> sudo dnf localinstall mysql80-community-release-fc29-\{version-number\}.noarch.rpm
```

The installation command adds the MySQL Yum repository to your system's repository list and downloads the GnuPG key to check the integrity of the software packages. See Section 2.1.3.2, “Signature Checking Using GnuPG” for details on GnuPG key checking.

You can check that the MySQL Yum repository has been successfully added by the following command (for dnf-enabled systems, replace `yum` in the command with `dnf`):

```
shell> yum repolist enabled | grep "mysql.*-community.*"
```

Note

Once the MySQL Yum repository is enabled on your system, any system-wide update by the `yum update` command (or `dnf upgrade` for dnf-enabled systems) will upgrade MySQL packages on your system and also replace any native third-party packages, if Yum finds replacements for them in the MySQL Yum repository; see Section 2.11.7, “Upgrading MySQL with the MySQL Yum Repository” and, for a discussion on some possible effects of that on your system, see Upgrading the Shared Client Libraries.

Selecting a Release Series

When using the MySQL Yum repository, the latest GA series (currently MySQL 8.0) is selected for installation by default. If this is what you want, you can skip to the next step, Installing MySQL.

Within the MySQL Yum repository, different release series of the MySQL Community Server are hosted in different subrepositories. The subrepository for the latest GA series (currently MySQL 8.0) is enabled by default, and the subrepositories for all other series (for example, the MySQL 8.0 series) are disabled by default. Use this command to see all the subrepositories in the MySQL Yum repository, and see which of them are enabled or disabled (for dnf-enabled systems, replace `yum` in the command with `dnf`):

```
shell> yum repolist all | grep mysql
```

To install the latest release from the latest GA series, no configuration is needed. To install the latest release from a specific series other than the latest GA series, disable the subrepository for the latest GA series and enable the subrepository for the specific series before running the installation command. If your platform supports `yum-config-manager`, you can do that by issuing these commands, which disable the subrepository for the 5.7 series and enable the one for the 8.0 series:
Installing MySQL on Linux Using the MySQL Yum Repository

shell> sudo yum-config-manager --disable mysql57-community
shell> sudo yum-config-manager --enable mysql80-community

For dnf-enabled platforms:

shell> sudo dnf config-manager --disable mysql57-community
shell> sudo dnf config-manager --enable mysql80-community

Besides using `yum-config-manager` or the `dnf config-manager` command, you can also select a release series by editing manually the `/etc/yum.repos.d/mysql-community.repo` file. This is a typical entry for a release series' subrepository in the file:

```
[mysql57-community]
name=MySQL 5.7 Community Server
baseurl=http://repo.mysql.com/yum/mysql-5.7-community/el/6/$basearch/
enabled=1
gpgcheck=1
gpgkey=file:///etc/pki/rpm-gpg/RPM-GPG-KEY-mysql
```

Find the entry for the subrepository you want to configure, and edit the `enabled` option. Specify `enabled=0` to disable a subrepository, or `enabled=1` to enable a subrepository. For example, to install MySQL 8.0, make sure you have `enabled=0` for the above subrepository entry for MySQL 5.7, and have `enabled=1` for the entry for the 8.0 series:

```
# Enable to use MySQL 8.0
[mysql80-community]
name=MySQL 8.0 Community Server
baseurl=http://repo.mysql.com/yum/mysql-8.0-community/el/6/$basearch/
enabled=1
gpgcheck=1
gpgkey=file:///etc/pki/rpm-gpg/RPM-GPG-KEY-mysql
```

You should only enable subrepository for one release series at any time. When subrepositories for more than one release series are enabled, the latest series will be used by Yum.

Verify that the correct subrepositories have been enabled and disabled by running the following command and checking its output (for dnf-enabled systems, replace `yum` in the command with `dnf`):

```
shell> yum repolist enabled | grep mysql
```

### Installing MySQL

Install MySQL by the following command (for dnf-enabled systems, replace `yum` in the command with `dnf`):

```
shell> sudo yum install mysql-community-server
```

This installs the package for MySQL server (`mysql-community-server`) and also packages for the components required to run the server, including packages for the client (`mysql-community-client`), the common error messages and character sets for client and server (`mysql-community-common`), and the shared client libraries (`mysql-community-libs`).

### Starting the MySQL Server

Start the MySQL server with the following command:

```
shell> sudo service mysqld start
```
Installing MySQL on Linux Using the MySQL Yum Repository

Starting mysqld: [ OK ]

You can check the status of the MySQL server with the following command:

```shell
sudo service mysqld status
```
```
mysqld (pid 3066) is running.
```

At the initial start up of the server, the following happens, given that the data directory of the server is empty:

- The server is initialized.
- SSL certificate and key files are generated in the data directory.
- `validate_password` is installed and enabled.
- A superuser account 'root'@'localhost' is created. A password for the superuser is set and stored in the error log file. To reveal it, use the following command:

```shell
sudo grep 'temporary password' /var/log/mysqld.log
```

Change the root password as soon as possible by logging in with the generated, temporary password and set a custom password for the superuser account:

```shell
mysql -u root -p
```
```
mysql> ALTER USER 'root'@'localhost' IDENTIFIED BY 'MyNewPass4!';
```

**Note**

`validate_password` is installed by default. The default password policy implemented by `validate_password` requires that passwords contain at least one upper case letter, one lower case letter, one digit, and one special character, and that the total password length is at least 8 characters.

For more information on the postinstallation procedures, see Section 2.10, "Postinstallation Setup and Testing".

**Note**

**Compatibility Information for EL7-based platforms:** The following RPM packages from the native software repositories of the platforms are incompatible with the package from the MySQL Yum repository that installs the MySQL server. Once you have installed MySQL using the MySQL Yum repository, you will not be able to install these packages (and vice versa).

- akonadi-mysql

### Installing Additional MySQL Products and Components with Yum

You can use Yum to install and manage individual components of MySQL. Some of these components are hosted in sub-repositories of the MySQL Yum repository: for example, the MySQL Connectors are to be found in the MySQL Connectors Community sub-repository, and the MySQL Workbench in MySQL Tools Community. You can use the following command to list the packages for all the MySQL components available for your platform from the MySQL Yum repository (for dnf-enabled systems, replace `yum` in the command with `dnf`):

```shell
sudo yum --disablerepo=*/ --enablerepo=mysql*-community* list available
```
Install any packages of your choice with the following command, replacing `package-name` with name of the package (for dnf-enabled systems, replace `yum` in the command with `dnf`):

```
shell> sudo yum install package-name
```

For example, to install MySQL Workbench on Fedora:

```
shell> sudo dnf install mysql-workbench-community
```

To install the shared client libraries (for dnf-enabled systems, replace `yum` in the command with `dnf`):

```
shell> sudo yum install mysql-community-libs
```

**Platform Specific Notes**

**ARM Support**

ARM 64-bit (aarch64) is supported on Oracle Linux 7 and requires the Oracle Linux 7 Software Collections Repository (ol7_software_collections). For example, to install the server:

```
shell> yum-config-manager --enable ol7_software_collections
shell> yum install mysql-community-server
```

**Note**

ARM 64-bit (aarch64) is supported on Oracle Linux 7 as of MySQL 8.0.12.

**Known Limitation**

The 8.0.12 release requires you to adjust the `libstdc++` path by executing `ln -s /opt/oracle/oracle-armtoolset-1/root/usr/lib64 /usr/lib64/gcc7` after executing the `yum install` step.

**Updating MySQL with Yum**

Besides installation, you can also perform updates for MySQL products and components using the MySQL Yum repository. See Section 2.11.7, “Upgrading MySQL with the MySQL Yum Repository” for details.

### 2.5.2 Installing MySQL on Linux Using the MySQL APT Repository

The MySQL APT repository provides `deb` packages for installing and managing the MySQL server, client, and other components on the following Linux platforms:

- Debian 9
- Ubuntu 16.04, 17.10, and 18.04

Instructions for using the MySQL APT Repository are available in A Quick Guide to Using the MySQL APT Repository.

### 2.5.3 Installing MySQL on Linux Using the MySQL SLES Repository

The MySQL SLES repository provides RPM packages for installing and managing the MySQL server, client, and other components on SUSE Enterprise Linux Server.

Instructions for using the MySQL SLES repository are available in A Quick Guide to Using the MySQL SLES Repository.

### 2.5.4 Installing MySQL on Linux Using RPM Packages from Oracle
The recommended way to install MySQL on RPM-based Linux distributions is by using the RPM packages provided by Oracle. There are two sources for obtaining them, for the Community Edition of MySQL:

- From the MySQL software repositories:
  - The MySQL Yum repository (see Section 2.5.1, “Installing MySQL on Linux Using the MySQL Yum Repository” for details).
  - The MySQL SLES repository (see Section 2.5.3, “Installing MySQL on Linux Using the MySQL SLES Repository” for details).

- From the Download MySQL Community Server page in the MySQL Developer Zone.

**Note**

RPM distributions of MySQL are also provided by other vendors. Be aware that they may differ from those built by Oracle in features, capabilities, and conventions (including communication setup), and that the installation instructions in this manual do not necessarily apply to them. The vendor’s instructions should be consulted instead.

### MySQL RPM Packages

**Table 2.8 RPM Packages for MySQL Community Edition**

<table>
<thead>
<tr>
<th>Package Name</th>
<th>Summary</th>
</tr>
</thead>
<tbody>
<tr>
<td>mysql-community-client</td>
<td>MySQL client applications and tools</td>
</tr>
<tr>
<td>mysql-community-common</td>
<td>Common files for server and client libraries</td>
</tr>
<tr>
<td>mysql-community-devel</td>
<td>Development header files and libraries for MySQL database client applications</td>
</tr>
<tr>
<td>mysql-community-embedded-compat</td>
<td>MySQL server as an embedded library with compatibility for applications using version 18 of the library</td>
</tr>
<tr>
<td>mysql-community-libs</td>
<td>Shared libraries for MySQL database client applications</td>
</tr>
<tr>
<td>mysql-community-libs-compat</td>
<td>Shared compatibility libraries for previous MySQL installations</td>
</tr>
<tr>
<td>mysql-community-server</td>
<td>Database server and related tools</td>
</tr>
<tr>
<td>mysql-community-test</td>
<td>Test suite for the MySQL server</td>
</tr>
<tr>
<td>mysql-community</td>
<td>The source code RPM looks similar to mysql-community-8.0.18-1.el7.src.rpm, depending on selected OS</td>
</tr>
</tbody>
</table>
Table 2.9 RPM Packages for the MySQL Enterprise Edition

<table>
<thead>
<tr>
<th>Package Name</th>
<th>Summary</th>
</tr>
</thead>
<tbody>
<tr>
<td>mysql-commercial-backup</td>
<td>MySQL Enterprise Backup (added in 8.0.11)</td>
</tr>
<tr>
<td>mysql-commercial-client</td>
<td>MySQL client applications and tools</td>
</tr>
<tr>
<td>mysql-commercial-common</td>
<td>Common files for server and client libraries</td>
</tr>
<tr>
<td>mysql-commercial-devel</td>
<td>Development header files and libraries for MySQL database client applications</td>
</tr>
<tr>
<td>mysql-commercial-embedded-compat</td>
<td>MySQL server as an embedded library with compatibility for applications using version 18 of the library</td>
</tr>
<tr>
<td>mysql-commercial-libs</td>
<td>Shared libraries for MySQL database client applications</td>
</tr>
<tr>
<td>mysql-commercial-libs-compat</td>
<td>Shared compatibility libraries for previous MySQL installations; the version of the libraries matches the version of the libraries installed by default by the distribution you are using</td>
</tr>
<tr>
<td>mysql-commercial-server</td>
<td>Database server and related tools</td>
</tr>
<tr>
<td>mysql-commercial-test</td>
<td>Test suite for the MySQL server</td>
</tr>
</tbody>
</table>

The full names for the RPMs have the following syntax:

packagename-version-distribution-arch.rpm

The distribution and arch values indicate the Linux distribution and the processor type for which the package was built. See the table below for lists of the distribution identifiers:

Table 2.10 MySQL Linux RPM Package Distribution Identifiers

<table>
<thead>
<tr>
<th>Distribution Value</th>
<th>Intended Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>el6, el7</td>
<td>Red Hat Enterprise Linux/Oracle Linux/CentOS 6 or 7</td>
</tr>
<tr>
<td>fc29 fc30</td>
<td>Fedora 29 and 30</td>
</tr>
<tr>
<td>sles12</td>
<td>SUSE Linux Enterprise Server 12</td>
</tr>
</tbody>
</table>

To see all files in an RPM package (for example, mysql-community-server), use the following command:

shell> rpm --qpl mysql-community-server-version-distribution-arch.rpm
Installing MySQL on Linux Using RPM Packages from Oracle

The discussion in the rest of this section applies only to an installation process using the RPM packages directly downloaded from Oracle, instead of through a MySQL repository.

Dependency relationships exist among some of the packages. If you plan to install many of the packages, you may wish to download the RPM bundle.tar file instead, which contains all the RPM packages listed above, so that you need not download them separately.

In most cases, you need to install the mysql-community-server, mysql-community-client, mysql-community-libs, mysql-community-common, and mysql-community-libs-compat packages to get a functional, standard MySQL installation. To perform such a standard, basic installation, go to the folder that contains all those packages (and, preferably, no other RPM packages with similar names), and issue the following command:

```
shell> sudo yum install mysql-community-{server,client,common,libs}-*
```

Replace `yum` with `zypper` for SLES, and with `dnf` for Fedora.

While it is much preferable to use a high-level package management tool like `yum` to install the packages, users who prefer direct `rpm` commands can replace the `yum install` command with the `rpm -Uvh` command; however, using `rpm -Uvh` instead makes the installation process more prone to failure, due to potential dependency issues the installation process might run into.

To install only the client programs, you can skip `mysql-community-server` in your list of packages to install; issue the following command:

```
shell> sudo yum install mysql-community-{client,common,libs}-*
```

Replace `yum` with `zypper` for SLES, and with `dnf` for Fedora.

A standard installation of MySQL using the RPM packages result in files and resources created under the system directories, shown in the following table.

Table 2.11 MySQL Installation Layout for Linux RPM Packages from the MySQL Developer Zone

<table>
<thead>
<tr>
<th>Files or Resources</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>Client programs and scripts</td>
<td>/usr/bin</td>
</tr>
<tr>
<td>mysqld server</td>
<td>/usr/sbin</td>
</tr>
<tr>
<td>Configuration file</td>
<td>/etc/my.cnf</td>
</tr>
<tr>

<tr>
<td>Socket</td>
<td>/var/lib/mysql/mysql.sock</td>
</tr>
<tr>
<td>Keyring directory</td>
<td>/var/lib/mysql/mysql-keyring</td>
</tr>
<tr>
<td>Unix manual pages</td>
<td>/usr/share/man</td>
</tr>
</tbody>
</table>
Installing MySQL on Linux Using RPM Packages from Oracle

<table>
<thead>
<tr>
<th>Files or Resources</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>Include (header) files</td>
<td>/usr/include/mysql</td>
</tr>
<tr>
<td>Libraries</td>
<td>/usr/lib/mysql</td>
</tr>
<tr>
<td>Miscellaneous support files (for example, error</td>
<td>/usr/share/mysql</td>
</tr>
<tr>
<td>messages, and character set files)</td>
<td></td>
</tr>
</tbody>
</table>

The installation also creates a user named mysql and a group named mysql on the system.

**Note**

Installation of previous versions of MySQL using older packages might have created a configuration file named /usr/my.cnf. It is highly recommended that you examine the contents of the file and migrate the desired settings inside to the file /etc/my.cnf file, then remove /usr/my.cnf.

MySQL is NOT automatically started at the end of the installation process. For Red Hat Enterprise Linux, Oracle Linux, CentOS, and Fedora systems, use the following command to start MySQL:

```
shell> systemctl start mysqld
```

For SLES systems, the command is the same, but the service name is different:

```
shell> systemctl start mysql
```

If the operating system is systemd enabled, standard systemctl (or alternatively, service with the arguments reversed) commands such as stop, start, status, and restart should be used to manage the MySQL server service. The mysqld service is enabled by default, and it starts at system reboot. Notice that certain things might work differently on systemd platforms: for example, changing the location of the data directory might cause issues. See Section 2.5.9, “Managing MySQL Server with systemd” for additional information.

During an upgrade installation using RPM packages, if the MySQL server is running when the upgrade occurs then the MySQL server is stopped, the upgrade occurs, and the MySQL server is restarted. One exception: if the edition also changes during an upgrade (such as community to commercial, or vice-versa), then MySQL server is not restarted.

At the initial start up of the server, the following happens, given that the data directory of the server is empty:

- The server is initialized.
- An SSL certificate and key files are generated in the data directory.
- validate_password is installed and enabled.
- A superuser account 'root'@'localhost' is created. A password for the superuser is set and stored in the error log file. To reveal it, use the following command for RHEL, Oracle Linux, CentOS, and Fedora systems:

```
shell> sudo grep 'temporary password' /var/log/mysqld.log
```

Use the following command for SLES systems:

```
shell> sudo grep 'temporary password' /var/log/mysql/mysqld.log
```

The next step is to log in with the generated, temporary password and set a custom password for the superuser account:
shell> mysql -uroot -p

mysql> ALTER USER 'root'@'localhost' IDENTIFIED BY 'MyNewPass4!';

Note
validate_password is installed by default. The default password policy implemented by validate_password requires that passwords contain at least one upper case letter, one lower case letter, one digit, and one special character, and that the total password length is at least 8 characters.

If something goes wrong during installation, you might find debug information in the error log file /var/log/mysqld.log.

For some Linux distributions, it might be necessary to increase the limit on number of file descriptors available to mysqld. See Section B.4.2.17, "File Not Found and Similar Errors"

Installing Client Libraries from Multiple MySQL Versions. It is possible to install multiple client library versions, such as for the case that you want to maintain compatibility with older applications linked against previous libraries. To install an older client library, use the --oldpackage option with rpm. For example, to install mysql-community-libs-5.5 on an EL6 system that has libmysqlclient.21 from MySQL 8.0, use a command like this:

shell> rpm --oldpackage -ivh mysql-community-libs-5.5.50-2.el6.x86_64.rpm

Debug Package. A special variant of MySQL Server compiled with the debug package has been included in the server RPM packages. It performs debugging and memory allocation checks and produces a trace file when the server is running. To use that debug version, start MySQL with /usr/sbin/mysqld-debug, instead of starting it as a service or with /usr/sbin/mysqld. See Section 29.5.4, "The DBUG Package" for the debug options you can use.

Note
The default plugin directory for debug builds changed from /usr/lib64/mysql/plugin to /usr/lib64/mysql/plugin/debug in MySQL 8.0.4. Previously, it was necessary to change plugin_dir to /usr/lib64/mysql/plugin/debug for debug builds.

Rebuilding RPMs from source SRPMs. Source code SRPM packages for MySQL are available for download. They can be used as-is to rebuild the MySQL RPMs with the standard rpmbuild tool chain.

2.5.5 Installing MySQL on Linux Using Debian Packages from Oracle

Oracle provides Debian packages for installing MySQL on Debian or Debian-like Linux systems. The packages are available through two different channels:

- The MySQL APT Repository. This is the preferred method for installing MySQL on Debian-like systems, as it provides a simple and convenient way to install and update MySQL products. For details, see Section 2.5.2, "Installing MySQL on Linux Using the MySQL APT Repository".

- The MySQL Developer Zone's Download Area. For details, see Section 2.1.2, "How to Get MySQL". The following are some information on the Debian packages available there and the instructions for installing them:

  - Various Debian packages are provided in the MySQL Developer Zone for installing different components of MySQL on different Debian or Ubuntu platforms (currently, Debian 9, and Ubuntu 16, 17, and 18 are supported). The preferred method is to use the tarball bundle, which contains the packages needed for a basic setup of MySQL. The tarball bundles have names in the format of mysql-server_MVER-DVER_CPU.deb-bundle.tar. MVER is the MySQL version and DVER is the Linux distribution version. The CPU value indicates the processor type or family for which the package is built, as shown in the following table:
Table 2.12 MySQL Debian and Ubuntu Installation Packages CPU Identifiers

<table>
<thead>
<tr>
<th>CPU</th>
<th>Intended Processor Type or Family</th>
</tr>
</thead>
<tbody>
<tr>
<td>i386</td>
<td>Pentium processor or better, 32 bit</td>
</tr>
<tr>
<td>amd64</td>
<td>64-bit x86 processor</td>
</tr>
</tbody>
</table>

- After downloading the tarball, unpack it with the following command:

  shell> tar -xvf mysql-server_MVER-DVER_CPU.deb-bundle.tar

- You may need to install the `libaio` library if it is not already present on your system:

  shell> sudo apt-get install libaio1

- Preconfigure the MySQL server package with the following command:

  shell> sudo dpkg-preconfigure mysql-community-server_*.deb

You will be asked to provide a password for the root user for your MySQL installation. You might also be asked other questions regarding the installation.

**Important**

Make sure you remember the root password you set. Users who want to set a password later can leave the password field blank in the dialogue box and just press OK; in that case, root access to the server is authenticated using the MySQL Socket Peer-Credential Authentication Plugin for connections using a Unix socket file. You can set the root password later using `mysql_secure_installation`.

- For a basic installation of the MySQL server, install the database common files package, the client package, the client metapackage, the server package, and the server metapackage (in that order); you can do that with a single command:

  shell> sudo dpkg -i mysql-{common,community-client,client,community-server,server}_*.deb

There are also packages with `server-core` and `client-core` in the package names. These contain binaries only and are installed automatically by the standard packages. Installing them by themselves will not result in a functioning MySQL setup.

If you are being warned of unmet dependencies by `dpkg`, you can fix them using `apt-get`:

  sudo apt-get -f install

Here are where the files are installed on the system:

- All configuration files (like `my.cnf`) are under `/etc/mysql`
- All binaries, libraries, headers, etc., are under `/usr/bin` and `/usr/sbin`
- The data directory is under `/var/lib/mysql`

**Note**

Debian distributions of MySQL are also provided by other vendors. Be aware that they may differ from those built by Oracle in features, capabilities, and conventions (including communication setup), and that the instructions in this
manual do not necessarily apply to installing them. The vendor's instructions should be consulted instead.

2.5.6 Deploying MySQL on Linux with Docker

The Docker deployment framework supports easy installation and configuration of MySQL Server. This section explains how to use a MySQL Server Docker image.

You need to have Docker installed on your system before you can use a MySQL Server Docker image. See Install Docker for instructions.

Important

You need to either run docker commands with sudo, or create a docker usergroup, and then add to it any users who want to run docker commands. See details here. Because Docker containers are always run with root privileges, you should understand the Docker daemon attack surface and properly mitigate the related risks.

2.5.6.1 Basic Steps for MySQL Server Deployment with Docker

Warning

The MySQL Docker images maintained by the MySQL team are built specifically for Linux platforms. Other platforms are not supported, and users using these MySQL Docker images on them are doing so at their own risk. See the discussion here for some known limitations for running these containers on non-Linux operating systems.

- Downloading a MySQL Server Docker Image
- Starting a MySQL Server Instance
- Connecting to MySQL Server from within the Container
- Container Shell Access
- Stopping and Deleting a MySQL Container
- Upgrading a MySQL Server Container
- More Topics on Deploying MySQL Server with Docker

Downloading a MySQL Server Docker Image

Downloading the server image in a separate step is not strictly necessary; however, performing this step before you create your Docker container ensures your local image is up to date. To download the MySQL Community Edition image, run this command:

```
docker pull mysql/mysql-server:tag
```

The tag is the label for the image version you want to pull (for example, 5.5, 5.6, 5.7, 8.0, or latest). If :tag is omitted, the latest label is used, and the image for the latest GA version of MySQL Community Server is downloaded. Refer to the list of tags for available versions on the mysql/mysql-server page in the Docker Hub.

You can list downloaded Docker images with this command:

```
docker images
```

<table>
<thead>
<tr>
<th>REPOSITORY</th>
<th>TAG</th>
<th>IMAGE ID</th>
<th>CREATED</th>
<th>SIZE</th>
</tr>
</thead>
<tbody>
<tr>
<td>mysql/mysql-server</td>
<td>latest</td>
<td>3157d7f55f8d</td>
<td>4 weeks ago</td>
<td>241MB</td>
</tr>
</tbody>
</table>

To download the MySQL Enterprise Edition image from the My Oracle Support website, sign in to your Oracle account, download from Patches and Updates the tar.zip file for the Docker image mysql-
Deploying MySQL on Linux with Docker

Starting a MySQL Server Instance

To start a new Docker container for a MySQL Server, use the following command:

```bash
docker run --name=container_name -d image_name:tag
```

The image name can be obtained using the `docker images` command, as explained in Downloading a MySQL Server Docker Image. The `--name` option, for supplying a custom name for your server container, is optional; if no container name is supplied, a random one is generated.

For example, to start a new Docker container for the MySQL Community Server, use this command:

```bash
docker run --name=mysql1 -d mysql/mysql-server:8.0
```

To start a new Docker container for the MySQL Enterprise Server with a Docker image downloaded from My Oracle Support, use this command:

```bash
docker run --name=mysql1 -d mysql/enterprise-server:8.0
```

If the Docker image of the specified name and tag has not been downloaded by an earlier `docker pull` or `docker run` command, the image is now downloaded. Initialization for the container begins, and the container appears in the list of running containers when you run the `docker ps` command.

For example:

```
shell> docker ps
CONTAINER ID   IMAGE                COMMAND                  CREATED             STATUS                              PORTS                NAMES
a24888f0d6f4   mysql/mysql-server   "/entrypoint.sh my..."   14 seconds ago      Up 13 seconds (health: starting)    3306/tcp, 33060/tcp  mysql1
```

The container initialization might take some time. When the server is ready for use, the STATUS of the container in the output of the `docker ps` command changes from (health: starting) to (healthy).

The `-d` option used in the `docker run` command above makes the container run in the background. Use this command to monitor the output from the container:

```bash
docker logs mysql1
```

Once initialization is finished, the command's output is going to contain the random password generated for the root user; check the password with, for example, this command:

```
shell> docker logs mysql1 2>&1 | grep GENERATED
GENERATED ROOT PASSWORD: Axegh3kAJyDLaRuBemecissESh0s
```

Connecting to MySQL Server from within the Container

Once the server is ready, you can run the `mysql` client within the MySQL Server container you just started, and connect it to the MySQL Server. Use the `docker exec -it` command to start a `mysql` client inside the Docker container you have started, like the following:

```bash
docker exec -it mysql1 mysql -uroot -p
```

When asked, enter the generated root password (see the last step in Starting a MySQL Server Instance above on how to find the password). Because the `MYSQL_ONETIME_PASSWORD` option is true by default, after you have connected a `mysql` client to the server, you must reset the server root password by issuing this statement:

```
mysql> ALTER USER 'root'@'localhost' IDENTIFIED BY 'password';
```

Substitute `password` with the password of your choice. Once the password is reset, the server is ready for use.
Deploying MySQL on Linux with Docker

Container Shell Access

To have shell access to your MySQL Server container, use the `docker exec -it` command to start a bash shell inside the container:

```
shell> docker exec -it mysql1 bash
bash-4.2#
```

You can then run Linux commands inside the container. For example, to view contents in the server’s data directory inside the container, use this command:

```
bash-4.2# ls /var/lib/mysql
auto.cnf    ca.pem      client-key.pem  ib_logfile0  ibdata1  mysql       mysql.sock.lock    private_key.pem  server-cert.pem  sys
ca-key.pem  client-cert.pem  ib_buffer_pool  ib_logfile1  ibtmp1   mysql.sock  performance_schema  public_key.pem   server-key.pem
```

Stopping and Deleting a MySQL Container

To stop the MySQL Server container we have created, use this command:

```
docker stop mysql1
```

docker stop sends a SIGTERM signal to the mysqld process, so that the server is shut down gracefully.

Also notice that when the main process of a container (mysqld in the case of a MySQL Server container) is stopped, the Docker container stops automatically.

To start the MySQL Server container again:

```
docker start mysql1
```

To stop and start again the MySQL Server container with a single command:

```
docker restart mysql1
```

To delete the MySQL container, stop it first, and then use the `docker rm` command:

```
docker stop mysql1
docker rm mysql1
```

If you want the Docker volume for the server’s data directory to be deleted at the same time, add the `-v` option to the `docker rm` command.

Upgrading a MySQL Server Container

**Important**

- Before performing any upgrade to MySQL, follow carefully the instructions in Section 2.11, “Upgrading MySQL”. Among other instructions discussed there, it is especially important to back up your database before the upgrade.

- The instructions in this section require that the server’s data and configuration have been persisted on the host. See Persisting Data and Configuration Changes for details.

Follow these steps to upgrade a Docker installation of MySQL 5.7 to 8.0:

- Stop the MySQL 5.7 server (container name is `mysql57` in this example):

```
docker stop mysql57
```

- Download the MySQL 8.0 Server Docker image. See instructions in Downloading a MySQL Server Docker Image; make sure you use the right tag for MySQL 8.0.

- Start a new MySQL 8.0 Docker container (named `mysql80` in this example) with the old server data and configuration (with proper modifications if needed—see Section 2.11, “Upgrading MySQL”) that
Deploying MySQL on Linux with Docker

have been persisted on the host (by bind-mounting in this example). For the MySQL Community Server, run this command:

```
docker run --name=mysql80 \
  --mount type=bind,src=/path-on-host-machine/my.cnf,dst=/etc/my.cnf \
  --mount type=bind,src=/path-on-host-machine/datadir,dst=/var/lib/mysql \
  -d mysql/mysql-server:8.0
```

If needed, adjust `mysql/mysql-server` to the correct repository name—for example, replace it with `mysql/enterprise-server` for MySQL Enterprise Edition images downloaded from My Oracle Support.

• Wait for the server to finish startup. You can check the status of the server using the `docker ps` command (see Starting a MySQL Server Instance for how to do that).

• For MySQL 8.0.15 and earlier: Run the `mysql_upgrade` utility in the MySQL 8.0 Server container (not required for MySQL 8.0.16 and later):

```
docker exec -it mysql80 mysql_upgrade -uroot -p
```

When prompted, enter the root password for your old MySQL 5.7 Server.

• Finish the upgrade by restarting the MySQL 8.0 Server container:

```
docker restart mysql80
```

More Topics on Deploying MySQL Server with Docker

For more topics on deploying MySQL Server with Docker like server configuration, persisting data and configuration, server error log, and container environment variables, see Section 2.5.6.2, “More Topics on Deploying MySQL Server with Docker”.

2.5.6.2 More Topics on Deploying MySQL Server with Docker

Note

Most of the sample commands below have `mysql/mysql-server` as the Docker image repository when that has to be specified (like with the `docker pull` and `docker run` commands); change that if your image is from another repository—for example, replace it with `mysql/enterprise-server` for MySQL Enterprise Edition images downloaded from My Oracle Support.

• The Optimized MySQL Installation for Docker
• Configuring the MySQL Server
• Persisting Data and Configuration Changes
• Running Additional Initialization Scripts
• Connect to MySQL from an Application in Another Docker Container
• Server Error Log
• Using MySQL Enterprise Backup with Docker
• Docker Environment Variables

The Optimized MySQL Installation for Docker

Docker images for MySQL are optimized for code size, which means they only include crucial components that are expected to be relevant for the majority of users who run MySQL instances in Docker containers. A MySQL Docker installation is different from a common, non-Docker installation in the following aspects:
• Included binaries are limited to:
  • /usr/bin/my_print_defaults
  • /usr/bin/mysql
  • /usr/bin/mysql_config
  • /usr/bin/mysql_install_db
  • /usr/bin/mysql_tzinfo_to_sql
  • /usr/bin/mysql_upgrade
  • /usr/bin/mysqladmin
  • /usr/bin/mysqlcheck
  • /usr/bin/mysqldump
  • /usr/bin/mysqlpump
  • /usr/bin/mysqlbackup (for MySQL Enterprise Edition 8.0 only)
  • /usr/sbin/mysqld
  • All binaries are stripped; they contain no debug information.

Configuring the MySQL Server

When you start the MySQL Docker container, you can pass configuration options to the server through the `docker run` command. For example:

```
docker run --name mysql1 -d mysql/mysql-server:tag --character-set-server=utf8mb4 --collation-server=utf8mb4_col
```

The command starts your MySQL Server with `utf8mb4` as the default character set and `utf8mb4_col` as the default collation for your databases.

Another way to configure the MySQL Server is to prepare a configuration file and mount it at the location of the server configuration file inside the container. See Persisting Data and Configuration Changes for details.

Persisting Data and Configuration Changes

Docker containers are in principle ephemeral, and any data or configuration are expected to be lost if the container is deleted or corrupted (see discussions here). Docker volumes, however, provides a mechanism to persist data created inside a Docker container. At its initialization, the MySQL Server container creates a Docker volume for the server data directory. The JSON output for running the `docker inspect` command on the container has a `Mount` key, whose value provides information on the data directory volume:

```
shell> docker inspect mysql1
...
"Mounts": [
  {
    "Type": "volume",
    "Name": "4f2d463cfc4bdd4baebcb098c97d7da3337195ed2c6572bc0b89f7e845d27652",
    "Source": "/var/lib/docker/volumes/4f2d463cfc4bdd4baebcb098c97d7da3337195ed2c6572bc0b89f7e845d27652/_data",
    "Destination": "/var/lib/mysql",
    "Driver": "local",
    "Mode": "",
    "RW": true,
    "Propagation": ""
  }
],
```
Deploying MySQL on Linux with Docker

The output shows that the source folder `/var/lib/docker/volumes/4f2d463cfc4bddd4baebcb098c97d7da3337195ed2c6572bc0b89f7e845d27652/_data`, in which data is persisted on the host, has been mounted at `/var/lib/mysql`, the server data directory inside the container.

Another way to preserve data is to bind-mount a host directory using the `--mount` option when creating the container. The same technique can be used to persist the configuration of the server. The following command creates a MySQL Server container and bind-mounts both the data directory and the server configuration file:

```bash
docker run --name=mysql1 --mount type=bind,src=/path-on-host-machine/my.cnf,dst=/etc/my.cnf --mount type=bind,src=/path-on-host-machine/datadir,dst=/var/lib/mysql -d mysql/mysql-server:tag
```

The command mounts `path-on-host-machine/my.cnf` at `/etc/my.cnf` (the server configuration file inside the container), and `path-on-host-machine/datadir` at `/var/lib/mysql` (the data directory inside the container). The following conditions must be met for the bind-mounting to work:

- The configuration file `path-on-host-machine/my.cnf` must already exist, and it must contain the specification for starting the server using the user `mysql`:

  ```
  [mysqld]
  user=mysql
  ```

  You can also include other server configuration options in the file.

- The data directory `path-on-host-machine/datadir` must already exist. For server initialization to happen, the directory must be empty. You can also mount a directory prepopulated with data and start the server with it; however, you must make sure you start the Docker container with the same configuration as the server that created the data, and any host files or directories required are mounted when starting the container.

Running Additional Initialization Scripts

If there are any `.sh` or `.sql` scripts you want to run on the database immediately after it has been created, you can put them into a host directory and then mount the directory at `/docker-entrypoint-initdb.d/` inside the container. For example:

```bash
docker run --name=mysql1 --mount type=bind,src=/path-on-host-machine/scripts/,dst=/docker-entrypoint-initdb.d/ --mount type=bind,src=/path-on-host-machine/my.cnf,dst=/etc/my.cnf 
```

Connect to MySQL from an Application in Another Docker Container

By setting up a Docker network, you can allow multiple Docker containers to communicate with each other, so that a client application in another Docker container can access the MySQL Server in the server container. First, create a Docker network:

```bash
docker network create my-custom-net
```

Then, when you are creating and starting the server and the client containers, use the `--network` option to put them on network you created. For example:

```bash
docker run --name=mysql1 --network=my-custom-net -d mysql/mysql-server
docker run --name=myapp1 --network=my-custom-net -d myapp
```

The `myapp1` container can then connect to the `mysql1` container with the `mysql1` hostname and vice versa, as Docker automatically sets up a DNS for the given container names. In the following example, we run the MySQL client from inside the `myapp1` container to connect to host `mysql1` in its own container:

```bash
docker exec -it myapp1 mysql --host=mysql1 --user=myuser --password
```
For other networking techniques for containers, see the Docker container networking section in the Docker Documentation.

Server Error Log

When the MySQL Server is first started with your server container, a server error log is NOT generated if either of the following conditions is true:

- A server configuration file from the host has been mounted, but the file does not contain the system variable `log_error` (see Persisting Data and Configuration Changes on bind-mounting a server configuration file).

- A server configuration file from the host has not been mounted, but the Docker environment variable `MYSQL_LOG_CONSOLE` is true (which is the variable's default state for MySQL 8.0 server containers). The MySQL Server's error log is then redirected to `stderr`, so that the error log goes into the Docker container's log and is viewable using the `docker logs mysqld-container` command.

To make MySQL Server generate an error log when either of the two conditions is true, use the `--log-error` option to configure the server to generate the error log at a specific location inside the container. To persist the error log, mount a host file at the location of the error log inside the container as explained in Persisting Data and Configuration Changes. However, you must make sure your MySQL Server inside its container has write access to the mounted host file.

Using MySQL Enterprise Backup with Docker

In the following example, we assume that you already have a MySQL Server running in a Docker container (see Section 2.5.6.1, “Basic Steps for MySQL Server Deployment with Docker” on how to start a MySQL Server instance with Docker). For MySQL Enterprise Backup to back up the MySQL Server, it must have access to the server's data directory. This can be achieved by, for example, bind-mounting a host directory on the data directory of the MySQL Server when you start the server:

```
docker run --name=mysqlserver \
  --mount type=bind,src=/path-on-host-machine/datadir/,dst=/var/lib/mysql \
  -d mysql/enterprise-server:8.0
```

With this command, the MySQL Server is started with a Docker image of the MySQL Enterprise Edition, and the host directory `/path-on-host-machine/datadir/` has been mounted onto the server's data directory (`/var/lib/mysql`) inside the server container. We also assume that, after the server has been started, the required privileges have also been set up for MySQL Enterprise Backup to access the server (see Grant MySQL Privileges to Backup Administrator for details). Use the following steps then to backup and restore a MySQL Server instance.

To backup a MySQL Server instance running in a Docker container using MySQL Enterprise Backup with Docker:

1. On the same host where the MySQL Server container is running, start another container with an image of MySQL Enterprise Edition to perform a back up with the MySQL Enterprise Backup command `backup-to-image`. Provide access to the server's data directory using the bind mount we created in the last step. Also, mount a host directory (`/path-on-host-machine/backups/` in this example) onto the storage folder for backups in the container (`/data/backups` in the example) to persist the backups we are creating. Here is a sample command for this step, in which MySQL Enterprise Backup is started with a Docker image downloaded from My Oracle Support):

```
shell> docker run \
  --mount type=bind,src=/path-on-host-machine/datadir/,dst=/var/lib/mysql \
  --mount type=bind,src=/path-on-host-machine/backups/,dst=/data/backups \
  --rm mysql/enterprise-server:8.0
```
Deploying MySQL on Linux with Docker

```bash
mysqlbackup --user=mysqlbackup --password mysqlbackup --backup-dir=/tmp/backup-tmp --with-timestamp --backup-image=/data/backups/db.mbi backup-to-image
```

[Entrypoint] MySQL Docker Image 8.0.11-1.1.5
MySQL Enterprise Backup version 8.0.11 Linux-4.1.12-61.1.16.el7uek.x86_64-x86_64 [2018-04-08 07:06:45]

180921 17:27:25 MAIN INFO: A thread created with Id '140594390935680'
180921 17:27:25 MAIN INFO: Starting with following command line ...
...

Parameters Summary

<table>
<thead>
<tr>
<th>Start LSN</th>
<th>29615616</th>
</tr>
</thead>
<tbody>
<tr>
<td>End LSN</td>
<td>29651854</td>
</tr>
</tbody>
</table>

mysqlbackup completed OK!

It is important to check the end of the output by `mysqlbackup` to make sure the backup has been completed successfully.

2. The container exits once the backup job is finished and, with the `--rm` option used to start it, it is removed after it exits. An image backup has been created, and can be found in the host directory mounted in the last step for storing backups:

```bash
shell> ls /tmp/backups
db.mbi
```

To restore a MySQL Server instance in a Docker container using MySQL Enterprise Backup with Docker:

1. Stop the MySQL Server container, which also stops the MySQL Server running inside:

```bash
docker stop mysqlserver
```

2. On the host, delete all contents in the bind mount for the MySQL Server data directory:

```bash
rm -rf /path-on-host-machine/datadir/*
```

3. Start a container with an image of MySQL Enterprise Edition to perform the restore with the MySQL Enterprise Backup command `copy-back-and-apply-log`. Bind-mount the server's data directory and the storage folder for the backups, like what we did when we backed up the server:

```bash
shell> docker run \
--mount type=bind,src=/path-on-host-machine/datadir/,dst=/var/lib/mysql \
--mount type=bind,src=/path-on-host-machine/backups/,dst=/data/backups \
--rm mysql/enterprise-server:8.0 \
mysqlbackup --backup-dir=/tmp/backup-tmp --with-timestamp \
--datadir=/var/lib/mysql --backup-image=/data/backups/db.mbi copy-back-and-apply-log
```

[Entrypoint] MySQL Docker Image 8.0.11-1.1.5

and the new created log files are at '/var/lib/mysql'
180921 22:06:52 MAIN INFO: No Keyring file to process.
180921 22:06:52 MAIN INFO: Apply-log operation completed successfully.
180921 22:06:52 MAIN INFO: Full Backup has been restored successfully.

mysqlbackup completed OK! with 3 warnings
The container exits once the backup job is finished and, with the `--rm` option used when starting it, it is removed after it exits.

4. Restart the server container, which also restarts the restored server:

```bash
docker restart mysqlserver
```

Or, start a new MySQL Server on the restored data directory:

```bash
docker run --name=mysqlserver2 \
--mount type=bind,src=/path-on-host-machine/datadir/,dst=/var/lib/mysql \
-d mysql/enterprise-server:8.0
```

Log on to the server to check that the server is running with the restored data.

### Docker Environment Variables

When you create a MySQL Server container, you can configure the MySQL instance by using the `--env` option (`` in short) and specifying one or more of the following environment variables.

<table>
<thead>
<tr>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>- None of the variables below has any effect if the data directory you mount is not empty, as no server initialization is going to be attempted then (see Persisting Data and Configuration Changes for more details). Any pre-existing contents in the folder, including any old server settings, are not modified during the container startup.</td>
</tr>
<tr>
<td>- The boolean variables including <code>MYSQL_RANDOM_ROOT_PASSWORD</code>, <code>MYSQL_ONETIME_PASSWORD</code>, <code>MYSQL_ALLOW_EMPTY_PASSWORD</code>, and <code>MYSQL_LOG_CONSOLE</code> are made true by setting them with any strings of nonzero lengths. Therefore, setting them to, for example, “0”, “false”, or “no” does not make them false, but actually makes them true. This is a known issue of the MySQL Server containers.</td>
</tr>
<tr>
<td>- <code>MYSQL_RANDOM_ROOT_PASSWORD</code>: When this variable is true (which is its default state, unless <code>MYSQL_ROOT_PASSWORD</code> is set or <code>MYSQL_ALLOW_EMPTY_PASSWORD</code> is set to true), a random password for the server's root user is generated when the Docker container is started. The password is printed to stdout of the container and can be found by looking at the container's log (see Starting a MySQL Server Instance).</td>
</tr>
<tr>
<td>- <code>MYSQL_ONETIME_PASSWORD</code>: When the variable is true (which is its default state, unless <code>MYSQL_ROOT_PASSWORD</code> is set or <code>MYSQL_ALLOW_EMPTY_PASSWORD</code> is set to true), the root user's password is set as expired and must be changed before MySQL can be used normally.</td>
</tr>
<tr>
<td>- <code>MYSQL_DATABASE</code>: This variable allows you to specify the name of a database to be created on image startup. If a user name and a password are supplied with <code>MYSQL_USER</code> and <code>MYSQL_PASSWORD</code>, the user is created and granted superuser access to this database (corresponding to <code>GRANT ALL</code>). The specified database is created by a <code>CREATE DATABASE IF NOT EXIST</code> statement, so that the variable has no effect if the database already exists.</td>
</tr>
<tr>
<td>- <code>MYSQL_USER, MYSQL_PASSWORD</code>: These variables are used in conjunction to create a user and set that user's password, and the user is granted superuser permissions for the database specified by the <code>MYSQL_DATABASE</code> variable. Both <code>MYSQL_USER</code> and <code>MYSQL_PASSWORD</code> are required for a user to be created—if any of the two variables is not set, the other is ignored. If both variables are set but <code>MYSQL_DATABASE</code> is not, the user is created without any privileges.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>There is no need to use this mechanism to create the root superuser, which is created by default with the password set by</td>
</tr>
</tbody>
</table>
Deploying MySQL on Linux with Docker

either one of the mechanisms discussed in the descriptions for
MYSQL_ROOT_PASSWORD and MYSQL_RANDOM_ROOT_PASSWORD, unless
MYSQL_ALLOW_EMPTY_PASSWORD is true.

• MYSQL_ROOT_HOST: By default, MySQL creates the 'root'@'localhost' account. This account can only be connected to from inside the container as described in Connecting to MySQL Server from within the Container, To allow root connections from other hosts. set this environment variable. For example, the value 172.17.0.1, which is the default Docker gateway IP, allows connections from the host machine that runs the container. The option accepts only one entry, but wildcards are allowed (for example, MYSQL_ROOT_HOST=172.*.*.* or MYSQL_ROOT_HOST=%).

• MYSQL_LOG_CONSOLE: When the variable is true (which is its default state for MySQL 8.0 server containers), the MySQL Server's error log is redirected to stderr, so that the error log goes into the Docker container's log and is viewable using the docker logs myqld-container command.

> Note

The variable has no effect if a server configuration file from the host has been mounted (see Persisting Data and Configuration Changes on bind-mounting a configuration file).

> Warning

Setting the MySQL root user password on the command line is insecure. As an alternative to specifying the password explicitly, you can set the variable with a container file path for a password file, and then mount a file from your host that contains the password at the container file path. This is still not very secure, as the location of the password file is still exposed. It is preferable to use the default settings of MYSQL_RANDOM_ROOT_PASSWORD and MYSQL_ONETIME_PASSWORD both being true.

• MYSQL_ALLOW_EMPTY_PASSWORD. Set it to true to allow the container to be started with a blank password for the root user.

> Warning

Setting this variable to true is insecure, because it is going to leave your MySQL instance completely unprotected, allowing anyone to gain complete superuser access. It is preferable to use the default settings of MYSQL_RANDOM_ROOT_PASSWORD and MYSQL_ONETIME_PASSWORD both being true.

2.5.6.3 Deploying MySQL on Windows and Other Non-Linux Platforms with Docker

> Warning

The MySQL Docker images provided by Oracle are built specifically for Linux platforms. Other platforms are not supported, and users running the MySQL Docker images from Oracle on them are doing so at their own risk. This section discusses some known issues for the images when used on non-Linux platforms.

Known Issues for using the MySQL Server Docker images from Oracle on Windows include:

• If you are bind-mounting on the container's MySQL data directory (see Persisting Data and Configuration Changes for details), you have to set the location of the server socket file with the --socket option to somewhere outside of the MySQL data directory; otherwise, the server will fail to start. This is because the way Docker for Windows handles file mounting does not allow a host file from being bind-mounted on the socket file.
2.5.7 Installing MySQL on Linux from the Native Software Repositories

Many Linux distributions include a version of the MySQL server, client tools, and development components in their native software repositories and can be installed with the platforms' standard package management systems. This section provides basic instructions for installing MySQL using those package management systems.

Important

Native packages are often several versions behind the currently available release. You will also normally be unable to install development milestone releases (DMRs), as these are not usually made available in the native repositories. Before proceeding, we recommend that you check out the other installation options described in Section 2.5, “Installing MySQL on Linux”.

Distribution specific instructions are shown below:

- Red Hat Linux, Fedora, CentOS

Note

For a number of Linux distributions, you can install MySQL using the MySQL Yum repository instead of the platform's native software repository. See Section 2.5.1, “Installing MySQL on Linux Using the MySQL Yum Repository” for details.

For Red Hat and similar distributions, the MySQL distribution is divided into a number of separate packages, `mysql` for the client tools, `mysql-server` for the server and associated tools, and `mysql-libs` for the libraries. The libraries are required if you want to provide connectivity from different languages and environments such as Perl, Python and others.

To install, use the `yum` command to specify the packages that you want to install. For example:

```
root-shell> yum install mysql mysql-server mysql-libs
Loaded plugins: presto, refresh-packagekit

Complete!

MySQL and the MySQL server should now be installed. A sample configuration file is installed into /etc/my.cnf. An init script, to start and stop the server, will have been installed into /etc/init.d/mysqld. To start the MySQL server use service:

root-shell> service mysqld start

To enable the server to be started and stopped automatically during boot, use chkconfig:

root-shell> chkconfig --levels 235 mysqld on

Which enables the MySQL server to be started (and stopped) automatically at the specified the run levels.

The database tables will have been automatically created for you, if they do not already exist. You should, however, run mysql_secure_installation to set the root passwords on your server.

• Debian, Ubuntu, Kubuntu

Note
For supported Debian and Ubuntu versions, MySQL can be installed using the MySQL APT Repository instead of the platform’s native software repository. See Section 2.5.2, “Installing MySQL on Linux Using the MySQL APT Repository” for details.

On Debian and related distributions, there are two packages for MySQL in their software repositories, mysql-client and mysql-server, for the client and server components respectively. You should specify an explicit version, for example mysql-client-5.1, to ensure that you install the version of MySQL that you want.

To download and install, including any dependencies, use the apt-get command, specifying the packages that you want to install.
Installing MySQL on Linux from the Native Software Repositories

**Note**

Before installing, make sure that you update your `apt-get` index files to ensure you are downloading the latest available version.

A sample installation of the MySQL packages might look like this (some sections trimmed for clarity):

```
root-shell> apt-get install mysql-client-5.1 mysql-server-5.1
Reading package lists... Done
Building dependency tree
Reading state information... Done
The following packages were automatically installed and are no longer required:
  linux-headers-2.6.28-11 linux-headers-2.6.28-11-generic
Use 'apt-get autoremove' to remove them.
The following extra packages will be installed:
  bsd-mailx libdbd-mysql-perl libdbi-perl libhtml-template-perl
  libmysqlclient15off libmysqlclient16 libnet-daemon-perl libplrpc-perl mailx
  mysql-common postfix
Suggested packages:
  dbishell libdbpc-shardedcache-perl tinyca procmail postfix-mysql postfix-pgsql
  postfix-ldap postfix-pcre ss12-bin resolvconf postfix-cdb
The following NEW packages will be installed
  bsd-mailx libdbd-mysql-perl libdbi-perl libhtml-template-perl
  libmysqlclient15off libmysqlclient16 libnet-daemon-perl libplrpc-perl mailx
  mysql-client-5.1 mysql-common mysql-server-5.1 postfix

```

**Note**

The `apt-get` command will install a number of packages, including the MySQL server, in order to provide the typical tools and application environment. This can mean that you install a large number of packages in addition to the main MySQL package.
During installation, the initial database will be created, and you will be prompted for the MySQL root password (and confirmation). A configuration file will have been created in `/etc/mysql/my.cnf`. An init script will have been created in `/etc/init.d/mysql`.

The server will already be started. You can manually start and stop the server using:

```
root-shell> service mysql [start|stop]
```

The service will automatically be added to the 2, 3 and 4 run levels, with stop scripts in the single, shutdown and restart levels.

### 2.5.8 Installing MySQL on Linux with Juju

The Juju deployment framework supports easy installation and configuration of MySQL servers. For instructions, see [https://jujucharms.com/mysql/](https://jujucharms.com/mysql/).

### 2.5.9 Managing MySQL Server with systemd

If you install MySQL using an RPM or Debian package on the following Linux platforms, server startup and shutdown is managed by systemd:

- **RPM package platforms:**
  - Red Hat Enterprise Linux 7; Oracle Linux 7; CentOS 7
  - SUSE Linux Enterprise Server 12
  - Fedora 29 and 30
- **Debian package platforms:**
  - Debian 8 or higher
  - Ubuntu 16 or higher

If you install MySQL from a generic binary distribution on a platform that uses systemd, you can manually configure systemd support for MySQL following the instructions provided in the post-installation setup section of the MySQL 8.0 Secure Deployment Guide.

If you install MySQL from a source distribution on a platform that uses systemd, obtain systemd support for MySQL by configuring the distribution using the `-DWITH_SYSTEMD=1 CMake` option. See Section 2.9.4, “MySQL Source-Configuration Options”.

The following discussion covers these topics:

- **Overview of systemd**
- **Configuring systemd for MySQL**
- **Configuring Multiple MySQL Instances Using systemd**
- **Migrating from mysqld_safe to systemd**

**Note**

On platforms for which systemd support for MySQL is installed, scripts such as `mysqld_safe` and the System V initialization script are unnecessary and are not installed. For example, `mysqld_safe` can handle server restarts, but systemd provides the same capability, and does so in a manner consistent with management of other services rather than by using an application-specific program.
Because systemd has the capability of managing multiple MySQL instances on platforms for which systemd support for MySQL is installed, `mysqld_multi` and `mysqld_multi.server` are unnecessary and are not installed.

### Overview of systemd

systemd provides automatic MySQL server startup and shutdown. It also enables manual server management using the `systemctl` command. For example:

```bash
systemctl {start|stop|restart|status} mysqld
```

Alternatively, use the `service` command (with the arguments reversed), which is compatible with System V systems:

```bash
service mysqld {start|stop|restart|status}
```

**Note**

For the `systemctl` or `service` commands, if the MySQL service name is not `mysqld`, use the appropriate name. For example, use `mysql` rather than `mysqld` on Debian-based and SLES systems.

Support for systemd includes these files:

- `mysqld.service` (RPM platforms), `mysql.service` (Debian platforms): systemd service unit configuration file, with details about the MySQL service.
- `mysqld@.service` (RPM platforms), `mysql@.service` (Debian platforms): Like `mysqld.service` or `mysql.service`, but used for managing multiple MySQL instances.
- `mysqld.tmpfiles.d`: File containing information to support the `tmpfiles` feature. This file is installed under the name `mysql.conf`.
- `mysqld_pre_systemd` (RPM platforms), `mysql-system-start` (Debian platforms): Support script for the unit file. This script assists in creating the error log file only if the log location matches a pattern (`/var/log/mysql*.log` for RPM platforms, `/var/log/mysql/*.log` for Debian platforms). In other cases, the error log directory must be writable or the error log must be present and writable for the user running the `mysqld` process.

### Configuring systemd for MySQL

To add or change systemd options for MySQL, these methods are available:

- Use a localized systemd configuration file.
- Arrange for systemd to set environment variables for the MySQL server process.
- Set the `MYSQLD_OPTS` systemd variable.

To use a localized systemd configuration file, create the `/etc/systemd/system/mysqld.service.d` directory if it does not exist. In that directory, create a file that contains a `[Service]` section listing the desired settings. For example:

```ini
[Service]
LimitNOFILE=max_open_files
PIDfile=/path/to/pid/file
Nice=nicelvel
LimitCore=core_file_limit
Environment="LD_PRELOAD=/path/to/malloc/library"
Environment="TZ=time_zone_setting"
```
The discussion here uses `override.conf` as the name of this file. Newer versions of systemd support the following command, which opens an editor and permits you to edit the file:

```
systemctl edit mysqld  # RPM platforms
systemctl edit mysql   # Debian platforms
```

Whenever you create or change `override.conf`, reload the systemd configuration, then tell systemd to restart the MySQL service:

```
systemctl daemon-reload
systemctl restart mysqld  # RPM platforms
systemctl restart mysql   # Debian platforms
```

With systemd, the `override.conf` configuration method must be used for certain parameters, rather than settings in a `[mysqld]` or `[mysqld_safe]` group in a MySQL option file:

- For some parameters, `override.conf` must be used because systemd itself must know their values and it cannot read MySQL option files to get them.
- Parameters that specify values otherwise settable only using options known to `mysqld_safe` must be specified using systemd because there is no corresponding `mysqld` parameter.

For additional information about using systemd rather than `mysqld_safe`, see Migrating from `mysqld_safe` to systemd.

You can set the following parameters in `override.conf`:

- To specify the process ID file, use `override.conf` and change both `PIDFile` and `ExecStart` to name the PID file path name. Any setting of the process ID file in MySQL option files is ignored. To modify `ExecStart`, it must first be cleared. For example:

  ```ini
  [Service]
  PIDFile=/var/run/mysqld/mysqld-custom.pid
  ExecStart=/usr/sbin/mysqld --pid-file=/var/run/mysqld/mysqld-custom.pid $MYSQLD_OPTS
  ```

- To set the number of file descriptors available to the MySQL server, use `LimitNOFILE` in `override.conf` rather than the `open_files_limit` system variable for `mysqld` or `--open-files-limit` option for `mysqld_safe`.

- To set the maximum core file size, use `LimitCore` in `override.conf` rather than the `--core-file-size` option for `mysqld_safe`.

- To set the scheduling priority for the MySQL server, use `Nice` in `override.conf` rather than the `--nice` option for `mysqld_safe`.

Some MySQL parameters are configured using environment variables:

- `LD_PRELOAD`: Set this variable if the MySQL server should use a specific memory-allocation library.
- `NOTIFY_SOCKET`: This environment variable specifies the socket that `mysqld` uses to communicate notification of startup completion and service status change with systemd. It is set by systemd when the `mysqld` service is started. The `mysqld` service reads the variable setting and writes to the defined location. If the variable is not set, `mysqld` writes nothing.
- `TZ`: Set this variable to specify the default time zone for the server.

There are multiple ways to specify environment variable values for use by the MySQL server process managed by systemd:

- Use `Environment` lines in the `override.conf` file. For the syntax, see the example in the preceding discussion that describes how to use this file.
Managing MySQL Server with systemd

• Specify the values in the `/etc/sysconfig/mysql` file (create the file if it does not exist). Assign values using the following syntax:

```bash
LD_PRELOAD=/path/to/malloc/library
TZ=time_zone_setting
```

After modifying `/etc/sysconfig/mysql`, restart the server to make the changes effective:

```bash
systemctl restart mysqld  # RPM platforms
systemctl restart mysql   # Debian platforms
```

To specify options for `mysqld` without modifying systemd configuration files directly, set or unset the `MYSQLD_OPTS` systemd variable. For example:

```bash
systemctl set-environment MYSQLD_OPTS="--general_log=1"
systemctl unset-environment MYSQLD_OPTS
```

MySQLD_OPTS can also be set in the `/etc/sysconfig/mysql` file.

After modifying the systemd environment, restart the server to make the changes effective:

```bash
systemctl restart mysqld  # RPM platforms
systemctl restart mysql   # Debian platforms
```

For platforms that use systemd, the data directory is initialized if empty at server startup. This might be a problem if the data directory is a remote mount that has temporarily disappeared: The mount point would appear to be an empty data directory, which then would be initialized as a new data directory.

To suppress this automatic initialization behavior, specify the following line in the `/etc/sysconfig/mysql` file (create the file if it does not exist):

```bash
NO_INIT=true
```

Configuring Multiple MySQL Instances Using systemd

This section describes how to configure systemd for multiple instances of MySQL.

**Note**

Because systemd has the capability of managing multiple MySQL instances on platforms for which systemd support is installed, `mysqld_multi` and `mysqld_multi.server` are unnecessary and are not installed.

To use multiple-instance capability, modify the `my.cnf` option file to include configuration of key options for each instance. These file locations are typical:

• `/etc/my.cnf` or `/etc/mysql/my.cnf` (RPM platforms)

• `/etc/mysql/mysql.conf.d/mysqld.cnf` (Debian platforms)

For example, to manage two instances named `replica01` and `replica02`, add something like this to the option file:

**RPM platforms:**

```ini
[mysqld@replica01]
datadir=/var/lib/mysql-replica01
socket=/var/lib/mysql-replica01/mysql.sock
port=3307
log-error=/var/log/mysqld-replica01.log
```
Managing MySQL Server with systemd

Debian platforms:

```
[mysqld@replica02]
datadir=/var/lib/mysql-replica02
socket=/var/lib/mysql-replica02/mysql.sock
port=3308
log-error=/var/log/mysqld-replica02.log

[mysqld@replica01]
datadir=/var/lib/mysql-replica01
socket=/var/lib/mysql-replica01/mysql.sock
port=3307
log-error=/var/log/mysql/replica01.log

[mysqld@replica02]
datadir=/var/lib/mysql-replica02
socket=/var/lib/mysql-replica02/mysql.sock
port=3308
log-error=/var/log/mysql/replica02.log
```

The replica names shown here use `@` as the delimiter because that is the only delimiter supported by systemd.

Instances then are managed by normal systemd commands, such as:

```
systemctl start mysqld@replica01
systemctl start mysqld@replica02
```

To enable instances to run at boot time, do this:

```
systemctl enable mysqld@replica01
systemctl enable mysqld@replica02
```

Use of wildcards is also supported. For example, this command displays the status of all replica instances:

```
systemctl status 'mysqld@replica*'
```

For management of multiple MySQL instances on the same machine, systemd automatically uses a different unit file:

- `mysqld@.service` rather than `mysqld.service` (RPM platforms)
- `mysqld@.service` rather than `mysql.service` (Debian platforms)

In the unit file, `%I` and `%i` reference the parameter passed in after the `@` marker and are used to manage the specific instance. For a command such as this:

```
systemctl start mysqld@replica01
```

systemd starts the server using a command such as this:

```
mysqld --defaults-group-suffix=@%I ...
```

The result is that the `[server]`, `[mysqld]`, and `[mysqld@replica01]` option groups are read and used for that instance of the service.

**Note**

On Debian platforms, AppArmor prevents the server from reading or writing `/var/lib/mysql-replica*`, or anything other than the default locations. To address this, you must customize or disable the profile in `/etc/apparmor.d/usr.sbin.mysqld`.

```
On Debian platforms, the packaging scripts for MySQL uninstallation cannot currently handle `mysqld` instances. Before removing or upgrading the package, you must stop any extra instances manually first.

### Migrating from `mysqld_safe` to systemd

Because `mysqld_safe` is not installed on platforms that use systemd to manage MySQL, options previously specified for that program (for example, in an `[mysqld_safe]` option group) must be specified another way:

- Some `mysqld_safe` options are also understood by `mysqld` and can be moved from the `[mysqld_safe]` option group to the `[mysqld]` group. This does not include `--pid-file`, `--open-files-limit`, or `--nice`. To specify those options, use the `override.conf` systemd file, described previously.

- For some `mysqld_safe` options, there are alternative `mysqld` procedures. For example, the `mysqld_safe` option for enabling syslog logging is `--syslog`, which is deprecated. To write error log output to the system log, use the instructions at Section 5.4.2.7, "Error Logging to the System Log".

- `mysqld_safe` options not understood by `mysqld` can be specified in `override.conf` or environment variables. For example, with `mysqld_safe`, if the server should use a specific memory allocation library, this is specified using the `--malloc-lib` option. For installations that manage the server with systemd, arrange to set the `LD_PRELOAD` environment variable instead, as described previously.

#### 2.6 Installing MySQL Using Unbreakable Linux Network (ULN)

Linux supports a number of different solutions for installing MySQL, covered in Section 2.5, "Installing MySQL on Linux". One of the methods, covered in this section, is installing from Oracle's Unbreakable Linux Network (ULN). You can find information about Oracle Linux and ULN under [http://linux.oracle.com](http://linux.oracle.com).

To use ULN, you need to obtain a ULN login and register the machine used for installation with ULN. This is described in detail in the ULN FAQ. The page also describes how to install and update packages. The MySQL packages are in the "MySQL for Oracle Linux 6" and "MySQL for Oracle Linux 7" channels for your system architecture on ULN.

At the time of this writing, ULN provides MySQL 8.0 for Oracle Linux 6 and Oracle Linux 7.

Once MySQL has been installed using ULN, you can find information on starting and stopping the server, and more, in this section, particularly under Section 2.5.4, "Installing MySQL on Linux Using RPM Packages from Oracle".

If you're updating an existing MySQL installation to an installation using ULN, the recommended procedure is to export your data using `mysqldump`, remove the existing installation, install MySQL from ULN, and load the exported data into your freshly installed MySQL.

If the existing MySQL installation you're upgrading from is from a previous release series (prior to MySQL 8.0), make sure to read the section on upgrading MySQL, Section 2.11, "Upgrading MySQL".

#### 2.7 Installing MySQL on Solaris

MySQL 8.0 supports Solaris 11.4 and higher
MySQL on Solaris is available in a number of different formats.

- For information on installing using the native Solaris PKG format, see Section 2.7.1, “Installing MySQL on Solaris Using a Solaris PKG”.

- To use a standard `tar` binary installation, use the notes provided in Section 2.2, “Installing MySQL on Unix/Linux Using Generic Binaries”. Check the notes and hints at the end of this section for Solaris specific notes that you may need before or after installation.

**Important**

The installation packages have a dependency on the Oracle Developer Studio 12.6 Runtime Libraries, which must be installed before you run the MySQL installation package. See the download options for Oracle Developer Studio here. The installation package enables you to install the runtime libraries only instead of the full Oracle Developer Studio; see instructions in Installing Only the Runtime Libraries on Oracle Solaris 11.

To obtain a binary MySQL distribution for Solaris in tarball or PKG format, [https://dev.mysql.com/downloads/mysql/8.0.html](https://dev.mysql.com/downloads/mysql/8.0.html).

Additional notes to be aware of when installing and using MySQL on Solaris:

- If you want to use MySQL with the `mysql` user and group, use the `groupadd` and `useradd` commands:

  ```
groupadd mysql
useradd -g mysql -s /bin/false mysql
  ```

- If you install MySQL using a binary tarball distribution on Solaris, because the Solaris `tar` cannot handle long file names, use GNU `tar (gtar)` to unpack the distribution. If you do not have GNU `tar` on your system, install it with the following command:

  ```
pkg install archiver/gnu-tar
  ```

- You should mount any file systems on which you intend to store InnoDB files with the `forcedirectio` option. (By default mounting is done without this option.) Failing to do so will cause a significant drop in performance when using the InnoDB storage engine on this platform.

- If you would like MySQL to start automatically, you can copy `support-files/mysql.server` to `/etc/init.d` and create a symbolic link to it named `/etc/rc3.d/S99mysql.server`.

- If too many processes try to connect very rapidly to `mysqld`, you should see this error in the MySQL log:

  ```
Error in accept: Protocol error
  ```

  You might try starting the server with the `--back_log=50` option as a workaround for this.

- To configure the generation of core files on Solaris you should use the `coreadm` command. Because of the security implications of generating a core on a `setuid()` application, by default, Solaris does not support core files on `setuid()` programs. However, you can modify this behavior using `coreadm`. If you enable `setuid()` core files for the current user, they will be generated using the mode 600 and owned by the superuser.

### 2.7.1 Installing MySQL on Solaris Using a Solaris PKG

You can install MySQL on Solaris using a binary package of the native Solaris PKG format instead of the binary tarball distribution.
Installing MySQL on FreeBSD

181

Important

The installation package has a dependency on the Oracle Developer Studio 12.6 Runtime Libraries, which must be installed before you run the MySQL installation package. See the download options for Oracle Developer Studio here. The installation package enables you to install the runtime libraries only instead of the full Oracle Developer Studio; see instructions in Installing Only the Runtime Libraries on Oracle Solaris 11.

To use this package, download the corresponding `mysql-VERSION-solaris11-PLATFORM.pkg.gz` file, then uncompress it. For example:

```shell
gunzip mysql-8.0.18-solaris11-x86_64.pkg.gz
```

To install a new package, use `pkgadd` and follow the onscreen prompts. You must have root privileges to perform this operation:

```shell
pkgadd -d mysql-8.0.18-solaris11-x86_64.pkg
```

The following packages are available:

```
1  mysql     MySQL Community Server (GPL) (i86pc) 8.0.18
```

Select package(s) you wish to process (or 'all' to process all packages). (default: all) [?,,q]:

The PKG installer installs all of the files and tools needed, and then initializes your database if one does not exist. To complete the installation, you should set the root password for MySQL as provided in the instructions at the end of the installation. Alternatively, you can run the `mysql_secure_installation` script that comes with the installation.

By default, the PKG package installs MySQL under the root path `/opt/mysql`. You can change only the installation root path when using `pkgadd`, which can be used to install MySQL in a different Solaris zone. If you need to install in a specific directory, use a binary tar file distribution.

The `pkg` installer copies a suitable startup script for MySQL into `/etc/init.d/mysql`. To enable MySQL to startup and shutdown automatically, you should create a link between this file and the init script directories. For example, to ensure safe startup and shutdown of MySQL you could use the following commands to add the right links:

```shell
ln /etc/init.d/mysql /etc/rc3.d/S91mysql
ln /etc/init.d/mysql /etc/rc0.d/K02mysql
```

To remove MySQL, the installed package name is `mysql`. You can use this in combination with the `pkgrm` command to remove the installation.

To upgrade when using the Solaris package file format, you must remove the existing installation before installing the updated package. Removal of the package does not delete the existing database information, only the server, binaries and support files. The typical upgrade sequence is therefore:

```shell
mysqld_safe & # prior to MySQL 8.0.16 only
```

You should check the notes in Section 2.11, “Upgrading MySQL” before performing any upgrade.

### 2.8 Installing MySQL on FreeBSD

This section provides information about installing MySQL on variants of FreeBSD Unix.
You can install MySQL on FreeBSD by using the binary distribution provided by Oracle. For more information, see Section 2.2, “Installing MySQL on Unix/Linux Using Generic Binaries”.

The easiest (and preferred) way to install MySQL is to use the mysql-server and mysql-client ports available at http://www.freebsd.org/. Using these ports gives you the following benefits:

- A working MySQL with all optimizations enabled that are known to work on your version of FreeBSD.
- Automatic configuration and build.
- Startup scripts installed in /usr/local/etc/rc.d.
- The ability to use pkg_info -L to see which files are installed.
- The ability to use pkg_delete to remove MySQL if you no longer want it on your machine.

The MySQL build process requires GNU make (gmake) to work. If GNU make is not available, you must install it first before compiling MySQL.

![Note]

Prerequisite libraries as per ldd mysqld: libthrd, libcrypt, libm, librt, libexecinfo, libunwind, and libssl.

To install using the ports system:

```
# cd /usr/ports/databases/mysql80-server
# make
...
# cd /usr/ports/databases/mysql80-client
# make
...
```

The standard port installation places the server into /usr/local/libexec/mysqld, with the startup script for the MySQL server placed in /usr/local/etc/rc.d/mysql-server.

Some additional notes on the BSD implementation:

- To remove MySQL after installation using the ports system:

```
# cd /usr/ports/databases/mysql80-server
# make deinstall
...
# cd /usr/ports/databases/mysql80-client
# make deinstall
...
```

- If you get problems with the current date in MySQL, setting the TZ variable should help. See Section 4.9, “MySQL Environment Variables”.

### 2.9 Installing MySQL from Source

Building MySQL from the source code enables you to customize build parameters, compiler optimizations, and installation location. For a list of systems on which MySQL is known to run, see https://www.mysql.com/support/supportedplatforms/database.html.

Before you proceed with an installation from source, check whether Oracle produces a precompiled binary distribution for your platform and whether it works for you. We put a great deal of effort into ensuring that our binaries are built with the best possible options for optimal performance. Instructions for installing binary distributions are available in Section 2.2, “Installing MySQL on Unix/Linux Using Generic Binaries”.
Warning
Building MySQL with nonstandard options may lead to reduced functionality, performance, or security.

The MySQL source code contains internal documentation written using Doxygen. The generated Doxygen content is available at https://dev.mysql.com/doc/index-other.html. It is also possible to generate this content locally from a MySQL source distribution using the instructions at Section 2.9.7, "Generating MySQL Doxygen Documentation Content".

Source Installation Methods

There are two methods for installing MySQL from source:

- Use a standard MySQL source distribution. To obtain a standard distribution, see Section 2.1.2, "How to Get MySQL". For instructions on building from a standard distribution, see Section 2.9.2, "Installing MySQL Using a Standard Source Distribution".
  Standard distributions are available as compressed tar files, Zip archives, or RPM packages. Distribution files have names of the form mysql-VERSION.tar.gz, mysql-VERSION.zip, or mysql-VERSION.rpm, where VERSION is a number like 8.0.18. File names for source distributions can be distinguished from those for precompiled binary distributions in that source distribution names are generic and include no platform name, whereas binary distribution names include a platform name indicating the type of system for which the distribution is intended (for example, pc-linux-i686 or winx64).

- Use a MySQL development tree. For information on building from one of the development trees, see Section 2.9.3, "Installing MySQL Using a Development Source Tree".

Source Installation System Requirements

Installation of MySQL from source requires several development tools. Some of these tools are needed no matter whether you use a standard source distribution or a development source tree. Other tool requirements depend on which installation method you use.

To install MySQL from source, the following system requirements must be satisfied, regardless of installation method:

- CMake, which is used as the build framework on all platforms. CMake can be downloaded from http://www.cmake.org.

- A good make program. Although some platforms come with their own make implementations, it is highly recommended that you use GNU make 3.75 or higher. It may already be available on your system as gmake. GNU make is available from http://www.gnu.org/software/make/.

- MySQL 8.0 source code permits use of C++14 features. To enable a good level of C++14 support across all supported platforms, the following minimum compiler versions apply:
  - GCC 5.3 (Linux)
  - Clang 4.0 (FreeBSD)
  - XCode 9 (MacOS)
  - Developer Studio 12.6 (Solaris)
  - Visual Studio 2017 (Windows)

- The MySQL C API requires a C++ or C99 compiler to compile.

- The Boost C++ libraries are required to build MySQL (but not to use it). MySQL compilation requires a particular Boost version. Typically, that is the current Boost version, but if a specific MySQL source
distribution requires a different version, the configuration process will stop with a message indicating
the Boost version that it requires. To obtain Boost and its installation instructions, visit the official
site. After Boost is installed, tell the build system where the Boost files are located by defining the
\texttt{WITH\_BOOST} option when you invoke \texttt{CMake}. For example:

\begin{verbatim}
cmake \ -DWITH\_BOOST=/usr/local/boost\_version\_number
\end{verbatim}

Adjust the path as necessary to match your installation.

\begin{itemize}
\item The \texttt{ncurses} library.
\item Sufficient free memory. If you encounter problems such as “internal compiler error” when compiling
large source files, it may be that you have too little memory. If compiling on a virtual machine, try
increasing the memory allocation.
\item Perl is needed if you intend to run test scripts. Most Unix-like systems include Perl. On Windows, you
can use a version such as ActiveState Perl.
\end{itemize}

To install MySQL from a standard source distribution, one of the following tools is required to unpack
the distribution file:

\begin{itemize}
\item For a \texttt{.tar.gz} compressed \texttt{tar} file: GNU \texttt{gunzip} to uncompress the distribution and a reasonable
\texttt{tar} to unpack it. If your \texttt{tar} program supports the \texttt{z} option, it can both uncompress and unpack the
file.

GNU \texttt{tar} is known to work. The standard \texttt{tar} provided with some operating systems is not able to
unpack the long file names in the MySQL distribution. You should download and install GNU \texttt{tar}, or
if available, use a preinstalled version of GNU tar. Usually this is available as \texttt{gnutar}, \texttt{gtar}, or as
\texttt{tar} within a GNU or Free Software directory, such as \texttt{/usr/sfw/bin} or \texttt{/usr/local/bin}. GNU
\texttt{tar} is available from http://www.gnu.org/software/tar/.

\item For a \texttt{.zip} Zip archive: WinZip or another tool that can read \texttt{.zip} files.

\item For an \texttt{.rpm} RPM package: The \texttt{rpmbuild} program used to build the distribution unpacks it.
\end{itemize}

To install MySQL from a development source tree, the following additional tools are required:

\begin{itemize}
\item The Git revision control system is required to obtain the development source code. The GitHub
Help provides instructions for downloading and installing Git on different platforms. MySQL officially
joined GitHub in September, 2014. For more information about MySQL’s move to GitHub, refer to the
announcement on the MySQL Release Engineering blog: MySQL on GitHub

\item \texttt{bison} 2.1 or higher, available from http://www.gnu.org/software/bison/. (Version 1 is no longer
supported.) Use the latest version of \texttt{bison} where possible; if you experience problems, upgrade to
a later version, rather than revert to an earlier one.

\texttt{bison} is available from http://www.gnu.org/software/bison/. \texttt{bison} for Windows can be downloaded
package, excluding sources”. On Windows, the default location for \texttt{bison} is the \texttt{C:\Program
Files\GnuWin32} directory. Some utilities may fail to find \texttt{bison} because of the space in the
directory name. Also, Visual Studio may simply hang if there are spaces in the path. You can
resolve these problems by installing into a directory that does not contain a space (for example \texttt{C:\
GnuWin32}).

\item On Solaris Express, \texttt{m4} must be installed in addition to \texttt{bison}. \texttt{m4} is available from http://
www.gnu.org/software/m4/.
\end{itemize}

Note

If you have to install any programs, modify your \texttt{PATH} environment variable to
include any directories in which the programs are located. See Section 4.2.7,
“Setting Environment Variables”.

If you run into problems and need to file a bug report, please use the instructions in Section 1.7, “How to Report Bugs or Problems”.

### 2.9.1 MySQL Layout for Source Installation

By default, when you install MySQL after compiling it from source, the installation step installs files under `/usr/local/mysql`. The component locations under the installation directory are the same as for binary distributions. See Table 2.3, “MySQL Installation Layout for Generic Unix/Linux Binary Package”, and Section 2.3.1, “MySQL Installation Layout on Microsoft Windows”. To configure installation locations different from the defaults, use the options described at Section 2.9.4, “MySQL Source-Configuration Options”.

### 2.9.2 Installing MySQL Using a Standard Source Distribution

To install MySQL from a standard source distribution:

1. Verify that your system satisfies the tool requirements listed at Section 2.9, “Installing MySQL from Source”.
2. Obtain a distribution file using the instructions in Section 2.1.2, “How to Get MySQL”.
3. Configure, build, and install the distribution using the instructions in this section.
4. Perform postinstallation procedures using the instructions in Section 2.10, “Postinstallation Setup and Testing”.

In MySQL 8.0, **CMake** is used as the build framework on all platforms. The instructions given here should enable you to produce a working installation. For additional information on using CMake to build MySQL, see How to Build MySQL Server with CMake.

If you start from a source RPM, use the following command to make a binary RPM that you can install. If you do not have `rpmbuild`, use `rpm` instead.

```bash
shell> rpmbuild --rebuild --clean MySQL-VERSION.src.rpm
```

The result is one or more binary RPM packages that you install as indicated in Section 2.5.4, “Installing MySQL on Linux Using RPM Packages from Oracle”.

The sequence for installation from a compressed tar file or Zip archive source distribution is similar to the process for installing from a generic binary distribution (see Section 2.2, “Installing MySQL on Unix/Linux Using Generic Binaries”), except that it is used on all platforms and includes steps to configure and compile the distribution. For example, with a compressed tar file source distribution on Unix, the basic installation command sequence looks like this:

```bash
# Preconfiguration setup
shell> groupadd mysql
shell> useradd -r -g mysql -s /bin/false mysql
# Beginning of source-build specific instructions
shell> tar xzvf mysql-VERSION.tar.gz
shell> cd mysql-VERSION
shell> mkdir bld
shell> cd bld
shell> cmake ..
shell> make
shell> make install
# End of source-build specific instructions
# Postinstallation setup
shell> cd /usr/local/mysql
shell> mkdir mysql-files
shell> chown mysql:mysql mysql-files
shell> chmod 750 mysql-files
shell> bin/mysqld --initialize --user=mysql
shell> bin/mysql_ssl_rsa_setup
```
Installing MySQL Using a Standard Source Distribution

A more detailed version of the source-build specific instructions is shown following.

Note
The procedure shown here does not set up any passwords for MySQL accounts. After following the procedure, proceed to Section 2.10, “Postinstallation Setup and Testing”, for postinstallation setup and testing.

Perform Preconfiguration Setup
Obtain and Unpack the Distribution
Configure the Distribution
Build the Distribution
Install the Distribution
Perform Postinstallation Setup

Perform Preconfiguration Setup

On Unix, set up the mysql user and group that will be used to run and execute the MySQL server and own the database directory. For details, see Create a mysql User and Group. Then perform the following steps as the mysql user, except as noted.

Obtain and Unpack the Distribution

Pick the directory under which you want to unpack the distribution and change location into it.

Obtain a distribution file using the instructions in Section 2.1.2, “How to Get MySQL”.

Unpack the distribution into the current directory:

- To unpack a compressed tar file, tar can uncompress and unpack the distribution if it has z option support:

  ```shell>
  tar zxvf mysql-VERSION.tar.gz
  ```

  If your tar does not have z option support, use gunzip to unpack the distribution and tar to unpack it:

  ```shell>
  gunzip < mysql-VERSION.tar.gz | tar xvf -
  ```

  Alternatively, CMake can uncompress and unpack the distribution:

  ```shell>
  cmake -E tar zxvf mysql-VERSION.tar.gz
  ```

- To unpack a Zip archive, use WinZip or another tool that can read .zip files.

Unpacking the distribution file creates a directory named mysql-VERSION.

Configure the Distribution

Change location into the top-level directory of the unpacked distribution:

```shell>
  cd mysql-VERSION
```
Build outside of the source tree to keep the tree clean. If the top-level source directory is named `mysql-src` under your current working directory, you can build in a directory named `bld` at the same level. Create the directory and go there:

```
shell> mkdir bld
shell> cd bld
```

Configure the build directory. The minimum configuration command includes no options to override configuration defaults:

```
shell> cmake ../mysql-src
```

The build directory needs not be outside the source tree. For example, you can build in a directory named `bld` under the top-level source tree. To do this, starting with `mysql-src` as your current working directory, create the directory `bld` and then go there:

```
shell> mkdir bld
shell> cd bld
```

Configure the build directory. The minimum configuration command includes no options to override configuration defaults:

```
shell> cmake ..
```

If you have multiple source trees at the same level (for example, to build multiple versions of MySQL), the second strategy can be advantageous. The first strategy places all build directories at the same level, which requires that you choose a unique name for each. With the second strategy, you can use the same name for the build directory within each source tree. The following instructions assume this second strategy.

On Windows, specify the development environment. For example, the following commands configure MySQL for 32-bit or 64-bit builds, respectively:

```
shell> cmake .. -G "Visual Studio 12 2013"
shell> cmake .. -G "Visual Studio 12 2013 Win64"
```

On macOS, to use the Xcode IDE:

```
shell> cmake .. -G Xcode
```

When you run `cmake`, you might want to add options to the command line. Here are some examples:

- `-DBUILD_CONFIG=mysql_release`: Configure the source with the same build options used by Oracle to produce binary distributions for official MySQL releases.
- `-DCMAKE_INSTALL_PREFIX=dir_name`: Configure the distribution for installation under a particular location.
- `-DCPACK_MONOLITHIC_INSTALL=1`: Cause `make package` to generate a single installation file rather than multiple files.
- `-DWITH_DEBUG=1`: Build the distribution with debugging support.

For a more extensive list of options, see Section 2.9.4, “MySQL Source-Configuration Options”.

To list the configuration options, use one of the following commands:

```
shell> cmake .. -L # overview
shell> cmake .. -LH # overview with help text
shell> cmake .. -LAH # all params with help text
shell> ccmake .. # interactive display
```
If `CMake` fails, you might need to reconfigure by running it again with different options. If you do reconfigure, take note of the following:

- If `CMake` is run after it has previously been run, it may use information that was gathered during its previous invocation. This information is stored in `CMakeCache.txt`. When `CMake` starts, it looks for that file and reads its contents if it exists, on the assumption that the information is still correct. That assumption is invalid when you reconfigure.

- Each time you run `CMake`, you must run `make` again to recompile. However, you may want to remove old object files from previous builds first because they were compiled using different configuration options.

To prevent old object files or configuration information from being used, run these commands in the build directory on Unix before re-running `CMake`:

```
shell> make clean
shell> rm CMakeCache.txt
```

Or, on Windows:

```
shell> devenv MySQL.sln /clean
shell> del CMakeCache.txt
```

Before asking on the MySQL Community Slack, check the files in the `CMakeFiles` directory for useful information about the failure. To file a bug report, please use the instructions in Section 1.7, “How to Report Bugs or Problems”.

### Build the Distribution

#### On Unix:

```
shell> make
shell> make VERBOSE=1
```

The second command sets `VERBOSE` to show the commands for each compiled source.

Use `gmake` instead on systems where you are using GNU `make` and it has been installed as `gmake`.

#### On Windows:

```
shell> devenv MySQL.sln /build RelWithDebInfo
```

If you have gotten to the compilation stage, but the distribution does not build, see Section 2.9.5, “Dealing with Problems Compiling MySQL”, for help. If that does not solve the problem, please enter it into our bugs database using the instructions given in Section 1.7, “How to Report Bugs or Problems”. If you have installed the latest versions of the required tools, and they crash trying to process our configuration files, please report that also. However, if you get a `command not found` error or a similar problem for required tools, do not report it. Instead, make sure that all the required tools are installed and that your `PATH` variable is set correctly so that your shell can find them.

### Install the Distribution

#### On Unix:

```
shell> make install
```

This installs the files under the configured installation directory (by default, `/usr/local/mysql`). You might need to run the command as `root`.

To install in a specific directory, add a `DESTDIR` parameter to the command line:
Installing MySQL Using a Development Source Tree

Alternatively, generate installation package files that you can install where you like:

```
shell> make package
```

This operation produces one or more .tar.gz files that can be installed like generic binary distribution packages. See Section 2.2, “Installing MySQL on Unix/Linux Using Generic Binaries”. If you run CMake with -DCPACK_MONOLITHIC_INSTALL=1, the operation produces a single file. Otherwise, it produces multiple files.

On Windows, generate the data directory, then create a .zip archive installation package:

```
shell> devenv MySQL.sln /build RelWithDebInfo /project initial_database
shell> devenv MySQL.sln /build RelWithDebInfo /project package
```

You can install the resulting .zip archive where you like. See Section 2.3.5, “Installing MySQL on Microsoft Windows Using a noinstall ZIP Archive”.

Perform Postinstallation Setup

The remainder of the installation process involves setting up the configuration file, creating the core databases, and starting the MySQL server. For instructions, see Section 2.10, “Postinstallation Setup and Testing”.

Note

The accounts that are listed in the MySQL grant tables initially have no passwords. After starting the server, you should set up passwords for them using the instructions in Section 2.10, “Postinstallation Setup and Testing”.

2.9.3 Installing MySQL Using a Development Source Tree

This section describes how to install MySQL from the latest development source code, which is hosted on GitHub. To obtain the MySQL Server source code from this repository hosting service, you can set up a local MySQL Git repository.

On GitHub, MySQL Server and other MySQL projects are found on the MySQL page. The MySQL Server project is a single repository that contains branches for several MySQL series.

MySQL officially joined GitHub in September, 2014. For more information about MySQL’s move to GitHub, refer to the announcement on the MySQL Release Engineering blog: MySQL on GitHub

- Prerequisites for Installing from Development Source
- Setting Up a MySQL Git Repository

Prerequisites for Installing from Development Source

To install MySQL from a development source tree, your system must satisfy the tool requirements outlined in Section 2.9, “Installing MySQL from Source”.

Setting Up a MySQL Git Repository

To set up a MySQL Git repository on your machine, use this procedure:

1. Clone the MySQL Git repository to your machine. The following command clones the MySQL Git repository to a directory named mysql-server. The initial download will take some time to complete, depending on the speed of your connection.

```
~$ git clone https://github.com/mysql/mysql-server.git
```
Installing MySQL Using a Development Source Tree

Cloning into 'mysql-server'...
remote: Counting objects: 1198513, done.
remote: Total 1198513 (delta 0), reused 0 (delta 0), pack-reused 1198513
Receiving objects: 100% (1198513/1198513), 1.01 GiB | 7.44 MiB/s, done.
Resolving deltas: 100% (993200/993200), done.
Checking out files: 100% (25510/25510), done.

2. When the clone operation completes, the contents of your local MySQL Git repository appear similar to the following:

```bash
~$ cd mysql-server
~/mysql-server$ ls
BUILD                cmd-line-utils       libservices          sql
CMakeLists.txt       config.h.cmake       man                  sql-common
COPYING              configure.cmake      mysql-test           storage
Docs                 dbug                 mysys                strings
Doxyfile-perfschema  extra                mysys_ssl            support-files
INSTALL              include              packaging            testclients
README               libbinlogevents      plugin               unittest
VERSION              libbinlogstandalone  rapid               vio
client               libevent             regex                win
 cmake                libmysql             scripts              zlib
```

3. Use the `git branch -r` command to view the remote tracking branches for the MySQL repository.

```bash
~mysql-server$ git branch -r
 origin/5.5
 origin/5.6
 origin/5.7
 origin/8.0
 origin/HEAD -> origin/5.7
 origin/cluster-7.2
 origin/cluster-7.3
 origin/cluster-7.4
 origin/cluster-7.5
```

4. To view the branches that are checked out in your local repository, issue the `git branch` command. When you cloned the MySQL Git repository, the MySQL 5.7 branch was checked out automatically. The asterisk identifies the 5.7 branch as the active branch.

```bash
~mysql-server$ git branch
 * 5.7
```

5. To check out a different MySQL branch, run the `git checkout` command, specifying the branch name. For example, to check out the MySQL 8.0 branch:

```bash
~mysql-server$ git checkout 8.0
Checking out files: 100% (9600/9600), done.
Branch 8.0 set up to track remote branch 8.0 from origin.
Switched to a new branch '8.0'
```

6. Run `git branch` to verify that the MySQL 8.0 branch is present. MySQL 8.0, which is the last branch you checked out, is marked by an asterisk indicating that it is the active branch.

```bash
~mysql-server$ git branch
  5.7
  * 8.0
```

7. Use the `git checkout` command to switch between branches. For example:

```bash
~mysql-server$ git checkout 5.7
```

8. To obtain changes made after your initial setup of the MySQL Git repository, switch to the branch you want to update and issue the `git pull` command:

```bash
~mysql-server$ git checkout 8.0
~mysql-server$ git pull
```
To examine the commit history, use the `git log` option:

```
~/mysql-server$ git log
```

You can also browse commit history and source code on the GitHub MySQL site.

If you see changes or code that you have a question about, ask on the MySQL Community Slack. For information about contributing a patch, see Contributing to MySQL Server.

9. After you have cloned the MySQL Git repository and have checked out the branch you want to build, you can build MySQL Server from the source code. Instructions are provided in Section 2.9.2, “Installing MySQL Using a Standard Source Distribution”, except that you skip the part about obtaining and unpacking the distribution.

Be careful about installing a build from a distribution source tree on a production machine. The installation command may overwrite your live release installation. If you already have MySQL installed and do not want to overwrite it, run CMake with values for the CMAKE_INSTALL_PREFIX, MYSQL_TCP_PORT, and MYSQL_UNIX_ADDR options different from those used by your production server. For additional information about preventing multiple servers from interfering with each other, see Section 5.8, “Running Multiple MySQL Instances on One Machine”.

Play hard with your new installation. For example, try to make new features crash. Start by running `make test`. See Section 29.1.2, “The MySQL Test Suite”.

### 2.9.4 MySQL Source-Configuration Options

The CMake program provides a great deal of control over how you configure a MySQL source distribution. Typically, you do this using options on the CMake command line. For information about options supported by CMake, run either of these commands in the top-level source directory:

```
cmake . -LH
ccmake .
```

You can also affect CMake using certain environment variables. See Section 4.9, “MySQL Environment Variables”.

For boolean options, the value may be specified as 1 or `ON` to enable the option, or as 0 or `OFF` to disable the option.

Many options configure compile-time defaults that can be overridden at server startup. For example, the CMAKE_INSTALL_PREFIX, MYSQL_TCP_PORT, and MYSQL_UNIX_ADDR options that configure the default installation base directory location, TCP/IP port number, and Unix socket file can be changed at server startup with the `--basedir`, `--port`, and `--socket` options for mysqld. Where applicable, configuration option descriptions indicate the corresponding mysqld startup option.

The following sections provide more information about CMake options.

- CMake Option Reference
- General Options
- Installation Layout Options
- Storage Engine Options
- Feature Options
- Compiler Flags
- CMake Options for Compiling NDB Cluster
## CMake Option Reference

The following table shows the available CMake options. In the Default column, PREFIX stands for the value of the CMAKE_INSTALL_PREFIX option, which specifies the installation base directory. This value is used as the parent location for several of the installation subdirectories.

</tbody>
</table>

**General Options**

- `-DBUILD_CONFIG=mysql_release`

  This option configures a source distribution with the same build options used by Oracle to produce binary distributions for official MySQL releases.

- `-DBUNDLE_RUNTIME_LIBRARIES=bool`

  Whether to bundle runtime libraries with server MSI and Zip packages for Windows.

- `-DCMAKE_BUILD_TYPE=type`

  The type of build to produce:
  
  - `RelWithDebInfo`: Enable optimizations and generate debugging information. This is the default MySQL build type.
  
  - `Release`: Enable optimizations but omit debugging information to reduce the build size. This build type was added in MySQL 8.0.13.
  
  - `Debug`: Disable optimizations and generate debugging information. This build type is also used if the `WITH_DEBUG` option is enabled. That is, `-DWITH_DEBUG=1` has the same effect as `DCMAKE_BUILD_TYPE=Debug`.

- `-DCPACK_MONOLITHIC_INSTALL=bool`

  This option affects whether the `make package` operation produces multiple installation package files or a single file. If disabled, the operation produces multiple installation package files, which may be useful if you want to install only a subset of a full MySQL installation. If enabled, it produces a single file for installing everything.
MySQL Source-Configuration Options

-DFORCE_INSOURCE_BUILD=bool

Defines whether to force an in-source build. Out-of-source builds are recommended, as they permit multiple builds from the same source, and cleanup can be performed quickly by removing the build directory. To force an in-source build, invoke CMake with -DFORCE_INSOURCE_BUILD=ON.

Installation Layout Options

The CMAKE_INSTALL_PREFIX option indicates the base installation directory. Other options with names of the form INSTALL_xxx that indicate component locations are interpreted relative to the prefix and their values are relative pathnames. Their values should not include the prefix.

-DCMAKE_INSTALL_PREFIX=dir_name

The installation base directory.

This value can be set at server startup with the --basedir option.

-DINSTALL_BINDIR=dir_name

Where to install user programs.

-DINSTALL_DOC_DIR=dir_name

Where to install documentation.

-DINSTALL_DOC_README_DIR=dir_name

Where to install README files.

-DINSTALL_INCLUDE_DIR=dir_name

Where to install header files.

-DINSTALL_INFO_DIR=dir_name

Where to install Info files.

-DINSTALL_LAYOUT=name

Select a predefined installation layout:

- STANDALONE: Same layout as used for .tar.gz and .zip packages. This is the default.
- RPM: Layout similar to RPM packages.
- SVR4: Solaris package layout.
- DEB: DEB package layout (experimental).

You can select a predefined layout but modify individual component installation locations by specifying other options. For example:

```
cmake . -DINSTALL_LAYOUT=SVR4 -DMYSQL_DATADIR=/var/mysql/data
```

The INSTALL_LAYOUT value determines the default value of the secure_file_priv, keyring_encrypted_file_data, and keyring_file_data system variables. See the descriptions of those variables in Section 5.1.8, “Server System Variables”, and Section 6.4.4.11, “Keyring System Variables”.

-DINSTALL_LIB_DIR=dir_name

Where to install library files.
• –DINSTALL_MANDIR=dir_name
Where to install manual pages.

• –DINSTALL_MYSQLKEYRINGDIR=dir_path
The default directory to use as the location of the keyring_file plugin data file. The default value is platform specific and depends on the value of the INSTALL_LAYOUT CMake option; see the description of the keyring_file_data system variable in Section 5.1.8, “Server System Variables”.

• –DINSTALL_MYSQLSHAREDIR=dir_name
Where to install shared data files.

• –DINSTALL_MYSQLTESTDIR=dir_name
Where to install the mysql-test directory. To suppress installation of this directory, explicitly set the option to the empty value (`–DINSTALL_MYSQLTESTDIR=`).

• –DINSTALL_PKGCONFIGDIR=dir_name
The directory in which to install the mysqlclient.pc file for use by pkg-config. The default value is INSTALL_LIBDIR/pkgconfig, unless INSTALL_LIBDIR ends with /mysql, in which case that is removed first.

• –DINSTALL_PLUGINDIR=dir_name
The location of the plugin directory.
This value can be set at server startup with the --plugin_dir option.

• –DINSTALL_SBINDIR=dir_name
Where to install the mysqld server.

• –DINSTALL_SECURE_FILE_PRIVDIR=dir_name
The default value for the secure_file_priv system variable. The default value is platform specific and depends on the value of the INSTALL_LAYOUT CMake option; see the description of the secure_file_priv system variable in Section 5.1.8, “Server System Variables”.

• –DINSTALL_SHAREDIR=dir_name
Where to install aclocal/mysql.m4.

• –DINSTALL_STATIC_LIBRARIES=bool
Whether to install static libraries. The default is ON. If set to OFF, these libraries are not installed:
libmysqlclient.a, libmysqlservices.a.

• –DINSTALL_SUPPORTFILESDIR=dir_name
Where to install extra support files.

• –DLINK_RANDOMIZE=bool
Whether to randomize the order of symbols in the mysqld binary. The default is OFF. This option should be enabled only for debugging purposes.

• –DLINK_RANDOMIZE_SEED=val
Seed value for the LINK_RANDOMIZE option. The value is a string. The default is mysql, an arbitrary choice.
MySQL Source-Configuration Options

- **-DMYSQL_DATADIR=dir_name**
  
The location of the MySQL data directory.
  
  This value can be set at server startup with the **--datadir** option.

- **-DODBC_INCLUDES=dir_name**
  
The location of the ODBC includes directory, and may be used while configuring Connector/ODBC.

- **-DODBC_LIB_DIR=dir_name**
  
The location of the ODBC library directory, and may be used while configuring Connector/ODBC.

- **-DSYSCONFDIR=dir_name**
  
The default **my.cnf** option file directory.
  
  This location cannot be set at server startup, but you can start the server with a given option file using the **--defaults-file=file_name** option, where **file_name** is the full path name to the file.

- **-DSYSTEMD_PID_DIR=dir_name**
  
The name of the directory in which to create the PID file when MySQL is managed by systemd. The default is /var/run/mysqld; this might be changed implicitly according to the INSTALL_LAYOUT value.
  
  This option is ignored unless **WITH_SYSTEMD** is enabled.

- **-DSYSTEMD_SERVICE_NAME=name**
  
The name of the MySQL service to use when MySQL is managed by systemd. The default is mysqld; this might be changed implicitly according to the INSTALL_LAYOUT value.
  
  This option is ignored unless **WITH_SYSTEMD** is enabled.

- **-DTMPDIR=dir_name**
  
The default location to use for the tmpdir system variable. If unspecified, the value defaults to P_tmpdir in <stdio.h>.

Storage Engine Options

Storage engines are built as plugins. You can build a plugin as a static module (compiled into the server) or a dynamic module (built as a dynamic library that must be installed into the server using the INSTALL PLUGIN statement or the **--plugin-load** option before it can be used). Some plugins might not support static or dynamic building.

The InnoDB, MyISAM, MERGE, MEMORY, and CSV engines are mandatory (always compiled into the server) and need not be installed explicitly.

To compile a storage engine statically into the server, use **-DWITH_engine_STORAGE_ENGINE=1**. Some permissible engine values are ARCHIVE, BLACKHOLE, EXAMPLE, FEDERATED, and NDB or NDBCLUSTER (NDB support). Examples:

```
-DWITH_ARCHIVE_STORAGE_ENGINE=1
-DWITH_BLACKHOLE_STORAGE_ENGINE=1
```
Note

It is not possible to compile without Performance Schema support. If it is desired to compile without particular types of instrumentation, that can be done with the following CMake options:

DISABLE_PSI_COND
DISABLE_PSI_DATA_LOCK
DISABLE_PSI_ERROR
DISABLE_PSI_FILE
DISABLE_PSI_IDLE
DISABLE_PSI_MEMORY
DISABLE_PSI_METADATA
DISABLE_PSI_MUTEX
DISABLE_PSI_PS
DISABLE_PSI_RWLOCK
DISABLE_PSI_SOCKET
DISABLE_PSI_SF
DISABLE_PSI_STAGE
DISABLE_PSI_STATEMENT
DISABLE_PSI_STATEMENT_DIGEST
DISABLE_PSI_TABLE
DISABLE_PSI_THREAD
DISABLE_PSI_TRANSACTION

For example, to compile without mutex instrumentation, configure MySQL using the -DDISABLE_PSI_MUTEX=1 option.

To exclude a storage engine from the build, use -DWITH_engine_STORAGE_ENGINE=0. Examples:

- DWITH_ARCHIVE_STORAGE_ENGINE=0
- DWITH_EXAMPLE_STORAGE_ENGINE=0
- DWITH_FEDERATED_STORAGE_ENGINE=0

It is also possible to exclude a storage engine from the build using - DWITHOUT_engine_STORAGE_ENGINE=1 (but -DWITH_engine_STORAGE_ENGINE=0 is preferred). Examples:

- DWITHOUT_ARCHIVE_STORAGE_ENGINE=1
- DWITHOUT_EXAMPLE_STORAGE_ENGINE=1
- DWITHOUT_FEDERATED_STORAGE_ENGINE=1

If neither -DWITH_engine_STORAGE_ENGINE nor -DWITHOUT_engine_STORAGE_ENGINE are specified for a given storage engine, the engine is built as a shared module, or excluded if it cannot be built as a shared module.

Feature Options

- -DCOMPIILATION_COMMENT=string

A descriptive comment about the compilation environment. As of MySQL 8.0.14, mysqld uses COMPILATIONCOMMENT_SERVER. Other programs continue to use COMPILATION_COMMENT.

- -DCOMPIILATIONCOMMENT_SERVER=string

A descriptive comment about the compilation environment for use by mysqld (for example, to set the version_comment system variable). This option was added in MySQL 8.0.14. Prior to 8.0.14, the server uses COMPILATION_COMMENT.

- -DDEFAULT_CHARSET=charset_name

The server character set. By default, MySQL uses the utf8mb4 character set.
charset_name may be one of binary, armSCII8, ascii, big5, cp1250, cp1251, cp1256, cp1257, cp850, cp852, cp866, cp932, dec8, eucjpms, euckr, gb2312, gbk, geostd8, greek, hebrew, hp8, keybcs2, koi8r, koi8u, latin1, latin2, latin5, latin7, macce, macroman, sjis, swe7, tis620, ucs2, ujis, utf8, utf8mb4, utf16, utf16le, utf32. The permissible character sets are listed in the cmake/character_sets.cmake file as the value of CHARSETS_AVAILABLE.

This value can be set at server startup with the --character_set_server option.

• -DDISABLE_PSI_COND=bool

Whether to exclude the Performance Schema condition instrumentation. The default is OFF (include).

• -DDISABLE_PSI_FILE=bool

Whether to exclude the Performance Schema file instrumentation. The default is OFF (include).

• -DDISABLE_PSI_IDLE=bool

Whether to exclude the Performance Schema idle instrumentation. The default is OFF (include).

• -DDISABLE_PSI_MEMORY=bool

Whether to exclude the Performance Schema memory instrumentation. The default is OFF (include).

• -DDISABLE_PSI_METADATA=bool

Whether to exclude the Performance Schema metadata instrumentation. The default is OFF (include).

• -DDISABLE_PSI_MUTEX=bool

Whether to exclude the Performance Schema mutex instrumentation. The default is OFF (include).

• -DDISABLE_PSI_RWLOCK=bool

Whether to exclude the Performance Schema rwlock instrumentation. The default is OFF (include).

• -DDISABLE_PSI_SOCKET=bool

Whether to exclude the Performance Schema socket instrumentation. The default is OFF (include).

• -DDISABLE_PSI_SP=bool

Whether to exclude the Performance Schema stored program instrumentation. The default is OFF (include).

• -DDISABLE_PSI_STAGE=bool

Whether to exclude the Performance Schema stage instrumentation. The default is OFF (include).

• -DDISABLE_PSI_STATEMENT=bool

Whether to exclude the Performance Schema statement instrumentation. The default is OFF (include).
MySQL Source-Configuration Options

- **-DDISABLE_PSI_STATEMENT_DIGEST=bool**
  Whether to exclude the Performance Schema statement_diggest instrumentation. The default is OFF (include).

- **-DDISABLE_PSI_TABLE=bool**
  Whether to exclude the Performance Schema table instrumentation. The default is OFF (include).

- **-DDISABLE_SHARED=bool**
  Whether to disable building shared libraries and compile position-dependent code. The default is OFF (compile position-independent code).

  Enabling this option disables `-fPIC`, with the consequence that shared libraries are not built, including plugins and components. Invoking CMake produces this warning: `Dynamic plugins are disabled.`

- **-DDISABLE_PSI_PS=bool**
  Exclude the performance schema prepared statements instances instrumentation. The default is OFF (include).

- **-DDISABLE_PSI_THREAD=bool**
  Exclude the performance schema thread instrumentation. The default is OFF (include).

  Only disable threads when building without any instrumentation, because other instrumentations have a dependency on threads.

- **-DDISABLE_PSI_TRANSACTION=bool**
  Exclude the performance schema transaction instrumentation. The default is OFF (include).

- **-DDISABLE_PSI_DATA_LOCK=bool**
  Exclude the performance schema data lock instrumentation. The default is OFF (include).

- **-DDISABLE_PSI_ERROR=bool**
  Exclude the performance schema server error instrumentation. The default is OFF (include).

- **-DDOWNLOAD_BOOST=bool**
  Whether to download the Boost library. The default is OFF.

  See the WITH_BOOST option for additional discussion about using Boost.

- **-DDOWNLOAD_BOOST_TIMEOUT=seconds**
  The timeout in seconds for downloading the Boost library. The default is 600 seconds.

  See the WITH_BOOST option for additional discussion about using Boost.

- **-DENABLE_DEBUG_SYNC=bool**
  As of MySQL 8.0.1, ENABLE_DEBUG_SYNC is removed and enabling WITH_DEBUG enables Debug Sync.

- **-DENABLE_DOWNLOADS=bool**
  Whether to download optional files. For example, with this option enabled, CMake downloads the Google Test distribution that is used by the test suite to run unit tests, or Ant and JUnit required for building GCS Java wrapper.
MySQL Source-Configuration Options

- **-DENABLE_DTRACE=bool**
  Whether to include support for DTrace probes.
  This option was removed in MySQL 8.0.1.

- **-DENABLE_EXPERIMENTAL_SYSVARS=bool**
  Whether to enable experimental InnoDB system variables. Experimental system variables are intended for those engaged in MySQL development, should only be used in a development or test environment, and may be removed without notice in a future MySQL release. For information about experimental system variables, refer to `/storage/innobase/handler/ha_innodb.cc` in the MySQL source tree. Experimental system variables can be identified by searching for “PLUGIN_VAR_EXPERIMENTAL”.

- **-DENABLE_GCOV=bool**
  Whether to include gcov support (Linux only).

- **-DENABLE_GPROF=bool**
  Whether to enable gprof (optimized Linux builds only).

- **-DENABLED_LOCAL_INFILE=bool**
  This option controls the compiled-in default LOCAL capability for the MySQL client library. Clients that make no explicit arrangements therefore have LOCAL capability disabled or enabled according to the ENABLED_LOCAL_INFILE setting specified at MySQL build time.

  By default, the client library in MySQL binary distributions is compiled with ENABLED_LOCAL_INFILE disabled. If you compile MySQL from source, configure it with ENABLED_LOCAL_INFILE disabled or enabled based on whether clients that make no explicit arrangements should have LOCAL capability disabled or enabled, respectively.

  ENABLED_LOCAL_INFILE controls the default for client-side LOCAL capability. For the server, the local_infile system variable controls server-side LOCAL capability. To explicitly cause the server to refuse or permit LOAD DATA LOCAL statements (regardless of how client programs and libraries are configured at build time or runtime), start mysqld with local_infile disabled or enabled, respectively. local_infile can also be set at runtime. See Section 6.1.6, “Security Issues with LOAD DATA LOCAL”.

- **-DENABLED_PROFILING=bool**
  Whether to enable query profiling code (for the SHOW PROFILE and SHOW PROFILES statements).

- **-DFORCE_UNSUPPORTED_COMPILER=bool**
  By default, CMake checks for minimum versions of supported compilers: Visual Studio 2015 (Windows); GCC 4.8 or Clang 3.4 (Linux); Developer Studio 12.5 (Solaris server); Developer Studio 12.4 or GCC 4.8 (Solaris client library); Clang 3.6 (macOS), Clang 3.4 (FreeBSD). To disable this check, use -DFORCE_UNSUPPORTED_COMPILER=ON.

- **-DIGNORE_AIO_CHECK=bool**
  If the -DBUILD_CONFIG=mysql_release option is given on Linux, the libaio library must be linked in by default. If you do not have libaio or do not want to install it, you can suppress the check for it by specifying -DIGNORE_AIO_CHECK=1.

- **-DMAX_INDEXES=num**
  The maximum number of indexes per table. The default is 64. The maximum is 255. Values smaller than 64 are ignored and the default of 64 is used.
• `-DMYSQL_MAINTAINER_MODE=bool`

Whether to enable a MySQL maintainer-specific development environment. If enabled, this option causes compiler warnings to become errors.

• `-DMUTEX_TYPE=type`

The mutex type used by InnoDB. Options include:

  • `event`: Use event mutexes. This is the default value and the original InnoDB mutex implementation.
  
  • `sys`: Use POSIX mutexes on UNIX systems. Use `CRITICAL_SECTION` objects on Windows, if available.
  
  • `futex`: Use Linux futexes instead of condition variables to schedule waiting threads.

• `-DMYSQL_TCP_PORT=port_num`

The port number on which X Plugin listens for TCP/IP connections. The default is 33060.

This value can be set at server startup with the `mysqlx_port` system variable.

• `-DMYSQL_UNIX_ADDR=file_name`

The Unix socket file path on which the server listens for X Plugin socket connections. This must be an absolute path name. The default is `/tmp/mysqlx.sock`.

This value can be set at server startup with the `mysqlx_port` system variable.

• `-DMYSQL_PROJECT_NAME=name`

For Windows or macOS, the project name to incorporate into the project file name.

• `-DMYSQL_TCP_PORT=port_num`

The port number on which the server listens for TCP/IP connections. The default is 3306.

This value can be set at server startup with the `--port` option.

• `-DMYSQL_UNIX_ADDR=file_name`

The Unix socket file path on which the server listens for socket connections. This must be an absolute path name. The default is `/tmp/mysql.sock`.

This value can be set at server startup with the `--socket` option.

• `-DOPTIMIZER_TRACE=bool`

Whether to support optimizer tracing. See MySQL Internals: Tracing the Optimizer.

• `-DREPRODUCIBLE_BUILD=bool`

For builds on Linux systems, this option controls whether to take extra care to create a build result independent of build location and time.

This option was added in MySQL 8.0.11. As of MySQL 8.0.12, it defaults to `ON` for `RelWithDebInfo` builds.

• `-DUSE_LD_GOLD=bool`

CMake causes the build process to link with the GNU gold linker if it is available and not explicitly disabled. To disable use of this linker, specify the `-DUSE_LD_GOLD=OFF` option.
MySQL Source-Configuration Options

- **-DUSE_LD_LLD=bool**

  CMake causes the build process to link with the `llvm llld` linker for Clang if it is available and not explicitly disabled. To disable use of this linker, specify the `DUSE_LD_LLD=OFF` option.

  This option was added in MySQL 8.0.16.

- **-DWIN_DEBUG_NO_INLINE=bool**

  Whether to disable function inlining on Windows. The default is off (inlining enabled).

- **-DWITH_ANT=path_name**

  Set the path to Ant, required when building GCS Java wrapper. Works in a similar way to the existing `WITH_BOOST` CMake option. Set `WITH_ANT` to the path of a directory where the Ant tarball, or an already unpacked archive, is saved. When `WITH_ANT` is not set, or is set with the special value `system`, the build assumes a binary `ant` exists in `$PATH`.

- **-DWITH_ASAN=bool**

  Whether to enable the AddressSanitizer, for compilers that support it. The default is off.

- **-DWITH_ASAN_SCOPE=bool**

  Whether to enable the AddressSanitizer `-fsanitize-address-use-after-scope` Clang flag for use-after-scope detection. The default is off. To use this option, `-DWITH_ASAN` must also be enabled.

- **-DWITH_AUTHENTICATION_LDAP=bool**

  Whether to report an error if the LDAP authentication plugins cannot be built:

  - If this option is disabled (the default), the LDAP plugins are built if the required header files and libraries are found. If they are not, CMake displays a note about it.
  
  - If this option is enabled, a failure to find the required header file and libraries causes CMake to produce an error, preventing the server from being built.

- **-DWITH_AUTHENTICATION_PAM=bool**

  Whether to build the PAM authentication plugin, for source trees that include this plugin. (See Section 6.4.1.5, “PAM Pluggable Authentication”.) If this option is specified and the plugin cannot be compiled, the build fails.

- **-DWITH_AWS_SDK=path_name**

  The location of the Amazon Web Services software development kit.

- **-DWITH_BOOST=path_name**

  The Boost library is required to build MySQL. These CMake options enable control over the library source location, and whether to download it automatically:

  - `DWITH_BOOST=path_name` specifies the Boost library directory location. It is also possible to specify the Boost location by setting the `BOOST_ROOT` or `WITH_BOOST` environment variable.

  - `DWITH_BOOST=system` is also permitted and indicates that the correct version of Boost is installed on the compilation host in the standard location. In this case, the installed version of Boost is used rather than any version included with a MySQL source distribution.

  - `DDOWNLOAD_BOOST=bool` specifies whether to download the Boost source if it is not present in the specified location. The default is OFF.
• `-DDOWNLOAD_BOOST_TIMEOUT=seconds` the timeout in seconds for downloading the Boost library. The default is 600 seconds.

For example, if you normally build MySQL placing the object output in the `bld` subdirectory of your MySQL source tree, you can build with Boost like this:

```bash
mkdir bld
cd bld
cmake .. -DDOWNLOAD_BOOST=ON -DWITH_BOOST=$HOME/my_boost
```

This causes Boost to be downloaded into the `my_boost` directory under your home directory. If the required Boost version is already there, no download is done. If the required Boost version changes, the newer version is downloaded.

If Boost is already installed locally and your compiler finds the Boost header files on its own, it may not be necessary to specify the preceding CMake options. However, if the version of Boost required by MySQL changes and the locally installed version has not been upgraded, you may have build problems. Using the CMake options should give you a successful build.

With the above settings that allow Boost download into a specified location, when the required Boost version changes, you need to remove the `bld` folder, recreate it, and perform the `cmake` step again. Otherwise, the new Boost version might not get downloaded, and compilation might fail.

• `-DWITH_CLIENT_PROTOCOL_TRACING=bool`

Whether to build the client-side protocol tracing framework into the client library. By default, this option is enabled.

For information about writing protocol trace client plugins, see Section 29.2.4.11, “Writing Protocol Trace Plugins”.

See also the `WITH_TEST_TRACE_PLUGIN` option.

• `-DWITH_CURL=curl_type`

The location of the `curl` library. `curl_type` can be `system` (use the system `curl` library) or a path name to the `curl` library.

• `-DWITH_DEBUG=bool`

Whether to include debugging support.

Configuring MySQL with debugging support enables you to use the `--debug="d,parser_debug"` option when you start the server. This causes the Bison parser that is used to process SQL statements to dump a parser trace to the server’s standard error output. Typically, this output is written to the error log.

Sync debug checking for the InnoDB storage engine is defined under `UNIV_DEBUG` and is available when debugging support is compiled in using the `WITH_DEBUG` option. When debugging support is compiled in, the `innodb_sync_debug` configuration option can be used to enable or disable InnoDB sync debug checking.

Enabling `WITH_DEBUG` also enables Debug Sync. This facility is used for testing and debugging. When compiled in, Debug Sync is disabled by default at runtime. To enable it, start `mysqld` with the `--debug-sync-timeout=N` option, where `N` is a timeout value greater than 0. (The default value is 0, which disables Debug Sync.) `N` becomes the default timeout for individual synchronization points.

Sync debug checking for the InnoDB storage engine is available when debugging support is compiled in using the `WITH_DEBUG` option.
MySQL Source-Configuration Options

For a description of the Debug Sync facility and how to use synchronization points, see MySQL Internals: Test Synchronization.

- \texttt{-DWITH_DEFAULT_FEATURE_SET=bool}

Whether to use the flags from \texttt{cmake/build_configurations/feature_set.cmake}.

- \texttt{-DWITH_EDITLINE=value}

Which \texttt{libedit/editline} library to use. The permitted values are \texttt{bundled} (the default) and \texttt{system}.

- \texttt{-DWITH_ICU={icu_type|path_name}}

MySQL uses International Components for Unicode (ICU) to support regular expression operations. The \texttt{WITH_ICU} option indicates the type of ICU support to include or the path name to the ICU installation to use.

  - \texttt{icu_type} can be one of the following values:
    - \texttt{bundled}: Use the ICU library bundled with the distribution. This is the default, and is the only supported option for Windows.
    - \texttt{system}: Use the system ICU library.

  - \texttt{path_name} is the path name to the ICU installation to use. This can be preferable to using the \texttt{icu_type} value of \texttt{system} because it can prevent CMake from detecting and using an older or incorrect ICU version installed on the system. (Another permitted way to do the same thing is to set \texttt{WITH_ICU} to \texttt{system} and set the \texttt{CMAKE_PREFIX_PATH} option to \texttt{path_name}.)

- \texttt{-DWITH_INNODB_EXTRA_DEBUG=bool}

Whether to include extra InnoDB debugging support.

Enabling \texttt{WITH_INNODB_EXTRA_DEBUG} turns on extra InnoDB debug checks. This option can only be enabled when \texttt{WITH_DEBUG} is enabled.

- \texttt{-DWITH_GMOCK=path_name}

The path to the googlemock distribution, for use with Google Test-based unit tests. The option value is the path to the distribution Zip file. Alternatively, set the \texttt{WITH_GMOCK} environment variable to the path name. It is also possible to use \texttt{-DENABLE_DOWNLOA.$$s=1} and \texttt{CMake} will download the distribution from GitHub.

If you build MySQL without the Google Test-based unit tests (by configuring without \texttt{WITH_GMOCK}), \texttt{CMake} displays a message indicating how to download it.

- \texttt{-DWITH_INNODB_MEMCACHED=bool}

Whether to generate memcached shared libraries (\texttt{libmemcached.so} and \texttt{innodb_engine.so}).

- \texttt{-DWITH_JEMALLOC=bool}

Whether to link with \texttt{-ljemalloc}. If enabled, built-in \texttt{malloc()}, \texttt{calloc()}, \texttt{realloc()}, and \texttt{free()} routines are disabled. The default is \texttt{OFF}.

This option was added in MySQL 8.0.16.

- \texttt{-DWITH_KEYRING_TEST=bool}

Whether to build the test program that accompanies the \texttt{keyring_file} plugin. The default is \texttt{OFF}. Test file source code is located in the \texttt{plugin/keyring/keyring-test} directory.
MySQL Source-Configuration Options

• \texttt{-DWITH_LIBEVENT=string}

Which libevent library to use. Permitted values are \texttt{bundled} (default), \texttt{system}, and \texttt{yes}. If you specify \texttt{system} or \texttt{yes}, the system libevent library is used if present. If the system library is not found, the bundled libevent library is used. The libevent library is required by InnoDB memcached.

• \texttt{-DWITH_LIBWRAP=bool}

Whether to include libwrap (TCP wrappers) support.

• \texttt{-DWITH_LOCK_ORDER=bool}

Whether to enable LOCK_ORDER tooling. By default, this option is disabled and server builds contain no tooling. If tooling is enabled, the LOCK_ORDER tool is available and can be used as described in Section 29.5.3, “The LOCK_ORDER Tool”.

\begin{flushright}
\textbf{Note}
\end{flushright}

With the \texttt{WITH_LOCK_ORDER} option enabled, MySQL builds require the \texttt{flex} program.

This option was added in MySQL 8.0.17.

• \texttt{-DWITH_LSAN=bool}

Whether to run LeakSanitizer, without AddressSanitizer. The default is \texttt{OFF}.

This option was added in MySQL 8.0.16.

• \texttt{-DWITH_LTO=bool}

Whether to enable the link-time optimizer, if the compiler supports it. The default is \texttt{OFF}.

This option was added in MySQL 8.0.13.

• \texttt{-DWITH_LZ4=lz4\_type}

The \texttt{WITH_LZ4} indicates the source of zlib support:

\begin{itemize}
  \item \texttt{bundled}: Use the \texttt{lz4} library bundled with the distribution. This is the default.
  \item \texttt{system}: Use the system \texttt{lz4} library. If \texttt{WITH_LZ4} is set to this value, the \texttt{lz4\_decompress} utility is not built. In this case, the system \texttt{lz4} command can be used instead.
\end{itemize}

• \texttt{-DWITH_MSAN=bool}

Whether to enable MemorySanitizer, for compilers that support it. The default is off.

For this option to have an effect if enabled, all libraries linked to MySQL must also have been compiled with the option enabled.

• \texttt{-DWITH_MECAB={disabled|system|path\_name}}

Use this option to compile the MeCab parser. If you have installed MeCab to its default installation directory, set \texttt{-DWITH_MECAB=system}. The \texttt{system} option applies to MeCab installations performed from source or from binaries using a native package management utility. If you installed MeCab to a custom installation directory, specify the path to the MeCab installation. For example, \texttt{-DWITH_MECAB=/opt/mecab}. If the \texttt{system} option does not work, specifying the MeCab installation path should work in all cases.

For related information, see Section 12.9.9, “MeCab Full-Text Parser Plugin”.
MySQL Source-Configuration Options

- **-DWITH_MSCRT_DEBUG=bool**
  
  Whether to enable Visual Studio CRT memory leak tracing. The default is **OFF**.

- **-DWITH_MYSQLX=bool**
  
  Whether to build with support for X Plugin. Default **ON**. See Chapter 20, Using MySQL as a Document Store.

- **-DWITH_NUMA=bool**
  
  Explicitly set the NUMA memory allocation policy. **CMake** sets the default **WITH_NUMA** value based on whether the current platform has **NUMA** support. For platforms without NUMA support, **CMake** behaves as follows:
  - With no NUMA option (the normal case), **CMake** continues normally, producing only this warning: NUMA library missing or required version not available
  - With **-DWITH_NUMA=ON**, **CMake** aborts with this error: NUMA library missing or required version not available

- **-DWITH_PROTOBUF=protobuf_type**
  
  Which Protocol Buffers package to use. **protobuf_type** can be one of the following values:
  - **bundled**: Use the package bundled with the distribution. This is the default.
  - **system**: Use the package installed on the system.
  
  Other values are ignored, with a fallback to **bundled**.

- **-DWITH_RAPID=bool**
  
  Whether to build the rapid development cycle plugins. When enabled, a **rapid** directory is created in the build tree containing these plugins. When disabled, no **rapid** directory is created in the build tree. The default is **ON**, unless the **rapid** directory is removed from the source tree, in which case the default becomes **OFF**.

- **-DWITH_RAPIDJSON=rapidjson_type**
  
  The type of RapidJSON library support to include. **rapidjson_type** can be one of the following values:
  - **bundled**: Use the RapidJSON library bundled with the distribution. This is the default.
  - **system**: Use the system RapidJSON library. Version 1.1.0 or higher is required.
  
  This option was added in MySQL 8.0.13.

- **-DWITH_LZMA=lzma_type**
  
  The type of LZMA library support to include. **lzma_type** can be one of the following values:
  - **bundled**: Use the LZMA library bundled with the distribution. This is the default.
  - **system**: Use the system LZMA library.
  
  This option was removed in MySQL 8.0.16.

- **-DWITH_RE2=re2_type**
  
  The type of RE2 library support to include. **re2_type** can be one of the following values:
MySQL Source-Configuration Options

- **bundled**: Use the RE2 library bundled with the distribution. This is the default.
- **system**: Use the system RE2 library.

As of MySQL 8.0.18, MySQL no longer uses the RE2 library and this option was removed.

- **-DWITH_ROUTER=bool**
  
  Whether to build MySQL Router. The default is **ON**.

  This option was added in MySQL 8.0.16.

- **-DWITH_SSL={ssl_type|path_name}**
  
  The type of SSL support to include or the path name to the OpenSSL installation to use.

  - **ssl_type** can be one of the following values:
    - **system**: Use the system OpenSSL library. This is the default.
      
      On macOS and Windows, using **system** builds as if CMake was invoked with **path_name** and points to the installed OpenSSL library. This is because they do not have system SSL libraries. On macOS, `brew install openssl` installs to `/usr/local/opt/openssl` and `system` will find it. On Windows, it checks `%ProgramFiles%\OpenSSL`, `%ProgramFiles%\OpenSSL-Win32`, `%ProgramFiles%\OpenSSL-Win64`, `C:\OpenSSL`, `C:\OpenSSL-Win32`, and `C:\OpenSSL-Win64`.
    - **yes**: This is a synonym for **system**.
    - **wolfssl**: Use the wolfSSL library. To use this option value, you must follow the instructions in the `extra/README-wolfssl.txt` file.
    - **path_name** is the path name to the OpenSSL installation to use. This can be preferable to using the **ssl_type** value of **system** because it can prevent CMake from detecting and using an older or incorrect OpenSSL version installed on the system. (Another permitted way to do the same thing is to set **WITH_SSL** to **system** and set the **CMAKE_PREFIX_PATH** option to **path_name**.)

  For information about using SSL support, see Section 6.3, “Using Encrypted Connections”.

- **-DWITH_SYSTEMD=bool**
  
  Whether to enable installation of systemd support files. By default, this option is disabled. When enabled, systemd support files are installed, and scripts such as **mysqld_safe** and the System V initialization script are not installed. On platforms where systemd is not available, enabling **WITH_SYSTEMD** results in an error from CMake.

  For more information about using systemd, see Section 2.5.9, “Managing MySQL Server with systemd”. That section also includes information about specifying options previously specified in `[mysqld_safe]` option groups. Because **mysqld_safe** is not installed when systemd is used, such options must be specified another way.

- **-DWITH_SYSTEM_LIBS=bool**
  
  This option serves as an “umbrella” option to set the **system** value of any of the following CMake options that are not set explicitly: **WITH_CURL**, **WITH_EDITLINE**, **WITH_ICU**, **WITH_LIBEVENT**, **WITH_LZ4**, **WITH_LZMA**, **WITH_PROTOBUF**, **WITH_RE2**, **WITH_SSL**, **WITH_ZLIB**, **WITH_ZSTD**.

- **-DWITH_TEST_TRACE_PLUGIN=bool**
  
  Whether to build the test protocol trace client plugin (see Using the Test Protocol Trace Plugin). By default, this option is disabled. Enabling this option has no effect unless the **WITH_CLIENT_PROTOCOL_TRACING** option is enabled. If MySQL is configured with both options
enabled, the `libmysqlclient` client library is built with the test protocol trace plugin built in, and all
the standard MySQL clients load the plugin. However, even when the test plugin is enabled, it has no
effect by default. Control over the plugin is afforded using environment variables; see Using the Test
Protocol Trace Plugin.

**Note**

Do not enable the `WITH_TEST_TRACE_PLUGIN` option if you want to use
your own protocol trace plugins because only one such plugin can be loaded
at a time and an error occurs for attempts to load a second one. If you have
already built MySQL with the test protocol trace plugin enabled to see how
it works, you must rebuild MySQL without it before you can use your own
plugins.

For information about writing trace plugins, see Section 29.2.4.11, “Writing Protocol Trace Plugins”.

- **-DWITH_TSAN=bool**
  Whether to enable the ThreadSanitizer, for compilers that support it. The default is off.

- **-DWITH_UBSAN=bool**
  Whether to enable the Undefined Behavior Sanitizer, for compilers that support it. The default is off.

- **-DWITH_UNIT_TESTS={ON|OFF}**
  If enabled, compile MySQL with unit tests. The default is ON unless the server is not being compiled.

- **-DWITH_UNIXODBC=1**
  Enables unixODBC support, for Connector/ODBC.

- **-DWITH_VALGRIND=bool**
  Whether to compile in the Valgrind header files, which exposes the Valgrind API to MySQL code.
The default is OFF.

  To generate a Valgrind-aware debug build, `-DWITH_VALGRIND=1` normally is combined with
  `-DWITH_DEBUG=1`. See Building Debug Configurations.

- **-DWITH_ZLIB=zlib_type**
  Some features require that the server be built with compression library support, such as the
  `COMPRESS()` and `UNCOMPRESS()` functions, and compression of the client/server protocol. The
  `WITH_ZLIB` indicates the source of zlib support:

  - **bundled**: Use the `zlib` library bundled with the distribution. This is the default.

  - **system**: Use the system `zlib` library. If `WITH_ZLIB` is set to this value, the `zlib_decompress`
    utility is not built. In this case, the system `openssl zlib` command can be used instead.

- **-DWITH_ZSTD=stderr_type**
  Connection compression using the `zstd` algorithm (see Section 4.2.6, “Connection Compression
  Control”) requires that the server be built with `zstd` library support. The `WITH_ZSTD` indicates the
  source of `zstd` support:

  - **bundled**: Use the `zstd` library bundled with the distribution. This is the default.

  - **system**: Use the system `zstd` library.

This option was added in MySQL 8.0.18.
MySQL Source-Configuration Options

Compiler Flags

- **-DCMAKE_C_FLAGS=“flags”**
  Flags for the C Compiler.

- **-DCMAKE_CXX_FLAGS=“flags”**
  Flags for the C++ Compiler.

- **-DWITH_DEFAULT_COMPILER_OPTIONS=bool**
  Whether to use the flags from `cmake/build_configurations/compiler_options.cmake`.

**Note**

All optimization flags were carefully chosen and tested by the MySQL build team. Overriding them can lead to unexpected results and is done at your own risk.

To specify your own C and C++ compiler flags, for flags that do not affect optimization, use the `CMAKE_C_FLAGS` and `CMAKE_CXX_FLAGS` CMake options.

When providing your own compiler flags, you might want to specify `CMAKE_BUILD_TYPE` as well.

For example, to create a 32-bit release build on a 64-bit Linux machine, do this:

```bash
mkdir bld
cd bld
make .. -DCMAKE_C_FLAGS=-m32 \
    -DCMAKE_CXX_FLAGS=-m32 \
    -DCMAKE_BUILD_TYPE=RelWithDebInfo
```

If you set flags that affect optimization (`-O` number), you must set the `CMAKE_C_FLAGS_build_type` and/or `CMAKE_CXX_FLAGS_build_type` options, where `build_type` corresponds to the `CMAKE_BUILD_TYPE` value. To specify a different optimization for the default build type (`RelWithDebInfo`) set the `CMAKE_C_FLAGS_RELWITHDEBINFO` and `CMAKE_CXX_FLAGS_RELWITHDEBINFO` options. For example, to compile on Linux with `-O3` and with debug symbols, do this:

```bash
make .. -DCMAKE_C_FLAGS_RELWITHDEBINFO=-O3 -g" \
    -DCMAKE_CXX_FLAGS_RELWITHDEBINFO=-O3 -g"
```

CMake Options for Compiling NDB Cluster

The following options are for use when building MySQL 8.0 sources with NDB Cluster support.

- **-DMEMCACHED_HOME=dir_name**

  Perform the build using the memcached (version 1.6 or later) installed in the system directory indicated by `dir_name`. Files from this installation that are used in the build include the memcached binary, header files, and libraries, as well as the `memcached_utilities` library and the header file `engine_testapp.h`.

  You must leave this option unset when building `ndbmemcache` using the bundled memcached sources (with `WITH_BUNDLED_MEMCACHED` option); in other words, the bundled sources are used by default).

  While additional CMake options—such as for SASL authorization and for providing `dtrace` support—are available for use when compiling `memcached` from external sources, these options are currently not enabled for the `memcached` sources bundled with NDB Cluster.

- **-DWITH_BUNDLED_LIBEVENT={ON|OFF}**
MySQL Source-Configuration Options

Use the `libevent` included in the NDB Cluster sources when building NDB Cluster with `ndbmemcached` support. Enabled by default. `OFF` causes the system's `libevent` to be used instead.

- `--WITH_BUNDLED_MEMCACHED={ON|OFF}`

Build the memcached sources included in the NDB Cluster source tree, then use the resulting memcached server when building the `ndbmemcache` engine. In this case, `make install` places the `memcached` binary in the installation `bin` directory, and the `ndbmemcache` engine shared library file `ndb_engine.so` in the installation `lib` directory.

This option is ON by default.

- `--WITH_CLASSPATH=path`

Sets the classpath for building NDB Cluster Connector for Java. The default is empty. This option is ignored if `--WITH_NDB_JAVA=OFF` is used.

- `--WITH_ERROR_INSERT={ON|OFF}`

Enables error injection in the NDB kernel. For testing only; not intended for use in building production binaries. The default is OFF.

- `--WITH_NDBCLUSTER_STORAGE_ENGINE={ON|OFF}`

This is an alias for `WITH_NDBCLUSTER`.

- `--WITH_NDBCLUSTER={ON|OFF}`

Build and link in support for the NDB (`NDBCLUSTER`) storage engine in `mysqld`. The default is ON.

- `--WITH_NDBMTD={ON|OFF}`

Build the multithreaded data node executable `ndbmtd`. The default is ON.

- `--WITH_NDB_BINLOG={ON|OFF}`

Enable binary logging by default in the `mysqld` built using this option. ON by default.

- `--WITH_NDB_DEBUG={ON|OFF}`

Enable building the debug versions of the NDB Cluster binaries. OFF by default.

- `--WITH_NDB_JAVA={ON|OFF}`

Enable building NDB Cluster with Java support, including `ClusterJ`. This option is ON by default. If you do not wish to compile NDB Cluster with Java support, you must disable it explicitly by specifying `--WITH_NDB_JAVA=OFF` when running `CMake`. Otherwise, if Java cannot be found, configuration of the build fails.

- `--WITH_NDB_PORT=port`

Causes the NDB Cluster management server (`ndb_mgmd`) that is built to use this `port` by default. If this option is unset, the resulting management server tries to use port 1186 by default.

- `--WITH_NDB_TEST={ON|OFF}`

If enabled, include a set of NDB API test programs. The default is OFF.

- `--WITH_PLUGIN_NDBCLUSTER={ON|OFF}`

Alias for `WITH_NDBCLUSTER`. 

2.9.5 Dealing with Problems Compiling MySQL

The solution to many problems involves reconfiguring. If you do reconfigure, take note of the following:

- If CMake is run after it has previously been run, it may use information that was gathered during its previous invocation. This information is stored in CMakeCache.txt. When CMake starts, it looks for that file and reads its contents if it exists, on the assumption that the information is still correct. That assumption is invalid when you reconfigure.

- Each time you run CMake, you must run make again to recompile. However, you may want to remove old object files from previous builds first because they were compiled using different configuration options.

To prevent old object files or configuration information from being used, run the following commands before re-running CMake:

On Unix:

```
shell> make clean
shell> rm CMakeCache.txt
```

On Windows:

```
shell> devenv MySQL.sln /clean
shell> del CMakeCache.txt
```

If you build outside of the source tree, remove and recreate your build directory before re-running CMake. For instructions on building outside of the source tree, see How to Build MySQL Server with CMake.

On some systems, warnings may occur due to differences in system include files. The following list describes other problems that have been found to occur most often when compiling MySQL:

- To define which C and C++ compilers to use, you can define the \texttt{CC} and \texttt{CXX} environment variables. For example:

  ```
  shell> CC=gcc
  shell> CXX=g++
  shell> export CC CXX
  ```

  To specify your own C and C++ compiler flags, use the \texttt{CMAKE_C_FLAGS} and \texttt{CMAKE_CXX_FLAGS} CMake options. See Compiler Flags.

  To see what flags you might need to specify, invoke \texttt{mysql_config} with the \texttt{--cflags} and \texttt{--cxxflags} options.

- To see what commands are executed during the compile stage, after using CMake to configure MySQL, run `make VERBOSE=1` rather than just `make`.

- If compilation fails, check whether the \texttt{MYSQL_MAINTAINER_MODE} option is enabled. This mode causes compiler warnings to become errors, so disabling it may enable compilation to proceed.

- If your compile fails with errors such as any of the following, you must upgrade your version of make to GNU make:

  ```
  make: Fatal error in reader: Makefile, line 18:
  Badly formed macro assignment
  ```

  Or:

  ```
  make: file `Makefile' line 18: Must be a separator (:)
  ```
Or:

```
pthread.h: No such file or directory
```

Solaris and FreeBSD are known to have troublesome `make` programs. GNU `make` 3.75 is known to work.

- The `sql_yacc.cc` file is generated from `sql_yacc.yy`. Normally, the build process does not need to create `sql_yacc.cc` because MySQL comes with a pregenerated copy. However, if you do need to re-create it, you might encounter this error:

```
"sql_yacc.yy", line xxx fatal: default action causes potential...
```

This is a sign that your version of `yacc` is deficient. You probably need to install a recent version of `bison` (the GNU version of `yacc`) and use that instead.

Versions of `bison` older than 1.75 may report this error:

```
sql_yacc.yy:#####: fatal error: maximum table size (32767) exceeded
```

The maximum table size is not actually exceeded; the error is caused by bugs in older versions of `bison`.

For information about acquiring or updating tools, see the system requirements in Section 2.9, “Installing MySQL from Source”.

### 2.9.6 MySQL Configuration and Third-Party Tools

Third-party tools that need to determine the MySQL version from the MySQL source can read the `VERSION` file in the top-level source directory. The file lists the pieces of the version separately. For example, if the version is MySQL 8.0.4-rc, the file looks like this:

```
MYSQL_VERSION_MAJOR=8
MYSQL_VERSION_MINOR=0
MYSQL_VERSION_PATCH=4
MYSQL_VERSION_EXTRA=-rc
```

If the source is not for a General Availability (GA) release, the `MYSQL_VERSION_EXTRA` value will be nonempty. For the example, the value corresponds to Release Candidate.

To construct a five-digit number from the version components, use this formula:

```
MYSQL_VERSION_MAJOR*10000 + MYSQL_VERSION_MINOR*100 + MYSQL_VERSION_PATCH
```

### 2.9.7 Generating MySQL Doxygen Documentation Content

The MySQL source code contains internal documentation written using Doxygen. The generated Doxygen content is available at [https://dev.mysql.com/doc/index-other.html](https://dev.mysql.com/doc/index-other.html). It is also possible to generate this content locally from a MySQL source distribution using the following procedure:

1. Install `doxygen` 1.8.11 or higher. Distributions are available here:

```
http://www.stack.nl/~dimitri/doxygen/download.html
```

After installing `doxygen`, verify the version number:
2. Install PlantUML. Distributions are available here:

http://plantuml.com/download.html

When you install PlantUML on Windows (tested on Windows 10), you must run it at least once as administrator so it creates the registry keys. Open an administrator console and run this command:

```
java -jar path-to-plantuml.jar
```

The command should open a GUI window and return no errors on the console.

3. Install the Graphviz `dot` command. Distributions are available here:

http://www.graphviz.org/

After installing Graphviz, verify `dot` availability. For example:

```
shell> which dot
/usr/bin/dot
shell> dot -V
dot - graphviz version 2.28.0 (20130928.0220)
```

4. Set the `PLANTUML_JAR_PATH` environment to the location where you installed PlantUML. For example:

```
export PLANTUML_JAR_PATH=path-to-plantuml.jar
```

5. To invoke `doxygen`, change location to the top-level directory of your MySQL source distribution and execute these commands:

```
mkdir -p generated/doxygen
doxygen
```

Inspect the error log. It is available in the `doxyerror.log` file in the top-level directory. Assuming that the build executed successfully, view the generated output using a browser. For example:

```
firefox generated/doxygen/html/index.html
```

You can use a different browser, and even bookmark the page.

### 2.10 Postinstallation Setup and Testing

This section discusses tasks that you should perform after installing MySQL:

- If necessary, initialize the data directory and create the MySQL grant tables. For some MySQL installation methods, data directory initialization may be done for you automatically:
  - Windows installation operations performed by MySQL Installer.
  - Installation on Linux using a server RPM or Debian distribution from Oracle.
  - Installation using the native packaging system on many platforms, including Debian Linux, Ubuntu Linux, Gentoo Linux, and others.
  - Installation on macOS using a DMG distribution.
For other platforms and installation types, you must initialize the data directory manually. These include installation from generic binary and source distributions on Unix and Unix-like system, and installation from a ZIP Archive package on Windows. For instructions, see Section 2.10.1, “Initializing the Data Directory”:

- Start the server and make sure that it can be accessed. For instructions, see Section 2.10.2, “Starting the Server”, and Section 2.10.3, “Testing the Server”.

- Assign passwords to the initial root account in the grant tables, if that was not already done during data directory initialization. Passwords prevent unauthorized access to the MySQL server. For instructions, see Section 2.10.4, “Securing the Initial MySQL Account”.

- Optionally, arrange for the server to start and stop automatically when your system starts and stops. For instructions, see Section 2.10.5, “Starting and Stopping MySQL Automatically”.

- Optionally, populate time zone tables to enable recognition of named time zones. For instructions, see Section 5.1.13, “MySQL Server Time Zone Support”.

When you are ready to create additional user accounts, you can find information on the MySQL access control system and account management in Section 6.2, “Access Control and Account Management”.

### 2.10.1 Initializing the Data Directory

After MySQL is installed, the data directory must be initialized, including the tables in the mysql system schema:

- For some MySQL installation methods, data directory initialization is automatic, as described in Section 2.10, “Postinstallation Setup and Testing”.

- For other installation methods, you must initialize the data directory manually. These include installation from generic binary and source distributions on Unix and Unix-like systems, and installation from a ZIP Archive package on Windows.

This section describes how to initialize the data directory manually for MySQL installation methods for which data directory initialization is not automatic. For some suggested commands that enable testing whether the server is accessible and working properly, see Section 2.10.3, “Testing the Server”.

**Note**

In MySQL 8.0, the default authentication plugin has changed from mysql_native_password to caching_sha2_password, and the 'root'@'localhost' administrative account uses caching_sha2_password by default. If you prefer that the root account use the previous default authentication plugin (mysql_native_password), see caching_sha2_password and the root Administrative Account.

- Data Directory Initialization Overview
- Data Directory Initialization Procedure
- Server Actions During Data Directory Initialization
- Post-Initialization root Password Assignment

**Data Directory Initialization Overview**

In the examples shown here, the server is intended to run under the user ID of the mysql login account. Either create the account if it does not exist (see Create a mysql User and Group), or substitute the name of a different existing login account that you plan to use for running the server.
1. Change location to the top-level directory of your MySQL installation, which is typically `/usr/local/mysql` (adjust the path name for your system as necessary):

   ```
cd /usr/local/mysql
   
   Within the directory you will find several files and subdirectories, including the bin subdirectory that contains the server as well as client and utility programs.
```

2. The `secure_file_priv` system variable limits import and export operations to a specific directory. Create a directory whose location can be specified as the value of that variable:

   ```
   mkdir mysql-files
   
   Grant directory user and group ownership to the mysql user and mysql group, and set the directory permissions appropriately:
   
   chown mysql:mysql mysql-files
   chmod 750 mysql-files
   ```

3. Use the server to initialize the data directory, including the mysql schema containing the initial MySQL grant tables that determine how users are permitted to connect to the server. For example:

   ```
   bin/mysqld --initialize --user=mysql
   
   For important information about the command, especially regarding command options you might use, see Data Directory Initialization Procedure. For details about how the server performs initialization, see Server Actions During Data Directory Initialization.
   
   Typically, data directory initialization need be done only after you first install MySQL. (For upgrades to an existing installation, perform the upgrade procedure instead; see Section 2.11, "Upgrading MySQL".) However, the command that initializes the data directory does not overwrite any existing mysql schema tables, so it is safe to run in any circumstances.
```

4. If you want to deploy the server with automatic support for secure connections, use the `mysql_ssl_rsa_setup` utility to create default SSL and RSA files:

   ```
   bin/mysql_ssl_rsa_setup
   
   For more information, see Section 4.4.3, "mysql_ssl_rsa_setup — Create SSL/RSA Files".
```

5. In the absence of any option files, the server starts with its default settings. (See Section 5.1.2, "Server Configuration Defaults"). To explicitly specify options that the MySQL server should use at startup, put them in an option file such as `/etc/my.cnf` or `/etc/mysql/my.cnf`. (See Section 4.2.2.2, "Using Option Files"). For example, you can use an option file to set the `secure_file_priv` system variable.

6. To arrange for MySQL to start without manual intervention at system boot time, see Section 2.10.5, "Starting and Stopping MySQL Automatically".

7. Data directory initialization creates time zone tables in the mysql schema but does not populate them. To do so, use the instructions in Section 5.1.13, "MySQL Server Time Zone Support".

**Data Directory Initialization Procedure**

Change location to the top-level directory of your MySQL installation, which is typically `/usr/local/mysql` (adjust the path name for your system as necessary):

```
cd /usr/local/mysql
```
To initialize the data directory, invoke `mysqld` with the `--initialize` or `--initialize-insecure` option, depending on whether you want the server to generate a random initial password for the `root'@'localhost` account, or to create that account with no password:

- Use `--initialize` for "secure by default" installation (that is, including generation of a random initial root password). In this case, the password is marked as expired and you will need to choose a new one.

- With `--initialize-insecure`, no root password is generated. This is insecure; it is assumed that you will assign a password to the account in timely fashion before putting the server into production use.

For instructions on assigning a new `root'@'localhost` password, see Post-Initialization root Password Assignment.

**Note**

The server writes any messages (including any initial password) to its standard error output. This may be redirected to the error log, so look there if you do not see the messages on your screen. For information about the error log, including where it is located, see Section 5.4.2, "The Error Log".

On Windows, use the `--console` option to direct messages to the console.

On Unix and Unix-like systems, it is important for the database directories and files to be owned by the `mysql` login account so that the server has read and write access to them when you run it later. To ensure this, start `mysqld` from the system root account and include the `--user` option as shown here:

```
bin/mysqld --initialize --user=mysql
bin/mysqld --initialize-insecure --user=mysql
```

Alternatively, execute `mysqld` while logged in as `mysql`, in which case you can omit the `--user` option from the command.

On Windows, use one of these commands:

```
bin\mysqld --initialize --console
bin\mysqld --initialize-insecure --console
```

**Note**

Data directory initialization might fail if required system libraries are missing. For example, you might see an error like this:

```
bin/mysqld: error while loading shared libraries:
libnuma.so.1: cannot open shared object file:
No such file or directory
```

If this happens, you must install the missing libraries manually or with your system's package manager. Then retry the data directory initialization command.

It might be necessary to specify other options such as `--basedir` or `--datadir` if `mysqld` cannot identify the correct locations for the installation directory or data directory. For example (enter the command on a single line):

```
bin/mysqld --initialize --user=mysql
--basedir=/opt/mysql/mysql
--datadir=/opt/mysql/mysql/data
```
Initializing the Data Directory

Alternatively, put the relevant option settings in an option file and pass the name of that file to `mysqld`. For Unix and Unix-like systems, suppose that the option file name is `/opt/mysql/mysql/etc/my.cnf`. Put these lines in the file:

```ini
[mysqld]
basedir=/opt/mysql/mysql
datadir=/opt/mysql/mysql/data
```

Then invoke `mysqld` as follows (enter the command on a single line with the `--defaults-file` option first):

```bash
bin/mysqld --defaults-file=/opt/mysql/mysql/etc/my.cnf
   --initialize --user=mysql
```

On Windows, suppose that `C:\my.ini` contains these lines:

```ini
[mysqld]
basedir=C:\Program Files\MySQL\MySQL Server 8.0
datadir=D:\MySQLdata
```

Then invoke `mysqld` as follows (enter the command on a single line with the `--defaults-file` option first):

```bash
bin\mysqld --defaults-file=C:\my.ini
   --initialize --console
```

Server Actions During Data Directory Initialization

**Note**

The data directory initialization sequence performed by the server does not substitute for the actions performed by `mysql_secure_installation` and `mysql_ssl_rsa_setup`. See Section 4.4.2, "mysql_secure_installation — Improve MySQL Installation Security", and Section 4.4.3, "mysql_ssl_rsa_setup — Create SSL/RSA Files".

When invoked with the `--initialize` or `--initialize-insecure` option, `mysqld` performs the following actions during the data directory initialization sequence:

1. The server checks for the existence of the data directory as follows:
   - If no data directory exists, the server creates it.
   - If the data directory exists but is not empty (that is, it contains files or subdirectories), the server exits after producing an error message:

   ```shell
   [ERROR] --initialize specified but the data directory exists. Aborting.
   ```
   
   In this case, remove or rename the data directory and try again.
   
   An existing data directory is permitted to be nonempty if every entry has a name that begins with a period (`.`).

2. Within the data directory, the server creates the `mysql` system schema and its tables, including the data dictionary tables, grant tables, time zone tables, and server-side help tables. See Section 5.3, "The mysql System Schema".

3. The server initializes the `system tablespace` and related data structures needed to manage InnoDB tables.
Note

After `mysqld` sets up the InnoDB system tablespace, certain changes to tablespace characteristics require setting up a whole new instance. Qualifying changes include the file name of the first file in the system tablespace and the number of undo logs. If you do not want to use the default values, make sure that the settings for the `innodb_data_file_path` and `innodb_log_file_size` configuration parameters are in place in the MySQL configuration file before running `mysqld`. Also make sure to specify as necessary other parameters that affect the creation and location of InnoDB files, such as `innodb_data_home_dir` and `innodb_log_group_home_dir`.

If those options are in your configuration file but that file is not in a location that MySQL reads by default, specify the file location using the `--defaults-extra-file` option when you run `mysqld`.

4. The server creates a 'root'@'localhost' superuser account and other reserved accounts (see Section 6.2.9, “Reserved Accounts”). Some reserved accounts are locked and cannot be used by clients, but 'root'@'localhost' is intended for administrative use and you should assign it a password.

Server actions with respect to a password for the 'root'@'localhost' account depend on how you invoke it:

- With `--initialize` but not `--initialize-insecure`, the server generates a random password, marks it as expired, and writes a message displaying the password:

```
[Warning] A temporary password is generated for root@localhost:
iTag*AfrHSej
```

- With `--initialize-insecure`, (either with or without `--initialize` because `--initialize-insecure` implies `--initialize`), the server does not generate a password or mark it expired, and writes a warning message:

```
[Warning] root@localhost is created with an empty password ! Please consider switching off the --initialize-insecure option.
```

For instructions on assigning a new 'root'@'localhost' password, see Post-Initialization root Password Assignment.

5. The server populates the server-side help tables used for the `HELP` statement (see Section 13.8.3, “HELP Syntax”). The server does not populate the time zone tables. To do so manually, see Section 5.1.13, “MySQL Server Time Zone Support”.

6. If the `--init-file` option was given to name a file of SQL statements, the server executes the statements in the file. This option enables you to perform custom bootstrapping sequences. When the server operates in bootstrap mode, some functionality is unavailable that limits the statements permitted in the file. These include statements that relate to account management (such as `CREATE USER` or `GRANT`), replication, and global transaction identifiers.

7. The server exits.

Post-Initialization root Password Assignment

After you initialize the data directory by starting the server with `--initialize` or `--initialize-insecure`, start the server normally (that is, without either of those options) and assign the 'root'@'localhost' account a new password:
1. Start the server. For instructions, see Section 2.10.2, “Starting the Server”.

2. Connect to the server:
   
   • If you used `--initialize` but not `--initialize-insecure` to initialize the data directory, connect to the server as `root`:
     
     ```
     mysql -u root -p
     ```
     
     Then, at the password prompt, enter the random password that the server generated during the initialization sequence:
     
     ```
     Enter password: (enter the random root password here)
     ```
     
     Look in the server error log if you do not know this password.
   
   • If you used `--initialize-insecure` to initialize the data directory, connect to the server as `root` without a password:
     
     ```
     mysql -u root --skip-password
     ```
     
3. After connecting, use an `ALTER USER` statement to assign a new `root` password:

   ```
   ALTER USER 'root'@'localhost' IDENTIFIED BY 'root-password';
   ```

   See also Section 2.10.4, “Securing the Initial MySQL Account”.

   **Note**

   Attempts to connect to the host `127.0.0.1` normally resolve to the `localhost` account. However, this fails if the server is run with the `--skip-name-resolve` option. If you plan to do that, make sure that an account exists that can accept a connection. For example, to be able to connect as `root` using `--host=127.0.0.1` or `--host=::1`, create these accounts:

   ```
   CREATE USER 'root'@'127.0.0.1' IDENTIFIED BY 'root-password';
   CREATE USER 'root'@'::1' IDENTIFIED BY 'root-password';
   ```

   It is possible to put those statements in a file to be executed by the `--init-file` option discussed in Server Actions During Data Directory Initialization.

### 2.10.2 Starting the Server

This section describes how start the server on Unix and Unix-like systems. (For Windows, see Section 2.3.5.5, “Starting the Server for the First Time”.) For some suggested commands that you can use to test whether the server is accessible and working properly, see Section 2.10.3, “Testing the Server”.

Start the MySQL server like this if your installation includes `mysqld_safe`:

```shell
shell> bin/mysqld_safe --user=mysql &
```
Start the server like this if your installation includes systemd support:

```
shell> systemctl start mysqld
```

Substitute the appropriate service name if it differs from `mysqld` (for example, `mysql` on SLES systems).

It is important that the MySQL server be run using an unprivileged (non-root) login account. To ensure this, run `mysqld_safe` as `root` and include the `--user` option as shown. Otherwise, you should execute the program while logged in as `mysql`, in which case you can omit the `--user` option from the command.

For further instructions for running MySQL as an unprivileged user, see Section 6.1.5, “How to Run MySQL as a Normal User”.

If the command fails immediately and prints `mysqld ended`, look for information in the error log (which by default is the `host_name.err` file in the data directory).

If the server is unable to access the data directory it starts or read the grant tables in the `mysql` schema, it writes a message to its error log. Such problems can occur if you neglected to create the grant tables by initializing the data directory before proceeding to this step, or if you ran the command that initializes the data directory without the `--user` option. Remove the data directory and run the command with the `--user` option.

If you have other problems starting the server, see Section 2.10.2.1, “Troubleshooting Problems Starting the MySQL Server”. For more information about `mysqld_safe`, see Section 4.3.2, “mysqld_safe — MySQL Server Startup Script”. For more information about systemd support, see Section 2.5.9, “Managing MySQL Server with systemd”.

### 2.10.2.1 Troubleshooting Problems Starting the MySQL Server

This section provides troubleshooting suggestions for problems starting the server. For additional suggestions for Windows systems, see Section 2.3.6, “Troubleshooting a Microsoft Windows MySQL Server Installation”.

If you have problems starting the server, here are some things to try:

- Check the error log to see why the server does not start. Log files are located in the data directory (typically `C:\Program Files\MySQL\MySQL Server 8.0\data` on Windows, `/usr/local/mysql/data` for a Unix/Linux binary distribution, and `/usr/local/var` for a Unix/Linux source distribution). Look in the data directory for files with names of the form `host_name.err` and `host_name.log`, where `host_name` is the name of your server host. Then examine the last few lines of these files. Use `tail` to display them:

  ```
  shell> tail host_name.err
  shell> tail host_name.log
  ```

- Specify any special options needed by the storage engines you are using. You can create a `my.cnf` file and specify startup options for the engines that you plan to use. If you are going to use storage engines that support transactional tables (InnoDB, NDB), be sure that you have them configured the way you want before starting the server. If you are using InnoDB tables, see Section 15.8, “InnoDB Configuration” for guidelines and Section 15.13, “InnoDB Startup Options and System Variables” for option syntax.

  Although storage engines use default values for options that you omit, Oracle recommends that you review the available options and specify explicit values for any options whose defaults are not appropriate for your installation.

- Make sure that the server knows where to find the data directory. The `mysqld` server uses this directory as its current directory. This is where it expects to find databases and where it expects to write log files. The server also writes the pid (process ID) file in the data directory.
Starting the Server

The default data directory location is hardcoded when the server is compiled. To determine what the default path settings are, invoke `mysqld` with the `--verbose` and `--help` options. If the data directory is located somewhere else on your system, specify that location with the `--datadir` option to `mysqld` or `mysqld_safe`, on the command line or in an option file. Otherwise, the server will not work properly. As an alternative to the `--datadir` option, you can specify `mysqld` the location of the base directory under which MySQL is installed with the `--basedir`, and `mysqld` looks for the data directory there.

To check the effect of specifying path options, invoke `mysqld` with those options followed by the `--verbose` and `--help` options. For example, if you change location to the directory where `mysqld` is installed and then run the following command, it shows the effect of starting the server with a base directory of `/usr/local`:

```
shell> ./mysqld --basedir=/usr/local --verbose --help
```

You can specify other options such as `--datadir` as well, but `--verbose` and `--help` must be the last options.

Once you determine the path settings you want, start the server without `--verbose` and `--help`.

If `mysqld` is currently running, you can find out what path settings it is using by executing this command:

```
shell> mysqladmin variables
```

Or:

```
shell> mysqladmin -h host_name variables
```

`host_name` is the name of the MySQL server host.

- Make sure that the server can access the data directory. The ownership and permissions of the data directory and its contents must allow the server to read and modify them.

If you get `Errcode 13` (which means `Permission denied`) when starting `mysqld`, this means that the privileges of the data directory or its contents do not permit server access. In this case, you change the permissions for the involved files and directories so that the server has the right to use them. You can also start the server as `root`, but this raises security issues and should be avoided.

Change location to the data directory and check the ownership of the data directory and its contents to make sure the server has access. For example, if the data directory is `/usr/local/mysql/var`, use this command:

```
shell> ls -la /usr/local/mysql/var
```

If the data directory or its files or subdirectories are not owned by the login account that you use for running the server, change their ownership to that account. If the account is named `mysql`, use these commands:

```
shell> chown -R mysql /usr/local/mysql/var
shell> chgrp -R mysql /usr/local/mysql/var
```

Even with correct ownership, MySQL might fail to start up if there is other security software running on your system that manages application access to various parts of the file system. In this case, reconfigure that software to enable `mysqld` to access the directories it uses during normal operation.

- Verify that the network interfaces the server wants to use are available.
If either of the following errors occur, it means that some other program (perhaps another mysqld server) is using the TCP/IP port or Unix socket file that mysqld is trying to use:

- Can't start server: Bind on TCP/IP port: Address already in use
- Can't start server: Bind on unix socket...

Use `ps` to determine whether you have another mysqld server running. If so, shut down the server before starting mysqld again. (If another server is running, and you really want to run multiple servers, you can find information about how to do so in Section 5.8, “Running Multiple MySQL Instances on One Machine”.)

If no other server is running, execute the command `telnet your_host_name tcp_ip_port_number` (The default MySQL port number is 3306.) Then press Enter a couple of times. If you do not get an error message like `telnet: Unable to connect to remote host: Connection refused`, some other program is using the TCP/IP port that mysqld is trying to use. Track down what program this is and disable it, or tell mysqld to listen to a different port with the --port option. In this case, specify the same non-default port number for client programs when connecting to the server using TCP/IP.

Another reason the port might be inaccessible is that you have a firewall running that blocks connections to it. If so, modify the firewall settings to permit access to the port.

If the server starts but you cannot connect to it, make sure that you have an entry in `/etc/hosts` that looks like this:

```
127.0.0.1   localhost
```

- If you cannot get mysqld to start, try to make a trace file to find the problem by using the --debug option. See Section 29.5.4, “The DBUG Package”.

### 2.10.3 Testing the Server

After the data directory is initialized and you have started the server, perform some simple tests to make sure that it works satisfactorily. This section assumes that your current location is the MySQL installation directory and that it has a `bin` subdirectory containing the MySQL programs used here. If that is not true, adjust the command path names accordingly.

Alternatively, add the `bin` directory to your PATH environment variable setting. That enables your shell (command interpreter) to find MySQL programs properly, so that you can run a program by typing only its name, not its path name. See Section 4.2.7, “Setting Environment Variables”.

Use `mysqladmin` to verify that the server is running. The following commands provide simple tests to check whether the server is up and responding to connections:

```
shell> bin/mysqladmin version
shell> bin/mysqladmin variables
```

If you cannot connect to the server, specify a `-u root` option to connect as root. If you have assigned a password for the root account already, you'll also need to specify `-p` on the command line and enter the password when prompted. For example:

```
shell> bin/mysqladmin -u root -p version
Enter password: (enter root password here)
```

The output from `mysqladmin version` varies slightly depending on your platform and version of MySQL, but should be similar to that shown here:
Testing the Server

shell> `bin/mysqladmin version`
mysqladmin  Ver 14.12 Distrib 8.0.18, for pc-linux-gnu on i686
...
Server version  8.0.18
Protocol version  10
Connection  Localhost via UNIX socket
UNIX socket  /var/lib/mysql/mysql.sock
Uptime:  14 days 5 hours 5 min 21 sec

Threads: 1  Questions: 366  Slow queries: 0
Opens: 0  Flush tables: 1  Open tables: 19
Queries per second avg: 0.000

To see what else you can do with `mysqladmin`, invoke it with the `--help` option.

Verify that you can shut down the server (include a `-p` option if the root account has a password already):

shell> `bin/mysqladmin -u root shutdown`

Verify that you can start the server again. Do this by using `mysqld_safe` or by invoking `mysqld` directly. For example:

shell> `bin/mysqld_safe --user=mysql &`

If `mysqld_safe` fails, see Section 2.10.2.1, “Troubleshooting Problems Starting the MySQL Server”.

Run some simple tests to verify that you can retrieve information from the server. The output should be similar to that shown here.

Use `mysqlshow` to see what databases exist:

shell> `bin/mysqlshow`
+--------------------+
|     Databases      |
+--------------------+
| information_schema |
| mysql              |
| performance_schema |
| sys                |
+--------------------+

The list of installed databases may vary, but always includes at least `mysql` and `information_schema`.

If you specify a database name, `mysqlshow` displays a list of the tables within the database:

shell> `bin/mysqlshow mysql`
Database: mysql
+---------------------------+
|          Tables           |
+---------------------------+
| columns_priv              |
| component                 |
| db                        |
| default_roles             |
| engine_cost               |
| func                      |
| general_log               |
| global_grants             |
| gtid_executed             |
| help_category             |
| help_keyword              |
Securing the Initial MySQL Account

Use the `mysql` program to select information from a table in the `mysql` schema:

```shell
shell> bin/mysql -e "SELECT User, Host, plugin FROM mysql.user" mysql
```

<table>
<thead>
<tr>
<th>User</th>
<th>Host</th>
<th>plugin</th>
</tr>
</thead>
<tbody>
<tr>
<td>root</td>
<td>localhost</td>
<td>caching_sha2_password</td>
</tr>
</tbody>
</table>

At this point, your server is running and you can access it. To tighten security if you have not yet assigned a password to the initial account, follow the instructions in Section 2.10.4, “Securing the Initial MySQL Account”.

For more information about `mysql`, `mysqladmin`, and `mysqlshow`, see Section 4.5.1, “mysql — The MySQL Command-Line Client”, Section 4.5.2, “mysqladmin — Client for Administering a MySQL Server”, and Section 4.5.7, “mysqlshow — Display Database, Table, and Column Information”.

2.10.4 Securing the Initial MySQL Account

The MySQL installation process involves initializing the data directory, including the grant tables in the `mysql` system schema that define MySQL accounts. For details, see Section 2.10.1, “Initializing the Data Directory”.

This section describes how to assign a password to the initial `root` account created during the MySQL installation procedure, if you have not already done so.

**Note**

Alternative means for performing the process described in this section:

- On Windows, you can perform the process during installation with MySQL Installer (see Section 2.3.3, “MySQL Installer for Windows”).

- On all platforms, the MySQL distribution includes `mysql_secure_installation`, a command-line utility that automates much of the process of securing a MySQL installation.

- On all platforms, MySQL Workbench is available and offers the ability to manage user accounts (see Chapter 31, *MySQL Workbench*).
Securing the Initial MySQL Account

A password may already be assigned to the initial account under these circumstances:

- On Windows, installations performed using MySQL Installer give you the option of assigning a password.
- Installation using the macOS installer generates an initial random password, which the installer displays to the user in a dialog box.
- Installation using RPM packages generates an initial random password, which is written to the server error log.
- Installations using Debian packages give you the option of assigning a password.
- For data directory initialization performed manually using `mysqld --initialize`, `mysqld` generates an initial random password, marks it expired, and writes it to the server error log. See Section 2.10.1, “Initializing the Data Directory”.

The `mysql.user` grant table defines the initial MySQL user account and its access privileges. Installation of MySQL creates only a `'root'@'localhost'` superuser account that has all privileges and can do anything. If the `root` account has an empty password, your MySQL installation is unprotected: Anyone can connect to the MySQL server as `root` without a password and be granted all privileges.

The `'root'@'localhost'` account also has a row in the `mysql.proxies_priv` table that enables granting the `PROXY` privilege for `''@''`, that is, for all users and all hosts. This enables `root` to set up proxy users, as well as to delegate to other accounts the authority to set up proxy users. See Section 6.2.18, “Proxy Users”.

To assign a password for the initial MySQL `root` account, use the following procedure. Replace `root-password` in the examples with the password that you want to use.

Start the server if it is not running. For instructions, see Section 2.10.2, “Starting the Server”.

The initial `root` account may or may not have a password. Choose whichever of the following procedures applies:

- If the `root` account exists with an initial random password that has been expired, connect to the server as `root` using that password, then choose a new password. This is the case if the data directory was initialized using `mysqld --initialize`, either manually or using an installer that does not give you the option of specifying a password during the install operation. Because the password exists, you must use it to connect to the server. But because the password is expired, you cannot use the account for any purpose other than to choose a new password, until you do choose one.
  1. If you do not know the initial random password, look in the server error log.
  2. Connect to the server as `root` using the password:

```bash
shell> mysql -u root -p
Enter password: (enter the random root password here)
```

  3. Choose a new password to replace the random password:

```bash
mysql> ALTER USER 'root'@'localhost' IDENTIFIED BY 'root-password';
```

- If the `root` account exists but has no password, connect to the server as `root` using no password, then assign a password. This is the case if you initialized the data directory using `mysqld --initialize-insecure`.
  1. Connect to the server as `root` using no password:
Starting and Stopping MySQL Automatically

2. Assign a password:

After assigning the root account a password, you must supply that password whenever you connect to the server using the account. For example, to connect to the server using the mysql client, use this command:

```
shell> mysql -u root -p
Enter password: (enter root password here)
```

To shut down the server with mysqladmin, use this command:

```
shell> mysqladmin -u root -p shutdown
Enter password: (enter root password here)
```

Note

For additional information about setting passwords, see Section 6.2.14, “Assigning Account Passwords”. If you forget your root password after setting it, see Section B.4.3.2, “How to Reset the Root Password”.

To set up additional accounts, see Section 6.2.8, “Adding Accounts, Assigning Privileges, and Dropping Accounts”.

2.10.5 Starting and Stopping MySQL Automatically

This section discusses methods for starting and stopping the MySQL server.

Generally, you start the mysql server in one of these ways:

- Invoke mysqld directly. This works on any platform.
- On Windows, you can set up a MySQL service that runs automatically when Windows starts. See Section 2.3.5.8, “Starting MySQL as a Windows Service”.
- On Unix and Unix-like systems, you can invoke mysqld_safe, which tries to determine the proper options for mysqld and then runs it with those options. See Section 4.3.2, "mysqld_safe — MySQL Server Startup Script".
- On Linux systems that support systemd, you can use it to control the server. See Section 2.5.9, “Managing MySQL Server with systemd”.
- On systems that use System V-style run directories (that is, /etc/init.d and run-level specific directories), invoke mysql.server. This script is used primarily at system startup and shutdown. It usually is installed under the name mysql. The mysql.server script starts the server by invoking mysqld_safe. See Section 4.3.3, "mysql.server — MySQL Server Startup Script".
- On macOS, install a launchd daemon to enable automatic MySQL startup at system startup. The daemon starts the server by invoking mysqld_safe. For details, see Section 2.4.3, “Installing and Using the MySQL Launch Daemon”. A MySQL Preference Pane also provides control for starting and stopping MySQL through the System Preferences. See Section 2.4.4, “Installing and Using the MySQL Preference Pane”.
- On Solaris, use the service management framework (SMF) system to initiate and control MySQL startup.
systemd, the `mysqld_safe` and `mysql.server` scripts, Solaris SMF, and the macOS Startup Item (or MySQL Preference Pane) can be used to start the server manually, or automatically at system startup time. systemd, `mysql.server`, and the Startup Item also can be used to stop the server. The following table shows which option groups the server and startup scripts read from option files.

Table 2.14 MySQL Startup Scripts and Supported Server Option Groups

<table>
<thead>
<tr>
<th>Script</th>
<th>Option Groups</th>
</tr>
</thead>
<tbody>
<tr>
<td>mysqld</td>
<td>[mysqld], [server], [mysqld-major_version]</td>
</tr>
<tr>
<td>mysql_safe</td>
<td>[mysqld], [server], [mysqld_safe]</td>
</tr>
<tr>
<td>mysql.server</td>
<td>[mysqld], [mysql.server], [server]</td>
</tr>
</tbody>
</table>

[mysqld-major_version] means that groups with names like [mysqld-5.7] and [mysqld-8.0] are read by servers having versions 5.7.x, 8.0.x, and so forth. This feature can be used to specify options that can be read only by servers within a given release series.

For backward compatibility, `mysql.server` also reads the [mysql_server] group and `mysqld_safe` also reads the [safe_mysqld] group. To be current, you should update your option files to use the [mysql.server] and [mysqld_safe] groups instead.

For more information on MySQL configuration files and their structure and contents, see Section 4.2.2.2, “Using Option Files”.

2.11 Upgrading MySQL

This section describes the steps to upgrade a MySQL installation. Upgrading is a common procedure, as you pick up bug fixes within the same MySQL release series or significant features between major MySQL releases. You perform this procedure first on some test systems to make sure everything works smoothly, and then on the production systems.

Note

In the following discussion, MySQL commands that must be run using a MySQL account with administrative privileges include `-u root` on the command line to specify the MySQL root user. Commands that require a password for root also include a -p option. Because -p is followed by no option value, such commands prompt for the password. Type the password when prompted and press Enter.

SQL statements can be executed using the `mysql` command-line client (connect as root to ensure that you have the necessary privileges).

2.11.1 Before You Begin

Review the information in this section before upgrading. Perform any recommended actions.

- Understand what may occur during an upgrade. See Section 2.11.3, “What the MySQL Upgrade Process Upgrades”.

- Protect your data by creating a backup. The backup should include the `mysql` system database, which contains the MySQL data dictionary tables and system tables. See Section 7.2, “Database Backup Methods”.

Important

Downgrade from MySQL 8.0 to MySQL 5.7, or from a MySQL 8.0 release to a previous MySQL 8.0 release, is not supported. The only supported alternative
is to restore a backup taken before upgrading. It is therefore imperative that you backup your data before starting the upgrade process.

- Review Section 2.11.2, “Upgrade Paths” to ensure that your intended upgrade path is supported.
- Review Section 2.11.4, “Changes in MySQL 8.0” for changes that you should be aware of before upgrading. Some changes may require action.
- Review Section 1.4, “What Is New in MySQL 8.0” for deprecated and removed features. An upgrade may require changes with respect to those features if you use any of them.
- Review Section 1.5, “Server and Status Variables and Options Added, Deprecated, or Removed in MySQL 8.0”. If you use deprecated or removed variables, an upgrade may require configuration changes.
- Review the Release Notes for information about fixes, changes, and new features.
- If you use replication, review Section 17.4.3, “Upgrading a Replication Setup”.

Upgrade procedures vary by platform and how the initial installation was performed. Use the procedure that applies to your current MySQL installation:

- For binary and package-based installations on non-Windows platforms, refer to Section 2.11.6, “Upgrading MySQL Binary or Package-based Installations on Unix/Linux”.

Note
For supported Linux distributions, the preferred method for upgrading package-based installations is to use the MySQL software repositories (MySQL Yum Repository, MySQL APT Repository, and MySQL SLES Repository).

- For installations on an Enterprise Linux platform or Fedora using the MySQL Yum Repository, refer to Section 2.11.7, “Upgrading MySQL with the MySQL Yum Repository”.
- For installations on Ubuntu using the MySQL APT repository, refer to Section 2.11.8, “Upgrading MySQL with the MySQL APT Repository”.
- For installations on SLES using the MySQL SLES repository, refer to Section 2.11.9, “Upgrading MySQL with the MySQL SLES Repository”.
- For installations performed using Docker, refer to Section 2.11.11, “Upgrading a Docker Installation of MySQL”.
- For installations on Windows, refer to Section 2.11.10, “Upgrading MySQL on Windows”.

If your MySQL installation contains a large amount of data that might take a long time to convert after an in-place upgrade, it may be useful to create a test instance for assessing the conversions that are required and the work involved to perform them. To create a test instance, make a copy of your MySQL instance that contains the mysql database and other databases without the data. Run the upgrade procedure on the test instance to assess the work involved to perform the actual data conversion.

Rebuilding and reinstalling MySQL language interfaces is recommended when you install or upgrade to a new release of MySQL. This applies to MySQL interfaces such as PHP mysql extensions and the Perl DBD::mysql module.

2.11.2 Upgrade Paths

- Upgrade from MySQL 5.7 to 8.0 is supported. However, upgrade is only supported between General Availability (GA) releases. For MySQL 8.0, it is required that you upgrade from a MySQL 5.7 GA release (5.7.9 or higher). Upgrades from non-GA releases of MySQL 5.7 are not supported.
• Upgrading to the latest release is recommended before upgrading to the next version. For example, upgrade to the latest MySQL 5.7 release before upgrading to MySQL 8.0.

• Upgrade that skips versions is not supported. For example, upgrading directly from MySQL 5.6 to 8.0 is not supported.

• Once a release series reaches General Availability (GA) status, upgrade within the release series (from one GA version to another GA version) is supported. For example, upgrading from MySQL 8.0.x to 8.0.y is supported. (Upgrade involving development-status non-GA releases is not supported.) Skipping a release is also supported. For example, upgrading from MySQL 8.0.x to 8.0.z is supported. MySQL 8.0.11 is the first GA status release within the MySQL 8.0 release series.

2.11.3 What the MySQL Upgrade Process Upgrades

Installing a new version of MySQL may require upgrading these parts of the existing installation:

• The `mysql` system schema, which contains tables that store information required by the MySQL server as it runs (see Section 5.3, “The mysql System Schema”). `mysql` schema tables fall into two broad categories:
  • Data dictionary tables, which store database object metadata.
  • System tables (that is, the remaining non-data dictionary tables), which are used for other operational purposes.

• Other schemas, some of which are built in and may be considered “owned” by the server, and others which are not:
  • The Performance Schema, `INFORMATION_SCHEMA`, and `sys` schema.
  • User schemas.

Two distinct version numbers are associated with parts of the installation that may require upgrading:

• The data dictionary version. This applies to the data dictionary tables.

• The server version, also known as the MySQL version. This applies to the system tables and objects in other schemas.

In both cases, the actual version applicable to the existing MySQL installation is stored in the data dictionary, and the current expected version is compiled into the new version of MySQL. When an actual version is lower than the current expected version, those parts of the installation associated with that version must be upgraded to the current version. If both versions indicate an upgrade is needed, the data dictionary upgrade must occur first.

As a reflection of the two distinct versions just mentioned, the upgrade occurs in two steps:

• Step 1: Data dictionary upgrade.
  
  This step upgrades:
  • The data dictionary tables in the `mysql` schema. If the actual data dictionary version is lower than the current expected version, the server creates data dictionary tables with updated definitions, copies persisted metadata to the new tables, atomically replaces the old tables with the new ones, and reinitializes the data dictionary.
  • The Performance Schema and `INFORMATION_SCHEMA`.

• Step 2: Server upgrade.
  
  This step comprises all other upgrade tasks. If the server version of the existing MySQL installation is lower than that of the new installed MySQL version, everything else must be upgraded:
What the MySQL Upgrade Process Upgrades

- The system tables in the `mysql` schema (the remaining non-data dictionary tables).
- The `sys` schema.
- User schemas.

The data dictionary upgrade (step 1) is the responsibility of the server, which performs this task as necessary at startup unless invoked with an option that prevents it from doing so. The option is `--upgrade=NONE` as of MySQL 8.0.16, `--no-dd-upgrade` prior to MySQL 8.0.16.

If the data dictionary is out of date but the server is prevented from upgrading it, the server will not run and exits with an error. For example:

```
[ERROR] [MY-013381] [Server] Server shutting down because upgrade is required, yet prohibited by the command line option '--upgrade=NONE'.
[ERROR] [MY-010334] [Server] Failed to initialize DD Storage Engine
[ERROR] [MY-010020] [Server] Data Dictionary initialization failed.
```

Some changes to the responsibility for step 2 occurred in MySQL 8.0.16:

- Prior to MySQL 8.0.16, `mysql_upgrade` upgrades the Performance Schema, the `INFORMATION_SCHEMA`, and the objects described in step 2. The DBA is expected to invoke `mysql_upgrade` manually after starting the server.
- As of MySQL 8.0.16, the server performs all tasks previously handled by `mysql_upgrade`. Although upgrading remains a two-step operation, the server performs them both, resulting in a simpler process.

Depending on the version of MySQL to which you are upgrading, the instructions in In-Place Upgrade and Logical Upgrade indicate whether the server performs all upgrade tasks or whether you must also invoke `mysql_upgrade` after server startup.

**Note**

Because the server upgrades the Performance Schema, `INFORMATION_SCHEMA`, and the objects described in step 2 as of MySQL 8.0.16, `mysql_upgrade` is unneeded and is deprecated as of that version, and will be removed in a future MySQL version.

Most aspects of what occurs during step 2 are the same prior to and as of MySQL 8.0.16, although different command options may be needed to achieve a particular effect.

As of MySQL 8.0.16, the `--upgrade` server option controls whether and how the server performs an automatic upgrade at startup:

- With no option or with `--upgrade=AUTO`, the server upgrades anything it determines to be out of date (steps 1 and 2).
- With `--upgrade=NONE`, the server upgrades nothing (skips steps 1 and 2), but also exits with an error if the data dictionary must be upgraded. It is not possible to run the server with an out-of-date data dictionary; the server insists on either upgrading it or exiting.
- With `--upgrade=MINIMAL`, the server upgrades the data dictionary, the Performance Schema, and the `INFORMATION_SCHEMA`, if necessary (step 1). Note that following an upgrade with this option, Group Replication cannot be started, because system tables on which the replication internals depend are not updated, and reduced functionality might also be apparent in other areas.
- With `--upgrade=FORCE`, the server upgrades the data dictionary, the Performance Schema, and the `INFORMATION_SCHEMA`, if necessary (step 1), and forces an upgrade of everything else (step 2). Expect server startup to take longer with this option because the server checks all objects in all schemas.
**FORCE** is useful to force step 2 actions to be performed if the server thinks they are not necessary. One way that **FORCE** differs from **AUTO** is that with **FORCE**, the server re-creates system tables such as help tables or time zone tables if they are missing.

The following list shows upgrade commands prior to MySQL 8.0.16 and the equivalent commands for MySQL 8.0.16 and higher:

- **Perform a normal upgrade (steps 1 and 2 as necessary):**
  - Prior to MySQL 8.0.16: `mysqld` followed by `mysql_upgrade`
  - As of MySQL 8.0.16: `mysqld`

- **Perform only step 1 as necessary:**
  - Prior to MySQL 8.0.16: It is not possible to perform all upgrade tasks described in step 1 while excluding those described in step 2. However, you can avoid upgrading user schemas and the sys schema using `mysqld` followed by `mysql_upgrade` with the `--upgrade-system-tables` and `--skip-sys-schema` options.
  - As of MySQL 8.0.16: `mysqld --upgrade=MINIMAL`

- **Perform step 1 as necessary, and force step 2:**
  - Prior to MySQL 8.0.16: `mysqld` followed by `mysql_upgrade --force`
  - As of MySQL 8.0.16: `mysqld --upgrade=FORCE`

Prior to MySQL 8.0.16, certain `mysql_upgrade` options affect the actions it performs. The following table shows which server `--upgrade` option values to use as of MySQL 8.0.16 to achieve similar effects. (These are not necessarily exact equivalents because a given `--upgrade` option value may have additional effects.)

<table>
<thead>
<tr>
<th>mysql_upgrade Option</th>
<th>Server Option</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--skip-sys-schema</code></td>
<td><code>--upgrade=NONE</code> or <code>--upgrade=MINIMAL</code></td>
</tr>
<tr>
<td><code>--upgrade-system-tables</code></td>
<td><code>--upgrade=NONE</code> or <code>--upgrade=MINIMAL</code></td>
</tr>
<tr>
<td><code>--force</code></td>
<td><code>--upgrade=FORCE</code></td>
</tr>
</tbody>
</table>

Additional notes about what occurs during upgrade step 2:

- Step 2 installs the sys schema if it is not installed, and upgrades it to the current version otherwise. An error occurs if a sys schema exists but has no version view, on the assumption that its absence indicates a user-created schema:

  A sys schema exists with no sys.version view. If you have a user created sys schema, this must be renamed for the upgrade to succeed.

  To upgrade in this case, remove or rename the existing sys schema first. Then perform the upgrade procedure again. (It may be necessary to force step 2.)

To prevent the sys schema check:

- As of MySQL 8.0.16: Start the server with the `--upgrade=NONE` or `--upgrade=MINIMAL` option.
- Prior to MySQL 8.0.16: Invoke `mysql_upgrade` with the `--skip-sys-schema` option.
- Step 2 processes all tables in all user schemas as necessary. Table checking might take a long time to complete. Each table is locked and therefore unavailable to other sessions while it is being
Changes in MySQL 8.0

processed. Check and repair operations can be time-consuming, particularly for large tables. Table checking uses the `FOR UPGRADE` option of the `CHECK TABLE` statement. For details about what this option entails, see Section 13.7.3.2, “CHECK TABLE Syntax”.

To prevent table checking:

- As of MySQL 8.0.16: Start the server with the `--upgrade=NONE` or `--upgrade=MINIMAL` option.
- Prior to MySQL 8.0.16: Invoke `mysql_upgrade` with the `--upgrade-system-tables` option.

To force table checking:

- As of MySQL 8.0.16: Start the server with the `--upgrade=FORCE` option.
- Prior to MySQL 8.0.16: Invoke `mysql_upgrade` with the `--force` option.
- Step 2 saves the MySQL version number in a file named `mysql_upgrade_info` in the data directory.

To ignore the `mysql_upgrade_info` file and perform the check regardless:

- As of MySQL 8.0.16: Start the server with the `--upgrade=FORCE` option.
- Prior to MySQL 8.0.16: Invoke `mysql_upgrade` with the `--force` option.

Note

- Step 2 marks all checked and repaired tables with the current MySQL version number. This ensures that the next time upgrade checking occurs with the same version of the server, it can be determined whether there is any need to check or repair a given table again.
- Step 2 upgrades the system tables to ensure that they have the current structure. This is true whether the server or `mysql_upgrade` performs the step. With respect to the content of the help tables and time zone tables, `mysql_upgrade` does not load either type of table, whereas the server loads the help tables, but not the time zone tables. (That is, prior to MySQL 8.0.16, the server loads the help tables only at data directory initialization time. As of MySQL 8.0.16, it loads the help tables at initialization and upgrade time.) The procedure for loading time zone tables is platform dependent and requires decision making by the DBA, so it cannot be done automatically.

2.11.4 Changes in MySQL 8.0

Before upgrading to MySQL 8.0, review the changes described in this section to identify those that apply to your current MySQL installation and applications. Perform any recommended actions.

Changes marked as **Incompatible change** are incompatibilities with earlier versions of MySQL, and may require your attention before upgrading. Our aim is to avoid these changes, but occasionally they are necessary to correct problems that would be worse than an incompatibility between releases. If an upgrade issue applicable to your installation involves an incompatibility, follow the instructions given in the description.

- **Data Dictionary Changes**
- `caching_sha2_password` as the Preferred Authentication Plugin
- **Configuration Changes**
- **Server Changes**
- **InnoDB Changes**
Changes in MySQL 8.0

• SQL Changes

Data Dictionary Changes

MySQL Server 8.0 incorporates a global data dictionary containing information about database objects in transactional tables. In previous MySQL series, dictionary data was stored in metadata files and nontransactional system tables. As a result, the upgrade procedure requires that you verify the upgrade readiness of your installation by checking specific prerequisites. For more information, see Section 2.11.5, “Preparing Your Installation for Upgrade”. A data dictionary-enabled server entails some general operational differences; see Section 14.7, “Data Dictionary Usage Differences”.

caching_sha2_password as the Preferred Authentication Plugin

The caching_sha2_password and sha256_password authentication plugins provide more secure password encryption than the mysql_native_password plugin, and caching_sha2_password provides better performance than sha256_password. Due to these superior security and performance characteristics of caching_sha2_password, it is as of MySQL 8.0 the preferred authentication plugin, and is also the default authentication plugin rather than mysql_native_password. This change affects both the server and the libmysqlclient client library:

• For the server, the default value of the default_authentication_plugin system variable changes from mysql_native_password to caching_sha2_password.

This change applies only to new accounts created after installing or upgrading to MySQL 8.0 or higher. For accounts already existing in an upgraded installation, their authentication plugin remains unchanged. Existing users who wish to switch to caching_sha2_password can do so using the ALTER USER statement:

```
ALTER USER user
IDENTIFIED WITH caching_sha2_password
BY 'password';
```

• The libmysqlclient library treats caching_sha2_password as the default authentication plugin rather than mysql_native_password.

The following sections discuss the implications of the more prominent role of caching_sha2_password:

• caching_sha2_password Compatibility Issues and Solutions
• caching_sha2_password-Compatible Clients and Connectors
• caching_sha2_password and the root Administrative Account
• caching_sha2_password and Replication

caching_sha2_password Compatibility Issues and Solutions

Important

If your MySQL installation must serve pre-8.0 clients and you encounter compatibility issues after upgrading to MySQL 8.0 or higher, the simplest way to address those issues and restore pre-8.0 compatibility is to reconfigure the server to revert to the previous default authentication plugin (mysql_native_password). For example, use these lines in the server option file:

```
[mysqld]
default_authentication_plugin=mysql_native_password
```
Changes in MySQL 8.0

That setting enables pre-8.0 clients to connect to 8.0 servers until such time as the clients and connectors in use at your installation are upgraded to know about `caching_sha2_password`. However, the setting should be viewed as temporary, not as a long term or permanent solution, because it causes new accounts created with the setting in effect to forego the improved authentication security provided by `caching_sha2_password`.

The use of `caching_sha2_password` offers more secure password hashing than `mysql_native_password` (and consequent improved client connection authentication). However, it also has compatibility implications that may affect existing MySQL installations:

- Clients and connectors that have not been updated to know about `caching_sha2_password` may have trouble connecting to a MySQL 8.0 server configured with `caching_sha2_password` as the default authentication plugin, even to use accounts that do not authenticate with `caching_sha2_password`. This issue occurs because the server specifies the name of its default authentication plugin to clients. If a client or connector is based on a client/server protocol implementation that does not gracefully handle an unrecognized default authentication plugin, it may fail with an error such as one of these:

```
Authentication plugin 'caching_sha2_password' is not supported
```

```
Authentication plugin 'caching_sha2_password' cannot be loaded: dlopen(/usr/local/mysql/lib/plugin/caching_sha2_password.so, 2): image not found
```

```
Warning: mysqli_connect(): The server requested authentication method unknown to the client [caching_sha2_password]
```

For information about writing connectors to gracefully handle requests from the server for unknown default authentication plugins, see Authentication Plugin Connector-Writing Considerations.

- Clients that use an account that authenticates with `caching_sha2_password` must use either a secure connection (made using TCP using TLS/SSL credentials, a Unix socket file, or shared memory), or an unencrypted connection that supports password exchange using an RSA key pair. This security requirement does not apply to `mysql_native_password`, so the switch to `caching_sha2_password` may require additional configuration (see Section 6.4.1.3, “Caching SHA-2 Pluggable Authentication”). However, client connections in MySQL 8.0 prefer use of TLS/SSL by default, so clients that already conform to that preference may need no additional configuration.

- Clients and connectors that have not been updated to know about `caching_sha2_password` cannot connect to accounts that authenticate with `caching_sha2_password` because they do not recognize this plugin as valid. (This is a particular instance of how client/server authentication plugin compatibility requirements apply, as discussed at Authentication Plugin Client/Server Compatibility.) To work around this issue, relink clients against `libmysqlclient` from MySQL 8.0 or higher, or obtain an updated connector that recognizes `caching_sha2_password`.

- Because `caching_sha2_password` is also now the default authentication plugin in the `libmysqlclient` client library, authentication requires an extra round trip in the client/server protocol for connections from MySQL 8.0 clients to accounts that use `mysql_native_password` (the previous default authentication plugin), unless the client program is invoked with a `--default-auth=mysql_native_password` option.

The `libmysqlclient` client library for pre-8.0 MySQL versions is able to connect to MySQL 8.0 servers (except for accounts that authenticate with `caching_sha2_password`). That means pre-8.0 clients based on `libmysqlclient` should also be able to connect. Examples:

- Standard MySQL clients such as `mysql` and `mysqladmin` are `libmysqlclient`-based.
- The DBD::mysql driver for Perl DBI is `libmysqlclient`-based.
MySQL Connector/Python has a C Extension module that is `libmysqlclient`-based. To use it, include the `use_pure=False` option at connect time.

When an existing MySQL 8.0 installation is upgraded to MySQL 8.0.4 or higher, some older `libmysqlclient`-based clients may “automatically” upgrade if they are dynamically linked, because they use the new client library installed by the upgrade. For example, if the DBD::mysql driver for Perl DBI uses dynamic linking, it can use the `libmysqlclient` in place after an upgrade to MySQL 8.0.4 or higher, with this result:

- Prior to the upgrade, DBI scripts that use DBD::mysql can connect to a MySQL 8.0 server, except for accounts that authenticate with `caching_sha2_password`.
- After the upgrade, the same scripts become able to use `caching_sha2_password` accounts as well.

However, the preceding results occur because `libmysqlclient` instances from MySQL 8.0 installations prior to 8.0.4 are binary compatible: They both use a shared library major version number of 21. For clients linked to `libmysqlclient` from MySQL 5.7 or older, they link to a shared library with a different version number that is not binary compatible. In this case, the client must be recompiled against `libmysqlclient` from 8.0.4 or higher for full compatibility with MySQL 8.0 servers and `caching_sha2_password` accounts.

MySQL Connector/J 5.1 through 8.0.8 is able to connect to MySQL 8.0 servers, except for accounts that authenticate with `caching_sha2_password`. (Connector/J 8.0.9 or higher is required to connect to `caching_sha2_password` accounts.)

Clients that use an implementation of the client/server protocol other than `libmysqlclient` may need to be upgraded to a newer version that understands the new authentication plugin. For example, in PHP, MySQL connectivity usually is based on `mysqlnd`, which currently does not know about `caching_sha2_password`. Until an updated version of `mysqlnd` is available, the way to enable PHP clients to connect to MySQL 8.0 is to reconfigure the server to revert to `mysql_native_password` as the default authentication plugin, as previously discussed.

If a client or connector supports an option to explicitly specify a default authentication plugin, use it to name a plugin other than `caching_sha2_password`. Examples:

- Some MySQL clients support a `--default-auth` option. (Standard MySQL clients such as `mysql` and `mysqladmin` support this option but can successfully connect to 8.0 servers without it. However, other clients may support a similar option. If so, it is worth trying it.)
- Programs that use the `libmysqlclient` C API can call the `mysql_options()` function with the `MYSQL_DEFAULT_AUTH` option.
- MySQL Connector/Python scripts that use the native Python implementation of the client/server protocol can specify the `auth_plugin` connection option. (Alternatively, use the Connector/Python C Extension, which is able to connect to MySQL 8.0 servers without the need for `auth_plugin`.)

### `caching_sha2_password`-Compatible Clients and Connectors

If a client or connector is available that has been updated to know about `caching_sha2_password`, using it is the best way to ensure compatibility when connecting to a MySQL 8.0 server configured with `caching_sha2_password` as the default authentication plugin.

These clients and connectors have been upgraded to support `caching_sha2_password`:

- The `libmysqlclient` client library in MySQL 8.0 (8.0.4 or higher). Standard MySQL clients such as `mysql` and `mysqladmin` are `libmysqlclient`-based, so they are compatible as well.
- The `libmysqlclient` client library in MySQL 5.7 (5.7.23 or higher). Standard MySQL clients such as `mysql` and `mysqladmin` are `libmysqlclient`-based, so they are compatible as well.
- MySQL Connector/C++ 1.1.11 or higher or 8.0.7 or higher.
Changes in MySQL 8.0

- MySQL Connector/J 8.0.9 or higher.
- MySQL Connector/NET 8.0.10 or higher (through the classic MySQL protocol).
- MySQL Connector/Node.js 8.0.9 or higher.
- PHP: the X DevAPI PHP extension (mysql_xdevapi) supports `caching_sha2_password`.

PHP: the PDO_MySQL and ext/mysqli extensions do not support `caching_sha2_password`. In addition, when used with PHP versions before 7.1.16 and PHP 7.2 before 7.2.4, they fail to connect with `default_authentication_plugin=caching_sha2_password` even if `caching_sha2_password` is not used.

**caching_sha2_password and the root Administrative Account**

For upgrades to MySQL 8.0, the authentication plugin existing accounts remains unchanged, including the plugin for the `'root'@'localhost'` administrative account.

For new MySQL 8.0 installations, when you initialize the data directory (using the instructions at Section 2.10.1, “Initializing the Data Directory”), the `'root'@'localhost'` account is created, and that account uses `caching_sha2_password` by default. To connect to the server following data directory initialization, you must therefore use a client or connector that supports `caching_sha2_password`. If you can do this but prefer that the `root` account use `mysql_native_password` after installation, install MySQL and initialize the data directory as you normally would. Then connect to the server as `root` and use `ALTER USER` as follows to change the account authentication plugin and password:

```
ALTER USER 'root'@'localhost'
    IDENTIFIED WITH mysql_native_password
    BY 'password';
```

If the client or connector that you use does not yet support `caching_sha2_password`, you can use a modified data directory-initialization procedure that associates the root account with `mysql_native_password` as soon as the account is created. To do so, use either of these techniques:

- Supply a `--default-authentication-plugin=mysql_native_password` option along with `--initialize` or `--initialize-insecure`.
- Set `default_authentication_plugin` to `mysql_native_password` in an option file, and name that option file using a `--defaults-file` option along with `--initialize` or `--initialize-insecure`. (In this case, if you continue to use that option file for subsequent server startups, new accounts will be created with `mysql_native_password` rather than `caching_sha2_password` unless you remove the `default_authentication_plugin` setting from the option file.)

**caching_sha2_password and Replication**

In replication scenarios for which all servers have been upgraded to MySQL 8.0.4 or higher, slave/replica connections to master/primary servers can use accounts that authenticate with `caching_sha2_password`. For such connections, the same requirement applies as for other clients that use accounts that authenticate with `caching_sha2_password`: Use a secure connection or RSA-based password exchange.

To connect to a `caching_sha2_password` account for master/slave replication:

- For MySQL built using OpenSSL, use any of the following `CHANGE MASTER TO` options:

```
MASTER_SSL = 1
GET_MASTER_PUBLIC_KEY = 1
MASTER_PUBLIC_KEY_PATH='path to RSA public key file'
```
Changes in MySQL 8.0

• For MySQL built using wolfSSL, use `MASTER_SSL=1` with `CHANGE MASTER TO`.

Alternatively, you can use the RSA public key-related options if the required keys are supplied at server startup.

To connect to a `caching_sha2_password` account for Group Replication:

• For MySQL built using OpenSSL, set any of the following system variables:

```
SET GLOBAL group_replication_recovery_use_ssl = ON;
SET GLOBAL group_replication_recovery_get_public_key = 1;
SET GLOBAL group_replication_recovery_public_key_path = 'path to RSA public key file';
```

• For MySQL built using wolfSSL, set this system variable:

```
SET GLOBAL group_replication_recovery_use_ssl = ON;
```

Alternatively, you can use the RSA public key-related options if the required keys are supplied at server startup.

Configuration Changes

• **Incompatible change**: A MySQL storage engine is now responsible for providing its own partitioning handler, and the MySQL server no longer provides generic partitioning support. InnoDB and NDB are the only storage engines that provide a native partitioning handler that is supported in MySQL 8.0. A partitioned table using any other storage engine must be altered—either to convert it to InnoDB or NDB, or to remove its partitioning—**before** upgrading the server, else it cannot be used afterwards.

For information about converting MyISAM tables to InnoDB, see Section 15.6.1.3, “Converting Tables from MyISAM to InnoDB”.

A table creation statement that would result in a partitioned table using a storage engine without such support fails with an error ([ER_CHECK_NOT_IMPLEMENTED](#)) in MySQL 8.0. If you import databases from a dump file created in MySQL 5.7 (or earlier) using `mysqldump` into a MySQL 8.0 server, you must make sure that any statements creating partitioned tables do not also specify an unsupported storage engine, either by removing any references to partitioning, or by specifying the storage engine as `InnoDB` or allowing it to be set as `InnoDB` by default.

**Note**

The procedure given at Section 2.11.5, “Preparing Your Installation for Upgrade”, describes how to identify partitioned tables that must be altered before upgrading to MySQL 8.0.

• **Incompatible change**: Several server error codes are not used and have been removed (for a list, see Features Removed in MySQL 8.0). Applications that test specifically for any of them should be updated.

• **Important change**: The default character set has changed from `latin1` to `utf8mb4`. These system variables are affected:

  • The default value of the `character_set_server` and `character_set_database` system variables has changed from `latin1` to `utf8mb4`.

  • The default value of the `collation_server` and `collation_database` system variables has changed from `latin1_swedish_ci` to `utf8mb4_0900_ai_ci`.

As a result, the default character set and collation for new objects differ from previously unless an explicit character set and collation are specified. This includes databases and objects within them,
such as tables, views, and stored programs. Assuming that the previous defaults were used, one way to preserve them is to start the server with these lines in the `my.cnf` file:

```ini
[mysqld]
character_set_server=latin1
collation_server=latin1_swedish_ci
```

In a replicated setting, when upgrading from MySQL 5.7 to 8.0, it is advisable to change the default character set back to the character set used in MySQL 5.7 before upgrading. After the upgrade is completed, the default character set can be changed to `utf8mb4`.

- **Incompatible change:** As of MySQL 8.0.11, it is prohibited to start the server with a `lower_case_table_names` setting that is different from the setting used when the server was initialized. The restriction is necessary because collations used by various data dictionary table fields are based on the `lower_case_table_names` setting that was defined when the server was initialized, and restarting the server with a different setting would introduce inconsistencies with respect to how identifiers are ordered and compared.

**Server Changes**

- In MySQL 8.0.11, several deprecated features related to account management have been removed, such as use of the `GRANT` statement to modify nonprivilege characteristics of user accounts, the `NO_AUTO_CREATE_USER` SQL mode, the `PASSWORD()` function, and the `old_passwords` system variable.

Replication from MySQL 5.7 to 8.0 of statements that refer to these removed features can cause replication failure. Applications that use any of the removed features should be revised to avoid them and use alternatives when possible, as described in Features Removed in MySQL 8.0.

To avoid a startup failure on MySQL 8.0, remove any instance of `NO_AUTO_CREATE_USER` from `sql_mode` system variable settings in MySQL option files.

Loading a dump file that includes the `NO_AUTO_CREATE_USER` SQL mode in stored program definitions into a MySQL 8.0 server causes a failure. As of MySQL 5.7.24 and MySQL 8.0.13, `mysqldump` removes `NO_AUTO_CREATE_USER` from stored program definitions. Dump files created with an earlier version of `mysqldump` must be modified manually to remove instances of `NO_AUTO_CREATE_USER`.

- In MySQL 8.0.11, these deprecated compatibility SQL modes were removed: `DB2`, `MAXDB`, `MSSQL`, `MYSQL323`, `MYSQL40`, `ORACLE`, `POSTGRESQL`, `NO_FIELD_OPTIONS`, `NO_KEY_OPTIONS`, `NO_TABLE_OPTIONS`. They can no longer be assigned to the `sql_mode` system variable or used as permitted values for the `mysqldump` --compatible option.

Removal of `MAXDB` means that the `TIMESTAMP` data type for `CREATE TABLE` or `ALTER TABLE` is no longer treated as `DATETIME`.

Replication from MySQL 5.7 to 8.0 of statements that refer to the removed SQL modes can cause replication failure. This includes replication of `CREATE` statements for stored programs (stored procedures and functions, triggers, and events) that are executed while the current `sql_mode` value includes any of the removed modes. Applications that use any of the removed modes should be revised to avoid them.

- As of MySQL 8.0.3, spatial data types permit an `SRID` attribute, to explicitly indicate the spatial reference system (SRS) for values stored in the column. See Section 11.5.1, “Spatial Data Types”.

A spatial column with an explicit `SRID` attribute is SRID-restricted: The column takes only values with that ID, and `SPATIAL` indexes on the column become subject to use by the optimizer. The optimizer ignores `SPATIAL` indexes on spatial columns with no `SRID` attribute. See Section 8.3.3, “SPATIAL Index Optimization”. If you want the optimizer to consider `SPATIAL` indexes on spatial columns that are not SRID-restricted, each such column should be modified:
• Verify that all values within the column have the same SRID. To determine the SRIDs contained in a geometry column `col_name`, use the following query:

```sql
SELECT DISTINCT ST_SRID(`col_name`) FROM `tbl_name`;
```

If the query returns more than one row, the column contains a mix of SRIDs. In that case, modify its contents so all values have the same SRID.

• Redefine the column to have an explicit `SRID` attribute.

• Recreate the `SPATIAL` index.

• Several spatial functions were removed in MySQL 8.0.0 due to a spatial function namespace change that implemented an `ST_` prefix for functions that perform an exact operation, or an `MBR` prefix for functions that perform an operation based on minimum bounding rectangles. The use of removed spatial functions in generated column definitions could cause an upgrade failure. Before upgrading, run `mysqlcheck --check-upgrade` for removed spatial functions and replace any that you find with their `ST_` or `MBR` named replacements. For a list of removed spatial functions, refer to [Features Removed in MySQL 8.0](#).

• The `BACKUP_ADMIN` privilege is automatically granted to users with the `RELOAD` privilege when performing an in-place upgrade to MySQL 8.0.3 or higher.

• From MySQL 8.0.13, because of differences between row-based or mixed replication mode and statement-based replication mode in the way that temporary tables are handled, there are new restrictions on switching the binary logging format at runtime.

• `SET @@SESSION.binlog_format` cannot be used if the session has any open temporary tables.

• `SET @@global.binlog_format` and `SET @@persist.binlog_format` cannot be used if any replication channel has any open temporary tables. `SET @@persist_only.binlog_format` is allowed if replication channels have open temporary tables, because unlike `PERSIST`, `PERSIST_ONLY` does not modify the runtime global system variable value.

• `SET @@global.binlog_format` and `SET @@persist.binlog_format` cannot be used if any replication channel applier is running. This is because the change only takes effect on a replication channel when its applier is restarted, at which time the replication channel might have open temporary tables. This behavior is more restrictive than before. `SET @@persist_only.binlog_format` is allowed if any replication channel applier is running.

### InnoDB Changes

• `INFORMATION_SCHEMA` views based on InnoDB system tables were replaced by internal system views on data dictionary tables. Affected `InnoDB INFORMATION_SCHEMA` views were renamed:

<table>
<thead>
<tr>
<th>Old Name</th>
<th>New Name</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>INNODB_SYS_COLUMNS</code></td>
<td><code>INNODB_COLUMNS</code></td>
</tr>
<tr>
<td><code>INNODB_SYS_DATAFILES</code></td>
<td><code>INNODB_DATAFILES</code></td>
</tr>
<tr>
<td><code>INNODB_SYS_FIELDS</code></td>
<td><code>INNODB_FIELDS</code></td>
</tr>
<tr>
<td><code>INNODB_SYS_FOREIGN</code></td>
<td><code>INNODB_FOREIGN</code></td>
</tr>
<tr>
<td><code>INNODB_SYS_FOREIGN_COLS</code></td>
<td><code>INNODB_FOREIGN_COLS</code></td>
</tr>
<tr>
<td><code>INNODB_SYS_INDEXES</code></td>
<td><code>INNODB_INDEXES</code></td>
</tr>
<tr>
<td><code>INNODB_SYS_TABLES</code></td>
<td><code>INNODB_TABLES</code></td>
</tr>
</tbody>
</table>
Changes in MySQL 8.0

<table>
<thead>
<tr>
<th>Old Name</th>
<th>New Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>INNODB_SYS_TABLESPACES</td>
<td>INNODB_TABLESPACES</td>
</tr>
<tr>
<td>INNODB_SYS_TABLESTATS</td>
<td>INNODB_TABLESTATS</td>
</tr>
<tr>
<td>INNODB_SYS_VIRTUAL</td>
<td>INNODB_VIRTUAL</td>
</tr>
</tbody>
</table>

After upgrading to MySQL 8.0.3 or higher, update any scripts that reference previous InnoDB INFORMATION_SCHEMA view names.

- The zlib library version bundled with MySQL was raised from version 1.2.3 to version 1.2.11.

  The zlib compressBound() function in zlib 1.2.11 returns a slightly higher estimate of the buffer size required to compress a given length of bytes than it did in zlib version 1.2.3. The compressBound() function is called by InnoDB functions that determine the maximum row size permitted when creating compressed InnoDB tables or inserting rows into compressed InnoDB tables. As a result, CREATE TABLE ... ROW_FORMAT=COMPRESSED or INSERT operations with row sizes very close to the maximum row size that were successful in earlier releases could now fail.

  If you have compressed InnoDB tables with large rows, it is recommended that you test compressed table CREATE TABLE statements on a MySQL 8.0 test instance prior to upgrading.

- With the introduction of the --innodb-directories feature, the location of file-per-table and general tablespace files created with an absolute path or in a location outside of the data directory should be added to the innodb_directories argument value. Otherwise, InnoDB is not able to locate these files during recovery. To view tablespace file locations, query the INFORMATION_SCHEMA.FILES table:

  ```
  SELECT TABLESPACE_NAME, FILE_NAME FROM INFORMATION_SCHEMA.FILES \G
  ```

- Undo logs can no longer reside in the system tablespace. In MySQL 8.0, undo logs reside in two undo tablespaces by default. For more information, see Section 15.6.3.4, “Undo Tablespaces”.

  When upgrading from MySQL 5.7 to MySQL 8.0, any undo tablespaces that exist in the MySQL 5.7 instance are removed and replaced by two new default undo tablespaces. Default undo tablespaces are created in the location defined by the innodb_undo_directory variable. If the innodb_undo_directory variable is undefined, undo tablespaces are created in the data directory. Upgrade from MySQL 5.7 to MySQL 8.0 requires a slow shutdown which ensures that undo tablespaces in the MySQL 5.7 instance are empty, permitting them to be removed safely.

  When upgrading to MySQL 8.0.14 or later from an earlier MySQL 8.0 release, undo tablespaces that exist in the pre-upgrade instance as a result of an innodb_undo_tablespaces setting greater than 2 are treated as user-defined undo tablespaces, which can be deactivated and dropped using ALTER UNDO TABLESPACE and DROP UNDO TABLESPACE syntax, respectively, after upgrading. Upgrade within the MySQL 8.0 release series may not always require a slow shutdown which means that existing undo tablespaces could contain undo logs. Therefore, existing undo tablespaces are not removed by the upgrade process.

- Incompatible change: As of MySQL 8.0.17, the CREATE TABLESPACE ... ADD DATAFILE clause does not permit circular directory references. For example, the circular directory reference (/../) in the following statement is not permitted:

  ```
  CREATE TABLESPACE ts1 ADD DATAFILE ts1.ibd 'any_directory/../../../ts1.ibd';
  ```

  An exception to the restriction exists on Linux, where a circular directory reference is permitted if the preceding directory is a symbolic link. For example, the data file path in the example above is permitted if any_directory is a symbolic link. (It is still permitted for data file paths to begin with './'.)
To avoid upgrade issues, remove any circular directory references from tablespace data file paths before upgrading to MySQL 8.0.17 or higher. To inspect tablespace paths, query the `INFORMATION_SCHEMA.INNODB_DATAFILES` table.

- Due to a regression introduced in MySQL 8.0.14, in-place upgrade on a case sensitive file system from MySQL 5.7 or a MySQL 8.0 release prior to MySQL 8.0.14 to MySQL 8.0.16 failed for instances with partitioned tables and `lower_case_table_names=1`. The failure was caused by a case mismatch issue related to partitioned table file names. The fix that introduced the regression was reverted, which permits upgrades to MySQL 8.0.17 from MySQL 5.7 or MySQL 8.0 releases prior to MySQL 8.0.14 to function as normal. However, the regression is still present in the MySQL 8.0.14, 8.0.15, and 8.0.16 releases.

In-place upgrade on a case sensitive file system from MySQL 8.0.14, 8.0.15, or 8.0.16 to MySQL 8.0.17 fails with the following error when starting the server after upgrading binaries or packages to MySQL 8.0.17 if partitioned tables are present and `lower_case_table_names=1`:

```
Upgrading from server version version_number with partitioned tables and lower_case_table_names == 1 on a case sensitive file system may cause issues, and is therefore prohibited. To upgrade anyway, restart the new server version with the command line option 'upgrade=FORCE'. When upgrade is completed, please execute 'RENAME TABLE part_table_name TO new_table_name; RENAME TABLE new_table_name TO part_table_name;' for each of the partitioned tables.
Please see the documentation for further information.
```

If you encounter this error when upgrading to MySQL 8.0.17, perform the following workaround:

1. Restart the server with `--upgrade=force` to force the upgrade operation to proceed.
2. Identify partitioned table file names with lowercase suffixes:
   ```
   mysql> SELECT FILE_NAME FROM INFORMATION_SCHEMA.FILES WHERE FILE_NAME LIKE '%#p#%' OR FILE_NAME LIKE '%#sp#%';
   ```
3. For each file identified, rename the associated table using a temporary name, then rename the table back to its original name.
   ```
   mysql> RENAME TABLE table_name TO temporary_table_name;
   mysql> RENAME TABLE temporary_table_name TO table_name;
   ```
4. Verify that there are no partitioned table file names with lowercase suffixes (an empty result set should be returned).
   ```
   mysql> SELECT FILE_NAME FROM INFORMATION_SCHEMA.FILES WHERE FILE_NAME LIKE '%#p#%' OR FILE_NAME LIKE '%#sp#%';
   Empty set (0.00 sec)
   ```

Because of the regression still present in the MySQL 8.0.14, 8.0.15, and 8.0.16 releases, importing partitioned tables from MySQL 8.0.14, 8.0.15, or 8.0.16 to MySQL 8.0.17 is not supported on case sensitive file systems where `lower_case_table_names=1`. Attempting to do so results in a “Tablespace is missing for table” error.

### SQL Changes

- **Incompatible change**: As of MySQL 8.0.13, the deprecated `ASC` or `DESC` qualifiers for `GROUP BY` clauses have been removed. Queries that previously relied on `GROUP BY` sorting may produce results that differ from previous MySQL versions. To produce a given sort order, provide an `ORDER BY` clause.

Queries and stored program definitions from MySQL 8.0.12 or lower that use `ASC` or `DESC` qualifiers for `GROUP BY` clauses should be amended. Otherwise, upgrading to MySQL 8.0.13 or higher may fail, as may replicating to MySQL 8.0.13 or higher slave servers.
Preparing Your Installation for Upgrade

• Some keywords may be reserved in MySQL 8.0 that were not reserved in MySQL 5.7. See Section 9.3, “Keywords and Reserved Words”. This can cause words previously used as identifiers to become illegal. To fix affected statements, use identifier quoting. See Section 9.2, “Schema Object Names”.

• After upgrading, it is recommended that you test optimizer hints specified in application code to ensure that the hints are still required to achieve the desired optimization strategy. Optimizer enhancements can sometimes render certain optimizer hints unnecessary. In some cases, an unnecessary optimizer hint may even be counterproductive.

• Incompatible change: In MySQL 5.7, specifying a FOREIGN KEY definition for an InnoDB table without a CONSTRAINT symbol clause, or specifying the CONSTRAINT keyword without a symbol, causes InnoDB to use a generated constraint name. That behavior changed in MySQL 8.0, with InnoDB using the FOREIGN KEY index_name value instead of a generated name. Because constraint names must be unique per schema (database), the change caused errors due to foreign key index names that were not unique per schema. To avoid such errors, the new constraint naming behavior has been reverted in MySQL 8.0.16, and InnoDB once again uses a generated constraint name.

For consistency with InnoDB, NDB releases based on MySQL 8.0.16 or higher use a generated constraint name if the CONSTRAINT symbol clause is not specified, or the CONSTRAINT keyword is specified without a symbol. NDB releases based on MySQL 5.7 and earlier MySQL 8.0 releases used the FOREIGN KEY index_name value.

The changes described above may introduce incompatibilities for applications that depend on the previous foreign key constraint naming behavior.

2.11.5 Preparing Your Installation for Upgrade

Before upgrading to the latest MySQL 8.0 release, ensure the upgrade readiness of your current MySQL 5.7 or MySQL 8.0 server instance by performing the preliminary checks described below. The upgrade process may fail otherwise.

The same checks and others can be performed using the MySQL Shell upgrade checker utility. For more information, see Upgrade Checker Utility.

Preliminary checks:

1. The following issues must not be present:
   • There must be no tables that use obsolete data types or functions.
     In-place upgrade to MySQL 8.0 is not supported if tables contain old temporal columns in pre-5.6.4 format (TIME, DATETIME, and TIMESTAMP columns without support for fractional seconds precision). If your tables still use the old temporal column format, upgrade them before attempting an in-place upgrade to MySQL 8.0. For more information, see Server Changes.
   • There must be no orphan .frm files.
   • Triggers must not have a missing or empty definer or an invalid creation context (indicated by the character_set_client, collation_connection, Database Collation attributes displayed by SHOW TRIGGERS or the INFORMATION_SCHEMA TRIGGERS table).

To check for these issues, execute this command:

```
mysqlcheck -u root -p --all-databases --check-upgrade
```

If mysqlcheck reports any errors, correct the issues.

2. There must be no partitioned tables that use a storage engine that does not have native partitioning support. To identify such tables, execute this query:
SELECT TABLE_SCHEMA, TABLE_NAME
FROM INFORMATION_SCHEMA.TABLES
WHERE ENGINE NOT IN ('innodb', 'ndbcluster')
AND CREATE_OPTIONS LIKE '%partitioned%';

Any table reported by the query must be altered to use InnoDB or be made nonpartitioned. To change a table storage engine to InnoDB, execute this statement:

```
ALTER TABLE table_name ENGINE = INNODB;
```

For information about converting MyISAM tables to InnoDB, see Section 15.6.1.3, “Converting Tables from MyISAM to InnoDB”.

To make a partitioned table nonpartitioned, execute this statement:

```
ALTER TABLE table_name REMOVE PARTITIONING;
```

3. Some keywords may be reserved in MySQL 8.0 that were not reserved previously. See Section 9.3, “Keywords and Reserved Words”. This can cause words previously used as identifiers to become illegal. To fix affected statements, use identifier quoting. See Section 9.2, “Schema Object Names”.

4. There must be no tables in the MySQL 5.7 mysql system database that have the same name as a table used by the MySQL 8.0 data dictionary. To identify tables with those names, execute this query:

```
SELECT TABLE_SCHEMA, TABLE_NAME
FROM INFORMATION_SCHEMA.TABLES
WHERE LOWER(TABLE_SCHEMA) = 'mysql'
and LOWER(TABLE_NAME) IN
  (  
    'catalogs',
    'character_sets',
    'check_constraints',
    'collations',
    'column_statistics',
    'column_type_elements',
    'columns',
    'dd_properties',
    'events',
    'foreign_key_column_usage',
    'foreign_keys',
    'index_column_usage',
    'index_partitions',
    'index_stats',
    'indexes',
    'parameter_type_elements',
    'parameters',
    'resource_groups',
    'routines',
    'schemata',
    'st_spatial_reference_systems',
    'table_partition_values',
    'table_partitions',
    'table_stats',
    'tables',
    'tablespace_files',
    'tablespaces',
    'triggers',
    'view_routine_usage',
    'view_table_usage'
  );
```

Any tables reported by the query must be renamed (use RENAME TABLE). This may also entail changes to applications that use the affected tables.
Preparing Your Installation for Upgrade

5. There must be no tables that have foreign key constraint names longer than 64 characters. To identify tables with too-long constraint names, execute this query:

```sql
SELECT TABLE_SCHEMA, TABLE_NAME
FROM INFORMATION_SCHEMA.TABLES
WHERE TABLE_NAME IN
  (SELECT LEFT(SUBSTR(ID, INSTR(ID, '/') + 1),
               INSTR(SUBSTR(ID, INSTR(ID, '/') + 1), '_ibfk_') - 1)
  FROM INFORMATION_SCHEMA.INNODB_SYS_FOREIGN
WHERE LENGTH(SUBSTR(ID, INSTR(ID, '/') + 1)) > 64);
```

Any tables reported by the query must be altered to have constraint names no longer than 64 characters (use `ALTER TABLE`).

6. There must be no obsolete SQL modes defined in your `sql_mode` system variable setting. Attempting to use an obsolete SQL mode will cause a startup failure on MySQL 8.0. Applications that use obsolete SQL modes should also be revised to avoid them. For information about SQL modes removed in MySQL 8.0, see Server Changes.

7. There must be no tables or stored procedures with individual `ENUM` or `SET` column elements that exceed 255 characters or 1020 bytes in length. Prior to MySQL 8.0, the maximum combined length of `ENUM` or `SET` column elements was 64K. In MySQL 8.0, the maximum character length of an individual `ENUM` or `SET` column element is 255 characters, and the maximum byte length is 1020 bytes. (The 1020 byte limit supports multibyte character sets). Before upgrading to MySQL 8.0, modify any `ENUM` or `SET` column elements that exceed the new limits. Failing to do so causes the upgrade to fail with an error.

8. Before upgrading to MySQL 8.0.13 or higher, there must be no table partitions that reside in shared InnoDB tablespaces, which include the system tablespace and general tablespaces. Identify table partitions in shared tablespaces by querying `INFORMATION_SCHEMA`:

```sql
SELECT DISTINCT NAME, SPACE, SPACE_TYPE FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES
WHERE NAME LIKE '%#P#%' AND SPACE_TYPE NOT LIKE 'Single';
```

Move table partitions from shared tablespaces to file-per-table tablespaces using `ALTER TABLE`:

```sql
ALTER TABLE table_name REORGANIZE PARTITION partition_name
INTO (partition_definition TABLESPACE=innodb_file_per_table);
```

9. There must be no queries and stored program definitions from MySQL 8.0.12 or lower that use `ASC` or `DESC` qualifiers for `GROUP BY` clauses. Otherwise, upgrading to MySQL 8.0.13 or higher may fail, as may replicating to MySQL 8.0.13 or higher slave servers. For additional details, see SQL Changes.

10. Your MySQL 5.7 installation must not use features that are not supported by MySQL 8.0. Any changes here are necessarily installation specific, but the following example illustrates the kind of thing to look for:

Some server startup options and system variables have been removed in MySQL 8.0. See Features Removed in MySQL 8.0, and Section 1.5, “Server and Status Variables and Options Added, Deprecated, or Removed in MySQL 8.0”. If you use any of these, an upgrade requires configuration changes.

Example: Because the data dictionary provides information about database objects, the server no longer checks directory names in the data directory to find databases. Consequently, the `--ignore-db-dir` option is extraneous and has been removed. To handle this, remove any instances of `--ignore-db-dir` from your startup configuration. In addition, remove or move the named data directory subdirectories before upgrading to MySQL 8.0. (Alternatively, let the
8.0 server add those directories to the data dictionary as databases, then remove each of those
databases using DROP DATABASE.)

2.11.6 Upgrading MySQL Binary or Package-based Installations on Unix/Linux

This section describes how to upgrade MySQL binary and package-based installations on Unix/Linux. In-place and logical upgrade methods are described.

- In-Place Upgrade
- Logical Upgrade
- MySQL Cluster Upgrade

In-Place Upgrade

An in-place upgrade involves shutting down the old MySQL server, replacing the old MySQL binaries or packages with the new ones, restarting MySQL on the existing data directory, and upgrading any remaining parts of the existing installation that require upgrading. For details about what may need upgrading, see Section 2.11.3, “What the MySQL Upgrade Process Upgrades”.

Note

If you are upgrading an installation originally produced by installing multiple RPM packages, upgrade all the packages, not just some. For example, if you previously installed the server and client RPMs, do not upgrade just the server RPM.

For some Linux platforms, MySQL installation from RPM or Debian packages includes systemd support for managing MySQL server startup and shutdown. On these platforms, \texttt{mysqld\_safe} is not installed. In such cases, use systemd for server startup and shutdown instead of the methods used in the following instructions. See Section 2.5.9, “Managing MySQL Server with systemd”.

For upgrades to MySQL Cluster installations, see also MySQL Cluster Upgrade.

To perform an in-place upgrade:

1. Review the information in Section 2.11.1, “Before You Begin”.

2. Ensure the upgrade readiness of your installation by completing the preliminary checks in Section 2.11.5, “Preparing Your Installation for Upgrade”.

3. If you use XA transactions with InnoDB, run \texttt{XA RECOVER} before upgrading to check for uncommitted XA transactions. If results are returned, either commit or rollback the XA transactions by issuing an \texttt{XA COMMIT} or \texttt{XA ROLLBACK} statement.

4. If there are encrypted InnoDB tablespaces, rotate the keyring master key by executing this statement:

\begin{verbatim}
ALTER INSTANCE ROTATE INNODB MASTER KEY;
\end{verbatim}

5. If you normally run your MySQL server configured with \texttt{innodb\_fast\_shutdown} set to 2 (cold shutdown), configure it to perform a fast or slow shutdown by executing either of these statements:

\begin{verbatim}
SET GLOBAL innodb\_fast\_shutdown = 1; -- fast shutdown
SET GLOBAL innodb\_fast\_shutdown = 0; -- slow shutdown
\end{verbatim}

With a fast or slow shutdown, InnoDB leaves its undo logs and data files in a state that can be dealt with in case of file format differences between releases.
6. Shut down the old MySQL server. For example:

```bash
mysqladmin -u root -p shutdown
```

7. Upgrade the MySQL binaries or packages. If upgrading a binary installation, unpack the new MySQL binary distribution package. See Obtain and Unpack the Distribution. For package-based installations, install the new packages.

8. Start the MySQL 8.0 server, using the existing data directory. For example:

```bash
mysqld_safe --user=mysql --datadir=/path/to/existing-datadir &
```

If there are encrypted InnoDB tablespaces, use the `--early-plugin-load` option to load the keyring plugin.

When you start the MySQL 8.0 server, it automatically detects whether data dictionary tables are present. If not, the server creates them in the data directory, populates them with metadata, and then proceeds with its normal startup sequence. During this process, the server upgrades metadata for all database objects, including databases, tablespaces, system and user tables, views, and stored programs (stored procedures and functions, triggers, and Event Scheduler events). The server also removes files that previously were used for metadata storage. For example, after upgrading from MySQL 5.7 to MySQL 8.0, you will notice that tables no longer have `.frm` files.

If this step fails, the server reverts all changes to the data directory. In this case, you should remove all redo log files, start your MySQL 5.7 server on the same data directory, and fix the cause of any errors. Then perform another slow shutdown of the 5.7 server and start the MySQL 8.0 server to try again.

9. In the previous step, the server upgrades the data dictionary as necessary. Now it is necessary to perform any remaining upgrade operations:

- As of MySQL 8.0.16, the server will already have done so in the previous step: It makes any changes required in the `mysql` system schema between MySQL 5.7 and MySQL 8.0, so that you can take advantage of new privileges or capabilities. It also brings the Performance Schema, INFORMATION_SCHEMA, and `sys` schema up to date for MySQL 8.0, and examines all user schemas for incompatibilities with the current version of MySQL.

- Prior to MySQL 8.0.16, the server upgrades only the data dictionary in the previous step. After the MySQL 8.0 server starts successfully, execute `mysql_upgrade` to perform the remaining upgrade tasks:

```bash
mysql_upgrade -u root -p
```

Then shut down and restart the MySQL server to ensure that any changes made to the system tables take effect. For example:

```bash
mysqladmin -u root -p shutdown
mysqld_safe --user=mysql --datadir=/path/to/existing-datadir &
```

The first time you start the MySQL 8.0 server (in an earlier step), you may notice messages in the error log regarding nonupgraded tables. If `mysql_upgrade` has been run successfully, there should be no such messages the second time you start the server.

---

**Note**

The upgrade process does not upgrade the contents of the time zone tables. For upgrade instructions, see Section 5.1.13, "MySQL Server Time Zone Support".
If the upgrade process uses `mysql_upgrade` (that is, prior to MySQL 8.0.16), the process does not upgrade the contents of the help tables, either. For upgrade instructions in that case, see Section 5.1.14, “Server-Side Help Support”.

**Logical Upgrade**

A logical upgrade involves exporting SQL from the old MySQL instance using a backup or export utility such as `mysqldump` or `mysqlpump`, installing the new MySQL server, and applying the SQL to your new MySQL instance. For details about what may need upgrading, see Section 2.11.3, “What the MySQL Upgrade Process Upgrades”.

**Note**

For some Linux platforms, MySQL installation from RPM or Debian packages includes systemd support for managing MySQL server startup and shutdown. On these platforms, `mysqld_safe` is not installed. In such cases, use systemd for server startup and shutdown instead of the methods used in the following instructions. See Section 2.5.9, “Managing MySQL Server with systemd”.

**Warning**

Applying SQL extracted from a previous MySQL release to a new MySQL release may result in errors due to incompatibilities introduced by new, changed, deprecated, or removed features and capabilities. Consequently, SQL extracted from a previous MySQL release may require modification to enable a logical upgrade.

To identify incompatibilities before upgrading to the latest MySQL 8.0 release, perform the steps described in Section 2.11.5, “Preparing Your Installation for Upgrade”.

To perform a logical upgrade:

1. Review the information in Section 2.11.1, “Before You Begin”.

2. Export your existing data from the previous MySQL installation:

   ```
   mysqldump -u root -p --add-drop-table --routines --events --all-databases --force > data-for-upgrade.sql
   ```

   **Note**

   Use the `--routines` and `--events` options with `mysqldump` (as shown above) if your databases include stored programs. The `--all-databases` option includes all databases in the dump, including the `mysql` database that holds the system tables.

   **Important**

   If you have tables that contain generated columns, use the `mysqldump` utility provided with MySQL 5.7.9 or higher to create your dump files. The `mysqldump` utility provided in earlier releases uses incorrect syntax for generated column definitions (Bug #20769542). You can use the `INFORMATION_SCHEMA.COLUMNS` table to identify tables with generated columns.

3. Shut down the old MySQL server. For example:
4. Install MySQL 8.0. For installation instructions, see Chapter 2, *Installing and Upgrading MySQL*.

5. Initialize a new data directory, as described in Section 2.10.1, “Initializing the Data Directory”. For example:

   `mysqld --initialize --datadir=/path/to/8.0-datadir`

Copy the temporary 'root'@'localhost' password displayed to your screen or written to your error log for later use.

6. Start the MySQL 8.0 server, using the new data directory. For example:

   `mysqld_safe --user=mysql --datadir=/path/to/8.0-datadir &`

7. Reset the root password:

   `shell> mysql -u root -p Enter password: **** < enter temporary root password`

   `mysql> ALTER USER USER() IDENTIFIED BY 'your new password';`

8. Load the previously created dump file into the new MySQL server. For example:

   `mysql -u root -p --force < data-for-upgrade.sql`

**Note**

It is not recommended to load a dump file when GTIDs are enabled on the server (*gtid_mode=ON*), if your dump file includes system tables. *mysqldump* issues DML instructions for the system tables which use the non-transactional MyISAM storage engine, and this combination is not permitted when GTIDs are enabled. Also be aware that loading a dump file from a server with GTIDs enabled, into another server with GTIDs enabled, causes different transaction identifiers to be generated.

9. Perform any remaining upgrade operations:

   - In MySQL 8.0.16 and higher, shut down the server, then restart it with the *--upgrade=FORCE* option to perform the remaining upgrade tasks:

```
mysqladmin -u root -p shutdown
mysqld_safe --user=mysql --datadir=/path/to/8.0-datadir --upgrade=FORCE &
```

   Upon restart with *--upgrade=FORCE*, the server makes any changes required in the *mysql* system schema between MySQL 5.7 and MySQL 8.0, so that you can take advantage of new privileges or capabilities. It also brings the Performance Schema, *INFORMATION_SCHEMA*, and *sys* schema up to date for MySQL 8.0, and examines all user schemas for incompatibilities with the current version of MySQL.

   - Prior to MySQL 8.0.16, execute *mysql_upgrade* to perform the remaining upgrade tasks:

```
mysql_upgrade -u root -p
```

Then shut down and restart the MySQL server to ensure that any changes made to the system tables take effect. For example:
mysqladmin -u root -p shutdown
mysqld_safe --user=mysql --datadir=/path/to/8.0-datadir &

**Note**

The upgrade process does not upgrade the contents of the time zone tables. For upgrade instructions, see Section 5.1.13, "MySQL Server Time Zone Support". If the upgrade process uses mysql_upgrade (that is, prior to MySQL 8.0.16), the process does not upgrade the contents of the help tables, either. For upgrade instructions in that case, see Section 5.1.14, "Server-Side Help Support".

**Note**

Loading a dump file that contains a MySQL 5.7 mysql schema re-creates two tables that are no longer used: event and proc. (The corresponding MySQL 8.0 tables are events and routines, both of which are data dictionary tables and are protected.) After you are satisfied that the upgrade was successful, you can remove the event and proc tables by executing these SQL statements:

```
DROP TABLE mysql.event;
DROP TABLE mysql.proc;
```

### MySQL Cluster Upgrade

The information in this section is an adjunct to the in-place upgrade procedure described in In-Place Upgrade, for use if you are upgrading MySQL Cluster.

As of MySQL 8.0.16, a MySQL Cluster upgrade can be performed as a regular rolling upgrade, following the usual three ordered steps:

1. Upgrade MGM nodes.
2. Upgrade data nodes one at a time.
3. Upgrade API nodes one at a time (including MySQL servers).

The way to upgrade each of the nodes remains almost the same as prior to MySQL 8.0.16 because there is a separation between upgrading the data dictionary and upgrading the system tables. There are two steps to upgrading each individual mysqld:

1. Import the data dictionary.

   Start the new server with the --upgrade=MINIMAL option to upgrade the data dictionary but not the system tables. This is essentially the same as the pre-MySQL 8.0.16 action of starting the server and not invoking mysql_upgrade.

   The MySQL server must be connected to NDB for this phase to complete. If any NDB or NDBINFO tables exist, and the server cannot connect to the cluster, it exits with an error message:

```
Failed to Populate DD tables.
```

2. Upgrade the system tables.

   Prior to MySQL 8.0.16, the DBA invokes the mysql_upgrade client to upgrade the system tables. As of MySQL 8.0.16, the server performs this action: To upgrade the system tables, restart each individual mysqld without the --upgrade=MINIMAL option.
### 2.11.7 Upgrading MySQL with the MySQL Yum Repository

For supported Yum-based platforms (see Section 2.5.1, “Installing MySQL on Linux Using the MySQL Yum Repository”, for a list), you can perform an in-place upgrade for MySQL (that is, replacing the old version and then running the new version using the old data files) with the MySQL Yum repository.

**Notes**

- Before performing any update to MySQL, follow carefully the instructions in Section 2.11, “Upgrading MySQL”. Among other instructions discussed there, it is especially important to back up your database before the update.

- The following instructions assume you have installed MySQL with the MySQL Yum repository or with an RPM package directly downloaded from MySQL Developer Zone’s MySQL Download page; if that is not the case, following the instructions in Replacing a Third-Party Distribution of MySQL Using the MySQL Yum Repository.

#### Selecting a Target Series

By default, the MySQL Yum repository updates MySQL to the latest version in the release series you have chosen during installation (see Selecting a Release Series for details), which means, for example, a 5.7.x installation will not be updated to a 8.0.x release automatically. To update to another release series, you need to first disable the subrepository for the series that has been selected (by default, or by yourself) and enable the subrepository for your target series. To do that, see the general instructions given in Selecting a Release Series. For upgrading from MySQL 5.7 to 8.0, perform the reverse of the steps illustrated in Selecting a Release Series, disabling the subrepository for the MySQL 5.7 series and enabling that for the MySQL 8.0 series.

As a general rule, to upgrade from one release series to another, go to the next series rather than skipping a series. For example, if you are currently running MySQL 5.6 and wish to upgrade to 8.0, upgrade to MySQL 5.7 first before upgrading to 8.0.

**Important**

For important information about upgrading from MySQL 5.7 to 8.0, see Upgrading from MySQL 5.7 to 8.0.

#### Upgrading MySQL

Upgrade MySQL and its components by the following command, for platforms that are not dnf-enabled:

```
sudo yum update mysql-server
```

For platforms that are dnf-enabled:

```
sudo dnf upgrade mysql-server
```

Alternatively, you can update MySQL by telling Yum to update everything on your system, which might take considerably more time. For platforms that are not dnf-enabled:

```
sudo yum update
```

For platforms that are dnf-enabled:

```
sudo dnf upgrade
```
### Restarting MySQL

The MySQL server always restarts after an update by Yum. Prior to MySQL 8.0.16, run `mysql_upgrade` after the server restarts to check and possibly resolve any incompatibilities between the old data and the upgraded software. `mysql_upgrade` also performs other functions; for details, see Section 4.4.5, “mysql_upgrade — Check and Upgrade MySQL Tables”. As of MySQL 8.0.16, this step is not required, as the server performs all tasks previously handled by `mysql_upgrade`.

You can also update only a specific component. Use the following command to list all the installed packages for the MySQL components (for dnf-enabled systems, replace `yum` in the command with `dnf`):

```
sudo yum list installed | grep "^mysql"
```

After identifying the package name of the component of your choice, update the package with the following command, replacing `package-name` with the name of the package. For platforms that are not dnf-enabled:

```
sudo yum update package-name
```

For dnf-enabled platforms:

```
sudo dnf upgrade package-name
```

### Upgrading the Shared Client Libraries

After updating MySQL using the Yum repository, applications compiled with older versions of the shared client libraries should continue to work.

*If you recompile applications and dynamically link them with the updated libraries:* As typical with new versions of shared libraries where there are differences or additions in symbol versioning between the newer and older libraries (for example, between the newer, standard 8.0 shared client libraries and some older—prior or variant—versions of the shared libraries shipped natively by the Linux distributions’ software repositories, or from some other sources), any applications compiled using the updated, newer shared libraries will require those updated libraries on systems where the applications are deployed. And, as expected, if those libraries are not in place, the applications requiring the shared libraries will fail. So, be sure to deploy the packages for the shared libraries from MySQL on those systems. To do this, add the MySQL Yum repository to the systems (see Adding the MySQL Yum Repository) and install the latest shared libraries using the instructions given in Installing Additional MySQL Products and Components with Yum.

### 2.11.8 Upgrading MySQL with the MySQL APT Repository

On Debian and Ubuntu platforms, to perform an in-place upgrade of MySQL and its components, use the MySQL APT repository. See Upgrading MySQL with the MySQL APT Repository in A Quick Guide to Using the MySQL APT Repository.

### 2.11.9 Upgrading MySQL with the MySQL SLES Repository

On the SUSE Linux Enterprise Server (SLES) platform, to perform an in-place upgrade of MySQL and its components, use the MySQL SLES repository. See Upgrading MySQL with the MySQL SLES Repository in A Quick Guide to Using the MySQL SLES Repository.

### 2.11.10 Upgrading MySQL on Windows

There are two approaches for upgrading MySQL on Windows:

- Using MySQL Installer
Upgrading MySQL on Windows

- Using the Windows ZIP archive distribution

The approach you select depends on how the existing installation was performed. Before proceeding, review Section 2.11, “Upgrading MySQL” for additional information on upgrading MySQL that is not specific to Windows.

Note
Whichever approach you choose, always back up your current MySQL installation before performing an upgrade. See Section 7.2, “Database Backup Methods”.

Upgrades between non-GA releases (or from a non-GA release to a GA release) are not supported. Significant development changes take place in non-GA releases and you may encounter compatibility issues or problems starting the server.

Note
MySQL Installer does not support upgrades between Community releases and Commercial releases. If you require this type of upgrade, perform it using the ZIP archive approach.

Upgrading MySQL with MySQL Installer

Performing an upgrade with MySQL Installer is the best approach when the current server installation was performed with it and the upgrade is within the current release series. MySQL Installer does not support upgrades between release series, such as from 5.7 to 8.0, and it does not provide an upgrade indicator to prompt you to upgrade. For instructions on upgrading between release series, see Upgrading MySQL Using the Windows ZIP Distribution.

To perform an upgrade using MySQL Installer:

1. Start MySQL Installer.

2. From the dashboard, click Catalog to download the latest changes to the catalog. The installed server can be upgraded only if the dashboard displays an arrow next to the version number of the server.

3. Click Upgrade. All products that have a newer version now appear in a list.

Note
MySQL Installer deselects the server upgrade option for milestone releases (Pre-Release) in the same release series. In addition, it displays a warning to indicate that the upgrade is not supported, identifies the risks of continuing, and provides a summary of the steps to perform an upgrade manually. You can reselect server upgrade and proceed at your own risk.

4. Deselect all but the MySQL server product, unless you intend to upgrade other products at this time, and click Next.

5. Click Execute to start the download. When the download finishes, click Next to begin the upgrade operation.

Upgrades to MySQL 8.0.16 and higher may show an option to skip the upgrade check and process for system tables. For more information about this option, see Important server upgrade conditions.

6. Configure the server.

Upgrading MySQL Using the Windows ZIP Distribution

To perform an upgrade using the Windows ZIP archive distribution:
1. Download the latest Windows ZIP Archive distribution of MySQL from https://dev.mysql.com/downloads/.

2. If the server is running, stop it. If the server is installed as a service, stop the service with the following command from the command prompt:

   ```bash
   C:\> SC STOP mysql_service_name
   ```

   Alternatively, use `NET STOP mysql_service_name`.

   If you are not running the MySQL server as a service, use `mysqladmin` to stop it. For example, before upgrading from MySQL 5.7 to 8.0, use `mysqladmin` from MySQL 5.7 as follows:

   ```bash
   C:\> "C:\Program Files\MySQL\MySQL Server 5.7\bin\mysqladmin" -u root shutdown
   ```

   **Note**

   If the MySQL root user account has a password, invoke `mysqladmin` with the `-p` option and enter the password when prompted.

3. Extract the ZIP archive. You may either overwrite your existing MySQL installation (usually located at `C:\mysql`), or install it into a different directory, such as `C:\mysql8`. Overwriting the existing installation is recommended.

4. Restart the server. For example, use the `SC START mysql_service_name` or `NET START mysql_service_name` command if you run MySQL as a service, or invoke `mysqld` directly otherwise.

5. Prior to MySQL 8.0.16, run `mysql_upgrade` as Administrator to check your tables, attempt to repair them if necessary, and update your grant tables if they have changed so that you can take advantage of any new capabilities. See Section 4.4.5, "mysql_upgrade — Check and Upgrade MySQL Tables". As of MySQL 8.0.16, this step is not required, as the server performs all tasks previously handled by `mysql_upgrade`.

6. If you encounter errors, see Section 2.3.6, "Troubleshooting a Microsoft Windows MySQL Server Installation".

### 2.11.11 Upgrading a Docker Installation of MySQL

To upgrade a Docker installation of MySQL, refer to Upgrading a MySQL Server Container.

### 2.11.12 Upgrade Troubleshooting

- A schema mismatch in a MySQL 5.7 instance between the `.frm` file of a table and the InnoDB data dictionary can cause an upgrade to MySQL 8.0 to fail. Such mismatches may be due to `.frm` file corruption. To address this issue, dump and restore affected tables before attempting the upgrade again.

- If problems occur, such as that the new `mysqld` server does not start, verify that you do not have an old `my.cnf` file from your previous installation. You can check this with the `--print-defaults` option (for example, `mysqld --print-defaults`). If this command displays anything other than the program name, you have an active `my.cnf` file that affects server or client operation.

- If, after an upgrade, you experience problems with compiled client programs, such as Commands out of sync or unexpected core dumps, you probably have used old header or library files when compiling your programs. In this case, check the date for your `mysql.h` file and `libmysqlclient.a` library to verify that they are from the new MySQL distribution. If not, recompile your programs with the new headers and libraries. Recompilation might also be necessary for programs compiled against the shared client library if the library major version number has changed (for example, from `libmysqlclient.so.20` to `libmysqlclient.so.21`).
• If you have created a user-defined function (UDF) with a given name and upgrade MySQL to a version that implements a new built-in function with the same name, the UDF becomes inaccessible. To correct this, use `DROP FUNCTION` to drop the UDF, and then use `CREATE FUNCTION` to re-create the UDF with a different nonconflicting name. The same is true if the new version of MySQL implements a built-in function with the same name as an existing stored function. See Section 9.2.4, “Function Name Parsing and Resolution”, for the rules describing how the server interprets references to different kinds of functions.

2.11.13 Rebuilding or Repairing Tables or Indexes

This section describes how to rebuild or repair tables or indexes, which may be necessitated by:

• Changes to how MySQL handles data types or character sets. For example, an error in a collation might have been corrected, necessitating a table rebuild to update the indexes for character columns that use the collation.

• Required table repairs or upgrades reported by `CHECK TABLE`, `mysqlcheck`, or `mysql_upgrade`.

Methods for rebuilding a table include:

• Dump and Reload Method
• ALTER TABLE Method
• REPAIR TABLE Method

Dump and Reload Method

If you are rebuilding tables because a different version of MySQL will not handle them after a binary (in-place) upgrade or downgrade, you must use the dump-and-reload method. Dump the tables before upgrading or downgrading using your original version of MySQL. Then reload the tables after upgrading or downgrading.

If you use the dump-and-reload method of rebuilding tables only for the purpose of rebuilding indexes, you can perform the dump either before or after upgrading or downgrading. Reloading still must be done afterward.

If you need to rebuild an InnoDB table because a `CHECK TABLE` operation indicates that a table upgrade is required, use `mysqldump` to create a dump file and `mysql` to reload the file. If the `CHECK TABLE` operation indicates that there is a corruption or causes InnoDB to fail, refer to Section 15.20.2, “Forcing InnoDB Recovery” for information about using the `innodb_force_recovery` option to restart InnoDB. To understand the type of problem that `CHECK TABLE` may be encountering, refer to the InnoDB notes in Section 13.7.3.2, “CHECK TABLE Syntax”.

To rebuild a table by dumping and reloading it, use `mysqldump` to create a dump file and `mysql` to reload the file:

```
mysqldump db_name t1 > dump.sql
mysql db_name < dump.sql
```

To rebuild all the tables in a single database, specify the database name without any following table name:

```
mysqldump db_name > dump.sql
mysql db_name < dump.sql
```

To rebuild all tables in all databases, use the `--all-databases` option:

```
mysqldump --all-databases > dump.sql
```
Copying MySQL Databases to Another Machine

MySQL < dump.sql

### ALTER TABLE Method

To rebuild a table with ALTER TABLE, use a “null” alteration; that is, an ALTER TABLE statement that “changes” the table to use the storage engine that it already has. For example, if `t1` is an InnoDB table, use this statement:

```
ALTER TABLE t1 ENGINE = InnoDB;
```

If you are not sure which storage engine to specify in the ALTER TABLE statement, use SHOW CREATE TABLE to display the table definition.

### REPAIR TABLE Method

The REPAIR TABLE method is only applicable to MyISAM, ARCHIVE, and CSV tables.

You can use REPAIR TABLE if the table checking operation indicates that there is a corruption or that an upgrade is required. For example, to repair a MyISAM table, use this statement:

```
REPAIR TABLE t1;
```

`mysqlcheck --repair` provides command-line access to the REPAIR TABLE statement. This can be a more convenient means of repairing tables because you can use the `--databases` or `--all-databases` option to repair all tables in specific databases or all databases, respectively:

```
mysqlcheck --repair --databases db_name ...
mysqlcheck --repair --all-databases
```

### 2.11.14 Copying MySQL Databases to Another Machine

In cases where you need to transfer databases between different architectures, you can use mysqldump to create a file containing SQL statements. You can then transfer the file to the other machine and feed it as input to the mysql client.

Use mysqldump --help to see what options are available.

**Note**

If GTIDs are in use on the server where you create the dump (`gtid_mode=ON`), by default, mysqldump includes the contents of the `gtid_executed` set in the dump to transfer these to the new machine. The results of this can vary depending on the MySQL Server versions involved. Check the description for mysqldump’s `--set-gtid-purged` option to find what happens with the versions you are using, and how to change the behavior if the outcome of the default behavior is not suitable for your situation.

The easiest (although not the fastest) way to move a database between two machines is to run the following commands on the machine on which the database is located:

```
mysqladmin -h 'other_hostname' create db_name
mysqldump db_name | mysql -h 'other_hostname' db_name
```

If you want to copy a database from a remote machine over a slow network, you can use these commands:

```
mysqladmin create db_name
mysqldump -h 'other_hostname' --compress db_name | mysql db_name
```
You can also store the dump in a file, transfer the file to the target machine, and then load the file into the database there. For example, you can dump a database to a compressed file on the source machine like this:

```
mysqldump --quick db_name | gzip > db_name.gz
```

Transfer the file containing the database contents to the target machine and run these commands there:

```
mysqladmin create db_name
gunzip < db_name.gz | mysql db_name
```

You can also use mysqldump and mysqlimport to transfer the database. For large tables, this is much faster than simply using mysqldump. In the following commands, `DUMPDIR` represents the full path name of the directory you use to store the output from mysqldump.

First, create the directory for the output files and dump the database:

```
mkdir DUMPDIR
mysqldump --tab=DUMPDIR db_name
```

Then transfer the files in the `DUMPDIR` directory to some corresponding directory on the target machine and load the files into MySQL there:

```
mysqladmin create db_name  # create database
cat DUMPDIR/*.sql | mysql db_name  # create tables in database
mysqlexport db_name DUMPDIR/*.txt  # load data into tables
```

Do not forget to copy the `mysql` database because that is where the grant tables are stored. You might have to run commands as the MySQL root user on the new machine until you have the `mysql` database in place.

After you import the `mysql` database on the new machine, execute `mysqladmin flush-privileges` so that the server reloads the grant table information.

### 2.12 Downgrading MySQL

Downgrade from MySQL 8.0 to MySQL 5.7, or from a MySQL 8.0 release to a previous MySQL 8.0 release, is not supported. The only supported alternative is to restore a backup taken before upgrading. It is therefore imperative that you backup your data before starting the upgrade process.

### 2.13 Perl Installation Notes

The Perl DBI module provides a generic interface for database access. You can write a DBI script that works with many different database engines without change. To use DBI, you must install the DBI module, as well as a DataBase Driver (DBD) module for each type of database server you want to access. For MySQL, this driver is the DBD::mysql module.

**Note**

Perl support is not included with MySQL distributions. You can obtain the necessary modules from [http://search.cpan.org](http://search.cpan.org) for Unix, or by using the ActiveState ppm program on Windows. The following sections describe how to do this.

The DBI/DBD interface requires Perl 5.6.0, and 5.6.1 or later is preferred. DBI does not work if you have an older version of Perl. You should use DBD::mysql 4.009 or higher. Although earlier versions are available, they do not support the full functionality of MySQL 8.0.
2.13.1 Installing Perl on Unix

MySQL Perl support requires that you have installed MySQL client programming support (libraries and header files). Most installation methods install the necessary files. If you install MySQL from RPM files on Linux, be sure to install the developer RPM as well. The client programs are in the client RPM, but client programming support is in the developer RPM.

The files you need for Perl support can be obtained from the CPAN (Comprehensive Perl Archive Network) at http://search.cpan.org.

The easiest way to install Perl modules on Unix is to use the CPAN module. For example:

```
shell> perl -MCPAN -e shell
cpan> install DBI
cpan> install DBD::mysql
```

The `DBD::mysql` installation runs a number of tests. These tests attempt to connect to the local MySQL server using the default user name and password. (The default user name is your login name on Unix, and ODBC on Windows. The default password is “no password.”) If you cannot connect to the server with those values (for example, if your account has a password), the tests fail. You can use `force install DBD::mysql` to ignore the failed tests.

DBI requires the Data::Dumper module. It may be installed; if not, you should install it before installing DBI.

It is also possible to download the module distributions in the form of compressed tar archives and build the modules manually. For example, to unpack and build a DBI distribution, use a procedure such as this:

1. Unpack the distribution into the current directory:

   ```
   shell> gunzip < DBI-VERSION.tar.gz | tar xvf -
   ```

   This command creates a directory named `DBI-VERSION`.

2. Change location into the top-level directory of the unpacked distribution:

   ```
   shell> cd DBI-VERSION
   ```

3. Build the distribution and compile everything:

   ```
   shell> perl Makefile.PL
   shell> make
   shell> make test
   shell> make install
   ```

   The `make test` command is important because it verifies that the module is working. Note that when you run that command during the `DBD::mysql` installation to exercise the interface code, the MySQL server must be running or the test fails.

   It is a good idea to rebuild and reinstall the `DBD::mysql` distribution whenever you install a new release of MySQL. This ensures that the latest versions of the MySQL client libraries are installed correctly.

   If you do not have access rights to install Perl modules in the system directory or if you want to install local Perl modules, the following reference may be useful: http://learn.perl.org/faq/perlfaq8.html#How-do-I-keep-my-own-module-library-directory-

2.13.2 Installing ActiveState Perl on Windows
Problems Using the Perl DBI/DBD Interface

On Windows, you should do the following to install the MySQL DBD module with ActiveState Perl:

1. Get ActiveState Perl from http://www.activestate.com/Products/ActivePerl/ and install it.
2. Open a console window.
3. If necessary, set the HTTP_proxy variable. For example, you might try a setting like this:

   ```
   C:\> set HTTP_proxy=my.proxy.com:3128
   ```
4. Start the PPM program:

   ```
   C:\> C:\perl\bin\ppm.pl
   ```
5. If you have not previously done so, install DBI:

   ```
   ppm> install DBI
   ```
6. If this succeeds, run the following command:

   ```
   ppm> install DBD-mysql
   ```

This procedure should work with ActiveState Perl 5.6 or higher.

If you cannot get the procedure to work, you should install the ODBC driver instead and connect to the MySQL server through ODBC:

```perl
use DBI;
$dbh= DBI->connect("DBI:ODBC:$dsn",$user,$password) ||
die "Got error $DBI::errstr when connecting to $dsn\n";
```

### 2.13.3 Problems Using the Perl DBI/DBD Interface

If Perl reports that it cannot find the `../mysql/mysql.so` module, the problem is probably that Perl cannot locate the `libmysqlclient.so` shared library. You should be able to fix this problem by one of the following methods:

- Copy `libmysqlclient.so` to the directory where your other shared libraries are located (probably `/usr/lib` or `/lib`).
- Modify the `-L` options used to compile `DBD::mysql` to reflect the actual location of `libmysqlclient.so`.
- On Linux, you can add the path name of the directory where `libmysqlclient.so` is located to the `/etc/ld.so.conf` file.
- Add the path name of the directory where `libmysqlclient.so` is located to the `LD_RUN_PATH` environment variable. Some systems use `LD_LIBRARY_PATH` instead.

Note that you may also need to modify the `-L` options if there are other libraries that the linker fails to find. For example, if the linker cannot find `libc` because it is in `/lib` and the link command specifies `-L/usr/lib`, change the `-L` option to `-L/lib` or add `-L/lib` to the existing link command.

If you get the following errors from `DBD::mysql`, you are probably using `gcc` (or using an old binary compiled with `gcc`):

```shell
/usr/bin/perl: can't resolve symbol '__moddi3'
/usr/bin/perl: can't resolve symbol '__divdi3'
```
Add `-L/usr/lib/gcc-lib/... -lgcc` to the link command when the `mysql.so` library gets built (check the output from `make` for `mysql.so` when you compile the Perl client). The `-L` option should specify the path name of the directory where `libgcc.a` is located on your system.

Another cause of this problem may be that Perl and MySQL are not both compiled with `gcc`. In this case, you can solve the mismatch by compiling both with `gcc`.

This chapter provides a tutorial introduction to MySQL by showing how to use the mysql client program to create and use a simple database. mysql (sometimes referred to as the “terminal monitor” or just “monitor”) is an interactive program that enables you to connect to a MySQL server, run queries, and view the results. mysql may also be used in batch mode: you place your queries in a file beforehand, then tell mysql to execute the contents of the file. Both ways of using mysql are covered here.

To see a list of options provided by mysql, invoke it with the --help option:

```
shell> mysql --help
```

This chapter assumes that mysql is installed on your machine and that a MySQL server is available to which you can connect. If this is not true, contact your MySQL administrator. (If you are the administrator, you need to consult the relevant portions of this manual, such as Chapter 5, MySQL Server Administration.)

This chapter describes the entire process of setting up and using a database. If you are interested only in accessing an existing database, you may want to skip the sections that describe how to create the database and the tables it contains.

Because this chapter is tutorial in nature, many details are necessarily omitted. Consult the relevant sections of the manual for more information on the topics covered here.

3.1 Connecting to and Disconnecting from the Server

To connect to the server, you will usually need to provide a MySQL user name when you invoke mysql and, most likely, a password. If the server runs on a machine other than the one where you log in, you will also need to specify a host name. Contact your administrator to find out what connection parameters you should use to connect (that is, what host, user name, and password to use). Once you know the proper parameters, you should be able to connect like this:
3.2 Entering Queries

Make sure that you are connected to the server, as discussed in the previous section. Doing so does not in itself select any database to work with, but that is okay. At this point, it is more important to find out a little about how to issue queries than to jump right in creating tables, loading data into them, and retrieving data from them. This section describes the basic principles of entering queries, using several queries you can try out to familiarize yourself with how `mysql` works.
Here is a simple query that asks the server to tell you its version number and the current date. Type it in as shown here following the `mysql>` prompt and press Enter:

```sql
mysql> SELECT VERSION(), CURRENT_DATE;
+-----------+--------------+
| VERSION() | CURRENT_DATE |
+-----------+--------------+
| 5.8.0-m17 | 2015-12-21   |
+-----------+--------------+
1 row in set (0.02 sec)
mysql>
```

This query illustrates several things about `mysql`:

- A query normally consists of an SQL statement followed by a semicolon. (There are some exceptions where a semicolon may be omitted. `QUIT`, mentioned earlier, is one of them. We'll get to others later.)

- When you issue a query, `mysql` sends it to the server for execution and displays the results, then prints another `mysql>` prompt to indicate that it is ready for another query.

- `mysql` displays query output in tabular form (rows and columns). The first row contains labels for the columns. The rows following are the query results. Normally, column labels are the names of the columns you fetch from database tables. If you're retrieving the value of an expression rather than a table column (as in the example just shown), `mysql` labels the column using the expression itself.

- `mysql` shows how many rows were returned and how long the query took to execute, which gives you a rough idea of server performance. These values are imprecise because they represent wall clock time (not CPU or machine time), and because they are affected by factors such as server load and network latency. (For brevity, the “rows in set” line is sometimes not shown in the remaining examples in this chapter.)

Keywords may be entered in any lettercase. The following queries are equivalent:

```sql
mysql> SELECT VERSION(), CURRENT_DATE;
mysql> select version(), current_date;
mysql> Select vErSiOn(), current_DATE;
```

Here is another query. It demonstrates that you can use `mysql` as a simple calculator:

```sql
mysql> SELECT SIN(PI()/4), (4+1)*5;
+------------------+---------+
| SIN(PI()/4)      | (4+1)*5 |
+------------------+---------+
| 0.70710678118655 |      25 |
+------------------+---------+
1 row in set (0.02 sec)
```

The queries shown thus far have been relatively short, single-line statements. You can even enter multiple statements on a single line. Just end each one with a semicolon:

```sql
mysql> SELECT VERSION(); SELECT NOW();
+-----------+
| VERSION() |
+-----------+
| 8.0.13    |
+-----------+
1 row in set (0.00 sec)

+---------------------+
| NOW()               |
+---------------------+
| 2018-08-24 00:56:40 |
```
A query need not be given all on a single line, so lengthy queries that require several lines are not a problem. *mysql* determines where your statement ends by looking for the terminating semicolon, not by looking for the end of the input line. (In other words, *mysql* accepts free-format input: it collects input lines but does not execute them until it sees the semicolon.)

Here is a simple multiple-line statement:

```
mysql> SELECT
    -> USER()
    -> ,
    -> CURRENT_DATE;
```

```
+---------------------+--------------+
| USER()              | CURRENT_DATE |
| jon@localhost       | 2018-08-24   |
+---------------------+--------------+
```

In this example, notice how the prompt changes from `mysql>` to `->` after you enter the first line of a multiple-line query. This is how *mysql* indicates that it has not yet seen a complete statement and is waiting for the rest. The prompt is your friend, because it provides valuable feedback. If you use that feedback, you can always be aware of what *mysql* is waiting for.

If you decide you do not want to execute a query that you are in the process of entering, cancel it by typing `\c`:

```
mysql> SELECT
    -> USER()
    -> \c
mysql>
```

Here, too, notice the prompt. It switches back to `mysql>` after you type `\c`, providing feedback to indicate that *mysql* is ready for a new query.

The following table shows each of the prompts you may see and summarizes what they mean about the state that *mysql* is in.

<table>
<thead>
<tr>
<th>Prompt</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>mysql&gt;</code></td>
<td>Ready for new query</td>
</tr>
<tr>
<td><code>-&gt;</code></td>
<td>Waiting for next line of multiple-line query</td>
</tr>
<tr>
<td><code>'&gt;</code></td>
<td>Waiting for next line, waiting for completion of a string that began with a single quote (<code>'</code>)</td>
</tr>
<tr>
<td><code>&quot;&gt;</code></td>
<td>Waiting for next line, waiting for completion of a string that began with a double quote (<code>&quot;</code>)</td>
</tr>
<tr>
<td><code>\&gt;</code></td>
<td>Waiting for next line, waiting for completion of an identifier that began with a backtick (``)</td>
</tr>
<tr>
<td><code>/*&gt;</code></td>
<td>Waiting for next line, waiting for completion of a comment that began with <code>/*</code></td>
</tr>
</tbody>
</table>

Multiple-line statements commonly occur by accident when you intend to issue a query on a single line, but forget the terminating semicolon. In this case, *mysql* waits for more input:

```
mysql> SELECT USER()
    ->
```

If this happens to you (you think you've entered a statement but the only response is a `->` prompt), most likely *mysql* is waiting for the semicolon. If you don't notice what the prompt is telling you, you
might sit there for a while before realizing what you need to do. Enter a semicolon to complete the statement, and `mysql` executes it:

```
mysql> SELECT USER()
    -> ;
+---------------+
| USER()        |
+---------------+
| jon@localhost |
+---------------+
```

The '>' and '"' prompts occur during string collection (another way of saying that MySQL is waiting for completion of a string). In MySQL, you can write strings surrounded by either ' or " characters (for example, 'hello' or "goodbye"), and `mysql` lets you enter strings that span multiple lines. When you see a '>' or '"' prompt, it means that you have entered a line containing a string that begins with a ' or " quote character, but have not yet entered the matching quote that terminates the string. This often indicates that you have inadvertently left out a quote character. For example:

```
mysql> SELECT * FROM my_table WHERE name = 'Smith AND age < 30;
>
```

If you enter this `SELECT` statement, then press `Enter` and wait for the result, nothing happens. Instead of wondering why this query takes so long, notice the clue provided by the '>' prompt. It tells you that `mysql` expects to see the rest of an unterminated string. (Do you see the error in the statement? The string 'Smith is missing the second single quotation mark.)

At this point, what do you do? The simplest thing is to cancel the query. However, you cannot just type `\c` in this case, because `mysql` interprets it as part of the string that it is collecting. Instead, enter the closing quote character (so `mysql` knows you've finished the string), then type `\c`:

```
mysql> SELECT * FROM my_table WHERE name = 'Smith AND age < 30;
>
mysql> \c

mysql>
```

The prompt changes back to `mysql>`, indicating that `mysql` is ready for a new query.

The '>' prompt is similar to the '>' and '"' prompts, but indicates that you have begun but not completed a backtick-quoted identifier.

It is important to know what the '>', '"', and '>' prompts signify, because if you mistakenly enter an unterminated string, any further lines you type appear to be ignored by `mysql`—including a line containing `QUIT`. This can be quite confusing, especially if you do not know that you need to supply the terminating quote before you can cancel the current query.

**Note**

Multiline statements from this point on are written without the secondary (-> or other) prompts, to make it easier to copy and paste the statements to try for yourself.

### 3.3 Creating and Using a Database

Once you know how to enter SQL statements, you are ready to access a database.

Suppose that you have several pets in your home (your menagerie) and you would like to keep track of various types of information about them. You can do so by creating tables to hold your data and loading them with the desired information. Then you can answer different sorts of questions about your animals by retrieving data from the tables. This section shows you how to perform the following operations:
Creating and Selecting a Database

- Create a database
- Create a table
- Load data into the table
- Retrieve data from the table in various ways
- Use multiple tables

The menagerie database is simple (deliberately), but it is not difficult to think of real-world situations in which a similar type of database might be used. For example, a database like this could be used by a farmer to keep track of livestock, or by a veterinarian to keep track of patient records. A menagerie distribution containing some of the queries and sample data used in the following sections can be obtained from the MySQL website. It is available in both compressed tar file and Zip formats at https://dev.mysql.com/doc/.

Use the `SHOW` statement to find out what databases currently exist on the server:

```
mysql> SHOW DATABASES;
+----------+
| Database |
+----------+
| mysql    |
| test     |
| tmp      |
+----------+
```

The `mysql` database describes user access privileges. The `test` database often is available as a workspace for users to try things out.

The list of databases displayed by the statement may be different on your machine; `SHOW DATABASES` does not show databases that you have no privileges for if you do not have the `SHOW DATABASES` privilege. See Section 13.7.6.14, “SHOW DATABASES Syntax”.

If the `test` database exists, try to access it:

```
mysql> USE test
Database changed
```

`USE`, like `QUIT`, does not require a semicolon. (You can terminate such statements with a semicolon if you like; it does no harm.) The `USE` statement is special in another way, too: it must be given on a single line.

You can use the `test` database (if you have access to it) for the examples that follow, but anything you create in that database can be removed by anyone else with access to it. For this reason, you should probably ask your MySQL administrator for permission to use a database of your own. Suppose that you want to call yours `menagerie`. The administrator needs to execute a statement like this:

```
mysql> GRANT ALL ON menagerie.* TO 'your_mysql_name'@'your_client_host';
```

where `your_mysql_name` is the MySQL user name assigned to you and `your_client_host` is the host from which you connect to the server.

### 3.3.1 Creating and Selecting a Database

If the administrator creates your database for you when setting up your permissions, you can begin using it. Otherwise, you need to create it yourself:
Creating a Table

Under Unix, database names are case-sensitive (unlike SQL keywords), so you must always refer to your database as `menagerie`, not as `Menagerie`, `MENAGERIE`, or some other variant. This is also true for table names. (Under Windows, this restriction does not apply, although you must refer to databases and tables using the same lettercase throughout a given query. However, for a variety of reasons, the recommended best practice is always to use the same lettercase that was used when the database was created.)

Note
If you get an error such as `ERROR 1044 (42000): Access denied for user 'micah'@'localhost' to database 'menagerie'` when attempting to create a database, this means that your user account does not have the necessary privileges to do so. Discuss this with the administrator or see Section 6.2, “Access Control and Account Management”.

Creating a database does not select it for use; you must do that explicitly. To make `menagerie` the current database, use this statement:

```sql
mysql> USE menagerie;
Database changed
```

Your database needs to be created only once, but you must select it for use each time you begin a `mysql` session. You can do this by issuing a `USE` statement as shown in the example. Alternatively, you can select the database on the command line when you invoke `mysql`. Just specify its name after any connection parameters that you might need to provide. For example:

```shell
shell> mysql -h host -u user -p menagerie
Enter password: ********
```

Important
`menagerie` in the command just shown is not your password. If you want to supply your password on the command line after the `-p` option, you must do so with no intervening space (for example, as `-ppassword`, not as `-p password`). However, putting your password on the command line is not recommended, because doing so exposes it to snooping by other users logged in on your machine.

Note
You can see at any time which database is currently selected using `SELECT DATABASE()`.

3.3.2 Creating a Table

Creating the database is the easy part, but at this point it is empty, as `SHOW TABLES` tells you:

```sql
mysql> SHOW TABLES;
Empty set (0.00 sec)
```

The harder part is deciding what the structure of your database should be: what tables you need and what columns should be in each of them.

You want a table that contains a record for each of your pets. This can be called the `pet` table, and it should contain, as a bare minimum, each animal's name. Because the name by itself is not very interesting, the table should contain other information. For example, if more than one person in your family keeps pets, you might want to list each animal's owner. You might also want to record some basic descriptive information such as species and sex.
How about age? That might be of interest, but it is not a good thing to store in a database. Age changes as time passes, which means you’d have to update your records often. Instead, it is better to store a fixed value such as date of birth. Then, whenever you need age, you can calculate it as the difference between the current date and the birth date. MySQL provides functions for doing date arithmetic, so this is not difficult. Storing birth date rather than age has other advantages, too:

- You can use the database for tasks such as generating reminders for upcoming pet birthdays. (If you think this type of query is somewhat silly, note that it is the same question you might ask in the context of a business database to identify clients to whom you need to send out birthday greetings in the current week or month, for that computer-assisted personal touch.)

- You can calculate age in relation to dates other than the current date. For example, if you store death date in the database, you can easily calculate how old a pet was when it died.

You can probably think of other types of information that would be useful in the pet table, but the ones identified so far are sufficient: name, owner, species, sex, birth, and death.

Use a `CREATE TABLE` statement to specify the layout of your table:

```sql
mysql> CREATE TABLE pet (name VARCHAR(20), owner VARCHAR(20),
                         species VARCHAR(20), sex CHAR(1), birth DATE, death DATE);
```

`VARCHAR` is a good choice for the `name`, `owner`, and `species` columns because the column values vary in length. The lengths in those column definitions need not all be the same, and need not be 20. You can normally pick any length from 1 to 65535, whatever seems most reasonable to you. If you make a poor choice and it turns out later that you need a longer field, MySQL provides an `ALTER TABLE` statement.

Several types of values can be chosen to represent sex in animal records, such as 'm' and 'f', or perhaps 'male' and 'female'. It is simplest to use the single characters 'm' and 'f'.

The use of the `DATE` data type for the `birth` and `death` columns is a fairly obvious choice.

Once you have created a table, `SHOW TABLES` should produce some output:

```sql
mysql> SHOW TABLES;
+---------------------+
| Tables in menagerie |
+---------------------+
| pet                 |
+---------------------+
```

To verify that your table was created the way you expected, use a `DESCRIBE` statement:

```sql
mysql> DESCRIBE pet;
+---------+-------------+------+-----+---------+-------+
| Field   | Type        | Null | Key | Default | Extra |
+---------+-------------+------+-----+---------+-------+
| name    | varchar(20) | YES  |     | NULL    |       |
| owner   | varchar(20) | YES  |     | NULL    |       |
| species | varchar(20) | YES  |     | NULL    |       |
| sex     | char(1)     | YES  |     | NULL    |       |
| birth   | date        | YES  |     | NULL    |       |
| death   | date        | YES  |     | NULL    |       |
+---------+-------------+------+-----+---------+-------+
```

You can use `DESCRIBE` any time, for example, if you forget the names of the columns in your table or what types they have.

For more information about MySQL data types, see Chapter 11, *Data Types*.

### 3.3.3 Loading Data into a Table
After creating your table, you need to populate it. The `LOAD DATA` and `INSERT` statements are useful for this.

Suppose that your pet records can be described as shown here. (Observe that MySQL expects dates in `'YYYY-MM-DD'` format; this may be different from what you are used to.)

<table>
<thead>
<tr>
<th>name</th>
<th>owner</th>
<th>species</th>
<th>sex</th>
<th>birth</th>
<th>death</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fluffy</td>
<td>Harold</td>
<td>cat</td>
<td>f</td>
<td>1993-02-04</td>
<td></td>
</tr>
<tr>
<td>Claws</td>
<td>Gwen</td>
<td>cat</td>
<td>m</td>
<td>1994-03-17</td>
<td></td>
</tr>
<tr>
<td>Buffy</td>
<td>Harold</td>
<td>dog</td>
<td>f</td>
<td>1989-05-13</td>
<td></td>
</tr>
<tr>
<td>Fang</td>
<td>Benny</td>
<td>dog</td>
<td>m</td>
<td>1990-08-27</td>
<td></td>
</tr>
<tr>
<td>Bowser</td>
<td>Diane</td>
<td>dog</td>
<td>m</td>
<td>1979-08-31</td>
<td>1995-07-29</td>
</tr>
<tr>
<td>Chirpy</td>
<td>Gwen</td>
<td>bird</td>
<td>f</td>
<td>1998-09-11</td>
<td></td>
</tr>
<tr>
<td>Whistler</td>
<td>Gwen</td>
<td>bird</td>
<td></td>
<td>1997-12-09</td>
<td></td>
</tr>
<tr>
<td>Slim</td>
<td>Benny</td>
<td>snake</td>
<td>m</td>
<td>1996-04-29</td>
<td></td>
</tr>
</tbody>
</table>

Because you are beginning with an empty table, an easy way to populate it is to create a text file containing a row for each of your animals, then load the contents of the file into the table with a single statement.

You could create a text file `pet.txt` containing one record per line, with values separated by tabs, and given in the order in which the columns were listed in the `CREATE TABLE` statement. For missing values (such as unknown sexes or death dates for animals that are still living), you can use `NULL` values. To represent these in your text file, use `\N` (backslash, capital-N). For example, the record for Whistler the bird would look like this (where the whitespace between values is a single tab character):

| Whistler | Gwen  | bird | \N | 1997-12-09 | \N |

To load the text file `pet.txt` into the `pet` table, use this statement:

```
mysql> LOAD DATA LOCAL INFILE '/path/pet.txt' INTO TABLE pet;
```

If you created the file on Windows with an editor that uses `\r\n` as a line terminator, you should use this statement instead:

```
mysql> LOAD DATA LOCAL INFILE '/path/pet.txt' INTO TABLE pet
    > LINES TERMINATED BY '\r\n';
```

(On an Apple machine running OS X, you would likely want to use `LINES TERMINATED BY '\r'.`)

You can specify the column value separator and end of line marker explicitly in the `LOAD DATA` statement if you wish, but the defaults are tab and linefeed. These are sufficient for the statement to read the file `pet.txt` properly.

If the statement fails, it is likely that your MySQL installation does not have local file capability enabled by default. See Section 6.1.6, “Security Issues with LOAD DATA LOCAL”, for information on how to change this.

When you want to add new records one at a time, the `INSERT` statement is useful. In its simplest form, you supply values for each column, in the order in which the columns were listed in the `CREATE TABLE` statement. Suppose that Diane gets a new hamster named “Puffball.” You could add a new record using an `INSERT` statement like this:
Retrieving Information from a Table

mysql> INSERT INTO pet
VALUES ('Puffball','Diane','hamster','f','1999-03-30',NULL);

String and date values are specified as quoted strings here. Also, with INSERT, you can insert NULL directly to represent a missing value. You do not use \N like you do with LOAD DATA.

From this example, you should be able to see that there would be a lot more typing involved to load your records initially using several INSERT statements rather than a single LOAD DATA statement.

3.3.4 Retrieving Information from a Table

The SELECT statement is used to pull information from a table. The general form of the statement is:

```
SELECT what_to_select
FROM which_table
WHERE conditions_to_satisfy;
```

what_to_select indicates what you want to see. This can be a list of columns, or * to indicate “all columns.” which_table indicates the table from which you want to retrieve data. The WHERE clause is optional. If it is present, conditions_to_satisfy specifies one or more conditions that rows must satisfy to qualify for retrieval.

3.3.4.1 Selecting All Data

The simplest form of SELECT retrieves everything from a table:

```
mysql> SELECT * FROM pet;
```

```
+----------+--------+---------+------+------------+------------+
| name     | owner  | species | sex  | birth      | death      |
+----------+--------+---------+------+------------+------------+
| Fluffy   | Harold | cat     | f    | 1993-02-04 | NULL       |
| Claws    | Gwen   | cat     | m    | 1994-03-17 | NULL       |
| Buffy    | Harold | dog     | f    | 1989-05-13 | NULL       |
| Fang     | Benny  | dog     | m    | 1990-08-27 | NULL       |
| Bowser   | Diane  | dog     | m    | 1979-08-31 | 1995-07-29 |
| Chirpy   | Gwen   | bird    | f    | 1998-09-11 | NULL       |
| Whistler | Gwen   | bird    | NULL | 1997-12-09 | NULL       |
| Slim     | Benny  | snake   | m    | 1996-04-29 | NULL       |
| Puffball | Diane  | hamster | f    | 1999-03-30 | NULL       |
+----------+--------+---------+------+------------+------------+
```

This form of SELECT is useful if you want to review your entire table, for example, after you've just loaded it with your initial data set. For example, you may happen to think that the birth date for Bowser doesn't seem quite right. Consulting your original pedigree papers, you find that the correct birth year should be 1989, not 1979.

There are at least two ways to fix this:

- Edit the file pet.txt to correct the error, then empty the table and reload it using DELETE and LOAD DATA:

  ```
  mysql> DELETE FROM pet;
  mysql> LOAD DATA LOCAL INFILE 'pet.txt' INTO TABLE pet;
  ```

  However, if you do this, you must also re-enter the record for Puffball.

- Fix only the erroneous record with an UPDATE statement:

  ```
  mysql> UPDATE pet SET birth = '1989-08-31' WHERE name = 'Bowser';
  ```

  The UPDATE changes only the record in question and does not require you to reload the table.
3.3.4.2 Selecting Particular Rows

As shown in the preceding section, it is easy to retrieve an entire table. Just omit the `WHERE` clause from the `SELECT` statement. But typically you don’t want to see the entire table, particularly when it becomes large. Instead, you’re usually more interested in answering a particular question, in which case you specify some constraints on the information you want. Let’s look at some selection queries in terms of questions about your pets that they answer.

You can select only particular rows from your table. For example, if you want to verify the change that you made to Bowser’s birth date, select Bowser’s record like this:

```
mysql> SELECT * FROM pet WHERE name = 'Bowser';
+--------+-------+---------+------+------------+------------+
| name   | owner | species | sex  | birth      | death      |
+--------+-------+---------+------+------------+------------+
| Bowser | Diane | dog     | m    | 1989-08-31 | 1995-07-29 |
+--------+-------+---------+------+------------+------------+
```

The output confirms that the year is correctly recorded as 1989, not 1979.

String comparisons normally are case-insensitive, so you can specify the name as ‘bowser’, ‘BOWSER’, and so forth. The query result is the same.

You can specify conditions on any column, not just `name`. For example, if you want to know which animals were born during or after 1998, test the `birth` column:

```
mysql> SELECT * FROM pet WHERE birth >= '1998-1-1';
+----------+-------+---------+------+------------+-------+
| name     | owner | species | sex  | birth      | death |
+----------+-------+---------+------+------------+-------+
| Chirpy   | Gwen  | bird    | f    | 1998-09-11 | NULL  |
| Puffball | Diane | hamster | f    | 1999-03-30 | NULL  |
+----------+-------+---------+------+------------+-------+
```

You can combine conditions, for example, to locate female dogs:

```
mysql> SELECT * FROM pet WHERE species = 'dog' AND sex = 'f';
+-------+--------+---------+------+------------+-------+
| name  | owner  | species | sex  | birth      | death |
+-------+--------+---------+------+------------+-------+
| Buffy | Harold | dog     | f    | 1989-05-13 | NULL  |
+-------+--------+---------+------+------------+-------+
```

The preceding query uses the `AND` logical operator. There is also an `OR` operator:

```
mysql> SELECT * FROM pet WHERE species = 'snake' OR species = 'bird';
+----------+-------+---------+------+------------+-------+
| name     | owner | species | sex  | birth      | death |
+----------+-------+---------+------+------------+-------+
| Chirpy   | Gwen  | bird    | f    | 1998-09-11 | NULL  |
| Whistler | Gwen  | bird    | NULL | 1997-12-09 | NULL  |
| Slim     | Benny | snake   | m    | 1996-04-29 | NULL  |
+----------+-------+---------+------+------------+-------+
```

`AND` and `OR` may be intermixed, although `AND` has higher precedence than `OR`. If you use both operators, it is a good idea to use parentheses to indicate explicitly how conditions should be grouped:

```
mysql> SELECT * FROM pet WHERE (species = 'cat' AND sex = 'm') OR (species = 'dog' AND sex = 'f');
+-------+--------+---------+------+------------+-------+
| name  | owner  | species | sex  | birth      | death |
+-------+--------+---------+------+------------+-------+
| Claws | Gwen   | cat     | m    | 1994-03-17 | NULL  |
+-------+--------+---------+------+------------+-------+
```
### 3.3.4.3 Selecting Particular Columns

If you do not want to see entire rows from your table, just name the columns in which you are interested, separated by commas. For example, if you want to know when your animals were born, select the `name` and `birth` columns:

```sql
mysql> SELECT name, birth FROM pet;
+----------+------------+
| name     | birth      |
|----------+------------+
| Fluffy   | 1993-02-04 |
| Claws    | 1994-03-17 |
| Buffy    | 1989-05-13 |
| Fang     | 1990-08-27 |
| Bowser   | 1989-08-31 |
| Chirpy   | 1998-09-11 |
| Whistler | 1997-12-09 |
| Slim     | 1996-04-29 |
| Puffball | 1999-03-30 |
+----------+------------+
```

To find out who owns pets, use this query:

```sql
mysql> SELECT owner FROM pet;
+--------+
| owner  |
+--------+
| Harold |
| Gwen   |
| Harold |
| Benny  |
| Diane  |
| Gwen   |
| Benny  |
| Diane  |
| Benny  |
| Diane  |
+--------+
```

Notice that the query simply retrieves the `owner` column from each record, and some of them appear more than once. To minimize the output, retrieve each unique output record just once by adding the keyword `DISTINCT`:

```sql
mysql> SELECT DISTINCT owner FROM pet;
+--------+
| owner  |
+--------+
| Benny  |
| Diane  |
| Gwen   |
| Harold |
+--------+
```

You can use a `WHERE` clause to combine row selection with column selection. For example, to get birth dates for dogs and cats only, use this query:

```sql
mysql> SELECT name, species, birth FROM pet
    WHERE species = 'dog' OR species = 'cat';
+----------+---------+------------+
| name     | species | birth      |
|----------+---------+------------+
| Fluffy   | cat     | 1993-02-04 |
| Claws    | cat     | 1994-03-17 |
+----------+---------+------------+
```
3.3.4.4 Sorting Rows

You may have noticed in the preceding examples that the result rows are displayed in no particular order. It is often easier to examine query output when the rows are sorted in some meaningful way. To sort a result, use an `ORDER BY` clause.

Here are animal birthdays, sorted by date:

```
mysql> SELECT name, birth FROM pet ORDER BY birth;
+----------+------------+
| name     | birth      |
+----------+------------+
| Buffy    | 1989-05-13 |
| Bowser   | 1989-08-31 |
| Fang     | 1990-08-27 |
| Fluffy   | 1993-02-04 |
| Claws    | 1994-03-17 |
| Slim     | 1996-04-29 |
| Whistler | 1997-12-09 |
| Chirpy   | 1998-09-11 |
| Puffball | 1999-03-30 |
+----------+------------+
```

On character type columns, sorting—like all other comparison operations—is normally performed in a case-insensitive fashion. This means that the order is undefined for columns that are identical except for their case. You can force a case-sensitive sort for a column by using `BINARY` like so: `ORDER BY BINARY col_name`.

The default sort order is ascending, with smallest values first. To sort in reverse (descending) order, add the `DESC` keyword to the name of the column you are sorting by:

```
mysql> SELECT name, birth FROM pet ORDER BY birth DESC;
+----------+------------+
| name     | birth      |
+----------+------------+
| Puffball | 1999-03-30 |
| Chirpy   | 1998-09-11 |
| Whistler | 1997-12-09 |
| Claws    | 1994-03-17 |
| Fluffy   | 1993-02-04 |
| Fang     | 1990-08-27 |
| Bowser   | 1989-08-31 |
| Buffy    | 1989-05-13 |
+----------+------------+
```

You can sort on multiple columns, and you can sort different columns in different directions. For example, to sort by type of animal in ascending order, then by birth date within animal type in descending order (youngest animals first), use the following query:

```
mysql> SELECT name, species, birth FROM pet
    ORDER BY species, birth DESC;
+----------+---------+------------+
| name     | species | birth      |
+----------+---------+------------+
| Chirpy   | bird    | 1998-09-11 |
| Whistler | bird    | 1997-12-09 |
| Claws    | cat     | 1994-03-17 |
| Fluffy   | cat     | 1993-02-04 |
| Fang     | cat     | 1990-08-27 |
| Bowser   | dog     | 1989-08-31 |
+----------+---------+------------+
```
Retrieving Information from a Table

| Buffy    | dog     | 1989-05-13 |
| Puffball | hamster | 1999-03-30 |
| Slim     | snake   | 1996-04-29 |

The **DESC** keyword applies only to the column name immediately preceding it (**birth**); it does not affect the **species** column sort order.

### 3.3.4.5 Date Calculations

MySQL provides several functions that you can use to perform calculations on dates, for example, to calculate ages or extract parts of dates.

To determine how many years old each of your pets is, use the **TIMESTAMPDIFF()** function. Its arguments are the unit in which you want the result expressed, and the two dates for which to take the difference. The following query shows, for each pet, the birth date, the current date, and the age in years. An alias (**age**) is used to make the final output column label more meaningful.

```sql
mysql> SELECT name, birth, CURDATE(),
TIMESTAMPDIFF(YEAR,birth,CURDATE()) AS age
FROM pet;
```

<table>
<thead>
<tr>
<th>name</th>
<th>birth</th>
<th>CURDATE()</th>
<th>age</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fluffy</td>
<td>1993-02-04</td>
<td>2003-08-19</td>
<td>10</td>
</tr>
<tr>
<td>Claws</td>
<td>1994-03-17</td>
<td>2003-08-19</td>
<td>9</td>
</tr>
<tr>
<td>Buffy</td>
<td>1989-05-13</td>
<td>2003-08-19</td>
<td>14</td>
</tr>
<tr>
<td>Fang</td>
<td>1990-08-27</td>
<td>2003-08-19</td>
<td>12</td>
</tr>
<tr>
<td>Bowser</td>
<td>1989-08-31</td>
<td>2003-08-19</td>
<td>13</td>
</tr>
<tr>
<td>Chirpy</td>
<td>1998-09-11</td>
<td>2003-08-19</td>
<td>4</td>
</tr>
<tr>
<td>Whistler</td>
<td>1997-12-09</td>
<td>2003-08-19</td>
<td>5</td>
</tr>
<tr>
<td>Slim</td>
<td>1996-04-29</td>
<td>2003-08-19</td>
<td>7</td>
</tr>
<tr>
<td>Puffball</td>
<td>1999-03-30</td>
<td>2003-08-19</td>
<td>4</td>
</tr>
</tbody>
</table>

The query works, but the result could be scanned more easily if the rows were presented in some order. This can be done by adding an **ORDER BY name** clause to sort the output by name:

```sql
mysql> SELECT name, birth, CURDATE(),
TIMESTAMPDIFF(YEAR,birth,CURDATE()) AS age
FROM pet ORDER BY name;
```

<table>
<thead>
<tr>
<th>name</th>
<th>birth</th>
<th>CURDATE()</th>
<th>age</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bowser</td>
<td>1989-08-31</td>
<td>2003-08-19</td>
<td>13</td>
</tr>
<tr>
<td>Buffy</td>
<td>1989-05-13</td>
<td>2003-08-19</td>
<td>14</td>
</tr>
<tr>
<td>Chirpy</td>
<td>1998-09-11</td>
<td>2003-08-19</td>
<td>4</td>
</tr>
<tr>
<td>Claws</td>
<td>1994-03-17</td>
<td>2003-08-19</td>
<td>9</td>
</tr>
<tr>
<td>Fang</td>
<td>1990-08-27</td>
<td>2003-08-19</td>
<td>12</td>
</tr>
<tr>
<td>Fluffy</td>
<td>1993-02-04</td>
<td>2003-08-19</td>
<td>10</td>
</tr>
<tr>
<td>Puffball</td>
<td>1999-03-30</td>
<td>2003-08-19</td>
<td>4</td>
</tr>
<tr>
<td>Slim</td>
<td>1996-04-29</td>
<td>2003-08-19</td>
<td>7</td>
</tr>
<tr>
<td>Whistler</td>
<td>1997-12-09</td>
<td>2003-08-19</td>
<td>5</td>
</tr>
</tbody>
</table>

To sort the output by **age** rather than **name**, just use a different **ORDER BY** clause:

```sql
mysql> SELECT name, birth, CURDATE(),
TIMESTAMPDIFF(YEAR,birth,CURDATE()) AS age
FROM pet ORDER BY age;
```

<table>
<thead>
<tr>
<th>name</th>
<th>birth</th>
<th>CURDATE()</th>
<th>age</th>
</tr>
</thead>
<tbody>
<tr>
<td>Chirpy</td>
<td>1998-09-11</td>
<td>2003-08-19</td>
<td>4</td>
</tr>
<tr>
<td>Puffball</td>
<td>1999-03-30</td>
<td>2003-08-19</td>
<td>4</td>
</tr>
<tr>
<td>Whistler</td>
<td>1997-12-09</td>
<td>2003-08-19</td>
<td>5</td>
</tr>
</tbody>
</table>
A similar query can be used to determine age at death for animals that have died. You determine which animals these are by checking whether the `death` value is `NULL`. Then, for those with non-`NULL` values, compute the difference between the `death` and `birth` values:

```sql
mysql> SELECT name, birth, death,
TIMESTAMPDIFF(YEAR,birth,death) AS age
FROM pet WHERE death IS NOT NULL ORDER BY age;
```

<table>
<thead>
<tr>
<th>name</th>
<th>birth</th>
<th>death</th>
<th>age</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bowser</td>
<td>1989-08-31</td>
<td>1995-07-29</td>
<td>7</td>
</tr>
</tbody>
</table>

The query uses `death IS NOT NULL` rather than `death <> NULL` because `NULL` is a special value that cannot be compared using the usual comparison operators. This is discussed later. See Section 3.3.4.6, “Working with NULL Values”.

What if you want to know which animals have birthdays next month? For this type of calculation, year and day are irrelevant; you simply want to extract the month part of the `birth` column. MySQL provides several functions for extracting parts of dates, such as `YEAR()`, `MONTH()`, and `DAYOFMONTH()`. `MONTH()` is the appropriate function here. To see how it works, run a simple query that displays the value of both `birth` and `MONTH(birth)`:

```sql
mysql> SELECT name, birth, MONTH(birth) FROM pet;
```

<table>
<thead>
<tr>
<th>name</th>
<th>birth</th>
<th>MONTH(birth)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fluffy</td>
<td>1993-02-04</td>
<td>2</td>
</tr>
<tr>
<td>Claws</td>
<td>1994-03-17</td>
<td>3</td>
</tr>
<tr>
<td>Buffy</td>
<td>1989-05-13</td>
<td>5</td>
</tr>
<tr>
<td>Fang</td>
<td>1990-08-27</td>
<td>8</td>
</tr>
<tr>
<td>Bowser</td>
<td>1989-08-31</td>
<td>8</td>
</tr>
<tr>
<td>Chirpy</td>
<td>1998-09-11</td>
<td>9</td>
</tr>
<tr>
<td>Whistler</td>
<td>1997-12-09</td>
<td>12</td>
</tr>
<tr>
<td>Slim</td>
<td>1996-04-29</td>
<td>4</td>
</tr>
<tr>
<td>Puffball</td>
<td>1999-03-30</td>
<td>3</td>
</tr>
</tbody>
</table>

Finding animals with birthdays in the upcoming month is also simple. Suppose that the current month is April. Then the month value is 4 and you can look for animals born in May (month 5) like this:

```sql
mysql> SELECT name, birth FROM pet WHERE MONTH(birth) = 5;
```

<table>
<thead>
<tr>
<th>name</th>
<th>birth</th>
</tr>
</thead>
<tbody>
<tr>
<td>Buffy</td>
<td>1989-05-13</td>
</tr>
</tbody>
</table>

There is a small complication if the current month is December. You cannot merely add one to the month number (12) and look for animals born in month 13, because there is no such month. Instead, you look for animals born in January (month 1).

You can write the query so that it works no matter what the current month is, so that you do not have to use the number for a particular month. `DATE_ADD()` enables you to add a time interval to a given date. If you add a month to the value of `CURDATE()`, then extract the month part with `MONTH()`, the result produces the month in which to look for birthdays:
Retrieving Information from a Table

Retrieving Information from a Table

mysql> SELECT name, birth FROM pet
    WHERE MONTH(birth) = MONTH(DATE_ADD(CURDATE(), INTERVAL 1 MONTH));

A different way to accomplish the same task is to add 1 to get the next month after the current one after using the modulo function (`MOD`) to wrap the month value to 0 if it is currently 12:

mysql> SELECT name, birth FROM pet
    WHERE MONTH(birth) = MOD(MONTH(CURDATE()), 12) + 1;

`MONTH()` returns a number between 1 and 12. And `MOD(something, 12)` returns a number between 0 and 11. So the addition has to be after the `MOD()`, otherwise we would go from November (11) to January (1).

If a calculation uses invalid dates, the calculation fails and produces warnings:

mysql> SELECT '2018-10-31' + INTERVAL 1 DAY;
+-------------------------------+
| '2018-10-31' + INTERVAL 1 DAY |
+-------------------------------+
| 2018-11-01                    |
+-------------------------------+
mysql> SELECT '2018-10-32' + INTERVAL 1 DAY;
+-------------------------------+
| '2018-10-32' + INTERVAL 1 DAY |
+-------------------------------+
| NULL                          |
+-------------------------------+
mysql> SHOW WARNINGS;
+---------+------+----------------------------------------+
| Level   | Code | Message                                |
+---------+------+----------------------------------------+
| Warning | 1292 | Incorrect datetime value: '2018-10-32' |
+---------+------+----------------------------------------+

3.3.4.6 Working with NULL Values

The `NULL` value can be surprising until you get used to it. Conceptually, `NULL` means “a missing unknown value” and it is treated somewhat differently from other values.

To test for `NULL`, use the `IS NULL` and `IS NOT NULL` operators, as shown here:

mysql> SELECT 1 IS NULL, 1 IS NOT NULL;
+-----------+---------------+
| 1 IS NULL | 1 IS NOT NULL |
+-----------+---------------+
|         0 |             1 |
+-----------+---------------+

You cannot use arithmetic comparison operators such as `=`, `<`, or `<>` to test for `NULL`. To demonstrate this for yourself, try the following query:

mysql> SELECT 1 = NULL, 1 <> NULL, 1 < NULL, 1 > NULL;
+----------+-----------+----------+----------+
| 1 = NULL | 1 <> NULL | 1 < NULL | 1 > NULL |
+----------+-----------+----------+----------+
|     NULL |      NULL |     NULL |     NULL |
+----------+-----------+----------+----------+

Because the result of any arithmetic comparison with `NULL` is also `NULL`, you cannot obtain any meaningful results from such comparisons.

In MySQL, 0 or `NULL` means false and anything else means true. The default truth value from a boolean operation is 1.
This special treatment of \texttt{NULL} is why, in the previous section, it was necessary to determine which animals are no longer alive using \texttt{death IS NOT NULL} instead of \texttt{death <> NULL}.

Two \texttt{NULL} values are regarded as equal in a \texttt{GROUP BY}.

When doing an \texttt{ORDER BY}, \texttt{NULL} values are presented first if you do \texttt{ORDER BY ... ASC} and last if you do \texttt{ORDER BY ... DESC}.

A common error when working with \texttt{NULL} is to assume that it is not possible to insert a zero or an empty string into a column defined as \texttt{NOT NULL}, but this is not the case. These are in fact values, whereas \texttt{NULL} means “not having a value.” You can test this easily enough by using \texttt{IS [NOT] NULL} as shown:

| mysql> SELECT 0 IS NULL, 0 IS NOT NULL, '' IS NULL, '' IS NOT NULL; |
|------------------------|------------------------|------------------------|------------------------|
| 0 IS NULL | 0 IS NOT NULL | '' IS NULL | '' IS NOT NULL |
| 0 | 1 | 0 | 1 |

Thus it is entirely possible to insert a zero or empty string into a \texttt{NOT NULL} column, as these are in fact \texttt{NOT NULL}. See Section B.4.4.3, “Problems with NULL Values”.

### 3.3.4.7 Pattern Matching

MySQL provides standard SQL pattern matching as well as a form of pattern matching based on extended regular expressions similar to those used by Unix utilities such as \texttt{vi}, \texttt{grep}, and \texttt{sed}.

SQL pattern matching enables you to use \_ to match any single character and \% to match an arbitrary number of characters (including zero characters). In MySQL, SQL patterns are case-insensitive by default. Some examples are shown here. Do not use \_ or <> when you use SQL patterns. Use the \texttt{LIKE} or \texttt{NOT LIKE} comparison operators instead.

To find names beginning with \texttt{b}:

| mysql> SELECT * FROM pet WHERE name LIKE 'b%'; |
| name | owner | species | sex | birth | death |
| Buff | Harold | dog | f | 1989-05-13 | NULL |
| Bowser | Diane | dog | m | 1989-08-31 | 1995-07-29 |

To find names ending with \texttt{fy}:

| mysql> SELECT * FROM pet WHERE name LIKE '%fy'; |
| name | owner | species | sex | birth | death |
| Fluffy | Harold | cat | f | 1993-02-04 | NULL |
| Buffy | Harold | dog | f | 1989-05-13 | NULL |

To find names containing a \texttt{w}:

| mysql> SELECT * FROM pet WHERE name LIKE '%w%'; |
| name | owner | species | sex | birth | death |
| Claws | Gwen | cat | m | 1994-03-17 | NULL |
| Bowser | Diane | dog | m | 1989-08-31 | 1995-07-29 |
| Whistler | Gwen | bird | NULL | 1997-12-09 | NULL |
To find names containing exactly five characters, use five instances of the _ pattern character:

```sql
mysql> SELECT * FROM pet WHERE name LIKE '_____';
+-------+--------+---------+------+------------+-------+
| name  | owner  | species | sex  | birth      | death |
|-------|--------|---------|------|------------|-------+
| Claws | Gwen   | cat     | m    | 1994-03-17 | NULL  |
| Buffy | Harold | dog     | f    | 1989-05-13 | NULL  |
+-------+--------+---------+------+------------+-------+
```

The other type of pattern matching provided by MySQL uses extended regular expressions. When you test for a match for this type of pattern, use the REGEXP_LIKE() function (or the REGEXP or RLIKE operators, which are synonyms for REGEXP_LIKE()).

The following list describes some characteristics of extended regular expressions:

- . matches any single character.
- A character class [abc] matches any character within the brackets. For example, [abc] matches a, b, or c. To name a range of characters, use a dash. [a-z] matches any letter, whereas [0-9] matches any digit.
- * matches zero or more instances of the thing preceding it. For example, x* matches any number of x characters, [0-9]* matches any number of digits, and .* matches any number of anything.
- A regular expression pattern match succeeds if the pattern matches anywhere in the value being tested. (This differs from a LIKE pattern match, which succeeds only if the pattern matches the entire value.)
- To anchor a pattern so that it must match the beginning or end of the value being tested, use ^ at the beginning or $ at the end of the pattern.

To demonstrate how extended regular expressions work, the LIKE queries shown previously are rewritten here to use REGEXP_LIKE().

To find names beginning with b, use ^ to match the beginning of the name:

```sql
mysql> SELECT * FROM pet WHERE REGEXP_LIKE(name, '^b');
+--------+--------+---------+------+------------+------------+
| name   | owner  | species | sex  | birth      | death      |
|--------|--------|---------|------|------------|------------+
| Buffy  | Harold | dog     | f    | 1989-05-13 | NULL       |
| Bowser | Diane  | dog     | m    | 1979-08-31 | 1995-07-29 |
+--------+--------+---------+------+------------+------------+
```

To force a regular expression comparison to be case sensitive, use a case-sensitive collation, or use the BINARY keyword to make one of the strings a binary string, or specify the c match-control character. Each of these queries matches only lowercase b at the beginning of a name:

```sql
SELECT * FROM pet WHERE REGEXP_LIKE(name, '^b' COLLATE utf8mb4_0900_as_cs);
SELECT * FROM pet WHERE REGEXP_LIKE(name, BINARY '^b');
SELECT * FROM pet WHERE REGEXP_LIKE(name, '^b', 'c');
```

To find names ending with fy, use $ to match the end of the name:

```sql
mysql> SELECT * FROM pet WHERE REGEXP_LIKE(name, 'fy$');
+-------+--------+---------+------+------------+-------+
| name  | owner  | species | sex  | birth      | death |
|-------|--------|---------|------|------------|-------+
| Fluffy | Harold | cat     | f    | 1993-02-04 | NULL  |
| Buffy  | Harold | dog     | f    | 1989-05-13 | NULL  |
+-------+--------+---------+------+------------+-------+
```
To find names containing a `w`, use this query:

```sql
mysql> SELECT * FROM pet WHERE REGEXP_LIKE(name, 'w');
```

+----------+-------+---------+------+------------+------------+
<table>
<thead>
<tr>
<th>name</th>
<th>owner</th>
<th>species</th>
<th>sex</th>
<th>birth</th>
<th>death</th>
</tr>
</thead>
<tbody>
<tr>
<td>Claws</td>
<td>Gwen</td>
<td>cat</td>
<td>m</td>
<td>1994-03-17</td>
<td>NULL</td>
</tr>
<tr>
<td>Bowser</td>
<td>Diane</td>
<td>dog</td>
<td>m</td>
<td>1989-08-31</td>
<td>1995-07-29</td>
</tr>
<tr>
<td>Whistler</td>
<td>Gwen</td>
<td>bird</td>
<td>NULL</td>
<td>1997-12-09</td>
<td>NULL</td>
</tr>
</tbody>
</table>
+----------+-------+---------+------+------------+------------+

Because a regular expression pattern matches if it occurs anywhere in the value, it is not necessary in the previous query to put a wildcard on either side of the pattern to get it to match the entire value as would be true with an SQL pattern.

To find names containing exactly five characters, use `^` and `$` to match the beginning and end of the name, and five instances of `. ` in between:

```sql
mysql> SELECT * FROM pet WHERE REGEXP_LIKE(name, '^.....$');
```

+-------+--------+---------+------+------------+-------+
<table>
<thead>
<tr>
<th>name</th>
<th>owner</th>
<th>species</th>
<th>sex</th>
<th>birth</th>
<th>death</th>
</tr>
</thead>
<tbody>
<tr>
<td>Claws</td>
<td>Gwen</td>
<td>cat</td>
<td>m</td>
<td>1994-03-17</td>
<td>NULL</td>
</tr>
<tr>
<td>Buffy</td>
<td>Harold</td>
<td>dog</td>
<td>f</td>
<td>1989-05-13</td>
<td>NULL</td>
</tr>
</tbody>
</table>
+-------+--------+---------+------+------------+-------+

You could also write the previous query using the `{n}` ("repeat-\(n\)-times") operator:

```sql
mysql> SELECT * FROM pet WHERE REGEXP_LIKE(name, '^.{5}$');
```

+-------+--------+---------+------+------------+-------+
<table>
<thead>
<tr>
<th>name</th>
<th>owner</th>
<th>species</th>
<th>sex</th>
<th>birth</th>
<th>death</th>
</tr>
</thead>
<tbody>
<tr>
<td>Claws</td>
<td>Gwen</td>
<td>cat</td>
<td>m</td>
<td>1994-03-17</td>
<td>NULL</td>
</tr>
<tr>
<td>Buffy</td>
<td>Harold</td>
<td>dog</td>
<td>f</td>
<td>1989-05-13</td>
<td>NULL</td>
</tr>
</tbody>
</table>
+-------+--------+---------+------+------------+-------+

For more information about the syntax for regular expressions, see Section 12.5.2, “Regular Expressions”.

### 3.3.4.8 Counting Rows

Databases are often used to answer the question, “How often does a certain type of data occur in a table?” For example, you might want to know how many pets you have, or how many pets each owner has, or you might want to perform various kinds of census operations on your animals.

Counting the total number of animals you have is the same question as “How many rows are in the pet table?” because there is one record per pet. `COUNT(*)` counts the number of rows, so the query to count your animals looks like this:

```sql
mysql> SELECT COUNT(*) FROM pet;
```

<table>
<thead>
<tr>
<th>COUNT(*)</th>
</tr>
</thead>
<tbody>
<tr>
<td>9</td>
</tr>
</tbody>
</table>

Earlier, you retrieved the names of the people who owned pets. You can use `COUNT()` if you want to find out how many pets each owner has:

```sql
mysql> SELECT owner, COUNT(*) FROM pet GROUP BY owner;
```

<table>
<thead>
<tr>
<th>owner</th>
<th>COUNT(*)</th>
</tr>
</thead>
</table>

283
The preceding query uses `GROUP BY` to group all records for each owner. The use of `COUNT()` in conjunction with `GROUP BY` is useful for characterizing your data under various groupings. The following examples show different ways to perform animal census operations.

**Number of animals per species:**

```
mysql> SELECT species, COUNT(*) FROM pet GROUP BY species;
```

```
+---------+----------+
| species | COUNT(*) |
+---------+----------+
| bird    |        2 |
| cat     |        2 |
| dog     |        3 |
| hamster |        1 |
| snake   |        1 |
+---------+----------+
```

**Number of animals per sex:**

```
mysql> SELECT sex, COUNT(*) FROM pet GROUP BY sex;
```

```
+------+----------+
| sex  | COUNT(*) |
+------+----------+
| NULL |        1 |
| f    |        4 |
| m    |        4 |
+------+----------+
```

(In this output, `NULL` indicates that the sex is unknown.)

**Number of animals per combination of species and sex:**

```
mysql> SELECT species, sex, COUNT(*) FROM pet GROUP BY species, sex;
```

```
+---------+------+----------+
| species | sex  | COUNT(*) |
+---------+------+----------+
| bird    | NULL |        1 |
| bird    | f    |        1 |
| cat     | f    |        1 |
| cat     | m    |        1 |
| dog     | f    |        1 |
| dog     | m    |        2 |
| hamster | f    |        1 |
| snake   | m    |        1 |
+---------+------+----------+
```

You need not retrieve an entire table when you use `COUNT()`. For example, the previous query, when performed just on dogs and cats, looks like this:

```
mysql> SELECT species, sex, COUNT(*) FROM pet
    WHERE species = 'dog' OR species = 'cat'
GROUP BY species, sex;
```

```
+---------+------+----------+
| species | sex  | COUNT(*) |
+---------+------+----------+
| cat     | f    |        1 |
| cat     | m    |        1 |
| dog     | f    |        1 |
| dog     | m    |        2 |
+---------+------+----------+
```
Or, if you wanted the number of animals per sex only for animals whose sex is known:

```sql
mysql> SELECT species, sex, COUNT(*) FROM pet
    WHERE sex IS NOT NULL
    GROUP BY species, sex;
```

<table>
<thead>
<tr>
<th>species</th>
<th>sex</th>
<th>COUNT(*)</th>
</tr>
</thead>
<tbody>
<tr>
<td>bird</td>
<td>f</td>
<td>1</td>
</tr>
<tr>
<td>cat</td>
<td>f</td>
<td>1</td>
</tr>
<tr>
<td>cat</td>
<td>m</td>
<td>1</td>
</tr>
<tr>
<td>dog</td>
<td>f</td>
<td>1</td>
</tr>
<tr>
<td>dog</td>
<td>m</td>
<td>2</td>
</tr>
<tr>
<td>hamster</td>
<td>f</td>
<td>1</td>
</tr>
<tr>
<td>snake</td>
<td>m</td>
<td>1</td>
</tr>
</tbody>
</table>

If you name columns to select in addition to the `COUNT()` value, a `GROUP BY` clause should be present that names those same columns. Otherwise, the following occurs:

- If the `ONLY_FULL_GROUP_BY` SQL mode is enabled, an error occurs:

  ```sql
  mysql> SET sql_mode = 'ONLY_FULL_GROUP_BY';
  Query OK, 0 rows affected (0.00 sec)
  mysql> SELECT owner, COUNT(*) FROM pet;
  Error 1140 (42000): In aggregated query without GROUP BY, expression #1 of SELECT list contains nonaggregated column 'menagerie.pet.owner'; this is incompatible with sql_mode=only_full_group_by
  ```

- If `ONLY_FULL_GROUP_BY` is not enabled, the query is processed by treating all rows as a single group, but the value selected for each named column is nondeterministic. The server is free to select the value from any row:

  ```sql
  mysql> SET sql_mode = '';
  Query OK, 0 rows affected (0.00 sec)
  mysql> SELECT owner, COUNT(*) FROM pet;
  +-------+----------+
  | owner | COUNT(*) |
  +-------+----------+
  | Harold | 8        |
  +-------+----------+
  1 row in set (0.00 sec)
  ```

See also Section 12.20.3, “MySQL Handling of GROUP BY”. See Section 12.20.1, “Aggregate (GROUP BY) Function Descriptions” for information about `COUNT(expr)` behavior and related optimizations.

### 3.3.4.9 Using More Than one Table

The `pet` table keeps track of which pets you have. If you want to record other information about them, such as events in their lives like visits to the vet or when litters are born, you need another table. What should this table look like? It needs to contain the following information:

- The pet name so that you know which animal each event pertains to.
- A date so that you know when the event occurred.
- A field to describe the event.
- An event type field, if you want to be able to categorize events.

Given these considerations, the `CREATE TABLE` statement for the `event` table might look like this:
Retrieving Information from a Table

mysql> CREATE TABLE event (name VARCHAR(20), date DATE, type VARCHAR(15), remark VARCHAR(255));

As with the pet table, it is easiest to load the initial records by creating a tab-delimited text file containing the following information.

<table>
<thead>
<tr>
<th>name</th>
<th>date</th>
<th>type</th>
<th>remark</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fluffy</td>
<td>1995-05-15</td>
<td>litter</td>
<td>4 kittens, 3 female, 1 male</td>
</tr>
<tr>
<td>Buffy</td>
<td>1993-06-23</td>
<td>litter</td>
<td>5 puppies, 2 female, 3 male</td>
</tr>
<tr>
<td>Buffy</td>
<td>1994-06-19</td>
<td>litter</td>
<td>3 puppies, 3 female</td>
</tr>
<tr>
<td>Chirpy</td>
<td>1999-03-21</td>
<td>vet</td>
<td>needed beak straightened</td>
</tr>
<tr>
<td>Slim</td>
<td>1997-08-03</td>
<td>vet</td>
<td>broken rib</td>
</tr>
<tr>
<td>Bowser</td>
<td>1991-10-12</td>
<td>kennel</td>
<td></td>
</tr>
<tr>
<td>Fang</td>
<td>1991-10-12</td>
<td>kennel</td>
<td></td>
</tr>
<tr>
<td>Fang</td>
<td>1998-08-28</td>
<td>birthday</td>
<td>Gave him a new chew toy</td>
</tr>
<tr>
<td>Claws</td>
<td>1998-03-17</td>
<td>birthday</td>
<td>Gave him a new flea collar</td>
</tr>
<tr>
<td>Whistler</td>
<td>1998-12-09</td>
<td>birthday</td>
<td>First birthday</td>
</tr>
</tbody>
</table>

Load the records like this:

mysql> LOAD DATA LOCAL INFILE 'event.txt' INTO TABLE event;

Based on what you have learned from the queries that you have run on the pet table, you should be able to perform retrievals on the records in the event table; the principles are the same. But when is the event table by itself insufficient to answer questions you might ask?

Suppose that you want to find out the ages at which each pet had its litters. We saw earlier how to calculate ages from two dates. The litter date of the mother is in the event table, but to calculate her age on that date you need her birth date, which is stored in the pet table. This means the query requires both tables:

```
mysql> SELECT pet.name, 
TIMESTAMPDIFF(YEAR,birth,date) AS age, 
remark 
FROM pet INNER JOIN event 
ON pet.name = event.name 
WHERE event.type = 'litter';
```

<table>
<thead>
<tr>
<th>name</th>
<th>age</th>
<th>remark</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fluffy</td>
<td>2</td>
<td>4 kittens, 3 female, 1 male</td>
</tr>
<tr>
<td>Buffy</td>
<td>4</td>
<td>5 puppies, 2 female, 3 male</td>
</tr>
<tr>
<td>Buffy</td>
<td>5</td>
<td>3 puppies, 3 female</td>
</tr>
</tbody>
</table>

There are several things to note about this query:

- The FROM clause joins two tables because the query needs to pull information from both of them.
- When combining (joining) information from multiple tables, you need to specify how records in one table can be matched to records in the other. This is easy because they both have a name column. The query uses an ON clause to match up records in the two tables based on the name values.
- The query uses an INNER JOIN to combine the tables. An INNER JOIN permits rows from either table to appear in the result if and only if both tables meet the conditions specified in the ON clause. In this example, the ON clause specifies that the name column in the pet table must match the name
column in the `event` table. If a name appears in one table but not the other, the row will not appear in the result because the condition in the `ON` clause fails.

- Because the `name` column occurs in both tables, you must be specific about which table you mean when referring to the column. This is done by prepending the table name to the column name.

You need not have two different tables to perform a join. Sometimes it is useful to join a table to itself, if you want to compare records in a table to other records in that same table. For example, to find breeding pairs among your pets, you can join the `pet` table with itself to produce candidate pairs of live males and females of like species:

```sql
mysql> SELECT p1.name, p1.sex, p2.name, p2.sex, p1.species
FROM pet AS p1 INNER JOIN pet AS p2
  ON p1.species = p2.species
  AND p1.sex = 'f' AND p1.death IS NULL
  AND p2.sex = 'm' AND p2.death IS NULL;
```

<table>
<thead>
<tr>
<th>name</th>
<th>sex</th>
<th>name</th>
<th>sex</th>
<th>species</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fluffy</td>
<td>f</td>
<td>Claws</td>
<td>m</td>
<td>cat</td>
</tr>
<tr>
<td>Buffy</td>
<td>f</td>
<td>Fang</td>
<td>m</td>
<td>dog</td>
</tr>
</tbody>
</table>

In this query, we specify aliases for the table name to refer to the columns and keep straight which instance of the table each column reference is associated with.

### 3.4 Getting Information About Databases and Tables

What if you forget the name of a database or table, or what the structure of a given table is (for example, what its columns are called)? MySQL addresses this problem through several statements that provide information about the databases and tables it supports.

You have previously seen `SHOW DATABASES`, which lists the databases managed by the server. To find out which database is currently selected, use the `DATABASE()` function:

```sql
mysql> SELECT DATABASE();
```

<table>
<thead>
<tr>
<th>DATABASE()</th>
</tr>
</thead>
<tbody>
<tr>
<td>menagerie</td>
</tr>
</tbody>
</table>

If you have not yet selected any database, the result is `NULL`.

To find out what tables the default database contains (for example, when you are not sure about the name of a table), use this statement:

```sql
mysql> SHOW TABLES;
```

<table>
<thead>
<tr>
<th>Tables_in_menagerie</th>
</tr>
</thead>
<tbody>
<tr>
<td>event</td>
</tr>
<tr>
<td>pet</td>
</tr>
</tbody>
</table>

The name of the column in the output produced by this statement is always `Tables_in_db_name`, where `db_name` is the name of the database. See Section 13.7.6.37, “SHOW TABLES Syntax”, for more information.

If you want to find out about the structure of a table, the `DESCRIBE` statement is useful; it displays information about each of a table’s columns:
Field indicates the column name, Type is the data type for the column, NULL indicates whether the column can contain NULL values, Key indicates whether the column is indexed, and Default specifies the column's default value. Extra displays special information about columns: If a column was created with the AUTO_INCREMENT option, the value will be auto_increment rather than empty.

DESC is a short form of DESCRIBE. See Section 13.8.1, “DESCRIBE Syntax”, for more information.

You can obtain the CREATE TABLE statement necessary to create an existing table using the SHOW CREATE TABLE statement. See Section 13.7.6.10, “SHOW CREATE TABLE Syntax”.

If you have indexes on a table, SHOW INDEX FROM tbl_name produces information about them. See Section 13.7.6.22, “SHOW INDEX Syntax”, for more about this statement.

### 3.5 Using mysql in Batch Mode

In the previous sections, you used `mysql` interactively to enter statements and view the results. You can also run `mysql` in batch mode. To do this, put the statements you want to run in a file, then tell `mysql` to read its input from the file:

```
shell> mysql < batch-file
```

If you are running `mysql` under Windows and have some special characters in the file that cause problems, you can do this:

```
C:\> mysql -e "source batch-file"
```

If you need to specify connection parameters on the command line, the command might look like this:

```
shell> mysql -h host -u user -p < batch-file
Enter password: ********
```

When you use `mysql` this way, you are creating a script file, then executing the script.

If you want the script to continue even if some of the statements in it produce errors, you should use the --force Command-line option.

Why use a script? Here are a few reasons:

- If you run a query repeatedly (say, every day or every week), making it a script enables you to avoid retyping it each time you execute it.
- You can generate new queries from existing ones that are similar by copying and editing script files.
- Batch mode can also be useful while you’re developing a query, particularly for multiple-line statements or multiple-statement sequences. If you make a mistake, you don’t have to retype everything. Just edit your script to correct the error, then tell `mysql` to execute it again.
- If you have a query that produces a lot of output, you can run the output through a pager rather than watching it scroll off the top of your screen:
Examples of Common Queries

3.6 Examples of Common Queries

Here are examples of how to solve some common problems with MySQL.

Some of the examples use the table shop to hold the price of each article (item number) for certain traders (dealers). Supposing that each trader has a single fixed price per article, then (article, dealer) is a primary key for the records.

Start the command-line tool mysql and select a database:

```
shell> mysql your-database-name
```

To create and populate the example table, use these statements:
CREATE TABLE shop (  
  article INT UNSIGNED  DEFAULT '0000' NOT NULL,  
  dealer CHAR(20)      DEFAULT ''     NOT NULL,  
  price DECIMAL(16,2) DEFAULT '0.00' NOT NULL,  
  PRIMARY KEY(article, dealer));  
INSERT INTO shop VALUES  
(1,'A',3.45),(1,'B',3.99),(2,'A',10.99),(3,'B',1.45),  
(3,'C',1.69),(3,'D',1.25),(4,'D',19.95);  

After issuing the statements, the table should have the following contents:

```
SELECT * FROM shop ORDER BY article;
+---------+--------+-------+
<table>
<thead>
<tr>
<th>article</th>
<th>dealer</th>
<th>price</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>A</td>
<td>3.45</td>
</tr>
<tr>
<td>1</td>
<td>B</td>
<td>3.99</td>
</tr>
<tr>
<td>2</td>
<td>A</td>
<td>10.99</td>
</tr>
<tr>
<td>3</td>
<td>B</td>
<td>1.45</td>
</tr>
<tr>
<td>3</td>
<td>C</td>
<td>1.69</td>
</tr>
<tr>
<td>3</td>
<td>D</td>
<td>1.25</td>
</tr>
<tr>
<td>4</td>
<td>D</td>
<td>19.95</td>
</tr>
</tbody>
</table>
+---------+--------+-------+
```

### 3.6.1 The Maximum Value for a Column

“What is the highest item number?”

```
SELECT MAX(article) AS article FROM shop;
+--------+
<table>
<thead>
<tr>
<th>article</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
</tr>
</tbody>
</table>
+--------+
```

### 3.6.2 The Row Holding the Maximum of a Certain Column

Task: Find the number, dealer, and price of the most expensive article.

This is easily done with a subquery:

```
SELECT article, dealer, price
FROM   shop
WHERE  price=(SELECT MAX(price) FROM shop);
+---------+--------+-------+
<table>
<thead>
<tr>
<th>article</th>
<th>dealer</th>
<th>price</th>
</tr>
</thead>
<tbody>
<tr>
<td>0004</td>
<td>D</td>
<td>19.95</td>
</tr>
</tbody>
</table>
+---------+--------+-------+
```

Other solutions are to use a `LEFT JOIN` or to sort all rows descending by price and get only the first row using the MySQL-specific `LIMIT` clause:

```
SELECT s1.article, s1.dealer, s1.price
FROM shop s1  
LEFT JOIN shop s2 ON s1.price < s2.price  
WHERE s2.article IS NULL;  

SELECT article, dealer, price
FROM shop  
ORDER BY price DESC  
LIMIT 1;
```
Note
If there were several most expensive articles, each with a price of 19.95, the 
LIMIT solution would show only one of them.

3.6.3 Maximum of Column per Group

Task: Find the highest price per article.

```
SELECT article, MAX(price) AS price
FROM   shop
GROUP BY article
ORDER BY article;
```

<table>
<thead>
<tr>
<th>article</th>
<th>price</th>
</tr>
</thead>
<tbody>
<tr>
<td>0001</td>
<td>3.99</td>
</tr>
<tr>
<td>0002</td>
<td>10.99</td>
</tr>
<tr>
<td>0003</td>
<td>1.69</td>
</tr>
<tr>
<td>0004</td>
<td>19.95</td>
</tr>
</tbody>
</table>

3.6.4 The Rows Holding the Group-wise Maximum of a Certain Column

Task: For each article, find the dealer or dealers with the most expensive price.

This problem can be solved with a subquery like this one:

```
SELECT article, dealer, price
FROM   shop s1
WHERE  price=(SELECT MAX(s2.price)
              FROM shop s2
              WHERE s1.article = s2.article)
ORDER BY article;
```

<table>
<thead>
<tr>
<th>article</th>
<th>dealer</th>
<th>price</th>
</tr>
</thead>
<tbody>
<tr>
<td>0001</td>
<td>B</td>
<td>3.99</td>
</tr>
<tr>
<td>0002</td>
<td>A</td>
<td>10.99</td>
</tr>
<tr>
<td>0003</td>
<td>C</td>
<td>1.69</td>
</tr>
<tr>
<td>0004</td>
<td>D</td>
<td>19.95</td>
</tr>
</tbody>
</table>

The preceding example uses a correlated subquery, which can be inefficient (see Section 13.2.11.7, "Correlated Subqueries"). Other possibilities for solving the problem are to use an uncorrelated subquery in the FROM clause, a LEFT JOIN, or a common table expression with a window function.

Uncorrelated subquery:

```
SELECT s1.article, dealer, s1.price
FROM shop s1
JOIN (SELECT article, MAX(price) AS price
       FROM shop
       GROUP BY article) AS s2
    ON s1.article = s2.article AND s1.price = s2.price
ORDER BY article;
```

LEFT JOIN:

```
SELECT s1.article, s1.dealer, s1.price
FROM shop s1
```
Using User-Defined Variables

The `LEFT JOIN` works on the basis that when `s1.price` is at its maximum value, there is no `s2.price` with a greater value and thus the corresponding `s2.article` value is `NULL`. See Section 13.2.10.2, "JOIN Syntax".

Common table expression with window function:

```sql
WITH s1 AS (
    SELECT article, dealer, price,
           RANK() OVER (PARTITION BY article
             ORDER BY price DESC
           ) AS `Rank`
    FROM shop
)
SELECT article, dealer, price
FROM s1
WHERE `Rank` = 1
ORDER BY article;
```

3.6.5 Using User-Defined Variables

You can employ MySQL user variables to remember results without having to store them in temporary variables in the client. (See Section 9.4, "User-Defined Variables".)

For example, to find the articles with the highest and lowest price you can do this:

```sql
mysql> SELECT @min_price:=MIN(price),@max_price:=MAX(price) FROM shop;
mysql> SELECT * FROM shop WHERE price=@min_price OR price=@max_price;
+---------+--------+-------+
<table>
<thead>
<tr>
<th>article</th>
<th>dealer</th>
<th>price</th>
</tr>
</thead>
<tbody>
<tr>
<td>0003</td>
<td>D</td>
<td>1.25</td>
</tr>
<tr>
<td>0004</td>
<td>D</td>
<td>19.95</td>
</tr>
</tbody>
</table>
+---------+--------+-------+
```

Note
It is also possible to store the name of a database object such as a table or a column in a user variable and then to use this variable in an SQL statement; however, this requires the use of a prepared statement. See Section 13.5, "Prepared SQL Statement Syntax", for more information.

3.6.6 Using Foreign Keys

In MySQL, InnoDB tables support checking of foreign key constraints. See Chapter 15, The InnoDB Storage Engine, and Section 1.8.2.3, "Foreign Key Differences".

A foreign key constraint is not required merely to join two tables. For storage engines other than InnoDB, it is possible when defining a column to use a `REFERENCES tbl_name(col_name)` clause, which has no actual effect, and serves only as a memo or comment to you that the column which you are currently defining is intended to refer to a column in another table. It is extremely important to realize when using this syntax that:

- MySQL does not perform any sort of check to make sure that `col_name` actually exists in `tbl_name` (or even that `tbl_name` itself exists).
- MySQL does not perform any sort of action on `tbl_name` such as deleting rows in response to actions taken on rows in the table which you are defining; in other words, this syntax induces no `ON DELETE` or `ON UPDATE` behavior whatsoever. (Although you can write an `ON DELETE` or `ON UPDATE` clause as part of the `REFERENCES` clause, it is also ignored.)
• This syntax creates a column; it does not create any sort of index or key.

You can use a column so created as a join column, as shown here:

```sql
CREATE TABLE person (  id SMALLINT UNSIGNED NOT NULL AUTO_INCREMENT,  name CHAR(60) NOT NULL,  PRIMARY KEY (id));

CREATE TABLE shirt (  id SMALLINT UNSIGNED NOT NULL AUTO_INCREMENT,  style ENUM('t-shirt', 'polo', 'dress') NOT NULL,  color ENUM('red', 'blue', 'orange', 'white', 'black') NOT NULL,  owner SMALLINT UNSIGNED NOT NULL REFERENCES person(id),  PRIMARY KEY (id));

INSERT INTO person VALUES (NULL, 'Antonio Paz');
SELECT @last := LAST_INSERT_ID();
INSERT INTO shirt VALUES (NULL, 'polo', 'blue', @last), (NULL, 'dress', 'white', @last), (NULL, 't-shirt', 'blue', @last);
INSERT INTO person VALUES (NULL, 'Lilliana Angelovska');
SELECT @last := LAST_INSERT_ID();
INSERT INTO shirt VALUES (NULL, 'dress', 'orange', @last), (NULL, 'polo', 'red', @last), (NULL, 'dress', 'blue', @last), (NULL, 't-shirt', 'white', @last);
SELECT * FROM person;
+----+---------------------+
| id | name                |
+----+---------------------+
|  1 | Antonio Paz         |
|  2 | Lilliana Angelovska |
+----+---------------------+
SELECT * FROM shirt;
+----+---------+--------+-------+
| id | style   | color  | owner |
+----+---------+--------+-------+
|  1 | polo    | blue   |     1 |
|  2 | dress   | white  |     1 |
|  3 | t-shirt | blue   |     1 |
|  4 | dress   | orange |     2 |
|  5 | polo    | red    |     2 |
|  6 | dress   | blue   |     2 |
|  7 | t-shirt | white  |     2 |
+----+---------+--------+-------+
SELECT s.* FROM person p INNER JOIN shirt s ON s.owner = p.id WHERE p.name LIKE 'Lilliana%' AND s.color <> 'white';
+----+-------+--------+-------+
| id | style | color  | owner |
+----+-------+--------+-------+
|  4 | dress | orange |     2 |
|  5 | polo  | red    |     2 |
|  6 | dress | blue   |     2 |
+----+-------+--------+-------+
```
When used in this fashion, the **REFERENCES** clause is not displayed in the output of **SHOW CREATE TABLE** or **DESCRIBE**:

```
SHOW CREATE TABLE shirt\G
*************************** 1. row ***************************
Table: shirt
Create Table: CREATE TABLE `shirt` (  
    `id` smallint(5) unsigned NOT NULL auto_increment,  
    `style` enum('t-shirt','polo','dress') NOT NULL,  
    `color` enum('red','blue','orange','white','black') NOT NULL,  
    `owner` smallint(5) unsigned NOT NULL,  
    PRIMARY KEY (`id`)  
) ENGINE=MyISAM DEFAULT CHARSET=utf8mb4
```

The use of **REFERENCES** in this way as a comment or “reminder” in a column definition works with **MyISAM** tables.

### 3.6.7 Searching on Two Keys

An **OR** using a single key is well optimized, as is the handling of **AND**.

The one tricky case is that of searching on two different keys combined with **OR**:

```
SELECT field1_index, field2_index FROM test_table  
WHERE field1_index = '1' OR  field2_index = '1'
```

This case is optimized. See Section 8.2.1.3, “Index Merge Optimization”.

You can also solve the problem efficiently by using a **UNION** that combines the output of two separate **SELECT** statements. See Section 13.2.10.3, “UNION Syntax”.

Each **SELECT** searches only one key and can be optimized:

```
SELECT field1_index, field2_index  
FROM test_table WHERE field1_index = '1'  
UNION  
SELECT field1_index, field2_index  
FROM test_table WHERE field2_index = '1';
```

### 3.6.8 Calculating Visits Per Day

The following example shows how you can use the bit group functions to calculate the number of days per month a user has visited a Web page.

```
CREATE TABLE t1 (year YEAR(4), month INT UNSIGNED,  
    day INT UNSIGNED);  
INSERT INTO t1 VALUES(2000,1,1),(2000,1,20),(2000,1,30),(2000,2,2),  
    (2000,2,23),(2000,2,23);
```

The example table contains year-month-day values representing visits by users to the page. To determine how many different days in each month these visits occur, use this query:

```
SELECT year,month,BIT_COUNT(BIT_OR(1<<day)) AS days FROM t1  
GROUP BY year,month;
```

Which returns:

```
+------+-------+------+
| year | month | days |
+------+-------+------+
| 2000 |     1 |    3 |
```
The query calculates how many different days appear in the table for each year/month combination, with automatic removal of duplicate entries.

### 3.6.9 Using AUTO_INCREMENT

The `AUTO_INCREMENT` attribute can be used to generate a unique identity for new rows:

```sql
CREATE TABLE animals (  
id MEDIUMINT NOT NULL AUTO_INCREMENT,  
name CHAR(30) NOT NULL,  
PRIMARY KEY (id)
);

INSERT INTO animals (name) VALUES  
('dog'),('cat'),('penguin'),  
('lax'),('whale'),('ostrich');

SELECT * FROM animals;
```

Which returns:

```plaintext
+----+---------+
| id | name    |
+----+---------+
|  1 | dog     |
|  2 | cat     |
|  3 | penguin |
|  4 | lax     |
|  5 | whale   |
|  6 | ostrich |
```

No value was specified for the `AUTO_INCREMENT` column, so MySQL assigned sequence numbers automatically. You can also explicitly assign 0 to the column to generate sequence numbers, unless the `NO_AUTO_VALUE_ON_ZERO` SQL mode is enabled. For example:

```sql
INSERT INTO animals (id,name) VALUES(0,'groundhog');
```

If the column is declared `NOT NULL`, it is also possible to assign `NULL` to the column to generate sequence numbers. For example:

```sql
INSERT INTO animals (id,name) VALUES(NULL,'squirrel');
```

When you insert any other value into an `AUTO_INCREMENT` column, the column is set to that value and the sequence is reset so that the next automatically generated value follows sequentially from the largest column value. For example:

```sql
INSERT INTO animals (id,name) VALUES(100,'rabbit');  
INSERT INTO animals (id,name) VALUES(NULL,'mouse');
SELECT * FROM animals;
```

<table>
<thead>
<tr>
<th>id</th>
<th>name</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>dog</td>
</tr>
<tr>
<td>2</td>
<td>cat</td>
</tr>
<tr>
<td>3</td>
<td>penguin</td>
</tr>
<tr>
<td>4</td>
<td>lax</td>
</tr>
<tr>
<td>5</td>
<td>whale</td>
</tr>
<tr>
<td>6</td>
<td>ostrich</td>
</tr>
<tr>
<td>7</td>
<td>groundhog</td>
</tr>
</tbody>
</table>
```
Using AUTO_INCREMENT

Updating an existing AUTO_INCREMENT column value also resets the AUTO_INCREMENT sequence.

You can retrieve the most recent automatically generated AUTO_INCREMENT value with the LAST_INSERT_ID() SQL function or the mysql_insert_id() C API function. These functions are connection-specific, so their return values are not affected by another connection which is also performing inserts.

Use the smallest integer data type for the AUTO_INCREMENT column that is large enough to hold the maximum sequence value you will need. When the column reaches the upper limit of the data type, the next attempt to generate a sequence number fails. Use the UNSIGNED attribute if possible to allow a greater range. For example, if you use TINYINT, the maximum permissible sequence number is 127. For TINYINT UNSIGNED, the maximum is 255. See Section 11.2.1, “Integer Types (Exact Value) - INTEGER, INT, SMALLINT, TINYINT, MEDIUMINT, BIGINT” for the ranges of all the integer types.

Note

For a multiple-row insert, LAST_INSERT_ID() and mysql_insert_id() actually return the AUTO_INCREMENT key from the first of the inserted rows. This enables multiple-row inserts to be reproduced correctly on other servers in a replication setup.

To start with an AUTO_INCREMENT value other than 1, set that value with CREATE TABLE or ALTER TABLE, like this:

```
mysql> ALTER TABLE tbl AUTO_INCREMENT = 100;
```

InnoDB Notes

For information about AUTO_INCREMENT usage specific to InnoDB, see Section 15.6.1.4, “AUTO_INCREMENT Handling in InnoDB”.

MyISAM Notes

• For MyISAM tables, you can specify AUTO_INCREMENT on a secondary column in a multiple-column index. In this case, the generated value for the AUTO_INCREMENT column is calculated as MAX(auto_increment_column) + 1 WHERE prefix=given-prefix. This is useful when you want to put data into ordered groups.

```
CREATE TABLE animals {
  grp ENUM('fish','mammal','bird') NOT NULL,
  id MEDIUMINT NOT NULL AUTO_INCREMENT,
  name CHAR(30) NOT NULL,
  PRIMARY KEY (grp,id)
} ENGINE=MyISAM;

INSERT INTO animals (grp,name) VALUES
  ('mammal','dog'), ('mammal','cat'),
  ('bird','penguin'), ('fish','lax'), ('mammal','whale'),
  ('bird','ostrich');

SELECT * FROM animals ORDER BY grp,id;
```

Which returns:

```
+--------+----+---------+
| grp    | id | name    |
+--------+----+---------+
```

296
In this case (when the AUTO_INCREMENT column is part of a multiple-column index), AUTO_INCREMENT values are reused if you delete the row with the biggest AUTO_INCREMENT value in any group. This happens even for MyISAM tables, for which AUTO_INCREMENT values normally are not reused.

- If the AUTO_INCREMENT column is part of multiple indexes, MySQL generates sequence values using the index that begins with the AUTO_INCREMENT column, if there is one. For example, if the animals table contained indexes PRIMARY KEY (grp, id) and INDEX (id), MySQL would ignore the PRIMARY KEY for generating sequence values. As a result, the table would contain a single sequence, not a sequence per grp value.

### Further Reading

More information about AUTO_INCREMENT is available here:

- How to assign the AUTO_INCREMENT attribute to a column: Section 13.1.20, “CREATE TABLE Syntax”, and Section 13.1.9, “ALTER TABLE Syntax”.
- How AUTO_INCREMENT behaves depending on the NO_AUTO_VALUE_ON_ZERO SQL mode: Section 5.1.11, “Server SQL Modes”.
- How to use the LAST_INSERT_ID() function to find the row that contains the most recent AUTO_INCREMENT value: Section 12.15, “Information Functions”.
- Setting the AUTO_INCREMENT value to be used: Section 5.1.8, “Server System Variables”.
- Section 15.6.1.4, “AUTO_INCREMENT Handling in InnoDB”
- AUTO_INCREMENT and replication: Section 17.4.1.1, “Replication and AUTO_INCREMENT”.
- Server-system variables related to AUTO_INCREMENT (auto_increment_increment and auto_increment_offset) that can be used for replication: Section 5.1.8, “Server System Variables”.

### 3.7 Using MySQL with Apache

There are programs that let you authenticate your users from a MySQL database and also let you write your log files into a MySQL table.

You can change the Apache logging format to be easily readable by MySQL by putting the following into the Apache configuration file:

```
LogFormat "%h","%{%Y%m%d%H%M%S}t,%>s","%b","%{Content-Type}o", "%U","%{Referer}i","%{User-Agent}i"
```

To load a log file in that format into MySQL, you can use a statement something like this:

```
LOAD DATA INFILE '/local/access_log' INTO TABLE tbl_name
FIELDS TERMINATED BY ',' OPTIONALLY ENCLOSED BY '"' ESCAPED BY '\'
```

The named table should be created to have columns that correspond to those that the LogFormat line writes to the log file.

This chapter provides a brief overview of the MySQL command-line programs provided by Oracle Corporation. It also discusses the general syntax for specifying options when you run these programs. Most programs have options that are specific to their own operation, but the option syntax is similar for
4.1 Overview of MySQL Programs

There are many different programs in a MySQL installation. This section provides a brief overview of them. Later sections provide a more detailed description of each one, with the exception of NDB Cluster programs. Each program's description indicates its invocation syntax and the options that it supports. Section 22.4, “NDB Cluster Programs”, describes programs specific to NDB Cluster.

Most MySQL distributions include all of these programs, except for those programs that are platform-specific. (For example, the server startup scripts are not used on Windows.) The exception is that RPM distributions are more specialized. There is one RPM for the server, another for client programs, and so forth. If you appear to be missing one or more programs, see Chapter 2, Installing and Upgrading MySQL, for information on types of distributions and what they contain. It may be that you have a distribution that does not include all programs and you need to install an additional package.

Each MySQL program takes many different options. Most programs provide a --help option that you can use to get a description of the program's different options. For example, try mysql --help.

You can override default option values for MySQL programs by specifying options on the command line or in an option file. See Section 4.2, “Using MySQL Programs”, for general information on invoking programs and specifying program options.

The MySQL server, mysqld, is the main program that does most of the work in a MySQL installation. The server is accompanied by several related scripts that assist you in starting and stopping the server:

• mysqld

The SQL daemon (that is, the MySQL server). To use client programs, mysqld must be running, because clients gain access to databases by connecting to the server. See Section 4.3.1, “mysqld — The MySQL Server”.

• mysqld_safe

A server startup script. mysqld_safe attempts to start mysqld. See Section 4.3.2, “mysqld_safe — MySQL Server Startup Script”.

• mysql.server

A server startup script. This script is used on systems that use System V-style run directories containing scripts that start system services for particular run levels. It invokes mysqld_safe to start the MySQL server. See Section 4.3.3, “mysql.server — MySQL Server Startup Script”.

• mysqld_multi

A server startup script that can start or stop multiple servers installed on the system. See Section 4.3.4, “mysqld_multi — Manage Multiple MySQL Servers”.

Several programs perform setup operations during MySQL installation or upgrading:

• comp_err

This program is used during the MySQL build/installation process. It compiles error message files from the error source files. See Section 4.4.1, “comp_err — Compile MySQL Error Message File”.

• mysql_secure_installation

This program enables you to improve the security of your MySQL installation. See Section 4.4.2, “mysql_secure_installation — Improve MySQL Installation Security”.

300
Overview of MySQL Programs

• **mysql_ssl_rsa_setup**

  This program creates the SSL certificate and key files and RSA key-pair files required to support secure connections, if those files are missing. Files created by `mysql_ssl_rsa_setup` can be used for secure connections using SSL or RSA. See **Section 4.4.3, “mysql_ssl_rsa_setup — Create SSL/RSA Files”**.

• **mysql_tzinfo_to_sql**

  This program loads the time zone tables in the `mysql` database using the contents of the host system `zoneinfo` database (the set of files describing time zones). See **Section 4.4.4, “mysql_tzinfo_to_sql — Load the Time Zone Tables”**.

• **mysql_upgrade**

  This program is used after a MySQL upgrade operation. It updates the grant tables with any changes that have been made in newer versions of MySQL, and checks tables for incompatibilities and repairs them if necessary. See **Section 4.4.5, “mysql_upgrade — Check and Upgrade MySQL Tables”**.

MySQL client programs that connect to the MySQL server:

• **mysql**

  The command-line tool for interactively entering SQL statements or executing them from a file in batch mode. See **Section 4.5.1, “mysql — The MySQL Command-Line Client”**.

• **mysqladmin**

  A client that performs administrative operations, such as creating or dropping databases, reloading the grant tables, flushing tables to disk, and reopening log files. `mysqladmin` can also be used to retrieve version, process, and status information from the server. See **Section 4.5.2, “mysqladmin — Client for Administering a MySQL Server”**.

• **mysqlcheck**

  A table-maintenance client that checks, repairs, analyzes, and optimizes tables. See **Section 4.5.3, “mysqlcheck — A Table Maintenance Program”**.

• **mysqldump**

  A client that dumps a MySQL database into a file as SQL, text, or XML. See **Section 4.5.4, “mysqldump — A Database Backup Program”**.

• **mysqlimport**

  A client that imports text files into their respective tables using **LOAD DATA**. See **Section 4.5.5, “mysqlimport — A Data Import Program”**.

• **mysqlpump**

  A client that dumps a MySQL database into a file as SQL. See **Section 4.5.6, “mysqlpump — A Database Backup Program”**.

• **mysqlsh**

  MySQL Shell is an advanced client and code editor for MySQL Server. See **MySQL Shell 8.0 (part of MySQL 8.0)**. In addition to the provided SQL functionality, similar to `mysql`, MySQL Shell provides scripting capabilities for JavaScript and Python and includes APIs for working with MySQL. X DevAPI enables you to work with both relational and document data, see **Chapter 20, Using MySQL as a Document Store**. AdminAPI enables you to work with InnoDB cluster, see **Chapter 21, InnoDB Cluster**.
Overview of MySQL Programs

- **mysqlshow**
  A client that displays information about databases, tables, columns, and indexes. See Section 4.5.7, "mysqlshow — Display Database, Table, and Column Information".

- **mysqlslap**
  A client that is designed to emulate client load for a MySQL server and report the timing of each stage. It works as if multiple clients are accessing the server. See Section 4.5.8, "mysqlslap — Load Emulation Client".

MySQL administrative and utility programs:

- **innochecksum**
  An offline InnoDB offline file checksum utility. See Section 4.6.2, "innochecksum — Offline InnoDB File Checksum Utility".

- **myisam_ftdump**
  A utility that displays information about full-text indexes in MyISAM tables. See Section 4.6.3, "myisam_ftdump — Display Full-Text Index information".

- **myisamchk**
  A utility to describe, check, optimize, and repair MyISAM tables. See Section 4.6.4, "myisamchk — MyISAM Table-Maintenance Utility".

- **myisamlog**
  A utility that processes the contents of a MyISAM log file. See Section 4.6.5, "myisamlog — Display MyISAM Log File Contents".

- **myisampack**
  A utility that compresses MyISAM tables to produce smaller read-only tables. See Section 4.6.6, "myisampack — Generate Compressed, Read-Only MyISAM Tables".

- **mysql_config_editor**
  A utility that enables you to store authentication credentials in a secure, encrypted login path file named .mylogin.cnf. See Section 4.6.7, "mysql_config_editor — MySQL Configuration Utility".

- **mysqlbinlog**
  A utility for reading statements from a binary log. The log of executed statements contained in the binary log files can be used to help recover from a crash. See Section 4.6.8, "mysqlbinlog — Utility for Processing Binary Log Files".

- **mysqldumpslow**
  A utility to read and summarize the contents of a slow query log. See Section 4.6.9, "mysqldumpslow — Summarize Slow Query Log Files".

MySQL program-development utilities:

- **mysql_config**
  A shell script that produces the option values needed when compiling MySQL programs. See Section 4.7.1, "mysql_config — Display Options for Compiling Clients".

- **my_print_defaults**
A utility that shows which options are present in option groups of option files. See Section 4.7.2, “my_print_defaults — Display Options from Option Files”.

Miscellaneous utilities:

- `lz4_decompress`

  A utility that decompresses `mysqlpump` output that was created using LZ4 compression. See Section 4.8.1, “lz4_decompress — Decompress mysqlpump LZ4-Compressed Output”.

- `perror`

  A utility that displays the meaning of system or MySQL error codes. See Section 4.8.2, “perror — Display MySQL Error Message Information”.

- `zlib_decompress`

  A utility that decompresses `mysqlpump` output that was created using ZLIB compression. See Section 4.8.3, “zlib_decompress — Decompress mysqlpump ZLIB-Compressed Output”.

Oracle Corporation also provides the MySQL Workbench GUI tool, which is used to administer MySQL servers and databases, to create, execute, and evaluate queries, and to migrate schemas and data from other relational database management systems for use with MySQL. Additional GUI tools include MySQL Notifier and MySQL for Excel.

MySQL client programs that communicate with the server using the MySQL client/server library use the following environment variables.

<table>
<thead>
<tr>
<th>Environment Variable</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>MYSQL_UNIX_PORT</code></td>
<td>The default Unix socket file; used for connections to <code>localhost</code></td>
</tr>
<tr>
<td><code>MYSQL_TCP_PORT</code></td>
<td>The default port number; used for TCP/IP connections</td>
</tr>
<tr>
<td><code>MYSQL_PWD</code></td>
<td>The default password</td>
</tr>
<tr>
<td><code>MYSQL_DEBUG</code></td>
<td>Debug trace options when debugging</td>
</tr>
<tr>
<td><code>TMPDIR</code></td>
<td>The directory where temporary tables and files are created</td>
</tr>
</tbody>
</table>

For a full list of environment variables used by MySQL programs, see Section 4.9, “MySQL Environment Variables”.

Use of `MYSQL_PWD` is insecure. See Section 6.1.2.1, “End-User Guidelines for Password Security”.

### 4.2 Using MySQL Programs

#### 4.2.1 Invoking MySQL Programs

To invoke a MySQL program from the command line (that is, from your shell or command prompt), enter the program name followed by any options or other arguments needed to instruct the program what you want it to do. The following commands show some sample program invocations. `shell>` represents the prompt for your command interpreter; it is not part of what you type. The particular prompt you see depends on your command interpreter. Typical prompts are $ for `sh`, `ksh`, or `bash`, % for `csh` or `tcsh`, and `C:\>` for the Windows `command.com` or `cmd.exe` command interpreters.

```
shell> mysql --user=root test
shell> mysqladmin extended-status variables
shell> mysqlshow --help
shell> mysqldump -u root personnel
```
Arguments that begin with a single or double dash ( -, -- ) specify program options. Options typically indicate the type of connection a program should make to the server or affect its operational mode. Option syntax is described in Section 4.2.2, “Specifying Program Options”.

Nonoption arguments (arguments with no leading dash) provide additional information to the program. For example, the mysql program interprets the first nonoption argument as a database name, so the command mysql --user=root test indicates that you want to use the test database.

Later sections that describe individual programs indicate which options a program supports and describe the meaning of any additional nonoption arguments.

Some options are common to a number of programs. The most frequently used of these are the --host (or -h), --user (or -u), and --password (or -p) options that specify connection parameters. They indicate the host where the MySQL server is running, and the user name and password of your MySQL account. All MySQL client programs understand these options; they enable you to specify which server to connect to and the account to use on that server. Other connection options are --port (or -P) to specify a TCP/IP port number and --socket (or -S) to specify a Unix socket file on Unix (or named-pipe name on Windows). For more information on options that specify connection options, see Section 4.2.4, “Connecting to the MySQL Server Using Command Options”.

You may find it necessary to invoke MySQL programs using the path name to the bin directory in which they are installed. This is likely to be the case if you get a “program not found” error whenever you attempt to run a MySQL program from any directory other than the bin directory. To make it more convenient to use MySQL, you can add the path name of the bin directory to your PATH environment variable setting. That enables you to run a program by typing only its name, not its entire path name. For example, if mysql is installed in /usr/local/mysql/bin, you can run the program by invoking it as mysql, and it is not necessary to invoke it as /usr/local/mysql/bin/mysql.

Consult the documentation for your command interpreter for instructions on setting your PATH variable. The syntax for setting environment variables is interpreter-specific. (Some information is given in Section 4.2.7, “Setting Environment Variables”.) After modifying your PATH setting, open a new console window on Windows or log in again on Unix so that the setting goes into effect.

### 4.2.2 Specifying Program Options

There are several ways to specify options for MySQL programs:

- List the options on the command line following the program name. This is common for options that apply to a specific invocation of the program.

- List the options in an option file that the program reads when it starts. This is common for options that you want the program to use each time it runs.

- List the options in environment variables (see Section 4.2.7, “Setting Environment Variables”). This method is useful for options that you want to apply each time the program runs. In practice, option files are used more commonly for this purpose, but Section 5.8.3, “Running Multiple MySQL Instances on Unix”, discusses one situation in which environment variables can be very helpful. It describes a handy technique that uses such variables to specify the TCP/IP port number and Unix socket file for the server and for client programs.

Options are processed in order, so if an option is specified multiple times, the last occurrence takes precedence. The following command causes mysql to connect to the server running on localhost:

```
mysql -h example.com -h localhost
```

If conflicting or related options are given, later options take precedence over earlier options. The following command runs mysql in “no column names” mode:

```
mysql -h localhost
```
Specifying Program Options

mysql --column-names --skip-column-names

MySQL programs determine which options are given first by examining environment variables, then by processing option files, and then by checking the command line. This means that environment variables have the lowest precedence and command-line options the highest.

For the server, one exception applies: The `mysqld-auto.cnf` option file in the data directory is processed last, so it takes precedence even over command-line options.

You can take advantage of the way that MySQL programs process options by specifying default option values for a program in an option file. That enables you to avoid typing them each time you run the program while enabling you to override the defaults if necessary by using command-line options.

### 4.2.2.1 Using Options on the Command Line

Program options specified on the command line follow these rules:

- Options are given after the command name.

- An option argument begins with one dash or two dashes, depending on whether it is a short form or long form of the option name. Many options have both short and long forms. For example, `-?` and `--help` are the short and long forms of the option that instructs a MySQL program to display its help message.

- Option names are case-sensitive. `-v` and `--verbose` are both legal and have different meanings. (They are the corresponding short forms of the `--verbose` and `--version` options.)

- Some options take a value following the option name. For example, `-h localhost` or `--host=localhost` indicate the MySQL server host to a client program. The option value tells the program the name of the host where the MySQL server is running.

- For a long option that takes a value, separate the option name and the value by an `=` sign. For a short option that takes a value, the option value can immediately follow the option letter, or there can be a space between: `-h localhost` and `-h localhost` are equivalent. An exception to this rule is the option for specifying your MySQL password. This option can be given in long form as `--password=pass_val` or as `--password`. In the latter case (with no password value given), the program interactively prompts you for the password. The password option also may be given in short form as `--password` or as `--password`. However, for the short form, if the password value is given, it must follow the option letter with no intervening space. The reason for this is that if a space follows the option letter, the program has no way to tell whether a following argument is supposed to be the password value or some other kind of argument. Consequently, the following two commands have two completely different meanings:

```
mysql -ptest
mysql -p test
```

The first command instructs `mysql` to use a password value of `test`, but specifies no default database. The second instructs `mysql` to prompt for the password value and to use `test` as the default database.

- Within option names, dash (`-`) and underscore (`_`) may be used interchangeably. For example, `--skip-grant-tables` and `--skip_grant_tables` are equivalent. (However, the leading dashes cannot be given as underscores.)

- For options that take a numeric value, the value can be given with a suffix of `K`, `M`, or `G` to indicate a multiplier of 1024, 1024² or 1024³. As of MySQL 8.0.14, a suffix can also be `T`, `P`, and `E` to indicate a multiplier of 1024⁴, 1024⁵ or 1024⁶. Suffix letters can be uppercase or lowercase.

For example, the following command tells `mysqladmin` to ping the server 1024 times, sleeping 10 seconds between each ping:
Specifying Program Options

mysqladmin --count=1K --sleep=10 ping

• When specifying file names as option values, avoid the use of the ~ shell metacharacter because it might not be interpreted as you expect.

Option values that contain spaces must be quoted when given on the command line. For example, the --execute (or -e) option can be used with mysql to pass SQL statements to the server. When this option is used, mysql executes the statements in the option value and exits. The statements must be enclosed by quotation marks. For example, you can use the following command to obtain a list of user accounts:

shell> mysql -u root -p --execute="SELECT User, Host FROM mysql.user"
Enter password: ******
+------+-----------+
<table>
<thead>
<tr>
<th>User</th>
<th>Host</th>
</tr>
</thead>
<tbody>
<tr>
<td>gigan</td>
<td>gigan</td>
</tr>
<tr>
<td>root</td>
<td>localhost</td>
</tr>
<tr>
<td>jon</td>
<td>localhost</td>
</tr>
<tr>
<td>root</td>
<td>localhost</td>
</tr>
</tbody>
</table>
+------+-----------+
shell>

Note

The long form (--execute) is followed by an equal sign (=).

If you wish to use quoted values within a statement, you will either need to escape the inner quotation marks, or use a different type of quotation marks within the statement from those used to quote the statement itself. The capabilities of your command processor dictate your choices for whether you can use single or double quotation marks and the syntax for escaping quote characters. For example, if your command processor supports quoting with single or double quotation marks, you can use double quotation marks around the statement, and single quotation marks for any quoted values within the statement.

Multiple SQL statements may be passed in the option value on the command line, separated by semicolons:

shell> mysql -u root -p -e "SELECT VERSION();SELECT NOW()"
Enter password: ******
+------------+
<table>
<thead>
<tr>
<th>VERSION()</th>
</tr>
</thead>
<tbody>
<tr>
<td>8.0.11</td>
</tr>
</tbody>
</table>
+------------+
| NOW()      |
| 2019-05-17 11:43:57 |
+---------------------+

4.2.2.2 Using Option Files

Most MySQL programs can read startup options from option files (sometimes called configuration files). Option files provide a convenient way to specify commonly used options so that they need not be entered on the command line each time you run a program.

To determine whether a program reads option files, invoke it with the --help option. (For mysqlld, use --verbose and --help.) If the program reads option files, the help message indicates which files it looks for and which option groups it recognizes.
Specifying Program Options

Note

A MySQL program started with the --no-defaults option reads no option files other than .mylogin.cnf.

A server started with the persistedGlobalsLoad system variable disabled does not read mysqld-auto.cnf.

Many option files are plain text files, created using any text editor. The exceptions are:

- The .mylogin.cnf file that contains login path options. This is an encrypted file created by the mysql_config_editor utility. See Section 4.6.7, "mysql_config_editor — MySQL Configuration Utility". A "login path" is an option group that permits only certain options: host, user, password, port and socket. Client programs specify which login path to read from .mylogin.cnf using the --login-path option.

To specify an alternative login path file name, set the MYSQL_TEST_LOGIN_FILE environment variable. This variable is used by the mysql-test-run.pl testing utility, but also is recognized by mysql_config_editor and by MySQL clients such as mysql, mysqladmin, and so forth.

- The mysqld-auto.cnf file in the data directory. This JSON-format file contains persisted system variable settings. It is created by the server upon execution of SET PERSIST or SET PERSIST_ONLY statements. See Section 5.1.9.3, "Persisted System Variables". Management of mysqld-auto.cnf should be left to the server and not performed manually.

MySQL looks for option files in the order described in the following discussion and reads any that exist. If an option file you want to use does not exist, create it using the appropriate method, as just discussed.

Note

For information about option files used with NDB Cluster programs, see Section 22.3, "Configuration of NDB Cluster".

On Windows, MySQL programs read startup options from the files shown in the following table, in the specified order (files listed first are read first, files read later take precedence).

### Table 4.1 Option Files Read on Windows Systems

<table>
<thead>
<tr>
<th>File Name</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>%WINDIR\my.ini, %WINDIR\my.cnf</td>
<td>Global options</td>
</tr>
<tr>
<td>C:\my.ini,C:\my.cnf</td>
<td>Global options</td>
</tr>
<tr>
<td>BASEDIR\my.ini, BASEDIR\my.cnf</td>
<td>Global options</td>
</tr>
<tr>
<td>defaults-extra-file</td>
<td>The file specified with --defaults-extra-file, if any</td>
</tr>
<tr>
<td>%APPDATA%\MySQL.my.login.cnf</td>
<td>Login path options (clients only)</td>
</tr>
<tr>
<td>DATADIR\mysqld-auto.cnf</td>
<td>System variables persisted with SET PERSIST or SET PERSIST_ONLY (server only)</td>
</tr>
</tbody>
</table>

In the preceding table, %WINDIR% represents the location of your Windows directory. This is commonly C:\WINDOWS. Use the following command to determine its exact location from the value of the WINDIR environment variable:

C:\> echo %WINDIR%
Specifying Program Options

%APPDATA% represents the value of the Windows application data directory. Use the following command to determine its exact location from the value of the APPDATA environment variable:

```
C:\> echo %APPDATA%
```

BASEDIR represents the MySQL base installation directory. When MySQL 8.0 has been installed using MySQL Installer, this is typically C:\PROGRAMDIR\MySQL\MySQL 8.0 Server where PROGRAMDIR represents the programs directory (usually Program Files on English-language versions of Windows). See Section 2.3.3, “MySQL Installer for Windows”.

DATADIR represents the MySQL data directory. As used to find mysqld-auto.cnf, its default value is the data directory location built in when MySQL was compiled, but can be changed by --datadir specified as an option-file or command-line option processed before mysqld-auto.cnf is processed.

On Unix and Unix-like systems, MySQL programs read startup options from the files shown in the following table, in the specified order (files listed first are read first, files read later take precedence).

Note
On Unix platforms, MySQL ignores configuration files that are world-writable. This is intentional as a security measure.

<table>
<thead>
<tr>
<th>File Name</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>/etc/my.cnf</td>
<td>Global options</td>
</tr>
<tr>
<td>/etc/mysql/my.cnf</td>
<td>Global options</td>
</tr>
<tr>
<td>$SYSCONFDIR/my.cnf</td>
<td>Global options</td>
</tr>
<tr>
<td>$MYSQL_HOME/my.cnf</td>
<td>Server-specific options (server only)</td>
</tr>
<tr>
<td><code>~/.my.cnf</code></td>
<td>The file specified with <code>--defaults-extra-file</code>, if any</td>
</tr>
<tr>
<td><code>~/.mylogin.cnf</code></td>
<td>User-specific options</td>
</tr>
<tr>
<td>DATADIR/mysqld-auto.cnf</td>
<td>System variables persisted with SET PERSIST or SET PERSIST_ONLY (server only)</td>
</tr>
</tbody>
</table>

In the preceding table, `~` represents the current user’s home directory (the value of $HOME).

SYSCONFDIR represents the directory specified with the SYSCONFDIR option to CMake when MySQL was built. By default, this is the etc directory located under the compiled-in installation directory.

MYSQL_HOME is an environment variable containing the path to the directory in which the server-specific my.cnf file resides. If MYSQL_HOME is not set and you start the server using the mysqld_safe program, mysqld_safe sets it to BASEDIR, the MySQL base installation directory.

DATADIR represents the MySQL data directory. As used to find mysqld-auto.cnf, its default value is the data directory location built in when MySQL was compiled, but can be changed by --datadir specified as an option-file or command-line option processed before mysqld-auto.cnf is processed.

If multiple instances of a given option are found, the last instance takes precedence, with one exception: For mysqld, the first instance of the --user option is used as a security precaution, to prevent a user specified in an option file from being overridden on the command line.

The following description of option file syntax applies to files that you edit manually. This excludes .mylogin.cnf, which is created using mysql_config_editor and is encrypted, and mysqld-auto.cnf, which the server creates in JSON format.
Any long option that may be given on the command line when running a MySQL program can be given in an option file as well. To get the list of available options for a program, run it with the --help option. (For mysqld, use --verbose and --help.)

The syntax for specifying options in an option file is similar to command-line syntax (see Section 4.2.2.1, “Using Options on the Command Line”). However, in an option file, you omit the leading two dashes from the option name and you specify only one option per line. For example, --quick and --host=localhost on the command line should be specified as quick and host=localhost on separate lines in an option file. To specify an option of the form --loose-opt_name in an option file, write it as loose-opt_name.

Empty lines in option files are ignored. Nonempty lines can take any of the following forms:

- #comment, ;comment
  Comment lines start with # or ;. A # comment can start in the middle of a line as well.

- [group]
  group is the name of the program or group for which you want to set options. After a group line, any option-setting lines apply to the named group until the end of the option file or another group line is given. Option group names are not case-sensitive.

- opt_name
  This is equivalent to --opt_name on the command line.

- opt_name=value
  This is equivalent to --opt_name=value on the command line. In an option file, you can have spaces around the = character, something that is not true on the command line. The value optionally can be enclosed within single quotation marks or double quotation marks, which is useful if the value contains a # comment character.

Leading and trailing spaces are automatically deleted from option names and values.

You can use the escape sequences \b, \t, \n, \r, \, and \s in option values to represent the backspace, tab, newline, carriage return, backslash, and space characters. In option files, these escaping rules apply:

- A backslash followed by a valid escape sequence character is converted to the character represented by the sequence. For example, \s is converted to a space.

- A backslash not followed by a valid escape sequence character remains unchanged. For example, \S is retained as is.

The preceding rules mean that a literal backslash can be given as \, or as \ if it is not followed by a valid escape sequence character.

The rules for escape sequences in option files differ slightly from the rules for escape sequences in string literals in SQL statements. In the latter context, if “x” is not a valid escape sequence character, \x becomes “x” rather than \x. See Section 9.1.1, “String Literals”.

The escaping rules for option file values are especially pertinent for Windows path names, which use \ as a path name separator. A separator in a Windows path name must be written as \ or if it is not followed by an escape sequence character. It can be written as \ or \ if it is not. Alternatively, / may be used in Windows path names and will be treated as \. Suppose that you want to specify a base directory of C:\Program Files\MySQL\MySQL Server 8.0 in an option file. This can be done several ways. Some examples:

```
basedir="C:\Program Files\MySQL\MySQL Server 8.0"
```
Specifying Program Options

If an option group name is the same as a program name, options in the group apply specifically to that program. For example, the [mysqld] and [mysql] groups apply to the mysqld server and the mysql client program, respectively.

The [client] option group is read by all client programs provided in MySQL distributions (but not by mysqld). To understand how third-party client programs that use the C API can use option files, see the C API documentation at Section 28.7.7.50, “mysql_options()”.

The [client] group enables you to specify options that apply to all clients. For example, [client] is the appropriate group to use to specify the password for connecting to the server. (But make sure that the option file is accessible only by yourself, so that other people cannot discover your password.) Be sure not to put an option in the [client] group unless it is recognized by all client programs that you use. Programs that do not understand the option quit after displaying an error message if you try to run them.

List more general option groups first and more specific groups later. For example, a [client] group is more general because it is read by all client programs, whereas a [mysqldump] group is read only by mysqldump. Options specified later override options specified earlier, so putting the option groups in the order [client], [mysqldump] enables mysqldump-specific options to override [client] options.

Here is a typical global option file:

```
[client]
port=3306
socket=/tmp/mysql.sock

[mysqld]
port=3306
socket=/tmp/mysql.sock
key_buffer_size=16M
max_allowed_packet=128M

[mysqldump]
quick
```

Here is a typical user option file:

```
[client]
#
password="my password"

[mysql]
no-auto-rehash
connect_timeout=2
```

To create option groups to be read only by mysqld servers from specific MySQL release series, use groups with names of [mysqld-5.7], [mysqld-8.0], and so forth. The following group indicates that the sql_mode setting should be used only by MySQL servers with 8.0.x version numbers:

```
[mysqld-8.0]
sql_mode=TRADITIONAL
```

It is possible to use !include directives in option files to include other option files and !includedir to search specific directories for option files. For example, to include the /home/mydir/myopt.cnf file, use the following directive:

```
!include /home/mydir/myopt.cnf
```
To search the `/home/mydir` directory and read option files found there, use this directive:

```sql
!includedir /home/mydir
```

MySQL makes no guarantee about the order in which option files in the directory are read.

**Note**

Any files to be found and included using the `!includedir` directive on Unix operating systems must have file names ending in `.cnf`. On Windows, this directive checks for files with the `.ini` or `.cnf` extension.

Write the contents of an included option file like any other option file. That is, it should contain groups of options, each preceded by a `[group]` line that indicates the program to which the options apply.

While an included file is being processed, only those options in groups that the current program is looking for are used. Other groups are ignored. Suppose that a `my.cnf` file contains this line:

```sql
!include /home/mydir/myopt.cnf
```

And suppose that `/home/mydir/myopt.cnf` looks like this:

```sql
[mysqladmin]
force
[mysqld]
key_buffer_size=16M
```

If `my.cnf` is processed by `mysqld`, only the `[mysqld]` group in `/home/mydir/myopt.cnf` is used. If the file is processed by `mysqladmin`, only the `[mysqladmin]` group is used. If the file is processed by any other program, no options in `/home/mydir/myopt.cnf` are used.

The `!includedir` directive is processed similarly except that all option files in the named directory are read.

If an option file contains `!include` or `!includedir` directives, files named by those directives are processed whenever the option file is processed, no matter where they appear in the file.

### 4.2.2.3 Command-Line Options that Affect Option-File Handling

Most MySQL programs that support option files handle the following options. Because these options affect option-file handling, they must be given on the command line and not in an option file. To work properly, each of these options must be given before other options, with these exceptions:

- `--print-defaults` may be used immediately after `--defaults-file`, `--defaults-extra-file`, or `--login-path`.

- On Windows, if the server is started with the `--defaults-file` and `--install` options, `--install` must be first. See Section 2.3.5.8, “Starting MySQL as a Windows Service”.

When specifying file names as option values, avoid the use of the `~` shell metacharacter because it might not be interpreted as you expect.

- `--defaults-extra-file=file_name`

Read this option file after the global option file but (on Unix) before the user option file and (on all platforms) before the login path file. (For information about the order in which option files are used, see Section 4.2.2.2, “Using Option Files”.) If the file does not exist or is otherwise inaccessible, an error occurs. `file_name` is interpreted relative to the current directory if given as a relative path name rather than a full path name.
Specifying Program Options

See the introduction to this section regarding constraints on the position in which this option may be specified.

• **--defaults-file=file_name**

Read only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. *file_name* is interpreted relative to the current directory if given as a relative path name rather than a full path name.

Exceptions: Even with **--defaults-file**, *mysql* reads *mysql-auto.cnf* and client programs read *.mylogin.cnf*.

See the introduction to this section regarding constraints on the position in which this option may be specified.

• **--defaults-group-suffix=str**

Read not only the usual option groups, but also groups with the usual names and a suffix of *str*. For example, the *mysql* client normally reads the [client] and [mysql] groups. If the **--defaults-group-suffix=_other** option is given, *mysql* also reads the [client_other] and [mysql_other] groups.

• **--login-path=name**

Read options from the named login path in the *.mylogin.cnf* login path file. A “login path” is an option group containing options that specify which MySQL server to connect to and which account to authenticate as. To create or modify a login path file, use the *mysql_config_editor* utility. See Section 4.6.7, "mysql_config_editor — MySQL Configuration Utility".

A client program reads the option group corresponding to the named login path, in addition to option groups that the program reads by default. Consider this command:

```bash
mysql --login-path=mypath
```

By default, the *mysql* client reads the [client] and [mysql] option groups. So for the command shown, *mysql* reads [client] and [mysql] from other option files, and [client], [mysql], and [mypath] from the login path file.

Client programs read the login path file even when the **--no-defaults** option is used.

To specify an alternate login path file name, set the *MYSQL_TEST_LOGIN_FILE* environment variable.

See the introduction to this section regarding constraints on the position in which this option may be specified.

• **--no-defaults**

Do not read any option files. If program startup fails due to reading unknown options from an option file, **--no-defaults** can be used to prevent them from being read.

The exception is that client programs read the *.mylogin.cnf* login path file, if it exists, even when **--no-defaults** is used. This permits passwords to be specified in a safer way than on the command line even if **--no-defaults** is present. (*.mylogin.cnf* is created by the *mysql_config_editor* utility. See Section 4.6.7, "mysql_config_editor — MySQL Configuration Utility").

• **--print-defaults**

Print the program name and all options that it gets from option files. Password values are masked.
See the introduction to this section regarding constraints on the position in which this option may be specified.

### 4.2.2.4 Program Option Modifiers

Some options are “boolean” and control behavior that can be turned on or off. For example, the mysql client supports a `--column-names` option that determines whether or not to display a row of column names at the beginning of query results. By default, this option is enabled. However, you may want to disable it in some instances, such as when sending the output of mysql into another program that expects to see only data and not an initial header line.

To disable column names, you can specify the option using any of these forms:

```
--disable-column-names
--skip-column-names
--column-names=0
```

The `--disable` and `--skip` prefixes and the `=0` suffix all have the same effect: They turn the option off.

The “enabled” form of the option may be specified in any of these ways:

```
--column-names
--enable-column-names
--column-names=1
```

The values `ON`, `TRUE`, `OFF`, and `FALSE` are also recognized for boolean options (not case-sensitive).

If an option is prefixed by `--loose`, a program does not exit with an error if it does not recognize the option, but instead issues only a warning:

```
shell> mysql --loose-no-such-option
mysql: WARNING: unknown option '--loose-no-such-option'
```

The `--loose` prefix can be useful when you run programs from multiple installations of MySQL on the same machine and list options in an option file. An option that may not be recognized by all versions of a program can be given using the `--loose` prefix (or `loose` in an option file). Versions of the program that recognize the option process it normally, and versions that do not recognize it issue a warning and ignore it.

The `--maximum` prefix is available for `mysqld` only and permits a limit to be placed on how large client programs can set session system variables. To do this, use a `--maximum` prefix with the variable name. For example, `--maximum-max_heap_table_size=32M` prevents any client from making the heap table size limit larger than 32M.

The `--maximum` prefix is intended for use with system variables that have a session value. If applied to a system variable that has only a global value, an error occurs. For example, with `--maximum-back_log=200`, the server produces this error:

```
Maximum value of 'back_log' cannot be set
```

### 4.2.2.5 Using Options to Set Program Variables

Many MySQL programs have internal variables that can be set at runtime using the `SET` statement. See Section 13.7.5.1, “SET Syntax for Variable Assignment”, and Section 5.1.9, “Using System Variables”.

Most of these program variables also can be set at server startup by using the same syntax that applies to specifying program options. For example, mysql has a `max_allowed_packet` variable that
controls the maximum size of its communication buffer. To set the `max_allowed_packet` variable for `mysql` to a value of 16MB, use either of the following commands:

```
mysql --max_allowed_packet=16777216
mysql --max_allowed_packet=16M
```

The first command specifies the value in bytes. The second specifies the value in megabytes. For variables that take a numeric value, the value can be given with a suffix of `K`, `M`, or `G` to indicate a multiplier of 1024, 1024² or 1024³. (For example, when used to set `max_allowed_packet`, the suffixes indicate units of kilobytes, megabytes, or gigabytes.) As of MySQL 8.0.14, a suffix can also be `T`, `P`, and `E` to indicate a multiplier of 1024⁴, 1024⁵ or 1024⁶. Suffix letters can be uppercase or lowercase.

In an option file, variable settings are given without the leading dashes:

```
[mysql]
max_allowed_packet=16777216
```

Or:

```
[mysql]
max_allowed_packet=16M
```

If you like, underscores in a variable name can be specified as dashes. The following option groups are equivalent. Both set the size of the server's key buffer to 512MB:

```
[mysqld]
key_buffer_size=512M
[
 mysqld
]
key-buffer-size=512M
```

A variable can be specified by writing it in full or as any unambiguous prefix. For example, the `max_allowed_packet` variable can be set for `mysql` as `--max_a`, but not as `--max` because the latter is ambiguous:

```
shell> mysql --max=1000000
mysql: ambiguous option '--max=1000000' (max_allowed_packet, max_join_size)
```

Be aware that the use of variable prefixes can cause problems in the event that new variables are implemented for a program. A prefix that is unambiguous now might become ambiguous in the future.

Suffixes for specifying a value multiplier can be used when setting a variable at program invocation time, but not to set the value with `SET` at runtime. On the other hand, with `SET`, you can assign a variable’s value using an expression, which is not true when you set a variable at server startup. For example, the first of the following lines is legal at program invocation time, but the second is not:

```
shell> mysql --max_allowed_packet=16M
shell> mysql --max_allowed_packet=16*1024*1024
```

Conversely, the second of the following lines is legal at runtime, but the first is not:

```
mysql> SET GLOBAL max_allowed_packet=16M;
mysql> SET GLOBAL max_allowed_packet=16*1024*1024;
```

### 4.2.2.6 Option Defaults, Options Expecting Values, and the `=` Sign

By convention, long forms of options that assign a value are written with an equals (`=`) sign, like this:
Specifying Program Options

mysql --host=tonfisk --user=jon

For options that require a value (that is, not having a default value), the equal sign is not required, and so the following is also valid:

mysql --host tonfisk --user jon

In both cases, the mysql client attempts to connect to a MySQL server running on the host named “tonfisk” using an account with the user name “jon”.

Due to this behavior, problems can occasionally arise when no value is provided for an option that expects one. Consider the following example, where a user connects to a MySQL server running on host tonfisk as user jon:

```
shell> mysql --host 85.224.35.45 --user jon
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 3
Server version: 8.0.18 Source distribution
Type 'help;' or '\h' for help. Type '\c' to clear the buffer.
mysql>
```

```
mysql> SELECT CURRENT_USER();
+----------------+
| CURRENT_USER() |
+----------------+
| jon@%          |
+----------------+
1 row in set (0.00 sec)
```

Omitting the required value for one of these option yields an error, such as the one shown here:

```
shell> mysql --host 85.224.35.45 --user
mysql: option '--user' requires an argument
```

In this case, mysql was unable to find a value following the --user option because nothing came after it on the command line. However, if you omit the value for an option that is not the last option to be used, you obtain a different error that you may not be expecting:

```
shell> mysql --host --user jon
ERROR 2005 (HY000): Unknown MySQL server host '--user' (1)
```

Because mysql assumes that any string following --host on the command line is a host name, --host --user is interpreted as --host=--user, and the client attempts to connect to a MySQL server running on a host named “--user”.

Options having default values always require an equal sign when assigning a value; failing to do so causes an error. For example, the MySQL server --log-error option has the default value host_name.err, where host_name is the name of the host on which MySQL is running. Assume that you are running MySQL on a computer whose host name is “tonfisk”, and consider the following invocation of mysqld_safe:

```
shell> mysqld_safe &
[1] 11699
shell> 080112 12:53:40 mysqld_safe Starting mysqld daemon with databases from /usr/local/mysql/var
```

After shutting down the server, restart it as follows:
Specifying Program Options

shell> mysqld_safe --log-error &
[1] 11699
shell> 080112 12:53:40 mysqld_safe Logging to '/usr/local/mysql/var/tonfisk.err'.
080112 12:53:40 mysqld_safe Starting mysqld daemon with databases from /usr/local/mysql/var
shell>

The result is the same, since --log-error is not followed by anything else on the command line, and it supplies its own default value. (The & character tells the operating system to run MySQL in the background; it is ignored by MySQL itself.) Now suppose that you wish to log errors to a file named my-errors.err. You might try starting the server with --log-error my-errors, but this does not have the intended effect, as shown here:

shell> mysqld_safe --log-error my-errors &
[1] 31357
shell> 080111 22:53:31 mysqld_safe Logging to '/usr/local/mysql/var/tonfisk.err'.
080111 22:53:32 mysqld_safe Starting mysqld daemon with databases from /usr/local/mysql/var
080111 22:53:34 mysqld_safe mysqld from pid file /usr/local/mysql/var/tonfisk.pid ended
[1]+ Done ./mysqld_safe --log-error my-errors

The server attempted to start using /usr/local/mysql/var/tonfisk.err as the error log, but then shut down. Examining the last few lines of this file shows the reason:

shell> tail /usr/local/mysql/var/tonfisk.err
2013-09-24T15:36:22.278034Z 0 [ERROR] Too many arguments (first extra is 'my-errors').
2013-09-24T15:36:22.278059Z 0 [Note] Use --verbose --help to get a list of available options!
2013-09-24T15:36:22.279704Z 0 [Note] InnoDB: Starting shutdown...
2013-09-24T15:36:23.777471Z 0 [Note] InnoDB: Shutdown completed; log sequence number 2319086

Because the --log-error option supplies a default value, you must use an equal sign to assign a different value to it, as shown here:

shell> mysqld_safe --log-error=my-errors &
[1] 31437
shell> 080111 22:54:15 mysqld_safe Logging to '/usr/local/mysql/var/my-errors.err'.
080111 22:54:15 mysqld_safe Starting mysqld daemon with databases from /usr/local/mysql/var
shell>

Now the server has been started successfully, and is logging errors to the file /usr/local/mysql/var/my-errors.err.

Similar issues can arise when specifying option values in option files. For example, consider a my.cnf file that contains the following:

[mysql]
host
user

When the mysql client reads this file, these entries are parsed as --host --user or --host=--user, with the result shown here:

shell> mysql
ERROR 2005 (HY000): Unknown MySQL server host '--user' (1)

However, in option files, an equal sign is not assumed. Suppose the my.cnf file is as shown here:
Specifying Program Options

```
[mysql]
user jon

Trying to start `mysql` in this case causes a different error:

```
shell> mysql
mysql: unknown option '--user jon'
```

A similar error would occur if you were to write `host tonfisk` in the option file rather than `host=tonfisk`. Instead, you must use the equal sign:

```
[mysql]
user=jon
```

Now the login attempt succeeds:

```
shell> mysql
Welcome to the MySQL monitor. Commands end with ; or \g.
Your MySQL connection id is 5
Server version: 8.0.18 Source distribution
Type 'help;' or '\h' for help. Type '\c' to clear the buffer.
mysql> SELECT USER();
+---------------+
| USER()        |
+---------------+
| jon@localhost |
+---------------+
1 row in set (0.00 sec)
```

This is not the same behavior as with the command line, where the equal sign is not required:

```
shell> mysql --user jon --host tonfisk
Welcome to the MySQL monitor. Commands end with ; or \g.
Your MySQL connection id is 6
Server version: 8.0.18 Source distribution
Type 'help;' or '\h' for help. Type '\c' to clear the buffer.
mysql> SELECT USER();
+---------------+
| USER()        |
+---------------+
| jon@tonfisk   |
+---------------+
1 row in set (0.00 sec)
```

Specifying an option requiring a value without a value in an option file causes the server to abort with an error. Suppose that `my.cnf` contains the following:

```
[mysqld]
log_error
relay_log
relay_log_index
```

This causes the server to fail on startup, as shown here:

```
shell> mysqld_safe &
```

```
130924 10:41:46 mysqld_safe Logging to '/home/jon/bin/mysql/var/tonfisk.err'.
```
The `--log-error` option does not require an argument; however, the `--relay-log` option requires one, as shown in the error log (which in the absence of a specified value, defaults to `datadir/hostname.err`):

```
shell> tail -n 3 ../var/tonfisk.err
```

This is a change from previous behavior, where the server would have interpreted the last two lines in the example `my.cnf` file as `--relay-log=relay_log_index` and created a relay log file using "relay_log_index" as the base name. (Bug #25192)

### 4.2.3 Command Options for Connecting to the Server

This section describes options supported by most MySQL client programs that control how client programs establish connections to the server, whether connections are encrypted, and whether connections are compressed. These options can be given on the command line or in an option file.

- Command Options for Connection Establishment
- Command Options for Encrypted Connections
- Command Options for Connection Compression

#### Command Options for Connection Establishment

This section describes options that control how client programs establish connections to the server. For additional information and examples showing how to use them, see Section 4.2.4, “Connecting to the MySQL Server Using Command Options”.

<table>
<thead>
<tr>

<tr>
<td>--user</td>
<td>MySQL user name to use when connecting to server</td>
<td></td>
</tr>
</tbody>
</table>

• `--default-auth=plugin`

A hint about which client-side authentication plugin to use. See Section 6.2.17, “Pluggable Authentication”. 

---

130924 10:41:46 mysqld_safe Starting mysqld daemon with databases from /home/jon/bin/mysql/var
130924 10:41:47 mysqld_safe mysqld from pid file /home/jon/bin/mysql/var/tonfisk.pid ended
Command Options for Connecting to the Server

- **--host=host_name, -h host_name**
  The host on which the MySQL server is running. The value can be a host name, IPv4 address, or IPv6 address. The default value is `localhost`.

- **--password=[=pass_val], -p[pass_val]**
  The password of the MySQL account used for connecting to the server. The password value is optional. If not given, the program prompts for one. If given, there must be no space between `--password=` or `-p` and the password following it. If no password option is specified, the default is to send no password.

Specifying a password on the command line should be considered insecure. To avoid giving the password on the command line, use an option file. See Section 6.1.2.1, “End-User Guidelines for Password Security”.

To explicitly specify that there is no password and that the client program should not prompt for one, use the `--skip-password` option.

- **--pipe, -W**
  On Windows, connect to the server using a named pipe. This option applies only if the server was started with the `named_pipe` system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the `named_pipe_full_access_group` system variable.

- **--plugin-dir=[dir_name]**
  The directory in which to look for plugins. Specify this option if the `--default-auth` option is used to specify an authentication plugin but the client program does not find it. See Section 6.2.17, “Pluggable Authentication”.

- **--port=[port_num], -P port_num**
  For TCP/IP connections, the port number to use. The default port number is 3306.

- **--protocol={TCP|SOCKET|PIPE|MEMORY}**
  This option explicitly specifies which protocol to use for connecting to the server. It is useful when other connection parameters normally result in use of a protocol other than the one you want. For example, connections on Unix to `localhost` are made using a Unix socket file by default:

  ```
  mysql --host=localhost
  ```

  To force a TCP/IP connection to be used instead, specify a `--protocol` option:

  ```
  mysql --host=localhost --protocol=TCP
  ```

  The following table shows the permissible `--protocol` option values and indicates the platforms on which each value may be used. The values are not case-sensitive.

<table>
<thead>
<tr>
<th><code>--protocol</code> Value</th>
<th>Connection Protocol</th>
<th>Permissible Operating Systems</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCP</td>
<td>TCP/IP connection to local or remote server</td>
<td>All</td>
</tr>
<tr>
<td>SOCKET</td>
<td>Unix socket file connection to local server</td>
<td>Unix only</td>
</tr>
<tr>

<td>Named-pipe connection to local or remote server</td>
<td>Windows only</td>
</tr>
<tr>
<td>MEMORY</td>
<td>Shared-memory connection to local server</td>
<td>Windows only</td>
</tr>
</tbody>
</table>

- **--secure-auth**
Command Options for Connecting to the Server

This option was removed in MySQL 8.0.3.

• **--shared-memory-base-name=name**

On Windows, the shared-memory name to use for connections made using shared memory to a local server. The default value is `MYSQL`. The shared-memory name is case-sensitive.

This option applies only if the server was started with the `shared_memory` system variable enabled to support shared-memory connections.

• **--socket=path, -S path**

On Unix, the name of the Unix socket file to use for connections made using a named pipe to a local server. The default Unix socket file name is `/tmp/mysql.sock`.

On Windows, the name of the named pipe to use for connections to a local server. The default Windows pipe name is `MySQL`. The pipe name is not case-sensitive.

On Windows, this option applies only if the server was started with the `named_pipe` system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the `named_pipe_full_access_group` system variable.

• **--user=user_name, -u user_name**

The user name of the MySQL account to use for connecting to the server. The default user name is `ODBC` on Windows or your Unix login name on Unix.

Command Options for Encrypted Connections

This section describes options that specify whether to use encrypted connections, the names of certificate and key files, and other parameters related to encrypted-connection support. For examples of suggested use and how to check whether a connection is encrypted, see Section 6.3.1, “Configuring MySQL to Use Encrypted Connections”.

For information about using encrypted connections from the MySQL C API, see Section 28.7.22, “C API Encrypted Connection Support”.

- **--get-server-public-key**

  Request from the server the public key required for RSA key pair-based password exchange. This option applies to clients that authenticate with the `caching_sha2_password` authentication plugin. For that plugin, the server does not send the public key unless requested. This option is ignored for accounts that do not authenticate with that plugin. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

  If `--server-public-key-path=file_name` is given and specifies a valid public key file, it takes precedence over `--get-server-public-key`.

  For information about the `caching_sha2_password` plugin, see Section 6.4.1.3, “Caching SHA-2 Pluggable Authentication”.

- **--server-public-key-path=file_name**

  The path name to a file containing a client-side copy of the public key required by the server for RSA key pair-based password exchange. The file must be in PEM format. This option applies to clients that authenticate with the `sha256_password` or `caching_sha2_password` authentication plugin. This option is ignored for accounts that do not authenticate with one of those plugins. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

  If `--server-public-key-path=file_name` is given and specifies a valid public key file, it takes precedence over `--get-server-public-key`.

  This option is available only if MySQL was built using OpenSSL.

  For information about the `sha256_password` and `caching_sha2_password` plugins, see Section 6.4.1.2, “SHA-256 Pluggable Authentication”, and Section 6.4.1.3, “Caching SHA-2 Pluggable Authentication”.

- **--ssl**, **--skip-ssl**

  ![](image.png)

  The client-side `--ssl` option is removed in MySQL 8.0. For client programs, use `--ssl-mode` instead.

  On the server side, the `--ssl` option specifies that the server permits but does not require encrypted connections. The option is enabled on the server side by default. `--ssl` is implied by other `--ssl-xxx` options, as indicated in the descriptions for those options.

  The `--ssl` option can be specified in negated form as `--skip-ssl` or a synonym (`--ssl=0`, `--disable-ssl`). In this case, the option specifies that the server does not permit encrypted connections and overrides other `--ssl-xxx` options.

  To specify additional parameters for encrypted connections, consider using at least `--ssl-cert` and `--ssl-key` on the server side and `--ssl-ca` on the client side. See Section 6.3.1, “Configuring MySQL to Use Encrypted Connections”, which also describes server capabilities for certificate and key file autogeneration and autodiscovery.
• **--ssl-ca=file_name**

The path name of the Certificate Authority (CA) certificate file in PEM format. On the server side, this option implies **--ssl**.

To tell the client not to authenticate the server certificate when establishing an encrypted connection to the server, specify neither **--ssl-ca** nor **--ssl-capath**. The server still verifies the client according to any applicable requirements established for the client account, and it still uses any **--ssl-ca** or **--ssl-capath** option values specified on the server side.

• **--ssl-capath=dir_name**

The path name of the directory that contains trusted SSL certificate authority (CA) certificate files in PEM format. On the server side, this option implies **--ssl**.

To tell the client not to authenticate the server certificate when establishing an encrypted connection to the server, specify neither **--ssl-ca** nor **--ssl-capath**. The server still verifies the client according to any applicable requirements established for the client account, and it still uses any **--ssl-ca** or **--ssl-capath** option values specified on the server side.

Support for this option depends on the SSL library used to compile MySQL. See Section 6.3.3, “SSL Library-Dependent Capabilities”.

• **--ssl-cert=file_name**

The path name of the SSL public key certificate file in PEM format. On the client side, this is the client public key certificate. On the server side, this is the server public key certificate. On the server side, this option implies **--ssl**.

• **--ssl-cipher=cipher_list**

The list of permissible ciphers for connection encryption. If no cipher in the list is supported, encrypted connections will not work. On the server side, this option implies **--ssl**.

For greatest portability, **cipher_list** should be a list of one or more cipher names, separated by colons. Examples:

```
--ssl-cipher=AES128-SHA
--ssl-cipher=DHE-RSA-AES128-GCM-SHA256:AES128-SHA
```

OpenSSL supports a more flexible syntax for specifying ciphers, as described in the OpenSSL documentation at https://www.openssl.org/docs/manmaster/man1/ciphers.html. wolfSSL does not, so attempts to use that extended syntax fail for a MySQL distribution compiled using wolfSSL.

For information about which encryption ciphers MySQL supports, see Section 6.3.5, “Encrypted Connection Protocols and Ciphers”.

• **--ssl-crl=file_name**

The path name of the file containing certificate revocation lists in PEM format. On the server side, this option implies **--ssl**.

If neither **--ssl-crl** nor **--ssl-crlpath** is given, no CRL checks are performed, even if the CA path contains certificate revocation lists.

Support for this option depends on the SSL library used to compile MySQL. See Section 6.3.3, “SSL Library-Dependent Capabilities”.

• **--ssl-crlpath=dir_name**
The path name of the directory that contains certificate revocation-list files in PEM format. On the server side, this option implies \texttt{--ssl}.

If neither \texttt{--ssl-crl} nor \texttt{--ssl-crlpath} is given, no CRL checks are performed, even if the CA path contains certificate revocation lists.

Support for this option depends on the SSL library used to compile MySQL. See Section 6.3.3, “SSL Library-Dependent Capabilities”.

\begin{itemize}
  \item \texttt{--ssl-fips-mode=\{OFF\mid ON\mid STRICT\}}
\end{itemize}

Controls whether to enable FIPS mode on the client side. The \texttt{--ssl-fips-mode} option differs from other \texttt{--ssl-xxx} options in that it is not used to establish encrypted connections, but rather to affect which cryptographic operations are permitted. See Section 6.5, “FIPS Support”.

These \texttt{--ssl-fips-mode} values are permissible:

\begin{itemize}
  \item \texttt{OFF}: Disable FIPS mode.
  \item \texttt{ON}: Enable FIPS mode.
  \item \texttt{STRICT}: Enable “strict” FIPS mode.
\end{itemize}

\textbf{Note}

If the OpenSSL FIPS Object Module is not available, the only permissible value for \texttt{--ssl-fips-mode} is \texttt{OFF}. In this case, setting \texttt{--ssl-fips-mode} to \texttt{ON} or \texttt{STRICT} causes the client to produce a warning at startup and to operate in non-FIPS mode.

To specify the FIPS mode for the server, use the \texttt{ssl_fips_mode} system variable.

\begin{itemize}
  \item \texttt{--ssl-key=file_name}
\end{itemize}

The path name of the SSL private key file in PEM format. On the client side, this is the client private key. On the server side, this is the server private key. On the server side, this option implies \texttt{--ssl}.

If the key file is protected by a passphrase, the program prompts the user for the passphrase. The password must be given interactively; it cannot be stored in a file. If the passphrase is incorrect, the program continues as if it could not read the key.

For better security, use a certificate with an RSA key size of at least 2048 bits.

\begin{itemize}
  \item \texttt{--ssl-mode=mode}
\end{itemize}

This option is available only for client programs, not the server. It specifies the desired security state of the connection to the server. These mode values are permissible, in order of increasing strictness:

\begin{itemize}
  \item \texttt{DISABLED}: Establish an unencrypted connection.
  \item \texttt{PREFERRED}: Establish an encrypted connection if the server supports encrypted connections, falling back to an unencrypted connection if an encrypted connection cannot be established. This is the default if \texttt{--ssl-mode} is not specified.
\end{itemize}

Encrypted connections over Unix sockets are disabled by default, so \texttt{PREFERRED} does not establish an encrypted connection. To enforce encryption for Unix socket connections, use a mode of \texttt{REQUIRED} or stricter.

\begin{itemize}
  \item \texttt{REQUIRED}: Establish an encrypted connection if the server supports encrypted connections. The connection attempt fails if an encrypted connection cannot be established.
\end{itemize}
Command Options for Connecting to the Server

- **VERIFY_CA**: Like **REQUIRED**, but additionally verify the server Certificate Authority (CA) certificate against the configured CA certificates. The connection attempt fails if no valid matching CA certificates are found.

- **VERIFY_IDENTITY**: Like **VERIFY_CA**, but additionally perform host name identity verification by checking the host name the client uses for connecting to the server against the identity in the certificate that the server sends to the client:
  - As of MySQL 8.0.12, if the client uses OpenSSL 1.0.2 or higher, the client checks whether the host name that it uses for connecting matches either the Subject Alternative Name value or the Common Name value in the server certificate.
  - Otherwise, the client checks whether the host name that it uses for connecting matches the Common Name value in the server certificate.

The connection fails if there is a mismatch. For encrypted connections, this option helps prevent man-in-the-middle attacks.

**Note**

Host name identity verification with **VERIFY_IDENTITY** does not work with self-signed certificates that are created automatically by the server or manually using **mysql_ssl_rsa_setup** (see Section 6.3.2.1, “Creating SSL and RSA Certificates and Keys using MySQL”). Such self-signed certificates do not contain the server name as the Common Name value.

Host name identity verification also does not work with certificates that specify the Common Name using wildcards because that name is compared verbatim to the server name.

The **--ssl-mode** option interacts with CA certificate options as follows:

- If **--ssl-mode** is not explicitly set otherwise, use of **--ssl-ca** or **--ssl-capath** implies **--ssl-mode=VERIFY_CA**.

- For **--ssl-mode** values of **VERIFY_CA** or **VERIFY_IDENTITY**, **--ssl-ca** or **--ssl-capath** is also required, to supply a CA certificate that matches the one used by the server.

- An explicit **--ssl-mode** option with a value other than **VERIFY_CA** or **VERIFY_IDENTITY**, together with an explicit **--ssl-ca** or **--ssl-capath** option, produces a warning that no verification of the server certificate will be done, despite a CA certificate option being specified.

To require use of encrypted connections by a MySQL account, use **CREATE USER** to create the account with a **REQUIRE SSL** clause, or use **ALTER USER** for an existing account to add a **REQUIRE SSL** clause. This causes connection attempts by clients that use the account to be rejected unless MySQL supports encrypted connections and an encrypted connection can be established.

The **REQUIRE** clause permits other encryption-related options, which can be used to enforce security requirements stricter than **REQUIRE SSL**. For additional details about which command options may or must be specified by clients that connect using accounts configured using the various **REQUIRE** options, see **CREATE USER SSL/TLS Options**.

- **--tls-ciphersuites=ciphersuite_list**

For client programs, the permissible TLSv1.3 ciphersuites for encrypted connections. The value is a list of one or more colon-separated ciphersuite names. For example:

```bash
mysql --tls-ciphersuites="suite1:suite2:suite3"
```
The ciphersuites that can be named for this option depend on the SSL library used to compile MySQL. For details, see Section 6.3.5, “Encrypted Connection Protocols and Ciphers”.

This option was added in MySQL 8.0.16.

To specify which ciphersuites the server permits, use the `tls_ciphersuites` system variable.

- `--tls-version=protocol_list`

For client programs, the TLS protocols the client permits for encrypted connections. The value is a list of one or more comma-separated protocol names. For example:

```sh
grep --tls-version="TLSv1.1,TLSv1.2"
```

The protocols that can be named for this option depend on the SSL library used to compile MySQL. For details, see Section 6.3.5, “Encrypted Connection Protocols and Ciphers”.

To specify which TLS protocols the server permits, use the `tls_version` system variable.

---

### Command Options for Connection Compression

This section describes options that enable client programs to control use of compression for connections to the server. For additional information and examples showing how to use them, see Section 4.2.6, “Connection Compression Control”.

<table>
<thead>

<tr>
<td>--zstd-compression-level</td>
<td>Compression level for connections to server that use zstd compression</td>
<td>8.0.18</td>
<td></td>
</tr>
</tbody>
</table>

- `--compress, -C`

Compress all information sent between the client and the server if possible.

As of MySQL 8.0.18, this option is deprecated. It will be removed in a future MySQL version. See Legacy Connection Compression Configuration.

- `--compression-algorithms=value`

The permitted compression algorithms for connections to the server. The available algorithms are the same as for the `protocol_compression_algorithms` system variable. The default value is uncompressed.

This option was added in MySQL 8.0.18.

- `--zstd-compression-level=level`

The compression level to use for connections to the server that use the `zstd` compression algorithm. The permitted levels are from 1 to 22, with larger values indicating increasing levels of compression. The default `zstd` compression level is 3. The compression level setting has no effect on connections that do not use `zstd` compression.

This option was added in MySQL 8.0.18.
4.2.4 Connecting to the MySQL Server Using Command Options

This section describes use of command-line options to specify how to establish connections to the MySQL server, for clients such as `mysql` or `mysqldump`. For information on establishing connections using URI-like connection strings or key-value pairs, for clients such as MySQL Shell, see Section 4.2.5, "Connecting to the Server Using URI-Like Strings or Key-Value Pairs". For additional information if you are unable to connect, see Section 6.2.21, "Troubleshooting Problems Connecting to MySQL".

For a client program to connect to the MySQL server, it must use the proper connection parameters, such as the name of the host where the server is running and the user name and password of your MySQL account. Each connection parameter has a default value, but you can override default values as necessary using program options specified either on the command line or in an option file.

The examples here use the `mysql` client program, but the principles apply to other clients such as `mysqldump`, `mysqladmin`, or `mysqlshow`.

This command invokes `mysql` without specifying any explicit connection parameters:

```bash
mysql
```

Because there are no parameter options, the default values apply:

- The default host name is `localhost`. On Unix, this has a special meaning, as described later.
- The default user name is `ODBC` on Windows or your Unix login name on Unix.
- No password is sent because neither `--password` nor `-p` is given.
- For `mysql`, the first nonoption argument is taken as the name of the default database. Because there is no such argument, `mysql` selects no default database.

To specify the host name and user name explicitly, as well as a password, supply appropriate options on the command line. To select a default database, add a database-name argument. Examples:

```bash
mysql --host=localhost --user=myname --password= password mydb
mysql -h localhost -u myname -p password mydb
```

For password options, the password value is optional:

- If you use a `--password` or `-p` option and specify a password value, there must be no space between `--password=` or `-p` and the password following it.
- If you use `--password` or `-p` but do not specify a password value, the client program prompts you to enter the password. The password is not displayed as you enter it. This is more secure than giving the password on the command line, which might enable other users on your system to see the password line by executing a command such as `ps`. See Section 6.1.2.1, "End-User Guidelines for Password Security".
- To explicitly specify that there is no password and that the client program should not prompt for one, use the `--skip-password` option.

As just mentioned, including the password value on the command line can be a security risk. To avoid this risk, specify the `--password` or `-p` option without any following password value:

```bash
mysql --host=localhost --user=myname --password mydb
mysql -h localhost -u myname -p mydb
```

When the `--password` or `-p` option is given with no password value, the client program prints a prompt and waits for you to enter the password. (In these examples, `mydb` is not interpreted as a password because it is separated from the preceding password option by a space.)
On some systems, the library routine that MySQL uses to prompt for a password automatically limits the password to eight characters. That limitation is a property of the system library, not MySQL. Internally, MySQL does not have any limit for the length of the password. To work around the limitation on systems affected by it, specify your password in an option file (see Section 4.2.2.2, “Using Option Files”). Another workaround is to change your MySQL password to a value that has eight or fewer characters, but that may be unacceptable because shorter passwords tend to be less secure.

Client programs determine what type of connection to make as follows:

- If the host is not specified or is `localhost`, a connection to the local host occurs:
  - On Windows, the client connects using a shared-memory connection, if the server was started with the `shared_memory` system variable enabled to support shared-memory connections.
  - On Unix, MySQL programs treat the host name `localhost` specially, in a way that is likely different from what you expect compared to other network-based programs: the client connects using a Unix socket file. The `--socket` option or the `MYSQL_UNIX_PORT` environment variable may be used to specify the socket name.
  - On Windows, if `host` is . (period), or TCP/IP is not enabled and `--socket` is not specified or the host is empty, the client connects using a named pipe, if the server was started with the `named_pipe` system variable enabled to support named-pipe connections. If named-pipe connections are not supported or if the user making the connection is not a member of the Windows group specified by the `named_pipe_full_access_group` system variable, an error occurs.
  - Otherwise, the connection uses TCP/IP.

The `--protocol` option enables you to establish a particular type of connection even when other options normally result in use of a different protocol. That is, `--protocol` specifies the connection protocol explicitly and overrides the preceding rules, even for `localhost`.

Only connection options that are relevant to the selected protocol are used or checked. Other connection options are ignored. For example, with `--host=localhost` on Unix, the client attempts to connect to the local server using a Unix socket file. This occurs even if a `--port` or `-P` option is given to specify a port number.

To ensure that the client makes a TCP/IP connection to the local server, use `--host` or `-h` to specify a host name value of `127.0.0.1`, or the IP address or name of the local server. You can also specify the connection protocol explicitly, even for `localhost`, by using the `--protocol=TCP` option.

Examples:

```
mysql --host=127.0.0.1
mysql --protocol=TCP
```

If the server is configured to accept IPv6 connections, clients can connect to the local server over IPv6 using `--host=:1`. See Section 5.1.12, “IPv6 Support”.

On Windows, you can force a MySQL client to use a named-pipe connection by specifying the `--pipe` or `--protocol=PIPE` option, or by specifying . (period) as the host name. If the server was not started with the `named_pipe` system variable enabled to support named-pipe connections or if the user making the connection is not a member of the Windows group specified by the `named_pipe_full_access_group` system variable, an error occurs. Use the `--socket` option to specify the name of the pipe if you do not want to use the default pipe name.

Connections to remote servers use TCP/IP. This command connects to the server running on `remote.example.com` using the default port number (3306):

```
mysql --host=remote.example.com
```

To specify a port number explicitly, use the `--port` or `-P` option:
Connecting to the Server Using URI-Like Strings or Key-Value Pairs

You can specify a port number for connections to a local server, too. However, as indicated previously, connections to `localhost` on Unix use a socket file by default, so unless you force a TCP/IP connection as previously described, any option that specifies a port number is ignored.

For this command, the program uses a socket file on Unix and the `--port` option is ignored:

```bash
mysql --port=13306 --host=localhost
```

To cause the port number to be used, force a TCP/IP connection. For example, invoke the program in either of these ways:

```bash
mysql --port=13306 --host=127.0.0.1
mysql --port=13306 --protocol=TCP
```

For additional information about options that control how client programs establish connections to the server, see Section 4.2.3, “Command Options for Connecting to the Server”.

It is possible to specify connection parameters without entering them on the command line each time you invoke a client program:

- Specify the connection parameters in the `[client]` section of an option file. The relevant section of the file might look like this:

  ```ini
  [client]
  host=host_name
  user=user_name
  password=password
  ```

  For more information, see Section 4.2.2.2, “Using Option Files”.

- Some connection parameters can be specified using environment variables. Examples:
  - To specify the host for `mysql`, use `MYSQL_HOST`.
  - On Windows, to specify the MySQL user name, use `USER`.
  - To specify the password, use `MYSQL_PWD`. However, this is insecure; see Section 6.1.2.1, “End-User Guidelines for Password Security”.

  For a list of supported environment variables, see Section 4.9, “MySQL Environment Variables”.

## 4.2.5 Connecting to the Server Using URI-Like Strings or Key-Value Pairs

This section describes use of URI-like connection strings or key-value pairs to specify how to establish connections to the MySQL server, for clients such as MySQL Shell. For information on establishing connections using command-line options, for clients such as `mysql` or `mysqldump`, see Section 4.2.4, “Connecting to the MySQL Server Using Command Options”. For additional information if you are unable to connect, see Section 6.2.21, “Troubleshooting Problems Connecting to MySQL”.

**Note**

The term “URI-like” signifies connection-string syntax that is similar to but not identical to the URI (uniform resource identifier) syntax defined by RFC 3986.

The following MySQL clients support connecting to a MySQL server using a URI-like connection string or key-value pairs:
Connecting to the Server Using URI-Like Strings or Key-Value Pairs

- MySQL Shell
- MySQL Router
- MySQL Connectors which implement X DevAPI

This section documents all valid URI-like string and key-value pair connection parameters, many of which are similar to those specified with command-line options:

- Parameters specified with a URI-like string use a syntax such as myuser@example.com:3306/main-schema. For the full syntax, see Connecting Using URI-Like Connection Strings.

- Parameters specified with key-value pairs use a syntax such as {user:'myuser', host:'example.com', port:3306, schema:'main-schema'}. For the full syntax, see Connecting Using Key-Value Pairs.

Connection parameters are not case-sensitive. Each parameter, if specified, can be given only once. If a parameter is specified more than once, an error occurs.

This section covers the following topics:

- Base Connection Parameters
- Additional Connection parameters
- Connecting Using URI-Like Connection Strings
- Connecting Using Key-Value Pairs

Base Connection Parameters

The following discussion describes the parameters available when specifying a connection to MySQL. These parameters can be provided using either a string that conforms to the base URI-like syntax (see Connecting Using URI-Like Connection Strings), or as key-value pairs (see Connecting Using Key-Value Pairs).

- **scheme**: The connection protocol to use. Use mysqlx for X Protocol connections and mysql for classic MySQL protocol connections (see MySQL Shell Sessions Explained). If no protocol is specified, the server attempts to guess the protocol.

- **user**: The MySQL user account to use for the authentication process.

- **password**: The password to use for the authentication process.

- **host**: The host on which the server instance is running. The value can be a host name, IPv4 address, or IPv6 address. If no host is specified, the default is localhost.

- **port**: The TCP/IP network port on which the target MySQL server is listening for connections. If no port is specified, the default is 33060 for X Protocol connections and 3306 for classic MySQL protocol connections.

- **socket**: The path to a Unix socket file or the name of a Windows named pipe. Values are local file paths. In URI-like strings, they must be encoded, using either percent encoding or by surrounding the path with parentheses. Parentheses eliminate the need to percent encode characters such as the / directory separator character. For example, to connect as root@localhost using the Unix socket /tmp/mysql.sock, specify the path using percent encoding as root@localhost?

**Warning**

Specifying an explicit password in the connection specification is insecure and not recommended. Later discussion shows how to cause an interactive prompt for the password to occur.
socket=%2Ftmp%2Fmysql.sock, or using parentheses as root@localhost?socket=({/tmp/mysql.sock).

- **schema**: The default database for the connection. If no database is specified, the connection has no default database.

**Additional Connection parameters**

You can specify options for the connection, either as attributes in a URI-like string by appending ?attribute=value, or as key-value pairs. The following options are available:

- **ssl-mode**: The desired security state for the connection. The following modes are permissible:
  - DISABLED
  - PREFERRED
  - REQUIRED
  - VERIFY_CA
  - VERIFY_IDENTITY
  
  For information about these modes, see the `--ssl-mode` option description in Command Options for Encrypted Connections.

- **ssl-ca**: The path to the X.509 certificate authority file in PEM format.

- **ssl-capath**: The path to the directory that contains the X.509 certificates authority files in PEM format.

- **ssl-cert**: The path to the X.509 certificate file in PEM format.

- **ssl-cipher**: The SSL cipher to use.

- **ssl-crl**: The path to the file that contains certificate revocation lists in PEM format.

- **ssl-crlpath**: The path to the directory that contains certificate revocation-list files in PEM format.

- **ssl-key**: The path to the X.509 key file in PEM format.

- **tls-version**: The permissible TLS protocols for encrypted connections. The value is a list of one or more comma-separated protocol names. For details, see Section 6.3.5, “Encrypted Connection Protocols and Ciphers”. The following versions are permissible:
  - TLSv1
  - TLSv1.1
  - TLSv1.2 (Supported only by commercial edition)

- **auth-method**: The authentication method to use for the connection. The default is AUTO, meaning that the server attempts to guess. The following methods are permissible:
  - AUTO
  - MYSQL41
  - SHA256_MEMORY
  - FROM_CAPABILITIES
  - FALLBACK
Connecting to the Server Using URI-Like Strings or Key-Value Pairs

• **PLAIN**

For X Protocol connections, any configured `auth-method` is overridden to this sequence of authentication methods: `MYSQL41, SHA256_MEMORY, PLAIN`.

• **get-server-public-key**: Request from the server the public key required for RSA key pair-based password exchange. Use when connecting to MySQL 8.0 servers over classic MySQL protocol with SSL mode `DISABLED`. You must specify the protocol in this case. For example:

```sql
mysql://user@localhost:3306?get-server-public-key=true
```

This option applies to clients that authenticate with the `caching_sha2_password` authentication plugin. For that plugin, the server does not send the public key unless requested. This option is ignored for accounts that do not authenticate with that plugin. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

If `server-public-key-path=file_name` is given and specifies a valid public key file, it takes precedence over `get-server-public-key`.

For information about the `caching_sha2_password` plugin, see Section 6.4.1.3, “Caching SHA-2 Pluggable Authentication”.

• **server-public-key-path**: The path name to a file containing a client-side copy of the public key required by the server for RSA key pair-based password exchange. Use when connecting to MySQL 8.0 servers over classic MySQL protocol with SSL mode `DISABLED`.

The file must be in PEM format. This option applies to clients that authenticate with the `sha256_password` or `caching_sha2_password` authentication plugin. This option is ignored for accounts that do not authenticate with one of those plugins. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

If `server-public-key-path=file_name` is given and specifies a valid public key file, it takes precedence over `get-server-public-key`.

For information about the `sha256_password` and `caching_sha2_password` plugins, see Section 6.4.1.2, “SHA-256 Pluggable Authentication”, and Section 6.4.1.3, “Caching SHA-2 Pluggable Authentication”.

• **connect-timeout**: An integer value used to configure the number of seconds that clients, such as MySQL Shell, wait until they stop trying to connect to an unresponsive MySQL server.

• **compression**: When set to `true` (or 1), this option enables compression of all information sent between the client and the server if possible. The default is no compression (`false` or 0). This option is available for MySQL Shell connections using classic MySQL protocol only. See Section 4.2.6, “Connection Compression Control”.

Connecting Using URI-Like Connection Strings

You can specify a connection to MySQL Server using a URI-like string. Such strings can be used with the MySQL Shell with the `--uri` command option, the MySQL Shell `\connect` command, MySQL Connectors which implement X DevAPI, and tools such as MySQL Router.

**Note**

The term “URI-like” signifies connection-string syntax that is similar to but not identical to the URI (uniform resource identifier) syntax defined by [RFC 3986](https://tools.ietf.org/html/rfc3986).

A URI-like connection string has the following syntax:
Connecting to the Server Using URI-Like Strings or Key-Value Pairs

Important
Percent encoding must be used for reserved characters in the elements of the URI-like string. For example, if you specify a string that includes the `@` character, the character must be replaced by `%40`. If you include a zone ID in an IPv6 address, the `%` character used as the separator must be replaced with `%25`.

The parameters you can use in a URI-like connection string are described at Base Connection Parameters.

MySQL Shell's `shell.parseUri()` and `shell.unparseUri()` methods can be used to deconstruct and assemble a URI-like connection string. Given a URI-like connection string, `shell.parseUri()` returns a dictionary containing each element found in the string. `shell.unparseUri()` converts a dictionary of URI components and connection options into a valid URI-like connection string for connecting to MySQL, which can be used in MySQL Shell or by MySQL Connectors which implement X DevAPI.

If no password is specified in the URI-like string, which is recommended, interactive clients prompt for the password. The following examples show how to specify URI-like strings with the user name `user_name`. In each case, the password is prompted for.

- An X Protocol connection to a local server instance listening at port 33065.
  ```
  mysqlx://user_name@localhost:33065
  ```

- A classic MySQL protocol connection to a local server instance listening at port 3333.
  ```
  mysql://user_name@localhost:3333
  ```

- An X Protocol connection to a remote server instance, using a host name, an IPv4 address, and an IPv6 address.
  ```
  mysqlx://user_name@server.example.com/
  mysqlx://user_name@198.51.100.14:123
  ```

- An X Protocol connection using a socket, with the path provided using either percent encoding or parentheses.
  ```
  mysqlx://user_name@/path%2Fto%2Fsocket.sock
  mysqlx://user_name@(/path/to/socket.sock)
  ```

- An optional path can be specified, which represents a database.
  ```
  # use 'world' as the default database
  mysqlx://user_name@198.51.100.1/world
  
  # use 'world_x' as the default database, encoding _ as %5F
  mysqlx://user_name@198.51.100.2:33060/world%5Fx
  ```

- An optional query can be specified, consisting of values each given as a `key=value` pair or as a single `key`. To specify multiple values, separate them by `,` characters. A mix of `key=value` and `key` values is permissible. Values can be of type list, with list values ordered by appearance. Strings must be either percent encoded or surrounded by parentheses. The following are equivalent.
  ```
  ssluser@127.0.0.1?ssl-ca=%2Froot%2Fclientcert%2Fca-cert.pem
  ```
Connecting to the Server Using URI-Like Strings or Key-Value Pairs

The previous examples assume that connections require a password. With interactive clients, the specified user's password is requested at the login prompt. If the user account has no password (which is insecure and not recommended), or if socket peer-credential authentication is in use (for example, with Unix socket connections), you must explicitly specify in the connection string that no password is being provided and the password prompt is not required. To do this, place a : after the user_name in the string but do not specify a password after it. For example:

```
mysqlx://user_name:@localhost
```

Connecting Using Key-Value Pairs

You can specify a connection to MySQL Server using key-value pairs, supplied in language-natural constructs for the implementation. For example, you can supply connection parameters using key-value pairs as a JSON object in JavaScript, or as a dictionary in Python. Regardless of the way the key-value pairs are supplied, the concept remains the same: the keys as described in this section can be assigned values that are used to specify a connection. You can specify connections using key-value pairs in MySQL Shell's `shell.connect()` method or InnoDB cluster's `dba.createCluster()` method, and with some of the MySQL Connectors which implement X DevAPI.

Generally, key-value pairs are surrounded by { and } characters and the , character is used as a separator between key-value pairs. The : character is used between keys and values, and strings must be delimited (for example, using the ' character). It is not necessary to percent encode strings, unlike URI-like connection strings.

A connection specified as key-value pairs has the following format:

```
{ key: value, key: value, ... }
```

The parameters you can use as keys for a connection are described at Base Connection Parameters.

If no password is specified in the key-value pairs, which is recommended, interactive clients prompt for the password. The following examples show how to specify connections using key-value pairs with the user name 'user_name'. In each case, the password is prompted for.

• An X Protocol connection to a local server instance listening at port 33065.

```
{user:'user_name', host:'localhost', port:33065}
```

• A classic MySQL protocol connection to a local server instance listening at port 3333.

```
{user:'user_name', host:'localhost', port:3333}
```

• An X Protocol connection to a remote server instance, using a host name, an IPv4 address, and an IPv6 address.

```
{user:'user_name', host:'server.example.com'}
{user:'user_name', host:'198.51.100.14:123'}
{user:'user_name', host:'[2001:db8:85a3:8d3:1319:8a2e:370:7348]'}
```

• An X Protocol connection using a socket.

```
{user:'user_name', socket:'/path/to/socket/file'}
```
• An optional schema can be specified, which represents a database.

```
{user:'user_name', host:'localhost', schema:'world'}
```

The previous examples assume that connections require a password. With interactive clients, the
specified user's password is requested at the login prompt. If the user account has no password (which
is insecure and not recommended), or if socket peer-credential authentication is in use (for example,
with Unix socket connections), you must explicitly specify that no password is being provided and the
password prompt is not required. To do this, provide an empty string using ' ' after the password key.
For example:

```
{user:'user_name', password:' ', host:'localhost'}
```

### 4.2.6 Connection Compression Control

Connections to the server can use a compressed protocol that reduces the number of bytes sent over
the connection. By default, connections are uncompressed, but can be compressed if the server and
the client agree on the compression algorithm to use.

This section describes the available compression-control configuration parameters and the information
sources available for monitoring use of compression.

Compression control applies to connections to the server by client programs and by servers
participating in master/slave replication or Group Replication. (In the following discussion, “client
connection” is shorthand for a connection to the server originating from any source for which
compression is supported, unless context indicates a specific connection type.) Compression control
does not apply to X Protocol connections or connections for FEDERATED tables.

Compressed connections originate on the client side but affect CPU load on both the client and server
sides because both sides perform compression and decompression operations. Because enabling
compression decreases performance, its benefits occur primarily when there is low network bandwidth,
network transfer time dominates the cost of compression and decompression operations, and result
sets are large.

• Connection Compression Configuration

• Legacy Connection Compression Configuration

• Connection Compression Monitoring

### Connection Compression Configuration

As of MySQL 8.0.18, these configuration parameters are available for controlling connection
compression:

• The `protocol_compression_algorithms` system variable configures which compression
algorithms the server permits for incoming connections.

• The `--compression-algorithms` and `--zstd-compression-level` command-line options
configure permitted compression algorithms and zstd compression level for these client programs:
`mysql`, `mysqladmin`, `mysqlbinlog`, `mysqlcheck`, `mysqldump`, `mysqlimport`, `mysqldump`,
`mysqlshow`, `mysqldump`, and `mysqltest`, and `mysql_upgrade`.

• The `MYSQL_OPT_COMPRESSION_ALGORITHMS` and `MYSQL_OPT_ZSTD_COMPRESSION_LEVEL`
options for the `mysql_options()` function configure permitted compression algorithms and zstd
compression level for client programs that use the MySQL C API.

• The `MASTER_COMPRESSION_ALGORITHMS` and `MASTER_ZSTD_COMPRESSION_LEVEL` options
for the `CHANGE MASTER TO` statement configure permitted compression algorithms and zstd
compression level for slave servers participating in master/slave replication.
• The `group_replication_recovery_compression_algorithm` and `group_replication_recovery_zstd_compression_level` system variables configure permitted compression algorithms and `zstd` compression level for Group Replication recovery connections when a new member joins a group and connects to a donor.

Configuration parameters that enable specifying compression algorithms are string-valued and take a list of one or more comma-separated compression algorithm names, in any order, chosen from the following items (not case-sensitive):

- `zlib`: Permit connections that use the `zlib` compression algorithm.
- `zstd`: Permit connections that use the `zstd` compression algorithm (`zstd 1.3`).
- `uncompressed`: Permit uncompressed connections.

**Note**

Because `uncompressed` is an algorithm name that may or may not be configured, it is possible to configure MySQL not to support uncompressed connections.

Examples:

• To configure which compression algorithms the server permits for incoming connections, set the `protocol_compression_algorithms` System variable. By default, the server permits all available algorithms. To configure that setting explicitly at startup, use these lines in the server `my.cnf` file:

```
[mysqld]
protocol_compression_algorithms=zlib,zstd,uncompressed
```

To set and persist the `protocol_compression_algorithms` system variable to that value at runtime, use this statement:

```
SET PERSIST protocol_compression_algorithms='zlib,zstd,uncompressed';
```

**SET PERSIST** sets the value for the running MySQL instance. It also saves the value, causing it to be used for subsequent server restarts. To change the value for the running MySQL instance without saving it for subsequent restarts, use the `GLOBAL` keyword rather than `PERSIST`. See Section 13.7.5.1, “SET Syntax for Variable Assignment”.

• To permit only incoming connections that use `zstd` compression, configure the server at startup like this:

```
[mysqld]
protocol_compression_algorithms=zstd
```

Or, to make the change at runtime:

```
SET PERSIST protocol_compression_algorithms='zstd';
```

• To permit the `mysql` client to initiate `zlib` or `uncompressed` connections, invoke it like this:

```
mysql --compression-algorithms=zlib,uncompressed
```

• To configure replication slaves to connect to the master using `zlib` or `zstd` connections, with a compression level of 7 for `zstd` connections, use a `CHANGE MASTER TO` statement:

```
CHANGE MASTER TO
```
This assumes that the `slave_compressed_protocol` system variable is disabled, for reasons described in Legacy Connection Compression Configuration.

For successful connection setup, both sides of the connection must agree on which compression algorithm to use. The algorithm-negotiation process attempts to use `zlib`, then `zstd`, then `uncompressed`. If the two sides can find no common algorithm, the connection attempt fails.

Because both sides must agree on the compression algorithm, and because `uncompressed` is an algorithm value that need not be supported, fallback to an uncompressed connection does not necessarily occur. For example, if the server is configured to permit `zstd` and a client is configured to permit `zlib,uncompressed`, the client cannot connect at all. In this case, no algorithm is common to both sides, so connection attempts fail.

Configuration parameters that enable specifying the `zstd` compression level take an integer value from 1 to 22, with larger values indicating increasing levels of compression. The default `zstd` compression level is 3. The compression level setting has no effect on connections that do not use `zstd` compression.

A configurable `zstd` compression level enables choosing between less network traffic and higher CPU load versus more network traffic and lower CPU load. Higher compression levels reduce network congestion but the additional CPU load may reduce server performance.

## Legacy Connection Compression Configuration

Prior to MySQL 8.0.18, these configuration parameters are available for controlling connection compression:

- Client programs support a `--compress` command-line option to specify use of compression for the connection to the server.

- MySQL Shell supports compression for connections that use classic MySQL protocol. It provides a `--compress` command-line option, a compression parameter for URI-like string and key-value pair connection specifications, and a `defaultCompress` configuration option. (These are available as of MySQL Shell 8.0.14.)

- For programs that use the MySQL C API, enabling the `MYSQL_OPT_COMPRESS` option for the `mysql_options()` function specifies use of compression for the connection to the server.

- For master/server replication, enabling the `slave_compressed_protocol` system variable specifies use of compression for slave connections to the master.

In each case, when use of compression is specified, the connection uses the `zlib` compression algorithm if both sides support it, with fallback to an uncompressed connection otherwise.

As of MySQL 8.0.18, the compression parameters just described become legacy parameters, due to the additional compression parameters introduced for more control over connection compression that are described in Connection Compression Configuration. The legacy compression parameters interact with the newer parameters and their semantics change as follows:

- The meaning of the legacy `--compress` option depends on whether `--compression-algorithms` is specified:
  
  - When `--compression-algorithms` is not specified, `--compress` is equivalent to specifying a client-side algorithm set of `zlib,uncompressed`.
  
  - When `--compression-algorithms` is specified, `--compress` is equivalent to specifying an algorithm set of `zlib` and the full client-side algorithm set is the union of `zlib` plus the algorithms specified by `--compression-algorithms`. For example, with both `--compress` and `--compression-algorithms=zlib,zstd`, the permitted-algorithm
set is zlib plus zlib,zstd; that is, zlib,zstd. With both --compress and --
compression-algorithms=zstd,uncompressed, the permitted-algorithm set is zlib plus
zstd,uncompressed; that is, zlib,zstd,uncompressed.

• The same type of interaction occurs between the legacy MYSQL_OPT_COMPRESS option and the
MYSQL_OPT_COMPRESSION_ALGORITHMS option for the mysql_options() C API function.

• If the slave_compressed_protocol system variable is enabled, it takes precedence over
MASTER_COMPRESSION_ALGORITHMS and connections to the master use zlib compression if both
master and slave support that algorithm. If slave_compressed_protocol is disabled, the value of
MASTER_COMPRESSION_ALGORITHMS applies.

Note
The legacy compression-control parameters are deprecated as of MySQL
8.0.18 and will be removed in a future MySQL version.

Connection Compression Monitoring

The Compression status variable is ON or OFF to indicate whether the current connection uses
compression.

The mysql client \status command displays a line that says Protocol: Compressed if
compression is enabled for the current connection. If that line is not present, the connection is
uncompressed.

As of 8.0.14, the MySQL Shell \status command displays a Compression: line that says
Disabled or Enabled to indicate whether the connection is compressed.

As of MySQL 8.0.18, these additional sources of information are available for monitoring connection
compression:

• To monitor compression in use for client connections, use the Compression_algorithm and
Compression_level status variables. For the current connection, their values indicate the
compression algorithm and compression level, respectively.

• To determine which compression algorithms the server is configured to permit for incoming
connections, check the protocol_compression_algorithms system variable.

• For master/slave replication connections, the configured compression algorithms and compression
level are available from multiple sources:

  • The Performance Schema replication_connection_configuration table has
    COMPRESSION_ALGORITHMS and ZSTD_COMPRESSION_LEVEL columns.

  • The mysql.slave_master_info system table has Master_compression_algorithms and
    Master_zstd_compression_level columns. If the master.info file exists, it contains lines
    for those values as well.

4.2.7 Setting Environment Variables

Environment variables can be set at the command prompt to affect the current invocation of your
command processor, or set permanently to affect future invocations. To set a variable permanently,
you can set it in a startup file or by using the interface provided by your system for this purpose.
Consult the documentation for your command interpreter for specific details. Section 4.9, “MySQL
Environment Variables”, lists all environment variables that affect MySQL program operation.

To specify a value for an environment variable, use the syntax appropriate for your command
processor. For example, on Windows, you can set the USER variable to specify your MySQL account
name. To do so, use this syntax:
SET USER=your_name

The syntax on Unix depends on your shell. Suppose that you want to specify the TCP/IP port number using the `MYSQL_TCP_PORT` variable. Typical syntax (such as for `sh`, `ksh`, `bash`, `zsh`, and so on) is as follows:

```
MYSQL_TCP_PORT=3306
export MYSQL_TCP_PORT
```

The first command sets the variable, and the `export` command exports the variable to the shell environment so that its value becomes accessible to MySQL and other processes.

For `csh` and `tcsh`, use `setenv` to make the shell variable available to the environment:

```
setenv MYSQL_TCP_PORT 3306
```

The commands to set environment variables can be executed at your command prompt to take effect immediately, but the settings persist only until you log out. To have the settings take effect each time you log in, use the interface provided by your system or place the appropriate command or commands in a startup file that your command interpreter reads each time it starts.

On Windows, you can set environment variables using the System Control Panel (under Advanced).

On Unix, typical shell startup files are `.bashrc` or `.bash_profile` for `bash`, or `.tcshrc` for `tcsh`.

Suppose that your MySQL programs are installed in `/usr/local/mysql/bin` and that you want to make it easy to invoke these programs. To do this, set the value of the `PATH` environment variable to include that directory. For example, if your shell is `bash`, add the following line to your `.bashrc` file:

```
PATH=${PATH}:/usr/local/mysql/bin
```

`bash` uses different startup files for login and nonlogin shells, so you might want to add the setting to `.bashrc` for login shells and to `.bash_profile` for nonlogin shells to make sure that `PATH` is set regardless.

If your shell is `tcsh`, add the following line to your `.tcshrc` file:

```
setenv PATH ${PATH}:/usr/local/mysql/bin
```

If the appropriate startup file does not exist in your home directory, create it with a text editor.

After modifying your `PATH` setting, open a new console window on Windows or log in again on Unix so that the setting goes into effect.

### 4.3 MySQL Server and Server-Startup Programs

This section describes `mysqld`, the MySQL server, and several programs that are used to start the server.

#### 4.3.1 `mysqld` — The MySQL Server

`mysqld`, also known as MySQL Server, is the main program that does most of the work in a MySQL installation. MySQL Server manages access to the MySQL data directory that contains databases and tables. The data directory is also the default location for other information such as log files and status files.

**Note**

Some installation packages contain a debugging version of the server named `mysqld-debug`. Invoke this version instead of `mysqld` for debugging support.
memory allocation checking, and trace file support (see Section 29.5.1.2, “Creating Trace Files”).

When MySQL server starts, it listens for network connections from client programs and manages access to databases on behalf of those clients.

The `mysqld` program has many options that can be specified at startup. For a complete list of options, run this command:

```
shell> mysqld --verbose --help
```

MySQL Server also has a set of system variables that affect its operation as it runs. System variables can be set at server startup, and many of them can be changed at runtime to effect dynamic server reconfiguration. MySQL Server also has a set of status variables that provide information about its operation. You can monitor these status variables to access runtime performance characteristics.

For a full description of MySQL Server command options, system variables, and status variables, see Section 5.1, “The MySQL Server”. For information about installing MySQL and setting up the initial configuration, see Chapter 2, *Installing and Upgrading MySQL*.

### 4.3.2 `mysqld_safe` — MySQL Server Startup Script

`mysqld_safe` is the recommended way to start a `mysqld` server on Unix. `mysqld_safe` adds some safety features such as restarting the server when an error occurs and logging runtime information to an error log. A description of error logging is given later in this section.

**Note**

For some Linux platforms, MySQL installation from RPM or Debian packages includes systemd support for managing MySQL server startup and shutdown. On these platforms, `mysqld_safe` is not installed because it is unnecessary. For more information, see Section 2.5.9, “Managing MySQL Server with systemd”.

`mysqld_safe` tries to start an executable named `mysqld`. To override the default behavior and specify explicitly the name of the server you want to run, specify a `--mysqld` or `--mysqld-version` option to `mysqld_safe`. You can also use `--ledir` to indicate the directory where `mysqld_safe` should look for the server.

Many of the options to `mysqld_safe` are the same as the options to `mysqld`. See Section 5.1.7, “Server Command Options”.

Options unknown to `mysqld_safe` are passed to `mysqld` if they are specified on the command line, but ignored if they are specified in the `[mysqld_safe]` group of an option file. See Section 4.2.2.2, “Using Option Files”.

`mysqld_safe` reads all options from the `[mysqld]`, `[server]`, and `[mysqld_safe]` sections in option files. For example, if you specify a `[mysqld]` section like this, `mysqld_safe` will find and use the `--log-error` option:

```
[mysqld]
log-error=error.log
```

For backward compatibility, `mysqld_safe` also reads `[safe_mysqld]` sections, but to be current you should rename such sections to `[mysqld_safe]`.

`mysqld_safe` accepts options on the command line and in option files, as described in the following table. For information about option files used by MySQL programs, see Section 4.2.2.2, “Using Option Files”.
### Table 4.6 mysqld_safe Options

<table>
<thead>
<tr>
<th>Option Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>--basedir</td>
<td>Path to MySQL installation directory</td>
</tr>
<tr>
<td>--core-file-size</td>
<td>Size of core file that mysqld should be able to create</td>
</tr>
<tr>
<td>--datadir</td>
<td>Path to data directory</td>
</tr>
<tr>
<td>--defaults-extra-file</td>
<td>Read named option file in addition to usual option files</td>
</tr>
<tr>
<td>--defaults-file</td>
<td>Read only named option file</td>
</tr>
<tr>
<td>--help</td>
<td>Display help message and exit</td>
</tr>
<tr>
<td>--ledir</td>
<td>Path to directory where server is located</td>
</tr>
<tr>
<td>--log-error</td>
<td>Write error log to named file</td>
</tr>
<tr>
<td>--malloc-lib</td>
<td>Alternative malloc library to use for mysqld</td>
</tr>
<tr>
<td>--mysqld</td>
<td>Name of server program to start (in ledir directory)</td>
</tr>
<tr>
<td>--mysqld-safe-log-timestamps</td>
<td>Timestamp format for logging</td>
</tr>
<tr>
<td>--mysqld-version</td>
<td>Suffix for server program name</td>
</tr>
<tr>
<td>--nice</td>
<td>Use nice program to set server scheduling priority</td>
</tr>
<tr>
<td>--no-defaults</td>
<td>Read no option files</td>
</tr>
<tr>
<td>--open-files-limit</td>
<td>Number of files that mysqld should be able to open</td>
</tr>
<tr>
<td>--pid-file</td>
<td>Path name of server process ID file</td>
</tr>
<tr>
<td>--plugin-dir</td>
<td>Directory where plugins are installed</td>
</tr>
<tr>
<td>--port</td>
<td>Port number on which to listen for TCP/IP connections</td>
</tr>
<tr>
<td>--skip-kill-mysqld</td>
<td>Do not try to kill stray mysqld processes</td>
</tr>
<tr>
<td>--skip-syslog</td>
<td>Do not write error messages to syslog; use error log file</td>
</tr>
<tr>
<td>--socket</td>
<td>Socket file on which to listen for Unix socket connections</td>
</tr>
<tr>
<td>--syslog</td>
<td>Write error messages to syslog</td>
</tr>
<tr>
<td>--syslog-tag</td>
<td>Tag suffix for messages written to syslog</td>
</tr>
<tr>
<td>--timezone</td>
<td>Set TZ time zone environment variable to named value</td>
</tr>
<tr>
<td>--user</td>
<td>Run mysqld as user having name user_name or numeric user ID user_id</td>
</tr>
</tbody>
</table>

- **--help**

  Display a help message and exit.

- **--basedir=dir_name**

  The path to the MySQL installation directory.

- **--core-file-size=size**

  The size of the core file that mysqld should be able to create. The option value is passed to `ulimit -c`.

**Note**

The `innodb_buffer_pool_in_core_file` variable can be used to reduce the size of core files on operating systems that support it. For more information, see Section 15.8.3.8, “Excluding Buffer Pool Pages from Core Files”.

- **--datadir=dir_name**
The path to the data directory.

• `--defaults-extra-file=file_name`

Read this option file in addition to the usual option files. If the file does not exist or is otherwise inaccessible, the server will exit with an error. `file_name` is interpreted relative to the current directory if given as a relative path name rather than a full path name. This must be the first option on the command line if it is used.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

• `--defaults-file=file_name`

Use only the given option file. If the file does not exist or is otherwise inaccessible, the server will exit with an error. `file_name` is interpreted relative to the current directory if given as a relative path name rather than a full path name. This must be the first option on the command line if it is used.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

• `--ledir=dir_name`

If `mysqld_safe` cannot find the server, use this option to indicate the path name to the directory where the server is located.

This option is accepted only on the command line, not in option files. On platforms that use systemd, the value can be specified in the value of `MYSQLD_OPTS`. See Section 2.5.9, “Managing MySQL Server with systemd”.

• `--log-error=file_name`

Write the error log to the given file. See Section 5.4.2, “The Error Log”.

• `--mysqld-safe-log-timestamps`

This option controls the format for timestamps in log output produced by `mysqld_safe`. The following list describes the permitted values. For any other value, `mysqld_safe` logs a warning and uses UTC format.

  • UTC, utc

  ISO 8601 UTC format (same as `--log-timestamps=UTC` for the server). This is the default.

  • SYSTEM, system

  ISO 8601 local time format (same as `--log-timestamps=SYSTEM` for the server).

  • HYPHEN, hyphen

  YY-MM-DD h:mm:ss format, as in `mysqld_safe` for MySQL 5.6.

  • LEGACY, legacy

  YYMMDD hh:mm:ss format, as in `mysqld_safe` prior to MySQL 5.6.

• `--malloc-lib=[lib_name]`

The name of the library to use for memory allocation instead of the system `malloc()` library. The option value must be one of the directories `/usr/lib`, `/usr/lib64`, `/usr/lib/i386-linux-gnu`, or `/usr/lib/x86_64-linux-gnu`. 
The `--malloc-lib` option works by modifying the `LD_PRELOAD` environment value to affect dynamic linking to enable the loader to find the memory-allocation library when `mysqld` runs:

- If the option is not given, or is given without a value (`--malloc-lib=`), `LD_PRELOAD` is not modified and no attempt is made to use `tcmalloc`.

- If the option is given as `--malloc-lib=tcmalloc`, `mysqld_safe` looks for a `tcmalloc` library in `/usr/lib`. If `tcmalloc` is found, its path name is added to the beginning of the `LD_PRELOAD` value for `mysqld`. If `tcmalloc` is not found, `mysqld_safe` aborts with an error.

- If the option is given as `--malloc-lib=/path/to/some/library`, that full path is added to the beginning of the `LD_PRELOAD` value. If the full path points to a nonexistent or unreadable file, `mysqld_safe` aborts with an error.

- For cases where `mysqld_safe` adds a path name to `LD_PRELOAD`, it adds the path to the beginning of any existing value the variable already has.

Note

On systems that manage the server using systemd, `mysqld_safe` is not available. Instead, specify the allocation library by setting `LD_PRELOAD` in `/etc/sysconfig/mysql`.

Linux users can use the `libtcmalloc_minimal.so` library on any platform for which a `tcmalloc` package is installed in `/usr/lib` by adding these lines to the `my.cnf` file:

```
[mysqld_safe]
malloc-lib=tcmalloc
```

To use a specific `tcmalloc` library, specify its full path name. Example:

```
[mysqld_safe]
malloc-lib=/opt/lib/libtcmalloc_minimal.so
```

- `--mysqld=prog_name`

The name of the server program (in the `ledir` directory) that you want to start. This option is needed if you use the MySQL binary distribution but have the data directory outside of the binary distribution. If `mysqld_safe` cannot find the server, use the `--ledir` option to indicate the path name to the directory where the server is located.

This option is accepted only on the command line, not in option files. On platforms that use systemd, the value can be specified in the value of `MYSQLD_OPTS`. See Section 2.5.9, “Managing MySQL Server with systemd”.

- `--mysqld-version=suffix`

This option is similar to the `--mysqld` option, but you specify only the suffix for the server program name. The base name is assumed to be `mysqld`. For example, if you use `--mysqld-version=debug`, `mysqld_safe` starts the `mysqld-debug` program in the `ledir` directory. If the argument to `--mysqld-version` is empty, `mysqld_safe` uses `mysqld` in the `ledir` directory.

This option is accepted only on the command line, not in option files. On platforms that use systemd, the value can be specified in the value of `MYSQLD_OPTS`. See Section 2.5.9, “Managing MySQL Server with systemd”.

- `--nice=priority`

Use the `nice` program to set the server’s scheduling priority to the given value.
- **--no-defaults**
  Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read. This must be the first option on the command line if it is used.

  For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- **--open-files-limit=count**
  The number of files that `mysqld` should be able to open. The option value is passed to `ulimit -n`.

  **Note**
  You must start `mysqld_safe` as *root* for this to function properly.

- **--pid-file=file_name**
  The path name that `mysqld` should use for its process ID file.

- **--plugin-dir=dir_name**
  The path name of the plugin directory.

- **--port=port_num**
  The port number that the server should use when listening for TCP/IP connections. The port number must be 1024 or higher unless the server is started by the *root* operating system user.

- **--skip-kill-mysqld**
  Do not try to kill stray `mysqld` processes at startup. This option works only on Linux.

- **--socket=path**
  The Unix socket file that the server should use when listening for local connections.

- **--syslog,** **--skip-syslog**
  `--syslog` causes error messages to be sent to `syslog` on systems that support the `logger` program. `--skip-syslog` suppresses the use of `syslog`; messages are written to an error log file.

  When `syslog` is used for error logging, the `daemon.err` facility/severity is used for all log messages.

  Using these options to control `mysqld` logging is deprecated. To write error log output to the system log, use the instructions at Section 5.4.2.7, “Error Logging to the System Log”. To control the facility, use the server `log_syslog_facility` system variable.

- **--syslog-tag=tag**
  For logging to `syslog`, messages from `mysqld_safe` and `mysqld` are written with identifiers of `mysqld_safe` and `mysqld`, respectively. To specify a suffix for the identifiers, use `--syslog-tag=tag`, which modifies the identifiers to be `mysqld_safe-tag` and `mysqld-tag`.

  Using this option to control `mysqld` logging is deprecated. Use the server `log_syslog_tag` system variable instead. See Section 5.4.2.7, “Error Logging to the System Log”.

- **--timezone=timezone**
  Set the `TZ` time zone environment variable to the given option value. Consult your operating system documentation for legal time zone specification formats.
• **--user={user_name|user_id}**

  Run the **mysqld** server as the user having the name `user_name` or the numeric user ID `user_id`. (“User” in this context refers to a system login account, not a MySQL user listed in the grant tables.)

  If you execute `mysqld_safe` with the `--defaults-file` or `--defaults-extra-file` option to name an option file, the option must be the first one given on the command line or the option file will not be used. For example, this command will not use the named option file:

  ```
  mysql> mysqld_safe --port=port_num --defaults-file=file_name
  ```

  Instead, use the following command:

  ```
  mysql> mysqld_safe --defaults-file=file_name --port=port_num
  ```

  The **mysqld_safe** script is written so that it normally can start a server that was installed from either a source or a binary distribution of MySQL, even though these types of distributions typically install the server in slightly different locations. (See Section 2.1.4, “Installation Layouts”.) `mysqld_safe` expects one of the following conditions to be true:

  • The server and databases can be found relative to the working directory (the directory from which `mysqld_safe` is invoked). For binary distributions, `mysqld_safe` looks under its working directory for `bin` and `data` directories. For source distributions, it looks for `libexec` and `var` directories. This condition should be met if you execute `mysqld_safe` from your MySQL installation directory (for example, `/usr/local/mysql` for a binary distribution).

  • If the server and databases cannot be found relative to the working directory, `mysqld_safe` attempts to locate them by absolute path names. Typical locations are `/usr/local/libexec` and `/usr/local/var`. The actual locations are determined from the values configured into the distribution at the time it was built. They should be correct if MySQL is installed in the location specified at configuration time.

  Because `mysqld_safe` tries to find the server and databases relative to its own working directory, you can install a binary distribution of MySQL anywhere, as long as you run `mysqld_safe` from the MySQL installation directory:

  ```
  shell> cd mysql_installation_directory
  shell> bin/mysqld_safe &
  ```

  If `mysqld_safe` fails, even when invoked from the MySQL installation directory, specify the `--ledir` and `--datadir` options to indicate the directories in which the server and databases are located on your system.

  `mysqld_safe` tries to use the **sleep** and **date** system utilities to determine how many times per second it has attempted to start. If these utilities are present and the attempted starts per second is greater than 5, `mysqld_safe` waits 1 full second before starting again. This is intended to prevent excessive CPU usage in the event of repeated failures. (Bug #11761530, Bug #54035)

  When you use **mysqld_safe** to start **mysqld**, **mysqld_safe** arranges for error (and notice) messages from itself and from **mysqld** to go to the same destination.

  There are several **mysqld_safe** options for controlling the destination of these messages:

  • **--log-error=file_name**: Write error messages to the named error file.

  • **--syslog**: Write error messages to **syslog** on systems that support the **logger** program.

  • **--skip-syslog**: Do not write error messages to **syslog**. Messages are written to the default error log file (`host_name.err` in the data directory), or to a named file if the **--log-error** option is given.
If none of these options is given, the default is \texttt{--skip-syslog}.

When \texttt{mysqld_safe} writes a message, notices go to the logging destination (\texttt{syslog} or the error log file) and \texttt{stdout}. Errors go to the logging destination and \texttt{stderr}.

\begin{itemize}
  \item \textbf{Note} Controlling \texttt{mysqld} logging from \texttt{mysqld_safe} is deprecated. Use the server's native \texttt{syslog} support instead. For more information, see Section 5.4.2.7, "Error Logging to the System Log".
\end{itemize}

4.3.3 \texttt{mysql.server} — MySQL Server Startup Script

MySQL distributions on Unix and Unix-like system include a script named \texttt{mysql.server}, which starts the MySQL server using \texttt{mysqld_safe}. It can be used on systems such as Linux and Solaris that use System V-style run directories to start and stop system services. It is also used by the macOS Startup Item for MySQL.

\texttt{mysql.server} is the script name as used within the MySQL source tree. The installed name might be different (for example, \texttt{mysqld} or \texttt{mysql}). In the following discussion, adjust the name \texttt{mysql.server} as appropriate for your system.

\begin{itemize}
  \item \textbf{Note} For some Linux platforms, MySQL installation from RPM or Debian packages includes systemd support for managing MySQL server startup and shutdown. On these platforms, \texttt{mysql.server} and \texttt{mysqld_safe} are not installed because they are unnecessary. For more information, see Section 2.5.9, "Managing MySQL Server with systemd".
\end{itemize}

To start or stop the server manually using the \texttt{mysql.server} script, invoke it from the command line with \texttt{start} or \texttt{stop} arguments:

\begin{verbatim}
shell> mysql.server start
shell> mysql.server stop
\end{verbatim}

\texttt{mysql.server} changes location to the MySQL installation directory, then invokes \texttt{mysqld_safe}. To run the server as some specific user, add an appropriate \texttt{user} option to the \texttt{[mysqld]} group of the global \texttt{/etc/my.cnf} option file, as shown later in this section. (It is possible that you must edit \texttt{mysql.server} if you've installed a binary distribution of MySQL in a nonstandard location. Modify it to change location into the proper directory before it runs \texttt{mysqld_safe}. If you do this, your modified version of \texttt{mysql.server} may be overwritten if you upgrade MySQL in the future; make a copy of your edited version that you can reinstall.)

\texttt{mysql.server stop} stops the server by sending a signal to it. You can also stop the server manually by executing \texttt{mysqladmin shutdown}.

To start and stop MySQL automatically on your server, you must add start and stop commands to the appropriate places in your \texttt{/etc/rc*} files:

\begin{itemize}
  \item If you use the Linux server RPM package (\texttt{MySQL-server-VERSION.rpm}), or a native Linux package installation, the \texttt{mysql.server} script may be installed in the \texttt{/etc/init.d} directory with the name \texttt{mysqld} or \texttt{mysql}. See Section 2.5.4, "Installing MySQL on Linux Using RPM Packages from Oracle", for more information on the Linux RPM packages.

  \item If you install MySQL from a source distribution or using a binary distribution format that does not install \texttt{mysql.server} automatically, you can install the script manually. It can be found in the \texttt{support-files} directory under the MySQL installation directory or in a MySQL source tree. Copy the script to the \texttt{/etc/init.d} directory with the name \texttt{mysql} and make it executable:
\end{itemize}
After installing the script, the commands needed to activate it to run at system startup depend on your operating system. On Linux, you can use `chkconfig`:

```
shell> chkconfig --add mysql
```

On some Linux systems, the following command also seems to be necessary to fully enable the `mysql` script:

```
shell> chkconfig --level 3 4 5 mysql on
```

- On FreeBSD, startup scripts generally should go in `/usr/local/etc/rc.d/`. Install the `mysql.server` script as `/usr/local/etc/rc.d/mysql.server.sh` to enable automatic startup. The `rc(8)` manual page states that scripts in this directory are executed only if their base name matches the `*.sh` shell file name pattern. Any other files or directories present within the directory are silently ignored.

- As an alternative to the preceding setup, some operating systems also use `/etc/rc.local` or `/etc/init.d/boot.local` to start additional services on startup. To start up MySQL using this method, append a command like the one following to the appropriate startup file:

```
/bin/sh -c 'cd /usr/local/mysql; ./bin/mysqld_safe --user=mysql &'
```

- For other systems, consult your operating system documentation to see how to install startup scripts.

`mysql.server` reads options from the `[mysql.server]` and `[mysqld]` sections of option files. For backward compatibility, it also reads `[mysql_server]` sections, but to be current you should rename such sections to `[mysql.server]`.

You can add options for `mysql.server` in a global `/etc/my.cnf` file. A typical `my.cnf` file might look like this:

```ini
[mysqld]
datadir=/usr/local/mysql/var
socket=/var/tmp/mysql.sock
port=3306
user=mysql

[mysql.server]
basedir=/usr/local/mysql
```

The `mysql.server` script supports the options shown in the following table. If specified, they must be placed in an option file, not on the command line. `mysql.server` supports only `start` and `stop` as command-line arguments.

### Table 4.7 mysql.server Option-File Options

<table>
<thead>
<tr>
<th>Option Name</th>
<th>Description</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>basedir</td>
<td>Path to MySQL installation directory</td>
<td>Directory name</td>
</tr>
<tr>
<td>datadir</td>
<td>Path to MySQL data directory</td>
<td>Directory name</td>
</tr>
<tr>
<td>pid-file</td>
<td>File in which server should write its process ID</td>
<td>File name</td>
</tr>
</tbody>
</table>
### mysqld_multi — Manage Multiple MySQL Servers

**Option Name** | **Description** | **Type**
---|---|---
`service-startup-timeout` | How long to wait for server startup | Integer

- **basedir=dir_name**
  The path to the MySQL installation directory.

- **datadir=dir_name**
  The path to the MySQL data directory.

- **pid-file=file_name**
  The path name of the file in which the server should write its process ID. The server creates the file in the data directory unless an absolute path name is given to specify a different directory.

  If this option is not given, `mysql.server` uses a default value of `host_name.pid`. The PID file value passed to `mysqld_safe` overrides any value specified in the `[mysqld_safe]` option file group. Because `mysql.server` reads the `[mysql]` option file group but not the `[mysqld_safe]` group, you can ensure that `mysqld_safe` gets the same value when invoked from `mysql.server` as when invoked manually by putting the same `pid-file` setting in both the `[mysqld_safe]` and `[mysqld]` groups.

- **service-startup-timeout=seconds**
  How long in seconds to wait for confirmation of server startup. If the server does not start within this time, `mysql.server` exits with an error. The default value is 900. A value of 0 means not to wait at all for startup. Negative values mean to wait forever (no timeout).

#### 4.3.4 mysqld_multi — Manage Multiple MySQL Servers

`mysqld_multi` is designed to manage several `mysqld` processes that listen for connections on different Unix socket files and TCP/IP ports. It can start or stop servers, or report their current status.

**Note**

For some Linux platforms, MySQL installation from RPM or Debian packages includes systemd support for managing MySQL server startup and shutdown. On these platforms, `mysqld_multi` is not installed because it is unnecessary. For information about using systemd to handle multiple MySQL instances, see Section 2.5.9, “Managing MySQL Server with systemd”.

`mysqld_multi` searches for groups named `[mysqldN]` in `my.cnf` (or in the file named by the `--defaults-file` option). `N` can be any positive integer. This number is referred to in the following discussion as the option group number, or `GNR`. Group numbers distinguish option groups from one another and are used as arguments to `mysqld_multi` to specify which servers you want to start, stop, or obtain a status report for. Options listed in these groups are the same that you would use in the `[mysql]` group used for starting `mysqld`. (See, for example, Section 2.10.5, “Starting and Stopping MySQL Automatically”.) However, when using multiple servers, it is necessary that each one use its own value for options such as the Unix socket file and TCP/IP port number. For more information on which options must be unique per server in a multiple-server environment, see Section 5.8, “Running Multiple MySQL Instances on One Machine”.

To invoke `mysqld_multi`, use the following syntax:

```shell
shell> mysqld_multi [options] {start|stop|reload|report} [GNR[,GNR] ...]
```

`start`, `stop`, `reload` (stop and restart), and `report` indicate which operation to perform. You can perform the designated operation for a single server or multiple servers, depending on the `GNR` list that
follows the option name. If there is no list, `mysqld_multi` performs the operation for all servers in the option file.

Each **GNR** value represents an option group number or range of group numbers. The value should be the number at the end of the group name in the option file. For example, the **GNR** for a group named `[mysqld17]` is 17. To specify a range of numbers, separate the first and last numbers by a dash. The **GNR** value 10–13 represents groups `[mysqld10]` through `[mysqld13]`. Multiple groups or group ranges can be specified on the command line, separated by commas. There must be no whitespace characters (spaces or tabs) in the **GNR** list; anything after a whitespace character is ignored.

This command starts a single server using option group `[mysqld17]`:

```
shell> mysqld_multi start 17
```

This command stops several servers, using option groups `[mysqld8]` and `[mysqld10]` through `[mysqld13]`:

```
shell> mysqld_multi stop 8,10-13
```

For an example of how you might set up an option file, use this command:

```
shell> mysqld_multi --example
```

`mysqld_multi` searches for option files as follows:

- With **--no-defaults**, no option files are read.
- With **--defaults-file=file_name**, only the named file is read.
- Otherwise, option files in the standard list of locations are read, including any file named by the **--defaults-extra-file=file_name** option, if one is given. (If the option is given multiple times, the last value is used.)

For additional information about these and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

Option files read are searched for `[mysqld_multi]` and `[mysqldN]` option groups. The `[mysqld_multi]` group can be used for options to `mysqld_multi` itself. `[mysqldN]` groups can be used for options passed to specific `mysqld` instances.

The `[mysql]` or `[mysqld_safe]` groups can be used for common options read by all instances of `mysql` or `mysqld_safe`. You can specify a **--defaults-file=file_name** option to use a different configuration file for that instance, in which case the `[mysql]` or `[mysqld_safe]` groups from that file will be used for that instance.

`mysqld_multi` supports the following options:

- **--help**
  
  Display a help message and exit.

- **--example**
  
  Display a sample option file.

- **--log=file_name**
  
  Specify the name of the log file. If the file exists, log output is appended to it.
mysqld_multi — Manage Multiple MySQL Servers

• --mysqladmin=prog_name

The mysqladmin binary to be used to stop servers.

• --mysqld=prog_name

The mysqld binary to be used. Note that you can specify mysqld_safe as the value for this option also. If you use mysqld_safe to start the server, you can include the mysqld or ledir options in the corresponding [mysqldN] option group. These options indicate the name of the server that mysqld_safe should start and the path name of the directory where the server is located. (See the descriptions for these options in Section 4.3.2, "mysqld_safe — MySQL Server Startup Script"). Example:

[mysqld38]
mysqld = mysqld-debug
ledir = /opt/local/mysql/libexec

• --no-log

Print log information to stdout rather than to the log file. By default, output goes to the log file.

• --password=password

The password of the MySQL account to use when invoking mysqladmin. Note that the password value is not optional for this option, unlike for other MySQL programs.

• --silent

Silent mode; disable warnings.

• --tcp-ip

Connect to each MySQL server through the TCP/IP port instead of the Unix socket file. (If a socket file is missing, the server might still be running, but accessible only through the TCP/IP port.) By default, connections are made using the Unix socket file. This option affects stop and report operations.

• --user=user_name

The user name of the MySQL account to use when invoking mysqladmin.

• --verbose

Be more verbose.

• --version

Display version information and exit.

Some notes about mysqld_multi:

• Most important: Before using mysqld_multi be sure that you understand the meanings of the options that are passed to the mysqld servers and why you would want to have separate mysqld processes. Beware of the dangers of using multiple mysqld servers with the same data directory. Use separate data directories, unless you know what you are doing. Starting multiple servers with the same data directory does not give you extra performance in a threaded system. See Section 5.8, “Running Multiple MySQL Instances on One Machine”.

Important

Make sure that the data directory for each server is fully accessible to the Unix account that the specific mysqld process is started as. Do not use
the Unix root account for this, unless you know what you are doing. See Section 6.1.5, “How to Run MySQL as a Normal User”.

- Make sure that the MySQL account used for stopping the mysql servers (with the mysqladmin program) has the same user name and password for each server. Also, make sure that the account has the SHUTDOWN privilege. If the servers that you want to manage have different user names or passwords for the administrative accounts, you might want to create an account on each server that has the same user name and password. For example, you might set up a common multi_admin account by executing the following commands for each server:

```
shell> mysql -u root -S /tmp/mysql.sock -p
Enter password:
mysql> CREATE USER 'multi_admin'@'localhost' IDENTIFIED BY 'multipass';
mysql> GRANT SHUTDOWN ON *.* TO 'multi_admin'@'localhost';
```

See Section 6.2, “Access Control and Account Management”. You have to do this for each mysql server. Change the connection parameters appropriately when connecting to each one. Note that the host name part of the account name must permit you to connect as multi_admin from the host where you want to run mysql_multi.

- The Unix socket file and the TCP/IP port number must be different for every mysql. (Alternatively, if the host has multiple network addresses, you can set the bind_address system variable to cause different servers to listen to different interfaces.)

- The --pid-file option is very important if you are using mysql_safe to start mysql (for example, --mysqld=mysqld_safe) Every mysql should have its own process ID file. The advantage of using mysql_safe instead of mysql is that mysql_safe monitors its mysql process and restarts it if the process terminates due to a signal sent using kill -9 or for other reasons, such as a segmentation fault.

- You might want to use the --user option for mysql, but to do this you need to run the mysql_multi script as the Unix superuser (root). Having the option in the option file doesn't matter; you just get a warning if you are not the superuser and the mysql processes are started under your own Unix account.

The following example shows how you might set up an option file for use with mysql_multi. The order in which the mysql programs are started or stopped depends on the order in which they appear in the option file. Group numbers need not form an unbroken sequence. The first and fifth [mysqld] groups were intentionally omitted from the example to illustrate that you can have “gaps” in the option file. This gives you more flexibility.

```
# This is an example of a my.cnf file for mysql_multi.
# Usually this file is located in home dir ~/.my.cnf or /etc/my.cnf

[mysqld_multi]
mysqld = /usr/local/mysql/bin/mysqld_safe
mysqladmin = /usr/local/mysql/bin/mysqladmin
user = multi_admin
password = my_password

[mysqld2]
socket = /tmp/mysql.sock2
port = 3307
pid-file = /usr/local/mysql/data2/hostname.pid2
datadir = /usr/local/mysql/data2
language = /usr/local/mysql/share/mysql/english
user = unix_user1

[mysqld3]
mysqld = /path/to/mysqld_safe
ledir = /path/to/mysqld-binary/
mysqladmin = /path/to/mysqladmin
socket = /tmp/mysql.sock3
```
4.4 MySQL Installation-Related Programs

The programs in this section are used when installing or upgrading MySQL.

4.4.1 **comp_err** — Compile MySQL Error Message File

`comp_err` creates the `errmsg.sys` file that is used by `mysqld` to determine the error messages to display for different error codes. `comp_err` normally is run automatically when MySQL is built. It compiles the `errmsg.sys` file from the text file located at `sql/share/errmsg-utf8.txt` in MySQL source distributions.

`comp_err` also generates `mysqld_error.h`, `mysqld_ename.h`, and `sql_state.h` header files.

For more information about how error messages are defined, see the MySQL Internals Manual.

Invoke `comp_err` like this:

```
shell> comp_err [options]
```

`comp_err` supports the following options.

- **--help, -?**
  
  Display a help message and exit.

- **--charset=dir_name, -C dir_name**
  
  The character set directory. The default is `../sql/share/charsets`.

- **--debug=debug_options, -# debug_options**
  
  Write a debugging log. A typical `debug_options` string is `d:t,O,file_name`. The default is `d:t:0,/tmp/comp_err.trace`.

- **--debug-info, -T**
  
  Print some debugging information when the program exits.

- **--header_file=file_name, -H file_name**
  
  Invokes `comp_err` with options that are currently set in the specified header file.
The name of the error header file. The default is mysqld_error.h.

- --in_file=file_name, -F file_name
  The name of the input file. The default is ../sql/share/errmsg-utf8.txt.

- --name_file=file_name, -N file_name
  The name of the error name file. The default is mysqld_ername.h.

- --out_dir=dir_name, -D dir_name
  The name of the output base directory. The default is ../sql/share/.

- --out_file=file_name, -O file_name
  The name of the output file. The default is errmsg.sys.

- --statefile=file_name, -S file_name
  The name for the SQLSTATE header file. The default is sql_state.h.

- --version, -V
  Display version information and exit.

4.4.2 mysql_secure_installation — Improve MySQL Installation Security

This program enables you to improve the security of your MySQL installation in the following ways:

- You can set a password for root accounts.
- You can remove root accounts that are accessible from outside the local host.
- You can remove anonymous-user accounts.
- You can remove the test database (which by default can be accessed by all users, even anonymous users), and privileges that permit anyone to access databases with names that start with test._

mysql_secure_installation helps you implement security recommendations similar to those described at Section 2.10.4, “Securing the Initial MySQL Account”.

Normal usage is to connect to the local MySQL server; invoke mysql_secure_installation without arguments:

shell> mysql_secure_installation

When executed, mysql_secure_installation prompts you to determine which actions to perform.

The validate_password component can be used for password strength checking. If the plugin is not installed, mysql_secure_installation prompts the user whether to install it. Any passwords entered later are checked using the plugin if it is enabled.

Most of the usual MySQL client options such as --host and --port can be used on the command line and in option files. For example, to connect to the local server over IPv6 using port 3307, use this command:
mysql_secure_installation supports the following options, which can be specified on the command line or in the [mysql_secure_installation] and [client] groups of an option file. For information about option files used by MySQL programs, see Section 4.2.2.2, “Using Option Files”.

Table 4.8 mysql_secure_installation Options

<table>
<thead>
<tr>
<th>Option Name</th>
<th>Description</th>
<th>Introduced</th>
</tr>
</thead>
<tbody>
<tr>
<td>--defaults-extra-file</td>
<td>Read named option file in addition to usual option files</td>
<td></td>
</tr>
<tr>
<td>--defaults-file</td>
<td>Read only named option file</td>
<td></td>
</tr>
<tr>
<td>--defaults-group-suffix</td>
<td>Option group suffix value</td>
<td></td>
</tr>
<tr>
<td>--help</td>
<td>Display help message and exit</td>
<td></td>
</tr>
<tr>
<td>--host</td>
<td>Host on which MySQL server is located</td>
<td></td>
</tr>
<tr>
<td>--no-defaults</td>
<td>Read no option files</td>
<td></td>
</tr>
<tr>
<td>--password</td>
<td>Accepted but always ignored. Whenever mysql_secure_installation is invoked, the user is prompted for a password, regardless.</td>
<td></td>
</tr>
<tr>
<td>--port</td>
<td>TCP/IP port number for connection</td>
<td></td>
</tr>
<tr>
<td>--print-defaults</td>
<td>Print default options</td>
<td></td>
</tr>
<tr>
<td>--protocol</td>
<td>Connection protocol to use</td>
<td></td>
</tr>
<tr>
<td>--socket</td>
<td>Unix socket file or Windows named pipe to use</td>
<td></td>
</tr>
<tr>
<td>--ssl-ca</td>
<td>File that contains list of trusted SSL Certificate Authorities</td>
<td></td>
</tr>
<tr>
<td>--ssl-capath</td>
<td>Directory that contains trusted SSL Certificate Authority certificate files</td>
<td></td>
</tr>
<tr>
<td>--ssl-cert</td>
<td>File that contains X.509 certificate</td>
<td></td>
</tr>
<tr>
<td>--ssl-cipher</td>
<td>Permissible ciphers for connection encryption</td>
<td></td>
</tr>
<tr>
<td>--ssl-crl</td>
<td>File that contains certificate revocation lists</td>
<td></td>
</tr>
<tr>
<td>--ssl-crlpath</td>
<td>Directory that contains certificate revocation-list files</td>
<td></td>
</tr>
<tr>
<td>--ssl-fips-mode</td>
<td>Whether to enable FIPS mode on client side</td>
<td>8.0.11</td>
</tr>
<tr>
<td>--ssl-key</td>
<td>File that contains X.509 key</td>
<td></td>
</tr>
<tr>
<td>--tls-ciphersuites</td>
<td>Permissible TLSv1.3 ciphersuites for encrypted connections</td>
<td>8.0.16</td>
</tr>
<tr>
<td>--tls-version</td>
<td>Permissible TLS protocols for encrypted connections</td>
<td></td>
</tr>
<tr>
<td>--use-default</td>
<td>Execute with no user interactivity</td>
<td></td>
</tr>
<tr>
<td>--user</td>
<td>MySQL user name to use when connecting to server</td>
<td></td>
</tr>
</tbody>
</table>

- **--help, -?**
  
  Display a help message and exit.

- **--defaults-extra-file=file_name**
  
  Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. *file_name* is interpreted relative to the current directory if given as a relative path name rather than a full path name.

  For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- **--defaults-file=file_name**
Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. 

`file_name` is interpreted relative to the current directory if given as a relative path name rather than a full path name.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- `--defaults-group-suffix=string`

Read not only the usual option groups, but also groups with the usual names and a suffix of `string`. For example, `mysql_secure_installation` normally reads the `[client]` and `[mysql_secure_installation]` groups. If the `--defaults-group-suffix=_other` option is given, `mysql_secure_installation` also reads the `[client_other]` and `[mysql_secure_installation_other]` groups.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- `--host=host_name, -h host_name`

Connect to the MySQL server on the given host.

- `--no-defaults`

Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

The exception is that the `.mylogin.cnf` file, if it exists, is read in all cases. This permits passwords to be specified in a safer way than on the command line even when `--no-defaults` is used. (`.mylogin.cnf` is created by the `mysql_config_editor` utility. See Section 4.6.7, “mysql_config_editor — MySQL Configuration Utility”.)

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- `--password=password, -p password`

This option is accepted but ignored. Whether or not this option is used, `mysql_secure_installation` always prompts the user for a password.

- `--port=port_num, -P port_num`

For TCP/IP connections, the port number to use.

- `--print-defaults`

Print the program name and all options that it gets from option files.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- `--protocol={TCP|SOCKET|PIPE|MEMORY}`

The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally result in use of a protocol other than the one you want. For details on the permissible values, see Section 4.2.4, “Connecting to the MySQL Server Using Command Options”.

- `--socket=path, -S path`

For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.
On Windows, this option applies only if the server was started with the `named_pipe` system variable enabled to support named-pipe connections. In addition, the the connection must be a member of the Windows group specified by the `named_pipe_full_access_group` system variable.

- `--ssl*`

Options that begin with `--ssl` specify whether to connect to the server using SSL and indicate where to find SSL keys and certificates. See Command Options for Encrypted Connections.

- `--ssl-fips-mode={OFF|ON|STRICT}`

Controls whether to enable FIPS mode on the client side. The `--ssl-fips-mode` option differs from other `--ssl-xxx` options in that it is not used to establish encrypted connections, but rather to affect which cryptographic operations are permitted. See Section 6.5, "FIPS Support".

These `--ssl-fips-mode` values are permitted:

- **OFF**: Disable FIPS mode.
- **ON**: Enable FIPS mode.
- **STRICT**: Enable “strict” FIPS mode.

Note

If the OpenSSL FIPS Object Module is not available, the only permitted value for `--ssl-fips-mode` is `OFF`. In this case, setting `--ssl-fips-mode` to `ON` or `STRICT` causes the client to produce a warning at startup and to operate in non-FIPS mode.

- `--tls-ciphersuites=ciphersuite_list`

For client programs, specifies which TLSv1.3 ciphersuites the client permits for encrypted connections. The value is a list of one or more colon-separated ciphersuite names. The ciphersuites that can be named for this option depend on the SSL library used to compile MySQL. For details, see Section 6.3.5, "Encrypted Connection Protocols and Ciphers".

This option was added in MySQL 8.0.16.

- `--tls-version=protocol_list`

The permissible TLS protocols for encrypted connections. The value is a list of one or more comma-separated protocol names. The protocols that can be named for this option depend on the SSL library used to compile MySQL. For details, see Section 6.3.5, "Encrypted Connection Protocols and Ciphers".

- `--use-default`

Execute noninteractively. This option can be used for unattended installation operations.

  - `--user=user_name, -u user_name`

The user name of the MySQL account to use for connecting to the server.

### 4.4.3 mysql_ssl_rsa_setup — Create SSL/RSA Files

This program creates the SSL certificate and key files and RSA key-pair files required to support secure connections using SSL and secure password exchange using RSA over unencrypted connections, if those files are missing. `mysql_ssl_rsa_setup` can also be used to create new SSL files if the existing ones have expired.
mysql_ssl_rsa_setup — Create SSL/RSA Files

**Note**

mysql_ssl_rsa_setup uses the openssl command, so its use is contingent on having OpenSSL installed on your machine.

Another way to generate SSL and RSA files, for MySQL distributions compiled using OpenSSL, is to have the server generate them automatically. See Section 6.3.2.1, “Creating SSL and RSA Certificates and Keys using MySQL”.

**Important**

mysql_ssl_rsa_setup helps lower the barrier to using SSL by making it easier to generate the required files. However, certificates generated by mysql_ssl_rsa_setup are self-signed, which is not very secure. After you gain experience using the files created by mysql_ssl_rsa_setup, consider obtaining a CA certificate from a registered certificate authority.

Invoke `mysql_ssl_rsa_setup` like this:

```
shell> mysql_ssl_rsa_setup [options]
```

Typical options are `--datadir` to specify where to create the files, and `--verbose` to see the openssl commands that `mysql_ssl_rsa_setup` executes.

mysql_ssl_rsa_setup attempts to create SSL and RSA files using a default set of file names. It works as follows:

1. `mysql_ssl_rsa_setup` checks for the openssl binary at the locations specified by the `PATH` environment variable. If openssl is not found, `mysql_ssl_rsa_setup` does nothing. If openssl is present, `mysql_ssl_rsa_setup` looks for default SSL and RSA files in the MySQL data directory specified by the `--datadir` option, or the compiled-in data directory if the `--datadir` option is not given.

2. `mysql_ssl_rsa_setup` checks the data directory for SSL files with the following names:
   
   ```
   ca.pem
   server-cert.pem
   server-key.pem
   ```

3. If any of those files are present, `mysql_ssl_rsa_setup` creates no SSL files. Otherwise, it invokes openssl to create them, plus some additional files:
   
   ```
   ca.pem               Self-signed CA certificate
   ca-key.pem           CA private key
   server-cert.pem      Server certificate
   server-key.pem       Server private key
   client-cert.pem      Client certificate
   client-key.pem       Client private key
   ```

   These files enable secure client connections using SSL; see Section 6.3.1, “Configuring MySQL to Use Encrypted Connections”.

4. `mysql_ssl_rsa_setup` checks the data directory for RSA files with the following names:
   
   ```
   private_key.pem       Private member of private/public key pair
   public_key.pem        Public member of private/public key pair
   ```

5. If any of these files are present, `mysql_ssl_rsa_setup` creates no RSA files. Otherwise, it invokes openssl to create them. These files enable secure password exchange using RSA over unencrypted connections for accounts authenticated by the `sha256_password` or
caching_sha2_password plugin; see Section 6.4.1.2, “SHA-256 Pluggable Authentication”, and Section 6.4.1.3, “Caching SHA-2 Pluggable Authentication”.

For information about the characteristics of files created by `mysql_ssl_rsa_setup`, see Section 6.3.2.1, “Creating SSL and RSA Certificates and Keys using MySQL”.

At startup, the MySQL server automatically uses the SSL files created by `mysql_ssl_rsa_setup` to enable SSL if no explicit SSL options are given other than `--ssl` (possibly along with `--ssl-cipher`). If you prefer to designate the files explicitly, invoke clients with the `--ssl-ca`, `--ssl-cert`, and `--ssl-key` options at startup to name the `ca.pem`, `server-cert.pem`, and `server-key.pem` files, respectively.

The server also automatically uses the RSA files created by `mysql_ssl_rsa_setup` to enable RSA if no explicit RSA options are given.

If the server is SSL-enabled, clients use SSL by default for the connection. To specify certificate and key files explicitly, use the `--ssl-ca`, `--ssl-cert`, and `--ssl-key` options to name the `ca.pem`, `client-cert.pem`, and `client-key.pem` files, respectively. However, some additional client setup may be required first because `mysql_ssl_rsa_setup` by default creates those files in the data directory. The permissions for the data directory normally enable access only to the system account that runs the MySQL server, so client programs cannot use files located there. To make the files available, copy them to a directory that is readable (but not writable) by clients:

- For local clients, the MySQL installation directory can be used. For example, if the data directory is a subdirectory of the installation directory and your current location is the data directory, you can copy the files like this:

```bash
cp ca.pem client-cert.pem client-key.pem ..
```

- For remote clients, distribute the files using a secure channel to ensure they are not tampered with during transit.

If the SSL files used for a MySQL installation have expired, you can use `mysql_ssl_rsa_setup` to create new ones:

1. Stop the server.
2. Rename or remove the existing SSL files. You may wish to make a backup of them first. (The RSA files do not expire, so you need not remove them. `mysql_ssl_rsa_setup` will see that they exist and not overwrite them.)
3. Run `mysql_ssl_rsa_setup` with the `--datadir` option to specify where to create the new files.
4. Restart the server.

`mysql_ssl_rsa_setup` supports the following command-line options, which can be specified on the command line or in the `[mysql_ssl_rsa_setup]` and `[mysqld]` groups of an option file. For information about option files used by MySQL programs, see Section 4.2.2.2, “Using Option Files”.

<table>
<thead>
<tr>
<th>Option Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--datadir</code></td>
<td>Path to data directory</td>
</tr>
<tr>
<td><code>--help</code></td>
<td>Display help message and exit</td>
</tr>
<tr>
<td><code>--suffix</code></td>
<td>Suffix for X.509 certificate Common Name attribute</td>
</tr>
<tr>
<td><code>--uid</code></td>
<td>Name of effective user to use for file permissions</td>
</tr>
<tr>
<td><code>--verbose</code></td>
<td>Verbose mode</td>
</tr>
<tr>
<td><code>--version</code></td>
<td>Display version information and exit</td>
</tr>
</tbody>
</table>

- `--help`, ?
Display a help message and exit.

- **--datadir=dir_name**
  The path to the directory that `mysql_ssl_rsa_setup` should check for default SSL and RSA files and in which it should create files if they are missing. The default is the compiled-in data directory.

- **--suffix=str**
  The suffix for the Common Name attribute in X.509 certificates. The suffix value is limited to 17 characters. The default is based on the MySQL version number.

- **--uid=name, -v**
  The name of the user who should be the owner of any created files. The value is a user name, not a numeric user ID. In the absence of this option, files created by `mysql_ssl_rsa_setup` are owned by the user who executes it. This option is valid only if you execute the program as `root` on a system that supports the `chown()` system call.

- **--verbose, -v**
  Verbose mode. Produce more output about what the program does. For example, the program shows the `openssl` commands it runs, and produces output to indicate whether it skips SSL or RSA file creation because some default file already exists.

- **--version, -V**
  Display version information and exit.

### 4.4.4 `mysql_tzinfo_to_sql` — Load the Time Zone Tables

The `mysql_tzinfo_to_sql` program loads the time zone tables in the `mysql` database. It is used on systems that have a `zoneinfo` database (the set of files describing time zones). Examples of such systems are Linux, FreeBSD, Solaris, and OS X. One likely location for these files is the `/usr/share/zoneinfo` directory (`/usr/share/lib/zoneinfo` on Solaris). If your system does not have a `zoneinfo` database, you can use the downloadable package described in Section 5.1.13, “MySQL Server Time Zone Support”.

`mysql_tzinfo_to_sql` can be invoked several ways:

```bash
shell> mysql_tzinfo_to_sql tz_dir
shell> mysql_tzinfo_to_sql tz_file tz_name
shell> mysql_tzinfo_to_sql --leap tz_file
```

For the first invocation syntax, pass the zoneinfo directory path name to `mysql_tzinfo_to_sql` and send the output into the `mysql` program. For example:

```bash
shell> mysql_tzinfo_to_sql /usr/share/zoneinfo | mysql -u root mysql
```

`mysql_tzinfo_to_sql` reads your system’s time zone files and generates SQL statements from them. `mysql` processes those statements to load the time zone tables.

The second syntax causes `mysql_tzinfo_to_sql` to load a single time zone file `tz_file` that corresponds to a time zone name `tz_name`:

```bash
shell> mysql_tzinfo_to_sql tz_file tz_name | mysql -u root mysql
```

If your time zone needs to account for leap seconds, invoke `mysql_tzinfo_to_sql` using the third syntax, which initializes the leap second information. `tz_file` is the name of your time zone file:
After running `mysql_tzinfo_to_sql`, it is best to restart the server so that it does not continue to use any previously cached time zone data.

**Note**
As of MySQL 8.0.16, the MySQL server performs the upgrade tasks previously handled by `mysql_upgrade` (for details, see Section 2.11.3, “What the MySQL Upgrade Process Upgrades”). Consequently, `mysql_upgrade` is unneeded and is deprecated as of that version, and will be removed in a future MySQL version. Because `mysql_upgrade` no longer performs upgrade tasks, it exits with status 0 unconditionally.

Each time you upgrade MySQL, you should execute `mysql_upgrade`, which looks for incompatibilities with the upgraded MySQL server:

- It upgrades the system tables in the `mysql` schema so that you can take advantage of new privileges or capabilities that might have been added.
- It upgrades the Performance Schema, `INFORMATION_SCHEMA`, and `sys` schema.
- It examines user schemas.

If `mysql_upgrade` finds that a table has a possible incompatibility, it performs a table check and, if problems are found, attempts a table repair. If the table cannot be repaired, see Section 2.11.13, “Rebuilding or Repairing Tables or Indexes” for manual table repair strategies.

`mysql_upgrade` communicates directly with the MySQL server, sending it the SQL statements required to perform an upgrade.

**Caution**
You should always back up your current MySQL installation before performing an upgrade. See Section 7.2, “Database Backup Methods”.

Some upgrade incompatibilities may require special handling before upgrading your MySQL installation and running `mysql_upgrade`. See Section 2.11, “Upgrading MySQL”, for instructions on determining whether any such incompatibilities apply to your installation and how to handle them.

Use `mysql_upgrade` like this:

1. Ensure that the server is running.

2. Invoke `mysql_upgrade` to upgrade the system tables in the `mysql` schema and check and repair tables in other schemas:

   ```shell> mysql_upgrade [options]```

3. Stop the server and restart it so that any system table changes take effect.

If you have multiple MySQL server instances to upgrade, invoke `mysql_upgrade` with connection parameters appropriate for connecting to each of the desired servers. For example, with servers running on the local host on parts 3306 through 3308, upgrade each of them by connecting to the appropriate port:

```shell> mysql_upgrade --protocol=tcp -P 3306 [other_options]
shell> mysql_upgrade --protocol=tcp -P 3307 [other_options]
shell> mysql_upgrade --protocol=tcp -P 3308 [other_options]```
mysql_upgrade — Check and Upgrade MySQL Tables

For local host connections on Unix, the --protocol=tcp option forces a connection using TCP/IP rather than the Unix socket file.

By default, mysql_upgrade runs as the MySQL root user. If the root password is expired when you run mysql_upgrade, you will see a message that your password is expired and that mysql_upgrade failed as a result. To correct this, reset the root password to unexpire it and run mysql_upgrade again. First, connect to the server as root:

```
shell> mysql -u root -p
Enter password: ****
```

Reset the password using ALTER USER:

```
mysql> ALTER USER USER() IDENTIFIED BY 'root-password';
```

Then exit mysql and run mysql_upgrade again:

```
shell> mysql_upgrade [options]
```

Note

If you run the server with the disabled_storage_engines system variable set to disable certain storage engines (for example, MyISAM), mysql_upgrade might fail with an error like this:

```
mysql_upgrade: [ERROR] 3161: Storage engine MyISAM is disabled (Table creation is disallowed).
```

To handle this, restart the server with disabled_storage_engines disabled. Then you should be able to run mysql_upgrade successfully. After that, restart the server with disabled_storage_engines set to its original value.

Unless invoked with the --upgrade-system-tables option, mysql_upgrade processes all tables in all user schemas as necessary. Table checking might take a long time to complete. Each table is locked and therefore unavailable to other sessions while it is being processed. Check and repair operations can be time-consuming, particularly for large tables. Table checking uses the FOR_UPGRADE option of the CHECK TABLE statement. For details about what this option entails, see Section 13.7.3.2, “CHECK TABLE Syntax”.

mysql_upgrade marks all checked and repaired tables with the current MySQL version number. This ensures that the next time you run mysql_upgrade with the same version of the server, it can be determined whether there is any need to check or repair a given table again.

mysql_upgrade saves the MySQL version number in a file named mysql_upgrade_info in the data directory. This is used to quickly check whether all tables have been checked for this release so that table-checking can be skipped. To ignore this file and perform the check regardless, use the --force option.

Note

The mysql_upgrade_info file is deprecated and will be removed in a future MySQL version.

mysql_upgrade checks mysql.user system table rows and, for any row with an empty plugin column, sets that column to 'mysql_native_password' if the credentials use a hash format compatible with that plugin. Rows with a pre-4.1 password hash must be upgraded manually.

mysql_upgrade does not upgrade the contents of the time zone tables or help tables. For upgrade instructions, see Section 5.1.13, “MySQL Server Time Zone Support”, and Section 5.1.14, “Server-Side Help Support”.

360
Unless invoked with the `--skip-sys-schema` option, `mysql_upgrade` installs the `sys` schema if it is not installed, and upgrades it to the current version otherwise. An error occurs if a `sys` schema exists but has no `version` view, on the assumption that its absence indicates a user-created schema:

A sys schema exists with no sys.version view. If you have a user created sys schema, this must be renamed for the upgrade to succeed.

To upgrade in this case, remove or rename the existing `sys` schema first.

`mysql_upgrade` supports the following options, which can be specified on the command line or in the `[mysql_upgrade]` and `[client]` groups of an option file. For information about option files used by MySQL programs, see Section 4.2.2.2, “Using Option Files”.

Table 4.10 `mysql_upgrade` Options

<table>
<thead>
<tr>
<th>Option Name</th>
<th>Description</th>
<th>Introduced</th>
<th>Deprecated</th>
</tr>
</thead>
<tbody>
<tr>
<td>--bind-address</td>
<td>Use specified network interface to connect to MySQL Server</td>

<td></td>
</tr>
<tr>
<td>--zstd-compression-level</td>
<td>Compression level for connections to server that use zstd compression</td>
<td>8.0.18</td>
<td></td>
</tr>
</tbody>
</table>

- **--help**

Display a short help message and exit.

- **--bind-address=ip_address**

On a computer having multiple network interfaces, use this option to select which interface to use for connecting to the MySQL server.

- **--character-sets-dir=dir_name**

The directory where character sets are installed. See Section 10.14, “Character Set Configuration”.

- **--compress, -C**

Compress all information sent between the client and the server if possible. See Section 4.2.6, “Connection Compression Control”.
As of MySQL 8.0.18, this option is deprecated. It will be removed in a future MySQL version. See Legacy Connection Compression Configuration.

- **--compression-algorithms=value**

  The permitted compression algorithms for connections to the server. The available algorithms are the same as for the `protocol_compression_algorithms` system variable. The default value is uncompressed.

  For more information, see Section 4.2.6, “Connection Compression Control”.

  This option was added in MySQL 8.0.18.

- **--debug[=debug_options],-# [debug_options]**

  Write a debugging log. A typical `debug_options` string is `d:t:o, file_name`. The default is `d:t:o, /tmp/mysql_upgrade.trace`.

- **--debug-check**

  Print some debugging information when the program exits.

- **--debug-info,-T**

  Print debugging information and memory and CPU usage statistics when the program exits.

- **--default-auth=plugin**

  A hint about which client-side authentication plugin to use. See Section 6.2.17, “Pluggable Authentication”.

- **--default-character-set=charset_name**

  Use `charset_name` as the default character set. See Section 10.14, “Character Set Configuration”.

- **--defaults-extra-file=file_name**

  Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. `file_name` is interpreted relative to the current directory if given as a relative path name rather than a full path name.

  For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- **--defaults-file=file_name**

  Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. `file_name` is interpreted relative to the current directory if given as a relative path name rather than a full path name.

  For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- **--defaults-group-suffix=str**

  Read not only the usual option groups, but also groups with the usual names and a suffix of `str`. For example, `mysql_upgrade` normally reads the `[client]` and `[mysql_upgrade]` groups. If the `--defaults-group-suffix=_other` option is given, `mysql_upgrade` also reads the `[client_other]` and `[mysql_upgrade_other]` groups.

  For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

---

363
mysql_upgrade — Check and Upgrade MySQL Tables

- **--force**

Ignore the `mysql_upgrade_info` file and force execution even if `mysql_upgrade` has already been executed for the current version of MySQL.

- **--get-server-public-key**

Request from the server the public key required for RSA key pair-based password exchange. This option applies to clients that authenticate with the `caching_sha2_password` authentication plugin. For that plugin, the server does not send the public key unless requested. This option is ignored for accounts that do not authenticate with that plugin. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

If `--server-public-key-path=file_name` is given and specifies a valid public key file, it takes precedence over `--get-server-public-key`.

For information about the `caching_sha2_password` plugin, see Section 6.4.1.3, “Caching SHA-2 Pluggable Authentication”.

- **--host=host_name, -h host_name**

Connect to the MySQL server on the given host.

- **--login-path=name**

Read options from the named login path in the `.mylogin.cnf` login path file. A “login path” is an option group containing options that specify which MySQL server to connect to and which account to authenticate as. To create or modify a login path file, use the `mysql_config_editor` utility. See Section 4.6.7, “`mysql_config_editor` — MySQL Configuration Utility”.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- **--max-allowed-packet=value**

The maximum size of the buffer for client/server communication. The default value is 24MB. The minimum and maximum values are 4KB and 2GB.

- **--net-buffer-length=value**

The initial size of the buffer for client/server communication. The default value is 1MB − 1KB. The minimum and maximum values are 4KB and 16MB.

- **--no-defaults**

Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

The exception is that the `.mylogin.cnf` file, if it exists, is read in all cases. This permits passwords to be specified in a safer way than on the command line even when `--no-defaults` is used. (.mylogin.cnf is created by the `mysql_config_editor` utility. See Section 4.6.7, “`mysql_config_editor` — MySQL Configuration Utility”.)

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- **--password[=password], -p[password]**

The password of the MySQL account used for connecting to the server. The password value is optional. If not given, `mysql_upgrade` prompts for one. If given, there must be no space between
mysql_upgrade — Check and Upgrade MySQL Tables

--password= or -p and the password following it. If no password option is specified, the default is to send no password.

Specifying a password on the command line should be considered insecure. To avoid giving the password on the command line, use an option file. See Section 6.1.2.1, “End-User Guidelines for Password Security”.

To explicitly specify that there is no password and that mysql_upgrade should not prompt for one, use the --skip-password option.

• --pipe, -W

On Windows, connect to the server using a named pipe. This option applies only if the server was started with the named_pipe system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the named_pipe_full_access_group system variable.

• --plugin-dir=dir_name

The directory in which to look for plugins. Specify this option if the --default-auth option is used to specify an authentication plugin but mysql_upgrade does not find it. See Section 6.2.17, “Pluggable Authentication”.

• --port=port_num, -P port_num

For TCP/IP connections, the port number to use.

• --print-defaults

Print the program name and all options that it gets from option files.

• --protocol={TCP|SOCKET|PIPE|MEMORY}

The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally result in use of a protocol other than the one you want. For details on the permissible values, see Section 4.2.4, “Connecting to the MySQL Server Using Command Options”.

• --server-public-key-path=file_name

The path name to a file containing a client-side copy of the public key required by the server for RSA key pair-based password exchange. The file must be in PEM format. This option applies to clients that authenticate with the sha256_password or caching_sha2_password authentication plugin. This option is ignored for accounts that do not authenticate with one of those plugins. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

If --server-public-key-path=file_name is given and specifies a valid public key file, it takes precedence over --get-server-public-key.

For sha256_password, this option applies only if MySQL was built using OpenSSL.

For information about the sha256_password and caching_sha2_password plugins, see Section 6.4.1.2, “SHA-256 Pluggable Authentication”, and Section 6.4.1.3, “Caching SHA-2 Pluggable Authentication”.

• --shared-memory-base-name=name

On Windows, the shared-memory name to use for connections made using shared memory to a local server. The default value is MYSQL. The shared-memory name is case-sensitive.

This option applies only if the server was started with the shared_memory system variable enabled to support shared-memory connections.
• **--skip-sys-schema**

By default, `mysql_upgrade` installs the `sys` schema if it is not installed, and upgrades it to the current version otherwise. The `--skip-sys-schema` option suppresses this behavior.

• **--socket=path, -S path**

For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

On Windows, this option applies only if the server was started with the `named_pipe` system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the `named_pipe_full_access_group` system variable.

• **--ssl***

Options that begin with `--ssl` specify whether to connect to the server using SSL and indicate where to find SSL keys and certificates. See Command Options for Encrypted Connections.

• **--ssl-fips-mode={OFF|ON|STRICT}**

Controls whether to enable FIPS mode on the client side. The `--ssl-fips-mode` option differs from other `--ssl-xxx` options in that it is not used to establish encrypted connections, but rather to affect which cryptographic operations are permitted. See Section 6.5, “FIPS Support”.

These `--ssl-fips-mode` values are permitted:

• **OFF**: Disable FIPS mode.

• **ON**: Enable FIPS mode.

• **STRICT**: Enable “strict” FIPS mode.

  **Note**

  If the OpenSSL FIPS Object Module is not available, the only permitted value for `--ssl-fips-mode` is OFF. In this case, setting `--ssl-fips-mode` to ON or STRICT causes the client to produce a warning at startup and to operate in non-FIPS mode.

• **--tls-ciphersuites=ciphersuite_list**

For client programs, specifies which TLSv1.3 ciphersuites the client permits for encrypted connections. The value is a list of one or more colon-separated ciphersuite names. The ciphersuites that can be named for this option depend on the SSL library used to compile MySQL. For details, see Section 6.3.5, “Encrypted Connection Protocols and Ciphers”.

This option was added in MySQL 8.0.16.

• **--tls-version=protocol_list**

The permissible TLS protocols for encrypted connections. The value is a list of one or more comma-separated protocol names. The protocols that can be named for this option depend on the SSL library used to compile MySQL. For details, see Section 6.3.5, “Encrypted Connection Protocols and Ciphers”.

• **--upgrade-system-tables, --s**

Upgrade only the system tables in the `mysql` schema, do not upgrade user schemas.

• **--user=user_name, -u user_name**
The user name of the MySQL account to use for connecting to the server. The default user name is root.

- **--verbose**
  Verbose mode. Print more information about what the program does.

- **--version-check, -k**
  Check the version of the server to which mysql_upgrade is connecting to verify that it is the same as the version for which mysql_upgrade was built. If not, mysql_upgrade exits. This option is enabled by default; to disable the check, use --skip-version-check.

- **--write-binlog**
  By default, binary logging by mysql_upgrade is disabled. Invoke the program with --write-binlog if you want its actions to be written to the binary log.

  When the server is running with global transaction identifiers (GTIDs) enabled (gtid_mode=ON), do not enable binary logging by mysql_upgrade.

- **--zstd-compression-level=level**
  The compression level to use for connections to the server that use the zstd compression algorithm. The permitted levels are from 1 to 22, with larger values indicating increasing levels of compression. The default zstd compression level is 3. The compression level setting has no effect on connections that do not use zstd compression.

  For more information, see Section 4.2.6, “Connection Compression Control”.

This option was added in MySQL 8.0.18.

### 4.5 MySQL Client Programs

This section describes client programs that connect to the MySQL server.

#### 4.5.1 mysql — The MySQL Command-Line Client

mysql is a simple SQL shell with input line editing capabilities. It supports interactive and noninteractive use. When used interactively, query results are presented in an ASCII-table format. When used noninteractively (for example, as a filter), the result is presented in tab-separated format. The output format can be changed using command options.

If you have problems due to insufficient memory for large result sets, use the --quick option. This forces mysql to retrieve results from the server a row at a time rather than retrieving the entire result set and buffering it in memory before displaying it. This is done by returning the result set using the mysql_use_result() C API function in the client/server library rather than mysql_store_result().

**Note**

Alternatively, MySQL Shell offers access to the X DevAPI. For details, see MySQL Shell 8.0 (part of MySQL 8.0).

Using mysql is very easy. Invoke it from the prompt of your command interpreter as follows:

```shell
shell> mysql db_name
```

Or:

```shell
shell> mysql --user=user_name --password db_name
```
Enter password: your_password

Then type an SQL statement, end it with ;, \g, or \G and press Enter.

Typing Control+C interrupts the current statement if there is one, or cancels any partial input line otherwise.

You can execute SQL statements in a script file (batch file) like this:

```
shell> mysql db_name < script.sql > output.tab
```

On Unix, the mysql client logs statements executed interactively to a history file. See Section 4.5.1.3, “mysql Client Logging”.

### 4.5.1.1 mysql Client Options

mysql supports the following options, which can be specified on the command line or in the [mysql] and [client] groups of an option file. For information about option files used by MySQL programs, see Section 4.2.2.2, “Using Option Files”.

#### Table 4.11 mysql Client Options

<table>
<thead>
<tr>
<th>Option Name</th>
<th>Description</th>
<th>Introduced</th>
<th>Deprecated</th>
<th>Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--auto-rehash</td>
<td>Enable automatic rehashing</td>

<td>Compression level for connections to server that use zstd compression</td>
<td>8.0.18</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

- `--help`, `--?

Display a help message and exit.

- `--auto-rehash

Enable automatic rehashing. This option is on by default, which enables database, table, and column name completion. Use `--disable-auto-rehash` to disable rehashing. That causes `mysql` to start faster, but you must issue the `rehash` command or its `\#` shortcut if you want to use name completion.

To complete a name, enter the first part and press Tab. If the name is unambiguous, `mysql` completes it. Otherwise, you can press Tab again to see the possible names that begin with what you have typed so far. Completion does not occur if there is no default database.

**Note**

This feature requires a MySQL client that is compiled with the `readline` library. Typically, the `readline` library is not available on Windows.

- `--auto-vertical-output

Cause result sets to be displayed vertically if they are too wide for the current window, and using normal tabular format otherwise. (This applies to statements terminated by `;` or `\G`.)

- `--batch`, `-B

Print results using tab as the column separator, with each row on a new line. With this option, `mysql` does not use the history file.

Batch mode results in nontabular output format and escaping of special characters. Escaping may be disabled by using raw mode; see the description for the `--raw` option.

- `--binary-as-hex

When this option is given, `mysql` displays binary data using hexadecimal notation (`\xvalue`). This occurs whether the overall output display format is tabular, vertical, HTML, or XML.

- `--binary-mode

This option helps when processing `mysqlbinlog` output that may contain `BLOB` values. By default, `mysql` translates `\r\n` in statement strings to `\n` and interprets `\0` as the statement terminator.
--binary-mode disables both features. It also disables all `mysql` commands except `charset` and `delimiter` in noninteractive mode (for input piped to `mysql` or loaded using the `source` command).

- **--bind-address=ip_address**

  On a computer having multiple network interfaces, use this option to select which interface to use for connecting to the MySQL server.

- **--character-sets-dir=dir_name**

  The directory where character sets are installed. See Section 10.14, “Character Set Configuration”.

- **--column-names**

  Write column names in results.

- **--column-type-info**

  Display result set metadata.

- **--comments, -c**

  Whether to strip or preserve comments in statements sent to the server. The default is `--skip-comments` (strip comments), enable with `--comments` (preserve comments).

  **Note**

  The `mysql` client always passes optimizer hints to the server, regardless of whether this option is given.

  Comment stripping is deprecated. This feature and the options to control it will be removed in a future MySQL release.

- **--compress, -C**

  Compress all information sent between the client and the server if possible. See Section 4.2.6, “Connection Compression Control”.

  As of MySQL 8.0.18, this option is deprecated. It will be removed in a future MySQL version. See Legacy Connection Compression Configuration.

- **--compression-algorithms=value**

  The permitted compression algorithms for connections to the server. The available algorithms are the same as for the `protocol_compression_algorithms` system variable. The default value is `uncompressed`.

  For more information, see Section 4.2.6, “Connection Compression Control”.

  This option was added in MySQL 8.0.18.

- **--connect-expired-password**

  Indicate to the server that the client can handle sandbox mode if the account used to connect has an expired password. This can be useful for noninteractive invocations of `mysql` because normally the server disconnects noninteractive clients that attempt to connect using an account with an expired password. (See Section 6.2.16, “Server Handling of Expired Passwords”.)

- **--connect-timeout=value**

  The number of seconds before connection timeout. (Default value is 0.)
• `--database=db_name, -D db_name`

The database to use. This is useful primarily in an option file.

• `--debug[=debug_options], -# [debug_options]`

Write a debugging log. A typical `debug_options` string is `d:t:o, file_name`. The default is `d:t:o, /tmp/mysql.trace`.

This option is available only if MySQL was built using `WITH_DEBUG`. MySQL release binaries provided by Oracle are not built using this option.

• `--debug-check`

Print some debugging information when the program exits.

• `--debug-info, -T`

Print debugging information and memory and CPU usage statistics when the program exits.

• `--default-auth=plugin`

A hint about which client-side authentication plugin to use. See Section 6.2.17, “Pluggable Authentication”.

• `--default-character-set=charset_name`

Use `charset_name` as the default character set for the client and connection.

This option can be useful if the operating system uses one character set and the `mysql` client by default uses another. In this case, output may be formatted incorrectly. You can usually fix such issues by using this option to force the client to use the system character set instead.

For more information, see Section 10.4, “Connection Character Sets and Collations”, and Section 10.14, “Character Set Configuration”.

• `--defaults-extra-file=filename`

Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. `filename` is interpreted relative to the current directory if given as a relative path name rather than a full path name.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

• `--defaults-file=filename`

Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. `filename` is interpreted relative to the current directory if given as a relative path name rather than a full path name.

Exception: Even with `--defaults-file`, client programs read `.mylogin.cnf`.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

• `--defaults-group-suffix=str`

Read not only the usual option groups, but also groups with the usual names and a suffix of `str`. For example, `mysql` normally reads the `[client]` and `[mysql]` groups. If the `--defaults-group-suffix_other` option is given, `mysql` also reads the `[client_other]` and `[mysql_other]` groups.
mysql — The MySQL Command-Line Client

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

• **--delimiter=str**

  Set the statement delimiter. The default is the semicolon character (;).

• **--disable-named-commands**

  Disable named commands. Use the `\*` form only, or use named commands only at the beginning of a line ending with a semicolon (;). mysql starts with this option enabled by default. However, even with this option, long-format commands still work from the first line. See Section 4.5.1.2, “mysql Client Commands”.

• **--enable-cleartext-plugin**

  Enable the mysql_clear_password cleartext authentication plugin. (See Section 6.4.1.4, “Client-Side Cleartext Pluggable Authentication”.)

• **--execute=statement, -e statement**

  Execute the statement and quit. The default output format is like that produced with **--batch**. See Section 4.2.2.1, “Using Options on the Command Line”, for some examples. With this option, mysql does not use the history file.

• **--force, -f**

  Continue even if an SQL error occurs.

• **--get-server-public-key**

  Request from the server the public key required for RSA key pair-based password exchange. This option applies to clients that authenticate with the caching_sha2_password authentication plugin. For that plugin, the server does not send the public key unless requested. This option is ignored for accounts that do not authenticate with that plugin. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

  If **--server-public-key-path=file_name** is given and specifies a valid public key file, it takes precedence over **--get-server-public-key**.

  For information about the caching_sha2_password plugin, see Section 6.4.1.3, “Caching SHA-2 Pluggable Authentication”.

• **--histignore**

  A list of one or more colon-separated patterns specifying statements to ignore for logging purposes. These patterns are added to the default pattern list ("*IDENTIFIED*:*PASSWORD*"). The value specified for this option affects logging of statements written to the history file, and to syslog if the **--syslog** option is given. For more information, see Section 4.5.1.3, “mysql Client Logging”.

• **--host=host_name, -h host_name**

  Connect to the MySQL server on the given host.

• **--html, -H**

  Produce HTML output.

• **--ignore-spaces, -i**
Ignore spaces after function names. The effect of this is described in the discussion for the `IGNORE_SPACE` SQL mode (see Section 5.1.11, “Server SQL Modes”).

- `--init-command=str`
  SQL statement to execute after connecting to the server. If auto-reconnect is enabled, the statement is executed again after reconnection occurs.

- `--line-numbers`
  Write line numbers for errors. Disable this with `--skip-line-numbers`.

- `--local-infile[{0|1}]`
  Enable or disable `LOCAL` capability for `LOAD DATA`. For `mysql`, this capability is disabled by default. With no value, the option enables `LOCAL`. The option may be given as `--local-infile=0` or `--local-infile=1` to explicitly disable or enable `LOCAL`. Enabling local data loading also requires that the server permits it; see Section 6.1.6, “Security Issues with LOAD DATA LOCAL”.

- `--login-path=name`
  Read options from the named login path in the `.mylogin.cnf` login path file. A “login path” is an option group containing options that specify which MySQL server to connect to and which account to authenticate as. To create or modify a login path file, use the `mysql_config_editor` utility. See Section 4.6.7, “mysql_config_editor — MySQL Configuration Utility”.

  For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- `--max-allowed-packet=value`
  The maximum size of the buffer for client/server communication. The default is 16MB, the maximum is 1GB.

- `--max-join-size=value`
  The automatic limit for rows in a join when using `--safe-updates`. (Default value is 1,000,000.)

- `--named-commands,-G`
  Enable named `mysql` commands. Long-format commands are permitted, not just short-format commands. For example, `quit` and `\q` both are recognized. Use `--skip-named-commands` to disable named commands. See Section 4.5.1.2, “mysql Client Commands”.

- `--net-buffer-length=value`
  The buffer size for TCP/IP and socket communication. (Default value is 16KB.)

- `--no-auto-rehash,-A`
  This has the same effect as `--skip-auto-rehash`. See the description for `--auto-rehash`.

- `--no-beep,-b`
  Do not beep when errors occur.

- `--no-defaults`
  Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

  The exception is that the `.mylogin.cnf` file, if it exists, is read in all cases. This permits passwords to be specified in a safer way than on the command line even when `--no-defaults`
is used. (.mylogin.cnf is created by the mysql_config_editor utility. See Section 4.6.7, "mysql_config_editor — MySQL Configuration Utility").

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- **--one-database, -o**

  Ignore statements except those that occur while the default database is the one named on the command line. This option is rudimentary and should be used with care. Statement filtering is based only on USE statements.

Initially, mysql executes statements in the input because specifying a database db_name on the command line is equivalent to inserting USE db_name at the beginning of the input. Then, for each USE statement encountered, mysql accepts or rejects following statements depending on whether the database named is the one on the command line. The content of the statements is immaterial.

Suppose that mysql is invoked to process this set of statements:

```sql
DELETE FROM db2.t2;
USE db2;
DROP TABLE db1.t1;
CREATE TABLE db1.t1 (i INT);
USE db1;
INSERT INTO t1 (i) VALUES(1);
CREATE TABLE db2.t1 (j INT);
```

If the command line is mysql --force --one-database db1, mysql handles the input as follows:

- The DELETE statement is executed because the default database is db1, even though the statement names a table in a different database.
- The DROP TABLE and CREATE TABLE statements are not executed because the default database is not db1, even though the statements name a table in db1.
- The INSERT and CREATE TABLE statements are executed because the default database is db1, even though the CREATE TABLE statement names a table in a different database.
- **--pager[=command]**

  Use the given command for paging query output. If the command is omitted, the default pager is the value of your PAGER environment variable. Valid pagers are less, more, cat [> filename], and so forth. This option works only on Unix and only in interactive mode. To disable paging, use --skip-pager. Section 4.5.1.2, “mysql Client Commands”, discusses output paging further.

- **--password[=password], -p[password]**

  The password of the MySQL account used for connecting to the server. The password value is optional. If not given, mysql prompts for one. If given, there must be no space between --password= or -p and the password following it. If no password option is specified, the default is to send no password.

  Specifying a password on the command line should be considered insecure. To avoid giving the password on the command line, use an option file. See Section 6.1.2.1, “End-User Guidelines for Password Security”.

  To explicitly specify that there is no password and that mysql should not prompt for one, use the --skip-password option.

- **--pipe, -W**
On Windows, connect to the server using a named pipe. This option applies only if the server was started with the `named_pipe` system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the `named_pipe_full_access_group` system variable.

- **--plugin-dir=dir_name**
  
  The directory in which to look for plugins. Specify this option if the `--default-auth` option is used to specify an authentication plugin but `mysql` does not find it. See Section 6.2.17, “Pluggable Authentication”.

- **--port=port_num, -P port_num**
  
  For TCP/IP connections, the port number to use.

- **--print-defaults**
  
  Print the program name and all options that it gets from option files.

  For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- **--prompt=format_str**
  
  Set the prompt to the specified format. The default is `mysql>`. The special sequences that the prompt can contain are described in Section 4.5.1.2, “mysql Client Commands”.

- **--protocol={TCP|SOCKET|PIPE|MEMORY}**
  
  The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally result in use of a protocol other than the one you want. For details on the permissible values, see Section 4.2.4, “Connecting to the MySQL Server Using Command Options”.

- **--quick, -q**
  
  Do not cache each query result, print each row as it is received. This may slow down the server if the output is suspended. With this option, `mysql` does not use the history file.

- **--raw, -r**
  
  For tabular output, the “boxing” around columns enables one column value to be distinguished from another. For nontabular output (such as is produced in batch mode or when the `--batch` or `--silent` option is given), special characters are escaped in the output so they can be identified easily. Newline, tab, `NUL`, and backslash are written as `\n`, `\t`, `\0`, and `\\`. The `--raw` option disables this character escaping.

  The following example demonstrates tabular versus nontabular output and the use of raw mode to disable escaping:

```sql
% mysql
mysql> SELECT CHAR(92);
+----------+
| CHAR(92) |
+----------+
| \        |
+----------+
%
mysql -s
mysql> SELECT CHAR(92);  
CHAR(92)  
\   
% mysql -s -r
```
mysql — The MySQL Command-Line Client

mysql> SELECT CHAR(92);
CHAR(92)
\n
• **--reconnect**

If the connection to the server is lost, automatically try to reconnect. A single reconnect attempt is made each time the connection is lost. To suppress reconnection behavior, use **--skip-reconnect**.

• **--safe-updates, --i-am-a-dummy, -U**

If this option is enabled, *UPDATE* and *DELETE* statements that do not use a key in the *WHERE* clause or a *LIMIT* clause produce an error. In addition, restrictions are placed on *SELECT* statements that produce (or are estimated to produce) very large result sets. If you have set this option in an option file, you can use **--skip-safe-updates** on the command line to override it. For more information about this option, see Using Safe-Updates Mode (**--safe-updates**).

• **--secure-auth**

This option was removed in MySQL 8.0.3.

• **--select-limit=value**

The automatic limit for *SELECT* statements when using **--safe-updates**. (Default value is 1,000.)

• **--server-public-key-path=file_name**

The path name to a file containing a client-side copy of the public key required by the server for RSA key pair-based password exchange. The file must be in PEM format. This option applies to clients that authenticate with the *sha256_password* or *caching_sha2_password* authentication plugin. This option is ignored for accounts that do not authenticate with one of those plugins. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

If **--server-public-key-path=file_name** is given and specifies a valid public key file, it takes precedence over **--get-server-public-key**.

This option is available only if MySQL was built using OpenSSL.

For information about the *sha256_password* and *caching_sha2_password* plugins, see Section 6.4.1.2, “SHA-256 Pluggable Authentication”, and Section 6.4.1.3, “Caching SHA-2 Pluggable Authentication”.

• **--shared-memory-base-name=name**

On Windows, the shared-memory name to use for connections made using shared memory to a local server. The default value is *MYSQL*. The shared-memory name is case-sensitive.

This option applies only if the server was started with the *shared_memory* system variable enabled to support shared-memory connections.

• **--show-warnings**

Cause warnings to be shown after each statement if there are any. This option applies to interactive and batch mode.

• **--sigint-ignore**

Ignore SIGINT signals (typically the result of typing Control+C).

• **--silent, -s**
Silent mode. Produce less output. This option can be given multiple times to produce less and less output.

This option results in nontabular output format and escaping of special characters. Escaping may be disabled by using raw mode; see the description for the --raw option.

- **--skip-column-names, -N**
  Do not write column names in results.

- **--skip-line-numbers, -L**
  Do not write line numbers for errors. Useful when you want to compare result files that include error messages.

- **--socket=path, -S path**
  For connections to localhost, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

  On Windows, this option applies only if the server was started with the named_pipe system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the named_pipe_full_access_group system variable.

- **--ssl***
  Options that begin with --ssl specify whether to connect to the server using SSL and indicate where to find SSL keys and certificates. See Command Options for Encrypted Connections.

- **--ssl-fips-mode={OFF|ON|STRICT}**
  Controls whether to enable FIPS mode on the client side. The --ssl-fips-mode option differs from other --ssl-xxx options in that it is not used to establish encrypted connections, but rather to affect which cryptographic operations are permitted. See Section 6.5, “FIPS Support”.

  These --ssl-fips-mode values are permitted:

  - **OFF**: Disable FIPS mode.
  - **ON**: Enable FIPS mode.
  - **STRICT**: Enable “strict” FIPS mode.

  **Note**
  If the OpenSSL FIPS Object Module is not available, the only permitted value for --ssl-fips-mode is OFF. In this case, setting --ssl-fips-mode to ON or STRICT causes the client to produce a warning at startup and to operate in non-FIPS mode.

- **--syslog, -j**
  This option causes mysql to send interactive statements to the system logging facility. On Unix, this is syslog; on Windows, it is the Windows Event Log. The destination where logged messages appear is system dependent. On Linux, the destination is often the /var/log/messages file.

  Here is a sample of output generated on Linux by using --syslog. This output is formatted for readability; each logged message actually takes a single line.

```
Mar  7 12:39:25 myhost MysqlClient[20824]:
```
For more information, see Section 4.5.1.3, “mysql Client Logging”.

- **--table, -t**
  Display output in table format. This is the default for interactive use, but can be used to produce table output in batch mode.

- **--tee=file_name**
  Append a copy of output to the given file. This option works only in interactive mode. Section 4.5.1.2, “mysql Client Commands”, discusses tee files further.

- **--tls-ciphersuites=ciphersuite_list**
  The permissible TLSv1.3 ciphersuites for encrypted connections. The value is a list of one or more colon-separated ciphersuite names. The ciphersuites that can be named for this option depend on the SSL library used to compile MySQL. For details, see Section 6.3.5, “Encrypted Connection Protocols and Ciphers”.

  This option was added in MySQL 8.0.16.

- **--tls-version=protocol_list**
  The permissible TLS protocols for encrypted connections. The value is a list of one or more comma-separated protocol names. The protocols that can be named for this option depend on the SSL library used to compile MySQL. For details, see Section 6.3.5, “Encrypted Connection Protocols and Ciphers”.

- **--unbuffered, -n**
  Flush the buffer after each query.

- **--user=user_name, -u user_name**
  The user name of the MySQL account to use for connecting to the server.

- **--verbose, -v**
  Verbose mode. Produce more output about what the program does. This option can be given multiple times to produce more and more output. (For example, -v -v -v produces table output format even in batch mode.)

- **--version, -V**
  Display version information and exit.

- **--vertical, -E**
  Print query output rows vertically (one line per column value). Without this option, you can specify vertical output for individual statements by terminating them with \G.

- **--wait, -w**
  If the connection cannot be established, wait and retry instead of aborting.

- **--xml, -X**
  Produce XML output.
The output when --xml is used with mysql matches that of mysqldump --xml. See Section 4.5.4, “mysqldump — A Database Backup Program”, for details.

The XML output also uses an XML namespace, as shown here:

```bash
shell> mysql --xml -uroot -e "SHOW VARIABLES LIKE 'version%';"
<?xml version="1.0"?>
<resultset statement="SHOW VARIABLES LIKE 'version%'">
    <row>
        <field name="Variable_name">version</field>
        <field name="Value">5.0.40-debug</field>
    </row>
    <row>
        <field name="Variable_name">version_comment</field>
        <field name="Value">Source distribution</field>
    </row>
    <row>
        <field name="Variable_name">version_compile_machine</field>
        <field name="Value">i686</field>
    </row>
    <row>
        <field name="Variable_name">version_compile_os</field>
        <field name="Value">suse-linux-gnu</field>
    </row>
</resultset>
```

• --zstd-compression-level=level

The compression level to use for connections to the server that use the zstd compression algorithm. The permitted levels are from 1 to 22, with larger values indicating increasing levels of compression. The default zstd compression level is 3. The compression level setting has no effect on connections that do not use zstd compression.

For more information, see Section 4.2.6, “Connection Compression Control”.

This option was added in MySQL 8.0.18.

4.5.1.2 mysql Client Commands

mysql sends each SQL statement that you issue to the server to be executed. There is also a set of commands that mysql itself interprets. For a list of these commands, type help or \h at the mysql> prompt:

```
mysql> help
List of all MySQL commands:
Note that all text commands must be first on line and end with ';
?
\? (\?) Synonym for 'help'.
clear \(c\) Clear the current input statement.
connect \(r\) Reconnect to the server. Optional arguments are db and host.
delimiter \(d\) Set statement delimiter.
edit \(e\) Edit command with $EDITOR.
escape \(g\) Send command to mysql server, display result vertically.
exit \(q\) Exit mysql. Same as quit.
go \(g\) Send command to mysql server.
help \(h\) Display this help.
nopager \(n\) Disable pager, print to stdout.
notee \(t\) Don’t write into outfile.
pager \(P\) Set PAGER [to_pager]. Print the query results via PAGER.
```
print \( (p) \) Print current command.
prompt \( (R) \) Change your mysql prompt.
quit \( (q) \) Quit mysql.
rehash \( (#) \) Rebuild completion hash.
source \( (.) \) Execute an SQL script file. Takes a file name as an argument.
status \( (s) \) Get status information from the server.
system \( (!) \) Execute a system shell command.
tee \( (T) \) Set outfile \[to_outfile\]. Append everything into given outfile.
use \( (u) \) Use another database. Takes database name as argument.
charset \( (C) \) Switch to another charset. Might be needed for processing binlog with multi-byte charsets.
warnings \( (W) \) Show warnings after every statement.
nowarning \( (w) \) Don't show warnings after every statement.
resetconnection \( (x) \) Clean session context.

For server side help, type 'help contents'

If mysql is invoked with the --binary-mode option, all mysql commands are disabled except charset and delimiter in noninteractive mode (for input piped to mysql or loaded using the source command).

Each command has both a long and short form. The long form is not case-sensitive; the short form is. The long form can be followed by an optional semicolon terminator, but the short form should not.

The use of short-form commands within multiple-line /* ... */ comments is not supported.

• help \[arg\], \h \[arg\], \? \[arg\], ? \[arg\]

Display a help message listing the available mysql commands.

If you provide an argument to the help command, mysql uses it as a search string to access server-side help from the contents of the MySQL Reference Manual. For more information, see Section 4.5.1.4, "mysql Client Server-Side Help".

• charset charset_name, \C charset_name

Change the default character set and issue a SET NAMES statement. This enables the character set to remain synchronized on the client and server if mysql is run with auto-reconnect enabled (which is not recommended), because the specified character set is used for reconnects.

• clear, \c

Clear the current input. Use this if you change your mind about executing the statement that you are entering.

• connect \[db_name host_name]\], \r \[db_name host_name]\)

Reconnect to the server. The optional database name and host name arguments may be given to specify the default database or the host where the server is running. If omitted, the current values are used.

• delimiter str, \d str

Change the string that mysql interprets as the separator between SQL statements. The default is the semicolon character (;).

The delimiter string can be specified as an unquoted or quoted argument on the delimiter command line. Quoting can be done with either single quote ('), double quote ('"'), or backtick ('`') characters. To include a quote within a quoted string, either quote the string with a different quote character or escape the quote with a backslash (\) character. Backslash should be avoided outside of quoted strings because it is the escape character for MySQL. For an unquoted argument, the delimiter is read up to the first space or end of line. For a quoted argument, the delimiter is read up to the matching quote on the line.
mysql interprets instances of the delimiter string as a statement delimiter anywhere it occurs, except within quoted strings. Be careful about defining a delimiter that might occur within other words. For example, if you define the delimiter as \( X \), you will be unable to use the word INDEX in statements. mysql interprets this as INDE followed by the delimiter \( X \).

When the delimiter recognized by mysql is set to something other than the default of ;, instances of that character are sent to the server without interpretation. However, the server itself still interprets ; as a statement delimiter and processes statements accordingly. This behavior on the server side comes into play for multiple-statement execution (see Section 28.7.23, “C API Multiple Statement Execution Support”), and for parsing the body of stored procedures and functions, triggers, and events (see Section 24.1, “Defining Stored Programs”).

• **edit, \e**

  Edit the current input statement. mysql checks the values of the EDITOR and VISUAL environment variables to determine which editor to use. The default editor is vi if neither variable is set.

  The edit command works only in Unix.

• **ego, \G**

  Send the current statement to the server to be executed and display the result using vertical format.

• **exit, \q**

  Exit mysql.

• **go, \g**

  Send the current statement to the server to be executed.

• **nopager, \n**

  Disable output paging. See the description for pager.

  The nopager command works only in Unix.

• **notee, \t**

  Disable output copying to the tee file. See the description for tee.

• **nowarning, \w**

  Disable display of warnings after each statement.

• **pager [command], \P [command]**

  Enable output paging. By using the --pager option when you invoke mysql, it is possible to browse or search query results in interactive mode with Unix programs such as less, more, or any other similar program. If you specify no value for the option, mysql checks the value of the PAGER environment variable and sets the pager to that. Pager functionality works only in interactive mode.

  Output paging can be enabled interactively with the pager command and disabled with nopager. The command takes an optional argument; if given, the paging program is set to that. With no argument, the pager is set to the pager that was set on the command line, or stdout if no pager was specified.

  Output paging works only in Unix because it uses the popen() function, which does not exist on Windows. For Windows, the tee option can be used instead to save query output, although it is not as convenient as pager for browsing output in some situations.

• **print, \p**
Print the current input statement without executing it.

- **prompt** `str`, `\R` `str`

Reconfigure the mysql prompt to the given string. The special character sequences that can be used in the prompt are described later in this section.

If you specify the **prompt** command with no argument, mysql resets the prompt to the default of `mysql>`.

- **quit**, `\q`

Exit mysql.

- **rehash**, `\#`

Rebuild the completion hash that enables database, table, and column name completion while you are entering statements. (See the description for the **--auto-rehash** option.)

- **resetconnection**, `\x`

Reset the connection to clear the session state.

Resetting a connection has effects similar to mysql_change_user() or an auto-reconnect except that the connection is not closed and reopened, and re-authentication is not done. See Section 28.7.7.3, “mysql_change_user()” and see Section 28.7.28, “C API Automatic Reconnection Control”.

This example shows how **resetconnection** clears a value maintained in the session state:

```sql
mysql> SELECT LAST_INSERT_ID(3);
+-------------------+
<table>
<thead>
<tr>
<th>LAST_INSERT_ID(3)</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
</tr>
</tbody>
</table>
+-------------------+

mysql> SELECT LAST_INSERT_ID();
+------------------+
<table>
<thead>
<tr>
<th>LAST_INSERT_ID()</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
</tr>
</tbody>
</table>
+------------------+

mysql> resetconnection;

mysql> SELECT LAST_INSERT_ID();
+------------------+
<table>
<thead>
<tr>
<th>LAST_INSERT_ID()</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
</tr>
</tbody>
</table>
+------------------+
```

- **source** `file_name`, `\file_name`

Read the named file and executes the statements contained therein. On Windows, you can specify path name separators as `/` or `\`.

Quote characters are taken as part of the file name itself. For best results, the name should not include space characters.

- **status**, `\s`
Provide status information about the connection and the server you are using. If you are running with
`--safe-updates` enabled, `status` also prints the values for the `mysql` variables that affect your
queries.

- **system command, `\! command`**

Execute the given command using your default command interpreter.

The `system` command works only in Unix.

- **tee [file_name], `\T [file_name]`**

By using the `--tee` option when you invoke `mysql`, you can log statements and their output. All the
data displayed on the screen is appended into a given file. This can be very useful for debugging
purposes also. `mysql` flushes results to the file after each statement, just before it prints its next
prompt. Tee functionality works only in interactive mode.

You can enable this feature interactively with the `tee` command. Without a parameter, the previous
file is used. The `tee` file can be disabled with the `notee` command. Executing `tee` again re-enables
logging.

- **use db_name, `\u db_name`**

Use `db_name` as the default database.

- **warnings, `\W`**

Enable display of warnings after each statement (if there are any).

Here are a few tips about the `pager` command:

- You can use it to write to a file and the results go only to the file:

  ```
  mysql> pager cat > /tmp/log.txt
  ```

  You can also pass any options for the program that you want to use as your pager:

  ```
  mysql> pager less -n -i -S
  ```

- In the preceding example, note the `-S` option. You may find it very useful for browsing wide query
  results. Sometimes a very wide result set is difficult to read on the screen. The `-S` option to `less`
can make the result set much more readable because you can scroll it horizontally using the left-
arrow and right-arrow keys. You can also use `-S` interactively within `less` to switch the horizontal-
browse mode on and off. For more information, read the `less` manual page:

  ```
  shell> man less
  ```

- The `-F` and `-X` options may be used with `less` to cause it to exit if output fits on one screen, which
  is convenient when no scrolling is necessary:

  ```
  mysql> pager less -n -i -S -F -X
  ```

- You can specify very complex pager commands for handling query output:

  ```
  mysql> pager cat | tee /dr1/tmp/res.txt \        
  | tee /dr2/tmp/res2.txt | less -n -i -S
  ```

  In this example, the command would send query results to two files in two different directories on two
different file systems mounted on `/dr1` and `/dr2`, yet still display the results onscreen using `less`. 
You can also combine the `tee` and `pager` functions. Have a `tee` file enabled and `pager` set to `less`, and you are able to browse the results using the `less` program and still have everything appended into a file the same time. The difference between the Unix `tee` used with the `pager` command and the `mysql` built-in `tee` command is that the built-in `tee` works even if you do not have the Unix `tee` available. The built-in `tee` also logs everything that is printed on the screen, whereas the Unix `tee` used with `pager` does not log quite that much. Additionally, `tee` file logging can be turned on and off interactively from within `mysql`. This is useful when you want to log some queries to a file, but not others.

The `prompt` command reconfigures the default `mysql>` prompt. The string for defining the prompt can contain the following special sequences.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\C</td>
<td>The current connection identifier</td>
</tr>
<tr>
<td>\c</td>
<td>A counter that increments for each statement you issue</td>
</tr>
<tr>
<td>\D</td>
<td>The full current date</td>
</tr>
<tr>
<td>\d</td>
<td>The default database</td>
</tr>
<tr>
<td>\h</td>
<td>The server host</td>
</tr>
<tr>
<td>\l</td>
<td>The current delimiter</td>
</tr>
<tr>
<td>\m</td>
<td>Minutes of the current time</td>
</tr>
<tr>
<td>\n</td>
<td>A newline character</td>
</tr>
<tr>
<td>\O</td>
<td>The current month in three-letter format (Jan, Feb, …)</td>
</tr>
<tr>
<td>\o</td>
<td>The current month in numeric format</td>
</tr>
<tr>
<td>\P</td>
<td>am/pm</td>
</tr>
<tr>
<td>\p</td>
<td>The current TCP/IP port or socket file</td>
</tr>
<tr>
<td>\R</td>
<td>The current time, in 24-hour military time (0–23)</td>
</tr>
<tr>
<td>\r</td>
<td>The current time, standard 12-hour time (1–12)</td>
</tr>
<tr>
<td>\S</td>
<td>Semicolon</td>
</tr>
<tr>
<td>\s</td>
<td>Seconds of the current time</td>
</tr>
<tr>
<td>\t</td>
<td>A tab character</td>
</tr>
<tr>
<td>\U</td>
<td>Your full <code>user_name@host_name</code> account name</td>
</tr>
<tr>
<td>\u</td>
<td>Your user name</td>
</tr>
<tr>
<td>\v</td>
<td>The server version</td>
</tr>
<tr>
<td>\w</td>
<td>The current day of the week in three-letter format (Mon, Tue, …)</td>
</tr>
<tr>
<td>\Y</td>
<td>The current year, four digits</td>
</tr>
<tr>
<td>\y</td>
<td>The current year, two digits</td>
</tr>
<tr>
<td>_</td>
<td>A space</td>
</tr>
<tr>
<td>\</td>
<td>A space (a space follows the backslash)</td>
</tr>
<tr>
<td>'</td>
<td>Single quote</td>
</tr>
<tr>
<td>&quot;</td>
<td>Double quote</td>
</tr>
<tr>
<td>\</td>
<td>A literal <code>\</code> backslash character</td>
</tr>
<tr>
<td>\x</td>
<td><code>x</code>, for any “<code>x</code>” not listed above</td>
</tr>
</tbody>
</table>

You can set the prompt in several ways:

- **Use an environment variable.** You can set the `MYSQL_PS1` environment variable to a prompt string. For example:
Use a command-line option. You can set the `--prompt` option on the command line to `mysql`. For example:

```
shell> export MYSQL_PS1="(\u@\h) [\d]> "
```

Use an option file. You can set the `prompt` option in the `[mysql]` group of any MySQL option file, such as `/etc/my.cnf` or the `.my.cnf` file in your home directory. For example:

```
[misc]
prompt=(\u@\h) [\d]>_
```

In this example, note that the backslashes are doubled. If you set the prompt using the `prompt` option in an option file, it is advisable to double the backslashes when using the special prompt options. There is some overlap in the set of permissible prompt options and the set of special escape sequences that are recognized in option files. (The rules for escape sequences in option files are listed in Section 4.2.2.2, "Using Option Files"). The overlap may cause you problems if you use single backslashes. For example, `\s` is interpreted as a space rather than as the current seconds value. The following example shows how to define a prompt within an option file to include the current time in `hh:mm:ss` format:

```
[misc]
prompt="\r:\m:\s> "
```

Set the prompt interactively. You can change your prompt interactively by using the `prompt` (or `\R`) command. For example:

```
mysql> prompt (\u@\h) [\d]>
PROMPT set to ' (\u@\h) [\d]>
(\u@\h) [\d]> prompt
Returning to default PROMPT of mysql>
```

### 4.5.1.3 `mysql` Client Logging

The `mysql` client can do these types of logging for statements executed interactively:

- On Unix, `mysql` writes the statements to a history file. By default, this file is named `.mysql_history` in your home directory. To specify a different file, set the value of the `MYSQL_HISTFILE` environment variable.

- On all platforms, if the `--syslog` option is given, `mysql` writes the statements to the system logging facility. On Unix, this is `syslog`; on Windows, it is the Windows Event Log. The destination where logged messages appear is system dependent. On Linux, the destination is often the `/var/log/messages` file.

The following discussion describes characteristics that apply to all logging types and provides information specific to each logging type.

- How Logging Occurs
- Controlling the History File
- syslog Logging Characteristics
How Logging Occurs

For each enabled logging destination, statement logging occurs as follows:

• Statements are logged only when executed interactively. Statements are noninteractive, for example, when read from a file or a pipe. It is also possible to suppress statement logging by using the --batch or --execute option.

• Statements are ignored and not logged if they match any pattern in the "ignore" list. This list is described later.

• mysql logs each nonignored, nonempty statement line individually.

• If a nonignored statement spans multiple lines (not including the terminating delimiter), mysql concatenates the lines to form the complete statement, maps newlines to spaces, and logs the result, plus a delimiter.

Consequently, an input statement that spans multiple lines can be logged twice. Consider this input:

```
mysql> SELECT
       -> 'Today is'
       -> ,
       -> CURDATE()
       -> ;
```

In this case, mysql logs the "SELECT", "'Today is'", ",", "CURDATE()", and ";" lines as it reads them. It also logs the complete statement, after mapping `SELECT
'Today is'
, 
CURDATE()` to `SELECT 'Today is' , CURDATE();`, plus a delimiter. Thus, these lines appear in logged output:

```
SELECT
'Today is'
, 
CURDATE()
;
SELECT 'Today is' , CURDATE();
```

mysql ignores for logging purposes statements that match any pattern in the "ignore" list. By default, the pattern list is "*IDENTIFIED:*PASSWORD*", to ignore statements that refer to passwords. Pattern matching is not case-sensitive. Within patterns, two characters are special:

• ? matches any single character.

• * matches any sequence of zero or more characters.

To specify additional patterns, use the --histignore option or set the MYSQL_HISTIGNORE environment variable. (If both are specified, the option value takes precedence.) The value should be a list of one or more colon-separated patterns, which are appended to the default pattern list.

Patterns specified on the command line might need to be quoted or escaped to prevent your command interpreter from treating them specially. For example, to suppress logging for UPDATE and DELETE statements in addition to statements that refer to passwords, invoke mysql like this:

```
shell> mysql --histignore="*UPDATE*:DELETE"
```

Controlling the History File

The .mysql_history file should be protected with a restrictive access mode because sensitive information might be written to it, such as the text of SQL statements that contain passwords. See Section 6.1.2.1, "End-User Guidelines for Password Security". Statements in the file are accessible from the mysql client when the up-arrow key is used to recall the history. See Disabling Interactive History.
If you do not want to maintain a history file, first remove `.mysql_history` if it exists. Then use either of the following techniques to prevent it from being created again:

- Set the `MYSQL_HISTFILE` environment variable to `/dev/null`. To cause this setting to take effect each time you log in, put it in one of your shell’s startup files.

- Create `.mysql_history` as a symbolic link to `/dev/null`; this need be done only once:

  ```shell
  ln -s /dev/null $HOME/.mysql_history
  ```

### syslog Logging Characteristics

If the `--syslog` option is given, `mysql` writes interactive statements to the system logging facility. Message logging has the following characteristics.

Logging occurs at the “information” level. This corresponds to the `LOG_INFO` priority for `syslog` on Unix/Linux `syslog` capability and to `EVENTLOG_INFORMATION_TYPE` for the Windows Event Log. Consult your system documentation for configuration of your logging capability.

Message size is limited to 1024 bytes.

Messages consist of the identifier `MysqlClient` followed by these values:

- `SYSTEM_USER`
  The operating system user name (login name) or `--` if the user is unknown.

- `MYSQL_USER`
  The MySQL user name (specified with the `--user` option) or `--` if the user is unknown.

- `CONNECTION_ID`:
  The client connection identifier. This is the same as the `CONNECTION_ID()` function value within the session.

- `DB_SERVER`
  The server host or `--` if the host is unknown.

- `DB`
  The default database or `--` if no database has been selected.

- `QUERY`
  The text of the logged statement.

Here is a sample of output generated on Linux by using `--syslog`. This output is formatted for readability; each logged message actually takes a single line.

```
Mar  7 12:39:25 myhost MysqlClient[20824]:
  SYSTEM_USER:'oscar', MYSQL_USER:'my_oscar', CONNECTION_ID:23,
  DB_SERVER:'127.0.0.1', DB:'--', QUERY:'USE test;'
Mar  7 12:39:28 myhost MysqlClient[20824]:
  SYSTEM_USER:'oscar', MYSQL_USER:'my_oscar', CONNECTION_ID:23,
  DB_SERVER:'127.0.0.1', DB:'test', QUERY:'SHOW TABLES;'
```
**mysql> help search_string**

If you provide an argument to the `help` command, `mysql` uses it as a search string to access server-side help from the contents of the MySQL Reference Manual. The proper operation of this command requires that the help tables in the `mysql` database be initialized with help topic information (see Section 5.1.14, “Server-Side Help Support”).

If there is no match for the search string, the search fails:

```sql
mysql> help me
Nothing found
Please try to run 'help contents' for a list of all accessible topics
```

Use `help contents` to see a list of the help categories:

```sql
mysql> help contents
You asked for help about help category: "Contents"
For more information, type 'help <item>', where <item> is one of the following categories:
  Account Management
  Administration
  Data Definition
  Data Manipulation
  Data Types
  Functions
  Functions and Modifiers for Use with GROUP BY
  Geographic Features
  Language Structure
  Plugins
  Storage Engines
  Stored Routines
  Table Maintenance
  Transactions
  Triggers
```

If the search string matches multiple items, `mysql` shows a list of matching topics:

```sql
mysql> help logs
Many help items for your request exist.
To make a more specific request, please type 'help <item>',
where <item> is one of the following topics:
  SHOW
  SHOW BINARY LOGS
  SHOW ENGINE
  SHOW LOGS
```

Use a topic as the search string to see the help entry for that topic:

```sql
mysql> help show binary logs
Name: 'SHOW BINARY LOGS'
Description:
Syntax:
SHOW BINARY LOGS
SHOW MASTER LOGS

Lists the binary log files on the server. This statement is used as part of the procedure described in [purge-binary-logs], that shows how to determine which logs can be purged.

```sql
mysql> SHOW BINARY LOGS;
+---------------+-----------+-----------+
| Log_name      | File_size | Encrypted |
|---------------+-----------+-----------|
| binlog.000015 | 724935    | Yes       |
| binlog.000016 | 733481    | Yes       |
+---------------+-----------+-----------+
```
The search string can contain the wildcard characters % and _. These have the same meaning as for pattern-matching operations performed with the LIKE operator. For example, HELP rep% returns a list of topics that begin with rep:

```
mysql> HELP rep%
Many help items for your request exist.
To make a more specific request, please type 'help <item>',
where <item> is one of the following
topics:
   REPAIR TABLE
   REPEAT FUNCTION
   REPEAT LOOP
   REPLACE
   REPLACE FUNCTION
```

### 4.5.1.5 Executing SQL Statements from a Text File

The `mysql` client typically is used interactively, like this:

```
shell> mysql db_name
```

However, it is also possible to put your SQL statements in a file and then tell `mysql` to read its input from that file. To do so, create a text file `text_file` that contains the statements you wish to execute. Then invoke `mysql` as shown here:

```
shell> mysql db_name < text_file
```

If you place a `USE db_name` statement as the first statement in the file, it is unnecessary to specify the database name on the command line:

```
shell> mysql < text_file
```

If you are already running `mysql`, you can execute an SQL script file using the `source` command or `\.` command:

```
mysql> source file_name
mysql> \ file_name
```

Sometimes you may want your script to display progress information to the user. For this you can insert statements like this:

```
SELECT '<info_to_display>' AS ' ';
```

The statement shown outputs `<info_to_display>`.

You can also invoke `mysql` with the `--verbose` option, which causes each statement to be displayed before the result that it produces.

`mysql` ignores Unicode byte order mark (BOM) characters at the beginning of input files. Previously, it read them and sent them to the server, resulting in a syntax error. Presence of a BOM does not cause `mysql` to change its default character set. To do that, invoke `mysql` with an option such as `--default-character-set=utf8`.

For more information about batch mode, see Section 3.5, “Using mysql in Batch Mode”.

### 4.5.1.6 mysql Client Tips

This section provides information about techniques for more effective use of `mysql` and about `mysql` operational behavior.

- Input-Line Editing
Input-Line Editing

mysql supports input-line editing, which enables you to modify the current input line in place or recall previous input lines. For example, the **left-arrow** and **right-arrow** keys move horizontally within the current input line, and the **up-arrow** and **down-arrow** keys move up and down through the set of previously entered lines. **Backspace** deletes the character before the cursor and typing new characters enters them at the cursor position. To enter the line, press **Enter**.

On Windows, the editing key sequences are the same as supported for command editing in console windows. On Unix, the key sequences depend on the input library used to build mysql (for example, the libedit or readline library).

Documentation for the libedit and readline libraries is available online. To change the set of key sequences permitted by a given input library, define key bindings in the library startup file. This is a file in your home directory: .editrc for libedit and .inputrc for readline.

For example, in libedit, **Control+W** deletes everything before the current cursor position and **Control+U** deletes the entire line. In readline, **Control+W** deletes the word before the cursor and **Control+U** deletes everything before the current cursor position. If mysql was built using libedit, a user who prefers the readline behavior for these two keys can put the following lines in the .editrc file (creating the file if necessary):

```
bind ">W" ed-delete-prev-word
bind "U" vi-kill-line-prev
```

To see the current set of key bindings, temporarily put a line that says only **bind** at the end of .editrc. mysql will show the bindings when it starts.

Disabling Interactive History

The **up-arrow** key enables you to recall input lines from current and previous sessions. In cases where a console is shared, this behavior may be unsuitable. mysql supports disabling the interactive history partially or fully, depending on the host platform.

On Windows, the history is stored in memory. **Alt+F7** deletes all input lines stored in memory for the current history buffer. It also deletes the list of sequential numbers in front of the input lines displayed with **F7** and recalled (by number) with **F9**. New input lines entered after you press **Alt+F7** repopulate the current history buffer. Clearing the buffer does not prevent logging to the Windows Event Viewer, if the **--syslog** option was used to start mysql. Closing the console window also clears the current history buffer.

To disable interactive history on Unix, first delete the .mysql_history file, if it exists (previous entries are recalled otherwise). Then start mysql with the **--histignore="*"** option to ignore all new input lines. To re-enable the recall (and logging) behavior, restart mysql without the option.

If you prevent the .mysql_history file from being created (see Controlling the History File) and use **--histignore="*"** to start the mysql client, the interactive history recall facility is disabled fully. Alternatively, if you omit the **--histignore** option, you can recall the input lines entered during the current session.
Unicode Support on Windows

Windows provides APIs based on UTF-16LE for reading from and writing to the console; the `mysql` client for Windows is able to use these APIs. The Windows installer creates an item in the MySQL menu named `MySQL command line client - Unicode`. This item invokes the `mysql` client with properties set to communicate through the console to the MySQL server using Unicode.

To take advantage of this support manually, run `mysql` within a console that uses a compatible Unicode font and set the default character set to a Unicode character set that is supported for communication with the server:

1. Open a console window.
2. Go to the console window properties, select the font tab, and choose Lucida Console or some other compatible Unicode font. This is necessary because console windows start by default using a DOS raster font that is inadequate for Unicode.
3. Execute `mysql.exe` with the `--default-character-set=utf8` (or `utf8mb4`) option. This option is necessary because `utf16le` is one of the character sets that cannot be used as the client character set. See Impermissible Client Character Sets.

With those changes, `mysql` will use the Windows APIs to communicate with the console using UTF-16LE, and communicate with the server using UTF-8. (The menu item mentioned previously sets the font and character set as just described.)

To avoid those steps each time you run `mysql`, you can create a shortcut that invokes `mysql.exe`. The shortcut should set the console font to Lucida Console or some other compatible Unicode font, and pass the `--default-character-set=utf8` (or `utf8mb4`) option to `mysql.exe`.

Alternatively, create a shortcut that only sets the console font, and set the character set in the `[mysql]` group of your `my.ini` file:

```
[mysql]
default-character-set=utf8
```

Displaying Query Results Vertically

Some query results are much more readable when displayed vertically, instead of in the usual horizontal table format. Queries can be displayed vertically by terminating the query with `\G` instead of a semicolon. For example, longer text values that include newlines often are much easier to read with vertical output:

```
mysql> SELECT * FROM mails WHERE LENGTH(txt) < 300 LIMIT 300,1 \G
*************************** 1. row ***************************
msg_nro: 3068
date: 2000-03-01 23:29:50
time_zone: +0200
mail_from: Monty
reply: monty@no.spam.com
mail_to: "Thimble Smith" <tim@no.spam.com>
subj: UTF-8
txt: >>>>> "Thimble" == Thimble Smith writes:

Thimble> Hi. I think this is a good idea. Is anyone familiar Thimble> with UTF-8 or Unicode? Otherwise, I'll put this on my Thimble> TODO list and see what happens.

Yes, please do that.

Regards,
Monty
    file: inbox-jani-1
    hash: 190402944
1 row in set (0.09 sec)
```
Using Safe-Updates Mode (--safe-updates)

For beginners, a useful startup option is --safe-updates (or --i-am-a-dummy, which has the same effect). Safe-updates mode is helpful for cases when you might have issued an UPDATE or DELETE statement but forgotten the WHERE clause indicating which rows to modify. Normally, such statements update or delete all rows in the table. With --safe-updates, you can modify rows only by specifying the key values that identify them, or a LIMIT clause, or both. This helps prevent accidents. Safe-updates mode also restricts SELECT statements that produce (or are estimated to produce) very large result sets.

The --safe-updates option causes mysql to execute the following statement when it connects to the MySQL server, to set the session values of the sql_safe_updates, sql_select_limit, and max_join_size system variables:

```
SET sql_safe_updates=1, sql_select_limit=1000, max_join_size=1000000;
```

The SET statement affects statement processing as follows:

- Enabling sql_safe_updates causes UPDATE and DELETE statements to produce an error if they do not specify a key constraint in the WHERE clause, or provide a LIMIT clause, or both. For example:

  ```
  UPDATE tbl_name SET not_key_column=val WHERE key_column=val;
  UPDATE tbl_name SET not_key_column=val LIMIT 1;
  ```

- Setting sql_select_limit to 1,000 causes the server to limit all SELECT result sets to 1,000 rows unless the statement includes a LIMIT clause.

- Setting max_join_size to 1,000,000 causes multiple-table SELECT statements to produce an error if the server estimates it must examine more than 1,000,000 row combinations.

To specify result set limits different from 1,000 and 1,000,000, you can override the defaults by using the --select-limit and --max-join-size options when you invoke mysql:

```
mysql --safe-updates --select-limit=500 --max-join-size=10000
```

It is possible for UPDATE and DELETE statements to produce an error in safe-updates mode even with a key specified in the WHERE clause, if the optimizer decides not to use the index on the key column:

- Range access on the index cannot be used if memory usage exceeds that permitted by the range_optimizer_max_mem_size system variable. The optimizer then falls back to a table scan. See Limiting Memory Use for Range Optimization.

- If key comparisons require type conversion, the index may not be used (see Section 8.3.1, “How MySQL Uses Indexes”). Suppose that an indexed string column c1 is compared to a numeric value using WHERE c1 = 2222. For such comparisons, the string value is converted to a number and the operands are compared numerically (see Section 12.2, “Type Conversion in Expression Evaluation”), preventing use of the index. If safe-updates mode is enabled, an error occurs.

As of MySQL 8.0.13, safe-updates mode also includes these behaviors:

- EXPLAIN with UPDATE and DELETE statements does not produce safe-updates errors. This enables use of EXPLAIN plus SHOW WARNINGS to see why an index is not used, which can be helpful in cases such as when a range_optimizer_max_mem_size violation or type conversion occurs and the optimizer does not use an index even though a key column was specified in the WHERE clause.

- When a safe-updates error occurs, the error message includes the first diagnostic that was produced, to provide information about the reason for failure. For example, the message may indicate that the range_optimizer_max_mem_size value was exceeded or type conversion occurred, either of which can preclude use of an index.
For multiple-table deletes and updates, an error is produced with safe updates enabled only if any target table uses a table scan.

Disabling mysql Auto-Reconnect

If the **mysql** client loses its connection to the server while sending a statement, it immediately and automatically tries to reconnect once to the server and send the statement again. However, even if **mysql** succeeds in reconnecting, your first connection has ended and all your previous session objects and settings are lost: temporary tables, the autocommit mode, and user-defined and session variables. Also, any current transaction rolls back. This behavior may be dangerous for you, as in the following example where the server was shut down and restarted between the first and second statements without you knowing it:

```
mysql> SET @a=1;
Query OK, 0 rows affected (0.05 sec)

can't connect to local MySQL server through socket '/var/run/mysql/mysql.sock' (2)
```

The `@a` user variable has been lost with the connection, and after the reconnection it is undefined. If it is important to have **mysql** terminate with an error if the connection has been lost, you can start the **mysql** client with the --skip-reconnect option.

For more information about auto-reconnect and its effect on state information when a reconnection occurs, see Section 28.7.28, “C API Automatic Reconnection Control”.

mysql Client Parser Versus Server Parser

The **mysql** client uses a parser on the client side that is not a duplicate of the complete parser used by the **mysqld** server on the server side. This can lead to differences in treatment of certain constructs. Examples:

- The server parser treats strings delimited by " characters as identifiers rather than as plain strings if the ANSI_QUOTES SQL mode is enabled.

  The **mysql** client parser does not take the ANSI_QUOTES SQL mode into account. It treats strings delimited by "", ', and ` characters the same, regardless of whether ANSI_QUOTES is enabled.

- Within /*! ... */ and /*+ ... */ comments, the **mysql** client parser interprets short-form **mysql** commands. The server parser does not interpret them because these commands have no meaning on the server side.

  If it is desirable for **mysql** not to interpret short-form commands within comments, a partial workaround is to use the --binary-mode option, which causes all **mysql** commands to be disabled except \C and \d in noninteractive mode (for input piped to **mysql** or loaded using the source command).

4.5.2 **mysqladmin** — Client for Administering a MySQL Server

**mysqladmin** is a client for performing administrative operations. You can use it to check the server’s configuration and current status, to create and drop databases, and more.
Invoke `mysqladmin` like this:

```
shell> mysqladmin [options] command [command-arg] [command [command-arg]] ...
```

`mysqladmin` supports the following commands. Some of the commands take an argument following the command name.

- **create db_name**
  
  Create a new database named `db_name`.

- **debug**
  
  Tell the server to write debug information to the error log. The connected user must have the `SUPER` privilege. Format and content of this information is subject to change.
  
  This includes information about the Event Scheduler. See Section 24.4.5, “Event Scheduler Status”.

- **drop db_name**
  
  Delete the database named `db_name` and all its tables.

- **extended-status**
  
  Display the server status variables and their values.

- **flush-hosts**
  
  Flush all information in the host cache. See Section 8.12.4.2, “DNS Lookup Optimization and the Host Cache”.

- **flush-logs [log_type ...]**
  
  Flush all logs.
  
  The `mysqladmin flush-logs` command permits optional log types to be given, to specify which logs to flush. Following the `flush-logs` command, you can provide a space-separated list of one or more of the following log types: `binary`, `engine`, `error`, `general`, `relay`, `slow`. These correspond to the log types that can be specified for the `FLUSH LOGS` SQL statement.

- **flush-privileges**
  
  Reload the grant tables (same as `reload`).

- **flush-status**
  
  Clear status variables.

- **flush-tables**
  
  Flush all tables.

- **flush-threads**
  
  Flush the thread cache.

- **kill id,id,...**
  
  Kill server threads. If multiple thread ID values are given, there must be no spaces in the list.
  
  To kill threads belonging to other users, the connected user must have the `CONNECTION_ADMIN` or `SUPER` privilege.
**password new_password**

Set a new password. This changes the password to `new_password` for the account that you use with `mysqladmin` for connecting to the server. Thus, the next time you invoke `mysqladmin` (or any other client program) using the same account, you will need to specify the new password.

**Warning**

Setting a password using `mysqladmin` should be considered insecure. On some systems, your password becomes visible to system status programs such as `ps` that may be invoked by other users to display command lines. MySQL clients typically overwrite the command-line password argument with zeros during their initialization sequence. However, there is still a brief interval during which the value is visible. Also, on some systems this overwriting strategy is ineffective and the password remains visible to `ps`. (SystemV Unix systems and perhaps others are subject to this problem.)

If the `new_password` value contains spaces or other characters that are special to your command interpreter, you need to enclose it within quotation marks. On Windows, be sure to use double quotation marks rather than single quotation marks; single quotation marks are not stripped from the password, but rather are interpreted as part of the password. For example:

```
shell> mysqladmin password "my new password"
```

The new password can be omitted following the `password` command. In this case, `mysqladmin` prompts for the password value, which enables you to avoid specifying the password on the command line. Omitting the password value should be done only if `password` is the final command on the `mysqladmin` command line. Otherwise, the next argument is taken as the password.

**Caution**

Do not use this command used if the server was started with the `--skip-grant-tables` option. No password change will be applied. This is true even if you precede the `password` command with `flush-privileges` on the same command line to re-enable the grant tables because the flush operation occurs after you connect. However, you can use `mysqladmin flush-privileges` to re-enable the grant table and then use a separate `mysqladmin password` command to change the password.

**ping**

Check whether the server is available. The return status from `mysqladmin` is 0 if the server is running, 1 if it is not. This is 0 even in case of an error such as `Access denied`, because this means that the server is running but refused the connection, which is different from the server not running.

**processlist**

Show a list of active server threads. This is like the output of the `SHOW PROCESSLIST` statement. If the `--verbose` option is given, the output is like that of `SHOW FULL PROCESSLIST`. (See Section 13.7.6.29, “SHOW PROCESSLIST Syntax”.)

**reload**

Reload the grant tables.

**refresh**

Flush all tables and close and open log files.

**shutdown**
Stop the server.

- **start-slave**
  Start replication on a slave server.

- **status**
  Display a short server status message.

- **stop-slave**
  Stop replication on a slave server.

- **variables**
  Display the server system variables and their values.

- **version**
  Display version information from the server.

All commands can be shortened to any unique prefix. For example:

```
shell> mysqladmin proc stat
```

| Id | User  | Host      | db | Command | Time | State | Info             |
|----|-------+-----------+----+---------+------|-------+------------------|
| 51 | monty | localhost |    | Query   | 0    |       | show processlist |

Uptime: 1473624  Threads: 1  Questions: 39487
Slow queries: 0  Opens: 541  Flush tables: 1
Open tables: 19  Queries per second avg: 0.0268

The `mysqladmin status` command result displays the following values:

- **Uptime**
  The number of seconds the MySQL server has been running.

- **Threads**
  The number of active threads (clients).

- **Questions**
  The number of questions (queries) from clients since the server was started.

- **Slow queries**
  The number of queries that have taken more than `long_query_time` seconds. See Section 5.4.5, "The Slow Query Log".

- **Opens**
  The number of tables the server has opened.

- **Flush tables**
  The number of `flush-*`, `refresh`, and `reload` commands the server has executed.

- **Open tables**
The number of tables that currently are open.

If you execute `mysqladmin shutdown` when connecting to a local server using a Unix socket file, `mysqladmin` waits until the server’s process ID file has been removed, to ensure that the server has stopped properly.

`mysqladmin` supports the following options, which can be specified on the command line or in the `[mysqladmin]` and `[client]` groups of an option file. For information about option files used by MySQL programs, see Section 4.2.2.2, “Using Option Files”.

**Table 4.12 mysqladmin Options**

<table>
<thead>
<tr>
<th>Option Name</th>

<td></td>
<td></td>
</tr>
</tbody>
</table>

- **--help, -?**

Display a help message and exit.
- **--bind-address=ip_address**
  On a computer having multiple network interfaces, use this option to select which interface to use for connecting to the MySQL server.

- **--character-sets-dir=dir_name**
  The directory where character sets are installed. See Section 10.14, “Character Set Configuration”.

- **--compress, -C**
  Compress all information sent between the client and the server if possible. See Section 4.2.6, “Connection Compression Control”.

  As of MySQL 8.0.18, this option is deprecated. It will be removed in a future MySQL version. See Legacy Connection Compression Configuration.

- **--compression-algorithms=value**
  The permitted compression algorithms for connections to the server. The available algorithms are the same as for the protocol_compression_algorithms system variable. The default value is uncompressed.

  For more information, see Section 4.2.6, “Connection Compression Control”.

  This option was added in MySQL 8.0.18.

- **--count=N, -c N**
  The number of iterations to make for repeated command execution if the --sleep option is given.

- **--debug[=debug_options], -# [debug_options]**
  Write a debugging log. A typical debug_options string is d:t:o, file_name. The default is d:t:o,/tmp/mysqladmin.trace.

- **--debug-check**
  Print some debugging information when the program exits.

- **--debug-info**
  Print debugging information and memory and CPU usage statistics when the program exits.

- **--default-auth=plugin**
  A hint about which client-side authentication plugin to use. See Section 6.2.17, “Pluggable Authentication”.

- **--default-character-set=charset_name**
  Use charset_name as the default character set. See Section 10.14, “Character Set Configuration”.

- **--defaults-extra-file=file_name**
  Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. file_name is interpreted relative to the current directory if given as a relative path name rather than a full path name.

  For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- **--defaults-file=file_name**
Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. `file_name` is interpreted relative to the current directory if given as a relative path name rather than a full path name.

**Exception:** Even with `--defaults-file`, client programs read `.mylogin.cnf`.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

• `--defaults-group-suffix=str`

Read not only the usual option groups, but also groups with the usual names and a suffix of `str`. For example, `mysqladmin` normally reads the `[client]` and `[mysqladmin]` groups. If the `--defaults-group-suffix=_other` option is given, `mysqladmin` also reads the `[client_other]` and `[mysqladmin_other]` groups.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

• `--enable-cleartext-plugin`

Enable the `mysql_clear_password` cleartext authentication plugin. (See Section 6.4.1.4, “Client-Side Cleartext Pluggable Authentication”.)

• `--force, -f`

Do not ask for confirmation for the `drop db_name` command. With multiple commands, continue even if an error occurs.

• `--get-server-public-key`

Request from the server the public key required for RSA key pair-based password exchange. This option applies to clients that authenticate with the `caching_sha2_password` authentication plugin. For that plugin, the server does not send the public key unless requested. This option is ignored for accounts that do not authenticate with that plugin. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

If `--server-public-key-path=file_name` is given and specifies a valid public key file, it takes precedence over `--get-server-public-key`.

For information about the `caching_sha2_password` plugin, see Section 6.4.1.3, “Caching SHA-2 Pluggable Authentication”.

• `--host=host_name, -h host_name`

Connect to the MySQL server on the given host.

• `--login-path=name`

Read options from the named login path in the `.mylogin.cnf` login path file. A “login path” is an option group containing options that specify which MySQL server to connect to and which account to authenticate as. To create or modify a login path file, use the `mysql_config_editor` utility. See Section 4.6.7, “mysql_config_editor — MySQL Configuration Utility”.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

• `--no-beep, -b`
Suppress the warning beep that is emitted by default for errors such as a failure to connect to the server.

• --no-defaults

Do not read any option files. If program startup fails due to reading unknown options from an option file, --no-defaults can be used to prevent them from being read.

The exception is that the .mylogin.cnf file, if it exists, is read in all cases. This permits passwords to be specified in a safer way than on the command line even when --no-defaults is used. (.mylogin.cnf is created by the mysql_config_editor utility. See Section 4.6.7, “mysql_config_editor — MySQL Configuration Utility”.)

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

• --password[=password], -p [password]

The password of the MySQL account used for connecting to the server. The password value is optional. If not given, mysqladmin prompts for one. If given, there must be no space between --password= or -p and the password following it. If no password option is specified, the default is to send no password.

Specifying a password on the command line should be considered insecure. To avoid giving the password on the command line, use an option file. See Section 6.1.2.1, “End-User Guidelines for Password Security”.

To explicitly specify that there is no password and that mysqladmin should not prompt for one, use the --skip-password option.

• --pipe, -W

On Windows, connect to the server using a named pipe. This option applies only if the server was started with the named_pipe system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the named_pipe_full_access_group system variable.

• --plugin-dir=dir_name

The directory in which to look for plugins. Specify this option if the --default-auth option is used to specify an authentication plugin but mysqladmin does not find it. See Section 6.2.17, “Pluggable Authentication”.

• --port=port_num, -P port_num

For TCP/IP connections, the port number to use.

• --print-defaults

Print the program name and all options that it gets from option files.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

• --protocol={TCP|SOCKET|PIPE|MEMORY}

The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally result in use of a protocol other than the one you want. For details on the permissible values, see Section 4.2.4, “Connecting to the MySQL Server Using Command Options”.

• --relative, -r
Show the difference between the current and previous values when used with the `--sleep` option. This option works only with the `extended-status` command.

- `--secure-auth`

This option was removed in MySQL 8.0.3.

- `--server-public-key-path=file_name`

The path name to a file containing a client-side copy of the public key required by the server for RSA key pair-based password exchange. The file must be in PEM format. This option applies to clients that authenticate with the `sha256_password` or `caching_sha2_password` authentication plugin. This option is ignored for accounts that do not authenticate with one of those plugins. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

If `--server-public-key-path=file_name` is given and specifies a valid public key file, it takes precedence over `--get-server-public-key`.

For `sha256_password`, this option applies only if MySQL was built using OpenSSL.

For information about the `sha256_password` and `caching_sha2_password` plugins, see Section 6.4.1.2, “SHA-256 Pluggable Authentication”, and Section 6.4.1.3, “Caching SHA-2 Pluggable Authentication”.

- `--shared-memory-base-name=name`

On Windows, the shared-memory name to use for connections made using shared memory to a local server. The default value is `MYSQL`. The shared-memory name is case-sensitive.

This option applies only if the server was started with the `shared_memory` system variable enabled to support shared-memory connections.

- `--show-warnings`

Show warnings resulting from execution of statements sent to the server.

- `--silent, -s`

Exit silently if a connection to the server cannot be established.

- `--sleep=delay, -i delay`

Execute commands repeatedly, sleeping for `delay` seconds in between. The `--count` option determines the number of iterations. If `--count` is not given, `mysqladmin` executes commands indefinitely until interrupted.

- `--socket=path, -S path`

For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

On Windows, this option applies only if the server was started with the `named_pipe` system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the `named_pipe_full_access_group` system variable.

- `--ssl*`

Options that begin with `--ssl` specify whether to connect to the server using SSL and indicate where to find SSL keys and certificates. See Command Options for Encrypted Connections.
mysqladmin — Client for Administering a MySQL Server

- **--ssl-fips-mode={OFF|ON|STRICT}**

  Controls whether to enable FIPS mode on the client side. The `--ssl-fips-mode` option differs from other `--ssl-xxx` options in that it is not used to establish encrypted connections, but rather to affect which cryptographic operations are permitted. See Section 6.5, "FIPS Support".

  These `--ssl-fips-mode` values are permitted:
  - **OFF**: Disable FIPS mode.
  - **ON**: Enable FIPS mode.
  - **STRICT**: Enable “strict” FIPS mode.

  **Note**

  If the OpenSSL FIPS Object Module is not available, the only permitted value for `--ssl-fips-mode` is OFF. In this case, setting `--ssl-fips-mode` to ON or STRICT causes the client to produce a warning at startup and to operate in non-FIPS mode.

- **--tls-ciphersuites=ciphersuite_list**

  The permissible TLSv1.3 ciphersuites for encrypted connections. The value is a list of one or more colon-separated ciphersuite names. The ciphersuites that can be named for this option depend on the SSL library used to compile MySQL. For details, see Section 6.3.5, "Encrypted Connection Protocols and Ciphers".

  This option was added in MySQL 8.0.16.

- **--tls-version=protocol_list**

  The permissible TLS protocols for encrypted connections. The value is a list of one or more comma-separated protocol names. The protocols that can be named for this option depend on the SSL library used to compile MySQL. For details, see Section 6.3.5, "Encrypted Connection Protocols and Ciphers".

- **--user=user_name, -u user_name**

  The user name of the MySQL account to use for connecting to the server.

- **--verbose, -v**

  Verbose mode. Print more information about what the program does.

- **--version, -V**

  Display version information and exit.

- **--vertical, -E**

  Print output vertically. This is similar to `--relative`, but prints output vertically.

- **--wait[=count], -w[count]**

  If the connection cannot be established, wait and retry instead of aborting. If a `count` value is given, it indicates the number of times to retry. The default is one time.

- **--zstd-compression-level=level**

  The compression level to use for connections to the server that use the zstd compression algorithm. The permitted levels are from 1 to 22, with larger values indicating increasing levels of compression.
The default `zstd` compression level is 3. The compression level setting has no effect on connections that do not use `zstd` compression.

For more information, see Section 4.2.6, “Connection Compression Control”.

This option was added in MySQL 8.0.18.

You can also set the following variables by using `--var_name=value`.

- `connect_timeout`
  The maximum number of seconds before connection timeout. The default value is 43200 (12 hours).
- `shutdown_timeout`
  The maximum number of seconds to wait for server shutdown. The default value is 3600 (1 hour).

**4.5.3 mysqlcheck — A Table Maintenance Program**

The `mysqlcheck` client performs table maintenance: It checks, repairs, optimizes, or analyzes tables.

Each table is locked and therefore unavailable to other sessions while it is being processed, although for check operations, the table is locked with a **READ** lock only (see Section 13.3.6, “LOCK TABLES and UNLOCK TABLES Syntax”, for more information about **READ** and **WRITE** locks).

Table maintenance operations can be time-consuming, particularly for large tables. If you use the `--databases` or `--all-databases` option to process all tables in one or more databases, an invocation of `mysqlcheck` might take a long time. (This is also true for the MySQL upgrade procedure if it determines that table checking is needed because it processes tables the same way.)

`mysqlcheck` must be used when the `mysqld` server is running, which means that you do not have to stop the server to perform table maintenance.

`mysqlcheck` uses the SQL statements `CHECK TABLE`, `REPAIR TABLE`, `ANALYZE TABLE`, and `OPTIMIZE TABLE` in a convenient way for the user. It determines which statements to use for the operation you want to perform, and then sends the statements to the server to be executed. For details about which storage engines each statement works with, see the descriptions for those statements in Section 13.7.3, “Table Maintenance Statements”.

All storage engines do not necessarily support all four maintenance operations. In such cases, an error message is displayed. For example, if `test.t` is an `MEMORY` table, an attempt to check it produces this result:

```shell
shell> mysqlcheck test t
test.t
note : The storage engine for the table doesn't support check
```

If `mysqlcheck` is unable to repair a table, see Section 2.11.13, “Rebuilding or Repairing Tables or Indexes” for manual table repair strategies. This will be the case, for example, for InnoDB tables, which can be checked with `CHECK TABLE`, but not repaired with `REPAIR TABLE`.

**Caution**

It is best to make a backup of a table before performing a table repair operation; under some circumstances the operation might cause data loss. Possible causes include but are not limited to file system errors.

There are three general ways to invoke `mysqlcheck`:

- `shell> mysqlcheck [options] db_name [tbl_name ...]`
- `shell> mysqlcheck [options] --databases db_name ...`
- `shell> mysqlcheck [options] --all-databases`
If you do not name any tables following `db_name` or if you use the `--databases` or `--all-databases` option, entire databases are checked.

`mysqlcheck` has a special feature compared to other client programs. The default behavior of checking tables (`--check`) can be changed by renaming the binary. If you want to have a tool that repairs tables by default, you should just make a copy of `mysqlcheck` named `mysqlrepair`, or make a symbolic link to `mysqlcheck` named `mysqlrepair`. If you invoke `mysqlrepair`, it repairs tables.

The names shown in the following table can be used to change `mysqlcheck` default behavior.

<table>
<thead>
<tr>
<th>Command</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>mysqlrepair</code></td>
<td>The default option is <code>--repair</code></td>
</tr>
<tr>
<td><code>mysqlanalyze</code></td>
<td>The default option is <code>--analyze</code></td>
</tr>
<tr>
<td><code>mysqloptimize</code></td>
<td>The default option is <code>--optimize</code></td>
</tr>
</tbody>
</table>

`mysqlcheck` supports the following options, which can be specified on the command line or in the `[mysqlcheck]` and `[client]` groups of an option file. For information about option files used by MySQL programs, see Section 4.2.2.2, “Using Option Files”.

### Table 4.13 mysqlcheck Options

<table>
<thead>
<tr>
<th>Option Name</th>
<th>Description</th>
<th>Introduced</th>
<th>Deprecated</th>
<th>Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--all-databases</code></td>
<td>Check all tables in all databases</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--all-in-1</code></td>
<td>Execute a single statement for each database that names all the tables from that database</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--analyze</code></td>
<td>Analyze the tables</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--auto-repair</code></td>
<td>If a checked table is corrupted, automatically fix it</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--bind-address</code></td>
<td>Use specified network interface to connect to MySQL Server</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--character-sets-dir</code></td>
<td>Directory where character sets are installed</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--check</code></td>
<td>Check the tables for errors</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--check-only-changed</code></td>
<td>Check only tables that have changed since the last check</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--check-upgrade</code></td>
<td>Invoke CHECK TABLE with the FOR UPGRADE option</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--compress</code></td>
<td>Compress all information sent between client and server</td>
<td></td>
<td>8.0.18</td>
<td></td>
</tr>
<tr>
<td><code>--compression-algorithms</code></td>
<td>Permitted compression algorithms for connections to server</td>
<td></td>
<td>8.0.18</td>
<td></td>
</tr>
<tr>
<td><code>--databases</code></td>
<td>Interpret all arguments as database names</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--debug</code></td>
<td>Write debugging log</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--debug-check</code></td>
<td>Print debugging information when program exits</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--debug-info</code></td>
<td>Print debugging information, memory, and CPU statistics when program exits</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--default-auth</code></td>
<td>Authentication plugin to use</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--default-character-set</code></td>
<td>Specify default character set</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--defaults-extra-file</code></td>
<td>Read named option file in addition to usual option files</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Option Name</td>
<td>Description</td>
<td>Introduced</td>
<td>Deprecated</td>
<td>Removed</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>---------------------------------------------------------------</td>
<td>------------</td>
<td>------------</td>
<td>---------</td>
</tr>
<tr>
<td><code>--defaults-file</code></td>
<td>Read only named option file</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--defaults-group-suffix</code></td>
<td>Option group suffix value</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--enable-cleartext-plugin</code></td>
<td>Enable cleartext authentication plugin</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--extended</code></td>
<td>Check and repair tables</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--fast</code></td>
<td>Check only tables that have not been closed properly</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--force</code></td>
<td>Continue even if an SQL error occurs</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--get-server-public-key</code></td>
<td>Request RSA public key from server</td>
<td>8.0.3</td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--help</code></td>
<td>Display help message and exit</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--host</code></td>
<td>Host on which MySQL server is located</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--login-path</code></td>
<td>Read login path options from .mylogin.cnf</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--medium-check</code></td>
<td>Do a check that is faster than an <code>--extended</code> operation</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--no-defaults</code></td>
<td>Read no option files</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--optimize</code></td>
<td>Optimize the tables</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--password</code></td>
<td>Password to use when connecting to server</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--pipe</code></td>
<td>Connect to server using named pipe</td>
<td>(Windows only)</td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--plugin-dir</code></td>
<td>Directory where plugins are installed</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--port</code></td>
<td>TCP/IP port number for connection</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--print-defaults</code></td>
<td>Print default options</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--protocol</code></td>
<td>Connection protocol to use</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--quick</code></td>
<td>The fastest method of checking</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--repair</code></td>
<td>Perform a repair that can fix almost anything except unique keys that are not unique</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--secure-auth</code></td>
<td>Do not send passwords to server in old (pre-4.1) format</td>
<td>8.0.3</td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--server-public-key-path</code></td>
<td>Path name to file containing RSA public key</td>
<td>8.0.4</td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--shared-memory-base-name</code></td>
<td>Name of shared memory to use for shared-memory connections</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--silent</code></td>
<td>Silent mode</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--skip-database</code></td>
<td>Omit this database from performed operations</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--socket</code></td>
<td>Unix socket file or Windows named pipe to use</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--ssl-ca</code></td>
<td>File that contains list of trusted SSL Certificate Authorities</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--ssl-capath</code></td>
<td>Directory that contains trusted SSL Certificate Authority certificate files</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--ssl-cert</code></td>
<td>File that contains X.509 certificate</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--ssl-cipher</code></td>
<td>Permissible ciphers for connection encryption</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--ssl-crl</code></td>
<td>File that contains certificate revocation lists</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--ssl-crlpath</code></td>
<td>Directory that contains certificate revocation-list files</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Option Name</td>
<td>Description</td>
<td>Introduced</td>
<td>Deprecated</td>
<td>Removed</td>
</tr>
<tr>
<td>--------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>------------</td>
<td>------------</td>
<td>---------</td>
</tr>
<tr>
<td>--ssl-fips-mode</td>
<td>Whether to enable FIPS mode on client side</td>
<td>8.0.11</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--ssl-key</td>
<td>File that contains X.509 key</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--ssl-mode</td>
<td>Desired security state of connection to server</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--tables</td>
<td>Overrides the --databases or -B option</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--tls-ciphersuites</td>
<td>Permissible TLSv1.3 ciphersuites for encrypted connections</td>
<td>8.0.16</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--tls-version</td>
<td>Permissible TLS protocols for encrypted connections</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--use frm</td>
<td>For repair operations on MyISAM tables</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--user</td>
<td>MySQL user name to use when connecting to server</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--verbose</td>
<td>Verbose mode</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--version</td>
<td>Display version information and exit</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--write-binlog</td>
<td>Log ANALYZE, OPTIMIZE, REPAIR statements to binary log. --skip-write-binlog adds NO_WRITE_TO_BINLOG to these statements.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--zstd-compression-level</td>
<td>Compression level for connections to server that use zstd compression</td>
<td>8.0.18</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

- **--help, --?**
  
  Display a help message and exit.

- **--all-databases, -A**
  
  Check all tables in all databases. This is the same as using the --databases option and naming all the databases on the command line, except that the INFORMATION_SCHEMA and performance_schema databases are not checked. They can be checked by explicitly naming them with the --databases option.

- **--all-in-1, -1**
  
  Instead of issuing a statement for each table, execute a single statement for each database that names all the tables from that database to be processed.

- **--analyze, -a**
  
  Analyze the tables.

- **--auto-repair**
  
  If a checked table is corrupted, automatically fix it. Any necessary repairs are done after all tables have been checked.

- **--bind-address=ip_address**
  
  On a computer having multiple network interfaces, use this option to select which interface to use for connecting to the MySQL server.

- **--character-sets-dir=dir_name**
  
  The directory where character sets are installed. See Section 10.14, “Character Set Configuration”.

- **--check, -c**
Check the tables for errors. This is the default operation.

- **--check-only-changed, -C**
  Check only tables that have changed since the last check or that have not been closed properly.

- **--check-upgrade, -g**
  Invoke `CHECK TABLE` with the `FOR UPGRADE` option to check tables for incompatibilities with the current version of the server.

- **--compress**
  Compress all information sent between the client and the server if possible. See Section 4.2.6, “Connection Compression Control”.

  As of MySQL 8.0.18, this option is deprecated. It will be removed in a future MySQL version. See Legacy Connection Compression Configuration.

- **--compression-algorithms=value**
  The permitted compression algorithms for connections to the server. The available algorithms are the same as for the `protocol_compression_algorithms` system variable. The default value is uncompressed.

  For more information, see Section 4.2.6, “Connection Compression Control”.

  This option was added in MySQL 8.0.18.

- **--databases, -B**
  Process all tables in the named databases. Normally, `mysqlcheck` treats the first name argument on the command line as a database name and any following names as table names. With this option, it treats all name arguments as database names.

- **--debug[=debug_options], -# [debug_options]**
  Write a debugging log. A typical `debug_options` string is `d:t:o, file_name`. The default is `d:t:o`.

- **--debug-check**
  Print some debugging information when the program exits.

- **--debug-info**
  Print debugging information and memory and CPU usage statistics when the program exits.

- **--default-character-set=charset_name**
  Use `charset_name` as the default character set. See Section 10.14, “Character Set Configuration”.

- **--defaults-extra-file=file_name**
  Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. `file_name` is interpreted relative to the current directory if given as a relative path name rather than a full path name.

  For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- **--defaults-file=file_name**
Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. `file_name` is interpreted relative to the current directory if given as a relative path name rather than a full path name.

Exception: Even with `--defaults-file`, client programs read `.mylogin.cnf`.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- `--defaults-group-suffix=...`

  Read not only the usual option groups, but also groups with the usual names and a suffix of `str`. For example, `mysqlcheck` normally reads the `[client]` and `[mysqlcheck]` groups. If the `--defaults-group-suffix=_other` option is given, `mysqlcheck` also reads the `[client_other]` and `[mysqlcheck_other]` groups.

  For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- `--extended, -e`

  If you are using this option to check tables, it ensures that they are 100% consistent but takes a long time.

  If you are using this option to repair tables, it runs an extended repair that may not only take a long time to execute, but may produce a lot of garbage rows also!

- `--default-auth=plugin`

  A hint about which client-side authentication plugin to use. See Section 6.2.17, “Pluggable Authentication”.

- `--enable-cleartext-plugin`

  Enable the `mysql_clear_password` cleartext authentication plugin. (See Section 6.4.1.4, “Client-Side Cleartext Pluggable Authentication”.)

- `--fast, -F`

  Check only tables that have not been closed properly.

- `--force, -f`

  Continue even if an SQL error occurs.

- `--get-server-public-key`

  Request from the server the public key required for RSA key pair-based password exchange. This option applies to clients that authenticate with the `caching_sha2_password` authentication plugin. For that plugin, the server does not send the public key unless requested. This option is ignored for accounts that do not authenticate with that plugin. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

  If `--server-public-key-path=file_name` is given and specifies a valid public key file, it takes precedence over `--get-server-public-key`.

  For information about the `caching_sha2_password` plugin, see Section 6.4.1.3, “Caching SHA-2 Pluggable Authentication”.

- `--host=host_name, -h host_name`
Connect to the MySQL server on the given host.

- **--login-path=name**

Read options from the named login path in the .mylogin.cnf login path file. A “login path” is an option group containing options that specify which MySQL server to connect to and which account to authenticate as. To create or modify a login path file, use the mysql_config_editor utility. See Section 4.6.7, "mysql_config_editor — MySQL Configuration Utility".

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- **--medium-check, -m**

Do a check that is faster than an --extended operation. This finds only 99.99% of all errors, which should be good enough in most cases.

- **--no-defaults**

Do not read any option files. If program startup fails due to reading unknown options from an option file, --no-defaults can be used to prevent them from being read.

The exception is that the .mylogin.cnf file, if it exists, is read in all cases. This permits passwords to be specified in a safer way than on the command line even when --no-defaults is used. (.mylogin.cnf is created by the mysql_config_editor utility. See Section 4.6.7, "mysql_config_editor — MySQL Configuration Utility".)

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- **--optimize, -o**

Optimize the tables.

- **--password[=password], -p[password]**

The password of the MySQL account used for connecting to the server. The password value is optional. If not given, mysqlcheck prompts for one. If given, there must be no space between --password= or -p and the password following it. If no password option is specified, the default is to send no password.

Specifying a password on the command line should be considered insecure. To avoid giving the password on the command line, use an option file. See Section 6.1.2.1, "End-User Guidelines for Password Security".

To explicitly specify that there is no password and that mysqlcheck should not prompt for one, use the --skip-password option.

- **--pipe, -W**

On Windows, connect to the server using a named pipe. This option applies only if the server was started with the named_pipe system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the named_pipe_full_access_group system variable.

- **--plugin-dir=dir_name**

The directory in which to look for plugins. Specify this option if the --default-auth option is used to specify an authentication plugin but mysqlcheck does not find it. See Section 6.2.17, “Pluggable Authentication”.
• **--port=port_num, -P port_num**
  
  For TCP/IP connections, the port number to use.

• **--print-defaults**
  
  Print the program name and all options that it gets from option files.

  For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

• **--protocol={TCP|SOCKET|PIPE|MEMORY}**
  
  The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally result in use of a protocol other than the one you want. For details on the permissible values, see Section 4.2.4, “Connecting to the MySQL Server Using Command Options”.

• **--quick, -q**
  
  If you are using this option to check tables, it prevents the check from scanning the rows to check for incorrect links. This is the fastest check method.

  If you are using this option to repair tables, it tries to repair only the index tree. This is the fastest repair method.

• **--repair, -r**
  
  Perform a repair that can fix almost anything except unique keys that are not unique.

• **--secure-auth**
  
  This option was removed in MySQL 8.0.3.

• **--server-public-key-path=file_name**
  
  The path name to a file containing a client-side copy of the public key required by the server for RSA key pair-based password exchange. The file must be in PEM format. This option applies to clients that authenticate with the sha256_password or caching_sha2_password authentication plugin. This option is ignored for accounts that do not authenticate with one of those plugins. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

  If **--server-public-key-path=file_name** is given and specifies a valid public key file, it takes precedence over **--get-server-public-key**.

  For sha256_password, this option applies only if MySQL was built using OpenSSL.

  For information about the sha256_password and caching_sha2_password plugins, see Section 6.4.1.2, “SHA-256 Pluggable Authentication”, and Section 6.4.1.3, “Caching SHA-2 Pluggable Authentication”.

• **--shared-memory-base-name=name**
  
  On Windows, the shared-memory name to use for connections made using shared memory to a local server. The default value is MYSQL. The shared-memory name is case-sensitive.

  This option applies only if the server was started with the shared_memory system variable enabled to support shared-memory connections.

• **--silent, -s**
  
  Silent mode. Print only error messages.
• **--skip-database=**db_name

Do not include the named database (case-sensitive) in the operations performed by `mysqlcheck`.

• **--socket=path,** `-S path`

For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

On Windows, this option applies only if the server was started with the `named_pipe` system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the `named_pipe_full_access_group` system variable.

• **--ssl**

Options that begin with `--ssl` specify whether to connect to the server using SSL and indicate where to find SSL keys and certificates. See Command Options for Encrypted Connections.

• **--ssl-fips-mode={OFF|ON|STRICT}**

Controls whether to enable FIPS mode on the client side. The `--ssl-fips-mode` option differs from other `--ssl-xxx` options in that it is not used to establish encrypted connections, but rather to affect which cryptographic operations are permitted. See Section 6.5, “FIPS Support”.

These `--ssl-fips-mode` values are permitted:

- **OFF**: Disable FIPS mode.
- **ON**: Enable FIPS mode.
- **STRICT**: Enable “strict” FIPS mode.

**Note**

If the OpenSSL FIPS Object Module is not available, the only permitted value for `--ssl-fips-mode` is **OFF**. In this case, setting `--ssl-fips-mode` to **ON** or **STRICT** causes the client to produce a warning at startup and to operate in non-FIPS mode.

• **--tables**

Override the `--databases` or `-B` option. All name arguments following the option are regarded as table names.

• **--tls-ciphersuites=ciphersuite_list**

The permissible TLSv1.3 ciphersuites for encrypted connections. The value is a list of one or more colon-separated ciphersuite names. The ciphersuites that can be named for this option depend on the SSL library used to compile MySQL. For details, see Section 6.3.5, “Encrypted Connection Protocols and Ciphers”.

This option was added in MySQL 8.0.16.

• **--tls-version=protocol_list**

The permissible TLS protocols for encrypted connections. The value is a list of one or more comma-separated protocol names. The protocols that can be named for this option depend on the SSL library used to compile MySQL. For details, see Section 6.3.5, “Encrypted Connection Protocols and Ciphers”.

• **--use frm**
For repair operations on MyISAM tables, get the table structure from the data dictionary so that the table can be repaired even if the .MYI header is corrupted.

- **--user=user_name, -u user_name**
  The user name of the MySQL account to use for connecting to the server.

- **--verbose, -v**
  Verbose mode. Print information about the various stages of program operation.

- **--version, -V**
  Display version information and exit.

- **--write-binlog**
  This option is enabled by default, so that ANALYZE TABLE, OPTIMIZE TABLE, and REPAIR TABLE statements generated by mysqlcheck are written to the binary log. Use --skip-write-binlog to cause NO_WRITE_TO_BINLOG to be added to the statements so that they are not logged. Use the --skip-write-binlog when these statements should not be sent to replication slaves or run when using the binary logs for recovery from backup.

- **--zstd-compression-level=level**
  The compression level to use for connections to the server that use the zstd compression algorithm. The permitted levels are from 1 to 22, with larger values indicating increasing levels of compression. The default zstd compression level is 3. The compression level setting has no effect on connections that do not use zstd compression.

  For more information, see Section 4.2.6, “Connection Compression Control”.

This option was added in MySQL 8.0.18.

### 4.5.4 mysqldump — A Database Backup Program

The mysqldump client utility performs logical backups, producing a set of SQL statements that can be executed to reproduce the original database object definitions and table data. It dumps one or more MySQL databases for backup or transfer to another SQL server. The mysqldump command can also generate output in CSV, other delimited text, or XML format.

- **Performance and Scalability Considerations**
- **Invocation Syntax**
- **Option Syntax - Alphabetical Summary**
- **Connection Options**
- **Option-File Options**
- **DDL Options**
- **Debug Options**
- **Help Options**
- **Internationalization Options**
- **Replication Options**
- **Format Options**
- **Filtering Options**
Performance and Scalability Considerations

myqldump advantages include the convenience and flexibility of viewing or even editing the output before restoring. You can clone databases for development and DBA work, or produce slight variations of an existing database for testing. It is not intended as a fast or scalable solution for backing up substantial amounts of data. With large data sizes, even if the backup step takes a reasonable time, restoring the data can be very slow because replaying the SQL statements involves disk I/O for insertion, index creation, and so on.

For large-scale backup and restore, a physical backup is more appropriate, to copy the data files in their original format that can be restored quickly:

- If your tables are primarily InnoDB tables, or if you have a mix of InnoDB and MyISAM tables, consider using the mysqlbackup command of the MySQL Enterprise Backup product. (Available as part of the Enterprise subscription.) It provides the best performance for InnoDB backups with minimal disruption; it can also back up tables from MyISAM and other storage engines; and it provides a number of convenient options to accommodate different backup scenarios. See Section 30.2, “MySQL Enterprise Backup Overview”.

myqldump can retrieve and dump table contents row by row, or it can retrieve the entire content from a table and buffer it in memory before dumping it. Buffering in memory can be a problem if you are dumping large tables. To dump tables row by row, use the --quick option (or --opt, which enables --quick). The --opt option (and hence --quick) is enabled by default, so to enable memory buffering, use --skip-quick.

If you are using a recent version of myqldump to generate a dump to be reloaded into a very old MySQL server, use the --skip-opt option instead of the --opt or --extended-insert option.
For additional information about mysqldump, see Section 7.4, “Using mysqldump for Backups”.

**Invocation Syntax**

There are in general three ways to use `mysqldump`—in order to dump a set of one or more tables, a set of one or more complete databases, or an entire MySQL server—as shown here:

```
shell> mysqldump [options] db_name [tbl_name ...]
shell> mysqldump [options] --databases db_name ...
shell> mysqldump [options] --all-databases
```

To dump entire databases, do not name any tables following `db_name`, or use the `--databases` or `--all-databases` option.

To see a list of the options your version of `mysqldump` supports, issue the command `mysqldump --help`.

**Option Syntax - Alphabetical Summary**

`mysqldump` supports the following options, which can be specified on the command line or in the `[mysqldump]` and `[client]` groups of an option file. For information about option files used by MySQL programs, see Section 4.2.2.2, “Using Option Files”.

**Table 4.14 mysqldump Options**

<table>
<thead>
<tr>
<th>Option Name</th>
<th>Description</th>
<th>Introduced</th>
<th>Deprecated</th>
<th>Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--add-drop-database</td>
<td>Add DROP DATABASE statement before each CREATE DATABASE statement</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--add-drop-table</td>
<td>Add DROP TABLE statement before each CREATE TABLE statement</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--add-drop-trigger</td>
<td>Add DROP TRIGGER statement before each CREATE TRIGGER statement</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--add-locks</td>
<td>Surround each table dump with LOCK TABLES and UNLOCK TABLES statements</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--all-databases</td>
<td>Dump all tables in all databases</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--allow-keywords</td>
<td>Allow creation of column names that are keywords</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--apply-slave-statements</td>
<td>Include STOP SLAVE prior to CHANGE MASTER statement and START SLAVE at end of output</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--bind-address</td>
<td>Use specified network interface to connect to MySQL Server</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--character-sets-dir</td>
<td>Directory where character sets are installed</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--column-statistics</td>
<td>Write ANALYZE TABLE statements to generate statistics histograms</td>
<td>8.0.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--comments</td>
<td>Add comments to dump file</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--compact</td>
<td>Produce more compact output</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--compatible</td>
<td>Produce output that is more compatible with other database systems or with older MySQL servers</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--complete-insert</td>
<td>Use complete INSERT statements that include column names</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--compress</td>
<td>Compress all information sent between client and server</td>
<td>8.0.18</td>
<td></td>
<td></td>
</tr>
<tr>

<tr>
<td>--defaults-file</td>
<td>Read only named option file</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--defaults-group-suffix</td>
<td>Option group suffix value</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--delete-master-logs</td>
<td>On a master replication server, delete the binary logs after performing the dump operation</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--disable-keys</td>
<td>For each table, surround INSERT statements with statements to disable and enable keys</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--dump-date</td>
<td>Include dump date as &quot;Dump completed on&quot; comment if --comments is given</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--dump-slave</td>
<td>Include CHANGE MASTER statement that lists binary log coordinates of slave's master</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--enable-cleartext-plugin</td>
<td>Enable cleartext authentication plugin</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--events</td>
<td>Dump events from dumped databases</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--extended-insert</td>
<td>Use multiple-row INSERT syntax</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--fields-enclosed-by</td>
<td>This option is used with the --tab option and has the same meaning as the corresponding clause for LOAD DATA</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--fields-escaped-by</td>
<td>This option is used with the --tab option and has the same meaning as the corresponding clause for LOAD DATA</td>
<td></td>
<td></td>
<td></td>

<tr>
<td>--insert-ignore</td>
<td>Write INSERT IGNORE rather than INSERT statements</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--lines-terminated-by</td>
<td>This option is used with the --tab option and has the same meaning as</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>the corresponding clause for LOAD DATA</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--lock-all-tables</td>
<td>Lock all tables across all databases</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--lock-tables</td>
<td>Lock all tables before dumping them</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--log-error</td>
<td>Append warnings and errors to named file</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--login-path</td>
<td>Read login path options from .mylogin.cnf</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--master-data</td>
<td>Write the binary log file name and position to the output</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--max-allowed-packet</td>
<td>Maximum packet length to send to or receive from server</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--net-buffer-length</td>
<td>Buffer size for TCP/IP and socket communication</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--network-timeout</td>
<td>Increase network timeouts to permit larger table dumps</td>
<td></td>
<td></td>
<td>8.0.1</td>
</tr>
<tr>
<td>--no-autocommit</td>
<td>Enclose the INSERT statements for each dumped table within SET autocommit =</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>0 and COMMIT statements</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--no-create-db</td>
<td>Do not write CREATE DATABASE statements</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--no-create-info</td>
<td>Do not write CREATE TABLE statements that re-create each dumped table</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--no-data</td>
<td>Do not dump table contents</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--no-defaults</td>
<td>Read no option files</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--no-set-names</td>
<td>Same as --skip-set-charset</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--no-tablespaces</td>
<td>Do not write any CREATE LOGFILE GROUP or CREATE TABLESPACE statements in</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>output</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--opt</td>
<td>Shorthand for --add-drop-table --add-locks --create-options --disable-keys</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>--extended-insert --lock-tables --quick --set-charset.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--order-by-primary</td>
<td>Dump each table's rows sorted by its primary key, or by its first unique</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>index</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--password</td>
<td>Password to use when connecting to server</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Option Name</td>
<td>Description</td>
<td>Introduced</td>
<td>Deprecated</td>
<td>Removed</td>
</tr>
<tr>
<td>----------------</td>
<td>------------------------------------------------------------------------------</td>
<td>------------</td>
<td>------------</td>
<td>---------</td>
</tr>
<tr>
<td>--pipe</td>
<td>Connect to server using named pipe (Windows only)</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--plugin-dir</td>
<td>Directory where plugins are installed</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--port</td>
<td>TCP/IP port number for connection</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--print-defaults</td>
<td>Print default options</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--protocol</td>
<td>Connection protocol to use</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--quick</td>
<td>Retrieve rows for a table from the server a row at a time</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--quote-names</td>
<td>Quote identifiers within backtick characters</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--replace</td>
<td>Write REPLACE statements rather than INSERT statements</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--result-file</td>
<td>Direct output to a given file</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--routines</td>
<td>Dump stored routines (procedures and functions) from dumped databases</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--secure-auth</td>
<td>Do not send passwords to server in old (pre-4.1) format</td>
<td>8.0.3</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--server-public-key-path</td>
<td>Path name to file containing RSA public key</td>
<td>8.0.4</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--set-charset</td>
<td>Add SET NAMES default_character_set to output</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--set-gtid-purged</td>
<td>Whether to add SET @@GLOBAL.GTID_PURGED to output</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--shared-memory-base-name</td>
<td>Name of shared memory to use for shared-memory connections</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--single-transaction</td>
<td>Issue a BEGIN SQL statement before dumping data from server</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--skip-add-drop-table</td>
<td>Do not add a DROP TABLE statement before each CREATE TABLE statement</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--skip-add-locks</td>
<td>Do not add locks</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--skip-comments</td>
<td>Do not add comments to dump file</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--skip-compact</td>
<td>Do not produce more compact output</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--skip-disable-keys</td>
<td>Do not disable keys</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--skip-extended-insert</td>
<td>Turn off extended-insert</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--skip-opt</td>
<td>Turn off options set by --opt</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--skip-quick</td>
<td>Do not retrieve rows for a table from the server a row at a time</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--skip-quote-names</td>
<td>Do not quote identifiers</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--skip-set-charset</td>
<td>Do not write SET NAMES statement</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--skip-triggers</td>
<td>Do not dump triggers</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--skip-tz-utc</td>
<td>Turn off tz-utc</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--socket</td>
<td>Unix socket file or Windows named pipe to use</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--ssl-ca</td>
<td>File that contains list of trusted SSL Certificate Authorities</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--ssl-capath</td>
<td>Directory that contains trusted SSL Certificate Authority certificate files</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
### Connection Options

The *mysqldump* command logs into a MySQL server to extract information. The following options specify how to connect to the MySQL server, either on the same machine or a remote system.

- **--bind-address=ip_address**
  On a computer having multiple network interfaces, use this option to select which interface to use for connecting to the MySQL server.

- **--compress, -C**
  Compress all information sent between the client and the server if possible. See Section 4.2.6, “Connection Compression Control”.

As of MySQL 8.0.18, this option is deprecated. It will be removed in a future MySQL version. See Legacy Connection Compression Configuration.

- **--compression-algorithms=value**
  The permitted compression algorithms for connections to the server. The available algorithms are the same as for the `protocol_compression_algorithms` system variable. The default value is uncompressed.

For more information, see Section 4.2.6, “Connection Compression Control”.

</tbody>
</table>
This option was added in MySQL 8.0.18.

- **--default-auth=plugin**
  A hint about which client-side authentication plugin to use. See Section 6.2.17, “Pluggable Authentication”.

- **--enable-cleartext-plugin**
  Enable the `mysql_clear_password` cleartext authentication plugin. (See Section 6.4.1.4, “Client-Side Cleartext Pluggable Authentication”.)

- **--get-server-public-key**
  Request from the server the public key required for RSA key pair-based password exchange. This option applies to clients that authenticate with the `caching_sha2_password` authentication plugin. For that plugin, the server does not send the public key unless requested. This option is ignored for accounts that do not authenticate with that plugin. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

  If `--server-public-key-path=file_name` is given and specifies a valid public key file, it takes precedence over `--get-server-public-key`.

  For information about the `caching_sha2_password` plugin, see Section 6.4.1.3, “Caching SHA-2 Pluggable Authentication”.

- **--host=host_name, -h host_name**
  Dump data from the MySQL server on the given host. The default host is `localhost`.

- **--login-path=name**
  Read options from the named login path in the `.mylogin.cnf` login path file. A “login path” is an option group containing options that specify which MySQL server to connect to and which account to authenticate as. To create or modify a login path file, use the `mysql_config_editor` utility. See Section 4.6.7, “mysql_config_editor — MySQL Configuration Utility”.

  For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- **--password[=password], -p[password]**
  The password of the MySQL account used for connecting to the server. The password value is optional. If not given, `mysqldump` prompts for one. If given, there must be no space between `--password=` or `-p` and the password following it. If no password option is specified, the default is to send no password.

  Specifying a password on the command line should be considered insecure. To avoid giving the password on the command line, use an option file. See Section 6.1.2.1, “End-User Guidelines for Password Security”.

  To explicitly specify that there is no password and that `mysqldump` should not prompt for one, use the `--skip-password` option.

- **--pipe, -W**
  On Windows, connect to the server using a named pipe. This option applies only if the server was started with the `named_pipe` system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the `named_pipe_full_access_group` system variable.
• **--plugin-dir=dir_name**
  
The directory in which to look for plugins. Specify this option if the **--default-auth** option is used to specify an authentication plugin but mysqlump does not find it. See Section 6.2.17, “Pluggable Authentication”.

• **--port=port_num, -P port_num**
  
  For TCP/IP connections, the port number to use.

• **--protocol={TCP|SOCKET|PIPE|MEMORY}**
  
The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally result in use of a protocol other than the one you want. For details on the permissible values, see Section 4.2.4, “Connecting to the MySQL Server Using Command Options”.

• **--secure-auth**
  
  This option was removed in MySQL 8.0.3.

• **--server-public-key-path=file_name**
  
The path name to a file containing a client-side copy of the public key required by the server for RSA key pair-based password exchange. The file must be in PEM format. This option applies to clients that authenticate with the sha256_password or caching_sha2_password authentication plugin. This option is ignored for accounts that do not authenticate with one of those plugins. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

  If **--server-public-key-path=file_name** is given and specifies a valid public key file, it takes precedence over **--get-server-public-key**.

  For sha256_password, this option applies only if MySQL was built using OpenSSL.

  For information about the sha256_password and caching_sha2_password plugins, see Section 6.4.1.2, “SHA-256 Pluggable Authentication”, and Section 6.4.1.3, “Caching SHA-2 Pluggable Authentication”.

• **--socket=path, -S path**
  
  For connections to localhost, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

  On Windows, this option applies only if the server was started with the named_pipe system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the named_pipe_full_access_group system variable.

• **--ssl**
  
  Options that begin with **--ssl** specify whether to connect to the server using SSL and indicate where to find SSL keys and certificates. See Command Options for Encrypted Connections.

• **--ssl-fips-mode={OFF|ON|STRICT}**
  
  Controls whether to enable FIPS mode on the client side. The **--ssl-fips-mode** option differs from other **--ssl-xxx** options in that it is not used to establish encrypted connections, but rather to affect which cryptographic operations are permitted. See Section 6.5, “FIPS Support”.

  These **--ssl-fips-mode** values are permitted:

  • **OFF**: Disable FIPS mode.
• **ON**: Enable FIPS mode.

• **STRICT**: Enable “strict” FIPS mode.

**Note**
If the OpenSSL FIPS Object Module is not available, the only permitted value for `--ssl-fips-mode` is **OFF**. In this case, setting `--ssl-fips-mode` to ON or STRICT causes the client to produce a warning at startup and to operate in non-FIPS mode.

• `--tls-ciphersuites=ciphersuite_list`

   The permissible TLSv1.3 ciphersuites for encrypted connections. The value is a list of one or more colon-separated ciphersuite names. The ciphersuites that can be named for this option depend on the SSL library used to compile MySQL. For details, see Section 6.3.5, “Encrypted Connection Protocols and Ciphers”.

   This option was added in MySQL 8.0.16.

• `--tls-version=protocol_list`

   The permissible TLS protocols for encrypted connections. The value is a list of one or more comma-separated protocol names. The protocols that can be named for this option depend on the SSL library used to compile MySQL. For details, see Section 6.3.5, “Encrypted Connection Protocols and Ciphers”.

• `--user=user_name, -u user_name`

   The user name of the MySQL account to use for connecting to the server.

• `--zstd-compression-level=level`

   The compression level to use for connections to the server that use the **zstd** compression algorithm. The permitted levels are from 1 to 22, with larger values indicating increasing levels of compression. The default **zstd** compression level is 3. The compression level setting has no effect on connections that do not use **zstd** compression.

   For more information, see Section 4.2.6, “Connection Compression Control”.

   This option was added in MySQL 8.0.18.

### Option-File Options

These options are used to control which option files to read.

• `--defaults-extra-file=file_name`

   Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. *file_name* is interpreted relative to the current directory if given as a relative path name rather than a full path name.

   For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

• `--defaults-file=file_name`

   Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. *file_name* is interpreted relative to the current directory if given as a relative path name rather than a full path name.

   Exception: Even with `--defaults-file`, client programs read `.mylogin.cnf`.
For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- **--defaults-group-suffix=str**

Read not only the usual option groups, but also groups with the usual names and a suffix of str. For example, `mysqldump` normally reads the `[client]` and `[mysqldump]` groups. If the `--defaults-group-suffix=_other` option is given, `mysqldump` also reads the `[client_other]` and `[mysqldump_other]` groups.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- **--no-defaults**

Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

The exception is that the `.mylogin.cnf` file, if it exists, is read in all cases. This permits passwords to be specified in a safer way than on the command line even when `--no-defaults` is used. (.mylogin.cnf is created by the `mysql_config_editor` utility. See Section 4.6.7, “mysql_config_editor — MySQL Configuration Utility”.)

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- **--print-defaults**

Print the program name and all options that it gets from option files.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

### DDL Options

Usage scenarios for `mysqldump` include setting up an entire new MySQL instance (including database tables), and replacing data inside an existing instance with existing databases and tables. The following options let you specify which things to tear down and set up when restoring a dump, by encoding various DDL statements within the dump file.

- **--add-drop-database**

Write a `DROP DATABASE` statement before each `CREATE DATABASE` statement. This option is typically used in conjunction with the `--all-databases` or `--databases` option because no `CREATE DATABASE` statements are written unless one of those options is specified.

- **--add-drop-table**

Write a `DROP TABLE` statement before each `CREATE TABLE` statement.

- **--add-drop-trigger**

Write a `DROP TRIGGER` statement before each `CREATE TRIGGER` statement.

- **--all-tablespaces, -Y**

Adds to a table dump all SQL statements needed to create any tablespaces used by an NDB table. This information is not otherwise included in the output from `mysqldump`. This option is currently relevant only to NDB Cluster tables.

- **--no-create-db, -n**
Suppose the `CREATE DATABASE` statements that are otherwise included in the output if the `--databases` or `--all-databases` option is given.

- `--no-create-info, -t`

Do not write `CREATE TABLE` statements that create each dumped table.

**Note**

This option does not exclude statements creating log file groups or tablespace from `mysqldump` output; however, you can use the `--no-tablespaces` option for this purpose.

- `--no-tablespaces, -y`

This option suppresses all `CREATE LOGFILE GROUP` and `CREATE TABLESPACE` statements in the output of `mysqldump`.

- `--replace`

Write REPLACE statements rather than INSERT statements.

### Debug Options

The following options print debugging information, encode debugging information in the dump file, or let the dump operation proceed regardless of potential problems.

- `--allow-keywords`

  Permit creation of column names that are keywords. This works by prefixing each column name with the table name.

- `--comments, -i`

  Write additional information in the dump file such as program version, server version, and host. This option is enabled by default. To suppress this additional information, use `--skip-comments`.

- `--debug[=debug_options], -# [debug_options]`

  Write a debugging log. A typical `debug_options` string is `d:t:o, file_name`. The default value is `d:t:o, /tmp/mysqldump.trace`.

- `--debug-check`

  Print some debugging information when the program exits.

- `--debug-info`

  Print debugging information and memory and CPU usage statistics when the program exits.

- `--dump-date`

  If the `--comments` option is given, `mysqldump` produces a comment at the end of the dump of the following form:

  ```
  -- Dump completed on DATE
  ```

  However, the date causes dump files taken at different times to appear to be different, even if the data are otherwise identical. `--dump-date` and `--skip-dump-date` control whether the date is added to the comment. The default is `--dump-date` (include the date in the comment). `--skip-dump-date` suppresses date printing.
• --force, -f

Ignore all errors; continue even if an SQL error occurs during a table dump.

One use for this option is to cause mysqldump to continue executing even when it encounters a view that has become invalid because the definition refers to a table that has been dropped. Without --force, mysqldump exits with an error message. With --force, mysqldump prints the error message, but it also writes an SQL comment containing the view definition to the dump output and continues executing.

If the --ignore-error option is also given to ignore specific errors, --force takes precedence.

• --log-error=file_name

Log warnings and errors by appending them to the named file. The default is to do no logging.

• --skip-comments

See the description for the --comments option.

• --verbose, -v

Verbose mode. Print more information about what the program does.

Help Options

The following options display information about the mysqldump command itself.

• --help, -?

Display a help message and exit.

• --version, -V

Display version information and exit.

Internationalization Options

The following options change how the mysqldump command represents character data with national language settings.

• --character-sets-dir=dir_name

The directory where character sets are installed. See Section 10.14, “Character Set Configuration”.

• --default-character-set=charset_name

Use charset_name as the default character set. See Section 10.14, “Character Set Configuration”. If no character set is specified, mysqldump uses utf8.

• --no-set-names, -N

Turns off the --set-charset setting, the same as specifying --skip-set-charset.

• --set-charset

Write SET NAMES default_character_set to the output. This option is enabled by default. To suppress the SET NAMES statement, use --skip-set-charset.

Replication Options

The mysqldump command is frequently used to create an empty instance, or an instance including data, on a slave server in a replication configuration. The following options apply to dumping and restoring data on replication master and slave servers.
• **--apply-slave-statements**

For a slave dump produced with the **--dump-slave** option, add a **STOP SLAVE** statement before the **CHANGE MASTER TO** statement and a **START SLAVE** statement at the end of the output.

• **--delete-master-logs**

On a master replication server, delete the binary logs by sending a **PURGE BINARY LOGS** statement to the server after performing the dump operation. This option automatically enables **--master-data**.

• **--dump-slave[=value]**

This option is similar to **--master-data** except that it is used to dump a replication slave server to produce a dump file that can be used to set up another server as a slave that has the same master as the dumped server. It causes the dump output to include a **CHANGE MASTER TO** statement that indicates the binary log coordinates (file name and position) of the dumped slave’s master. The **CHANGE MASTER TO** statement reads the values of **Relay_Master_Log_File** and **Exec_Master_Log_Pos** from the **SHOW SLAVE STATUS** output and uses them for **MASTER_LOG_FILE** and **MASTER_LOG_POS** respectively. These are the master server coordinates from which the slave should start replicating.

---

**Note**

Inconsistencies in the sequence of transactions from the relay log which have been executed can cause the wrong position to be used. See Section 17.4.1.33, "Replication and Transaction Inconsistencies" for more information.

**--dump-slave** causes the coordinates from the master to be used rather than those of the dumped server, as is done by the **--master-data** option. In addition, specifying this option causes the **--master-data** option to be overridden, if used, and effectively ignored.

---

**Warning**

This option should not be used if the server where the dump is going to be applied uses **gtid_mode=ON** and **MASTER_AUTOPOSITION=1**.

The option value is handled the same way as for **--master-data** (setting no value or 1 causes a **CHANGE MASTER TO** statement to be written to the dump, setting 2 causes the statement to be written but encased in SQL comments) and has the same effect as **--master-data** in terms of enabling or disabling other options and in how locking is handled.

This option causes **mysqlimport** to stop the slave SQL thread before the dump and restart it again after.

In conjunction with **--dump-slave**, the **--apply-slave-statements** and **--include-master-host-port** options can also be used.

• **--include-master-host-port**

For the **CHANGE MASTER TO** statement in a slave dump produced with the **--dump-slave** option, add **MASTER_HOST** and **MASTER_PORT** options for the host name and TCP/IP port number of the slave’s master.

• **--master-data[=value]**

Use this option to dump a master replication server to produce a dump file that can be used to set up another server as a slave of the master. It causes the dump output to include a **CHANGE MASTER TO** statement that indicates the binary log coordinates (file name and position) of the dumped server.
These are the master server coordinates from which the slave should start replicating after you load the dump file into the slave.

If the option value is 2, the `CHANGE MASTER TO` statement is written as an SQL comment, and thus is informative only; it has no effect when the dump file is reloaded. If the option value is 1, the statement is not written as a comment and takes effect when the dump file is reloaded. If no option value is specified, the default value is 1.

This option requires the `RELOAD` privilege and the binary log must be enabled.

The `--master-data` option automatically turns off `--lock-tables`. It also turns on `--lock-all-tables`, unless `--single-transaction` also is specified, in which case, a global read lock is acquired only for a short time at the beginning of the dump (see the description for `--single-transaction`). In all cases, any action on logs happens at the exact moment of the dump.

It is also possible to set up a slave by dumping an existing slave of the master, using the `--dump-slave` option, which overrides `--master-data` and causes it to be ignored if both options are used.

• `--set-gtid-purged=value`

This option is for servers that use GTID-based replication (`gtid_mode=ON`). It controls the inclusion of a `SET @@GLOBAL.gtid_purged` statement in the dump output, which updates the value of `gtid_purged` on a server where the dump file is reloaded, to add the GTID set from the source server’s `gtid_executed` system variable. `gtid_purged` holds the GTIDs of all transactions that have been applied on the server, but do not exist on any binary log file on the server. `mysqldump` therefore adds the GTIDs for the transactions that were executed on the source server, so that the target server records these transactions as applied, although it does not have them in its binary logs. `--set-gtid-purged` also controls the inclusion of a `SET @@SESSION.sql_log_bin=0` statement, which disables binary logging while the dump file is being reloaded. This statement prevents new GTIDs from being generated and assigned to the transactions in the dump file as they are executed, so that the original GTIDs for the transactions are used.

If you do not set the `--set-gtid-purged` option, the default is that a `SET @@GLOBAL.gtid_purged` statement is included in the dump output if GTIDs are enabled on the server you are backing up, and the set of GTIDs in the global value of the `gtid_executed` system variable is not empty. A `SET @@SESSION.sql_log_bin=0` statement is also included if GTIDs are enabled on the server.

In MySQL 5.6 and 5.7, you can replace the value of `gtid_purged` with a specified GTID set, provided that `gtid_executed` and `gtid_purged` are empty. From MySQL 8.0, you can either replace the value of `gtid_purged` with a specified GTID set, or you can add a plus sign (+) to the statement to append a specified GTID set to the GTID set that is already held by `gtid_purged`. `mysqldump`'s `SET @@GLOBAL.gtid_purged` statement includes a plus sign (+) in a version comment that takes effect when the dump file is replayed on releases from MySQL 8.0, meaning that for these releases, the GTID set from the dump file is added to the existing `gtid_purged` value. For MySQL 5.6 and 5.7, the value of `gtid_purged` is replaced with the GTID set from the dump file, which can only happen when `gtid_executed` is the empty set (so when replication has not been started previously, or when replication was not previously using GTIDs). For the exact details of how the `SET @@GLOBAL.gtid_purged` statement operates, see the `gtid_purged` description for the release where the dump file is to be replayed.

It is important to note that the value that is included by `mysqldump` for the `SET @@GLOBAL.gtid_purged` statement includes the GTIDs of all transactions in the `gtid_executed` set on the server, even those that changed suppressed parts of the database, or other databases on the server that were not included in a partial dump. This can mean that after the `gtid_purged` value has been updated on the server where the dump file is replayed, GTIDs are present that do not relate to any data on the target server. If you do not replay any further dump files on the target server, the extraneous GTIDs do not cause any problems with the future operation of the server,
but they make it harder to compare or reconcile GTID sets on different servers in the replication topology. If you do replay a further dump file on the target server that contains the same GTIDs (for example, another partial dump from the same origin server), any `SET @@GLOBAL.gtid_purged` statement in the second dump file fails. In this case, either remove the statement manually before replaying the dump file, or output the dump file without the statement.

**Note**

For MySQL 5.6 and 5.7, it is not recommended to load a dump file when GTIDs are enabled on the server (`gtid_mode=ON`), if your dump file includes system tables. `mysqldump` issues DML instructions for the system tables which use the non-transactional MyISAM storage engine, and this combination is not permitted when GTIDs are enabled.

If the `SET @@GLOBAL.gtid_purged` statement would not have the desired result on your target server, you can exclude the statement from the output, or (from MySQL 8.0.17) include it but comment it out so that it is not actioned automatically. You can also include the statement but manually edit it in the dump file to achieve the desired result.

The possible values for the `--set-gtid-purged` option are as follows:

**AUTO**

The default value. If GTIDs are enabled on the server you are backing up and `gtid_executed` is not empty, `SET @@GLOBAL.gtid_purged` is added to the output, containing the GTID set from `gtid_executed`. If GTIDs are enabled, `SET @@SESSION.sql_log_bin=0` is added to the output. If GTIDs are not enabled on the server, the statements are not added to the output.

**OFF**

`SET @@GLOBAL.gtid_purged` is not added to the output, and `SET @@SESSION.sql_log_bin=0` is not added to the output. For a server where GTIDs are not in use, use this option or AUTO. Only use this option for a server where GTIDs are in use if you are sure that the required GTID set is already present in `gtid_purged` on the target server and should not be changed, or if you plan to identify and add any missing GTIDs manually.

**ON**

If GTIDs are enabled on the server you are backing up, `SET @@GLOBAL.gtid_purged` is added to the output (unless `gtid_executed` is empty), and `SET @@SESSION.sql_log_bin=0` is added to the output. An error occurs if you set this option but GTIDs are not enabled on the server. For a server where GTIDs are in use, use this option or AUTO, unless you are sure that the GTIDs in `gtid_executed` are not needed on the target server.

**COMMENTED**

Available from MySQL 8.0.17. If GTIDs are enabled on the server you are backing up, `SET @@GLOBAL.gtid_purged` is added to the output (unless `gtid_executed` is empty), but it is commented out. This means that the value of `gtid_executed` is available in the output, but no action is taken automatically when the dump file is reloaded. `SET @@SESSION.sql_log_bin=0` is added to the output, and it is not commented out. With COMMENTED, you can control the use of the `gtid_executed` set manually or through automation. For example, you might prefer to do this if you are migrating data to another server that already has different active databases.
Format Options

The following options specify how to represent the entire dump file or certain kinds of data in the dump file. They also control whether certain optional information is written to the dump file.

- **--compact**

- **--compatible=name**
  Produce output that is more compatible with other database systems or with older MySQL servers. The only permitted value for this option is **ansi**, which has the same meaning as the corresponding option for setting the server SQL mode. See Section 5.1.11, “Server SQL Modes”.

- **--complete-insert, -c**
  Use complete **INSERT** statements that include column names.

- **--create-options**
  Include all MySQL-specific table options in the **CREATE TABLE** statements.

- **--fields-terminated-by=...**, **--fields-enclosed-by=...**, **--fields-optionally-enclosed-by=...**, **--fields-escaped-by=...**
  These options are used with the **--tab** option and have the same meaning as the corresponding **FIELDS** clauses for **LOAD DATA**. See Section 13.2.7, “LOAD DATA Syntax”.

- **--hex-blob**
  Dump binary columns using hexadecimal notation (for example, 'abc' becomes 0x616263). The affected data types are **BINARY**, **VARBINARY**, **BLOB** types, **BIT**, all spatial data types, and other non-binary data types when used with the **binary** character set.

- **--lines-terminated-by=...**
  This option is used with the **--tab** option and has the same meaning as the corresponding **LINES** clause for **LOAD DATA**. See Section 13.2.7, “LOAD DATA Syntax”.

- **--quote-names, -Q**
  Quote identifiers (such as database, table, and column names) within ` characters. If the **ANSI_QUOTES** SQL mode is enabled, identifiers are quoted within " characters. This option is enabled by default. It can be disabled with **--skip-quote-names**, but this option should be given after any option such as **--compatible** that may enable **--quote-names**.

- **--result-file=file_name, -r file_name**
  Direct output to the named file. The result file is created and its previous contents overwritten, even if an error occurs while generating the dump.

  This option should be used on Windows to prevent newline \n characters from being converted to \r\n carriage return/newline sequences.

- **--tab=dir_name, -T dir_name**
  Produce tab-separated text-format data files. For each dumped table, **mysqldump** creates a **tbl_name.sql** file that contains the **CREATE TABLE** statement that creates the table, and the server writes a **tbl_name.txt** file that contains its data. The option value is the directory in which to write the files.
Note

This option should be used only when \textit{mysqldump} is run on the same
machine as the \textit{mysqld} server. Because the server creates *.txt files in
the directory that you specify, the directory must be writable by the server
and the MySQL account that you use must have the \texttt{FILE} privilege. Because
\textit{mysqldump} creates *.sql in the same directory, it must be writable by your
system login account.

By default, the .txt data files are formatted using tab characters between column values and
a newline at the end of each line. The format can be specified explicitly using the \texttt{--fields-xxx} and
\texttt{--lines-terminated-by} options.

Column values are converted to the character set specified by the \texttt{--default-character-set}
option.

- \texttt{--tz-utc}

This option enables TIMESTAMP columns to be dumped and reloaded between servers
in different time zones. \textit{mysqldump} sets its connection time zone to UTC and adds \texttt{SET
TIME_ZONE='+00:00'} to the dump file. Without this option, TIMESTAMP columns are dumped and
reloaded in the time zones local to the source and destination servers, which can cause the values
to change if the servers are in different time zones. \texttt{--tz-utc} also protects against changes due to
daylight saving time. \texttt{--tz-utc} is enabled by default. To disable it, use \texttt{--skip-tz-utc}.

- \texttt{--xml}, \texttt{-X}

Write dump output as well-formed XML.

\textbf{NULL, 'NULL', and Empty Values}: For a column named \textit{column_name}, the NULL value, an empty
string, and the string value 'NULL' are distinguished from one another in the output generated by
this option as follows.

<table>
<thead>
<tr>
<th>Value:</th>
<th>XML Representation:</th>
</tr>
</thead>
<tbody>
<tr>
<td>NULL (unknown value)</td>
<td>&lt;field name=&quot;column_name&quot; xsi:nil=&quot;true&quot; /&gt;</td>
</tr>
<tr>
<td>' ' (empty string)</td>
<td>&lt;field name=&quot;column_name&quot;&gt;&lt;/field&gt;</td>
</tr>
<tr>
<td>'NULL' (string value)</td>
<td>&lt;field name=&quot;column_name&quot;&gt;NULL&lt;/field&gt;</td>
</tr>
</tbody>
</table>

The output from the \textit{mysql} client when run using the \texttt{--xml} option also follows the preceding rules.
(See Section 4.5.1.1, 'mysql Client Options'.)

XML output from \textit{mysqldump} includes the XML namespace, as shown here:

```
shell> mysqldump --xml -u root world City
<xml version="1.0">
<mysqldump xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
<database name="world">
<table_structure name="City">
<field Field="ID" Type="int(11)" Null="NO" Key="PRI" Extra="auto_increment" />
<field Field="Name" Type="char(35)" Null="NO" Key="" Default="" Extra="" />
<field Field="CountryCode" Type="char(3)" Null="NO" Key="" Default="" Extra="" />
<field Field="District" Type="char(20)" Null="NO" Key="" Default="" Extra="" />
<field Field="Population" Type="int(11)" Null="NO" Key="" Default="0" Extra="" />
<key Table="City" Non_unique="0" Key_name="PRIMARY" Seq_in_index="1" Column_name="ID"
Collation="A" Cardinality="4079" Null="" Index_type="BTREE" Comment="" />
<options Name="City" Engine="MyISAM" Version="10" Row_format="Fixed" Rows="4079"
Avg_row_length="67" Data_length="273293" Max_data_length="18858823439613951"
Index_length="43008" Data_free="0" Auto_increment="4080"
```
Filtering Options

The following options control which kinds of schema objects are written to the dump file: by category, such as triggers or events; by name, for example, choosing which databases and tables to dump; or even filtering rows from the table data using a `WHERE` clause.

- `--all-databases`, `-A`

Dump all tables in all databases. This is the same as using the `--databases` option and naming all the databases on the command line.

Prior to MySQL 8.0, the `--routines` and `--events` options for `mysqldump` and `mysqlpump` were not required to include stored routines and events when using the `--all-databases` option: The dump included the `mysql` system database, and therefore also the `mysql.proc` and `mysql.event` tables containing stored routine and event definitions. As of MySQL 8.0, the `mysql.event` and `mysql.proc` tables are not used. Definitions for the corresponding objects are stored in data dictionary tables, but those tables are not dumped. To include stored routines and events in a dump made using `--all-databases`, use the `--routines` and `--events` options explicitly.

- `--databases`, `-B`

Dump several databases. Normally, `mysqldump` treats the first name argument on the command line as a database name and following names as table names. With this option, it treats all name arguments as database names. `CREATE DATABASE` and `USE` statements are included in the output before each new database.

This option may be used to dump the `performance_schema` database, which normally is not dumped even with the `--all-databases` option. (Also use the `--skip-lock-tables` option.)

- `--events`, `-E`

Include Event Scheduler events for the dumped databases in the output. This option requires the `EVENT` privileges for those databases.

The output generated by using `--events` contains `CREATE EVENT` statements to create the events.

- `--ignore-error=error[,error]...`
Ignore the specified errors. The option value is a list of comma-separated error numbers specifying the errors to ignore during *mysqldump* execution. If the *--force* option is also given to ignore all errors, *--force* takes precedence.

- **--ignore-table=** *db_name.tbl_name*

  Do not dump the given table, which must be specified using both the database and table names. To ignore multiple tables, use this option multiple times. This option also can be used to ignore views.

- **--no-data, -d**

  Do not write any table row information (that is, do not dump table contents). This is useful if you want to dump only the *CREATE TABLE* statement for the table (for example, to create an empty copy of the table by loading the dump file).

- **--routines, -R**

  Include stored routines (procedures and functions) for the dumped databases in the output. This option requires the global *SELECT* privilege.

  The output generated by using *--routines* contains *CREATE PROCEDURE* and *CREATE FUNCTION* statements to create the routines.

- **--tables**

  Override the *--databases* or *-B* option. *mysqldump* regards all name arguments following the option as table names.

- **--triggers**

  Include triggers for each dumped table in the output. This option is enabled by default; disable it with *--skip-triggers*.

  To be able to dump a table's triggers, you must have the *TRIGGER* privilege for the table.

  Multiple triggers are permitted. *mysqldump* dumps triggers in activation order so that when the dump file is reloaded, triggers are created in the same activation order. However, if a *mysqldump* dump file contains multiple triggers for a table that have the same trigger event and action time, an error occurs for attempts to load the dump file into an older server that does not support multiple triggers. (For a workaround, see *Downgrade Notes*; you can convert triggers to be compatible with older servers.)

- **--where='** *where_condition* **' , -w '** *where_condition* **'**

  Dump only rows selected by the given *WHERE* condition. Quotes around the condition are mandatory if it contains spaces or other characters that are special to your command interpreter.

  **Examples:**

  ```
  --where="user='jimf'"
  -w"userid>1"
  -w"userid<1"
  ```

**Performance Options**

The following options are the most relevant for the performance particularly of the restore operations. For large data sets, restore operation (processing the *INSERT* statements in the dump file) is the most time-consuming part. When it is urgent to restore data quickly, plan and test the performance of this stage in advance. For restore times measured in hours, you might prefer an alternative backup and restore solution, such as MySQL Enterprise Backup for InnoDB-only and mixed-use databases.
Performance is also affected by the transactional options, primarily for the dump operation.

• **--column-statistics**

   Add **ANALYZE TABLE** statements to the output to generate histogram statistics for dumped tables when the dump file is reloaded. This option is disabled by default because histogram generation for large tables can take a long time.

• **--disable-keys, -K**

   For each table, surround the **INSERT** statements with ```/*!40000 ALTER TABLE tbl_name DISABLE KEYS */``` and ```/*!40000 ALTER TABLE tbl_name ENABLE KEYS */``` statements. This makes loading the dump file faster because the indexes are created after all rows are inserted. This option is effective only for nonunique indexes of **MyISAM** tables.

• **--extended-insert, -e**

   Write **INSERT** statements using multiple-row syntax that includes several **VALUES** lists. This results in a smaller dump file and speeds up inserts when the file is reloaded.

• **--insert-ignore**

   Write **INSERT IGNORE** statements rather than **INSERT** statements.

• **--max-allowed-packet=value**

   The maximum size of the buffer for client/server communication. The default is 24MB, the maximum is 1GB.

• **--net-buffer-length=value**

   The initial size of the buffer for client/server communication. When creating multiple-row **INSERT** statements (as with the **--extended-insert** or **--opt** option), **mysqldump** creates rows up to **--net-buffer-length** bytes long. If you increase this variable, ensure that the MySQL server **net_buffer_length** system variable has a value at least this large.

• **--network-timeout, -M**

   Enable large tables to be dumped by setting **--max-allowed-packet** to its maximum value and network read and write timeouts to a large value. This option is enabled by default. To disable it, use **--skip-network-timeout**.

• **--opt**

   This option, enabled by default, is shorthand for the combination of **--add-drop-table** **--add-locks** **--create-options** **--disable-keys** **--extended-insert** **--lock-tables** **--quick** **--set-charset**. It gives a fast dump operation and produces a dump file that can be reloaded into a MySQL server quickly.

   Because the **--opt** option is enabled by default, you only specify its converse, the **--skip-opt** to turn off several default settings. See the discussion of **mysqldump option groups** for information about selectively enabling or disabling a subset of the options affected by **--opt**.

• **--quick, -q**

   This option is useful for dumping large tables. It forces **mysqldump** to retrieve rows for a table from the server a row at a time rather than retrieving the entire row set and buffering it in memory before writing it out.

• **--skip-opt**

   See the description for the **--opt** option.
Transactional Options

The following options trade off the performance of the dump operation, against the reliability and consistency of the exported data.

- **--add-locks**

  Surround each table dump with `LOCK TABLES` and `UNLOCK TABLES` statements. This results in faster inserts when the dump file is reloaded. See Section 8.2.5.1, “Optimizing INSERT Statements”.

- **--flush-logs, -F**

  Flush the MySQL server log files before starting the dump. This option requires the `RELOAD` privilege. If you use this option in combination with the `--all-databases` option, the logs are flushed for each database dumped. The exception is when using `--lock-all-tables`, `--master-data`, or `--single-transaction`: In this case, the logs are flushed only once, corresponding to the moment that all tables are locked by `FLUSH TABLES WITH READ LOCK`. If you want your dump and the log flush to happen at exactly the same moment, you should use `--flush-logs` together with `--lock-all-tables`, `--master-data`, or `--single-transaction`.

- **--flush-privileges**

  Add a `FLUSH PRIVILEGES` statement to the dump output after dumping the `mysql` database. This option should be used any time the dump contains the `mysql` database and any other database that depends on the data in the `mysql` database for proper restoration.

  **Note**

  For upgrades to MySQL 5.7.2 or higher from older versions, do not use `--flush-privileges`. For upgrade instructions in this case, see Section 2.11.4, “Changes in MySQL 8.0”.

- **--lock-all-tables, -x**

  Lock all tables across all databases. This is achieved by acquiring a global read lock for the duration of the whole dump. This option automatically turns off `--single-transaction` and `--lock-tables`.

- **--lock-tables, -l**

  For each dumped database, lock all tables to be dumped before dumping them. The tables are locked with `READ LOCAL` to permit concurrent inserts in the case of `MyISAM` tables. For transactional tables such as `InnoDB`, `--single-transaction` is a much better option than `--lock-tables` because it does not need to lock the tables at all.

  Because `--lock-tables` locks tables for each database separately, this option does not guarantee that the tables in the dump file are logically consistent between databases. Tables in different databases may be dumped in completely different states.

  Some options, such as `--opt`, automatically enable `--lock-tables`. If you want to override this, use `--skip-lock-tables` at the end of the option list.

- **--no-autocommit**

  Enclose the `INSERT` statements for each dumped table within `SET autocommit = 0` and `COMMIT` statements.

- **--order-by-primary**
Dump each table's rows sorted by its primary key, or by its first unique index, if such an index exists. This is useful when dumping a MyISAM table to be loaded into an InnoDB table, but makes the dump operation take considerably longer.

- --shared-memory-base-name=name

On Windows, the shared-memory name to use for connections made using shared memory to a local server. The default value is MYSQL. The shared-memory name is case-sensitive.

This option applies only if the server was started with the shared_memory system variable enabled to support shared-memory connections.

- --single-transaction

This option sets the transaction isolation mode to REPEATABLE READ and sends a START TRANSACTION SQL statement to the server before dumping data. It is useful only with transactional tables such as InnoDB, because then it dumps the consistent state of the database at the time when START TRANSACTION was issued without blocking any applications.

When using this option, you should keep in mind that only InnoDB tables are dumped in a consistent state. For example, any MyISAM or MEMORY tables dumped while using this option may still change state.

While a --single-transaction dump is in process, to ensure a valid dump file (correct table contents and binary log coordinates), no other connection should use the following statements: ALTER TABLE, CREATE TABLE, DROP TABLE, RENAME TABLE, TRUNCATE TABLE. A consistent read is not isolated from those statements, so use of them on a table to be dumped can cause the SELECT that is performed by mysqldump to retrieve the table contents to obtain incorrect contents or fail.

The --single-transaction option and the --lock-tables option are mutually exclusive because LOCK TABLES causes any pending transactions to be committed implicitly.

To dump large tables, combine the --single-transaction option with the --quick option.

**Option Groups**

- The --opt option turns on several settings that work together to perform a fast dump operation. All of these settings are on by default, because --opt is on by default. Thus you rarely if ever specify --opt. Instead, you can turn these settings off as a group by specifying --skip-opt, the optionally re-enable certain settings by specifying the associated options later on the command line.

- The --compact option turns off several settings that control whether optional statements and comments appear in the output. Again, you can follow this option with other options that re-enable certain settings, or turn all the settings on by using the --skip-compact form.

When you selectively enable or disable the effect of a group option, order is important because options are processed first to last. For example, --disable-keys --lock-tables --skip-opt would not have the intended effect; it is the same as --skip-opt by itself.

**Examples**

To make a backup of an entire database:

```
shell> mysqldump db_name > backup-file.sql
```

To load the dump file back into the server:

```
shell> mysql db_name < backup-file.sql
```
Another way to reload the dump file:

```
shell> mysql -e "source /path-to-backup/backup-file.sql" db_name
```

mysqldump is also very useful for populating databases by copying data from one MySQL server to another:

```
shell> mysqldump --opt db_name | mysql --host=remote_host -C db_name
```

You can dump several databases with one command:

```
shell> mysqldump --databases db_name1 [db_name2 ...] > my_databases.sql
```

To dump all databases, use the `--all-databases` option:

```
shell> mysqldump --all-databases > all_databases.sql
```

For InnoDB tables, mysqldump provides a way of making an online backup:

```
shell> mysqldump --all-databases --master-data --single-transaction > all_databases.sql
```

This backup acquires a global read lock on all tables (using `FLUSH TABLES WITH READ LOCK`) at the beginning of the dump. As soon as this lock has been acquired, the binary log coordinates are read and the lock is released. If long updating statements are running when the `FLUSH` statement is issued, the MySQL server may get stalled until those statements finish. After that, the dump becomes lock free and does not disturb reads and writes on the tables. If the update statements that the MySQL server receives are short (in terms of execution time), the initial lock period should not be noticeable, even with many updates.

For point-in-time recovery (also known as “roll-forward,” when you need to restore an old backup and replay the changes that happened since that backup), it is often useful to rotate the binary log (see Section 5.4.4, “The Binary Log”) or at least know the binary log coordinates to which the dump corresponds:

```
shell> mysqldump --all-databases --master-data=2 > all_databases.sql
```

Or:

```
shell> mysqldump --all-databases --flush-logs --master-data=2
            > all_databases.sql
```

The `--master-data` and `--single-transaction` options can be used simultaneously, which provides a convenient way to make an online backup suitable for use prior to point-in-time recovery if tables are stored using the InnoDB storage engine.

For more information on making backups, see Section 7.2, “Database Backup Methods”, and Section 7.3, “Example Backup and Recovery Strategy”.

- To select the effect of `--opt` except for some features, use the `--skip` option for each feature. To disable extended inserts and memory buffering, use `--opt --skip-extended-insert --skip-quick`. (Actually, `--skip-extended-insert --skip-quick` is sufficient because `--opt` is on by default.)

- To reverse `--opt` for all features except index disabling and table locking, use `--skip-opt --disable-keys --lock-tables`.

**Restrictions**
**mysqldump** does not dump the `performance_schema` or `sys` schema by default. To dump any of these, name them explicitly on the command line. You can also name them with the `--databases` option. For `performance_schema`, also use the `--skip-lock-tables` option.

`mysqldump` does not dump the `INFORMATION_SCHEMA` schema.

`mysqldump` does not dump InnoDB `CREATE TABLESPACE` statements.

`mysqldump` does not dump the NDB Cluster `ndbinfo` information database.

`mysqldump` includes statements to recreate the `general_log` and `slow_query_log` tables for dumps of the `mysql` database. Log table contents are not dumped.

If you encounter problems backing up views due to insufficient privileges, see Section C.5, “Restrictions on Views” for a workaround.

### 4.5.5 **mysqlimport** — A Data Import Program

The `mysqlimport` client provides a command-line interface to the `LOAD DATA` SQL statement. Most options to `mysqlimport` correspond directly to clauses of `LOAD DATA` syntax. See Section 13.2.7, “LOAD DATA Syntax”.

Invoke `mysqlimport` like this:

```
shell> mysqlimport [options] db_name textfile1 [textfile2 ...]
```

For each text file named on the command line, `mysqlimport` strips any extension from the file name and uses the result to determine the name of the table into which to import the file's contents. For example, files named `patient.txt`, `patient.text`, and `patient` all would be imported into a table named `patient`.

`mysqlimport` supports the following options, which can be specified on the command line or in the `[mysqlimport]` and `[client]` groups of an option file. For information about option files used by MySQL programs, see Section 4.2.2.2, “Using Option Files”.

**Table 4.15 mysqlimport Options**

<table>

</table>

- **--help, --?**
  
  Display a help message and exit.

- **--bind-address=ip_address**
  
  On a computer having multiple network interfaces, use this option to select which interface to use for connecting to the MySQL server.

- **--character-sets-dir=dir_name**
  
  The directory where character sets are installed. See Section 10.14, “Character Set Configuration”.

- **--columns=column_list, --c column_list**
  
  This option takes a list of comma-separated column names as its value. The order of the column names indicates how to match data file columns with table columns.

- **--compress, --C**
  
  Compress all information sent between the client and the server if possible. See Section 4.2.6, “Connection Compression Control”.
  
  As of MySQL 8.0.18, this option is deprecated. It will be removed in a future MySQL version. See Legacy Connection Compression Configuration.

- **--compression-algorithms=value**
  
  The permitted compression algorithms for connections to the server. The available algorithms are the same as for the `protocol_compression_algorithms` system variable. The default value is uncompressed.
For more information, see Section 4.2.6, “Connection Compression Control”.

This option was added in MySQL 8.0.18.

- **--debug[=debug_options],--debug**

Write a debugging log. A typical `debug_options` string is `d:t:o,file_name`. The default is `d:t:o`.

- **--debug-check**

Print some debugging information when the program exits.

- **--debug-info**

Print debugging information and memory and CPU usage statistics when the program exits.

- **--default-character-set=charset_name**

Use `charset_name` as the default character set. See Section 10.14, “Character Set Configuration”.

- **--default-auth=plugin**

A hint about which client-side authentication plugin to use. See Section 6.2.17, “Pluggable Authentication”.

- **--defaults-extra-file=file_name**

Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. `file_name` is interpreted relative to the current directory if given as a relative path name rather than a full path name.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- **--defaults-file=file_name**

Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. `file_name` is interpreted relative to the current directory if given as a relative path name rather than a full path name.

Exception: Even with `--defaults-file`, client programs read `.mylogin.cnf`.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- **--defaults-group-suffix=str**

Read not only the usual option groups, but also groups with the usual names and a suffix of `str`. For example, `mysqlimport` normally reads the [client] and [mysqlimport] groups. If the `--defaults-group-suffix=_other` option is given, `mysqlimport` also reads the [client_other] and [mysqlimport_other] groups.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- **--delete, -D**

Empty the table before importing the text file.

- **--enable-cleartext-plugin**
Enable the `mysql_clear_password` cleartext authentication plugin. (See Section 6.4.1.4, “Client-Side Cleartext Pluggable Authentication”.)

- `--fields-terminated-by=...`, `--fields-enclosed-by=...`, `--fields optionally-enclosed-by=...`, `--fields-escaped-by=...`

These options have the same meaning as the corresponding clauses for LOAD DATA. See Section 13.2.7, “LOAD DATA Syntax”.

- `--force`, `-f`
  
  Ignore errors. For example, if a table for a text file does not exist, continue processing any remaining files. Without `--force`, `mysqlimport` exits if a table does not exist.

- `--get-server-public-key`
  
  Request from the server the public key required for RSA key pair-based password exchange. This option applies to clients that authenticate with the `caching_sha2_password` authentication plugin. For that plugin, the server does not send the public key unless requested. This option is ignored for accounts that do not authenticate with that plugin. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

  If `--server-public-key-path=file_name` is given and specifies a valid public key file, it takes precedence over `--get-server-public-key`.

  For information about the `caching_sha2_password` plugin, see Section 6.4.1.3, “Caching SHA-2 Pluggable Authentication”.

- `--host=host_name`, `-h host_name`
  
  Import data to the MySQL server on the given host. The default host is `localhost`.

- `--ignore`, `-i`
  
  See the description for the `--replace` option.

- `--ignore-lines=N`
  
  Ignore the first N lines of the data file.

- `--lines-terminated-by=...`
  
  This option has the same meaning as the corresponding clause for LOAD DATA. For example, to import Windows files that have lines terminated with carriage return/linefeed pairs, use `--lines-terminated-by=\r\n`. (You might have to double the backslashes, depending on the escaping conventions of your command interpreter.) See Section 13.2.7, “LOAD DATA Syntax”.

- `--local`, `-L`
  
  By default, files are read by the server on the server host. With this option, `mysqlimport` reads input files locally on the client host. Enabling local data loading also requires that the server permits it; see Section 6.1.6, “Security Issues with LOAD DATA LOCAL”

- `--lock-tables`, `-l`
  
  Lock all tables for writing before processing any text files. This ensures that all tables are synchronized on the server.

- `--login-path=name`
mysqlimport — A Data Import Program

Read options from the named login path in the .mylogin.cnf login path file. A “login path” is an option group containing options that specify which MySQL server to connect to and which account to authenticate as. To create or modify a login path file, use the mysql_config_editor utility. See Section 4.6.7, "mysql_config_editor — MySQL Configuration Utility”.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- **--low-priority**

  Use LOW_PRIORITY when loading the table. This affects only storage engines that use only table-level locking (such as MyISAM, MEMORY, and MERGE).

- **--no-defaults**

  Do not read any option files. If program startup fails due to reading unknown options from an option file, --no-defaults can be used to prevent them from being read.

  The exception is that the .mylogin.cnf file, if it exists, is read in all cases. This permits passwords to be specified in a safer way than on the command line even when --no-defaults is used. (.mylogin.cnf is created by the mysql_config_editor utility. See Section 4.6.7, "mysql_config_editor — MySQL Configuration Utility”.)

  For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- **--password[=password], -p[password]**

  The password of the MySQL account used for connecting to the server. The password value is optional. If not given, mysqlimport prompts for one. If given, there must be **no space** between --password= or -p and the password following it. If no password option is specified, the default is to send no password.

  Specifying a password on the command line should be considered insecure. To avoid giving the password on the command line, use an option file. See Section 6.1.2.1, “End-User Guidelines for Password Security”.

  To explicitly specify that there is no password and that mysqlimport should not prompt for one, use the --skip-password option.

- **--pipe, -W**

  On Windows, connect to the server using a named pipe. This option applies only if the server was started with the named_pipe system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the named_pipe_full_access_group system variable.

- **--plugin-dir=dir_name**

  The directory in which to look for plugins. Specify this option if the --default-auth option is used to specify an authentication plugin but mysqlimport does not find it. See Section 6.2.17, “Pluggable Authentication”.

- **--port=port_num, -P port_num**

  For TCP/IP connections, the port number to use.

- **--print-defaults**

  Print the program name and all options that it gets from option files.
For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- **--protocol={TCP|SOCKET|PIPE|MEMORY}**

The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally result in use of a protocol other than the one you want. For details on the permissible values, see Section 4.2.4, “Connecting to the MySQL Server Using Command Options”.

- **--replace,-r**

The `--replace` and `--ignore` options control handling of input rows that duplicate existing rows on unique key values. If you specify `--replace`, new rows replace existing rows that have the same unique key value. If you specify `--ignore`, input rows that duplicate an existing row on a unique key value are skipped. If you do not specify either option, an error occurs when a duplicate key value is found, and the rest of the text file is ignored.

- **--secure-auth**

This option was removed in MySQL 8.0.3.

- **--server-public-key-path=file_name**

The path name to a file containing a client-side copy of the public key required by the server for RSA key pair-based password exchange. The file must be in PEM format. This option applies to clients that authenticate with the `sha256_password` or `caching_sha2_password` authentication plugin. This option is ignored for accounts that do not authenticate with one of those plugins. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

If `--server-public-key-path=file_name` is given and specifies a valid public key file, it takes precedence over `--get-server-public-key`.

For `sha256_password`, this option applies only if MySQL was built using OpenSSL.

For information about the `sha256_password` and `caching_sha2_password` plugins, see Section 6.4.1.2, “SHA-256 Pluggable Authentication”, and Section 6.4.1.3, “Caching SHA-2 Pluggable Authentication”.

- **--shared-memory-base-name=name**

On Windows, the shared-memory name to use for connections made using shared memory to a local server. The default value is `MYSQL`. The shared-memory name is case-sensitive.

This option applies only if the server was started with the `shared_memory` system variable enabled to support shared-memory connections.

- **--silent,-s**

Silent mode. Produce output only when errors occur.

- **--socket=path,-S path**

For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

On Windows, this option applies only if the server was started with the `named_pipe` system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the `named_pipe_full_access_group` system variable.
• **--ssl**

Options that begin with **--ssl** specify whether to connect to the server using SSL and indicate where to find SSL keys and certificates. See Command Options for Encrypted Connections.

• **--ssl-fips-mode={OFF|ON|STRICT}**

Controls whether to enable FIPS mode on the client side. The **--ssl-fips-mode** option differs from other **--ssl-xxx** options in that it is not used to establish encrypted connections, but rather to affect which cryptographic operations are permitted. See Section 6.5, “FIPS Support”.

These **--ssl-fips-mode** values are permitted:

• **OFF**: Disable FIPS mode.

• **ON**: Enable FIPS mode.

• **STRICT**: Enable “strict” FIPS mode.

**Note**

If the OpenSSL FIPS Object Module is not available, the only permitted value for **--ssl-fips-mode** is **OFF**. In this case, setting **--ssl-fips-mode** to **ON** or **STRICT** causes the client to produce a warning at startup and to operate in non-FIPS mode.

• **--tls-ciphersuites=ciphersuite_list**

The permissible TLSv1.3 ciphersuites for encrypted connections. The value is a list of one or more colon-separated ciphersuite names. The ciphersuites that can be named for this option depend on the SSL library used to compile MySQL. For details, see Section 6.3.5, “Encrypted Connection Protocols and Ciphers”.

This option was added in MySQL 8.0.16.

• **--tls-version=protocol_list**

The permissible TLS protocols for encrypted connections. The value is a list of one or more comma-separated protocol names. The protocols that can be named for this option depend on the SSL library used to compile MySQL. For details, see Section 6.3.5, “Encrypted Connection Protocols and Ciphers”.

• **--user=user_name, -u user_name**

The user name of the MySQL account to use for connecting to the server.

• **--use-threads=N**

Load files in parallel using **N** threads.

• **--verbose, -v**

Verbose mode. Print more information about what the program does.

• **--version, -V**

Display version information and exit.

• **--zstd-compression-level=level**

The compression level to use for connections to the server that use the **zstd** compression algorithm. The permitted levels are from 1 to 22, with larger values indicating increasing levels of compression.
The default `zstd` compression level is 3. The compression level setting has no effect on connections that do not use `zstd` compression.

For more information, see Section 4.2.6, "Connection Compression Control".

This option was added in MySQL 8.0.18.

Here is a sample session that demonstrates use of `mysqlimport`:

```
shell> mysql -e 'CREATE TABLE imptest(id INT, n VARCHAR(30))' test
shell> ed
100     Max Sydow
101     Count Dracula
w imptest.txt
q
shell> od -c imptest.txt
0000000   1   0   0  	   M   a   x       S   y   d   o   w  
   1   0
0000020   1  	   C   o   u   n   t       D   r   a   c   u   l   a  

shell> mysqlimport --local test imptest.txt
test.imptest: Records: 2  Deleted: 0  Skipped: 0  Warnings: 0
shell> mysql -e 'SELECT * FROM imptest' test
+------+---------------+
| id   | n             |
+------+---------------+
| 100  | Max Sydow     |
| 101  | Count Dracula |
+------+---------------+
```

4.5.6 **mysqlpump — A Database Backup Program**

- mysqlpump Invocation Syntax
- mysqlpump Option Summary
- mysqlpump Option Descriptions
- mysqlpump Object Selection
- mysqlpump Parallel Processing
- mysqlpump Restrictions

The `mysqlpump` client utility performs logical backups, producing a set of SQL statements that can be executed to reproduce the original database object definitions and table data. It dumps one or more MySQL databases for backup or transfer to another SQL server.

`mysqlpump` features include:

- Parallel processing of databases, and of objects within databases, to speed up the dump process
- Better control over which databases and database objects (tables, stored programs, user accounts) to dump
- Dumping of user accounts as account-management statements (`CREATE USER`, `GRANT`) rather than as inserts into the `mysql` system database
- Capability of creating compressed output
- Progress indicator (the values are estimates)
- For dump file reloading, faster secondary index creation for InnoDB tables by adding indexes after rows are inserted
mysqlpump — A Database Backup Program

Note

mysqlpump uses MySQL features introduced in MySQL 5.7, and thus assumes use with MySQL 5.7 or higher.

mysqlpump requires at least the SELECT privilege for dumped tables, SHOW VIEW for dumped views, TRIGGER for dumped triggers, and LOCK TABLES if the --single-transaction option is not used. The SELECT privilege on the mysql system database is required to dump user definitions. Certain options might require other privileges as noted in the option descriptions.

To reload a dump file, you must have the privileges required to execute the statements that it contains, such as the appropriate CREATE privileges for objects created by those statements.

Note

A dump made using PowerShell on Windows with output redirection creates a file that has UTF-16 encoding:

```
shell> mysqlpump [options] > dump.sql
```

However, UTF-16 is not permitted as a connection character set (see Section 10.4, “Connection Character Sets and Collations”), so the dump file will not load correctly. To work around this issue, use the --result-file option, which creates the output in ASCII format:

```
shell> mysqlpump [options] --result-file=dump.sql
```

mysqlpump Invocation Syntax

By default, mysqlpump dumps all databases (with certain exceptions noted in mysqlpump Restrictions). To specify this behavior explicitly, use the --all-databases option:

```
shell> mysqlpump --all-databases
```

To dump a single database, or certain tables within that database, name the database on the command line, optionally followed by table names:

```
shell> mysqlpump db_name
shell> mysqlpump db_name tbl_name1 tbl_name2 ...
```

To treat all name arguments as database names, use the --databases option:

```
shell> mysqlpump --databases db_name1 db_name2 ...
```

By default, mysqlpump does not dump user account definitions, even if you dump the mysql system database that contains the grant tables. To dump grant table contents as logical definitions in the form of CREATE USER and GRANT statements, use the --users option and suppress all database dumping:

```
shell> mysqlpump --exclude-databases=% --users
```

In the preceding command, % is a wildcard that matches all database names for the --exclude-databases option.

mysqlpump supports several options for including or excluding databases, tables, stored programs, and user definitions. See mysqlpump Object Selection.

To reload a dump file, execute the statements that it contains. For example, use the mysql client:

```
shell> mysql dump.sql
```
mysqlpump — A Database Backup Program

shell> mysqlpump [options] > dump.sql
shell> mysql < dump.sql

The following discussion provides additional mysqlpump usage examples.

To see a list of the options mysqlpump supports, issue the command mysqlpump --help.

mysqlpump Option Summary

mysqlpump supports the following options, which can be specified on the command line or in the [mysqlpump] and [client] groups of an option file. For information about option files used by MySQL programs, see Section 4.2.2.2, “Using Option Files”.

Table 4.16 mysqlpump Options

<table>
<thead>
<tr>
<th>Option Name</th>
<th>Description</th>
<th>Introduced</th>
<th>Deprecated</th>
<th>Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--add-drop-database</td>
<td>Add DROP DATABASE statement before each CREATE DATABASE statement</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--add-drop-table</td>
<td>Add DROP TABLE statement before each CREATE TABLE statement</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--add-drop-user</td>
<td>Add DROP USER statement before each CREATE USER statement</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--add-locks</td>
<td>Surround each table dump with LOCK TABLES and UNLOCK TABLES statements</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--all-databases</td>
<td>Dump all databases</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--bind-address</td>
<td>Use specified network interface to connect to MySQL Server</td>
<td></td>
<td></td>

<td></td>
</tr>
<tr>
<td><code>--extended-insert</code></td>
<td>Use multiple-row INSERT syntax</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--get-server-public-key</code></td>
<td>Request RSA public key from server</td>
<td>8.0.3</td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--help</code></td>
<td>Display help message and exit</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--hex-blob</code></td>
<td>Dump binary columns using hexadecimal notation</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--host</code></td>
<td>Host on which MySQL server is located</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--include-databases</code></td>
<td>Databases to include in dump</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--include-events</code></td>
<td>Events to include in dump</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--include-routines</code></td>
<td>Routines to include in dump</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--include-tables</code></td>
<td>Tables to include in dump</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--include-triggers</code></td>
<td>Triggers to include in dump</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--include-users</code></td>
<td>Users to include in dump</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--insert-ignore</code></td>
<td>Write INSERT IGNORE rather than INSERT statements</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--log-error-file</code></td>
<td>Append warnings and errors to named file</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--login-path</code></td>
<td>Read login path options from .mylogin.cnf</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--max-allowed-packet</code></td>
<td>Maximum packet length to send to or receive from server</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--net-buffer-length</code></td>
<td>Buffer size for TCP/IP and socket communication</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--no-create-db</code></td>
<td>Do not write CREATE DATABASE statements</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--no-create-info</code></td>
<td>Do not write CREATE TABLE statements that re-create each dumped table</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--no-defaults</code></td>
<td>Read no option files</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--parallel-schemas</code></td>
<td>Specify schema-processing parallelism</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--password</code></td>
<td>Password to use when connecting to server</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--plugin-dir</code></td>
<td>Directory where plugins are installed</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>

<td>Print default options</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--protocol</code></td>
<td>Connection protocol to use</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--replace</code></td>
<td>Write REPLACE statements rather than INSERT statements</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--result-file</code></td>
<td>Direct output to a given file</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
## mysqlpump Option Descriptions

- `--help, -?`  
  Display a help message and exit.
• --add-drop-database
   Write a DROP DATABASE statement before each CREATE DATABASE statement.

• --add-drop-table
   Write a DROP TABLE statement before each CREATE TABLE statement.

• --add-drop-user
   Write a DROP USER statement before each CREATE USER statement.

• --add-locks
   Surround each table dump with LOCK TABLES and UNLOCK TABLES statements. This results in faster inserts when the dump file is reloaded. See Section 8.2.5.1, “Optimizing INSERT Statements”.

   This option does not work with parallelism because INSERT statements from different tables can be interleaved and UNLOCK TABLES following the end of the inserts for one table could release locks on tables for which inserts remain.

   --add-locks and --single-transaction are mutually exclusive.

• --all-databases, -A
   Dump all databases (with certain exceptions noted in mysqlpump Restrictions). This is the default behavior if no other is specified explicitly.

   --all-databases and --databases are mutually exclusive.

   Prior to MySQL 8.0, the --routines and --events options for mysqldump and mysqlpump were not required to include stored routines and events when using the --all-databases option: The dump included the mysql system database, and therefore also the mysql.proc and mysql.event tables containing stored routine and event definitions. As of MySQL 8.0, the mysql.event and mysql.proc tables are not used. Definitions for the corresponding objects are stored in data dictionary tables, but those tables are not dumped. To include stored routines and events in a dump made using --all-databases, use the --routines and --events options explicitly.

• --bind-address=ip_address
   On a computer having multiple network interfaces, use this option to select which interface to use for connecting to the MySQL server.

• --character-sets-dir=path
   The directory where character sets are installed. See Section 10.14, “Character Set Configuration”.

• --column-statistics
   Add ANALYZE TABLE statements to the output to generate histogram statistics for dumped tables when the dump file is reloaded. This option is disabled by default because histogram generation for large tables can take a long time.

• --complete-insert
   Write complete INSERT statements that include column names.

• --compress, -C
   Compress all information sent between the client and the server if possible. See Section 4.2.6, “Connection Compression Control”.
As of MySQL 8.0.18, this option is deprecated. It will be removed in a future MySQL version. See Legacy Connection Compression Configuration.

• **--compress-output=algorithm**

By default, `mysqlpump` does not compress output. This option specifies output compression using the specified algorithm. Permitted algorithms are **LZ4** and **ZLIB**.

To uncompress compressed output, you must have an appropriate utility. If the system commands `lz4` and `openssl zlib` are not available, MySQL distributions include `lz4_decompress` and `zlib_decompress` utilities that can be used to decompress `mysqlpump` output that was compressed using the **--compress-output=LZ4** and **--compress-output=ZLIB** options. For more information, see Section 4.8.1, "lz4_decompress — Decompress mysqlpump LZ4-Compressed Output", and Section 4.8.3, "zlib_decompress — Decompress mysqlpump ZLIB-Compressed Output".

• **--compression-algorithms=value**

The permitted compression algorithms for connections to the server. The available algorithms are the same as for the `protocol_compression_algorithms` system variable. The default value is uncompressed.

For more information, see Section 4.2.6, “Connection Compression Control”.

This option was added in MySQL 8.0.18.

• **--databases,-B**

Normally, `mysqlpump` treats the first name argument on the command line as a database name and any following names as table names. With this option, it treats all name arguments as database names. `CREATE DATABASE` statements are included in the output before each new database.

**--all-databases** and **--databases** are mutually exclusive.

• **--debug[=debug_options],-# [debug_options]**

Write a debugging log. A typical `debug_options` string is `d:t:o,file_name`. The default is `d:t:o,/tmp/mysqlpump.trace`.

• **--debug-check**

Print some debugging information when the program exits.

• **--debug-info,-T**

Print debugging information and memory and CPU usage statistics when the program exits.

• **--default-auth=plugin**

A hint about which client-side authentication plugin to use. See Section 6.2.17, “Pluggable Authentication”.

• **--default-character-set=charset_name**

Use `charset_name` as the default character set. See Section 10.14, “Character Set Configuration”. If no character set is specified, `mysqlpump` uses `utf8`.

• **--default-parallelism=N**

The default number of threads for each parallel processing queue. The default is 2.
The **--parallel-schemas** option also affects parallelism and can be used to override the default number of threads. For more information, see *mysqlpump Parallel Processing*.

With **--default-parallelism=0** and no **--parallel-schemas** options, mysqlpump runs as a single-threaded process and creates no queues.

With parallelism enabled, it is possible for output from different databases to be interleaved.

- **--defaults-extra-file=\*filename**

Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. \*filename is interpreted relative to the current directory if given as a relative path name rather than a full path name.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- **--defaults-file=\*filename**

Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. \*filename is interpreted relative to the current directory if given as a relative path name rather than a full path name.

Exception: Even with **--defaults-file**, client programs read .mylogin.cnf.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- **--defaults-group-suffix=\*str**

Read not only the usual option groups, but also groups with the usual names and a suffix of \*str. For example, mysqlpump normally reads the [client] and [mysqlpump] groups. If the **--defaults-group-suffix=_other** option is given, mysqlpump also reads the [client_other] and [mysqlpump_other] groups.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- **--defer-table-indexes**

In the dump output, defer index creation for each table until after its rows have been loaded. This works for all storage engines, but for InnoDB applies only for secondary indexes.

This option is enabled by default; use **--skip-defer-table-indexes** to disable it.

- **--events**

Include Event Scheduler events for the dumped databases in the output. Event dumping requires the EVENT privileges for those databases.

The output generated by using **--events** contains CREATE EVENT statements to create the events.

This option is enabled by default; use **--skip-events** to disable it.

- **--exclude-databases=\*db_list**

Do not dump the databases in \*db_list, which is a list of one or more comma-separated database names. Multiple instances of this option are additive. For more information, see *mysqlpump Object Selection*.

- **--exclude-events=\*event_list**
Do not dump the databases in `event_list`, which is a list of one or more comma-separated event names. Multiple instances of this option are additive. For more information, see `mysqlpump Object Selection`.

- `--exclude-routines=routine_list`

Do not dump the events in `routine_list`, which is a list of one or more comma-separated routine (stored procedure or function) names. Multiple instances of this option are additive. For more information, see `mysqlpump Object Selection`.

- `--exclude-tables=table_list`

Do not dump the tables in `table_list`, which is a list of one or more comma-separated table names. Multiple instances of this option are additive. For more information, see `mysqlpump Object Selection`.

- `--exclude-triggers=trigger_list`

Do not dump the triggers in `trigger_list`, which is a list of one or more comma-separated trigger names. Multiple instances of this option are additive. For more information, see `mysqlpump Object Selection`.

- `--exclude-users=user_list`

Do not dump the user accounts in `user_list`, which is a list of one or more comma-separated account names. Multiple instances of this option are additive. For more information, see `mysqlpump Object Selection`.

- `--extended-insert=N`

Write `INSERT` statements using multiple-row syntax that includes several `VALUES` lists. This results in a smaller dump file and speeds up inserts when the file is reloaded.

The option value indicates the number of rows to include in each `INSERT` statement. The default is 250. A value of 1 produces one `INSERT` statement per table row.

- `--get-server-public-key`

Request from the server the public key required for RSA key pair-based password exchange. This option applies to clients that authenticate with the `caching_sha2_password` authentication plugin. For that plugin, the server does not send the public key unless requested. This option is ignored for accounts that do not authenticate with that plugin. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

If `--server-public-key-path=file_name` is given and specifies a valid public key file, it takes precedence over `--get-server-public-key`.

For information about the `caching_sha2_password` plugin, see `Section 6.4.1.3, “Caching SHA-2 Pluggable Authentication”`.

- `--hex-blob`

Dump binary columns using hexadecimal notation (for example, `'abc' becomes 0x616263`). The affected data types are `BINARY`, `VARBINARY`, the `BLOB` types, and `BIT`.

- `--host=host_name, -h host_name`

Dump data from the MySQL server on the given host.

- `--include-databases=db_list`
Dump the databases in `db_list`, which is a list of one or more comma-separated database names. The dump includes all objects in the named databases. Multiple instances of this option are additive. For more information, see `mysqlpump Object Selection`.

- `--include-events=event_list`

  Dump the events in `event_list`, which is a list of one or more comma-separated event names. Multiple instances of this option are additive. For more information, see `mysqlpump Object Selection`.

- `--include-routines=routine_list`

  Dump the routines in `routine_list`, which is a list of one or more comma-separated routine (stored procedure or function) names. Multiple instances of this option are additive. For more information, see `mysqlpump Object Selection`.

- `--include-tables=table_list`

  Dump the tables in `table_list`, which is a list of one or more comma-separated table names. Multiple instances of this option are additive. For more information, see `mysqlpump Object Selection`.

- `--include-triggers=trigger_list`

  Dump the triggers in `trigger_list`, which is a list of one or more comma-separated trigger names. Multiple instances of this option are additive. For more information, see `mysqlpump Object Selection`.

- `--include-users=user_list`

  Dump the user accounts in `user_list`, which is a list of one or more comma-separated user names. Multiple instances of this option are additive. For more information, see `mysqlpump Object Selection`.

- `--insert-ignore`

  Write `INSERT IGNORE` statements rather than `INSERT` statements.

- `--log-error-file=file_name`

  Log warnings and errors by appending them to the named file. If this option is not given, `mysqlpump` writes warnings and errors to the standard error output.

- `--login-path=name`

  Read options from the named login path in the `.mylogin.cnf` login path file. A “login path” is an option group containing options that specify which MySQL server to connect to and which account to authenticate as. To create or modify a login path file, use the `mysql_config_editor` utility. See Section 4.6.7, “mysql_config_editor — MySQL Configuration Utility”.

  For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- `--max-allowed-packet=N`

  The maximum size of the buffer for client/server communication. The default is 24MB, the maximum is 1GB.

- `--net-buffer-length=N`

  The initial size of the buffer for client/server communication. When creating multiple-row `INSERT` statements (as with the `--extended-insert` option), `mysqlpump` creates rows up to `N` bytes long. If you use this option to increase the value, ensure that the MySQL server `net_buffer_length` system variable has a value at least this large.
• --no-create-db

Suppress any CREATE DATABASE statements that might otherwise be included in the output.

• --no-create-info, -t

Do not write CREATE TABLE statements that create each dumped table.

• --no-defaults

Do not read any option files. If program startup fails due to reading unknown options from an option file, --no-defaults can be used to prevent them from being read.

The exception is that the .mylogin.cnf file, if it exists, is read in all cases. This permits passwords to be specified in a safer way than on the command line even when --no-defaults is used. (.mylogin.cnf is created by the mysql_config_editor utility. See Section 4.6.7, "mysql_config_editor — MySQL Configuration Utility").

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

• --parallel-schemas=[N:]db_list

Create a queue for processing the databases in db_list, which is a list of one or more comma-separated database names. If N is given, the queue uses N threads. If N is not given, the --default-parallelism option determines the number of queue threads.

Multiple instances of this option create multiple queues. mysqlpump also creates a default queue to use for databases not named in any --parallel-schemas option, and for dumping user definitions if command options select them. For more information, see mysqlpump Parallel Processing.

• --password[=password], -p[password]

The password of the MySQL account used for connecting to the server. The password value is optional. If not given, mysqlpump prompts for one. If given, there must be no space between --password= or -p and the password following it. If no password option is specified, the default is to send no password.

Specifying a password on the command line should be considered insecure. To avoid giving the password on the command line, use an option file. See Section 6.1.2.1, “End-User Guidelines for Password Security”.

To explicitly specify that there is no password and that mysqlpump should not prompt for one, use the --skip-password option.

• --plugin-dir=dir_name

The directory in which to look for plugins. Specify this option if the --default-auth option is used to specify an authentication plugin but mysqlpump does not find it. See Section 6.2.17, “Pluggable Authentication”.

• --port=port_num, -P port_num

For TCP/IP connections, the port number to use.

• --print-defaults

Print the program name and all options that it gets from option files.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.
• **--protocol={TCP|SOCKET|PIPE|MEMORY}**

  The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally result in use of a protocol other than the one you want. For details on the permissible values, see Section 4.2.4, “Connecting to the MySQL Server Using Command Options”.

• **--replace**

  Write REPLACE statements rather than INSERT statements.

• **--result-file=file_name**

  Direct output to the named file. The result file is created and its previous contents overwritten, even if an error occurs while generating the dump.

  This option should be used on Windows to prevent newline \n characters from being converted to \r\n carriage return/newline sequences.

• **--routines**

  Include stored routines (procedures and functions) for the dumped databases in the output. This option requires the global SELECT privilege.

  The output generated by using --routines contains CREATE PROCEDURE and CREATE FUNCTION statements to create the routines.

  This option is enabled by default; use --skip-routines to disable it.

• **--secure-auth**

  This option was removed in MySQL 8.0.3.

• **--server-public-key-path=file_name**

  The path name to a file containing a client-side copy of the public key required by the server for RSA key pair-based password exchange. The file must be in PEM format. This option applies to clients that authenticate with the sha256_password or caching_sha2_password authentication plugin. This option is ignored for accounts that do not authenticate with one of those plugins. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

  If --server-public-key-path=file_name is given and specifies a valid public key file, it takes precedence over --get-server-public-key.

  For sha256_password, this option applies only if MySQL was built using OpenSSL.

  For information about the sha256_password and caching_sha2_password plugins, see Section 6.4.1.2, “SHA-256 Pluggable Authentication”, and Section 6.4.1.3, “Caching SHA-2 Pluggable Authentication”.

• **--set-charset**

  Write SET NAMES default_character_set to the output.

  This option is enabled by default. To disable it and suppress the SET NAMES statement, use --skip-set-charset.

• **--set-gtid-purged=value**

  This option enables control over global transaction ID (GTID) information written to the dump file, by indicating whether to add a SET @@GLOBAL.gtid_purged statement to the output. This option
may also cause a statement to be written to the output that disables binary logging while the dump file is being reloaded.

The following table shows the permitted option values. The default value is AUTO.

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>OFF</td>
<td>Add no SET statement to the output.</td>
</tr>
<tr>
<td>ON</td>
<td>Add a SET statement to the output. An error occurs if GTIDs are not enabled on the server.</td>
</tr>
<tr>
<td>AUTO</td>
<td>Add a SET statement to the output if GTIDs are enabled on the server.</td>
</tr>
</tbody>
</table>

The --set-gtid-purged option has the following effect on binary logging when the dump file is reloaded:

• --set-gtid-purged=OFF: SET @@SESSION.SQL_LOG_BIN=0; is not added to the output.
• --set-gtid-purged=ON: SET @@SESSION.SQL_LOG_BIN=0; is added to the output.
• --set-gtid-purged=AUTO: SET @@SESSION.SQL_LOG_BIN=0; is added to the output if GTIDs are enabled on the server you are backing up (that is, if AUTO evaluates to ON).

• --single-transaction

This option sets the transaction isolation mode to REPEATABLE READ and sends a START TRANSACTION SQL statement to the server before dumping data. It is useful only with transactional tables such as InnoDB, because then it dumps the consistent state of the database at the time when START TRANSACTION was issued without blocking any applications.

When using this option, you should keep in mind that only InnoDB tables are dumped in a consistent state. For example, any MyISAM or MEMORY tables dumped while using this option may still change state.

While a --single-transaction dump is in process, to ensure a valid dump file (correct table contents and binary log coordinates), no other connection should use the following statements: ALTER TABLE, CREATE TABLE, DROP TABLE, RENAME TABLE, TRUNCATE TABLE. A consistent read is not isolated from those statements, so use of them on a table to be dumped can cause the SELECT that is performed by mysqlpump to retrieve the table contents to obtain incorrect contents or fail.

--add-locks and --single-transaction are mutually exclusive.

• --skip-definer

Omit DEFINER and SQL SECURITY clauses from the CREATE statements for views and stored programs. The dump file, when reloaded, creates objects that use the default DEFINER and SQL SECURITY values. See Section 24.6, “Stored Object Access Control”.

• --skip-dump-rows, -d

Do not dump table rows.

• --socket=path, -S path

For connections to localhost, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

On Windows, this option applies only if the server was started with the named_pipe system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the named_pipe_full_access_group system variable.
• **--ssl**

Options that begin with **--ssl** specify whether to connect to the server using SSL and indicate where to find SSL keys and certificates. See Command Options for Encrypted Connections.

• **--ssl-fips-mode={OFF|ON|STRICT}**

Controls whether to enable FIPS mode on the client side. The **--ssl-fips-mode** option differs from other **--ssl-xxx** options in that it is not used to establish encrypted connections, but rather to affect which cryptographic operations are permitted. See Section 6.5, “FIPS Support”.

These **--ssl-fips-mode** values are permitted:

• **OFF**: Disable FIPS mode.

• **ON**: Enable FIPS mode.

• **STRICT**: Enable “strict” FIPS mode.

**Note**

If the OpenSSL FIPS Object Module is not available, the only permitted value for **--ssl-fips-mode** is OFF. In this case, setting **--ssl-fips-mode** to ON or STRICT causes the client to produce a warning at startup and to operate in non-FIPS mode.

• **--tls-ciphersuites=ciphersuite_list**

The permissible TLSv1.3 ciphersuites for encrypted connections. The value is a list of one or more colon-separated ciphersuite names. The ciphersuites that can be named for this option depend on the SSL library used to compile MySQL. For details, see Section 6.3.5, “Encrypted Connection Protocols and Ciphers”.

This option was added in MySQL 8.0.16.

• **--tls-version=protocol_list**

The permissible TLS protocols for encrypted connections. The value is a list of one or more comma-separated protocol names. The protocols that can be named for this option depend on the SSL library used to compile MySQL. For details, see Section 6.3.5, “Encrypted Connection Protocols and Ciphers”.

• **--triggers**

Include triggers for each dumped table in the output.

This option is enabled by default; use **--skip-triggers** to disable it.

• **--tz-utc**

This option enables **TIMESTAMP** columns to be dumped and reloaded between servers in different time zones. **mysqlpump** sets its connection time zone to UTC and adds **SET TIME_ZONE='+00:00'** to the dump file. Without this option, **TIMESTAMP** columns are dumped and reloaded in the time zones local to the source and destination servers, which can cause the values to change if the servers are in different time zones. **--tz-utc** also protects against changes due to daylight saving time.

This option is enabled by default; use **--skip-tz-utc** to disable it.

• **--user=user_name, -u user_name**

The user name of the MySQL account to use for connecting to the server.
mysqlpump — A Database Backup Program

• **--users**
  
  Dump user accounts as logical definitions in the form of `CREATE USER` and `GRANT` statements.

  User definitions are stored in the grant tables in the `mysql` system database. By default, `mysqlpump` does not include the grant tables in `mysql` database dumps. To dump the contents of the grant tables as logical definitions, use the `--users` option and suppress all database dumping:

  ```shell
  mysqlpump --exclude-databases=% --users
  ```

• **--version, -V**
  
  Display version information and exit.

• **--watch-progress**
  
  Periodically display a progress indicator that provides information about the completed and total number of tables, rows, and other objects.

  This option is enabled by default; use `--skip-watch-progress` to disable it.

• **--zstd-compression-level=level**
  
  The compression level to use for connections to the server that use the `zstd` compression algorithm. The permitted levels are from 1 to 22, with larger values indicating increasing levels of compression. The default `zstd` compression level is 3. The compression level setting has no effect on connections that do not use `zstd` compression.

  For more information, see Section 4.2.6, “Connection Compression Control”.

  This option was added in MySQL 8.0.18.

**mysqlpump Object Selection**

`mysqlpump` has a set of inclusion and exclusion options that enable filtering of several object types and provide flexible control over which objects to dump:

• **--include-databases** and **--exclude-databases** apply to databases and all objects within them.

• **--include-tables** and **--exclude-tables** apply to tables. These options also affect triggers associated with tables unless the trigger-specific options are given.

• **--include-triggers** and **--exclude-triggers** apply to triggers.

• **--include-routines** and **--exclude-routines** apply to stored procedures and functions. If a routine option matches a stored procedure name, it also matches a stored function of the same name.

• **--include-events** and **--exclude-events** apply to Event Scheduler events.

• **--include-users** and **--exclude-users** apply to user accounts.

Any inclusion or exclusion option may be given multiple times. The effect is additive. Order of these options does not matter.

The value of each inclusion and exclusion option is a list of comma-separated names of the appropriate object type. For example:

```
--exclude-databases=test,world
--include-tables=customer,invoice
```

Wildcard characters are permitted in the object names:
MySQLPump matches any sequence of zero or more characters.

_ matches any single character.

For example, `--include-tables=t%,__tmp` matches all table names that begin with t and all five-character table names that end with tmp.

For users, a name specified without a host part is interpreted with an implied host of %. For example, u1 and u1@% are equivalent. This is the same equivalence that applies in MySQL generally (see Section 6.2.4, “Specifying Account Names”).

Inclusion and exclusion options interact as follows:

- By default, with no inclusion or exclusion options, MySQLPump dumps all databases (with certain exceptions noted in MySQLPump Restrictions).
- If inclusion options are given in the absence of exclusion options, only the objects named as included are dumped.
- If exclusion options are given in the absence of inclusion options, all objects are dumped except those named as excluded.
- If inclusion and exclusion options are given, all objects named as excluded and not named as included are not dumped. All other objects are dumped.

If multiple databases are being dumped, it is possible to name tables, triggers, and routines in a specific database by qualifying the object names with the database name. The following command dumps databases db1 and db2, but excludes tables db1.t1 and db2.t2:

```
shell> mysqlpump --include-databases=db1,db2 --exclude-tables=db1.t1,db2.t2
```

The following options provide alternative ways to specify which databases to dump:

- The `--all-databases` option dumps all databases (with certain exceptions noted in MySQLPump Restrictions). It is equivalent to specifying no object options at all (the default MySQLPump action is to dump everything).
  
  `--include-databases=%` is similar to `--all-databases`, but selects all databases for dumping, even those that are exceptions for `--all-databases`.

- The `--databases` option causes MySQLPump to treat all name arguments as names of databases to dump. It is equivalent to an `--include-databases` option that names the same databases.

MySQLPump Parallel Processing

MySQLPump can use parallelism to achieve concurrent processing. You can select concurrency between databases (to dump multiple databases simultaneously) and within databases (to dump multiple objects from a given database simultaneously).

By default, MySQLPump sets up one queue with two threads. You can create additional queues and control the number of threads assigned to each one, including the default queue:

- `--default-parallelism=N` specifies the default number of threads used for each queue. In the absence of this option, N is 2.

  The default queue always uses the default number of threads. Additional queues use the default number of threads unless you specify otherwise.

- `--parallel-schemas=[N:]db_list` sets up a processing queue for dumping the databases named in `db_list` and optionally specifies how many threads the queue uses. `db_list` is a list of comma-separated database names. If the option argument begins with `N:`, the queue uses `N` threads. Otherwise, the `--default-parallelism` option determines the number of queue threads.
Multiple instances of the `--parallel-schemas` option create multiple queues.

Names in the database list are permitted to contain the same `%` and `_` wildcard characters supported for filtering options (see `mysqlpump Object Selection`).

`mysqlpump` uses the default queue for processing any databases not named explicitly with a `--parallel-schemas` option, and for dumping user definitions if command options select them.

In general, with multiple queues, `mysqlpump` uses parallelism between the sets of databases processed by the queues, to dump multiple databases simultaneously. For a queue that uses multiple threads, `mysqlpump` uses parallelism within databases, to dump multiple objects from a given database simultaneously. Exceptions can occur; for example, `mysqlpump` may block queues while it obtains from the server lists of objects in databases.

With parallelism enabled, it is possible for output from different databases to be interleaved. For example, `INSERT` statements from multiple tables dumped in parallel can be interleaved; the statements are not written in any particular order. This does not affect reloading because output statements qualify object names with database names or are preceded by `USE` statements as required.

The granularity for parallelism is a single database object. For example, a single table cannot be dumped in parallel using multiple threads.

Examples:

```
shell> mysqlpump --parallel-schemas=db1,db2 --parallel-schemas=db3
```

`mysqlpump` sets up a queue to process `db1` and `db2`, another queue to process `db3`, and a default queue to process all other databases. All queues use two threads.

```
shell> mysqlpump --parallel-schemas=db1,db2 --parallel-schemas=db3
               --default-parallelism=4
```

This is the same as the previous example except that all queues use four threads.

```
shell> mysqlpump --parallel-schemas=5:db1,db2 --parallel-schemas=3:db3
```

The queue for `db1` and `db2` uses five threads, the queue for `db3` uses three threads, and the default queue uses the default of two threads.

As a special case, with `--default-parallelism=0` and no `--parallel-schemas` options, `mysqlpump` runs as a single-threaded process and creates no queues.

`mysqlpump Restrictions`

`mysqlpump` does not dump the `performance_schema`, `ndbinfo`, or `sys` schema by default. To dump any of these, name them explicitly on the command line. You can also name them with the `--databases` or `--include-databases` option.

`mysqlpump` does not dump the `INFORMATION_SCHEMA` schema.

`mysqlpump` does not dump `InnoDB` `CREATE TABLESPACE` statements.

`mysqlpump` dumps user accounts in logical form using `CREATE USER` and `GRANT` statements (for example, when you use the `--include-users` or `--users` option). For this reason, dumps of the `mysql` system database do not by default include the grant tables that contain user definitions: `user`, `db`, `tables_priv`, `columns_priv`, `procs_priv`, or `proxies_priv`. To dump any of the grant tables, name the `mysql` database followed by the table names:

```
shell> mysqlpump mysql user db ...
```
4.5.7 mysqlshow — Display Database, Table, and Column Information

The `mysqlshow` client can be used to quickly see which databases exist, their tables, or a table's columns or indexes.

`mysqlshow` provides a command-line interface to several SQL `SHOW` statements. See Section 13.7.6, “SHOW Syntax”. The same information can be obtained by using those statements directly. For example, you can issue them from the `mysql` client program.

Invoke `mysqlshow` like this:

```
shell> mysqlshow [options] [db_name [tbl_name [col_name]]]
```

- If no database is given, a list of database names is shown.
- If no table is given, all matching tables in the database are shown.
- If no column is given, all matching columns and column types in the table are shown.

The output displays only the names of those databases, tables, or columns for which you have some privileges.

If the last argument contains shell or SQL wildcard characters (`*`, `?`, `%`, or `_`), only those names that are matched by the wildcard are shown. If a database name contains any underscores, those should be escaped with a backslash (some Unix shells require two) to get a list of the proper tables or columns. * and ? characters are converted into SQL % and _ wildcard characters. This might cause some confusion when you try to display the columns for a table with a _ in the name, because in this case, `mysqlshow` shows you only the table names that match the pattern. This is easily fixed by adding an extra % last on the command line as a separate argument.

`mysqlshow` supports the following options, which can be specified on the command line or in the `[mysqlshow]` and `[client]` groups of an option file. For information about option files used by MySQL programs, see Section 4.2.2.2, “Using Option Files”.

</tbody>
</table>
• **--help, -?**

Display a help message and exit.

• **--bind-address=ip_address**

On a computer having multiple network interfaces, use this option to select which interface to use for connecting to the MySQL server.

• **--character-sets-dir=dir_name**

The directory where character sets are installed. See Section 10.14, “Character Set Configuration”.

• **--compress, -C**

Compress all information sent between the client and the server if possible. See Section 4.2.6, “Connection Compression Control”.

As of MySQL 8.0.18, this option is deprecated. It will be removed in a future MySQL version. See Legacy Connection Compression Configuration.

• **--compression-algorithms=value**

The permitted compression algorithms for connections to the server. The available algorithms are the same as for the `protocol_compression_algorithms` system variable. The default value is uncompressed.

For more information, see Section 4.2.6, “Connection Compression Control”.

This option was added in MySQL 8.0.18.

• **--count**

Show the number of rows per table. This can be slow for non-MyISAM tables.

• **--debug[=debug_options], -# [debug_options]**

Write a debugging log. A typical `debug_options` string is `d:t:o, file_name`. The default is `d:t:o`.

• **--debug-check**

Print some debugging information when the program exits.

• **--debug-info**

Print debugging information and memory and CPU usage statistics when the program exits.

• **--default-character-set=charset_name**

Use `charset_name` as the default character set. See Section 10.14, “Character Set Configuration”.

• **--default-auth=plugin**

A hint about which client-side authentication plugin to use. See Section 6.2.17, “Pluggable Authentication”.

• **--defaults-extra-file=file_name**

Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. `file_name` is interpreted relative to the current directory if given as a relative path name rather than a full path name.
For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- **--defaults-file=file_name**

  Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. `file_name` is interpreted relative to the current directory if given as a relative path name rather than a full path name.

  Exception: Even with `--defaults-file`, client programs read `.mylogin.cnf`.

  For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- **--defaults-group-suffix=str**

  Read not only the usual option groups, but also groups with the usual names and a suffix of `str`. For example, `mysqlshow` normally reads the [client] and [mysqlshow] groups. If the `--defaults-group-suffix=_other` option is given, `mysqlshow` also reads the [client_other] and [mysqlshow_other] groups.

  For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- **--enable-cleartext-plugin**

  Enable the `mysql_clear_password` cleartext authentication plugin. (See Section 6.4.1.4, “Client-Side Cleartext Pluggable Authentication”.)

- **--get-server-public-key**

  Request from the server the RSA public key that it uses for key pair-based password exchange. This option applies to clients that connect to the server using an account that authenticates with the `caching_sha2_password` authentication plugin. For connections by such accounts, the server does not send the public key to the client unless requested. The option is ignored for accounts that do not authenticate with that plugin. It is also ignored if RSA-based password exchange is not needed, as is the case when the client connects to the server using a secure connection.

  If `--server-public-key-path=file_name` is given and specifies a valid public key file, it takes precedence over `--get-server-public-key`.

  For information about the `caching_sha2_password` plugin, see Section 6.4.1.3, “Caching SHA-2 Pluggable Authentication”.

- **--host=host_name, -h host_name**

  Connect to the MySQL server on the given host.

- **--keys, -k**

  Show table indexes.

- **--login-path=name**

  Read options from the named login path in the `.mylogin.cnf` login path file. A “login path” is an option group containing options that specify which MySQL server to connect to and which account to authenticate as. To create or modify a login path file, use the `mysql_config_editor` utility. See Section 4.6.7, “mysql_config_editor — MySQL Configuration Utility”.

  For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

• **--no-defaults**

Do not read any option files. If program startup fails due to reading unknown options from an option file, **--no-defaults** can be used to prevent them from being read.

The exception is that the `.mylogin.cnf` file, if it exists, is read in all cases. This permits passwords to be specified in a safer way than on the command line even when **--no-defaults** is used. `.mylogin.cnf` is created by the `mysql_config_editor` utility. See Section 4.6.7, "mysql_config_editor — MySQL Configuration Utility".

For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

• **--password[=password], -p[password]**

The password of the MySQL account used for connecting to the server. The password value is optional. If not given, `mysqlshow` prompts for one. If given, there must be no space between **--password=** or **-p** and the password following it. If no password option is specified, the default is to send no password.

Specifying a password on the command line should be considered insecure. To avoid giving the password on the command line, use an option file. See Section 6.1.2.1, "End-User Guidelines for Password Security".

To explicitly specify that there is no password and that `mysqlshow` should not prompt for one, use the **--skip-password** option.

• **--pipe, -W**

On Windows, connect to the server using a named pipe. This option applies only if the server was started with the `named_pipe` system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the `named_pipe_full_access_group` system variable.

• **--plugin-dir=dir_name**

The directory in which to look for plugins. Specify this option if the **--default-auth** option is used to specify an authentication plugin but `mysqlshow` does not find it. See Section 6.2.17, "Pluggable Authentication".

• **--port=port_num, -P port_num**

For TCP/IP connections, the port number to use.

• **--print-defaults**

Print the program name and all options that it gets from option files.

For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

• **--protocol={TCP|SOCKET|PIPE|MEMORY}**

The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally result in use of a protocol other than the one you want. For details on the permissible values, see Section 4.2.4, "Connecting to the MySQL Server Using Command Options".

• **--secure-auth**

This option was removed in MySQL 8.0.3.

• **--server-public-key-path=file_name**
The path name to a file containing a client-side copy of the public key required by the server for RSA key pair-based password exchange. The file must be in PEM format. This option applies to clients that authenticate with the `sha256_password` or `caching_sha2_password` authentication plugin. This option is ignored for accounts that do not authenticate with one of those plugins. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

If `--server-public-key-path=file_name` is given and specifies a valid public key file, it takes precedence over `--get-server-public-key`.

For `sha256_password`, this option applies only if MySQL was built using OpenSSL.

For information about the `sha256_password` and `caching_sha2_password` plugins, see Section 6.4.1.2, “SHA-256 Pluggable Authentication”, and Section 6.4.1.3, “Caching SHA-2 Pluggable Authentication”.

• `--shared-memory-base-name=name`

On Windows, the shared-memory name to use for connections made using shared memory to a local server. The default value is `MYSQL`. The shared-memory name is case-sensitive.

This option applies only if the server was started with the `shared_memory` system variable enabled to support shared-memory connections.

• `--show-table-type, -t`

Show a column indicating the table type, as in `SHOW FULL TABLES`. The type is `BASE TABLE` or `VIEW`.

• `--socket=path, -S path`

For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

On Windows, this option applies only if the server was started with the `named_pipe` system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the `named_pipe_full_access_group` system variable.

• `--ssl*`

Options that begin with `--ssl` specify whether to connect to the server using SSL and indicate where to find SSL keys and certificates. See Command Options for Encrypted Connections.

• `--ssl-fips-mode={OFF|ON|STRICT}`

Controls whether to enable FIPS mode on the client side. The `--ssl-fips-mode` option differs from other `--ssl-xxx` options in that it is not used to establish encrypted connections, but rather to affect which cryptographic operations are permitted. See Section 6.5, “FIPS Support”.

These `--ssl-fips-mode` values are permitted:

• **OFF**: Disable FIPS mode.

• **ON**: Enable FIPS mode.

• **STRICT**: Enable “strict” FIPS mode.
**Note**
If the OpenSSL FIPS Object Module is not available, the only permitted value for --ssl-fips-mode is OFF. In this case, setting --ssl-fips-mode to ON or STRICT causes the client to produce a warning at startup and to operate in non-FIPS mode.

- **--status, -i**
  Display extra information about each table.

- **--tls-ciphersuites=ciphersuite_list**
  The permissible TLSv1.3 ciphersuites for encrypted connections. The value is a list of one or more colon-separated ciphersuite names. The ciphersuites that can be named for this option depend on the SSL library used to compile MySQL. For details, see Section 6.3.5, “Encrypted Connection Protocols and Ciphers”.
  This option was added in MySQL 8.0.16.

- **--tls-version=protocol_list**
  The permissible TLS protocols for encrypted connections. The value is a list of one or more comma-separated protocol names. The protocols that can be named for this option depend on the SSL library used to compile MySQL. For details, see Section 6.3.5, “Encrypted Connection Protocols and Ciphers”.

- **--user=user_name, -u user_name**
  The user name of the MySQL account to use for connecting to the server.

- **--verbose, -v**
  Verbose mode. Print more information about what the program does. This option can be used multiple times to increase the amount of information.

- **--version, -V**
  Display version information and exit.

- **--zstd-compression-level=level**
  The compression level to use for connections to the server that use the zstd compression algorithm. The permitted levels are from 1 to 22, with larger values indicating increasing levels of compression. The default zstd compression level is 3. The compression level setting has no effect on connections that do not use zstd compression.
  For more information, see Section 4.2.6, “Connection Compression Control”.
  This option was added in MySQL 8.0.18.

### 4.5.8 mysqlslap — Load Emulation Client

mysqlslap is a diagnostic program designed to emulate client load for a MySQL server and to report the timing of each stage. It works as if multiple clients are accessing the server.

Invoke mysqlslap like this:

```shell
shell> mysqlslap [options]
```

Some options such as --create or --query enable you to specify a string containing an SQL statement or a file containing statements. If you specify a file, by default it must contain one statement
MySQLslap — Load Emulation Client

per line. (That is, the implicit statement delimiter is the newline character.) Use the `--delimiter` option to specify a different delimiter, which enables you to specify statements that span multiple lines or place multiple statements on a single line. You cannot include comments in a file; `mysqlslap` does not understand them.

`mysqlslap` runs in three stages:

1. Create schema, table, and optionally any stored programs or data to use for the test. This stage uses a single client connection.
2. Run the load test. This stage can use many client connections.
3. Clean up (disconnect, drop table if specified). This stage uses a single client connection.

Examples:

Supply your own create and query SQL statements, with 50 clients querying and 200 selects for each (enter the command on a single line):

```
mysqlslap --delimiter=";"
    --create="CREATE TABLE a (b int);INSERT INTO a VALUES (23)"
    --query="SELECT * FROM a" --concurrency=50 --iterations=200
```

Let `mysqlslap` build the query SQL statement with a table of two `INT` columns and three `VARCHAR` columns. Use five clients querying 20 times each. Do not create the table or insert the data (that is, use the previous test's schema and data):

```
mysqlslap --concurrency=5 --iterations=20
    --number-int-cols=2 --number-char-cols=3
    --auto-generate-sql
```

Tell the program to load the create, insert, and query SQL statements from the specified files, where the `create.sql` file has multiple table creation statements delimited by ';'; and multiple insert statements delimited by ';'. The `--query` file will have multiple queries delimited by ';'. Run all the load statements, then run all the queries in the query file with five clients (five times each):

```
mysqlslap --concurrency=5
    --iterations=5 --query=query.sql --create=create.sql
    --delimiter=";"
```

`mysqlslap` supports the following options, which can be specified on the command line or in the `[mysqlslap]` and `[client]` groups of an option file. For information about option files used by MySQL programs, see Section 4.2.2.2, “Using Option Files”.

### Table 4.18 mysqlslap Options

<table>
<thead>
<tr>
<th>Option Name</th>

- **--help, -?**
  Display a help message and exit.

- **--auto-generate-sql,-a**
  Generate SQL statements automatically when they are not supplied in files or using command options.

- **--auto-generate-sql-add-autoincrement**
  Add an AUTO_INCREMENT column to automatically generated tables.

- **--auto-generate-sql-execute-number=N**
  Specify how many queries to generate automatically.

- **--auto-generate-sql-guid-primary**
  Add a GUID-based primary key to automatically generated tables.

- **--auto-generate-sql-load-type=type**
  Specify the test load type. The permissible values are read (scan tables), write (insert into tables), key (read primary keys), update (update primary keys), or mixed (half inserts, half scanning selects). The default is mixed.

- **--auto-generate-sql-secondary-indexes=N**
  Specify how many secondary indexes to add to automatically generated tables. By default, none are added.

- **--auto-generate-sql-unique-query-number=N**
  How many different queries to generate for automatic tests. For example, if you run a key test that performs 1000 selects, you can use this option with a value of 1000 to run 1000 unique queries, or with a value of 50 to perform 50 different selects. The default is 10.

- **--auto-generate-sql-unique-write-number=N**
  How many different queries to generate for **--auto-generate-sql-write-number**. The default is 10.

- **--auto-generate-sql-write-number=N**
  How many row inserts to perform. The default is 100.

- **--commit=N**
mysqlslap — Load Emulation Client

How many statements to execute before committing. The default is 0 (no commits are done).

• --compress, -C

Compress all information sent between the client and the server if possible. See Section 4.2.6, “Connection Compression Control”.

As of MySQL 8.0.18, this option is deprecated. It will be removed in a future MySQL version. See Legacy Connection Compression Configuration.

• --compression-algorithms=value

The permitted compression algorithms for connections to the server. The available algorithms are the same as for the protocol_compression_algorithms system variable. The default value is uncompressed.

For more information, see Section 4.2.6, “Connection Compression Control”.

This option was added in MySQL 8.0.18.

• --concurrency=N, -c N

The number of parallel clients to simulate.

• --create=value

The file or string containing the statement to use for creating the table.

• --create-schema=value

The schema in which to run the tests.

Note

If the --auto-generate-sql option is also given, mysqlslap drops the schema at the end of the test run. To avoid this, use the --no-drop option as well.

• --csv[=file_name]

Generate output in comma-separated values format. The output goes to the named file, or to the standard output if no file is given.

• --debug[=debug_options], -# [debug_options]

Write a debugging log. A typical debug_options string is d:t:o, file_name. The default is d:t:o,/tmp/mysqlslap.trace.

• --debug-check

Print some debugging information when the program exits.

• --debug-info, -T

Print debugging information and memory and CPU usage statistics when the program exits.

• --default-auth=plugin

A hint about which client-side authentication plugin to use. See Section 6.2.17, “Pluggable Authentication”.

• --defaults-extra-file=file_name
Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. file_name is interpreted relative to the current directory if given as a relative path name rather than a full path name.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

• --defaults-file=file_name

Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. file_name is interpreted relative to the current directory if given as a relative path name rather than a full path name.

Exception: Even with --defaults-file, client programs read .mylogin.cnf.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

• --defaults-group-suffix=str

Read not only the usual option groups, but also groups with the usual names and a suffix of str. For example, mysqlslap normally reads the [client] and [mysqlslap] groups. If the --defaults-group-suffix=_other option is given, mysqlslap also reads the [client_other] and [mysqlslap_other] groups.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

• --delimiter=str, -F str

The delimiter to use in SQL statements supplied in files or using command options.

• --detach=N

Detach (close and reopen) each connection after each $N$ statements. The default is 0 (connections are not detached).

• --enable-cleartext-plugin

Enable the mysql_clear_password cleartext authentication plugin. (See Section 6.4.1.4, “Client-Side Cleartext Pluggable Authentication”.)

• --engine=engine_name, -e engine_name

The storage engine to use for creating tables.

• --get-server-public-key

Request from the server the RSA public key that it uses for key pair-based password exchange. This option applies to clients that connect to the server using an account that authenticates with the caching_sha2_password authentication plugin. For connections by such accounts, the server does not send the public key to the client unless requested. The option is ignored for accounts that do not authenticate with that plugin. It is also ignored if RSA-based password exchange is not needed, as is the case when the client connects to the server using a secure connection.

If --server-public-key-path=file_name is given and specifies a valid public key file, it takes precedence over --get-server-public-key.

For information about the caching_sha2_password plugin, see Section 6.4.1.3, “Caching SHA-2 Pluggable Authentication”.

• --host=host_name, -h host_name
Connect to the MySQL server on the given host.

- **--iterations=N, -i N**
  The number of times to run the tests.

- **--login-path=name**
  Read options from the named login path in the .mylogin.cnf login path file. A “login path” is an option group containing options that specify which MySQL server to connect to and which account to authenticate as. To create or modify a login path file, use the mysql_config_editor utility. See Section 4.6.7, “mysql_config_editor — MySQL Configuration Utility”.

  For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- **--no-drop**
  Prevent mysqlslap from dropping any schema it creates during the test run.

- **--no-defaults**
  Do not read any option files. If program startup fails due to reading unknown options from an option file, --no-defaults can be used to prevent them from being read.

  The exception is that the .mylogin.cnf file, if it exists, is read in all cases. This permits passwords to be specified in a safer way than on the command line even when --no-defaults is used. (.mylogin.cnf is created by the mysql_config_editor utility. See Section 4.6.7, “mysql_config_editor — MySQL Configuration Utility”.)

  For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- **--number-char-cols=N, -x N**
  The number of VARCHAR columns to use if --auto-generate-sql is specified.

- **--number-int-cols=N, -y N**
  The number of INT columns to use if --auto-generate-sql is specified.

- **--number-of-queries=N**
  Limit each client to approximately this many queries. Query counting takes into account the statement delimiter. For example, if you invoke mysqlslap as follows, the ; delimiter is recognized so that each instance of the query string counts as two queries. As a result, 5 rows (not 10) are inserted.

  ```shell
  shell> mysqlslap --delimiter=";" --number-of-queries=10
  --query="use test;insert into t values(null)"
  ```

- **--only-print**
  Do not connect to databases. mysqlslap only prints what it would have done.

- **--password[=password], -p[password]**
  The password of the MySQL account used for connecting to the server. The password value is optional. If not given, mysqlslap prompts for one. If given, there must be no space between --password or -p and the password following it. If no password option is specified, the default is to send no password.
Specifying a password on the command line should be considered insecure. To avoid giving the password on the command line, use an option file. See Section 6.1.2.1, "End-User Guidelines for Password Security".

To explicitly specify that there is no password and that `mysqlslap` should not prompt for one, use the `--skip-password` option.

- **--pipe**, `-W`

On Windows, connect to the server using a named pipe. This option applies only if the server was started with the `named_pipe` system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the `named_pipe_full_access_group` system variable.

- **--plugin-dir=dir_name**

  The directory in which to look for plugins. Specify this option if the `--default-auth` option is used to specify an authentication plugin but `mysqlslap` does not find it. See Section 6.2.17, "Pluggable Authentication".

- **--port=port_num, -P port_num**

  For TCP/IP connections, the port number to use.

- **--post-query=value**

  The file or string containing the statement to execute after the tests have completed. This execution is not counted for timing purposes.

- **--post-system=str**

  The string to execute using `system()` after the tests have completed. This execution is not counted for timing purposes.

- **--pre-query=value**

  The file or string containing the statement to execute before running the tests. This execution is not counted for timing purposes.

- **--pre-system=str**

  The string to execute using `system()` before running the tests. This execution is not counted for timing purposes.

- **--print-defaults**

  Print the program name and all options that it gets from option files.

  For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- **--protocol={TCP|SOCKET|PIPE|MEMORY}**

  The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally result in use of a protocol other than the one you want. For details on the permissible values, see Section 4.2.4, "Connecting to the MySQL Server Using Command Options".

- **--query=value, -q value**

  The file or string containing the `SELECT` statement to use for retrieving data.

- **--secure-auth**
This option was removed in MySQL 8.0.3.

• `--server-public-key-path=file_name`

The path name to a file containing a client-side copy of the public key required by the server for RSA key pair-based password exchange. The file must be in PEM format. This option applies to clients that authenticate with the `sha256_password` or `caching_sha2_password` authentication plugin. This option is ignored for accounts that do not authenticate with one of those plugins. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

If `--server-public-key-path=file_name` is given and specifies a valid public key file, it takes precedence over `--get-server-public-key`.

For `sha256_password`, this option applies only if MySQL was built using OpenSSL.

For information about the `sha256_password` and `caching_sha2_password` plugins, see Section 6.4.1.2, “SHA-256 Pluggable Authentication”, and Section 6.4.1.3, “Caching SHA-2 Pluggable Authentication”.

• `--shared-memory-base-name=name`

On Windows, the shared-memory name to use for connections made using shared memory to a local server. The default value is `MYSQL`. The shared-memory name is case-sensitive.

This option applies only if the server was started with the `shared_memory` system variable enabled to support shared-memory connections.

• `--silent, -s`

Silent mode. No output.

• `--socket=path, -S path`

For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

On Windows, this option applies only if the server was started with the `named_pipe` system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the `named_pipe_full_access_group` system variable.

• `--sql-mode=mode`

Set the SQL mode for the client session.

• `--ssl*`

Options that begin with `--ssl` specify whether to connect to the server using SSL and indicate where to find SSL keys and certificates. See Command Options for Encrypted Connections.

• `--ssl-fips-mode={OFF|ON|STRICT}`

Controls whether to enable FIPS mode on the client side. The `--ssl-fips-mode` option differs from other `--ssl-xxx` options in that it is not used to establish encrypted connections, but rather to affect which cryptographic operations are permitted. See Section 6.5, “FIPS Support”.

These `--ssl-fips-mode` values are permitted:

• `OFF`: Disable FIPS mode.

• `ON`: Enable FIPS mode.
MySQL Administrative and Utility Programs

- **STRICT**: Enable “strict” FIPS mode.

  **Note**
  If the OpenSSL FIPS Object Module is not available, the only permitted value for `--ssl-fips-mode` is **OFF**. In this case, setting `--ssl-fips-mode` to **ON** or **STRICT** causes the client to produce a warning at startup and to operate in non-FIPS mode.

- **--tls-ciphersuites=ciphersuite_list**
  The permissible TLSv1.3 ciphersuites for encrypted connections. The value is a list of one or more colon-separated ciphersuite names. The ciphersuites that can be named for this option depend on the SSL library used to compile MySQL. For details, see Section 6.3.5, “Encrypted Connection Protocols and Ciphers”.
  This option was added in MySQL 8.0.16.

- **--tls-version=protocol_list**
  The permissible TLS protocols for encrypted connections. The value is a list of one or more comma-separated protocol names. The protocols that can be named for this option depend on the SSL library used to compile MySQL. For details, see Section 6.3.5, “Encrypted Connection Protocols and Ciphers”.

- **--user=user_name, -u user_name**
  The user name of the MySQL account to use for connecting to the server.

- **--verbose, -v**
  Verbose mode. Print more information about what the program does. This option can be used multiple times to increase the amount of information.

- **--version, -V**
  Display version information and exit.

- **--zstd-compression-level=level**
  The compression level to use for connections to the server that use the **zstd** compression algorithm. The permitted levels are from 1 to 22, with larger values indicating increasing levels of compression. The default **zstd** compression level is 3. The compression level setting has no effect on connections that do not use **zstd** compression.
  For more information, see Section 4.2.6, “Connection Compression Control”.
  This option was added in MySQL 8.0.18.

# 4.6 MySQL Administrative and Utility Programs

This section describes administrative programs and programs that perform miscellaneous utility operations.

## 4.6.1 **ibd2sdi** — InnoDB Tablespace SDI Extraction Utility

**ibd2sdi** is a utility for extracting serialized dictionary information (SDI) from InnoDB tablespace files. SDI data is present all persistent InnoDB tablespace files.
**ibd2sdi** can be run on file-per-table tablespace files (*.ibd files), general tablespace files (*.ibd files), system tablespace files (ibdata* files), and the data dictionary tablespace (mysql.ibd). It is not supported for use with temporary tablespaces or undo tablespaces.

**ibd2sdi** can be used at runtime or while the server is offline. During DDL operations, ROLLBACK operations, and undo log purge operations related to SDI, there may be a short interval of time when **ibd2sdi** fails to read SDI data stored in the tablespace.

**ibd2sdi** performs an uncommitted read of SDI from the specified tablespace. Redo logs and undo logs are not accessed.

Invoke the **ibd2sdi** utility like this:

```
shell> ibd2sdi [options] file_name1 [file_name2 file_name3 ...]
```

**ibd2sdi** supports multi-file tablespaces like the InnoDB system tablespace, but it cannot be run on more than one tablespace at a time. For multi-file tablespaces, specify each file:

```
shell> ibd2sdi ibdata1 ibdata2
```

The files of a multi-file tablespace must be specified in order of the ascending page number. If two successive files have the same space ID, the later file must start with the last page number of the previous file + 1.

**ibd2sdi** outputs SDI (containing id, type, and data fields) in JSON format.

### **ibd2sdi** Options

**ibd2sdi** supports the following options:

- --help, -h

Displays command-line help.

```
shell> ibd2sdi --help
```

- -h, --help
  Display this help and exit.

- -v, --version
  Display version information and exit.

- -#, --debug=[name]

- -d, --dump-file=name
  Dump the tablespace SDI into the file passed by user. Without the filename, it will default to stdout

- -s, --skip-data
  Skip retrieving data from SDI records. Retrieve only id and type.

- -i, --id=#
  Retrieve the SDI record matching the id passed by user.

- -t, --type=#
  Retrieve the SDI records matching the type passed by user.

- -c, --strict-check=name
  Specify the strict checksum algorithm by the user.
  Allowed values are innodb, crc32, none.

- -n, --no-check
  Ignore the checksum verification.

- -P, --pretty
  Pretty format the SDI output. If false, SDI would be not human readable but it will be of less size
  (Defaults to on; use --skip-pretty to disable.)

### Variables

<table>
<thead>
<tr>
<th>Variable</th>
<th>Value (after reading options)</th>
</tr>
</thead>
<tbody>
<tr>
<td>debug</td>
<td>(No default value)</td>
</tr>
<tr>
<td>dump-file</td>
<td>(No default value)</td>
</tr>
<tr>
<td>skip-data</td>
<td>FALSE</td>
</tr>
<tr>
<td>id</td>
<td>0</td>
</tr>
</tbody>
</table>
**ibd2sdi** — InnoDB Tablespace SDI Extraction Utility

<table>
<thead>
<tr>
<th>type</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>strict-check</td>
<td>crc32</td>
</tr>
<tr>
<td>no-check</td>
<td>FALSE</td>
</tr>
<tr>
<td>pretty</td>
<td>TRUE</td>
</tr>
</tbody>
</table>

- **--version, -v**
  
  Displays MySQL version information.

  ```shell>
  ibd2sdi --version
  ibd2sdi  Ver 8.0.3-dmr for Linux on x86_64 (Source distribution)
  ```

- **--debug=[debug_options], -# [debug_options]**
  
  Prints a debug log. For debug options, refer to Section 29.5.4, “The DBUG Package”.

  ```shell>
  ibd2sdi --debug=d:t /tmp/ibd2sdi.trace
  ```

- **--dump-file=, -d**
  
  Dumps serialized dictionary information (SDI) into the specified dump file. If a dump file is not specified, the tablespace SDI is dumped to stdout.

  ```shell>
  ibd2sdi --dump-file=../data/test/t1.ibd
  ```

- **--skip-data, -s**
  
  Skips retrieval of data field values from the serialized dictionary information (SDI) and only retrieves the id and type field values, which are primary keys for SDI records.

  ```shell>
  ibd2sdi --skip-data ../data/test/t1.ibd
  ```

- **--id=, -i #**
  
  Retrieves serialized dictionary information (SDI) matching the specified table or tablespace object id. An object id is unique to the object type. Table and tablespace object IDs are also found in the id column of the mysql.tables and mysql.tablespace data dictionary tables. For information about data dictionary tables, see Section 14.1, “Data Dictionary Schema”.

  ```shell>
  ibd2sdi --id=7 ../data/test/t1.ibd
  ```
Retrieves serialized dictionary information (SDI) matching the specified object type. SDI is provided for table (type=1) and tablespace (type=2) objects.

shell> ibd2sdi --type=2 ../data/test/t1.ibd

In this example, the strict version of the \textit{innodb} checksum algorithm is specified:

shell> ibd2sdi --strict-check=innodb ../data/test/t1.ibd

In this example, the strict version of \textit{crc32} checksum algorithm is specified:

shell> ibd2sdi -c crc32 ../data/test/t1.ibd

If you do not specify the \textit{--strict-check} option, validation is performed against non-strict \textit{innodb}, \textit{crc32} and \textit{none} checksums.
4.6.2 **innochecksum** — Offline InnoDB File Checksum Utility

`innochecksum` prints checksums for InnoDB files. This tool reads an InnoDB tablespace file, calculates the checksum for each page, compares the calculated checksum to the stored checksum, and reports mismatches, which indicate damaged pages. It was originally developed to speed up verifying the integrity of tablespace files after power outages but can also be used after file copies. Because checksum mismatches cause InnoDB to deliberately shut down a running server, it may be preferable to use this tool rather than waiting for an in-production server to encounter the damaged pages.

`innochecksum` cannot be used on tablespace files that the server already has open. For such files, you should use `CHECK TABLE` to check tables within the tablespace. Attempting to run `innochecksum` on a tablespace that the server already has open will result in an "Unable to lock file" error.

If checksum mismatches are found, you would normally restore the tablespace from backup or start the server and attempt to use `mysqldump` to make a backup of the tables within the tablespace.

Invoke `innochecksum` like this:

```
shell> innochecksum [options] file_name
```

**innochecksum Options**

`innochecksum` supports the following options. For options that refer to page numbers, the numbers are zero-based.

- **--no-check, -n**
  Skips checksum validation for pages that are read.

  ```
  shell> ibd2sdi --no-check ../data/test/t1.ibd
  ```

- **--pretty, -p**
  Outputs SDI data in JSON pretty print format. Enabled by default. If disabled, SDI is not human readable but is smaller in size. Use `--skip-pretty` to disable.

  ```
  shell> ibd2sdi --skip-pretty ../data/test/t1.ibd
  ```

- **--help, -?**
  Displays command line help. Example usage:

  ```
  shell> innochecksum --help
  ```

- **--info, -I**
  Synonym for `--help`. Displays command line help. Example usage:

  ```
  shell> innochecksum --info
  ```

- **--version, -V**
  Displays version information. Example usage:

  ```
  shell> innochecksum --version
  ```

- **--verbose, -v**
**Verb** **se mode,** prints a progress indicator to the log file every five seconds. In order for the progress indicator to be printed, the log file must be specified using the **--log** option. To turn on **verbose** mode, run:

```
shell> innochecksum --verbose
```

To turn off verbose mode, run:

```
shell> innochecksum --verbose=FALSE
```

The **--verbose** option and **--log** option can be specified at the same time. For example:

```
shell> innochecksum --verbose --log=/var/lib/mysql/test/logtest.txt
```

To locate the progress indicator information in the log file, you can perform the following search:

```
shell> cat ./logtest.txt | grep -i "okay"
```

The progress indicator information in the log file appears similar to the following:

```
page 1663 okay: 2.863% done
page 8447 okay: 14.537% done
page 13695 okay: 23.568% done
page 18815 okay: 32.379% done
page 23039 okay: 39.648% done
page 28351 okay: 48.789% done
page 33023 okay: 56.828% done
page 37951 okay: 65.308% done
page 44095 okay: 75.881% done
page 49407 okay: 85.022% done
page 54463 okay: 93.722% done
...
```

- **--count, -c**

Print a count of the number of pages in the file and exit. Example usage:

```
shell> innochecksum --count ../data/test/tab1.ibd
```

- **--start-page=** **num, -s** **num**

Start at this page number. Example usage:

```
shell> innochecksum --start-page=600 ../data/test/tab1.ibd
```

or:

```
shell> innochecksum -s 600 ../data/test/tab1.ibd
```

- **--end-page=** **num, -e** **num**

End at this page number. Example usage:

```
shell> innochecksum --end-page=700 ../data/test/tab1.ibd
```

or:
shell> innochecksum --p 700 ../data/test/tab1.ibd

• --page=num, -p num

Check only this page number. Example usage:

shell> innochecksum --page=701 ../data/test/tab1.ibd

• --strict-check, -C

Specify a strict checksum algorithm. Options include innodb, crc32, and none.

In this example, the innodb checksum algorithm is specified:

shell> innochecksum --strict-check=innodb ../data/test/tab1.ibd

In this example, the crc32 checksum algorithm is specified:

shell> innochecksum -C crc32 ../data/test/tab1.ibd

The following conditions apply:

• If you do not specify the --strict-check option, innochecksum validates against innodb, crc32 and none.
• If you specify the none option, only checksums generated by none are allowed.
• If you specify the innodb option, only checksums generated by innodb are allowed.
• If you specify the crc32 option, only checksums generated by crc32 are allowed.

• --no-check, -n

Ignore the checksum verification when rewriting a checksum. This option may only be used with the innochecksum --write option. If the --write option is not specified, innochecksum will terminate.

In this example, an innodb checksum is rewritten to replace an invalid checksum:

shell> innochecksum --no-check --write innodb ../data/test/tab1.ibd

• --allow-mismatches, -a

The maximum number of checksum mismatches allowed before innochecksum terminates. The default setting is 0. If --allow-mismatches=N, where N>=0, N mismatches are permitted and innochecksum terminates at N+1. When --allow-mismatches is set to 0, innochecksum terminates on the first checksum mismatch.

In this example, an existing innodb checksum is rewritten to set --allow-mismatches to 1.

shell> innochecksum --allow-mismatches=1 --write innodb ../data/test/tab1.ibd

With --allow-mismatches set to 1, if there is a mismatch at page 600 and another at page 700 on a file with 1000 pages, the checksum is updated for pages 0-599 and 601-699. Because --allow-mismatches is set to 1, the checksum tolerates the first mismatch and terminates on the second mismatch, leaving page 600 and pages 700-999 unchanged.

• --write=name, -w num
Rewrite a checksum. When rewriting an invalid checksum, the `--no-check` option must be used together with the `--write` option. The `--no-check` option tells `innochecksum` to ignore verification of the invalid checksum. You do not have to specify the `--no-check` option if the current checksum is valid.

An algorithm must be specified when using the `--write` option. Possible values for the `--write` option are:

- `innodb`: A checksum calculated in software, using the original algorithm from InnoDB.
- `crc32`: A checksum calculated using the crc32 algorithm, possibly done with a hardware assist.
- `none`: A constant number.

The `--write` option rewrites entire pages to disk. If the new checksum is identical to the existing checksum, the new checksum is not written to disk in order to minimize I/O.

`innochecksum` obtains an exclusive lock when the `--write` option is used.

In this example, a `crc32` checksum is written for `tabl.ibd`:

```
shell> innochecksum --write crc32 ../data/test/tab1.ibd
```

In this example, a `crc32` checksum is rewritten to replace an invalid `crc32` checksum:

```
shell> innochecksum --no-check --write crc32 ../data/test/tab1.ibd
```

- `--page-type-summary`, `-S`

Display a count of each page type in a tablespace. Example usage:

```
shell> innochecksum --page-type-summary ../data/test/tab1.ibd
```

Sample output for `--page-type-summary`:

```
File:/..../data/test/tab1.ibd
-------------------------------PAGE TYPE SUMMARY-------------------------------
#PAGE_COUNT PAGE_TYPE
===============================================
  2        Index page
  0        Undo log page
  1        Inode page
  0        Insert buffer free list page
  2        Freshly allocated page
  1        Insert buffer bitmap
  0        System page
  0        Transaction system page
  1        File Space Header
  0        Extent descriptor page
  0        BLOB page
  0        Compressed BLOB page
  0        Other type of page

Undo page state: 0 active, 0 cached, 0 to_free, 0 to_purge, 0 prepared, 0 other
```

- `--page-type-dump`, `-D`

Dump the page type information for each page in a tablespace to `stderr` or `stdout`. Example usage:
shell> innochecksum --page-type-dump=/tmp/a.txt ../data/test/tab1.ibd

- **--log, -l**

Log output for the innochecksum tool. A log file name must be provided. Log output contains checksum values for each tablespace page. For uncompressed tables, LSN values are also provided. The **--log** replaces the **--debug** option, which was available in earlier releases. Example usage:

shell> innochecksum --log=/tmp/log.txt ../data/test/tab1.ibd

or:

shell> innochecksum -l /tmp/log.txt ../data/test/tab1.ibd

- **-** option.

Specify the **-** option to read from standard input. If the **-** option is missing when “read from standard in” is expected, innochecksum will output innochecksum usage information indicating that the “-” option was omitted. Example usages:

shell> cat t1.ibd | innochecksum -

In this example, innochecksum writes the crc32 checksum algorithm to a.ibd without changing the original t1.ibd file.

shell> cat t1.ibd | innochecksum --write=crc32 - > a.ibd

### Running innochecksum on Multiple User-defined Tablespace Files

The following examples demonstrate how to run innochecksum on multiple user-defined tablespace files (.ibd files).

Run innochecksum for all tablespace (.ibd) files in the “test” database:

shell> innochecksum ./data/test/*.ibd

Run innochecksum for all tablespace files (.ibd files) that have a file name starting with “t”:

shell> innochecksum ./data/test/t*.ibd

Run innochecksum for all tablespace files (.ibd files) in the data directory:

shell> innochecksum ./data/*/*.ibd

### Note

Running innochecksum on multiple user-defined tablespace files is not supported on Windows operating systems, as Windows shells such as cmd.exe do not support glob pattern expansion. On Windows systems, innochecksum must be run separately for each user-defined tablespace file. For example:

cmd> innochecksum.exe t1.ibd
cmd> innochecksum.exe t2.ibd
cmd> innochecksum.exe t3.ibd
Running innochecksum on Multiple System Tablespace Files

By default, there is only one InnoDB system tablespace file (ibdata1) but multiple files for the system tablespace can be defined using the `innodb_data_file_path` option. In the following example, three files for the system tablespace are defined using the `innodb_data_file_path` option: ibdata1, ibdata2, and ibdata3.

```
$ /bin/mysqld --no-defaults --innodb-data-file-path="ibdata1:10M;ibdata2:10M;ibdata3:10M:autoextend"
```

The three files (ibdata1, ibdata2, and ibdata3) form one logical system tablespace. To run `innochecksum` on multiple files that form one logical system tablespace, `innochecksum` requires the `-` option to read tablespace files in from standard input, which is equivalent to concatenating multiple files to create one single file. For the example provided above, the following `innochecksum` command would be used:

```
$ cat ibdata* | innochecksum -
```

Refer to the `innochecksum` options information for more information about the “-” option.

**Note**

Running `innochecksum` on multiple files in the same tablespace is not supported on Windows operating systems, as Windows shells such as `cmd.exe` do not support glob pattern expansion. On Windows systems, `innochecksum` must be run separately for each system tablespace file. For example:

```
$ innochecksum.exe ibdata1
$ innochecksum.exe ibdata2
$ innochecksum.exe ibdata3
```

4.6.3 myisam_ftdump — Display Full-Text Index information

`myisam_ftdump` displays information about FULLTEXT indexes in MyISAM tables. It reads the MyISAM index file directly, so it must be run on the server host where the table is located. Before using `myisam_ftdump`, be sure to issue a `FLUSH TABLES` statement first if the server is running.

`myisam_ftdump` scans and dumps the entire index, which is not particularly fast. On the other hand, the distribution of words changes infrequently, so it need not be run often.

Invoke `myisam_ftdump` like this:

```
$ myisam_ftdump [options] tbl_name index_num
```

The `tbl_name` argument should be the name of a MyISAM table. You can also specify a table by naming its index file (the file with the `.MYI` suffix). If you do not invoke `myisam_ftdump` in the directory where the table files are located, the table or index file name must be preceded by the path name to the table's database directory. Index numbers begin with 0.

Example: Suppose that the `test` database contains a table named `mytexttable` that has the following definition:

```sql
CREATE TABLE mytexttable
(
   id INT NOT NULL,
   txt TEXT NOT NULL,
   PRIMARY KEY (id),
   FULLTEXT (txt)
)```
The index on `id` is index 0 and the FULLTEXT index on `txt` is index 1. If your working directory is the `test` database directory, invoke `myisam_ftdump` as follows:

```
shell> myisam_ftdump mytexttable 1
```

If the path name to the `test` database directory is `/usr/local/mysql/data/test`, you can also specify the table name argument using that path name. This is useful if you do not invoke `myisam_ftdump` in the database directory:

```
shell> myisam_ftdump /usr/local/mysql/data/test/mytexttable 1
```

You can use `myisam_ftdump` to generate a list of index entries in order of frequency of occurrence like this on Unix-like systems:

```
shell> myisam_ftdump -c mytexttable 1 | sort -r
```

On Windows, use:

```
shell> myisam_ftdump -c mytexttable 1 | sort /R
```

`myisam_ftdump` supports the following options:

- `--help`, `-h`, `--?`
  Display a help message and exit.
- `--count`, `-c`
  Calculate per-word statistics (counts and global weights).
- `--dump`, `-d`
  Dump the index, including data offsets and word weights.
- `--length`, `-l`
  Report the length distribution.
- `--stats`, `-s`
  Report global index statistics. This is the default operation if no other operation is specified.
- `--verbose`, `-v`
  Verbose mode. Print more output about what the program does.

### 4.6.4 myisamchk — MyISAM Table-Maintenance Utility

The `myisamchk` utility gets information about your database tables or checks, repairs, or optimizes them. `myisamchk` works with MyISAM tables (tables that have `.MYD` and `.MYI` files for storing data and indexes).

You can also use the `CHECK TABLE` and `REPAIR TABLE` statements to check and repair MyISAM tables. See Section 13.7.3.2, “CHECK TABLE Syntax”, and Section 13.7.3.5, “REPAIR TABLE Syntax”.

The use of `myisamchk` with partitioned tables is not supported.
Caution

It is best to make a backup of a table before performing a table repair operation; under some circumstances the operation might cause data loss. Possible causes include but are not limited to file system errors.

Invoke `myisamchk` like this:

```
shell> myisamchk [options] tbl_name ...
```

The `options` specify what you want `myisamchk` to do. They are described in the following sections. You can also get a list of options by invoking `myisamchk --help`.

With no options, `myisamchk` simply checks your table as the default operation. To get more information or to tell `myisamchk` to take corrective action, specify options as described in the following discussion.

`tbl_name` is the database table you want to check or repair. If you run `myisamchk` somewhere other than in the database directory, you must specify the path to the database directory, because `myisamchk` has no idea where the database is located. In fact, `myisamchk` does not actually care whether the files you are working on are located in a database directory. You can copy the files that correspond to a database table into some other location and perform recovery operations on them there.

You can name several tables on the `myisamchk` command line if you wish. You can also specify a table by naming its index file (the file with the `.MYI` suffix). This enables you to specify all tables in a directory by using the pattern `*.MYI`. For example, if you are in a database directory, you can check all the `MyISAM` tables in that directory like this:

```
shell> myisamchk *.MYI
```

If you are not in the database directory, you can check all the tables there by specifying the path to the directory:

```
shell> myisamchk /path/to/database_dir/*.MYI
```

You can even check all tables in all databases by specifying a wildcard with the path to the MySQL data directory:

```
shell> myisamchk /path/to/datadir/*/*.MYI
```

The recommended way to quickly check all `MyISAM` tables is:

```
shell> myisamchk --silent --fast /path/to/datadir/*/*.MYI
```

If you want to check all `MyISAM` tables and repair any that are corrupted, you can use the following command:

```
shell> myisamchk --silent --force --fast --update-state \ 
   --key_buffer_size=64M --myisam_sort_buffer_size=64M \ 
   --read_buffer_size=1M --write_buffer_size=1M \ 
   /path/to/datadir/*/*.MYI
```

This command assumes that you have more than 64MB free. For more information about memory allocation with `myisamchk`, see Section 4.6.4.6, “myisamchk Memory Usage”.

For additional information about using `myisamchk`, see Section 7.6, “MyISAM Table Maintenance and Crash Recovery”.

491
Important

You must ensure that no other program is using the tables while you are running `myisamchk`. The most effective means of doing so is to shut down the MySQL server while running `myisamchk`, or to lock all tables that `myisamchk` is being used on.

Otherwise, when you run `myisamchk`, it may display the following error message:

```
warning: clients are using or haven't closed the table properly
```

This means that you are trying to check a table that has been updated by another program (such as the `mysqld` server) that hasn't yet closed the file or that has died without closing the file properly, which can sometimes lead to the corruption of one or more MyISAM tables.

If `mysqld` is running, you must force it to flush any table modifications that are still buffered in memory by using `FLUSH TABLES`. You should then ensure that no one is using the tables while you are running `myisamchk`.

However, the easiest way to avoid this problem is to use `CHECK TABLE` instead of `myisamchk` to check tables. See Section 13.7.3.2, “CHECK TABLE Syntax”.

`myisamchk` supports the following options, which can be specified on the command line or in the `[myisamchk]` group of an option file. For information about option files used by MySQL programs, see Section 4.2.2.2, “Using Option Files”.

### Table 4.19 myisamchk Options

<table>
<thead>
<tr>
<th>Option Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>--analyze</td>
<td>Analyze the distribution of key values</td>
</tr>
<tr>
<td>--backup</td>
<td>Make a backup of the .MYD file as file_name-time.BAK</td>
</tr>
<tr>
<td>--block-search</td>
<td>Find the record that a block at the given offset belongs to</td>
</tr>
<tr>
<td>--check</td>
<td>Check the table for errors</td>
</tr>
<tr>
<td>--check-only-changed</td>
<td>Check only tables that have changed since the last check</td>
</tr>
<tr>
<td>--correct-checksum</td>
<td>Correct the checksum information for the table</td>
</tr>
<tr>
<td>--data-file-length</td>
<td>Maximum length of the data file (when re-creating data file when it is full)</td>
</tr>
<tr>
<td>--debug</td>
<td>Write debugging log</td>
</tr>
<tr>
<td>--decode_bits</td>
<td>Decode_bits</td>
</tr>
<tr>
<td>--defaults-extra-file</td>
<td>Read named option file in addition to usual option files</td>
</tr>
<tr>
<td>--defaults-file</td>
<td>Read only named option file</td>
</tr>
<tr>
<td>--defaults-group-suffix</td>
<td>Option group suffix value</td>
</tr>
<tr>
<td>--description</td>
<td>Print some descriptive information about the table</td>
</tr>
<tr>
<td>--extend-check</td>
<td>Do very thorough table check or repair that tries to recover every possible row from the data file</td>
</tr>
<tr>
<td>--fast</td>
<td>Check only tables that haven't been closed properly</td>
</tr>
<tr>
<td>--force</td>
<td>Do a repair operation automatically if myisamchk finds any errors in the table</td>
</tr>
<tr>
<td>--force</td>
<td>Overwrite old temporary files. For use with the -r or -o option</td>
</tr>
<tr>
<td>--ft_max_word_len</td>
<td>Maximum word length for FULLTEXT indexes</td>
</tr>
<tr>
<td>Option Name</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>--ft_min_word_len</td>
<td>Minimum word length for FULLTEXT indexes</td>
</tr>
<tr>
<td>--ft_stopword_file</td>
<td>Use stopwords from this file instead of built-in list</td>
</tr>
<tr>
<td>--HELP</td>
<td>Display help message and exit</td>
</tr>
<tr>
<td>--help</td>
<td>Display help message and exit</td>
</tr>
<tr>
<td>--information</td>
<td>Print informational statistics about the table that is checked</td>
</tr>
<tr>
<td>--key_buffer_size</td>
<td>Size of buffer used for index blocks for MyISAM tables</td>
</tr>
<tr>
<td>--keys-used</td>
<td>A bit-value that indicates which indexes to update</td>
</tr>
<tr>
<td>--max-record-length</td>
<td>Skip rows larger than the given length if myisamchk cannot allocate memory to hold them</td>
</tr>
<tr>
<td>--medium-check</td>
<td>Do a check that is faster than an --extend-check operation</td>
</tr>
<tr>
<td>--myisam_block_size</td>
<td>Block size to be used for MyISAM index pages</td>
</tr>
<tr>
<td>--myisam_sort_buffer_size</td>
<td>The buffer that is allocated when sorting the index when doing a REPAIR or when creating indexes with CREATE INDEX or ALTER TABLE</td>
</tr>
<tr>
<td>--no-defaults</td>
<td>Read no option files</td>
</tr>
<tr>
<td>--parallel-recover</td>
<td>Uses the same technique as -r and -n, but creates all the keys in parallel, using different threads (beta)</td>
</tr>
<tr>
<td>--print-defaults</td>
<td>Print default options</td>
</tr>
<tr>
<td>--quick</td>
<td>Achieve a faster repair by not modifying the data file.</td>
</tr>
<tr>
<td>--read_buffer_size</td>
<td>Each thread that does a sequential scan allocates a buffer of this size for each table it scans</td>
</tr>
<tr>
<td>--read-only</td>
<td>Do not mark the table as checked</td>
</tr>
<tr>
<td>--recover</td>
<td>Do a repair that can fix almost any problem except unique keys that aren't unique</td>
</tr>
<tr>
<td>--safe-recover</td>
<td>Do a repair using an old recovery method that reads through all rows in order and updates all index trees based on the rows found</td>
</tr>
<tr>
<td>--set-auto-increment</td>
<td>Force AUTO_INCREMENT numbering for new records to start at the given value</td>
</tr>
<tr>
<td>--set-collation</td>
<td>Specify the collation to use for sorting table indexes</td>
</tr>
<tr>
<td>--silent</td>
<td>Silent mode</td>
</tr>
<tr>
<td>--sort_buffer_size</td>
<td>The buffer that is allocated when sorting the index when doing a REPAIR or when creating indexes with CREATE INDEX or ALTER TABLE</td>
</tr>
<tr>
<td>--sort-index</td>
<td>Sort the index tree blocks in high-low order</td>
</tr>
<tr>
<td>--sort_key_blocks</td>
<td>sort_key_blocks</td>
</tr>
<tr>
<td>--sort-records</td>
<td>Sort records according to a particular index</td>
</tr>
<tr>
<td>--sort-recover</td>
<td>Force myisamchk to use sorting to resolve the keys even if the temporary files would be very large</td>
</tr>
<tr>
<td>--stats_method</td>
<td>Specifies how MyISAM index statistics collection code should treat NULLS</td>
</tr>
<tr>
<td>--tmpdir</td>
<td>Directory to be used for storing temporary files</td>
</tr>
<tr>
<td>--unpack</td>
<td>Unpack a table that was packed with myisampack</td>
</tr>
<tr>
<td>--update-state</td>
<td>Store information in the .MYI file to indicate when the table was checked and whether the table crashed</td>
</tr>
<tr>
<td>Option Name</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------</td>
<td>----------------------------------------------</td>
</tr>
<tr>
<td>--verbose</td>
<td>Verbose mode</td>
</tr>
<tr>
<td>--version</td>
<td>Display version information and exit</td>
</tr>
<tr>
<td>--write_buffer_size</td>
<td>Write buffer size</td>
</tr>
</tbody>
</table>

### 4.6.4.1 myisamchk General Options

The options described in this section can be used for any type of table maintenance operation performed by `myisamchk`. The sections following this one describe options that pertain only to specific operations, such as table checking or repairing.

- **--help, -?**
  Display a help message and exit. Options are grouped by type of operation.

- **--HELP, -H**
  Display a help message and exit. Options are presented in a single list.

- **--debug=debug_options, -# debug_options**
  Write a debugging log. A typical `debug_options` string is `d:t:o, file_name`. The default is `d:t:o, /tmp/myisamchk.trace`.

- **--defaults-extra-file=file_name**
  Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. `file_name` is interpreted relative to the current directory if given as a relative path name rather than a full path name.

  For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- **--defaults-file=file_name**
  Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. `file_name` is interpreted relative to the current directory if given as a relative path name rather than a full path name.

  For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- **--defaults-group-suffix=str**
  Read not only the usual option groups, but also groups with the usual names and a suffix of `str`. For example, `myisamchk` normally reads the `[myisamchk]` group. If the `--defaults-group-suffix=_other` option is given, `myisamchk` also reads the `[myisamchk_other]` group.

  For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- **--no-defaults**
  Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

  The exception is that the `.mylogin.cnf` file, if it exists, is read in all cases. This permits passwords to be specified in a safer way than on the command line even when `--no-defaults` is used. `.mylogin.cnf` is created by the `mysql_config_editor` utility. See Section 4.6.7, “mysql_config_editor — MySQL Configuration Utility”.)
For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

• **--print-defaults**
  Print the program name and all options that it gets from option files.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

• **--silent, -s**
  Silent mode. Write output only when errors occur. You can use -s twice (-ss) to make myisamchk very silent.

• **--verbose, -v**
  Verbose mode. Print more information about what the program does. This can be used with -d and -e. Use -v multiple times (-vv, -vvv) for even more output.

• **--version, -V**
  Display version information and exit.

• **--wait, -w**
  Instead of terminating with an error if the table is locked, wait until the table is unlocked before continuing. If you are running mysql with external locking disabled, the table can be locked only by another myisamchk command.

You can also set the following variables by using **--var_name=value** syntax:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>decode_bits</td>
<td>9</td>
</tr>
<tr>
<td>ft_max_word_len</td>
<td>version-dependent</td>
</tr>
<tr>
<td>ft_min_word_len</td>
<td>4</td>
</tr>
<tr>
<td>ft_stopword_file</td>
<td>built-in list</td>
</tr>
<tr>
<td>key_buffer_size</td>
<td>523264</td>
</tr>
<tr>
<td>myisam_block_size</td>
<td>1024</td>
</tr>
<tr>
<td>myisam_sort_key_blocks</td>
<td>16</td>
</tr>
<tr>
<td>read_buffer_size</td>
<td>262136</td>
</tr>
<tr>
<td>sort_buffer_size</td>
<td>2097144</td>
</tr>
<tr>
<td>sort_key_blocks</td>
<td>16</td>
</tr>
<tr>
<td>stats_method</td>
<td>nulls_unequal</td>
</tr>
<tr>
<td>write_buffer_size</td>
<td>262136</td>
</tr>
</tbody>
</table>

The possible myisamchk variables and their default values can be examined with myisamchk --help:

- **myisam_sort_buffer_size** is used when the keys are repaired by sorting keys, which is the normal case when you use **--recover**. **sort_buffer_size** is a deprecated synonym for **myisam_sort_buffer_size**.
- **key_buffer_size** is used when you are checking the table with **--extend-check** or when the keys are repaired by inserting keys row by row into the table (like when doing normal inserts). Repairing through the key buffer is used in the following cases:
• You use `--safe-recover`.

• The temporary files needed to sort the keys would be more than twice as big as when creating the key file directly. This is often the case when you have large key values for `CHAR`, `VARCHAR`, or `TEXT` columns, because the sort operation needs to store the complete key values as it proceeds. If you have lots of temporary space and you can force `myisamchk` to repair by sorting, you can use the `--sort-recover` option.

Repairing through the key buffer takes much less disk space than using sorting, but is also much slower.

If you want a faster repair, set the `key_buffer_size` and `myisam_sort_buffer_size` variables to about 25% of your available memory. You can set both variables to large values, because only one of them is used at a time.

`myisam_block_size` is the size used for index blocks.

`stats_method` influences how NULL values are treated for index statistics collection when the `--analyze` option is given. It acts like the `myisam_stats_method` system variable. For more information, see the description of `myisam_stats_method` in Section 5.1.8, “Server System Variables”, and Section 8.3.8, “InnoDB and MyISAM Index Statistics Collection”.

`ft_min_word_len` and `ft_max_word_len` indicate the minimum and maximum word length for `FULLTEXT` indexes on MyISAM tables. `ft_stopword_file` names the stopword file. These need to be set under the following circumstances.

If you use `myisamchk` to perform an operation that modifies table indexes (such as repair or analyze), the `FULLTEXT` indexes are rebuilt using the default full-text parameter values for minimum and maximum word length and the stopword file unless you specify otherwise. This can result in queries failing.

The problem occurs because these parameters are known only by the server. They are not stored in MyISAM index files. To avoid the problem if you have modified the minimum or maximum word length or the stopword file in the server, specify the same `ft_min_word_len`, `ft_max_word_len`, and `ft_stopword_file` values to `myisamchk` that you use for `mysqld`. For example, if you have set the minimum word length to 3, you can repair a table with `myisamchk` like this:

```
shell> myisamchk --recover --ft_min_word_len=3 tbl_name.MYI
```

To ensure that `myisamchk` and the server use the same values for full-text parameters, you can place each one in both the `[mysqld]` and `[myisamchk]` sections of an option file:

```
[mysqld]
ft_min_word_len=3

[myisamchk]
ft_min_word_len=3
```

An alternative to using `myisamchk` is to use the `REPAIR TABLE`, `ANALYZE TABLE`, `OPTIMIZE TABLE`, or `ALTER TABLE`. These statements are performed by the server, which knows the proper full-text parameter values to use.

4.6.4.2 `myisamchk` Check Options

`myisamchk` supports the following options for table checking operations:

• `--check`, `-c`

  Check the table for errors. This is the default operation if you specify no option that selects an operation type explicitly.

• `--check-only-changed`, `-C`
myisamchk — MyISAM Table-Maintenance Utility

Check only tables that have changed since the last check.

• --extend-check, -e

Check the table very thoroughly. This is quite slow if the table has many indexes. This option should only be used in extreme cases. Normally, myisamchk or myisamchk --medium-check should be able to determine whether there are any errors in the table.

If you are using --extend-check and have plenty of memory, setting the key_buffer_size variable to a large value helps the repair operation run faster.

See also the description of this option under table repair options.

For a description of the output format, see Section 4.6.4.5, “Obtaining Table Information with myisamchk”.

• --fast, -F

Check only tables that haven't been closed properly.

• --force, -f

Do a repair operation automatically if myisamchk finds any errors in the table. The repair type is the same as that specified with the --recover or -r option.

• --information, -i

Print informational statistics about the table that is checked.

• --medium-check, -m

Do a check that is faster than an --extend-check operation. This finds only 99.99% of all errors, which should be good enough in most cases.

• --read-only, -T

Do not mark the table as checked. This is useful if you use myisamchk to check a table that is in use by some other application that does not use locking, such as mysqld when run with external locking disabled.

• --update-state, -U

Store information in the .MYI file to indicate when the table was checked and whether the table crashed. This should be used to get full benefit of the --check-only-changed option, but you shouldn't use this option if the mysqld server is using the table and you are running it with external locking disabled.

4.6.4.3 myisamchk Repair Options

myisamchk supports the following options for table repair operations (operations performed when an option such as --recover or --safe-recover is given):

• --backup, -B

Make a backup of the .MYD file as file_name-time.BAK

• --character-sets-dir=dir_name

The directory where character sets are installed. See Section 10.14, “Character Set Configuration”.

• --correct-checksum

Correct the checksum information for the table.
--data-file-length=len, -D len

The maximum length of the data file (when re-creating data file when it is “full”).

--extend-check, -e

Do a repair that tries to recover every possible row from the data file. Normally, this also finds a lot of garbage rows. Do not use this option unless you are desperate.

See also the description of this option under table checking options.

For a description of the output format, see Section 4.6.4.5, “Obtaining Table Information with myisamchk”.

--force, -f

Overwrite old intermediate files (files with names like tbl_name.TMD) instead of aborting.

--keys-used=val, -k val

For myisamchk, the option value is a bit value that indicates which indexes to update. Each binary bit of the option value corresponds to a table index, where the first index is bit 0. An option value of 0 disables updates to all indexes, which can be used to get faster inserts. Deactivated indexes can be reactivated by using myisamchk -r.

--no-symlinks, -l

Do not follow symbolic links. Normally myisamchk repairs the table that a symlink points to. This option does not exist as of MySQL 4.0 because versions from 4.0 on do not remove symlinks during repair operations.

--max-record-length=len

Skip rows larger than the given length if myisamchk cannot allocate memory to hold them.

--parallel-recover, -p

Use the same technique as -r and -n, but create all the keys in parallel, using different threads. This is beta-quality code. Use at your own risk!

--quick, -q

Achieve a faster repair by modifying only the index file, not the data file. You can specify this option twice to force myisamchk to modify the original data file in case of duplicate keys.

--recover, -r

Do a repair that can fix almost any problem except unique keys that are not unique (which is an extremely unlikely error with MyISAM tables). If you want to recover a table, this is the option to try first. You should try --safe-recover only if myisamchk reports that the table cannot be recovered using --recover. (In the unlikely case that --recover fails, the data file remains intact.)

If you have lots of memory, you should increase the value of myisam_sort_buffer_size.

--safe-recover, -o

Do a repair using an old recovery method that reads through all rows in order and updates all index trees based on the rows found. This is an order of magnitude slower than --recover, but can handle a couple of very unlikely cases that --recover cannot. This recovery method also uses much less disk space than --recover. Normally, you should repair first using --recover, and then with --safe-recover only if --recover fails.

If you have lots of memory, you should increase the value of key_buffer_size.
• `--set-collation=name`
  Specify the collation to use for sorting table indexes. The character set name is implied by the first part of the collation name.

• `--sort-recover,-n`
  Force `myisamchk` to use sorting to resolve the keys even if the temporary files would be very large.

• `--tmpdir=dir_name,-t dir_name`
  The path of the directory to be used for storing temporary files. If this is not set, `myisamchk` uses the value of the `TMPDIR` environment variable. `--tmpdir` can be set to a list of directory paths that are used successively in round-robin fashion for creating temporary files. The separator character between directory names is the colon (`:`) on Unix and the semicolon (`;`) on Windows.

• `--unpack,-u`
  Unpack a table that was packed with `mysampack`.

### 4.6.4.4 Other myisamchk Options

`myisamchk` supports the following options for actions other than table checks and repairs:

• `--analyze,-a`
  Analyze the distribution of key values. This improves join performance by enabling the join optimizer to better choose the order in which to join the tables and which indexes it should use. To obtain information about the key distribution, use a `myisamchk --description --verbose tbl_name` command or the `SHOW INDEX FROM tbl_name` statement.

• `--block-search=offset,-b offset`
  Find the record that a block at the given offset belongs to.

• `--description,-d`
  Print some descriptive information about the table. Specifying the `--verbose` option once or twice produces additional information. See Section 4.6.4.5, “Obtaining Table Information with myisamchk”.

• `--set-auto-increment[=value],-A[value]`
  Force `AUTO_INCREMENT` numbering for new records to start at the given value (or higher, if there are existing records with `AUTO_INCREMENT` values this large). If `value` is not specified, `AUTO_INCREMENT` numbers for new records begin with the largest value currently in the table, plus one.

• `--sort-index,-S`
  Sort the index tree blocks in high-low order. This optimizes seeks and makes table scans that use indexes faster.

• `--sort-records=N,-R N`
  Sort records according to a particular index. This makes your data much more localized and may speed up range-based `SELECT` and `ORDER BY` operations that use this index. (The first time you use this option to sort a table, it may be very slow.) To determine a table’s index numbers, use `SHOW INDEX`, which displays a table’s indexes in the same order that `myisamchk` sees them. Indexes are numbered beginning with 1.

  If keys are not packed (`PACK_KEYS=0`), they have the same length, so when `myisamchk` sorts and moves records, it just overwrites record offsets in the index. If keys are packed (`PACK_KEYS=1`),
4.6.4.5 Obtaining Table Information with myisamchk

To obtain a description of a MyISAM table or statistics about it, use the commands shown here. The output from these commands is explained later in this section.

- **myisamchk -d tbl_name**
  
  Runs myisamchk in “describe mode” to produce a description of your table. If you start the MySQL server with external locking disabled, myisamchk may report an error for a table that is updated while it runs. However, because myisamchk does not change the table in describe mode, there is no risk of destroying data.

- **myisamchk -dv tbl_name**
  
  Adding -v runs myisamchk in verbose mode so that it produces more information about the table. Adding -v a second time produces even more information.

- **myisamchk -eis tbl_name**
  
  Shows only the most important information from a table. This operation is slow because it must read the entire table.

- **myisamchk -eiv tbl_name**
  
  This is like -eis, but tells you what is being done.

The *tbl_name* argument can be either the name of a MyISAM table or the name of its index file, as described in Section 4.6.4, “myisamchk — MyISAM Table-Maintenance Utility”. Multiple *tbl_name* arguments can be given.

Suppose that a table named *person* has the following structure. (The MAX_ROWS table option is included so that in the example output from myisamchk shown later, some values are smaller and fit the output format more easily.)

```
CREATE TABLE person
(
  id         INT NOT NULL AUTO_INCREMENT,
  last_name  VARCHAR(20) NOT NULL,
  first_name VARCHAR(20) NOT NULL,
  birth      DATE,
  death      DATE,
  PRIMARY KEY (id),
  INDEX (last_name, first_name),
  INDEX (birth)
) MAX_ROWS = 1000000 ENGINE=MYISAM;
```

Suppose also that the table has these data and index file sizes:

```
-rw-rw----  1 mysql  mysql  9347072 Aug 19 11:47 person.MYD
-rw-rw----  1 mysql  mysql  6066176 Aug 19 11:47 person.MYI
```

Example of myisamchk -dvv output:

```
MyISAM file:         person
Record format:       Packed
Character set:       utf8mb4_0900_ai_ci (255)
File-version:        1
Creation time:       2017-03-30 21:21:30
Status:              checked,analyzed,optimized keys,sorted index pages
Auto increment key:              1  Last value:                306688
Data records:               306688  Deleted blocks:                 0
```
myisamchk — MyISAM Table-Maintenance Utility

</table>

Explanations for the types of information myisamchk produces are given here. “Keyfile” refers to the index file. “Record” and “row” are synonymous, as are “field” and “column.”

The initial part of the table description contains these values:

- **MyISAM file**
  
  Name of the MyISAM (index) file.

- **Record format**
  
  The format used to store table rows. The preceding examples use Fixed length. Other possible values are Compressed and Packed. (Packed corresponds to what SHOW TABLE STATUS reports as Dynamic.)

- **Character set**
  
  The table default character set.

- **File-version**
  
  Version of MyISAM format. Always 1.

- **Creation time**
  
  When the data file was created.

- **Recover time**
  
  When the index/data file was last reconstructed.

- **Status**
  
  Table status flags. Possible values are crashed, open, changed, analyzed, optimized keys, and sorted index pages.

- **Auto increment key, Last value**
  
  The key number associated the table’s AUTO_INCREMENT column, and the most recently generated value for this column. These fields do not appear if there is no such column.

- **Data records**
  
  The number of rows in the table.

- **Deleted blocks**
How many deleted blocks still have reserved space. You can optimize your table to minimize this space. See Section 7.6.4, “MyISAM Table Optimization”.

- **Datafile parts**
  For dynamic-row format, this indicates how many data blocks there are. For an optimized table without fragmented rows, this is the same as **Data records**.

- **Deleted data**
  How many bytes of unreclaimed deleted data there are. You can optimize your table to minimize this space. See Section 7.6.4, “MyISAM Table Optimization”.

- **Datafile pointer**
  The size of the data file pointer, in bytes. It is usually 2, 3, 4, or 5 bytes. Most tables manage with 2 bytes, but this cannot be controlled from MySQL yet. For fixed tables, this is a row address. For dynamic tables, this is a byte address.

- **Keyfile pointer**
  The size of the index file pointer, in bytes. It is usually 1, 2, or 3 bytes. Most tables manage with 2 bytes, but this is calculated automatically by MySQL. It is always a block address.

- **Max datafile length**
  How long the table data file can become, in bytes.

- **Max keyfile length**
  How long the table index file can become, in bytes.

- **Recordlength**
  How much space each row takes, in bytes.

The **table description** part of the output includes a list of all keys in the table. For each key, `myisamchk` displays some low-level information:

- **Key**
  This key's number. This value is shown only for the first column of the key. If this value is missing, the line corresponds to the second or later column of a multiple-column key. For the table shown in the example, there are two **table description** lines for the second index. This indicates that it is a multiple-part index with two parts.

- **Start**
  Where in the row this portion of the index starts.

- **Len**
  How long this portion of the index is. For packed numbers, this should always be the full length of the column. For strings, it may be shorter than the full length of the indexed column, because you can index a prefix of a string column. The total length of a multiple-part key is the sum of the **Len** values for all key parts.

- **Index**
  Whether a key value can exist multiple times in the index. Possible values are **unique** or **multip.** (multiple).

- **Type**
What data type this portion of the index has. This is a MyISAM data type with the possible values packed, stripped, or empty.

- Root
  Address of the root index block.

- Blocksize
  The size of each index block. By default this is 1024, but the value may be changed at compile time when MySQL is built from source.

- Rec/key
  This is a statistical value used by the optimizer. It tells how many rows there are per value for this index. A unique index always has a value of 1. This may be updated after a table is loaded (or greatly changed) with myisamchk -a. If this is not updated at all, a default value of 30 is given.

The last part of the output provides information about each column:

- Field
  The column number.

- Start
  The byte position of the column within table rows.

- Length
  The length of the column in bytes.

- Nullpos, Nullbit
  For columns that can be NULL, MyISAM stores NULL values as a flag in a byte. Depending on how many nullable columns there are, there can be one or more bytes used for this purpose. The Nullpos and Nullbit values, if nonempty, indicate which byte and bit contains that flag indicating whether the column is NULL.

  The position and number of bytes used to store NULL flags is shown in the line for field 1. This is why there are six Field lines for the person table even though it has only five columns.

- Type
  The data type. The value may contain any of the following descriptors:

  - constant
    All rows have the same value.

  - no endspace
    Do not store endspace.

  - no endspace, not_always
    Do not store endspace and do not do endspace compression for all values.

  - no endspace, no empty
    Do not store endspace. Do not store empty values.

  - table-lookup
The column was converted to an ENUM.

- **zerofill(N)**

  The most significant \( N \) bytes in the value are always 0 and are not stored.

- **no zeros**

  Do not store zeros.

- **always zero**

  Zero values are stored using one bit.

- **Huff tree**

  The number of the Huffman tree associated with the column.

- **Bits**

  The number of bits used in the Huffman tree.

The Huff tree and Bits fields are displayed if the table has been compressed with myisampack. See Section 4.6.6, "myisampack — Generate Compressed, Read-Only MyISAM Tables", for an example of this information.

Example of `myisamchk -eiv` output:

```
Checking MyISAM file: person
Data records:  306688   Deleted blocks:       0
- check file-size

Voluntary context switches 0, Involuntary context switches 0
Maximum memory usage: 1046926 bytes (1023k)

myisamchk –eiv output includes the following information:

- **Data records**

  The number of rows in the table.
```
• **Deleted blocks**
  How many deleted blocks still have reserved space. You can optimize your table to minimize this space. See Section 7.6.4, “MyISAM Table Optimization”.

• **Key**
  The key number.

• **Keyblocks used**
  What percentage of the keyblocks are used. When a table has just been reorganized with `myisamchk`, the values are very high (very near theoretical maximum).

• **Packed**
  MySQL tries to pack key values that have a common suffix. This can only be used for indexes on `CHAR` and `VARCHAR` columns. For long indexed strings that have similar leftmost parts, this can significantly reduce the space used. In the preceding example, the second key is 40 bytes long and a 97% reduction in space is achieved.

• **Max levels**
  How deep the B-tree for this key is. Large tables with long key values get high values.

• **Records**
  How many rows are in the table.

• **M.recordlength**
  The average row length. This is the exact row length for tables with fixed-length rows, because all rows have the same length.

• **Packed**
  MySQL strips spaces from the end of strings. The **Packed** value indicates the percentage of savings achieved by doing this.

• **Recordspace used**
  What percentage of the data file is used.

• **Empty space**
  What percentage of the data file is unused.

• **Blocks/Record**
  Average number of blocks per row (that is, how many links a fragmented row is composed of). This is always 1.0 for fixed-format tables. This value should stay as close to 1.0 as possible. If it gets too large, you can reorganize the table. See Section 7.6.4, “MyISAM Table Optimization”.

• **Recordblocks**
  How many blocks (links) are used. For fixed-format tables, this is the same as the number of rows.

• **Deleteblocks**
  How many blocks (links) are deleted.

• **Recorddata**
  How many bytes in the data file are used.
• **Deleted data**
  
  How many bytes in the data file are deleted (unused).

• **Lost space**
  
  If a row is updated to a shorter length, some space is lost. This is the sum of all such losses, in bytes.

• **Linkdata**
  
  When the dynamic table format is used, row fragments are linked with pointers (4 to 7 bytes each). **Linkdata** is the sum of the amount of storage used by all such pointers.

### 4.6.4.6 myisamchk Memory Usage

Memory allocation is important when you run `myisamchk`. `myisamchk` uses no more memory than its memory-related variables are set to. If you are going to use `myisamchk` on very large tables, you should first decide how much memory you want it to use. The default is to use only about 3MB to perform repairs. By using larger values, you can get `myisamchk` to operate faster. For example, if you have more than 512MB RAM available, you could use options such as these (in addition to any other options you might specify):

```sh
shell> myisamchk --myisam_sort_buffer_size=256M --key_buffer_size=512M --read_buffer_size=64M --write_buffer_size=64M ...
```

Using `--myisam_sort_buffer_size=16M` is probably enough for most cases.

Be aware that `myisamchk` uses temporary files in `TMPDIR`. If `TMPDIR` points to a memory file system, out of memory errors can easily occur. If this happens, run `myisamchk` with the `--tmpdir=dir_name` option to specify a directory located on a file system that has more space.

When performing repair operations, `myisamchk` also needs a lot of disk space:

• Twice the size of the data file (the original file and a copy). This space is not needed if you do a repair with `--quick`; in this case, only the index file is re-created. *This space must be available on the same file system as the original data file, as the copy is created in the same directory as the original.*

• Space for the new index file that replaces the old one. The old index file is truncated at the start of the repair operation, so you usually ignore this space. *This space must be available on the same file system as the original data file.*

• When using `--recover` or `--sort-recover` (but not when using `--safe-recover`), you need space on disk for sorting. *This space is allocated in the temporary directory (specified by `TMPDIR` or `--tmpdir=dir_name`). The following formula yields the amount of space required:*

```
(largest_key + row_pointer_length) * number_of_rows * 2
```

You can check the length of the keys and the `row_pointer_length` with `myisamchk -dv tbl_name` (see Section 4.6.4.5, “Obtaining Table Information with myisamchk”). The `row_pointer_length` and `number_of_rows` values are the Datafile pointer and Data records values in the table description. To determine the `largest_key` value, check the Key lines in the table description. The `Len` column indicates the number of bytes for each key part. For a multiple-column index, the key size is the sum of the `Len` values for all key parts.

If you have a problem with disk space during repair, you can try `--safe-recover` instead of `--recover`. 

### 4.6.5 myisamlog — Display MyISAM Log File Contents
myisamlog processes the contents of a MyISAM log file. To create such a file, start the server with a
--log-isam=log_file option.

Invoke myisamlog like this:

```
shell> myisamlog [options] [file_name [tbl_name] ...]
```

The default operation is update (-u). If a recovery is done (-r), all writes and possibly updates
and deletes are done and errors are only counted. The default log file name is myisam.log if no
log_file argument is given. If tables are named on the command line, only those tables are updated.

myisamlog supports the following options:

- -?, -I
  Display a help message and exit.
- -c N
  Execute only N commands.
- -f N
  Specify the maximum number of open files.
- -F filepath/
  Specify the file path with a trailing slash.
- -i
  Display extra information before exiting.
- -o offset
  Specify the starting offset.
- -p N
  Remove N components from path.
- -r
  Perform a recovery operation.
- -R record_pos_file record_pos
  Specify record position file and record position.
- -u
  Perform an update operation.
- -v
  Verbose mode. Print more output about what the program does. This option can be given multiple
times to produce more and more output.
- -w write_file
  Specify the write file.
- -V
  Display version information.
4.6.6 myisampack — Generate Compressed, Read-Only MyISAM Tables

The myisampack utility compresses MyISAM tables. myisampack works by compressing each column in the table separately. Usually, myisampack packs the data file 40% to 70%.

When the table is used later, the server reads into memory the information needed to decompress columns. This results in much better performance when accessing individual rows, because you only have to uncompress exactly one row.

MySQL uses mmap() when possible to perform memory mapping on compressed tables. If mmap() does not work, MySQL falls back to normal read/write file operations.

Please note the following:

• If the mysql server was invoked with external locking disabled, it is not a good idea to invoke myisampack if the table might be updated by the server during the packing process. It is safest to compress tables with the server stopped.

• After packing a table, it becomes read only. This is generally intended (such as when accessing packed tables on a CD).

• myisampack does not support partitioned tables.

Invoke myisampack like this:

shell> myisampack [options] file_name ...

Each file name argument should be the name of an index (.MYI) file. If you are not in the database directory, you should specify the path name to the file. It is permissible to omit the .MYI extension.

After you compress a table with myisampack, use myisamchk -rq to rebuild its indexes. Section 4.6.4, "myisamchk — MyISAM Table-Maintenance Utility".

myisampack supports the following options. It also reads option files and supports the options for processing them described at Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

• --help, -?
  Display a help message and exit.

• --backup, -b
  Make a backup of each table's data file using the name tbl_name.OLD.

• --character-sets-dir=dir_name
  The directory where character sets are installed. See Section 10.14, “Character Set Configuration”.

• --debug[=debug_options], -# [debug_options]
  Write a debugging log. A typical debug_options string is d:t:o, file_name. The default is d:t:o.

• --force, -f
  Produce a packed table even if it becomes larger than the original or if the intermediate file from an earlier invocation of myisampack exists. (myisampack creates an intermediate file named tbl_name.TMD in the database directory while it compresses the table. If you kill myisampack, the .TMD file might not be deleted.) Normally, myisampack exits with an error if it finds that tbl_name.TMD exists. With --force, myisampack packs the table anyway.

• --join=big_tbl_name, -j big_tbl_name
Join all tables named on the command line into a single packed table `big_tbl_name`. All tables that are to be combined must have identical structure (same column names and types, same indexes, and so forth).

`big_tbl_name` must not exist prior to the join operation. All source tables named on the command line to be merged into `big_tbl_name` must exist. The source tables are read for the join operation but not modified.

- **--silent, -s**
  Silent mode. Write output only when errors occur.

- **--test, -t**
  Do not actually pack the table, just test packing it.

- **--tmpdir=dir_name, -T dir_name**
  Use the named directory as the location where `myisampack` creates temporary files.

- **--verbose, -v**
  Verbose mode. Write information about the progress of the packing operation and its result.

- **--version, -V**
  Display version information and exit.

- **--wait, -w**
  Wait and retry if the table is in use. If the `mysqld` server was invoked with external locking disabled, it is not a good idea to invoke `myisampack` if the table might be updated by the server during the packing process.

The following sequence of commands illustrates a typical table compression session:

```bash
shell> ls -l station.*
-rw-rw-r--   1 monty    my         994128 Apr 17 19:00 station.MYD
-rw-rw-r--   1 monty    my          53248 Apr 17 19:00 station.MYI

shell> myisamchk -dvv station
MyISAM file:     station

```
myisampack displays the following kinds of information:

- **normal**
  
  The number of columns for which no extra packing is used.

- **empty-space**
  
  The number of columns containing values that are only spaces. These occupy one bit.

- **empty-zero**
  
  The number of columns containing values that are only binary zeros. These occupy one bit.

- **empty-fill**
  
  The number of integer columns that do not occupy the full byte range of their type. These are changed to a smaller type. For example, a BIGINT column (eight bytes) can be stored as a TINYINT column (one byte) if all its values are in the range from -128 to 127.

- **pre-space**
  
  The number of decimal columns that are stored with leading spaces. In this case, each value contains a count for the number of leading spaces.

- **end-space**
  
  The number of columns that have a lot of trailing spaces. In this case, each value contains a count for the number of trailing spaces.

- **table-lookup**
  
  The column had only a small number of different values, which were converted to an ENUM before Huffman compression.

- **zero**
  
  The number of columns for which all values are zero.

- **Original trees**
  
  The initial number of Huffman trees.

- **After join**
  
  The number of distinct Huffman trees left after joining trees to save some header space.

After a table has been compressed, the Field lines displayed by myisamchk -dvv include additional information about each column:

- **Type**
  
  The data type. The value may contain any of the following descriptors:

  - **constant**
    
    All rows have the same value.
• **no endspace**
  Do not store endspace.

• **no endspace, not_always**
  Do not store endspace and do not do endspace compression for all values.

• **no endspace, no empty**
  Do not store endspace. Do not store empty values.

• **table-lookup**
  The column was converted to an ENUM.

• **zerofill (N)**
  The most significant $N$ bytes in the value are always 0 and are not stored.

• **no zeros**
  Do not store zeros.

• **always zero**
  Zero values are stored using one bit.

• **Huff tree**
  The number of the Huffman tree associated with the column.

• **Bits**
  The number of bits used in the Huffman tree.

After you run `myisampack`, use `myisamchk` to re-create any indexes. At this time, you can also sort the index blocks and create statistics needed for the MySQL optimizer to work more efficiently:

```
shell> myisamchk -rq --sort-index --analyze tbl_name.MYI
```

After you have installed the packed table into the MySQL database directory, you should execute `mysqladmin flush-tables` to force `mysqld` to start using the new table.

To unpack a packed table, use the `--unpack` option to `myisamchk`.

### 4.6.7 mysql_config_editor — MySQL Configuration Utility

The **mysql_config_editor** utility enables you to store authentication credentials in an obfuscated login path file named `.mylogin.cnf`. The file location is the `%APPDATA%\MySQL` directory on Windows and the current user's home directory on non-Windows systems. The file can be read later by MySQL client programs to obtain authentication credentials for connecting to MySQL Server.

The unobfuscated format of the `.mylogin.cnf` login path file consists of option groups, similar to other option files. Each option group in `.mylogin.cnf` is called a “login path,” which is a group that permits only certain options: `host`, `user`, `password`, `port` and `socket`. Think of a login path option group as a set of options that specify which MySQL server to connect to and which account to authenticate as. Here is an unobfuscated example:

```
[client]
user = mydefaultname
```
When you invoke a client program to connect to the server, the client uses `.mylogin.cnf` in conjunction with other option files. Its precedence is higher than other option files, but less than options specified explicitly on the client command line. For information about the order in which option files are used, see Section 4.2.2.2, “Using Option Files”.

To specify an alternate login path file name, set the `MYSQL_TEST_LOGIN_FILE` environment variable. This variable is recognized by `mysql_config_editor`, by standard MySQL clients (`mysql`, `mysqladmin`, and so forth), and by the `mysql-test-run.pl` testing utility.

Programs use groups in the login path file as follows:

- **mysql_config_editor** operates on the client login path by default if you specify no `--login-path=` option to indicate explicitly which login path to use.

- Without a `--login-path` option, client programs read the same option groups from the login path file that they read from other option files. Consider this command:

  ```shell
  mysql
  ```

  By default, the `mysql` client reads the `[client]` and `[mysql]` groups from other option files, so it reads them from the login path file as well.

- With a `--login-path` option, client programs additionally read the named login path from the login path file. The option groups read from other option files remain the same. Consider this command:

  ```shell
  mysql --login-path=mypath
  ```

  The `mysql` client reads `[client]` and `[mysql]` from other option files, and `[client]`, `[mysql]`, and `[mypath]` from the login path file.

- Client programs read the login path file even when the `--no-defaults` option is used. This permits passwords to be specified in a safer way than on the command line even if `--no-defaults` is present.

`mysql_config_editor` obfuscates the `.mylogin.cnf` file so it cannot be read as cleartext, and its contents when unobfuscated by client programs are used only in memory. In this way, passwords can be stored in a file in non-cleartext format and used later without ever needing to be exposed on the command line or in an environment variable.`mysql_config_editor` provides a `print` command for displaying the login path file contents, but even in this case, password values are masked so as never to appear in a way that other users can see them.

The obfuscation used by `mysql_config_editor` prevents passwords from appearing in `.mylogin.cnf` as cleartext and provides a measure of security by preventing inadvertent password exposure. For example, if you display a regular unobfuscated `my.cnf` option file on the screen, any passwords it contains are visible for anyone to see. With `.mylogin.cnf`, that is not true. But the obfuscation used will not deter a determined attacker and you should not consider it unbreakable. A user who can gain system administration privileges on your machine to access your files could unobfuscate the `.mylogin.cnf` file with some effort.

The login path file must be readable and writable to the current user, and inaccessible to other users. Otherwise, `mysql_config_editor` ignores it, and client programs do not use it, either.

Invoke `mysql_config_editor` like this:

```shell
shell> mysql_config_editor [program_options] command [command_options]
```
If the login path file does not exist, `mysql_config_editor` creates it.

Command arguments are given as follows:

- **program_options** consists of general `mysql_config_editor` options.
- **command** indicates what action to perform on the `.mylogin.cnf` login path file. For example, `set` writes a login path to the file, `remove` removes a login path, and `print` displays login path contents.
- **command_options** indicates any additional options specific to the command, such as the login path name and the values to use in the login path.

The position of the command name within the set of program arguments is significant. For example, these command lines have the same arguments, but produce different results:

```
shell> mysql_config_editor --help set
shell> mysql_config_editor set --help
```

The first command line displays a general `mysql_config_editor` help message, and ignores the `set` command. The second command line displays a help message specific to the `set` command.

Suppose that you want to establish a `client` login path that defines your default connection parameters, and an additional login path named `remote` for connecting to the MySQL server the host `remote.example.com`. You want to log in as follows:

- By default, to the local server with a user name and password of `localuser` and `localpass`
- To the remote server with a user name and password of `remoteuser` and `remotepass`

To set up the login paths in the `.mylogin.cnf` file, use the following `set` commands. Enter each command on a single line, and enter the appropriate passwords when prompted:

```
shell> mysql_config_editor set --login-path=client
    --host=localhost --user=localuser --password
Enter password: enter password "localpass" here
shell> mysql_config_editor set --login-path=remote
    --host=remote.example.com --user=remoteuser --password
Enter password: enter password "remotepass" here
```

`mysql_config_editor` uses the `client` login path by default, so the `--login-path=client` option can be omitted from the first command without changing its effect.

To see what `mysql_config_editor` writes to the `.mylogin.cnf` file, use the `print` command:

```
shell> mysql_config_editor print --all
[client]
user = localuser
password = *****
host = localhost
[remote]
user = remoteuser
password = *****
host = remote.example.com
```

The `print` command displays each login path as a set of lines beginning with a group header indicating the login path name in square brackets, followed by the option values for the login path. Password values are masked and do not appear as cleartext.

If you do not specify `--all` to display all login paths or `--login-path=name` to display a named login path, the `print` command displays the `client` login path by default, if there is one.

As shown by the preceding example, the login path file can contain multiple login paths. In this way, `mysql_config_editor` makes it easy to set up multiple “personalities” for connecting to different MySQL servers, or for connecting to a given server using different accounts. Any of these can be
selected by name later using the `--login-path` option when you invoke a client program. For example, to connect to the remote server, use this command:

```
shell> mysql --login-path=remote
```

Here, `mysql` reads the `[client]` and `[mysql]` option groups from other option files, and the `[client]`, `[mysql]`, and `[remote]` groups from the login path file.

To connect to the local server, use this command:

```
shell> mysql --login-path=client
```

Because `mysql` reads the `client` and `mysql` login paths by default, the `--login-path` option does not add anything in this case. That command is equivalent to this one:

```
shell> mysql
```

Options read from the login path file take precedence over options read from other option files. Options read from login path groups appearing later in the login path file take precedence over options read from groups appearing earlier in the file.

`mysql_config_editor` adds login paths to the login path file in the order you create them, so you should create more general login paths first and more specific paths later. If you need to move a login path within the file, you can remove it, then recreate it to add it to the end. For example, a `client` login path is more general because it is read by all client programs, whereas a `mysqldump` login path is read only by `mysqldump`. Options specified later override options specified earlier, so putting the login paths in the order `client, mysqldump` enables `mysqldump`-specific options to override `client` options.

When you use the `set` command with `mysql_config_editor` to create a login path, you need not specify all possible option values (host name, user name, password, port, socket). Only those values given are written to the path. Any missing values required later can be specified when you invoke a client path to connect to the MySQL server, either in other option files or on the command line. Any options specified on the command line override those specified in the login path file or other option files. For example, if the credentials in the `remote` login path also apply for the host `remote2.example.com`, connect to the server on that host like this:

```
shell> mysql --login-path=remote --host=remote2.example.com
```

### `mysql_config_editor` General Options

`mysql_config_editor` supports the following general options, which may be used preceding any command named on the command line. For descriptions of command-specific options, see `mysql_config_editor` Commands and Command-Specific Options.

<table>
<thead>
<tr>
<th>Option Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--debug</code></td>
<td>Write debugging log</td>
</tr>
<tr>
<td><code>--help</code></td>
<td>Display help message and exit</td>
</tr>
<tr>
<td><code>--verbose</code></td>
<td>Verbose mode</td>
</tr>
<tr>
<td><code>--version</code></td>
<td>Display version information and exit</td>
</tr>
</tbody>
</table>

- `--help`, `-?

Display a general help message and exit.

To see a command-specific help message, invoke `mysql_config_editor` as follows, where `command` is a command other than `help`:
shell> mysql_config_editor command --help

- --debug=[debug_options], --# debug_options

Write a debugging log. A typical debug_options string is d:t:o, file_name. The default is d:t:o,/tmp/mysql_config_editor.trace.

- --verbose, -v

Verbose mode. Print more information about what the program does. This option may be helpful in diagnosing problems if an operation does not have the effect you expect.

- --version, -V

Display version information and exit.

mysql_config_editor Commands and Command-Specific Options

This section describes the permitted mysql_config_editor commands, and, for each one, the command-specific options permitted following the command name on the command line.

In addition, mysql_config_editor supports general options that can be used preceding any command. For descriptions of these options, see mysql_config_editor General Options.

mysql_config_editor supports these commands:

- help

Display a general help message and exit. This command takes no following options.

To see a command-specific help message, invoke mysql_config_editor as follows, where command is a command other than help:

shell> mysql_config_editor command --help

- print [options]

Print the contents of the login path file in unobfuscated form, with the exception that passwords are displayed as ******.

The default login path name is client if no login path is named. If both --all and --login-path are given, --all takes precedence.

The print command permits these options following the command name:

- --help, -?

Display a help message for the print command and exit.

To see a general help message, use mysql_config_editor --help.

- --all

Print the contents of all login paths in the login path file.

- --login-path=name, -G name

Print the contents of the named login path.

- remove [options]

Remove a login path from the login path file, or modify a login path by removing options from it.
This command removes from the login path only such options as are specified with the --host, --password, --port, --socket, and --user options. If none of those options are given, remove removes the entire login path. For example, this command removes only the user option from the mypath login path rather than the entire mypath login path:

```
shell> mysql_config_editor remove --login-path=mypath --user
```

This command removes the entire mypath login path:

```
shell> mysql_config_editor remove --login-path=mypath
```

The remove command permits these options following the command name:

- **--help, -?**
  
  Display a help message for the remove command and exit.
  
  To see a general help message, use `mysql_config_editor --help`.

- **--host, -h**
  
  Remove the host name from the login path.

- **--login-path=name, -G name**
  
  The login path to remove or modify. The default login path name is `client` if this option is not given.

- **--password, -p**
  
  Remove the password from the login path.

- **--port, -P**
  
  Remove the TCP/IP port number from the login path.

- **--socket, -S**
  
  Remove the Unix socket file name from the login path.

- **--user, -u**
  
  Remove the user name from the login path.

- **--warn, -w**
  
  Warn and prompt the user for confirmation if the command attempts to remove the default login path (`client`) and `--login-path=client` was not specified. This option is enabled by default; use `--skip-warn` to disable it.

- **reset [options]**
  
  Empty the contents of the login path file.

The reset command permits these options following the command name:

- **--help, -?**
  
  Display a help message for the reset command and exit.
To see a general help message, use `mysql_config_editor --help`.

- **set [options]**

Write a login path to the login path file.

This command writes to the login path only such options as are specified with the `--host`, `--password`, `--port`, `--socket`, and `--user` options. If none of those options are given, `mysql_config_editor` writes the login path as an empty group.

The `set` command permits these options following the command name:

- `--help`, `-?

  Display a help message for the `set` command and exit.

To see a general help message, use `mysql_config_editor --help`.

- `--host=host_name, -h host_name`

  The host name to write to the login path.

- `--login-path=name, -G name`

  The login path to create. The default login path name is `client` if this option is not given.

- `--password, -p`

  Prompt for a password to write to the login path. After `mysql_config_editor` displays the prompt, type the password and press Enter. To prevent other users from seeing the password, `mysql_config_editor` does not echo it.

  To specify an empty password, press Enter at the password prompt. The resulting login path written to the login path file will include a line like this:

  ```
  password = 
  ```

- `--port=port_num, -P port_num`

  The TCP/IP port number to write to the login path.

- `--socket=file_name, -S file_name`

  The Unix socket file name to write to the login path.

- `--user=user_name, -u user_name`

  The user name to write to the login path.

- `--warn, -w`

  Warn and prompt the user for confirmation if the command attempts to overwrite an existing login path. This option is enabled by default; use `--skip-warn` to disable it.

### 4.6.8 mysqlbinlog — Utility for Processing Binary Log Files

The server’s binary log consists of files containing “events” that describe modifications to database contents. The server writes these files in binary format. To display their contents in text format, use the `mysqlbinlog` utility. You can also use `mysqlbinlog` to display the contents of relay log files written by a slave server in a replication setup because relay logs have the same format as binary logs. The
Invoke `mysqlbinlog` like this:

```
shell> mysqlbinlog [options] log_file ...
```

For example, to display the contents of the binary log file named `binlog.000003`, use this command:

```
shell> mysqlbinlog binlog.000003
```

The output includes events contained in `binlog.000003`. For statement-based logging, event information includes the SQL statement, the ID of the server on which it was executed, the timestamp when the statement was executed, how much time it took, and so forth. For row-based logging, the event indicates a row change rather than an SQL statement. See Section 17.2.1, “Replication Formats”, for information about logging modes.

Events are preceded by header comments that provide additional information. For example:

```
# at 141
#100309  9:28:36 server id 123  end_log_pos 245
Query thread_id=3350  exec_time=11  error_code=0
```

In the first line, the number following `at` indicates the file offset, or starting position, of the event in the binary log file.

The second line starts with a date and time indicating when the statement started on the server where the event originated. For replication, this timestamp is propagated to slave servers. `server_id` is the `server_id` value of the server where the event originated. `end_log_pos` indicates where the next event starts (that is, it is the end position of the current event + 1). `thread_id` indicates which thread executed the event. `exec_time` is the time spent executing the event, on a master server. On a slave, it is the difference of the end execution time on the slave minus the beginning execution time on the master. The difference serves as an indicator of how much replication lags behind the master. `error_code` indicates the result from executing the event. Zero means that no error occurred.

**Note**

When using event groups, the file offsets of events may be grouped together and the comments of events may be grouped together. Do not mistake these grouped events for blank file offsets.

The output from `mysqlbinlog` can be re-executed (for example, by using it as input to `mysql`) to redo the statements in the log. This is useful for recovery operations after a server crash. For other usage examples, see the discussion later in this section and in Section 7.5, “Point-in-Time (Incremental) Recovery Using the Binary Log”.

You can use `mysqlbinlog` to read binary log files directly and apply them to the local MySQL server. You can also read binary logs from a remote server by using the `--read-from-remote-server` option. To read remote binary logs, the connection parameter options can be given to indicate how to connect to the server. These options are `--host`, `--password`, `--port`, `--protocol`, `--socket`, and `--user`.

When binary log files have been encrypted, which can be done from MySQL 8.0.14 onwards, `mysqlbinlog` cannot read them directly, but can read them from the server using the `--read-from-remote-server` option. Binary log files are encrypted when the server's `binlog_encryption` system variable is set to `ON`. The `SHOW BINARY LOGS` statement shows whether a particular binary log file is encrypted or unencrypted. Encrypted and unencrypted binary log files can also be distinguished using the magic number at the start of the file header for encrypted log files (0xFD62696E), which differs from that used for unencrypted log files (0xFE62696E). Note that from MySQL 8.0.14, `mysqlbinlog` returns a suitable error if you attempt to read an encrypted binary log file directly, but older versions of `mysqlbinlog` do not recognise the file as a binary log file at all. For
more information on binary log encryption, see Section 17.3.10, “Encrypting Binary Log Files and Relay Log Files”.

When running `mysqlbinlog` against a large binary log, be careful that the filesystem has enough space for the resulting files. To configure the directory that `mysqlbinlog` uses for temporary files, use the `TMPDIR` environment variable.

`mysqlbinlog` sets the value of `pseudo_slave_mode` to true before executing any SQL statements.

`mysqlbinlog` supports the following options, which can be specified on the command line or in the `[mysqlbinlog]` and `[client]` groups of an option file. For information about option files used by MySQL programs, see Section 4.2.2.2, “Using Option Files”.

### Table 4.21 mysqlbinlog Options

<table>
<thead>
<tr>
<th>Option Name</th>
<th>Description</th>
<th>Introduced</th>
<th>Deprecated</th>
<th>Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--base64-output</code></td>
<td>Print binary log entries using base-64 encoding</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--bind-address</code></td>
<td>Use specified network interface to connect to MySQL Server</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--binlog-row-event-max-size</code></td>
<td>Binary log max event size</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--character-sets-dir</code></td>
<td>Directory where character sets are installed</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--compress</code></td>
<td>Compress all information sent between client and server</td>
<td>8.0.17</td>
<td>8.0.18</td>
<td></td>
</tr>
<tr>
<td><code>--compression-algorithms</code></td>
<td>Permitted compression algorithms for connections to server</td>
<td>8.0.18</td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--connection-server-id</code></td>
<td>Used for testing and debugging. See text for applicable default values and other particulars.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--database</code></td>
<td>List entries for just this database</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--debug</code></td>
<td>Write debugging log</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--debug-check</code></td>
<td>Print debugging information when program exits</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--debug-info</code></td>
<td>Print debugging information, memory, and CPU statistics when program exits</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--default-auth</code></td>
<td>Authentication plugin to use</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--defaults-extra-file</code></td>
<td>Read named option file in addition to usual option files</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--defaults-file</code></td>
<td>Read only named option file</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--defaults-group-suffix</code></td>
<td>Option group suffix value</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--disable-log-bin</code></td>
<td>Disable binary logging</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--exclude-gtids</code></td>
<td>Do not show any of the groups in the GTID set provided</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--force-if-open</code></td>
<td>Read binary log files even if open or not closed properly</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--force-read</code></td>
<td>If <code>mysqlbinlog</code> reads a binary log event that it does not recognize, it prints a warning</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--get-server-public-key</code></td>
<td>Request RSA public key from server</td>
<td>8.0.3</td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--help</code></td>
<td>Display help message and exit</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--hexdump</code></td>
<td>Display a hex dump of the log in comments</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Option Name</td>
<td>Description</td>
<td>Introduced</td>
<td>Deprecated</td>
<td>Removed</td>
</tr>
<tr>
<td>---------------------</td>
<td>------------------------------------------------------------------------------</td>
<td>------------</td>
<td>------------</td>
<td>---------</td>
</tr>
<tr>
<td>--host</td>
<td>Host on which MySQL server is located</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--idempotent</td>
<td>Cause the server to use idempotent mode while processing binary log updates from this session only</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--include-gtids</td>
<td>Show only the groups in the GTID set provided</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--local-load</td>
<td>Prepare local temporary files for LOAD DATA in the specified directory</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--login-path</td>
<td>Read login path options from .mylogin.cnf</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--no-defaults</td>
<td>Read no option files</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--offset</td>
<td>Skip the first N entries in the log</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--password</td>
<td>Password to use when connecting to server</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--plugin-dir</td>
<td>Directory where plugins are installed</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--port</td>
<td>TCP/IP port number for connection</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--print-defaults</td>
<td>Print default options</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--print-table-metadata</td>
<td>Print table metadata</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--protocol</td>
<td>Connection protocol to use</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--raw</td>
<td>Write events in raw (binary) format to output files</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--read-from-remote-master</td>
<td>Read the binary log from a MySQL master rather than reading a local log file</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--read-from-remote-server</td>
<td>Read binary log from MySQL server rather than local log file</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--result-file</td>
<td>Direct output to named file</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--rewrite-db</td>
<td>Create rewrite rules for databases when playing back from logs written in row-based format. Can be used multiple times.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--secure-auth</td>
<td>Do not send passwords to server in old (pre-4.1) format</td>
<td>8.0.3</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--server-id</td>
<td>Extract only those events created by the server having the given server ID</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--server-id-bits</td>
<td>Tell mysqlbinlog how to interpret server IDs in binary log when log was written by a mysqld having its server-id-bits set to less than the maximum; supported only by MySQL Cluster version of mysqlbinlog</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--server-public-key-path</td>
<td>Path name to file containing RSA public key</td>
<td>8.0.4</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--set-charset</td>
<td>Add a SET NAMES charset_name statement to the output</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--shared-memory-base-name</td>
<td>Name of shared memory to use for shared-memory connections</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--short-form</td>
<td>Display only the statements contained in the log</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--skip-gtids</td>
<td>Do not print any GTIDs; use this when writing a dump file from binary logs containing GTIDs.</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
### mysqlbinlog — Utility for Processing Binary Log Files

<table>

<td>--zstd-compression-level</td>
<td>Compression level for connections to server that use zstd compression</td>
<td>8.0.18</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

- **--help, -?**

Display a help message and exit.

- **--base64-output=value**
This option determines when events should be displayed encoded as base-64 strings using `BINLOG` statements. The option has these permissible values (not case-sensitive):

- **AUTO** ("automatic") or **UNSPEC** ("unspecified") displays `BINLOG` statements automatically when necessary (that is, for format description events and row events). If no `--base64-output` option is given, the effect is the same as `--base64-output=AUTO`.

  **Note**

  Automatic `BINLOG` display is the only safe behavior if you intend to use the output of `mysqlbinlog` to re-execute binary log file contents. The other option values are intended only for debugging or testing purposes because they may produce output that does not include all events in executable form.

- **NEVER** causes `BINLOG` statements not to be displayed. `mysqlbinlog` exits with an error if a row event is found that must be displayed using `BINLOG`.

- **DECODE-ROWS** specifies to `mysqlbinlog` that you intend for row events to be decoded and displayed as commented SQL statements by also specifying the `--verbose` option. Like NEVER, DECODE-ROWS suppresses display of `BINLOG` statements, but unlike NEVER, it does not exit with an error if a row event is found.

For examples that show the effect of `--base64-output` and `--verbose` on row event output, see Section 4.6.8.2, "mysqlbinlog Row Event Display".

- **--bind-address=ip_address**

  On a computer having multiple network interfaces, use this option to select which interface to use for connecting to the MySQL server.

- **--binlog-row-event-max-size=N**

  Specify the maximum size of a row-based binary log event, in bytes. Rows are grouped into events smaller than this size if possible. The value should be a multiple of 256. The default is 4GB.

- **--character-sets-dir=dir_name**

  The directory where character sets are installed. See Section 10.14, "Character Set Configuration".

- **--compress**

  Compress all information sent between the client and the server if possible. See Section 4.2.6, "Connection Compression Control".

  This option was added in MySQL 8.0.17. As of MySQL 8.0.18 it is deprecated. It will be removed in a future MySQL version. See Legacy Connection Compression Configuration.

- **--compression-algorithms=value**
The permitted compression algorithms for connections to the server. The available algorithms are the same as for the `protocol_compression_algorithms` system variable. The default value is `uncompressed`.

For more information, see Section 4.2.6, “Connection Compression Control”.

This option was added in MySQL 8.0.18.

• **`--connection-server-id=server_id`**

  `--connection-server-id` specifies the server ID that `mysqlbinlog` reports when it connects to the server. It can be used to avoid a conflict with the ID of a slave server or another `mysqlbinlog` process.

  If the `--read-from-remote-server` option is specified, `mysqlbinlog` reports a server ID of 0, which tells the server to disconnect after sending the last log file (nonblocking behavior). If the `--stop-never` option is also specified to maintain the connection to the server, `mysqlbinlog` reports a server ID of 1 by default instead of 0, and `--connection-server-id` can be used to replace that server ID if required. See Section 4.6.8.4, “Specifying the `mysqlbinlog` Server ID”.

• **`--database=db_name`**, `-d db_name `  

  This option causes `mysqlbinlog` to output entries from the binary log (local log only) that occur while `db_name` is been selected as the default database by `USE`.

  The `--database` option for `mysqlbinlog` is similar to the `--binlog-do-db` option for `mysqld`, but can be used to specify only one database. If `--database` is given multiple times, only the last instance is used.

  The effects of this option depend on whether the statement-based or row-based logging format is in use, in the same way that the effects of `--binlog-do-db` depend on whether statement-based or row-based logging is in use.

  **Statement-based logging.** The `--database` option works as follows:

  • While `db_name` is the default database, statements are output whether they modify tables in `db_name` or a different database.

  • Unless `db_name` is selected as the default database, statements are not output, even if they modify tables in `db_name`.

  • There is an exception for `CREATE DATABASE`, `ALTER DATABASE`, and `DROP DATABASE`. The database being `created`, `altered`, or `dropped` is considered to be the default database when determining whether to output the statement.

  Suppose that the binary log was created by executing these statements using statement-based-logging:

  ```sql
  INSERT INTO test.t1 (i) VALUES(100);
  INSERT INTO db2.t2 (j) VALUES(200);
  USE test;
  INSERT INTO test.t1 (i) VALUES(101);
  INSERT INTO t1 (i) VALUES(102);
  INSERT INTO db2.t2 (j) VALUES(201);
  USE db2;
  INSERT INTO test.t1 (i) VALUES(103);
  INSERT INTO db2.t2 (j) VALUES(202);
  INSERT INTO t2 (j) VALUES(203);
  ```
mysqlbinlog --database=test does not output the first two INSERT statements because there is no default database. It outputs the three INSERT statements following USE test, but not the three INSERT statements following USE db2.

mysqlbinlog --database=db2 does not output the first two INSERT statements because there is no default database. It does not output the three INSERT statements following USE test, but does output the three INSERT statements following USE db2.

Row-based logging. mysqlbinlog outputs only entries that change tables belonging to db_name. The default database has no effect on this. Suppose that the binary log just described was created using row-based logging rather than statement-based logging. mysqlbinlog --database=test outputs only those entries that modify t1 in the test database, regardless of whether USE was issued or what the default database is.

If a server is running with binlog_format set to MIXED and you want it to be possible to use mysqlbinlog with the --database option, you must ensure that tables that are modified are in the database selected by USE. (In particular, no cross-database updates should be used.)

When used together with the --rewrite-db option, the --rewrite-db option is applied first; then the --database option is applied, using the rewritten database name. The order in which the options are provided makes no difference in this regard.

- --debug[=debug_options], -# [debug_options]
  Write a debugging log. A typical debug_options string is d:t:o, file_name. The default is d:t:o,/tmp/mysqlbinlog.trace.
- --debug-check
  Print some debugging information when the program exits.
- --debug-info
  Print debugging information and memory and CPU usage statistics when the program exits.
- --default-auth=plugin
  A hint about which client-side authentication plugin to use. See Section 6.2.17, “Pluggable Authentication”.
- --defaults-extra-file=file_name
  Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. file_name is interpreted relative to the current directory if given as a relative path name rather than a full path name.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.
- --defaults-file=file_name
  Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. file_name is interpreted relative to the current directory if given as a relative path name rather than a full path name.

Exception: Even with --defaults-file, client programs read .mylogin.cnf.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.
- --defaults-group-suffix=str
Read not only the usual option groups, but also groups with the usual names and a suffix of
str. For example, mysqlbinlog normally reads the [client] and [mysqlbinlog] groups. If the
--defaults-group-suffix=_other option is given, mysqlbinlog also reads the
[client_other] and [mysqlbinlog_other] groups.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-
Line Options that Affect Option-File Handling”.

• --disable-log-bin, -D

Disable binary logging. This is useful for avoiding an endless loop if you use the --to-last-
log option and are sending the output to the same MySQL server. This option also is useful when
restoring after a crash to avoid duplication of the statements you have logged.

This option causes mysqlbinlog to include a SET sql_log_bin = 0 statement in its output to
disable binary logging of the remaining output. Manipulating the session value of the sql_log_bin
system variable is a restricted operation, so this option requires that you have privileges sufficient to
set restricted session variables. See Section 5.1.9.1, “System Variable Privileges”.

• --exclude-gtids=gtid_set

Do not display any of the groups listed in the gtid_set.

• --force-if-open, -F

Read binary log files even if they are open or were not closed properly.

• --force-read, -f

With this option, if mysqlbinlog reads a binary log event that it does not recognize, it prints a
warning, ignores the event, and continues. Without this option, mysqlbinlog stops if it reads such
an event.

• --get-server-public-key

Request from the server the public key required for RSA key pair-based password exchange. This
option applies to clients that authenticate with the caching_sha2_password authentication
plugin. For that plugin, the server does not send the public key unless requested. This option
is ignored for accounts that do not authenticate with that plugin. This option
is also ignored if RSA-based
password exchange is not used, as is the case when the client connects to the server using a secure
connection.

If --server-public-key-path=file_name is given and specifies a valid public key file, it takes
precedence over --get-server-public-key.

For information about the caching_sha2_password plugin, see Section 6.4.1.3, “Caching SHA-2
Pluggable Authentication”.

• --hexdump, -H

Display a hex dump of the log in comments, as described in Section 4.6.8.1, “mysqlbinlog Hex Dump
Format”. The hex output can be helpful for replication debugging.

• --host=host_name, -h host_name

Get the binary log from the MySQL server on the given host.

• --idempotent

Tell the MySQL Server to use idempotent mode while processing updates; this causes suppression
of any duplicate-key or key-not-found errors that the server encounters in the current session while
processing updates. This option may prove useful whenever it is desirable or necessary to replay one or more binary logs to a MySQL Server which may not contain all of the data to which the logs refer.

The scope of effect for this option includes the current mysqlbinlog client and session only.

- **--include-gtids=gtid_set**
  Display only the groups listed in the gtid_set.

- **--local-load=dir_name, -l dir_name**
  Prepare local temporary files for LOAD DATA in the specified directory.

  **Important**
  These temporary files are not automatically removed by mysqlbinlog or any other MySQL program.

- **--login-path=name**
  Read options from the named login path in the .mylogin.cnf login path file. A “login path” is an option group containing options that specify which MySQL server to connect to and which account to authenticate as. To create or modify a login path file, use the mysql_config_editor utility. See Section 4.6.7, “mysql_config_editor — MySQL Configuration Utility”.

  For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- **--no-defaults**
  Do not read any option files. If program startup fails due to reading unknown options from an option file, **--no-defaults** can be used to prevent them from being read.

  The exception is that the .mylogin.cnf file, if it exists, is read in all cases. This permits passwords to be specified in a safer way than on the command line even when **--no-defaults** is used. (.mylogin.cnf is created by the mysql_config_editor utility. See Section 4.6.7, “mysql_config_editor — MySQL Configuration Utility”.)

  For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- **--offset=N, -o N**
  Skip the first $N$ entries in the log.

- **--open-files-limit=N**
  Specify the number of open file descriptors to reserve.

- **--password[=password], -p[password]**
  The password of the MySQL account used for connecting to the server. The password value is optional. If not given, mysqlbinlog prompts for one. If given, there must be no space between **--password=** or **-p** and the password following it. If no password option is specified, the default is to send no password.

  Specifying a password on the command line should be considered insecure. To avoid giving the password on the command line, use an option file. See Section 6.1.2.1, “End-User Guidelines for Password Security”.
To explicitly specify that there is no password and that `mysqlbinlog` should not prompt for one, use the `--skip-password` option.

- `--plugin-dir=dir_name`

  The directory in which to look for plugins. Specify this option if the `--default-auth` option is used to specify an authentication plugin but `mysqlbinlog` does not find it. See Section 6.2.17, “Pluggable Authentication”.

- `--port=port_num`, `-P port_num`

  The TCP/IP port number to use for connecting to a remote server.

- `--print-defaults`

  Print the program name and all options that it gets from option files.

  For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- `--print-table-metadata`

  Print table related metadata from the binary log. Configure the amount of table related metadata binary logged using `binlog-row-metadata`.

- `--protocol={TCP|SOCKET|PIPE|MEMORY}`

  The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally result in use of a protocol other than the one you want. For details on the permissible values, see Section 4.2.4, “Connecting to the MySQL Server Using Command Options”.

- `--raw`

  By default, `mysqlbinlog` reads binary log files and writes events in text format. The `--raw` option tells `mysqlbinlog` to write them in their original binary format. Its use requires that `--read-from-remote-server` also be used because the files are requested from a server. `mysqlbinlog` writes one output file for each file read from the server. The `--raw` option can be used to make a backup of a server’s binary log. With the `--stop-never` option, the backup is “live” because `mysqlbinlog` stays connected to the server. By default, output files are written in the current directory with the same names as the original log files. Output file names can be modified using the `--result-file` option. For more information, see Section 4.6.8.3, “Using mysqlbinlog to Back Up Binary Log Files”.

- `--read-from-remote-master=type`

  Read binary logs from a MySQL server with the `COM_BINLOG_DUMP` or `COM_BINLOG_DUMP_GTID` commands by setting the option value to either `BINLOG-DUMP-NON-GTIDS` or `BINLOG-DUMP-GTIDS`, respectively. If `--read-from-remote-master=BINLOG-DUMP-GTIDS` is combined with `--exclude-gtids`, transactions can be filtered out on the master, avoiding unnecessary network traffic.

  The connection parameter options are used with this option or the `--read-from-remote-server` option. These options are `--host`, `--password`, `--port`, `--protocol`, `--socket`, and `--user`. If neither of the remote options is specified, the connection parameter options are ignored.

  The `REPLICATION SLAVE` privilege is required to use this option.

- `--read-from-remote-server`, `-R`

  Read the binary log from a MySQL server rather than reading a local log file. This option requires that the remote server be running. It works only for binary log files on the remote server, not relay log files.
The connection parameter options are used with this option or the `--read-from-remote-master` option. These options are `--host`, `--password`, `--port`, `--protocol`, `--socket`, and `--user`. If neither of the remote options is specified, the connection parameter options are ignored.

The `REPLICATION SLAVE` privilege is required to use this option.

This option is like `--read-from-remote-master=BINLOG-DUMP-NON-GTIDS`.

- `--result-file=name, -r name`
  
  Without the `--raw` option, this option indicates the file to which `mysqlbinlog` writes text output. With `--raw`, `mysqlbinlog` writes one binary output file for each log file transferred from the server, writing them by default in the current directory using the same names as the original log file. In this case, the `--result-file` option value is treated as a prefix that modifies output file names.

- `--rewrite-db='from_name->to_name'`
  
  When reading from a row-based or statement-based log, rewrite all occurrences of `from_name` to `to_name`. Rewriting is done on the rows, for row-based logs, as well as on the `USE` clauses, for statement-based logs.

  **Warning**

  Statements in which table names are qualified with database names are not rewritten to use the new name when using this option.

  The rewrite rule employed as a value for this option is a string having the form `from_name->to_name`, as shown previously, and for this reason must be enclosed by quotation marks.

  To employ multiple rewrite rules, specify the option multiple times, as shown here:

  ```shell
  mysqlbinlog --rewrite-db='dbcurrent->dbold' --rewrite-db='dbtest->dbcurrent' binlog.00001 > /tmp/statements.sql
  ```

  When used together with the `--database` option, the `--rewrite-db` option is applied first; then `--database` option is applied, using the rewritten database name. The order in which the options are provided makes no difference in this regard.

  This means that, for example, if `mysqlbinlog` is started with `--rewrite-db='mydb->yourdb' --database=yourdb`, then all updates to any tables in databases `mydb` and `yourdb` are included in the output. On the other hand, if it is started with `--rewrite-db='mydb->yourdb' --database=mydb`, then `mysqlbinlog` outputs no statements at all: since all updates to `mydb` are first rewritten as updates to `yourdb` before applying the `--database` option, there remain no updates that match `--database=mydb`.

- `--secure-auth`

- `--server-id=id`

  Display only those events created by the server having the given server ID.

- `--server-id-bits=N`

  Use only the first `N` bits of the `server_id` to identify the server. If the binary log was written by a `mysqld` with server-id-bits set to less than 32 and user data stored in the most significant bit, running `mysqlbinlog` with `--server-id-bits` set to 32 enables this data to be seen.

  This option is supported only by the version of `mysqlbinlog` supplied with the NDB Cluster distribution, or built with NDB Cluster support.

- `--server-public-key-path=file_name`
The path name to a file containing a client-side copy of the public key required by the server for RSA key pair-based password exchange. The file must be in PEM format. This option applies to clients that authenticate with the `sha256_password` or `caching_sha2_password` authentication plugin. This option is ignored for accounts that do not authenticate with one of those plugins. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

If `--server-public-key-path=file_name` is given and specifies a valid public key file, it takes precedence over `--get-server-public-key`.

For `sha256_password`, this option applies only if MySQL was built using OpenSSL.

For information about the `sha256_password` and `caching_sha2_password` plugins, see Section 6.4.1.2, “SHA-256 Pluggable Authentication”, and Section 6.4.1.3, “Caching SHA-2 Pluggable Authentication”.

- **--set-charset=charset_name**

Add a `SET NAMES charset_name` statement to the output to specify the character set to be used for processing log files.

- **--shared-memory-base-name=name**

On Windows, the shared-memory name to use for connections made using shared memory to a local server. The default value is `MYSQL`. The shared-memory name is case-sensitive.

This option applies only if the server was started with the `shared_memory` system variable enabled to support shared-memory connections.

- **--short-form, -s**

Display only the statements contained in the log, without any extra information or row-based events. This is for testing only, and should not be used in production systems. It is deprecated, and will be removed in a future release.

- **--skip-gtids[=(true|false)]**

Do not display any GTIDs in the output. This is needed when writing to a dump file from one or more binary logs containing GTIDs, as shown in this example:

```
shell> mysqlbinlog --skip-gtids binlog.000001 > /tmp/dump.sql
shell> mysqlbinlog --skip-gtids binlog.000002 >> /tmp/dump.sql
shell> mysql -u root -p -e "source /tmp/dump.sql"
```

The use of this option is otherwise not normally recommended in production.

- **--socket=path, -S path**

For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

On Windows, this option applies only if the server was started with the `named_pipe` system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the `named_pipe_full_access_group` system variable.

- **--ssl**

Options that begin with `--ssl` specify whether to connect to the server using SSL and indicate where to find SSL keys and certificates. See Command Options for Encrypted Connections.
---

mysqlbinlog — Utility for Processing Binary Log Files

- **--ssl-fips-mode={OFF|ON|STRICT}**

  Controls whether to enable FIPS mode on the client side. The **--ssl-fips-mode** option differs from other **--ssl-xxx** options in that it is not used to establish encrypted connections, but rather to affect which cryptographic operations are permitted. See Section 6.5, “FIPS Support”.

  These **--ssl-fips-mode** values are permitted:

  - **OFF**: Disable FIPS mode.
  - **ON**: Enable FIPS mode.
  - **STRICT**: Enable “strict” FIPS mode.

  **Note**

  If the OpenSSL FIPS Object Module is not available, the only permitted value for **--ssl-fips-mode** is **OFF**. In this case, setting **--ssl-fips-mode** to **ON** or **STRICT** causes the client to produce a warning at startup and to operate in non-FIPS mode.

- **--start-datetime=**datetime

  Start reading the binary log at the first event having a timestamp equal to or later than the **datetime** argument. The **datetime** value is relative to the local time zone on the machine where you run mysqlbinlog. The value should be in a format accepted for the **DATETIME** or **TIMESTAMP** data types. For example:

  ```shell
  shell> mysqlbinlog --start-datetime="2005-12-25 11:25:56" binlog.000003
  ```

  This option is useful for point-in-time recovery. See Section 7.3, “Example Backup and Recovery Strategy”.

- **--start-position=N, -j N**

  Start reading the binary log at the first event having a position equal to or greater than **N**. This option applies to the first log file named on the command line.

  This option is useful for point-in-time recovery. See Section 7.3, “Example Backup and Recovery Strategy”.

- **--stop-datetime=**datetime

  Stop reading the binary log at the first event having a timestamp equal to or later than the **datetime** argument. This option is useful for point-in-time recovery. See the description of the **--start-datetime** option for information about the **datetime** value.

  This option is useful for point-in-time recovery. See Section 7.3, “Example Backup and Recovery Strategy”.

- **--stop-never**

  This option is used with **--read-from-remote-server**. It tells mysqlbinlog to remain connected to the server. Otherwise mysqlbinlog exits when the last log file has been transferred from the server. **--stop-never** implies **--to-last-log**, so only the first log file to transfer need be named on the command line.

  **--stop-never** is commonly used with **--raw** to make a live binary log backup, but also can be used without **--raw** to maintain a continuous text display of log events as the server generates them.
With `--stop-never`, by default, `mysqlbinlog` reports a server ID of 1 when it connects to the server. Use `--connection-server-id` to explicitly specify an alternative ID to report. It can be used to avoid a conflict with the ID of a slave server or another `mysqlbinlog` process. See Section 4.6.8.4, “Specifying the `mysqlbinlog` Server ID”.

- `--stop-never-slave-server-id=id`
  
  This option is deprecated and will be removed in a future release. Use the `--connection-server-id` option instead to specify a server ID for `mysqlbinlog` to report.

- `--stop-position=N`
  
  Stop reading the binary log at the first event having a position equal to or greater than `N`. This option applies to the last log file named on the command line.
  
  This option is useful for point-in-time recovery. See Section 7.3, “Example Backup and Recovery Strategy”.

- `--tls-ciphersuites=ciphersuite_list`
  
  For client programs, specifies which TLSv1.3 ciphersuites the client permits for encrypted connections. The value is a list of one or more colon-separated ciphersuite names. The ciphersuites that can be named for this option depend on the SSL library used to compile MySQL. For details, see Section 6.3.5, “Encrypted Connection Protocols and Ciphers”.
  
  This option was added in MySQL 8.0.16.

- `--tls-version=protocol_list`
  
  The permissible TLS protocols for encrypted connections. The value is a list of one or more comma-separated protocol names. The protocols that can be named for this option depend on the SSL library used to compile MySQL. For details, see Section 6.3.5, “Encrypted Connection Protocols and Ciphers”.

- `--to-last-log, -t`
  
  Do not stop at the end of the requested binary log from a MySQL server, but rather continue printing until the end of the last binary log. If you send the output to the same MySQL server, this may lead to an endless loop. This option requires `--read-from-remote-server`.

- `--user=user_name, -u user_name`
  
  The user name of the MySQL account to use when connecting to a remote server.

- `--verbose, -v`
  
  Reconstruct row events and display them as commented SQL statements, with table partition information where applicable. If this option is given twice (by passing in either `"-vv"` or `"--verbose --verbose"`), the output includes comments to indicate column data types and some metadata, and informational log events such as row query log events if the `binlog_rows_query_log_events` system variable is set to `TRUE`.
  
  For examples that show the effect of `--base64-output` and `--verbose` on row event output, see Section 4.6.8.2, “`mysqlbinlog` Row Event Display”.

- `--verify-binlog-checksum, -c`
  
  Verify checksums in binary log files.

- `--version, -V`
  
  Display version information and exit.
The `mysqlbinlog` version number shown when using this option is 3.4.

- **--zstd-compression-level=level**

  The compression level to use for connections to the server that use the `zstd` compression algorithm. The permitted levels are from 1 to 22, with larger values indicating increasing levels of compression. The default `zstd` compression level is 3. The compression level setting has no effect on connections that do not use `zstd` compression.

  For more information, see Section 4.2.6, “Connection Compression Control”.

  This option was added in MySQL 8.0.18.

You can pipe the output of `mysqlbinlog` into the `mysql` client to execute the events contained in the binary log. This technique is used to recover from a crash when you have an old backup (see Section 7.5, “Point-in-Time (Incremental) Recovery Using the Binary Log”). For example:

```
shell> mysqlbinlog binlog.000001 | mysql -u root -p
```

Or:

```
shell> mysqlbinlog binlog.[0-9]* | mysql -u root -p
```

If the statements produced by `mysqlbinlog` may contain `BLOB` values, these may cause problems when `mysql` processes them. In this case, invoke `mysql` with the `--binary-mode` option.

You can also redirect the output of `mysqlbinlog` to a text file instead, if you need to modify the statement log first (for example, to remove statements that you do not want to execute for some reason). After editing the file, execute the statements that it contains by using it as input to the `mysql` program:

```
shell> mysqlbinlog binlog.000001 > tmpfile
shell> ... edit tmpfile ...
shell> mysql -u root -p < tmpfile
```

When `mysqlbinlog` is invoked with the `--start-position` option, it displays only those events with an offset in the binary log greater than or equal to a given position (the given position must match the start of one event). It also has options to stop and start when it sees an event with a given date and time. This enables you to perform point-in-time recovery using the `--stop-datetime` option (to be able to say, for example, “roll forward my databases to how they were today at 10:30 a.m.”).

**Processing multiple files.** If you have more than one binary log to execute on the MySQL server, the safe method is to process them all using a single connection to the server. Here is an example that demonstrates what may be **unsafe**:

```
shell> mysqlbinlog binlog.000001 | mysql -u root -p # DANGER!!
shell> mysqlbinlog binlog.000002 | mysql -u root -p # DANGER!!
```

Processing binary logs this way using multiple connections to the server causes problems if the first log file contains a `CREATE TEMPORARY TABLE` statement and the second log contains a statement that uses the temporary table. When the first `mysql` process terminates, the server drops the temporary table. When the second `mysql` process attempts to use the table, the server reports “unknown table.”

To avoid problems like this, use a `single mysql` process to execute the contents of all binary logs that you want to process. Here is one way to do so:

```
shell> mysqlbinlog binlog.000001 binlog.000002 | mysql -u root -p
```

Another approach is to write all the logs to a single file and then process the file:
mysqlbinlog — Utility for Processing Binary Log Files

shell> mysqlbinlog binlog.000001 > /tmp/statements.sql
shell> mysqlbinlog binlog.000002 >> /tmp/statements.sql
shell> mysql -u root -p -e "source /tmp/statements.sql"

From MySQL 8.0.12, you can also supply multiple binary log files to mysqlbinlog as streamed input using a shell pipe. An archive of compressed binary log files can be decompressed and provided directly to mysqlbinlog. In this example, binlog-files_1.gz contains multiple binary log files for processing. The pipeline extracts the contents of binlog-files_1.gz, pipes the binary log files to mysqlbinlog as standard input, and pipes the output of mysqlbinlog into the mysql client for execution:

shell> gzip -cd binlog-files_1.gz | ./mysqlbinlog - | ./mysql -uroot -p

You can specify more than one archive file, for example:

shell> gzip -cd binlog-files_1.gz binlog-files_2.gz | ./mysqlbinlog - | ./mysql -uroot -p

For streamed input, do not use --stop-position, because mysqlbinlog cannot identify the last log file to apply this option.

LOAD DATA operations. mysqlbinlog can produce output that reproduces a LOAD DATA operation without the original data file. mysqlbinlog copies the data to a temporary file and writes a LOAD DATA LOCAL statement that refers to the file. The default location of the directory where these files are written is system-specific. To specify a directory explicitly, use the --local-load option.

Because mysqlbinlog converts LOAD DATA statements to LOAD DATA LOCAL statements (that is, it adds LOCAL), both the client and the server that you use to process the statements must be configured with the LOCAL capability enabled. See Section 6.1.6, “Security Issues with LOAD DATA LOCAL”.

Warning
The temporary files created for LOAD DATA LOCAL statements are not automatically deleted because they are needed until you actually execute those statements. You should delete the temporary files yourself after you no longer need the statement log. The files can be found in the temporary file directory and have names like original_file_name-#-#.

4.6.8.1 mysqlbinlog Hex Dump Format

The --hexdump option causes mysqlbinlog to produce a hex dump of the binary log contents:

shell> mysqlbinlog --hexdump master-bin.000001

The hex output consists of comment lines beginning with #, so the output might look like this for the preceding command:

/*140019 SET @@SESSION.max_insert_delayed_threads=0*/;
/*15003 SET @OLD_COMPLETION_TYPE=@@COMPLETION_TYPE,COMPLETION_TYPE=0*/;
# at 4
#051024 17:24:13 server id 1 end_log_pos 98
# Position Timestamp Type Master ID Size Master Pos Flags
# 00000004 9d fc 5c 43 0f 01 00 00 00 5e 00 00 00 62 00 00 00 00 00
# 00000077 04 00 35 2e 30 2e 31 35 2d 64 65 62 75 67 2d 6c |..5.0.15.debug.l|
# 00000087 04 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00
# 000000a7 04 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00
# 00000097 04 00 00 00 00 9d fc 5c 43 13 38 0d 00 08 00 12 00 ......C.8......
# 000000a7 04 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00
# Start: binlog v 4, server v 5.0.15-debug-log created 051024 17:24:13
# at startup
ROLLBACK;
Hex dump output currently contains the elements in the following list. This format is subject to change. For more information about binary log format, see MySQL Internals: The Binary Log.

- **Position**: The byte position within the log file.
- **Timestamp**: The event timestamp. In the example shown, '9d fc 5c 43' is the representation of '051024 17:24:13' in hexadecimal.
- **Type**: The event type code.
- **Master ID**: The server ID of the master that created the event.
- **Size**: The size in bytes of the event.
- **Master Pos**: The position of the next event in the original master log file.
- **Flags**: Event flag values.

### 4.6.8.2 mysqlbinlog Row Event Display

The following examples illustrate how mysqlbinlog displays row events that specify data modifications. These correspond to events with the WRITE_ROWS_EVENT, UPDATE_ROWS_EVENT, and DELETE_ROWS_EVENT type codes. The `--base64-output=DECODE-ROWS` and `--verbose` options may be used to affect row event output.

Suppose that the server is using row-based binary logging and that you execute the following sequence of statements:

```sql
CREATE TABLE t
(
  id   INT NOT NULL,
  name VARCHAR(20) NOT NULL,
  date DATE NULL
) ENGINE = InnoDB;
START TRANSACTION;
INSERT INTO t VALUES(1, 'apple', NULL);
UPDATE t SET name = 'pear', date = '2009-01-01' WHERE id = 1;
DELETE FROM t WHERE id = 1;
COMMIT;
```

By default, mysqlbinlog displays row events encoded as base-64 strings using BINLOG statements. Omitting extraneous lines, the output for the row events produced by the preceding statement sequence looks like this:

```
shell> mysqlbinlog log_file
...
# at 218
#080828 15:03:08 server id 1  end_log_pos 258   Write_rows: table id 17 flags: STMT_END_F
BINLOG 'fAS3SBMBAAAALAAAAnoAAAAABAAAABAAAAAAABHR1c3QAAXQAwMPCgIUAQ= fAS3SBcBAAAARKAAAAAIAAAQAABEAAAAAEAA//8AQAAMAwhcHBsZQ==' '/*'*/;
...
# at 302
#080828 15:03:08 server id 1  end_log_pos 356   Update_rows: table id 17 flags: STMT_END_F
BINLOG 'fAS3SBMBAAAALAAAAnoAAAAABAAAABAAAAAAABHR1c3QAAXQAwMPCgIUAQ= fAS3SBgBAAAANgAAAGQBAAAQAABEAAAAAEAA///AEAAAAFYXbwbG4AQAABAAwzWFyIbIP '/*'*/;
...
# at 400
#080828 15:03:08 server id 1  end_log_pos 442   Delete_rows: table id 17 flags: STMT_END_F
```
mysqlbinlog — Utility for Processing Binary Log Files

To see the row events as comments in the form of "pseudo-SQL" statements, run mysqlbinlog with the --verbose or -v option. This output level also shows table partition information where applicable. The output will contain lines beginning with ###:

```
shell> mysqlbinlog -v log_file
...
# at 218
#080828 15:03:08 server id 1  end_log_pos 258  Write_rows: table id 17 flags: STMT_END_F
BINLOG '
FAS3SBMBAAlanAAAAJABAAAAABEAAAAAAAAABHR1c3QAXQAAwMPCgIUAQ=
FAS3SBkAaAAAKgAAAALoBAAAQAABEAAAAAAAAEAA//4AQAAAAQw2WFyIbIP
'/*!*/;
### INSERT INTO test.t
### SET
###   @1=1
###   @2='apple'
###   @3=NULL
...
# at 302
#080828 15:03:08 server id 1  end_log_pos 356  Update_rows: table id 17 flags: STMT_END_F
BINLOG '
FAS3SBMBAalanAAAAbAAAABEAAAAAAAAABHR1c3QAXQAAwMPCgIUAQ=
FAS3SBcAaAAAIABAAAQAABEAAAAAAAAEAA//8AQAAAAVhcHBsZQ==
'/*!*/;
### UPDATE test.t
### WHERE
###   @1=1
###   @2='apple'
###   @3=NULL
### SET
###   @1=1
###   @2='pear'
###   @3='2009:01:01'
...
# at 400
#080828 15:03:08 server id 1  end_log_pos 442  Delete_rows: table id 17 flags: STMT_END_F
BINLOG '
FAS3SBMBAalanAAAAbAAAABEAAAAAAAAABHR1c3QAXQAAwMPCgIUAQ=
FAS3SBkAaAAAKgAAAALoBAAAQAABEAAAAAAAAEAA//4AQAAAAQw2WFyIbIP
'/*!*/;
### DELETE FROM test.t
### WHERE
###   @1=1
###   @2='pear'
###   @3='2009:01:01'
```

Specify --verbose or -v twice to also display data types and some metadata for each column, and informational log events such as row query log events if the `binlog_rows_query_log_events` system variable is set to TRUE. The output will contain an additional comment following each column change:

```
shell> mysqlbinlog --vv log_file
...
# at 218
#080828 15:03:08 server id 1  end_log_pos 258  Write_rows: table id 17 flags: STMT_END_F
BINLOG '
FAS3SBMBAalanAAAAJABAAAAABEAAAAAAAAABHR1c3QAXQAAwMPCgIUAQ=
FAS3SBkAaAAAKgAAAALoBAAAQAABEAAAAAAAAEAA//4AQAAAAQw2WFyIbIP
'/*!*/;
```
You can tell `mysqlbinlog` to suppress the `BINLOG` statements for row events by using the `--base64-output=DECODE-ROWS` option. This is similar to `--base64-output=NEVER` but does not exit with an error if a row event is found. The combination of `--base64-output=DECODE-ROWS` and `--verbose` provides a convenient way to see row events only as SQL statements:

```shell
shell> mysqlbinlog -v --base64-output=DECODE-ROWS log_file
```

```...`
```
--verbose for row events are much more readable than the corresponding BINLOG statements. However, they do not correspond exactly to the original SQL statements that generated the events. The following limitations apply:

- The original column names are lost and replaced by $@N$, where $N$ is a column number.
- Character set information is not available in the binary log, which affects string column display:
  - There is no distinction made between corresponding binary and nonbinary string types (BINARY and CHAR, VARBINARY and VARCHAR, BLOB and TEXT). The output uses a data type of STRING for fixed-length strings and VARSTRING for variable-length strings.
  - For multibyte character sets, the maximum number of bytes per character is not present in the binary log, so the length for string types is displayed in bytes rather than in characters. For example, STRING(4) will be used as the data type for values from either of these column types:

```
CHAR(4) CHARACTER SET latin1
CHAR(2) CHARACTER SET ucs2
```

- Due to the storage format for events of type UPDATE_ROWS_EVENT, UPDATE statements are displayed with the WHERE clause preceding the SET clause.

Proper interpretation of row events requires the information from the format description event at the beginning of the binary log. Because mysqlbinlog does not know in advance whether the rest of the log contains row events, by default it displays the format description event using a BINLOG statement in the initial part of the output.

If the binary log is known not to contain any events requiring a BINLOG statement (that is, no row events), the --base64-output=NEVER option can be used to prevent this header from being written.

### 4.6.8.3 Using mysqlbinlog to Back Up Binary Log Files

By default, mysqlbinlog reads binary log files and displays their contents in text format. This enables you to examine events within the files more easily and to re-execute them (for example, by using the output as input to mysql). mysqlbinlog can read log files directly from the local file system, or, with the --read-from-remote-server option, it can connect to a server and request binary log contents from that server. mysqlbinlog writes text output to its standard output, or to the file named as the value of the --result-file=file_name option if that option is given.

- `mysqlbinlog` Backup Capabilities
- `mysqlbinlog` Backup Options
- Static and Live Backups
- Output File Naming
- Example: mysqldump + mysqlbinlog for Backup and Restore
- `mysqlbinlog` Backup Restrictions

**mysqlbinlog Backup Capabilities**

mysqlbinlog can read binary log files and write new files containing the same content—that is, in binary format rather than text format. This capability enables you to easily back up a binary log in its original format. mysqlbinlog can make a static backup, backing up a set of log files and stopping when the end of the last file is reached. It can also make a continuous (“live”) backup, staying
connected to the server when it reaches the end of the last log file and continuing to copy new events as they are generated. In continuous-backup operation, `mysqlbinlog` runs until the connection ends (for example, when the server exits) or `mysqlbinlog` is forcibly terminated. When the connection ends, `mysqlbinlog` does not wait and retry the connection, unlike a slave replication server. To continue a live backup after the server has been restarted, you must also restart `mysqlbinlog`.

Important

`mysqlbinlog` can back up both encrypted and unencrypted binary log files. However, copies of encrypted binary log files that are generated using `mysqlbinlog` are stored in an unencrypted format.

mysqlbinlog Backup Options

Binary log backup requires that you invoke `mysqlbinlog` with two options at minimum:

- The `--read-from-remote-server` (or `-R`) option tells `mysqlbinlog` to connect to a server and request its binary log. (This is similar to a slave replication server connecting to its master server.)

- The `--raw` option tells `mysqlbinlog` to write raw (binary) output, not text output.

Along with `--read-from-remote-server`, it is common to specify other options: `--host` indicates where the server is running, and you may also need to specify connection options such as `--user` and `--password`.

Several other options are useful in conjunction with `--raw`:

- `--stop-never`: Stay connected to the server after reaching the end of the last log file and continue to read new events.

- `--connection-server-id=id`: The server ID that `mysqlbinlog` reports when it connects to a server. When `--stop-never` is used, the default reported server ID is 1. If this causes a conflict with the ID of a slave server or another `mysqlbinlog` process, use `--connection-server-id` to specify an alternative server ID. See Section 4.6.8.4, “Specifying the mysqlbinlog Server ID”.

- `--result-file`: A prefix for output file names, as described later.

Static and Live Backups

To back up a server’s binary log files with `mysqlbinlog`, you must specify file names that actually exist on the server. If you do not know the names, connect to the server and use the `SHOW BINARY LOGS` statement to see the current names. Suppose that the statement produces this output:

```
mysql> SHOW BINARY LOGS;
+---------------+-----------+-----------+
| Log_name      | File_size | Encrypted |
+---------------+-----------+-----------+
| binlog.000130 |     27459 | No        |
| binlog.000131 |     13719 | No        |
| binlog.000132 |     43268 | No        |
+---------------+-----------+-----------+
```

With that information, you can use `mysqlbinlog` to back up the binary log to the current directory as follows (enter each command on a single line):

- To make a static backup of `binlog.000130` through `binlog.000132`, use either of these commands:

  ```
  mysqlbinlog --read-from-remote-server --host=host_name --raw
  binlog.000130 binlog.000131 binlog.000132
  mysqlbinlog --read-from-remote-server --host=host_name --raw
  --to-last-log binlog.000130
  ```
The first command specifies every file name explicitly. The second names only the first file and uses --to-last-log to read through the last. A difference between these commands is that if the server happens to open binlog.000133 before mysqlbinlog reaches the end of binlog.000132, the first command will not read it, but the second command will.

- To make a live backup in which mysqlbinlog starts with binlog.000130 to copy existing log files, then stays connected to copy new events as the server generates them:

```
mysqlbinlog --read-from-remote-server --host=host_name --raw
            --stop-never binlog.000130
```

With --stop-never, it is not necessary to specify --to-last-log to read to the last log file because that option is implied.

**Output File Naming**

Without --raw, mysqlbinlog produces text output and the --result-file option, if given, specifies the name of the single file to which all output is written. With --raw, mysqlbinlog writes one binary output file for each log file transferred from the server. By default, mysqlbinlog writes the files in the current directory with the same names as the original log files. To modify the output file names, use the --result-file option. In conjunction with --raw, the --result-file option value is treated as a prefix that modifies the output file names.

Suppose that a server currently has binary log files named binlog.000999 and up. If you use mysqlbinlog --raw to back up the files, the --result-file option produces output file names as shown in the following table. You can write the files to a specific directory by beginning the --result-file value with the directory path. If the --result-file value consists only of a directory name, the value must end with the pathname separator character. Output files are overwritten if they exist.

<table>
<thead>
<tr>
<th>--result-file Option</th>
<th>Output File Names</th>
</tr>
</thead>
<tbody>
<tr>
<td>--result-file=x</td>
<td>xbinlog.000999 and up</td>
</tr>
<tr>
<td>--result-file=/tmp/</td>
<td>/tmp/binlog.000999 and up</td>
</tr>
<tr>
<td>--result-file=/tmp/x</td>
<td>/tmp/xbinlog.000999 and up</td>
</tr>
</tbody>
</table>

**Example: mysqldump + mysqlbinlog for Backup and Restore**

The following example describes a simple scenario that shows how to use mysqldump and mysqlbinlog together to back up a server's data and binary log, and how to use the backup to restore the server if data loss occurs. The example assumes that the server is running on host host_name and its first binary log file is named binlog.000999. Enter each command on a single line.

Use mysqlbinlog to make a continuous backup of the binary log:

```
mysqlbinlog --read-from-remote-server --host=host_name --raw
            --stop-never binlog.000999
```

Use mysqldump to create a dump file as a snapshot of the server's data. Use --all-databases, --events, and --routines to back up all data, and --master-data=2 to include the current binary log coordinates in the dump file.

```
mysqldump --host=host_name --all-databases --events --routines --master-data=2> dump_file
```

Execute the mysqldump command periodically to create newer snapshots as desired.

If data loss occurs (for example, if the server crashes), use the most recent dump file to restore the data:
mysqldumpslow — Summarize Slow Query Log Files

Then use the binary log backup to re-execute events that were written after the coordinates listed in the
dump file. Suppose that the coordinates in the file look like this:

```
-- CHANGE MASTER TO MASTER_LOG_FILE='binlog.001002', MASTER_LOG_POS=27284;
```

If the most recent backed-up log file is named `binlog.001004`, re-execute the log events like this:

```
mysqlbinlog --start-position=27284 binlog.001002 binlog.001003 binlog.001004
  | mysql --host=host_name -u root -p
```

You might find it easier to copy the backup files (dump file and binary log files) to the server host to
make it easier to perform the restore operation, or if MySQL does not allow remote root access.

### mysqlbinlog Backup Restrictions

Binary log backups with `mysqlbinlog` are subject to these restrictions:

- `mysqlbinlog` does not automatically reconnect to the MySQL server if the connection is lost (for
  example, if a server restart occurs or there is a network outage).
- The delay for a backup is similar to the delay for a replication slave.

#### 4.6.8.4 Specifying the mysqlbinlog Server ID

When invoked with the `--read-from-remote-server` option, `mysqlbinlog` connects to a MySQL
server, specifies a server ID to identify itself, and requests binary log files from the server. You can use
`mysqlbinlog` to request log files from a server in several ways:

- Specify an explicitly named set of files: For each file, `mysqlbinlog` connects and issues a `Binlog
dump` command. The server sends the file and disconnects. There is one connection per file.
- Specify the beginning file and `--to-last-log`: `mysqlbinlog` connects and issues a `Binlog
dump` command for all files. The server sends all files and disconnects.
- Specify the beginning file and `--stop-never` (which implies `--to-last-log`): `mysqlbinlog`
  connects and issues a `Binlog dump` command for all files. The server sends all files, but does not
disconnect after sending the last one.

With `--read-from-remote-server` only, `mysqlbinlog` connects using a server ID of 0, which
tells the server to disconnect after sending the last requested log file.

With `--read-from-remote-server` and `--stop-never`, `mysqlbinlog` connects using a nonzero
server ID, so the server does not disconnect after sending the last log file. The server ID is 1 by default,
but this can be changed with `--connection-server-id`.

Thus, for the first two ways of requesting files, the server disconnects because `mysqlbinlog` specifies
a server ID of 0. It does not disconnect if `--stop-never` is given because `mysqlbinlog` specifies a
nonzero server ID.

#### 4.6.9 mysqldumpslow — Summarize Slow Query Log Files

The MySQL slow query log contains information about queries that take a long time to execute (see
Section 5.4.5, "The Slow Query Log"). `mysqldumpslow` parses MySQL slow query log files and
summarizes their contents.

Normally, `mysqldumpslow` groups queries that are similar except for the particular values of number
and string data values. It "abstracts" these values to `N` and `'S'` when displaying summary output. To
modify value abstracting behavior, use the `-a` and `-n` options.
Invoke `mysqldumpslow` like this:

```
shell> mysqldumpslow [options] [log_file ...]
```

Example of usage:

```
shell> mysqldumpslow

Reading mysql slow query log from /usr/local/mysql/data/mysqld80-slow.log
Count: 1  Time=4.32s (4s)  Lock=0.00s (0s)  Rows=0.0 (0), root[root]@localhost
   insert into t2 select * from t1

Count: 3  Time=2.53s (7s)  Lock=0.00s (0s)  Rows=0.0 (0), root[root]@localhost
   insert into t2 select * from t1 limit N

Count: 3  Time=2.13s (6s)  Lock=0.00s (0s)  Rows=0.0 (0), root[root]@localhost
   insert into t1 select * from t1
```

`mysqldumpslow` supports the following options.

### Table 4.22 mysqldumpslow Options

<table>
<thead>
<tr>
<th>Option Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-a</td>
<td>Do not abstract all numbers to N and strings to 'S'</td>
</tr>
<tr>
<td>-n</td>
<td>Abstract numbers with at least the specified digits</td>
</tr>
<tr>
<td>--debug</td>
<td>Write debugging information</td>
</tr>
<tr>
<td>-g</td>
<td>Only consider statements that match the pattern</td>
</tr>
<tr>
<td>--help</td>
<td>Display help message and exit</td>
</tr>
<tr>
<td>-h</td>
<td>Host name of the server in the log file name</td>
</tr>
<tr>
<td>-i</td>
<td>Name of the server instance</td>
</tr>
<tr>
<td>-l</td>
<td>Do not subtract lock time from total time</td>
</tr>
<tr>
<td>-r</td>
<td>Reverse the sort order</td>
</tr>
<tr>
<td>-s</td>
<td>How to sort output</td>
</tr>
<tr>
<td>-t</td>
<td>Display only first num queries</td>
</tr>
<tr>
<td>--verbose</td>
<td>Verbosity mode</td>
</tr>
</tbody>
</table>

• **--help**
  
  Display a help message and exit.

• **-a**

  Do not abstract all numbers to N and strings to 'S'.

• **--debug, -d**

  Run in debug mode.

• **-g pattern**

  Consider only queries that match the (grep-style) pattern.

• **-h host_name**

  Host name of MySQL server for *-slow.log file name. The value can contain a wildcard. The default is * (match all).

• **-i name**
Name of server instance (if using \texttt{mysql.server} startup script).

\begin{itemize}
  \item \texttt{-l}
  \end{itemize}

Do not subtract lock time from total time.

\begin{itemize}
  \item \texttt{-n \textit{N}}
  \end{itemize}

Abstract numbers with at least \textit{N} digits within names.

\begin{itemize}
  \item \texttt{-r}
  \end{itemize}

Reverse the sort order.

\begin{itemize}
  \item \texttt{-s \texttt{sort\_type}}
  \end{itemize}

How to sort the output. The value of \texttt{sort\_type} should be chosen from the following list:

\begin{itemize}
  \item \texttt{t, at}: Sort by query time or average query time
  \item \texttt{l, al}: Sort by lock time or average lock time
  \item \texttt{r, ar}: Sort by rows sent or average rows sent
  \item \texttt{c}: Sort by count
  \end{itemize}

By default, \texttt{mysqldumpslow} sorts by average query time (equivalent to \texttt{-s at}).

\begin{itemize}
  \item \texttt{-t \textit{N}}
  \end{itemize}

Display only the first \textit{N} queries in the output.

\begin{itemize}
  \item \texttt{--verbose, -v}
  \end{itemize}

Verbose mode. Print more information about what the program does.

\section*{4.7 MySQL Program Development Utilities}

This section describes some utilities that you may find useful when developing MySQL programs.

In shell scripts, you can use the \texttt{my\_print\_defaults} program to parse option files and see what options would be used by a given program. The following example shows the output that \texttt{my\_print\_defaults} might produce when asked to show the options found in the \texttt{[client]} and \texttt{[mysql]} groups:

\begin{verbatim}
shell> my_print_defaults client mysql
--port=3306
--socket=/tmp/mysql.sock
--no-auto-rehash
\end{verbatim}

Note for developers: Option file handling is implemented in the C client library simply by processing all options in the appropriate group or groups before any command-line arguments. This works well for programs that use the last instance of an option that is specified multiple times. If you have a C or C++ program that handles multiply specified options this way but that doesn't read option files, you need add only two lines to give it that capability. Check the source code of any of the standard MySQL clients to see how to do this.

Several other language interfaces to MySQL are based on the C client library, and some of them provide a way to access option file contents. These include Perl and Python. For details, see the documentation for your preferred interface.
4.7.1 mysql_config — Display Options for Compiling Clients

mysql_config provides you with useful information for compiling your MySQL client and connecting it to MySQL. It is a shell script, so it is available only on Unix and Unix-like systems.

Note

pkg-config can be used as an alternative to mysql_config for obtaining information such as compiler flags or link libraries required to compile MySQL applications. For more information, see Section 28.7.4.2, “Building C API Client Programs Using pkg-config”.

mysql_config supports the following options.

• \--cflags

   C Compiler flags to find include files and critical compiler flags and defines used when compiling the libmysqlclient library. The options returned are tied to the specific compiler that was used when the library was created and might clash with the settings for your own compiler. Use \--include for more portable options that contain only include paths.

• \--cxxflags

   Like \--cflags, but for C++ compiler flags.

• \--include

   Compiler options to find MySQL include files.

• \--libs

   Libraries and options required to link with the MySQL client library.

• \--libs_r

   Libraries and options required to link with the thread-safe MySQL client library. In MySQL 8.0, all client libraries are thread-safe, so this option need not be used. The \--libs option can be used in all cases.

• \--plugindir

   The default plugin directory path name, defined when configuring MySQL.

• \--port

   The default TCP/IP port number, defined when configuring MySQL.

• \--socket

   The default Unix socket file, defined when configuring MySQL.

• \--variable=var_name

   Display the value of the named configuration variable. Permitted var_name values are pkgincludedir (the header file directory), pkglibdir (the library directory), and plugindir (the plugindir directory).

• \--version

   Version number for the MySQL distribution.

If you invoke mysql_config with no options, it displays a list of all options that it supports, and their values:
You can use `mysql_config` within a command line using backticks to include the output that it produces for particular options. For example, to compile and link a MySQL client program, use `mysql_config` as follows:

```sh
gcc -c `mysql_config --cflags` progname.c
gcc -o progname progname.o `mysql_config --libs`
```

### 4.7.2 `my_print_defaults` — Display Options from Option Files

`my_print_defaults` displays the options that are present in option groups of option files. The output indicates what options will be used by programs that read the specified option groups. For example, the `mysqlcheck` program reads the `[mysqlcheck]` and `[client]` option groups. To see what options are present in those groups in the standard option files, invoke `my_print_defaults` like this:

```sh
shell> my_print_defaults mysqlcheck client
--user=myusername
--password=password
--host=localhost
```

The output consists of options, one per line, in the form that they would be specified on the command line.

`my_print_defaults` supports the following options.

- **--help, -?**
  Display a help message and exit.

- **--config-file=file_name, --defaults-file=file_name, -c file_name**
  Read only the given option file.

- **--debug=debug_options, -# debug_options**
  Write a debugging log. A typical `debug_options` string is `d:t:o,file_name`. The default is `d:t:o,/tmp/my_print_defaults.trace`.

- **--defaults-extra-file=file_name, --extra-file=file_name, -e file_name**
  Read this option file after the global option file but (on Unix) before the user option file.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- **--defaults-group-suffix=suffix, -g suffix**
In addition to the groups named on the command line, read groups that have the given suffix.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

• \texttt{--login-path=\textit{name}, -l \textit{name}}

Read options from the named login path in the \texttt{.mylogin.cnf} login path file. A “login path” is an option group containing options that specify which MySQL server to connect to and which account to authenticate as. To create or modify a login path file, use the \texttt{mysql_config_editor} utility. See Section 4.6.7, “mysql_config_editor — MySQL Configuration Utility”.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

• \texttt{--no-defaults, -n}

Return an empty string.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

• \texttt{--show, -s}

\texttt{my_print_defaults} masks passwords by default. Use this option to display passwords as cleartext.

• \texttt{--verbose, -v}

Verbose mode. Print more information about what the program does.

• \texttt{--version, -V}

Display version information and exit.

\section*{4.8 Miscellaneous Programs}

\subsection*{4.8.1 \texttt{lz4_decompress} — Decompress mysqlpump LZ4-Compressed Output}

The \texttt{lz4_decompress} utility decompresses \texttt{mysqlpump} output that was created using LZ4 compression.

\begin{mdframed}[linecolor=gray,frametitle=Note]
If MySQL was configured with the \texttt{-DWITH_LZ4=system} option, \texttt{lz4_decompress} is not built. In this case, the system \texttt{lz4} command can be used instead.
\end{mdframed}

Invoke \texttt{lz4_decompress} like this:

\begin{verbatim}
shell> lz4_decompress input_file output_file
\end{verbatim}

Example:

\begin{verbatim}
shell> mysqlpump --compress-output=LZ4 > dump.lz4
shell> lz4_decompress dump.lz4 dump.txt
\end{verbatim}

To see a help message, invoke \texttt{lz4_decompress} with no arguments.
To decompress `mysqlpump` ZLIB-compressed output, use `zlib_decompress`. See Section 4.8.3, "zlib_decompress — Decompress mysqlpump ZLIB-Compressed Output".

### 4.8.2 perror — Display MySQL Error Message Information

`perror` displays the error message for MySQL or operating system error codes. Invoke `perror` like this:

```
shell> perror [options] errorcode ...
```

`perror` attempts to be flexible in understanding its arguments. For example, for the `ER_WRONG_VALUE_FOR_VAR` error, `perror` understands any of these arguments: 1231, 001231, `MY-1231`, or `MY-001231`, or `ER_WRONG_VALUE_FOR_VAR`.

```
shell> perror 1231
MySQL error code MY-001231 (ER_WRONG_VALUE_FOR_VAR): Variable '%-.64s' can't be set to the value of '%-.200s'
```

If an error number is in the range where MySQL and operating system errors overlap, `perror` displays both error messages:

```
shell> perror 1 13
OS error code 1: Operation not permitted
MySQL error code MY-000001: Can't create/write to file '%s' (OS errno %d - %s)
OS error code 13: Permission denied
MySQL error code MY-000013: Can't get stat of '%s' (OS errno %d - %s)
```

To obtain the error message for a MySQL Cluster error code, use the `ndb_perror` utility.

The meaning of system error messages may be dependent on your operating system. A given error code may mean different things on different operating systems.

`perror` supports the following options.

- `--help, --info, -I, --?`
  Display a help message and exit.

- `--ndb`
  Print the error message for a MySQL Cluster error code.
  This option was removed in MySQL 8.0.13. Use the `ndb_perror` utility instead.

- `--silent, -s`
  Silent mode. Print only the error message.

- `--verbose, -v`
  Verbose mode. Print error code and message. This is the default behavior.

- `--version, -V`
  Display version information and exit.

### 4.8.3 zlib_decompress — Decompress mysqlpump ZLIB-Compressed Output

The `zlib_decompress` utility decompresses `mysqlpump` output that was created using ZLIB compression.
4.9 MySQL Environment Variables

This section lists environment variables that are used directly or indirectly by MySQL. Most of these can also be found in other places in this manual.

Options on the command line take precedence over values specified in option files and environment variables, and values in option files take precedence over values in environment variables. In many cases, it is preferable to use an option file instead of environment variables to modify the behavior of MySQL. See Section 4.2.2.2, “Using Option Files”.

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>

<td>The default user name on Windows when connecting to mysqld.</td>
</tr>
</tbody>
</table>

For information about the mysql history file, see Section 4.5.1.3, “mysql Client Logging”.

MYSQL_TEST_LOGIN_FILE is the path name of the login path file (the file created by mysql_config_editor). If not set, the default value is %APPDATA%\MySQL\mylogin.cnf directory on Windows and $HOME/.mylogin.cnf on non-Windows systems. See Section 4.6.7, “mysql_config_editor — MySQL Configuration Utility”.

550
The `MYSQL_TEST_TRACE_DEBUG` and `MYSQL_TEST_TRACE_CRASH` variables control the test protocol trace client plugin, if MySQL is built with that plugin enabled. For more information, see Using the Test Protocol Trace Plugin.

The default `UMASK` and `UMASK_DIR` values are `0640` and `0750`, respectively. MySQL assumes that the value for `UMASK` or `UMASK_DIR` is in octal if it starts with a zero. For example, setting `UMASK=0600` is equivalent to `UMASK=384` because 0600 octal is 384 decimal.

The `UMASK` and `UMASK_DIR` variables, despite their names, are used as modes, not masks:

- If `UMASK` is set, `mysqld` uses `($UMASK | 0600)` as the mode for file creation, so that newly created files have a mode in the range from 0600 to 0666 (all values octal).

- If `UMASK_DIR` is set, `mysqld` uses `($UMASK_DIR | 0700)` as the base mode for directory creation, which then is AND-ed with `~($UMASK & 0666)`, so that newly created directories have a mode in the range from 0700 to 0777 (all values octal). The AND operation may remove read and write permissions from the directory mode, but not execute permissions.

It may be necessary to set `PKG_CONFIG_PATH` if you use `pkg-config` for building MySQL programs. See Section 28.7.4.2, “Building C API Client Programs Using pkg-config”.

MySQL Server (mysql) is the main program that does most of the work in a MySQL installation. This chapter provides an overview of MySQL Server and covers general server administration:

- Server configuration
• The data directory, particularly the `mysql` system schema

• The server log files

• Management of multiple servers on a single machine

For additional information on administrative topics, see also:

• Chapter 6, Security

• Chapter 7, Backup and Recovery

• Chapter 17, Replication

5.1 The MySQL Server

`mysqld` is the MySQL server. The following discussion covers these MySQL server configuration topics:

• Startup options that the server supports. You can specify these options on the command line, through configuration files, or both.

• Server system variables. These variables reflect the current state and values of the startup options, some of which can be modified while the server is running.

• Server status variables. These variables contain counters and statistics about runtime operation.

• How to set the server SQL mode. This setting modifies certain aspects of SQL syntax and semantics, for example for compatibility with code from other database systems, or to control the error handling for particular situations.

• Configuring and using IPv6 support.

• Configuring and using time zone support.

• Server-side help capabilities.

• The server shutdown process. There are performance and reliability considerations depending on the type of table (transactional or nontransactional) and whether you use replication.

For listings of MySQL server variables and options that have been added, deprecated, or removed in MySQL 8.0, see Section 1.5, “Server and Status Variables and Options Added, Deprecated, or Removed in MySQL 8.0”.

**Note**

Not all storage engines are supported by all MySQL server binaries and configurations. To find out how to determine which storage engines your MySQL server installation supports, see Section 13.7.6.16, “SHOW ENGINES Syntax”.

5.1.1 Configuring the Server

The MySQL server, `mysqld`, has many command options and system variables that can be set at startup to configure its operation. To determine the default command option and system variable values used by the server, execute this command:

```
shell> mysqld --verbose --help
```

The command produces a list of all `mysqld` options and configurable system variables. Its output includes the default option and variable values and looks something like this:
### Server Configuration Defaults

<table>
<thead>
<tr>
<th>Variable</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>abort-slave-event-count</td>
<td>0</td>
</tr>
<tr>
<td>allow-suspicious-udfs</td>
<td>FALSE</td>
</tr>
<tr>
<td>archive</td>
<td>ON</td>
</tr>
<tr>
<td>auto-increment-increment</td>
<td>1</td>
</tr>
<tr>
<td>auto-increment-offset</td>
<td>1</td>
</tr>
<tr>
<td>autocommit</td>
<td>TRUE</td>
</tr>
<tr>

<tr>
<td>validate-user-plugins</td>
<td>TRUE</td>
</tr>
<tr>
<td>verbose</td>
<td>TRUE</td>
</tr>
<tr>
<td>wait-timeout</td>
<td>28800</td>
</tr>
</tbody>
</table>

To see the current system variable values actually used by the server as it runs, connect to it and execute this statement:

```sql
mysql> SHOW VARIABLES;
```

To see some statistical and status indicators for a running server, execute this statement:

```sql
mysql> SHOW STATUS;
```

System variable and status information also is available using the `mysqladmin` command:

```shell
shell> mysqladmin variables
shell> mysqladmin extended-status
```

For a full description of all command options, system variables, and status variables, see these sections:

- Section 5.1.7, “Server Command Options”
- Section 5.1.8, “Server System Variables”
- Section 5.1.10, “Server Status Variables”

More detailed monitoring information is available from the Performance Schema; see Chapter 26, *MySQL Performance Schema*. In addition, the MySQL `sys` schema is a set of objects that provides convenient access to data collected by the Performance Schema; see Chapter 27, *MySQL sys Schema*.

If you specify an option on the command line for `mysqld` or `mysqld_safe`, it remains in effect only for that invocation of the server. To use the option every time the server runs, put it in an option file. See Section 4.2.2.2, “Using Option Files”.

### 5.1.2 Server Configuration Defaults

The MySQL server has many operating parameters, which you can change at server startup using command-line options or configuration files (option files). It is also possible to change many parameters at runtime. For general instructions on setting parameters at startup or runtime, see Section 5.1.7, “Server Command Options”, and Section 5.1.8, “Server System Variables”.

On Windows, MySQL Installer interacts with the user and creates a file named `my.ini` in the base installation directory as the default option file.
5.1.3 Server Configuration Validation

As of MySQL 8.0.16, MySQL Server supports a \--validate-config option that enables the startup configuration to be checked for problems without running the server in normal operational mode:

```
mysqld --validate-config
```

If no errors are found, the server terminates with an exit code of 0. If an error is found, the server displays a diagnostic message and terminates with an exit code of 1. For example:

```
shell> mysqld --validate-config --no-such-option
2018-11-05T17:50:12.738919Z 0 [ERROR] [MY-000068] [Server] unknown option '--no-such-option'.
2018-11-05T17:50:12.738962Z 0 [ERROR] [MY-010119] [Server] Aborting
```

The server terminates as soon as any error is found. For additional checks to occur, correct the initial problem and run the server with \--validate-config again.

For the preceding example, where use of \--validate-config results in display of an error message, the server exit code is 1. Warning and information messages may also be displayed, depending on the log_error_verbosity value, but do not produce immediate validation termination or an exit code of 1. For example, this command produces multiple warnings, both of which are displayed. But no error occurs, so the exit code is 0:

```
shell> mysqld --validate-config --log_error_verbosity=2
   --read-only=s --transaction_read_only=s
2018-11-05T17:50:12.738919Z 0 [ERROR] [MY-000068] [Server] unknown option '--no-such-option'.
2018-11-05T17:50:12.738962Z 0 [ERROR] [MY-010119] [Server] Aborting
```

This command produces the same warnings, but also an error, so the error message is displayed along with the warnings and the exit code is 1:

```
shell> mysqld --validate-config --log_error_verbosity=2
   --no-such-option --read-only=s --transaction_read_only=s
2018-11-05T17:50:12.738919Z 0 [ERROR] [MY-000068] [Server] unknown option '--no-such-option'.
2018-11-05T17:50:12.738962Z 0 [ERROR] [MY-010119] [Server] Aborting
```

The scope of the \--validate-config option is limited to configuration checking that the server can perform without undergoing its normal startup process. As such, the configuration check does not
initialize storage engines and other plugins, components, and so forth, and does not validate options associated with those uninitialized subsystems.

`--validate-config` can be used any time, but is particularly useful after an upgrade, to check whether any options previously used with the older server are considered by the upgraded server to be deprecated or obsolete. For example, the `tx_read_only` system variable was deprecated in MySQL 5.7 and removed in 8.0. Suppose that a MySQL 5.7 server was run using that system variable in its `my.cnf` file and then upgraded to MySQL 8.0. Running the upgraded server with `--validate-config` to check the configuration produces this result:

```
shell> mysqld --validate-config
2018-11-05T10:40:02.712141Z 0 [ERROR] [MY-000067] [Server] unknown variable 'tx_read_only=ON'.
2018-11-05T10:40:02.712178Z 0 [ERROR] [MY-010119] [Server] Aborting
```

`--validate-config` can be used with the `--defaults-file` option to validate only the options in a specific file:

```
shell> mysqld --defaults-file=./my.cnf-test --validate-config
2018-11-05T10:40:02.712141Z 0 [ERROR] [MY-000067] [Server] unknown variable 'tx_read_only=ON'.
2018-11-05T10:40:02.712178Z 0 [ERROR] [MY-010119] [Server] Aborting
```

Remember that `--defaults-file`, if specified, must be the first option on the command line. (Executing the preceding example with the option order reversed produces a message that `--defaults-file` itself is unknown.)

### 5.1.4 Server Option, System Variable, and Status Variable Reference

The following table lists all command-line options, system variables, and status variables applicable within `mysqld`.

The table lists command-line options (Cmd-line), options valid in configuration files (Option file), server system variables (System Var), and status variables (Status Var) in one unified list, with an indication of where each option or variable is valid. If a server option set on the command line or in an option file differs from the name of the corresponding system variable, the variable name is noted immediately below the corresponding option. For system and status variables, the scope of the variable (Var Scope) is Global, Session, or both. Please see the corresponding item descriptions for details on setting and using the options and variables. Where appropriate, direct links to further information about the items are provided.

For a version of this table that is specific to NDB Cluster, see Section 22.3.2.5, “NDB Cluster mysqld Option and Variable Reference”.

</tbody>
</table>
The following table lists all system variables applicable within *mysql*.

The table lists command-line options (Cmd-line), options valid in configuration files (Option file), server system variables (System Var), and status variables (Status var) in one unified list, with an indication of where each option or variable is valid. If a server option set on the command line or in an option file differs from the name of the corresponding system variable, the variable name is noted immediately below the corresponding option. The scope of the variable (Var Scope) is Global, Session, or both. Please see the corresponding item descriptions for details on setting and using the variables. Where appropriate, direct links to further information about the items are provided.

### Table 5.2 System Variable Summary

### Notes:

1. This option is dynamic, but only the server should set this information. You should not set the value of this variable manually.

### 5.1.6 Server Status Variable Reference

The following table lists all status variables applicable within `mysqld`.

The table lists each variable's data type and scope. The last column indicates whether the scope for each variable is Global, Session, or both. Please see the corresponding item descriptions for details on setting and using the variables. Where appropriate, direct links to further information about the items are provided.

#### Table 5.3 Status Variable Summary

**5.1.7 Server Command Options**

When you start the `mysqld` server, you can specify program options using any of the methods described in Section 4.2.2, “Specifying Program Options”. The most common methods are to provide options in an option file or on the command line. However, in most cases it is desirable to make sure that the server uses the same options each time it runs. The best way to ensure this is to list them in an option file. See Section 4.2.2.2, “Using Option Files”. That section also describes option file format and syntax.

`mysqld` reads options from the `[mysqld]` and `[server]` groups. `mysqld_safe` reads options from the `[mysqld],[server],[mysqld_safe], and [safe_mysqld] groups. `mysql.server` reads options from the `[mysqld] and [mysql.server] groups.

`mysqld` accepts many command options. For a brief summary, execute this command:

```
mysqld --help
```

To see the full list, use this command:

```
mysqld --verbose --help
```

Some of the items in the list are actually system variables that can be set at server startup. These can be displayed at runtime using the `SHOW VARIABLES` statement. Some items displayed by the preceding `mysqld` command do not appear in `SHOW VARIABLES` output; this is because they are options only and not system variables.

The following list shows some of the most common server options. Additional options are described in other sections:

- Options that affect security: See Section 6.1.4, “Security-Related mysqld Options and Variables”.

</table>
Server Command Options

- SSL-related options: See Command Options for Encrypted Connections.
- Binary log control options: See Section 5.4.4, “The Binary Log”.
- Replication-related options: See Section 17.1.6, “Replication and Binary Logging Options and Variables”.
- Options for loading plugins such as pluggable storage engines: See Section 5.6.1, “Installing and Uninstalling Plugins”.
- Options specific to particular storage engines: See Section 15.13, “InnoDB Startup Options and System Variables” and Section 16.2.1, “MyISAM Startup Options”.

Some options control the size of buffers or caches. For a given buffer, the server might need to allocate internal data structures. These structures typically are allocated from the total memory allocated to the buffer, and the amount of space required might be platform dependent. This means that when you assign a value to an option that controls a buffer size, the amount of space actually available might differ from the value assigned. In some cases, the amount might be less than the value assigned. It is also possible that the server will adjust a value upward. For example, if you assign a value of 0 to an option for which the minimal value is 1024, the server will set the value to 1024.

Values for buffer sizes, lengths, and stack sizes are given in bytes unless otherwise specified.

Some options take file name values. Unless otherwise specified, the default file location is the data directory if the value is a relative path name. To specify the location explicitly, use an absolute path name. Suppose that the data directory is /var/mysql/data. If a file-valued option is given as a relative path name, it will be located under /var/mysql/data. If the value is an absolute path name, its location is as given by the path name.

You can also set the values of server system variables at server startup by using variable names as options. To assign a value to a server system variable, use an option of the form --var_name=value. For example, --sort_buffer_size=384M sets the sort_buffer_size variable to a value of 384MB.

When you assign a value to a variable, MySQL might automatically correct the value to stay within a given range, or adjust the value to the closest permissible value if only certain values are permitted.

To restrict the maximum value to which a system variable can be set at runtime with the SET statement, specify this maximum by using an option of the form --maximum-var_name=value at server startup.

You can change the values of most system variables at runtime with the SET statement. See Section 13.7.5.1, “SET Syntax for Variable Assignment”.

Section 5.1.8, “Server System Variables”, provides a full description for all variables, and additional information for setting them at server startup and runtime. For information on changing system variables, see Section 5.1.1, “Configuring the Server”.

- --help, -?

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--help</td>
</tr>
</tbody>
</table>

Display a short help message and exit. Use both the --verbose and --help options to see the full message.

- --allow-suspicious-udfs

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--allow-suspicious-udfs=[{OFF</td>
</tr>
</tbody>
</table>
### Server Command Options

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Type</strong></td>
<td>Boolean</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>OFF</td>
</tr>
</tbody>
</table>

This option controls whether user-defined functions that have only an xxx symbol for the main function can be loaded. By default, the option is off and only UDFs that have at least one auxiliary symbol can be loaded; this prevents attempts at loading functions from shared object files other than those containing legitimate UDFs. See Section 29.4.2.6, “UDF Security Precautions”.

- **--ansi**

<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td><code>--ansi</code></td>
</tr>
</tbody>
</table>

Use standard (ANSI) SQL syntax instead of MySQL syntax. For more precise control over the server SQL mode, use the `--sql-mode` option instead. See Section 1.8, “MySQL Standards Compliance”, and Section 5.1.11, “Server SQL Modes”.

- **--basedir=dir_name, -b dir_name**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td><code>--basedir=dir_name</code></td>
</tr>
<tr>
<td><strong>System Variable</strong></td>
<td>basedir</td>
</tr>
<tr>
<td><strong>Scope</strong></td>
<td>Global</td>
</tr>
<tr>
<td><strong>Dynamic</strong></td>
<td>No</td>
</tr>
<tr>
<td><strong>SET_VAR Hint Applies</strong></td>
<td>No</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Directory name</td>
</tr>
<tr>
<td><strong>Default Value</strong> (&gt;= 8.0.2)</td>
<td>parent of mysql installation directory</td>
</tr>
<tr>
<td><strong>Default Value</strong> (&lt;= 8.0.1)</td>
<td>configuration-dependent default</td>
</tr>
</tbody>
</table>

The path to the MySQL installation directory. This option sets the `basedir` system variable.

The server executable determines its own full path name at startup and uses the parent of the directory in which it is located as the default `basedir` value. This in turn enables the server to use that `basedir` when searching for server-related information such as the `share` directory containing error messages.

- **--character-set-client-handshake**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td>`--character-set-client-handshake=[{OFF</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Boolean</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>ON</td>
</tr>
</tbody>
</table>

Do not ignore character set information sent by the client. To ignore client information and use the default server character set, use `--skip-character-set-client-handshake`; this makes MySQL behave like MySQL 4.0.

- **--chroot=dir_name, -r dir_name**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td><code>--chroot=dir_name</code></td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Directory name</td>
</tr>
</tbody>
</table>
Put the `mysqld` server in a closed environment during startup by using the `chroot()` system call. This is a recommended security measure. Use of this option somewhat limits `LOAD DATA` and `SELECT ... INTO OUTFILE`.

- **--console**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--console</td>
</tr>
<tr>
<td>Platform Specific</td>
<td>Windows</td>
</tr>
</tbody>
</table>

(Windows only.) Cause the default error log destination to be the console. This affects log writers that base their own output destination on the default destination. See Section 5.4.2, “The Error Log”. `mysqld` does not close the console window if this option is used.

`--console` takes precedence over `--log-error` if both are given.

- **--core-file**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--core-file[={OFF</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Write a core file if `mysqld` dies. The name and location of the core file is system dependent. On Linux, a core file named `core.pid` is written to the current working directory of the process, which for `mysqld` is the data directory. `pid` represents the process ID of the server process. On macOS, a core file named `core.pid` is written to the `/cores` directory. On Solaris, use the `coreadm` command to specify where to write the core file and how to name it.

For some systems, to get a core file you must also specify the `--core-file-size` option to `mysqld_safe`. See Section 4.3.2, “mysqld_safe — MySQL Server Startup Script”. On some systems, such as Solaris, you do not get a core file if you are also using the `--user` option. There might be additional restrictions or limitations. For example, it might be necessary to execute `ulimit -c unlimited` before starting the server. Consult your system documentation.

The `innodb_buffer_pool_in_core_file` variable can be used to reduce the size of core files on operating systems that support it. For more information, see Section 15.8.3.8, “Excluding Buffer Pool Pages from Core Files”.

- **--daemonize, -D**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--daemonize[={OFF</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

This option causes the server to run as a traditional, forking daemon, permitting it to work with operating systems that use systemd for process control. For more information, see Section 2.5.9, “Managing MySQL Server with systemd”.

`--daemonize` is mutually exclusive with `--initialize` and `--initialize-insecure`.

If the server is started using the `--daemonize` option and is not connected to a tty device, a default error logging option of `--log-error=""` is used in the absence of an explicit logging option, to direct error output to the default log file.
Server Command Options

-D is a synonym for --daemonize.

- --datadir=dir_name, -h dir_name

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--datadir=dir_name</td>
</tr>
<tr>
<td>System Variable</td>
<td>datadir</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Directory name</td>
</tr>
</tbody>
</table>

The path to the MySQL server data directory. This option sets the `datadir` system variable. See the description of that variable.

- --debug[=debug_options], -# [debug_options]

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--debug[=debug_options]</td>
</tr>
<tr>
<td>System Variable</td>
<td>debug</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value (Windows)</td>
<td>d:t:i:o,\mysqld.trace</td>
</tr>
<tr>
<td>Default Value (Unix)</td>
<td>d:t:i:o,/tmp/mysqld.trace</td>
</tr>
</tbody>
</table>

If MySQL is configured with the `-DWITH_DEBUG=1` CMake option, you can use this option to get a trace file of what `mysqld` is doing. A typical `debug_options` string is `d:t:o`, `file_name`. The default is `d:t:i:o,/tmp/mysqld.trace` on Unix and `d:t:i:o,\mysqld.trace` on Windows.

Using `-DWITH_DEBUG=1` to configure MySQL with debugging support enables you to use the `--debug="d,parser_debug"` option when you start the server. This causes the Bison parser that is used to process SQL statements to dump a parser trace to the server’s standard error output. Typically, this output is written to the error log.

This option may be given multiple times. Values that begin with `+` or `-` are added to or subtracted from the previous value. For example, `--debug=T --debug=+P` sets the value to `P:T`.

For more information, see Section 29.5.4, “The DBUG Package”.

- --debug-sync-timeout[=N]

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--debug-sync-timeout[=#]</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
</tbody>
</table>

Controls whether the Debug Sync facility for testing and debugging is enabled. Use of Debug Sync requires that MySQL be configured with the -DENABLE_DEBUG_SYNC=1 CMake option (see Section 2.9.4, “MySQL Source-Configuration Options”). If Debug Sync is not compiled in, this option is not available. The option value is a timeout in seconds. The default value is 0, which disables Debug Sync. To enable it, specify a value greater than 0; this value also becomes the default timeout.
for individual synchronization points. If the option is given without a value, the timeout is set to 300 seconds.

For a description of the Debug Sync facility and how to use synchronization points, see MySQL Internals: Test Synchronization.

• **--default-storage-engine=type**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><strong>--default-storage-engine=name</strong></td>
</tr>
<tr>
<td>System Variable</td>
<td>default_storage_engine</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>InnoDB</td>
</tr>
</tbody>
</table>

Set the default storage engine for tables. See Chapter 16, Alternative Storage Engines. This option sets the storage engine for permanent tables only. To set the storage engine for TEMPORARY tables, set the default_tmp_storage_engine system variable.

If you disable the default storage engine at server startup, you must set the default engine for both permanent and TEMPORARY tables to a different engine or the server will not start.

• **--default-time-zone=timezone**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><strong>--default-time-zone=name</strong></td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

Set the default server time zone. This option sets the global time_zone system variable. If this option is not given, the default time zone is the same as the system time zone (given by the value of the system_time_zone system variable.

• **--defaults-extra-file=file_name**

Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. file_name is interpreted relative to the current directory if given as a relative path name rather than a full path name. This must be the first option on the command line if it is used.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

• **--defaults-file=file_name**

Read only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. file_name is interpreted relative to the current directory if given as a relative path name rather than a full path name.

Exception: Even with --defaults-file, mysqld reads mysqld-auto.cnf.
install-manual) options, --install (or --install-manual) must be first.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

• --defaults-group-suffix=\texttt{str}

Read not only the usual option groups, but also groups with the usual names and a suffix of \texttt{str}. For example, \texttt{mysqld} normally reads the \texttt{[mysqld]} group. If the --defaults-group-suffix=\texttt{other} option is given, \texttt{mysqld} also reads the \texttt{[mysqld\_other]} group.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

• --des-key-file=\texttt{file\_name}

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--des-key-file=\texttt{file_name}</td>
</tr>
<tr>
<td>Deprecated</td>
<td>Yes (removed in 8.0.3)</td>
</tr>
</tbody>
</table>

This option was removed in MySQL 8.0.3.

• --early-plugin-load=\texttt{plugin\_list}

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--early-plugin-load=\texttt{plugin_list}</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>empty string</td>
</tr>
</tbody>
</table>

This option tells the server which plugins to load before loading mandatory built-in plugins and before storage engine initialization. If multiple --early-plugin-load options are given, only the last one is used.

The option value is a semicolon-separated list of \texttt{name=plugin\_library} and \texttt{plugin\_library} values. Each \texttt{name} is the name of a plugin to load, and \texttt{plugin\_library} is the name of the library file that contains the plugin code. If a plugin library is named without any preceding plugin name, the server loads all plugins in the library. The server looks for plugin library files in the directory named by the \texttt{plugin\_dir} system variable.

For example, if plugins named \texttt{myplug1} and \texttt{myplug2} have library files \texttt{myplug1.so} and \texttt{myplug2.so}, use this option to perform an early plugin load:

\begin{verbatim}
shell> mysqld --early-plugin-load="myplug1=myplug1.so;myplug2=myplug2.so"
\end{verbatim}

Quotes are used around the argument value because otherwise a semicolon (;) is interpreted as a special character by some command interpreters. (Unix shells treat it as a command terminator, for example.)

Each named plugin is loaded early for a single invocation of \texttt{mysqld} only. After a restart, the plugin is not loaded early unless --early-plugin-load is used again.

If the server is started using \texttt{--initialize} or \texttt{--initialize-insecure}, plugins specified by --early-plugin-load are not loaded.

If the server is run with \texttt{--help}, plugins specified by --early-plugin-load are loaded but not initialized. This behavior ensures that plugin options are displayed in the help message.
The default `--early-plugin-load` value is empty. To load the `keyring_file` plugin, you must use an explicit `--early-plugin-load` option with a nonempty value.

The InnoDB tablespace encryption feature relies on the `keyring_file` plugin for encryption key management, and the `keyring_file` plugin must be loaded prior to storage engine initialization to facilitate InnoDB recovery for encrypted tables. Administrators who want the `keyring_file` plugin loaded at startup should use the appropriate nonempty option value (for example, `keyring_file.so` on Unix and Unix-like systems and `keyring_file.dll` on Windows).

For information about InnoDB tablespace encryption, see Section 15.6.3.9, “InnoDB Data-at-Rest Encryption”. For general information about plugin loading, see Section 5.6.1, “Installing and Uninstalling Plugins”.

- `--event-scheduler[=value]`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--event-scheduler[=value]</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>event_scheduler</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value (<code>&gt;= 8.0.3</code>)</td>
<td><code>ON</code></td>
</tr>
<tr>
<td>Default Value (<code>&lt;= 8.0.2</code>)</td>
<td><code>OFF</code></td>
</tr>
<tr>
<td>Valid Values</td>
<td><code>ON</code> <code>OFF</code> <code>DISABLED</code></td>
</tr>
</tbody>
</table>

Enable or disable, and start or stop, the event scheduler.

For detailed information, see The `--event-scheduler` Option.

- `--exit-info[=flags], -T [flags]`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--exit-info[=flags]</code></td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
</tbody>
</table>

This is a bitmask of different flags that you can use for debugging the `mysqld` server. Do not use this option unless you know exactly what it does!

- `--external-locking`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--external-locking[={OFF</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>OFF</code></td>
</tr>
</tbody>
</table>

Enable external locking (system locking), which is disabled by default. If you use this option on a system on which `lockd` does not fully work (such as Linux), it is easy for `mysqld` to deadlock.
To disable external locking explicitly, use `--skip-external-locking`.

External locking affects only MyISAM table access. For more information, including conditions under which it can and cannot be used, see Section 8.11.5, “External Locking”.

- `--flush`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--flush={OFF</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>flush</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>OFF</code></td>
</tr>
</tbody>
</table>

Flush (synchronize) all changes to disk after each SQL statement. Normally, MySQL does a write of all changes to disk only after each SQL statement and lets the operating system handle the synchronizing to disk. See Section B.4.3.3, “What to Do If MySQL Keeps Crashing”.

Note

If `--flush` is specified, the value of `flush_time` does not matter and changes to `flush_time` have no effect on flush behavior.

- `--gdb`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--gdb={OFF</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>OFF</code></td>
</tr>
</tbody>
</table>

Install an interrupt handler for SIGINT (needed to stop `mysqld` with `^C` to set breakpoints) and disable stack tracing and core file handling. See Section 29.5, “Debugging and Porting MySQL”.

On Windows, this option also suppresses the forking that is used to implement the RESTART statement: Forking enables one process to act as a monitor to the other, which acts as the server. However, forking makes determining the server process to attach to for debugging more difficult, so starting the server with `--gdb` suppresses forking. For a server started with this option, RESTART simply exits and does not restart.

In non-debug settings, `--no-monitor` may be used to suppress forking the monitor process.

- `--general-log={0|1}`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--general-log={OFF</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>general_log</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
</tbody>
</table>
### Server Command Options

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Specify the initial general query log state. With no argument or an argument of 1, the `--general-log` option enables the log. If omitted or given with an argument of 0, the option disables the log.

* `--initialize, -I`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--initialize=[{OFF</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

This option is used to initialize a MySQL installation by creating the data directory and populating the tables in the `mysql` system database. For more information, see Section 2.10.1, “Initializing the Data Directory”.

When the server is started with `--initialize`, some functionality is unavailable that limits the statements permitted in any file named by the `--init-file` option. For more information, see the description of that option. In addition, the `disabled_storage_engines` system variable has no effect.

The `--ndbcluster` option is ignored when used together with `--initialize`.

`--initialize` is mutually exclusive with `--daemonize`.

`-I` is a synonym for `--initialize`.

* `--initialize-insecure`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--initialize-insecure=[{OFF</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

This option is used to initialize a MySQL installation by creating the data directory and populating the tables in the `mysql` system database. This option implies `--initialize`. For more information, see the description of that option, and Section 2.10.1, “Initializing the Data Directory”.

`--initialize-insecure` is mutually exclusive with `--daemonize`.

* `--init-file=file_name`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--init-file=file_name</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>init_file</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
</tbody>
</table>

Read SQL statements from this file at startup. Each statement must be on a single line and should not include comments.
If the server is started with the `--initialize` or `--initialize-insecure` option, it operates in bootstrap mode and some functionality is unavailable that limits the statements permitted in the file. These include statements that relate to account management (such as `CREATE USER` or `GRANT`), replication, and global transaction identifiers. See Section 17.1.3, “Replication with Global Transaction Identifiers”.

- `--innodb-xxx`

Set an option for the InnoDB storage engine. The InnoDB options are listed in Section 15.13, “InnoDB Startup Options and System Variables”.

- `--install [service_name]`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--install [service_name]</code></td>
</tr>
<tr>
<td>Platform Specific</td>
<td>Windows</td>
</tr>
</tbody>
</table>

(Windows only) Install the server as a Windows service that starts automatically during Windows startup. The default service name is MySQL if no `service_name` value is given. For more information, see Section 2.3.5.8, “Starting MySQL as a Windows Service”.

**Note**

If the server is started with the `--defaults-file` and `--install` options, `--install` must be first.

- `--install-manual [service_name]`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--install-manual [service_name]</code></td>
</tr>
<tr>
<td>Platform Specific</td>
<td>Windows</td>
</tr>
</tbody>
</table>

(Windows only) Install the server as a Windows service that must be started manually. It does not start automatically during Windows startup. The default service name is MySQL if no `service_name` value is given. For more information, see Section 2.3.5.8, “Starting MySQL as a Windows Service”.

**Note**

If the server is started with the `--defaults-file` and `--install-manual` options, `--install-manual` must be first.

- `--language=lang_name, -L lang_name`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--language=name</code></td>
</tr>
<tr>
<td>Deprecated</td>
<td>Yes; use <code>lc-messages-dir</code> instead</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>language</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Directory name</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>/usr/local/mysql/share/mysql/english/</code></td>
</tr>
</tbody>
</table>
The language to use for error messages. `lang_name` can be given as the language name or as the full path name to the directory where the language files are installed. See Section 10.11, “Setting the Error Message Language”.

`--lc-messages-dir` and `--lc-messages` should be used rather than `--language`, which is deprecated (and handled as an alias for `--lc-messages-dir`). The `--language` option will be removed in a future MySQL release.

- **`--large-pages`**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--large-pages[={OFF</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>large_pages</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Platform Specific</td>
<td>Linux</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Some hardware/operating system architectures support memory pages greater than the default (usually 4KB). The actual implementation of this support depends on the underlying hardware and operating system. Applications that perform a lot of memory accesses may obtain performance improvements by using large pages due to reduced Translation Lookaside Buffer (TLB) misses.

MySQL supports the Linux implementation of large page support (which is called HugeTLB in Linux). See Section 8.12.3.2, “Enabling Large Page Support”. For Solaris support of large pages, see the description of the `--super-large-pages` option.

`--large-pages` is disabled by default.

- **`--lc-messages=locale_name`**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--lc-messages=name</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>lc_messages</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>en_US</td>
</tr>
</tbody>
</table>

The locale to use for error messages. The default is `en_US`. The server converts the argument to a language name and combines it with the value of `--lc-messages-dir` to produce the location for the error message file. See Section 10.11, “Setting the Error Message Language”.

- **`--lc-messages-dir=dir_name`**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--lc-messages-dir=dir_name</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>lc_messages_dir</code></td>
</tr>
</tbody>
</table>
### Property | Value
---|---
**Scope** | Global
**Dynamic** | No
**SET_VAR Hint Applies** | No
**Type** | Directory name

The directory where error messages are located. The server uses the value together with the value of `--lc-messages` to produce the location for the error message file. See Section 10.11, “Setting the Error Message Language”.

- **--local-service**

(Windows only) A `--local-service` option following the service name causes the server to run using the LocalService Windows account that has limited system privileges. If both `--defaults-file` and `--local-service` are given following the service name, they can be in any order. See Section 2.3.5.8, “Starting MySQL as a Windows Service”.

- **--log-error[=file_name]**

Set the default error log destination to the named file. This affects log writers that base their own output destination on the default destination. See Section 5.4.2, “The Error Log”.

If the option names no file, the default error log destination on Unix and Unix-like systems is a file named `host_name.err` in the data directory. The default destination on Windows is the same, unless the `--pid-file` option is specified. In that case, the file name is the PID file base name with a suffix of `.err` in the data directory.

If the option names a file, the default destination is that file (with an `.err` suffix added if the name has no suffix), located under the data directory unless an absolute path name is given to specify a different location.

If error log output cannot be redirected to the error log file, an error occurs and startup fails.

On Windows, `--console` takes precedence over `--log-error` if both are given. In this case, the default error log destination is the console rather than a file.

- **--log-isam[=file_name]**

Log all MyISAM changes to this file (used only when debugging MyISAM).
Server Command Options

• **--log-queries-not-using-indexes**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--log-queries-not-using-indexes[={OFF</td>
</tr>
<tr>
<td>System Variable</td>
<td>log_queries_not_using_indexes</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

If you are using this option with the slow query log enabled, queries that are expected to retrieve all rows are logged. See Section 5.4.5, “The Slow Query Log”. This option does not necessarily mean that no index is used. For example, a query that uses a full index scan uses an index but would be logged because the index would not limit the number of rows.

• **--log-raw**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--log-raw[={OFF</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Passwords in certain statements written to the general query log, slow query log, and binary log are rewritten by the server not to occur literally in plain text. Password rewriting can be suppressed for the general query log by starting the server with the **--log-raw** option. This option may be useful for diagnostic purposes, to see the exact text of statements as received by the server, but for security reasons is not recommended for production use.

If a query rewrite plugin is installed, the **--log-raw** option affects statement logging as follows:

• Without **--log-raw**, the server logs the statement returned by the query rewrite plugin. This may differ from the statement as received.

• With **--log-raw**, the server logs the original statement as received.

For more information, see Section 6.1.2.3, “Passwords and Logging”.

• **--log-short-format**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--log-short-format[={OFF</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Log less information to the slow query log, if it has been activated.

• **--log-tc=file_name**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--log-tc=file_name</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td>tc.log</td>
</tr>
</tbody>
</table>
The name of the memory-mapped transaction coordinator log file (for XA transactions that affect multiple storage engines when the binary log is disabled). The default name is `tc.log`. The file is created under the data directory if not given as a full path name. This option is unused.

- **--log-tc-size=size**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--log-tc-size=#</code></td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>6 * page size</code></td>
</tr>
<tr>
<td>Minimum Value</td>
<td><code>6 * page size</code></td>
</tr>
<tr>
<td>Maximum Value (64-bit platforms)</td>
<td><code>18446744073709551615</code></td>
</tr>
<tr>
<td>Maximum Value (32-bit platforms)</td>
<td><code>4294967295</code></td>
</tr>
</tbody>
</table>

The size in bytes of the memory-mapped transaction coordinator log. The default and minimum values are 6 times the page size, and the value must be a multiple of the page size.

- **--log-warnings[=level], -W [level]**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--log-warnings[=#]</code></td>
</tr>
<tr>
<td>Deprecated</td>
<td>Yes (removed in 8.0.3)</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>log_warnings</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>2</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value (64-bit platforms)</td>
<td><code>18446744073709551615</code></td>
</tr>
<tr>
<td>Maximum Value (32-bit platforms)</td>
<td><code>4294967295</code></td>
</tr>
</tbody>
</table>

This option was removed in MySQL 8.0.3. Use the `log_error_verbosity` system variable instead.

- **--low-priority-updates**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--low-priority-updates[={OFF</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>low_priority_updates</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>
Server Command Options

Give table-modifying operations (INSERT, REPLACE, DELETE, UPDATE) lower priority than selects. This can also be done using (INSERT | REPLACE | DELETE | UPDATE) LOW_PRIORITY ... to lower the priority of only one query, or by SET LOW_PRIORITY_UPDATES=1 to change the priority in one thread. This affects only storage engines that use only table-level locking (MyISAM, MEMORY, MERGE). See Section 8.11.2, “Table Locking Issues”.

• --min-examined-row-limit=number

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--min-examined-row-limit=#</td>
</tr>
<tr>
<td>System Variable</td>
<td>min_examined_row_limit</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td><strong>Maximum Value (64-bit platforms)</strong></td>
<td>18446744073709551615</td>
</tr>
<tr>
<td><strong>Maximum Value (32-bit platforms)</strong></td>
<td>4294967295</td>
</tr>
</tbody>
</table>

When this option is set, queries which examine fewer than number rows are not written to the slow query log. The default is 0.

• --memlock

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--memlock=[{OFF</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Lock the mysqld process in memory. This option might help if you have a problem where the operating system is causing mysqld to swap to disk.

--memlock works on systems that support the mlockall() system call; this includes Solaris, most Linux distributions that use a 2.4 or higher kernel, and perhaps other Unix systems. On Linux systems, you can tell whether or not mlockall() (and thus this option) is supported by checking to see whether or not it is defined in the system mman.h file, like this:

```
shell> grep mlockall /usr/include/sys/mman.h
```

If mlockall() is supported, you should see in the output of the previous command something like the following:

```
extern int mlockall (int __flags) __THROW;
```

Important

Use of this option may require you to run the server as root, which, for reasons of security, is normally not a good idea. See Section 6.1.5, “How to Run MySQL as a Normal User”.

655
On Linux and perhaps other systems, you can avoid the need to run the server as root by changing the limits.conf file. See the notes regarding the memlock limit in Section 8.12.3.2, “Enabling Large Page Support”.

You must not try to use this option on a system that does not support the mlockall() system call; if you do so, mysqld will very likely crash as soon as you try to start it.

- **--myisam-block-size=N**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--myisam-block-size=#</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1024</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1024</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>16384</td>
</tr>
</tbody>
</table>

The block size to be used for MyISAM index pages.

- **--myisam-recover-options[=option[,option]...]**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--myisam-recover-options[=name]</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
<tr>
<td>Valid Values</td>
<td>OFF, DEFAULT, BACKUP, FORCE, QUICK</td>
</tr>
</tbody>
</table>

Set the MyISAM storage engine recovery mode. The option value is any combination of the values of OFF, DEFAULT, BACKUP, FORCE, or QUICK. If you specify multiple values, separate them by commas. Specifying the option with no argument is the same as specifying DEFAULT, and specifying with an explicit value of "" disables recovery (same as a value of OFF). If recovery is enabled, each time mysqld opens a MyISAM table, it checks whether the table is marked as crashed or was not closed properly. (The last option works only if you are running with external locking disabled.) If this is the case, mysqld runs a check on the table. If the table was corrupted, mysqld attempts to repair it.

The following options affect how the repair works.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>OFF</td>
<td>No recovery.</td>
</tr>
<tr>
<td>DEFAULT</td>
<td>Recovery without backup, forcing, or quick checking.</td>
</tr>
<tr>
<td>BACKUP</td>
<td>If the data file was changed during recovery, save a backup of the tbl_name.MYD file as tbl_name-datetime.BAK.</td>
</tr>
<tr>
<td>FORCE</td>
<td>Run recovery even if we would lose more than one row from the .MYD file.</td>
</tr>
</tbody>
</table>
Before the server automatically repairs a table, it writes a note about the repair to the error log. If you want to be able to recover from most problems without user intervention, you should use the options `BACKUP,FORCE`. This forces a repair of a table even if some rows would be deleted, but it keeps the old data file as a backup so that you can later examine what happened.

See Section 16.2.1, “MyISAM Startup Options”.

- **--no-defaults**

  Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read. This must be the first option on the command line if it is used.

  For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- **--no-dd-upgrade**

  Prevent automatic upgrade of the data dictionary tables during the MySQL server startup process. This option is typically used when starting the MySQL server following an in-place upgrade of an existing installation to a newer MySQL version, which may include changes to data dictionary table definitions.

  When `--no-dd-upgrade` is specified, and the server finds that its expected version of the data dictionary differs from the version stored in the data dictionary itself, startup fails with an error stating that data dictionary upgrade is prohibited;

  ```
  [ERROR] [MY-011091] [Server] Data dictionary upgrade prohibited by the command line option '--no_dd_upgrade'.
  [ERROR] [MY-010020] [Server] Data Dictionary initialization failed.
  ```

  During a normal startup, the data dictionary version of the server is compared to the version stored in the data dictionary to determine whether data dictionary table definitions should be upgraded. If an upgrade is necessary and supported, the server creates data dictionary tables with updated definitions, copies persisted metadata to the new tables, atomically replaces the old tables with the new ones, and reinitializes the data dictionary. If an upgrade is not necessary, startup continues without updating data dictionary tables.

- **--no-monitor**
### Server Command Options

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td>`--no-monitor[=(OFF</td>
</tr>
<tr>
<td><strong>Introduced</strong></td>
<td>8.0.12</td>
</tr>
<tr>
<td><strong>Platform Specific</strong></td>
<td>Windows</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Boolean</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>OFF</td>
</tr>
</tbody>
</table>

(Windows only). This option suppresses the forking that is used to implement the `RESTART` statement: Forking enables one process to act as a monitor to the other, which acts as the server. For a server started with this option, `RESTART` simply exits and does not restart. **--no-monitor** is not available prior to MySQL 8.0.12. The `--gdb` option can be used as a workaround.

- **--old-style-user-limits**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td>`--old-style-user-limits[=(OFF</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Boolean</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>OFF</td>
</tr>
</tbody>
</table>

Enable old-style user limits. (Before MySQL 5.0.3, account resource limits were counted separately for each host from which a user connected rather than per account row in the `user` table.) See Section 6.2.20, “Setting Account Resource Limits”.

- **--performance-schema-xxx**

Configure a Performance Schema option. For details, see Section 26.14, “Performance Schema Command Options”.

- **--pid-file=file_name**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td><code>--pid-file=file_name</code></td>
</tr>
<tr>
<td><strong>System Variable</strong></td>
<td><code>pid_file</code></td>
</tr>
<tr>
<td><strong>Scope</strong></td>
<td>Global</td>
</tr>
<tr>
<td><strong>Dynamic</strong></td>
<td>No</td>
</tr>
<tr>
<td><strong>SET_VAR</strong></td>
<td>No</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>File name</td>
</tr>
</tbody>
</table>

The path name of the file in which the server should write its process ID. The server creates the file in the data directory unless an absolute path name is given to specify a different directory. If you specify this option, you must specify a value. If you do not specify this option, MySQL uses a default value of `host_name.pid`, where `host_name` is the name of the host machine.

The process ID file is used by other programs such as `mysqld_safe` to determine the server's process ID. On Windows, this variable also affects the default error log file name. See Section 5.4.2, “The Error Log”.

- **--plugin-load=plugin_list**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td><code>--plugin-load=plugin_list</code></td>
</tr>
</tbody>
</table>
This option tells the server to load the named plugins at startup. If multiple `--plugin-load` options are given, only the last one is used. Additional plugins to load may be specified using `--plugin-load-add` options.

The option value is a semicolon-separated list of `name=plugin_library` and `plugin_library` values. Each `name` is the name of a plugin to load, and `plugin_library` is the name of the library file that contains the plugin code. If a plugin library is named without any preceding plugin name, the server loads all plugins in the library. The server looks for plugin library files in the directory named by the `plugin_dir` system variable.

For example, if plugins named `myplug1` and `myplug2` have library files `myplug1.so` and `myplug2.so`, use this option to perform an early plugin load:

```
shell> mysqld --plugin-load="myplug1=myplug1.so;myplug2=myplug2.so"
```

Quotes are used around the argument value here because otherwise semicolon (`;`) is interpreted as a special character by some command interpreters. (Unix shells treat it as a command terminator, for example.)

Each named plugin is loaded for a single invocation of `mysqld` only. After a restart, the plugin is not loaded unless `--plugin-load` is used again. This is in contrast to `INSTALL PLUGIN`, which adds an entry to the `mysql.plugins` table to cause the plugin to be loaded for every normal server startup.

Under normal startup, the server determines which plugins to load by reading the `mysql.plugins` system table. If the server is started with the `--skip-grant-tables` option, it does not consult the `mysql.plugins` table and does not load plugins listed there. `--plugin-load` enables plugins to be loaded even when `--skip-grant-tables` is given. `--plugin-load` also enables plugins to be loaded at startup that cannot be loaded at runtime.

For additional information about plugin loading, see Section 5.6.1, “Installing and Uninstalling Plugins”.

* `--plugin-load-add=plugin_list`

This option complements the `--plugin-load` option. `--plugin-load-add` adds a plugin or plugins to the set of plugins to be loaded at startup. The argument format is the same as for `--plugin-load`. `--plugin-load-add` can be used to avoid specifying a large set of plugins as a single long unwieldy `--plugin-load` argument.
--plugin-load-add can be given in the absence of --plugin-load, but any instance of --plugin-load-add that appears before --plugin-load, has no effect because --plugin-load resets the set of plugins to load. In other words, these options:

```
--plugin-load=x --plugin-load-add=y
```

are equivalent to this option:

```
--plugin-load="x;y"
```

But these options:

```
--plugin-load-add=y --plugin-load=x
```

are equivalent to this option:

```
--plugin-load=x
```

For additional information about plugin loading, see Section 5.6.1, "Installing and Uninstalling Plugins".

- **--plugin-xxx**

  Specifies an option that pertains to a server plugin. For example, many storage engines can be built as plugins, and for such engines, options for them can be specified with a --plugin prefix. Thus, the --innodb-file-per-table option for InnoDB can be specified as --plugin-innodb-file-per-table.

  For boolean options that can be enabled or disabled, the --skip prefix and other alternative formats are supported as well (see Section 4.2.2.4, "Program Option Modifiers"). For example, --skip-plugin-innodb-file-per-table disables innodb-file-per-table.

  The rationale for the --plugin prefix is that it enables plugin options to be specified unambiguously if there is a name conflict with a built-in server option. For example, were a plugin writer to name a plugin "sql" and implement a "mode" option, the option name might be --sql-mode, which would conflict with the built-in option of the same name. In such cases, references to the conflicting name are resolved in favor of the built-in option. To avoid the ambiguity, users can specify the plugin option as --plugin-sql-mode. Use of the --plugin prefix for plugin options is recommended to avoid any question of ambiguity.

- **--port=port_num, -P port_num**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--port=port_num</td>
</tr>
<tr>
<td>System Variable</td>
<td>port</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>3306</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>65535</td>
</tr>
</tbody>
</table>
The port number to use when listening for TCP/IP connections. On Unix and Unix-like systems, the port number must be 1024 or higher unless the server is started by the root operating system user. Setting this option to 0 causes the default value to be used.

- **--port-open-timeout=num**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--port-open-timeout=#</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
</tbody>
</table>

On some systems, when the server is stopped, the TCP/IP port might not become available immediately. If the server is restarted quickly afterward, its attempt to reopen the port can fail. This option indicates how many seconds the server should wait for the TCP/IP port to become free if it cannot be opened. The default is not to wait.

- **--print-defaults**

Print the program name and all options that it gets from option files. Password values are masked. This must be the first option on the command line if it is used, except that it may be used immediately after `--defaults-file` or `--defaults-extra-file`.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- **--remove [service_name]**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--remove [service_name]</td>
</tr>
<tr>
<td>Platform Specific</td>
<td>Windows</td>
</tr>
</tbody>
</table>

(Windows only) Remove a MySQL Windows service. The default service name is MySQL if no `service_name` value is given. For more information, see Section 2.3.5.8, “Starting MySQL as a Windows Service”.

- **--safe-user-create**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--safe-user-create[={OFF</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

If this option is enabled, a user cannot create new MySQL users by using the `GRANT` statement unless the user has the `INSERT` privilege for the `mysql.user` system table or any column in the table. If you want a user to have the ability to create new users that have those privileges that the user has the right to grant, you should grant the user the following privilege:

```sql
GRANT INSERT(user) ON mysql.user TO 'user_name'@'host_name';
```

This ensures that the user cannot change any privilege columns directly, but has to use the `GRANT` statement to give privileges to other users.

- **--secure-auth**
## Server Command Options

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td>(--\text{secure-auth}=[\text{OFF}</td>
</tr>
<tr>
<td><strong>Deprecated</strong></td>
<td>Yes (removed in 8.0.3)</td>
</tr>
<tr>
<td><strong>System Variable</strong></td>
<td>\text{secure_auth}</td>
</tr>
<tr>
<td><strong>Scope</strong></td>
<td>Global</td>
</tr>
<tr>
<td><strong>Dynamic</strong></td>
<td>Yes</td>
</tr>
<tr>
<td><strong>\text{SET_VAR}</strong> Hint Applies**</td>
<td>No</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Boolean</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>ON</td>
</tr>
<tr>
<td><strong>Valid Values</strong></td>
<td>ON</td>
</tr>
</tbody>
</table>

This option was removed in MySQL 8.0.3.

- \(--\text{secure-file-priv}=\text{dir\_name}\)

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td>(--\text{secure-file-priv}=\text{dir_name})</td>
</tr>
<tr>
<td><strong>System Variable</strong></td>
<td>\text{secure_file_priv}</td>
</tr>
<tr>
<td><strong>Scope</strong></td>
<td>Global</td>
</tr>
<tr>
<td><strong>Dynamic</strong></td>
<td>No</td>
</tr>
<tr>
<td><strong>\text{SET_VAR}</strong> Hint Applies**</td>
<td>No</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>String</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>\text{platform specific}</td>
</tr>
<tr>
<td><strong>Valid Values</strong></td>
<td>\text{empty string}</td>
</tr>
<tr>
<td></td>
<td>\text{dirname}</td>
</tr>
<tr>
<td></td>
<td>\text{NULL}</td>
</tr>
</tbody>
</table>

This option sets the \text{secure\_file\_priv} system variable, which is used to limit the effect of data import and export operations, such as those performed by the \text{LOAD DATA} and \text{SELECT \ldots INTO OUTFILE} statements and the \text{LOAD\_FILE()} function. For more information, see the description of \text{secure\_file\_priv}.

- \(--\text{skip-concurrent-insert}\)

Turn off the ability to select and insert at the same time on \text{MyISAM} tables. (This is to be used only if you think you have found a bug in this feature.) See Section 8.11.3, "Concurrent Inserts".

- \(--\text{skip-event-scheduler}\)

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td>(--\text{skip-event-scheduler})</td>
</tr>
<tr>
<td></td>
<td>(--\text{disable-event-scheduler})</td>
</tr>
</tbody>
</table>

Turns the Event Scheduler \text{OFF}. This is not the same as disabling the Event Scheduler, which requires setting \(--\text{event-scheduler=}\text{DISABLED}\); see The \(--\text{event-scheduler}\) Option, for more information.

- \(--\text{skip-grant-tables}\)
<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--skip-grant-tables[={OFF</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

This option causes the server to start without using the privilege system at all, which gives anyone with access to the server unrestricted access to all databases. You can cause a running server to start using the grant tables again by executing `mysqladmin flush-privileges` or `mysqladmin reload` command from a system shell, or by issuing a MySQL FLUSH PRIVILEGES statement after connecting to the server.

If the server is started with the `--skip-grant-tables` option to disable authentication checks, the server enables `--skip-networking` automatically to prevent remote connections.

This option also causes the server to suppress during its startup sequence the loading of user-defined functions (UDFs), scheduled events, and plugins that were installed with the INSTALL PLUGIN statement. To cause plugins to be loaded anyway, use the `--plugin-load` option. `--skip-grant-tables` also causes the disabled_storage_engines system variable to have no effect.

This option does not cause loading of server components to be suppressed during server startup.

**FLUSH PRIVILEGES** might be executed implicitly by other actions performed after startup (thus causing the server to start using the grant tables again). For example, `mysql_upgrade` flushes the privileges during the upgrade procedure.

- `--skip-host-cache`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--skip-host-cache</code></td>
</tr>
</tbody>
</table>

Disable use of the internal host cache for faster name-to-IP resolution. With the cache disabled, the server performs a DNS lookup every time a client connects.

Use of `--skip-host-cache` is similar to setting the `host_cache_size` system variable to 0, but `host_cache_size` is more flexible because it can also be used to resize, enable, or disable the host cache at runtime, not just at server startup.

If you start the server with `--skip-host-cache`, that does not prevent changes to the value of `host_cache_size`, but such changes have no effect and the cache is not re-enabled even if `host_cache_size` is set larger than 0.

For more information about how the host cache works, see [Section 8.12.4.2, “DNS Lookup Optimization and the Host Cache”](#).  

- `--skip-innodb`

Disable the InnoDB storage engine. In this case, because the default storage engine is InnoDB, the server will not start unless you also use `--default-storage-engine` and `--default-temporary-storage-engine` to set the default to some other engine for both permanent and temporary tables.

The InnoDB storage engine cannot be disabled, and the `--skip-innodb` option is deprecated and has no effect. Its use results in a warning. This option will be removed in a future MySQL release.

- `--skip-name-resolve`
Server Command Options

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td>`--skip-name-resolve={OFF</td>
</tr>
<tr>
<td><strong>System Variable</strong></td>
<td><code>skip_name_resolve</code></td>
</tr>
<tr>
<td><strong>Scope</strong></td>
<td>Global</td>
</tr>
<tr>
<td><strong>Dynamic</strong></td>
<td>No</td>
</tr>
<tr>
<td><strong>SET_VAR Hint Applies</strong></td>
<td>No</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Boolean</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>OFF</td>
</tr>
</tbody>
</table>

Do not resolve host names when checking client connections. Use only IP addresses. If you use this option, all `Host` column values in the grant tables must be IP addresses. See Section 8.12.4.2, “DNS Lookup Optimization and the Host Cache”.

Depending on the network configuration of your system and the `Host` values for your accounts, clients may need to connect using an explicit `--host` option, such as `--host=127.0.0.1` or `--host=:1`.

An attempt to connect to the host 127.0.0.1 normally resolves to the `localhost` account. However, this fails if the server is run with the `--skip-name-resolve` option. If you plan to do that, make sure that an account exists that can accept a connection. For example, to be able to connect as `root` using `--host=127.0.0.1` or `--host=:1`, create these accounts:

```
CREATE USER 'root'@'127.0.0.1' IDENTIFIED BY 'root-password';
CREATE USER 'root'@'::1' IDENTIFIED BY 'root-password';
```

- `--skip-networking`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td><code>--skip-networking</code></td>
</tr>
<tr>
<td><strong>System Variable</strong></td>
<td><code>skip_networking</code></td>
</tr>
<tr>
<td><strong>Scope</strong></td>
<td>Global</td>
</tr>
<tr>
<td><strong>Dynamic</strong></td>
<td>No</td>
</tr>
<tr>
<td><strong>SET_VAR Hint Applies</strong></td>
<td>No</td>
</tr>
</tbody>
</table>

Do not listen for TCP/IP connections at all. All interaction with `mysql` must be made using named pipes or shared memory (on Windows) or Unix socket files (on Unix). This option is highly recommended for systems where only local clients are permitted. See Section 8.12.4.2, “DNS Lookup Optimization and the Host Cache”.

If the server is started with the `--skip-grant-tables` option to disable authentication checks, the server enables `--skip-networking` to prevent remote connections.

- `--ssl`

Options that begin with `--ssl` specify whether to permit clients to connect using SSL and indicate where to find SSL keys and certificates. See Command Options for Encrypted Connections.

- `--standalone`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td><code>--standalone</code></td>
</tr>
<tr>
<td><strong>Platform Specific</strong></td>
<td>Windows</td>
</tr>
</tbody>
</table>
Available on Windows only; instructs the MySQL server not to run as a service.

- **--super-large-pages**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--super-large-pages=[{OFF</td>
</tr>
<tr>
<td>Platform Specific</td>
<td>Solaris</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Standard use of large pages in MySQL attempts to use the largest size supported, up to 4MB. Under Solaris, a “super large pages” feature enables uses of pages up to 256MB. This feature is available for recent SPARC platforms. It can be enabled or disabled by using the `--super-large-pages` or `--skip-super-large-pages` option.

- **--symbolic-links,** `--skip-symbolic-links`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--symbolic-links=[{OFF</td>
</tr>
<tr>
<td>Deprecated</td>
<td>8.0.2</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value (&gt;= 8.0.2)</td>
<td>OFF</td>
</tr>
<tr>
<td>Default Value (&lt;= 8.0.1)</td>
<td>ON</td>
</tr>
</tbody>
</table>

Enable or disable symbolic link support. On Unix, enabling symbolic links means that you can link a MyISAM index file or data file to another directory with the `INDEX DIRECTORY` or `DATA DIRECTORY` option of the `CREATE TABLE` statement. If you delete or rename the table, the files that its symbolic links point to also are deleted or renamed. See Section 8.12.2.2, “Using Symbolic Links for MyISAM Tables on Unix”.

**Note**

Symbolic link support, along with the `--symbolic-links` option that controls it, is deprecated and will be removed in a future version of MySQL. In addition, the option is disabled by default. The related `have_symlink` system variable also is deprecated and will be removed in a future version of MySQL.

This option has no meaning on Windows.

- **--skip-show-database**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--skip-show-database</td>
</tr>
<tr>
<td>System Variable</td>
<td>skip_show_database</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
</tbody>
</table>

This option sets the `skip_show_database` system variable that controls who is permitted to use the `SHOW DATABASES` statement. See Section 5.1.8, “Server System Variables”.

- **--skip-stack-trace**
### Server Command Options

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--skip-stack-trace</code></td>
</tr>
</tbody>
</table>

Do not write stack traces. This option is useful when you are running `mysqld` under a debugger. On some systems, you also must use this option to get a core file. See Section 29.5, "Debugging and Porting MySQL".

- **`--slow-query-log=[{0|1}]`**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--slow-query-log=[{OFF</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>slow_query_log</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Specify the initial slow query log state. With no argument or an argument of 1, the `--slow-query-log` option enables the log. If omitted or given with an argument of 0, the option disables the log.

- **`--slow-start-timeout=timeout`**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--slow-start-timeout=#</code></td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>15000</td>
</tr>
</tbody>
</table>

This option controls the Windows service control manager’s service start timeout. The value is the maximum number of milliseconds that the service control manager waits before trying to kill the windows service during startup. The default value is 15000 (15 seconds). If the MySQL service takes too long to start, you may need to increase this value. A value of 0 means there is no timeout.

- **`--socket=path`**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--socket={file_name</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>socket</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value (Other)</td>
<td><code>/tmp/mysql.sock</code></td>
</tr>
<tr>
<td>Default Value (Windows)</td>
<td><code>MySQL</code></td>
</tr>
</tbody>
</table>

On Unix, this option specifies the Unix socket file to use when listening for local connections. The default value is `/tmp/mysql.sock`. If this option is given, the server creates the file in the data directory unless an absolute path name is given to specify a different directory. On Windows, the option specifies the pipe name to use when listening for local connections that use a named pipe. The default value is `MySQL` (not case sensitive).
- `--sql-mode=value[,value[,value...]]`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--sql-mode=name</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>sql_mode</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Set</td>
</tr>
<tr>
<td>Default Value (<code>&gt;= 8.0.11</code>)</td>
<td><code>ONLY_FULL_GROUP_BY, STRICT_TRANS_TABLES, NO_ZERO_IN_DATE, NO_ZERO_DATE, ERROR_FOR_DIVISION_BY_ZERO, NO_ENGINE_SUBSTITUTION</code></td>
</tr>
<tr>

</tbody>
</table>
Table: Server Command Options

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>NO_FIELD_OPTIONS</td>
<td></td>
</tr>
<tr>
<td>NO_KEY_OPTIONS</td>
<td></td>
</tr>
<tr>
<td>NO_TABLE_OPTIONS</td>
<td></td>
</tr>
<tr>
<td>NO_UNSIGNED_SUBTRACTION</td>
<td></td>
</tr>
<tr>
<td>NO_ZERO_DATE</td>
<td></td>
</tr>
<tr>
<td>NO_ZERO_IN_DATE</td>
<td></td>
</tr>
<tr>
<td>ONLY_FULL_GROUP_BY</td>
<td></td>
</tr>
<tr>
<td>PAD_CHAR_TO_FULL_LENGTH</td>
<td></td>
</tr>
<tr>
<td>PIPES_AS_CONCAT</td>
<td></td>
</tr>
<tr>
<td>REAL_AS_FLOAT</td>
<td></td>
</tr>
<tr>
<td>STRICT_ALL_TABLES</td>
<td></td>
</tr>
<tr>
<td>STRICT_TRANS_TABLES</td>
<td></td>
</tr>
</tbody>
</table>

Set the SQL mode. See Section 5.1.11, “Server SQL Modes”.

**Note**

MySQL installation programs may configure the SQL mode during the installation process.

If the SQL mode differs from the default or from what you expect, check for a setting in an option file that the server reads at startup.

- **--sysdate-is-now**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--sysdate-is-now={OFF</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

`SYSDATE()` by default returns the time at which it executes, not the time at which the statement in which it occurs begins executing. This differs from the behavior of `NOW()`.

This option causes `SYSDATE()` to be an alias for `NOW()`. For information about the implications for binary logging and replication, see the description for `SYSDATE()` in Section 12.7, “Date and Time Functions” and for `SET TIMESTAMP` in Section 5.1.8, “Server System Variables”.

- **--tc-heuristic-recover={COMMIT|ROLLBACK}**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--tc-heuristic-recover=name</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>COMMIT</td>
</tr>
<tr>
<td>Valid Values</td>
<td>COMMIT, ROLLBACK</td>
</tr>
</tbody>
</table>
The type of decision to use in the heuristic recovery process. To use this option, two or more storage engines that support XA transactions must be installed.

- **--temp-pool**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--temp-pool=[{OFF</td>
</tr>
<tr>
<td>Deprecated</td>
<td>Yes (removed in 8.0.1)</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value (Other)</td>
<td>OFF</td>
</tr>
<tr>
<td>Default Value (Linux)</td>
<td>ON</td>
</tr>
</tbody>
</table>

This option is obsolete and was removed in MySQL 8.0.1.

- **--transaction-isolation=level**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--transaction-isolation=name</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>transaction_isolation</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>REPEATABLE-READ</td>
</tr>
<tr>
<td>Valid Values</td>
<td>READ-UNCOMMITTED</td>
</tr>
<tr>
<td></td>
<td>READ-COMMITTED</td>
</tr>
<tr>
<td></td>
<td>REPEATABLE-READ</td>
</tr>
<tr>
<td></td>
<td>SERIALIZABLE</td>
</tr>
</tbody>
</table>

Sets the default transaction isolation level. The `level` value can be `READ-UNCOMMITTED`, `READ-COMMITTED`, `REPEATABLE-READ`, or `SERIALIZABLE`. See Section 13.3.7, “SET TRANSACTION Syntax”.

The default transaction isolation level can also be set at runtime using the `SET TRANSACTION` statement or by setting the `transaction_isolation` system variable.

- **--transaction-read-only**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--transaction-read-only=[{OFF</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>transaction_read_only</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>
Server Command Options

Sets the default transaction access mode. By default, read-only mode is disabled, so the mode is read/write.

To set the default transaction access mode at runtime, use the `SET TRANSACTION` statement or set the `transaction_read_only` system variable. See Section 13.3.7, “SET TRANSACTION Syntax”.

- `--tmpdir=dir_name, -t dir_name`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--tmpdir=dir_name</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>tmpdir</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Directory name</td>
</tr>
</tbody>
</table>

The path of the directory to use for creating temporary files. It might be useful if your default `/tmp` directory resides on a partition that is too small to hold temporary tables. This option accepts several paths that are used in round-robin fashion. Paths should be separated by colon characters (`:`) on Unix and semicolon characters (`;`) on Windows.

`--tmpdir` can be a non-permanent location, such as a directory on a memory-based file system or a directory that is cleared when the server host restarts. If the MySQL server is acting as a replication slave, and you are using a non-permanent location for `--tmpdir`, consider setting a different temporary directory for the slave using the `--slave-load-tmpdir` option. For a replication slave, the temporary files used to replicate `LOAD DATA` statements are stored in this directory, so with a permanent location they can survive machine restarts, although replication can now continue after a restart if the temporary files have been removed.

For more information about the storage location of temporary files, see Section B.4.3.5, “Where MySQL Stores Temporary Files”.

- `--upgrade=value`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--upgrade=value</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.16</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>AUTO</td>
</tr>
<tr>
<td>Valid Values</td>
<td>AUTO</td>
</tr>
<tr>
<td></td>
<td>NONE</td>
</tr>
<tr>
<td></td>
<td>MINIMAL</td>
</tr>
<tr>
<td></td>
<td>FORCE</td>
</tr>
</tbody>
</table>

This option controls whether and how the server performs an automatic upgrade at startup. Automatic upgrade involves two steps:

- Step 1: Data dictionary upgrade.

  This step upgrades:
• The data dictionary tables in the `mysql` schema. If the actual data dictionary version is lower than the current expected version, the server upgrades the data dictionary. If it cannot, or is prevented from doing so, the server will not run.

• The Performance Schema and `INFORMATION_SCHEMA`.

• Step 2: Server upgrade.

This step comprises all other upgrade tasks. If the existing installation data has a lower MySQL version than the server expects, it must be upgraded:

• The system tables in the `mysql` schema (the remaining non-data dictionary tables).

• The `sys` schema.

• User schemas.

For details about upgrade steps 1 and 2, see Section 2.11.3, “What the MySQL Upgrade Process Upgrades”.

These `--upgrade` option values are permitted:

• **AUTO**

  The server performs an automatic upgrade of anything it finds to be out of date (steps 1 and 2). This is the default action if `--upgrade` is not specified explicitly.

• **NONE**

  The server performs no automatic upgrade steps during the startup process (skips steps 1 and 2). Because this option value prevents a data dictionary upgrade, the server exits with an error if the data dictionary is found to be out of date:

  ```
  [ERROR] [MY-013381] [Server] Server shutting down because upgrade is required, yet prohibited by the command line option '--upgrade=None'.
  [ERROR] [MY-010334] [Server] Failed to initialize DD Storage Engine
  [ERROR] [MY-010020] [Server] Data Dictionary initialization failed.
  ```

• **MINIMAL**

  The server upgrades the data dictionary, the Performance Schema, and the `INFORMATION_SCHEMA`, if necessary (step 1). Note that following an upgrade with this option, Group Replication cannot be started, because system tables on which the replication internals depend are not updated, and reduced functionality might also be apparent in other areas.

• **FORCE**

  The server upgrades the data dictionary, the Performance Schema, and the `INFORMATION_SCHEMA`, if necessary (step 1). In addition, the server forces an upgrade of everything else (step 2). Expect server startup to take longer with this option because the server checks all objects in all schemas.

  **FORCE** is useful to force step 2 actions to be performed if the server thinks they are not necessary. For example, you may believe that a system table is missing or has become damaged and want to force a repair.

The following table summarizes the actions taken by the server for each option value.
### Server System Variables

<table>
<thead>
<tr>
<th>Option Value</th>
<th>Server Performs Step 1?</th>
<th>Server Performs Step 2?</th>
</tr>
</thead>
<tbody>
<tr>
<td>AUTO</td>
<td>If necessary</td>
<td>If necessary</td>
</tr>
<tr>
<td>NONE</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>MINIMAL</td>
<td>If necessary</td>
<td>No</td>
</tr>
<tr>
<td>FORCE</td>
<td>If necessary</td>
<td>Yes</td>
</tr>
</tbody>
</table>

- `--user={user_name|user_id}, -u {user_name|user_id}`

### Property | Value
---|---
Command-Line Format | `--user=name`
Type | String

Run the mysqld server as the user having the name `user_name` or the numeric user ID `user_id`. (“User” in this context refers to a system login account, not a MySQL user listed in the grant tables.)

This option is *mandatory* when starting mysqld as `root`. The server changes its user ID during its startup sequence, causing it to run as that particular user rather than as `root`. See Section 6.1.1, “Security Guidelines”.

To avoid a possible security hole where a user adds a `--user=root` option to a my.cnf file (thus causing the server to run as `root`), mysqld uses only the first `--user` option specified and produces a warning if there are multiple `--user` options. Options in /etc/my.cnf and $MYSQL_HOME/my.cnf are processed before command-line options, so it is recommended that you put a `--user` option in /etc/my.cnf and specify a value other than `root`. The option in /etc/my.cnf is found before any other `--user` options, which ensures that the server runs as a user other than `root`, and that a warning results if any other `--user` option is found.

- `--validate-config`

### Property | Value
---|---
Command-Line Format | `--validate-config={OFF|ON}]`
Introduced | 8.0.16
Type | Boolean
Default Value | OFF

Validate the server startup configuration. If no errors are found, the server terminates with an exit code of 0. If an error is found, the server displays a diagnostic message and terminates with an exit code of 1. Warning and information messages may also be displayed, depending on the `log_error_verbosity` value, but do not produce immediate validation termination or an exit code of 1. For more information, see Section 5.1.3, “Server Configuration Validation”.

- `--verbose, -v`

Use this option with the `--help` option for detailed help.

- `--version, -V`

Display version information and exit.

### 5.1.8 Server System Variables

The MySQL server maintains many system variables that configure its operation. Each system variable has a default value. System variables can be set at server startup using options on the command line or in an option file. Most of them can be changed dynamically at runtime using the `SET` statement,
which enables you to modify operation of the server without having to stop and restart it. You can also use system variable values in expressions.

Setting a global system variable runtime value normally requires the `SYSTEM_VARIABLES_ADMIN` or `SUPER` privilege. Setting a session system runtime variable value normally requires no special privileges and can be done by any user, although there are exceptions. For more information, see Section 5.1.9.1, “System Variable Privileges”.

There are several ways to see the names and values of system variables:

- To see the values that a server will use based on its compiled-in defaults and any option files that it reads, use this command:

  ```
  mysqld --verbose --help
  ```

- To see the values that a server will use based only on its compiled-in defaults, ignoring the settings in any option files, use this command:

  ```
  mysqld --no-defaults --verbose --help
  ```

- To see the current values used by a running server, use the `SHOW VARIABLES` statement or the Performance Schema system variable tables. See Section 26.12.13, “Performance Schema System Variable Tables”.

This section provides a description of each system variable. For a system variable summary table, see Section 5.1.5, “Server System Variable Reference”. For more information about manipulation of system variables, see Section 5.1.9, “Using System Variables”.

For additional system variable information, see these sections:

- Section 5.1.9, “Using System Variables”, discusses the syntax for setting and displaying system variable values.

- Section 5.1.9.2, “Dynamic System Variables”, lists the variables that can be set at runtime.

- Information on tuning system variables can be found in Section 5.1.1, “Configuring the Server”.

- Section 15.13, “InnoDB Startup Options and System Variables”, lists InnoDB system variables.

- NDB Cluster System Variables, lists system variables which are specific to NDB Cluster.

- For information on server system variables specific to replication, see Section 17.1.6, “Replication and Binary Logging Options and Variables”.

**Note**

Some of the following variable descriptions refer to “enabling” or “disabling” a variable. These variables can be enabled with the `SET` statement by setting them to `ON` or `1`, or disabled by setting them to `OFF` or `0`. Boolean variables can be set at startup to the values `ON`, `TRUE`, `OFF`, and `FALSE` (not case sensitive), as well as `1` and `0`. See Section 4.2.2.4, “Program Option Modifiers”.

Some system variables control the size of buffers or caches. For a given buffer, the server might need to allocate internal data structures. These structures typically are allocated from the total memory allocated to the buffer, and the amount of space required might be platform dependent. This means that when you assign a value to a system variable that controls a buffer size, the amount of space actually available might differ from the value assigned. In some cases, the amount might be less than the value assigned. It is also possible that the server will adjust a value upward. For example, if you assign a value of 0 to a variable for which the minimal value is 1024, the server will set the value to 1024.
Values for buffer sizes, lengths, and stack sizes are given in bytes unless otherwise specified.

Some system variables take file name values. Unless otherwise specified, the default file location is the data directory if the value is a relative path name. To specify the location explicitly, use an absolute path name. Suppose that the data directory is `/var/mysql/data`. If a file-valued variable is given as a relative path name, it will be located under `/var/mysql/data`. If the value is an absolute path name, its location is as given by the path name.
