The result type depends on whether the arguments are evaluated as binary strings or numbers:

- Binary-string evaluation occurs when the arguments have a binary string type, and at least one of them is not a hexadecimal literal, bit literal, or NULL literal. Numeric evaluation occurs otherwise, with argument conversion to unsigned 64-bit integers as necessary.

- Binary-string evaluation produces a binary string of the same length as the arguments. If the arguments have unequal lengths, an ER_INVALID_BITWISE_OPERANDS_SIZE error occurs. Numeric evaluation produces an unsigned 64-bit integer.

For more information, see the introductory discussion in this section.

```sql
mysql> SELECT 1 ^ 1;
-> 0
mysql> SELECT 1 ^ 0;
-> 1
mysql> SELECT 11 ^ 3;
-> 8
mysql> SELECT HEX(_binary X'FEDC' ^ X'1111');
-> 'EFCD'
```

- <<

...
Shifts a longlong (BIGINT) number or binary string to the left.

The result type depends on whether the bit argument is evaluated as a binary string or number:

- Binary-string evaluation occurs when the bit argument has a binary string type, and is not a hexadecimal literal, bit literal, or NULL literal. Numeric evaluation occurs otherwise, with argument conversion to an unsigned 64-bit integer as necessary.

- Binary-string evaluation produces a binary string of the same length as the bit argument. Numeric evaluation produces an unsigned 64-bit integer.

Bits shifted off the end of the value are lost without warning, regardless of the argument type. In particular, if the shift count is greater or equal to the number of bits in the bit argument, all bits in the result are 0.

For more information, see the introductory discussion in this section.

```sql
mysql> SELECT 1 << 2;
-> 4
mysql> SELECT HEX(_binary X'00FF00FF00FF' << 8);
--> 'FF00FF00FF00'
```

• `>>`

Shifts a longlong (BIGINT) number or binary string to the right.

The result type depends on whether the bit argument is evaluated as a binary string or number:

- Binary-string evaluation occurs when the bit argument has a binary string type, and is not a hexadecimal literal, bit literal, or NULL literal. Numeric evaluation occurs otherwise, with argument conversion to an unsigned 64-bit integer as necessary.

- Binary-string evaluation produces a binary string of the same length as the bit argument. Numeric evaluation produces an unsigned 64-bit integer.

Bits shifted off the end of the value are lost without warning, regardless of the argument type. In particular, if the shift count is greater or equal to the number of bits in the bit argument, all bits in the result are 0.

For more information, see the introductory discussion in this section.

```sql
mysql> SELECT 4 >> 2;
-> 1
mysql> SELECT HEX(_binary X'00FF00FF00FF' >> 8);
--> '0000FF00FF00'
```

• `~`

Invert all bits.

The result type depends on whether the bit argument is evaluated as a binary string or number:

- Binary-string evaluation occurs when the bit argument has a binary string type, and is not a hexadecimal literal, bit literal, or NULL literal. Numeric evaluation occurs otherwise, with argument conversion to an unsigned 64-bit integer as necessary.

- Binary-string evaluation produces a binary string of the same length as the bit argument. Numeric evaluation produces an unsigned 64-bit integer.

For more information, see the introductory discussion in this section.

```sql
mysql> SELECT 5 & ~1;
--> 4
```
### Encryption and Compression Functions

#### Table 12.18 Encryption Functions

<table>

<td>UNCOMPRESSED_LENGTH()</td>
<td>Return the length of a string before compression</td>
</tr>
<tr>
<td>VALIDATE_PASSWORD_STRENGTH()</td>
<td>Determine strength of password</td>
</tr>
</tbody>
</table>

Many encryption and compression functions return strings for which the result might contain arbitrary byte values. If you want to store these results, use a column with a VARBINARY or BLOB binary string data type. This avoids potential problems with trailing space removal or character set conversion that would change data values, such as may occur if you use a nonbinary string data type (CHAR, VARCHAR, TEXT).

Some encryption functions return strings of ASCII characters: MD5(), SHA(), SHA1(), SHA2(), STATEMENT_DIGEST(), STATEMENT_DIGEST_TEXT(). Their return value is a string that has a character set and collation determined by the character_set_connection and collation_connection system variables. This is a nonbinary string unless the character set is binary.

If an application stores values from a function such as MD5() or SHA1() that returns a string of hex digits, more efficient storage and comparisons can be obtained by converting the hex representation to binary using UNHEX() and storing the result in a BINARY(N) column. Each pair of hexadecimal digits requires one byte in binary form, so the value of N depends on the length of the hex string. N is 16 for an MD5() value and 20 for a SHA1() value. For SHA2(), N ranges from 28 to 32 depending on the argument specifying the desired bit length of the result.

The size penalty for storing the hex string in a CHAR column is at least two times, up to eight times if the value is stored in a column that uses the utf8 character set (where each character uses 4 bytes). Storing the string also results in slower comparisons because of the larger values and the need to take character set collation rules into account.

Suppose that an application stores MD5() string values in a CHAR(32) column:
CREATE TABLE md5_tbl (md5_val CHAR(32), ...);
INSERT INTO md5_tbl (md5_val, ...) VALUES(MD5('abcdef'), ...);

To convert hex strings to more compact form, modify the application to use UNHEX (16) instead as follows:

CREATE TABLE md5_tbl (md5_val BINARY(16), ...);
INSERT INTO md5_tbl (md5_val, ...) VALUES(UNHEX(MD5('abcdef')), ...);

Applications should be prepared to handle the very rare case that a hashing function produces the same value for two different input values. One way to make collisions detectable is to make the hash column a primary key.

Note
Exploits for the MD5 and SHA-1 algorithms have become known. You may wish to consider using another one-way encryption function described in this section instead, such as SHA2 (16).

Caution
Passwords or other sensitive values supplied as arguments to encryption functions are sent as cleartext to the MySQL server unless an SSL connection is used. Also, such values appear in any MySQL logs to which they are written. To avoid these types of exposure, applications can encrypt sensitive values on the client side before sending them to the server. The same considerations apply to encryption keys. To avoid exposing these, applications can use stored procedures to encrypt and decrypt values on the server side.

• AES_DECRYPT(crypt_str, key_str[, init_vector])

This function decrypts data using the official AES (Advanced Encryption Standard) algorithm. For more information, see the description of AES_ENCRYPT (16).

Statements that use AES_DECRYPT (16) are unsafe for statement-based replication.

• AES_ENCRYPT(str, key_str[, init_vector])

AES_ENCRYPT (16) and AES_DECRYPT (16) implement encryption and decryption of data using the official AES (Advanced Encryption Standard) algorithm, previously known as “Rijndael.” The AES standard permits various key lengths. By default these functions implement AES with a 128-bit key length. Key lengths of 196 or 256 bits can be used, as described later. The key length is a trade off between performance and security.

AES_ENCRYPT (16) encrypts the string str using the key string key_str and returns a binary string containing the encrypted output. AES_DECRYPT (16) decrypts the encrypted string crypt_str using the key string key_str and returns the original plaintext string. If either function argument is NULL, the function returns NULL.

The str and crypt_str arguments can be any length, and padding is automatically added to str so it is a multiple of a block as required by block-based algorithms such as AES. This padding is automatically removed by the AES_DECRYPT (16) function. The length of crypt_str can be calculated using this formula:

16 * (trunc(string_length / 16) + 1)

For a key length of 128 bits, the most secure way to pass a key to the key_str argument is to create a truly random 128-bit value and pass it as a binary value. For example:

INSERT INTO t
VALUES (1,AES_ENCRYPT('text',UNHEX('F3229A0B371ED2D9441B830D21A390C3')));

A passphrase can be used to generate an AES key by hashing the passphrase. For example:
INSERT INTO t VALUES (1, AES_ENCRYPT('text', UNHEX(SHA2('My secret passphrase',512))));

Do not pass a password or passphrase directly to `crypt_str`, hash it first. Previous versions of this documentation suggested the former approach, but it is no longer recommended as the examples shown here are more secure.

If `AES_DECRYPT()` detects invalid data or incorrect padding, it returns `NULL`. However, it is possible for `AES_DECRYPT()` to return a non-`NULL` value (possibly garbage) if the input data or the key is invalid.

`AES_ENCRYPT()` and `AES_DECRYPT()` permit control of the block encryption mode and take an optional `init_vector` initialization vector argument:

- The `block_encryption_mode` system variable controls the mode for block-based encryption algorithms. Its default value is `aes-128-ecb`, which signifies encryption using a key length of 128 bits and ECB mode. For a description of the permitted values of this variable, see Section 5.1.8, “Server System Variables”.

- The optional `init_vector` argument provides an initialization vector for block encryption modes that require it.

For modes that require the optional `init_vector` argument, it must be 16 bytes or longer (bytes in excess of 16 are ignored). An error occurs if `init_vector` is missing.

For modes that do not require `init_vector`, it is ignored and a warning is generated if it is specified.

A random string of bytes to use for the initialization vector can be produced by calling `RANDOM_BYTES(16)`.

<table>
<thead>
<tr>
<th>Block Encryption Mode</th>
<th>Initialization Vector Required</th>
</tr>
</thead>
<tbody>
<tr>
<td>ECB</td>
<td>No</td>
</tr>
<tr>
<td>CBC</td>
<td>Yes</td>
</tr>
<tr>
<td>CFB1</td>
<td>Yes</td>
</tr>
<tr>
<td>CFB8</td>
<td>Yes</td>
</tr>
<tr>
<td>CFB128</td>
<td>Yes</td>
</tr>
<tr>
<td>OFB</td>
<td>Yes</td>
</tr>
</tbody>
</table>

Statements that use `AES_ENCRYPT()` or `AES_DECRYPT()` are unsafe for statement-based replication.
Encryption and Compression Functions

• COMPRESS(string_to_compress)

Compresses a string and returns the result as a binary string. This function requires MySQL to have been compiled with a compression library such as zlib. Otherwise, the return value is always NULL. The compressed string can be uncompressed with UNCOMPRESS().

<table>
<thead>
<tr>
<th>SQL Query</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>mysql&gt; SELECT LENGTH(COMPRESS(REPEAT('a',1000))); -&gt; 21</td>
<td></td>
</tr>
<tr>
<td>mysql&gt; SELECT LENGTH(COMPRESS(''));           -&gt; 0</td>
<td></td>
</tr>
<tr>
<td>mysql&gt; SELECT LENGTH(COMPRESS('a'));          -&gt; 13</td>
<td></td>
</tr>
<tr>
<td>mysql&gt; SELECT LENGTH(COMPRESS(REPEAT('a',16))); -&gt; 15</td>
<td></td>
</tr>
</tbody>
</table>

The compressed string contents are stored the following way:

• Empty strings are stored as empty strings.

• Nonempty strings are stored as a 4-byte length of the uncompressed string (low byte first), followed by the compressed string. If the string ends with space, an extra . character is added to avoid problems with endspace trimming should the result be stored in a CHAR or VARCHAR column. (However, use of nonbinary string data types such as CHAR or VARCHAR to store compressed strings is not recommended anyway because character set conversion may occur. Use a VARBINARY or BLOB binary string column instead.)

• MD5(str)

Calculates an MD5 128-bit checksum for the string. The value is returned as a string of 32 hexadecimal digits, or NULL if the argument was NULL. The return value can, for example, be used as a hash key. See the notes at the beginning of this section about storing hash values efficiently.

The return value is a string in the connection character set.

If FIPS mode is enabled, MD5() returns NULL. See Section 6.8, “FIPS Support”.

mysql> SELECT MD5('testing');
-> 'ae2b1fca515949e5d54fb22b8ed95575'

This is the “RSA Data Security, Inc. MD5 Message-Digest Algorithm.”

See the note regarding the MD5 algorithm at the beginning this section.

• RANDOM_BYTES(len)

This function returns a binary string of len random bytes generated using the random number generator of the SSL library. Permitted values of len range from 1 to 1024. For values outside that range, an error occurs.

RANDOM_BYTES() can be used to provide the initialization vector for the AES_DECRYPT() and AES_ENCRYPT() functions. For use in that context, len must be at least 16. Larger values are permitted, but bytes in excess of 16 are ignored.

RANDOM_BYTES() generates a random value, which makes its result nondeterministic. Consequently, statements that use this function are unsafe for statement-based replication.

• SHA1(str), SHA(str)

Calculates an SHA-1 160-bit checksum for the string, as described in RFC 3174 (Secure Hash Algorithm). The value is returned as a string of 40 hexadecimal digits, or NULL if the argument was
NULL. One of the possible uses for this function is as a hash key. See the notes at the beginning of this section about storing hash values efficiently. SHA() is synonymous with SHA1().

The return value is a string in the connection character set.

```sql
mysql> SELECT SHA1('abc');
-> 'a9993e364706816aba3e25717850c26c9cd0d89d'
```

SHA1() can be considered a cryptographically more secure equivalent of MD5(). However, see the note regarding the MD5 and SHA-1 algorithms at the beginning this section.

- **SHA2(str, hash_length)**

  Calculates the SHA-2 family of hash functions (SHA-224, SHA-256, SHA-384, and SHA-512). The first argument is the plaintext string to be hashed. The second argument indicates the desired bit length of the result, which must have a value of 224, 256, 384, 512, or 0 (which is equivalent to 256). If either argument is NULL or the hash length is not one of the permitted values, the return value is NULL. Otherwise, the function result is a hash value containing the desired number of bits. See the notes at the beginning of this section about storing hash values efficiently.

  The return value is a string in the connection character set.

```sql
mysql> SELECT SHA2('abc', 224);
-> '23097d223405d8228642a477bda255b32aadbc4bda0b3f7e36c9da7'
```

This function works only if MySQL has been configured with SSL support. See Section 6.3, “Using Encrypted Connections”.

SHA2() can be considered cryptographically more secure than MD5() or SHA1().

- **STATEMENT_DIGEST(statement)**

  Given an SQL statement as a string, returns the statement digest hash value as a string in the connection character set, or NULL if the argument is NULL. The related STATEMENT_DIGEST_TEXT() function returns the normalized statement digest. For information about statement digesting, see Section 27.10, “Performance Schema Statement Digests and Sampling”.

  Both functions use the MySQL parser to parse the statement. If parsing fails, an error occurs. The error message includes the parse error only if the statement is provided as a literal string.

  The max_digest_length system variable determines the maximum number of bytes available to these functions for computing normalized statement digests.

```sql
mysql> SET @stmt = 'SELECT * FROM mytable WHERE cola = 10 AND colb = 20';
mysql> SELECT STATEMENT_DIGEST(@stmt);
+------------------------------------------------------------------+
| STATEMENT_DIGEST(@stmt)                                          |
+------------------------------------------------------------------+
| 3bb95eeade896657c4526e74ff2a2862039d0a0fe8a9e7155b5fe492c6d7387  |
+------------------------------------------------------------------+
mysql> SELECT STATEMENT_DIGEST_TEXT(@stmt);
+----------------------------------------------------------+
| STATEMENT_DIGEST_TEXT(@stmt)                             |
+----------------------------------------------------------+
| SELECT * FROM `mytable` WHERE `cola` = ? AND `colb` = ?  |
+----------------------------------------------------------+
```

- **STATEMENT_DIGEST_TEXT(statement)**

  Given an SQL statement as a string, returns the normalized statement digest as a string in the connection character set, or NULL if the argument is NULL. For additional discussion and examples, see the description of the related STATEMENT_DIGEST() function.

- **UNCOMPRESS(string_to_uncompress)**
Uncompresses a string compressed by the `COMPRESS()` function. If the argument is not a compressed value, the result is `NULL`. This function requires MySQL to have been compiled with a compression library such as `zlib`. Otherwise, the return value is always `NULL`.

```sql
mysql> SELECT UNCOMPRESS(COMPRESS('any string'));
-> 'any string'
```

```sql
mysql> SELECT UNCOMPRESS('any string');
-> NULL
```

- **UNCOMPRESSED_LENGTH(compressed_string)**

Returns the length that the compressed string had before being compressed.

```sql
mysql> SELECT UNCOMPRESSED_LENGTH(COMPRESS(REPEAT('a',30)));
-> 30
```

- **VALIDATE_PASSWORD_STRENGTH(str)**

Given an argument representing a plaintext password, this function returns an integer to indicate how strong the password is. The return value ranges from 0 (weak) to 100 (strong).

Password assessment by `VALIDATE_PASSWORD_STRENGTH()` is done by the `validate_password` component. If that component is not installed, the function always returns 0. For information about installing `validate_password`, see Section 6.4.3, “The Password Validation Component”. To examine or configure the parameters that affect password testing, check or set the system variables implemented by `validate_password`. See Section 6.4.3.2, “Password Validation Options and Variables”.

The password is subjected to increasingly strict tests and the return value reflects which tests were satisfied, as shown in the following table. In addition, if the `validate_password.check_user_name` system variable is enabled and the password matches the user name, `VALIDATE_PASSWORD_STRENGTH()` returns 0 regardless of how other `validate_password` system variables are set.

<table>
<thead>
<tr>
<th>Password Test</th>
<th>Return Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Length &lt; 4</td>
<td>0</td>
</tr>
<tr>
<td>Length ≥ 4 and &lt; <code>validate_password.length</code></td>
<td>25</td>
</tr>
<tr>

<td>50</td>
</tr>
<tr>
<td>Satisfies policy 2 (MEDIUM)</td>
<td>75</td>
</tr>
<tr>
<td>Satisfies policy 3 (STRONG)</td>
<td>100</td>
</tr>
</tbody>
</table>

### 12.15 Locking Functions

This section describes functions used to manipulate user-level locks.

**Table 12.19 Locking Functions**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GET_LOCK()</td>
<td>Get a named lock</td>
</tr>
<tr>
<td>IS_FREE_LOCK()</td>
<td>Whether the named lock is free</td>
</tr>
<tr>
<td>IS_USED_LOCK()</td>
<td>Whether the named lock is in use; return connection identifier if true</td>
</tr>
<tr>
<td>RELEASE_ALL_LOCKS()</td>
<td>Release all current named locks</td>
</tr>
<tr>
<td>RELEASE_LOCK()</td>
<td>Release the named lock</td>
</tr>
</tbody>
</table>

- **GET_LOCK(str, timeout)**
Locking Functions

Tries to obtain a lock with a name given by the string `str`, using a timeout of `timeout` seconds. A negative `timeout` value means infinite timeout. The lock is exclusive. While held by one session, other sessions cannot obtain a lock of the same name.

Returns 1 if the lock was obtained successfully, 0 if the attempt timed out (for example, because another client has previously locked the name), or NULL if an error occurred (such as running out of memory or the thread was killed with `mysqladmin kill`).

A lock obtained with `GET_LOCK()` is released explicitly by executing `RELEASE_LOCK()` or implicitly when your session terminates (either normally or abnormally). Locks obtained with `GET_LOCK()` are not released when transactions commit or roll back.

`GET_LOCK()` is implemented using the metadata locking (MDL) subsystem. Multiple simultaneous locks can be acquired and `GET_LOCK()` does not release any existing locks. For example, suppose that you execute these statements:

```sql
SELECT GET_LOCK('lock1',10);
SELECT GET_LOCK('lock2',10);
SELECT RELEASE_LOCK('lock2');
SELECT RELEASE_LOCK('lock1');
```

The second `GET_LOCK()` acquires a second lock and both `RELEASE_LOCK()` calls return 1 (success).

It is even possible for a given session to acquire multiple locks for the same name. Other sessions cannot acquire a lock with that name until the acquiring session releases all its locks for the name.

Uniquely named locks acquired with `GET_LOCK()` appear in the Performance Schema `metadata_locks` table. The `OBJECT_TYPE` column says `USER LEVEL LOCK` and the `OBJECT_NAME` column indicates the lock name. In the case that multiple locks are acquired for the same name, only the first lock for the name registers a row in the `metadata_locks` table. Subsequent locks for the name increment a counter in the lock but do not acquire additional metadata locks. The `metadata_locks` row for the lock is deleted when the last lock instance on the name is released.

The capability of acquiring multiple locks means there is the possibility of deadlock among clients. When this happens, the server chooses a caller and terminates its lock-acquisition request with an `ER_USER_LOCK_DEADLOCK` error. This error does not cause transactions to roll back.

MySQL enforces a maximum length on lock names of 64 characters.

`GET_LOCK()` can be used to implement application locks or to simulate record locks. Names are locked on a server-wide basis. If a name has been locked within one session, `GET_LOCK()` blocks any request by another session for a lock with the same name. This enables clients that agree on a given lock name to use the name to perform cooperative advisory locking. But be aware that it also enables a client that is not among the set of cooperating clients to lock a name, either inadvertently or deliberately, and thus prevent any of the cooperating clients from locking that name. One way to
Locking Functions

reduce the likelihood of this is to use lock names that are database-specific or application-specific. For example, use lock names of the form `db_name.str` or `app_name.str`.

If multiple clients are waiting for a lock, the order in which they acquire it is undefined. Applications should not assume that clients acquire the lock in the same order that they issued the lock requests.

`GET_LOCK()` is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

Caution

With the capability of acquiring multiple named locks, it is possible for a single statement to acquire a large number of locks. For example:

```
INSERT INTO ... SELECT GET_LOCK(t1.col_name) FROM t1;
```

These types of statements may have certain adverse effects. For example, if the statement fails part way through and rolls back, locks acquired up to the point of failure still exist. If the intent is for there to be a correspondence between rows inserted and locks acquired, that intent is not satisfied. Also, if it is important that locks are granted in a certain order, be aware that result set order may differ depending on which execution plan the optimizer chooses. For these reasons, it may be best to limit applications to a single lock-acquisition call per statement.

A different locking interface is available as either a plugin service or a set of user-defined functions. This interface provides lock namespaces and distinct read and write locks, unlike the interface provided by `GET_LOCK()` and related functions. For details, see Section 5.6.9.1, “The Locking Service”.

- **IS_FREE_LOCK(str)**

  Checks whether the lock named `str` is free to use (that is, not locked). Returns 1 if the lock is free (no one is using the lock), 0 if the lock is in use, and `NULL` if an error occurs (such as an incorrect argument).

  This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

- **IS_USED_LOCK(str)**

  Checks whether the lock named `str` is in use (that is, locked). If so, it returns the connection identifier of the client session that holds the lock. Otherwise, it returns `NULL`.

  This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

- **RELEASE_ALL_LOCKS()**

  Releases all named locks held by the current session and returns the number of locks released (0 if there were none).

  This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

- **RELEASE_LOCK(str)**

  Releases the lock named by the string `str` that was obtained with `GET_LOCK()`. Returns 1 if the lock was released, 0 if the lock was not established by this thread (in which case the lock is not
released), and NULL if the named lock did not exist. The lock does not exist if it was never obtained by a call to GET_LOCK() or if it has previously been released.

The DO statement is convenient to use with RELEASE_LOCK(). See Section 13.2.3, “DO Statement”.

This function is unsafe for statement-based replication. A warning is logged if you use this function when binlog_format is set to STATEMENT.

### 12.16 Information Functions

Table 12.20 Information Functions

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BENCHMARK()</td>
<td>Repeatedly execute an expression</td>
</tr>
<tr>
<td>CHARSET()</td>
<td>Return the character set of the argument</td>
</tr>
<tr>
<td>COERCIBILITY()</td>
<td>Return the collation coercibility value of the string argument</td>
</tr>
<tr>
<td>COLLATION()</td>
<td>Return the collation of the string argument</td>
</tr>
<tr>
<td>CONNECTION_ID()</td>
<td>Return the connection ID (thread ID) for the connection</td>
</tr>
<tr>
<td>CURRENT_ROLE()</td>
<td>Return the current active roles</td>
</tr>
<tr>
<td>CURRENT_USER(),</td>
<td>The authenticated user name and host name</td>
</tr>
<tr>
<td>CURRENT_USER</td>

<tr>
<td>ROW_COUNT()</td>
<td>The number of rows updated</td>
</tr>
<tr>
<td>SCHEMA()</td>
<td>Synonym for DATABASE()</td>
</tr>
<tr>
<td>SESSION_USER()</td>
<td>Synonym for USER()</td>
</tr>
<tr>
<td>SYSTEM_USER()</td>
<td>Synonym for USER()</td>
</tr>
<tr>
<td>USER()</td>
<td>The user name and host name provided by the client</td>
</tr>
<tr>
<td>VERSION()</td>
<td>Return a string that indicates the MySQL server version</td>
</tr>
</tbody>
</table>

- **BENCHMARK(count, expr)**

  The BENCHMARK() function executes the expression expr repeatedly count times. It may be used to time how quickly MySQL processes the expression. The result value is 0, or NULL for inappropriate arguments such as a NULL or negative repeat count.

  The intended use is from within the mysql client, which reports query execution times:

  ```
  mysql> SELECT BENCHMARK(1000000, AES_ENCRYPT('hello', 'goodbye'));
  +---------------------------------------------------+
  | BENCHMARK(1000000, AES_ENCRYPT('hello', 'goodbye')) |
  +---------------------------------------------------+
  | 0                                                 |
  +---------------------------------------------------+
  1 row in set (4.74 sec)
  ```

  The time reported is elapsed time on the client end, not CPU time on the server end. It is advisable to execute BENCHMARK() several times, and to interpret the result with regard to how heavily loaded the server machine is.
**BENCHMARK()** is intended for measuring the runtime performance of scalar expressions, which has some significant implications for the way that you use it and interpret the results:

- Only scalar expressions can be used. Although the expression can be a subquery, it must return a single column and at most a single row. For example, `BENCHMARK(10, (SELECT * FROM t))` fails if the table `t` has more than one column or more than one row.

- Executing a `SELECT expr` statement \( N \) times differs from executing `SELECT BENCHMARK(N, expr)` in terms of the amount of overhead involved. The two have very different execution profiles and you should not expect them to take the same amount of time. The former involves the parser, optimizer, table locking, and runtime evaluation \( N \) times each. The latter involves only runtime evaluation \( N \) times, and all the other components just once. Memory structures already allocated are reused, and runtime optimizations such as local caching of results already evaluated for aggregate functions can alter the results. Use of `BENCHMARK()` thus measures performance of the runtime component by giving more weight to that component and removing the “noise” introduced by the network, parser, optimizer, and so forth.

**CHARSET(str)**

Returns the character set of the string argument.

```sql
code
mysql> SELECT CHARSET('abc');
-> 'utf8'
mysql> SELECT CHARSET(CONVERT('abc' USING latin1));
-> 'latin1'
mysql> SELECT CHARSET(USER());
-> 'utf8'
```

**COERCIBILITY(str)**

Returns the collation coercibility value of the string argument.

```sql
code
mysql> SELECT COERCIBILITY('abc' COLLATE utf8_swedish_ci);
-> 0
mysql> SELECT COERCIBILITY(USER());
-> 1
mysql> SELECT COERCIBILITY('abc');
-> 4
mysql> SELECT COERCIBILITY(1000);
-> 5
```

The return values have the meanings shown in the following table. Lower values have higher precedence.

<table>
<thead>
<tr>
<th>Coercibility</th>
<th>Meaning</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Explicit collation</td>
<td>Value with <strong>COLLATE</strong> clause</td>
</tr>
<tr>
<td>1</td>
<td>No collation</td>
<td>Concatenation of strings with different collations</td>
</tr>
<tr>
<td>2</td>
<td>Implicit collation</td>
<td>Column value, stored routine parameter or local variable</td>
</tr>
<tr>
<td>3</td>
<td>System constant</td>
<td><strong>USER()</strong> return value</td>
</tr>
<tr>
<td>4</td>
<td>Coercible</td>
<td>Literal string</td>
</tr>
<tr>
<td>5</td>
<td>Numeric</td>
<td>Numeric or temporal value</td>
</tr>
<tr>
<td>5</td>
<td>Ignorable</td>
<td>NULL or an expression derived from NULL</td>
</tr>
</tbody>
</table>

For more information, see Section 10.8.4, “Collation Coercibility in Expressions”. 

• **COLLATION**(str)

Returns the collation of the string argument.

```sql
mysql> SELECT COLLATION('abc');
-> 'utf8_general_ci'
mysql> SELECT COLLATION(_utf8mb4'abc');
-> 'utf8mb4_0900_ai_ci'
mysql> SELECT COLLATION(_latin1'abc');
-> 'latin1_swedish_ci'
```

• **CONNECTION_ID()**

Returns the connection ID (thread ID) for the connection. Every connection has an ID that is unique among the set of currently connected clients.

The value returned by **CONNECTION_ID()** is the same type of value as displayed in the **ID** column of the **INFORMATION_SCHEMA.PROCESSLIST** table, the **Id** column of **SHOW PROCESSLIST** output, and the **PROCESSLIST_ID** column of the Performance Schema **threads** table.

```sql
mysql> SELECT CONNECTION_ID();
-> 23786
```

**Warning**

Changing the session value of the **pseudo_thread_id** system variable changes the value returned by the **CONNECTION_ID()** function.

• **CURRENT_ROLE()**

Returns a **utf8** string containing the current active roles for the current session, separated by commas, or **NONE** if there are none. The value reflects the setting of the **sql_quote_show_create** system variable.

Suppose that an account is granted roles as follows:

```sql
GRANT 'r1', 'r2' TO 'u1'@'localhost';
SET DEFAULT ROLE ALL TO 'u1'@'localhost';
```

In sessions for **u1**, the initial **CURRENT_ROLE()** value names the default account roles. Using **SET ROLE** changes that:

```sql
mysql> SELECT CURRENT_ROLE();
+-------------------+
| CURRENT_ROLE()    |
+-------------------+
| `r1`@`%`,`r2`@`%` |
+-------------------+

mysql> SET ROLE 'r1'; SELECT CURRENT_ROLE();
+----------------+
| CURRENT_ROLE() |
+----------------+
| `r1`@`%`       |
+----------------+
```

• **CURRENT_USER, CURRENT_USER()**

Returns the user name and host name combination for the MySQL account that the server used to authenticate the current client. This account determines your access privileges. The return value is a string in the **utf8** character set.

The value of **CURRENT_USER()** can differ from the value of **USER()**.

```sql
mysql> SELECT USER();
-> 'davida@localhost'
mysql> SELECT * FROM mysql.user;
```

The example illustrates that although the client specified a user name of davida (as indicated by the value of the `USER()` function), the server authenticated the client using an anonymous user account (as seen by the empty user name part of the `CURRENT_USER()` value). One way this might occur is that there is no account listed in the grant tables for davida.

Within a stored program or view, `CURRENT_USER()` returns the account for the user who defined the object (as given by its `DEFINER` value) unless defined with the `SQL SECURITY INVOKER` characteristic. In the latter case, `CURRENT_USER()` returns the object's invoker.

Triggers and events have no option to define the `SQL SECURITY` characteristic, so for these objects, `CURRENT_USER()` returns the account for the user who defined the object. To return the invoker, use `USER()` or `SESSION_USER()`.

The following statements support use of the `CURRENT_USER()` function to take the place of the name of (and, possibly, a host for) an affected user or a definer; in such cases, `CURRENT_USER()` is expanded where and as needed:

- `DROP USER`
- `RENAME USER`
- `GRANT`
- `REVOKE`
- `CREATE FUNCTION`
- `CREATE PROCEDURE`
- `CREATE TRIGGER`
- `CREATE EVENT`
- `CREATE VIEW`
- `ALTER EVENT`
- `ALTER VIEW`
- `SET PASSWORD`

For information about the implications that this expansion of `CURRENT_USER()` has for replication, see Section 17.5.1.8, “Replication of `CURRENT_USER()`”.

- `DATABASE()`

Returns the default (current) database name as a string in the `utf8` character set. If there is no default database, `DATABASE()` returns `NULL`. Within a stored routine, the default database is the database that the routine is associated with, which is not necessarily the same as the database that is the default in the calling context.

```
mysql> SELECT DATABASE();
-> 'test'
```

If there is no default database, `DATABASE()` returns `NULL`. 
Information Functions

• **FOUND_ROWS()**

Note

The **SQL_CALC_FOUND_ROWS** query modifier and accompanying **FOUND_ROWS()** function are deprecated as of MySQL 8.0.17; expect them to be removed in a future version of MySQL. As a replacement, considering executing your query with **LIMIT**, and then a second query with **COUNT(*)** and without **LIMIT** to determine whether there are additional rows. For example, instead of these queries:

```sql
SELECT SQL_CALC_FOUND_ROWS * FROM tbl_name WHERE id > 100 LIMIT 10;
SELECT FOUND_ROWS();
```

Use these queries instead:

```sql
SELECT * FROM tbl_name WHERE id > 100 LIMIT 10;
SELECT COUNT(*) FROM tbl_name WHERE id > 100;
```

**COUNT(*)** is subject to certain optimizations. **SQL_CALC_FOUND_ROWS** causes some optimizations to be disabled.

A **SELECT** statement may include a **LIMIT** clause to restrict the number of rows the server returns to the client. In some cases, it is desirable to know how many rows the statement would have returned without the **LIMIT**, but without running the statement again. To obtain this row count, include an **SQL_CALC_FOUND_ROWS** option in the **SELECT** statement, and then invoke **FOUND_ROWS()** afterward:

```sql
mysql> SELECT SQL_CALC_FOUND_ROWS * FROM ... ;
```

The second **SELECT** returns a number indicating how many rows the first **SELECT** would have returned had it been written without the **LIMIT** clause.

In the absence of the **SQL_CALC_FOUND_ROWS** option in the most recent successful **SELECT** statement, **FOUND_ROWS()** returns the number of rows in the result set returned by that statement. If the statement includes a **LIMIT** clause, **FOUND_ROWS()** returns the number of rows up to the limit. For example, **FOUND_ROWS()** returns 10 or 60, respectively, if the statement includes **LIMIT 10** or **LIMIT 50, 10**.

The row count available through **FOUND_ROWS()** is transient and not intended to be available past the statement following the **SELECT SQL_CALC_FOUND_ROWS** statement. If you need to refer to the value later, save it:

```sql
mysql> SET @rows = FOUND_ROWS();
```

If you are using **SELECT SQL_CALC_FOUND_ROWS**, MySQL must calculate how many rows are in the full result set. However, this is faster than running the query again without **LIMIT**, because the result set need not be sent to the client.

**SQL_CALC_FOUND_ROWS** and **FOUND_ROWS()** can be useful in situations when you want to restrict the number of rows that a query returns, but also determine the number of rows in the full result set without running the query again. An example is a Web script that presents a paged display...
containing links to the pages that show other sections of a search result. Using `FOUND_ROWS()` enables you to determine how many other pages are needed for the rest of the result.

The use of `SQL_CALC_FOUND_ROWS` and `FOUND_ROWS()` is more complex for `UNION` statements than for simple `SELECT` statements, because `LIMIT` may occur at multiple places in a `UNION`. It may be applied to individual `SELECT` statements in the `UNION`, or global to the `UNION` result as a whole.

The intent of `SQL_CALC_FOUND_ROWS` for `UNION` is that it should return the row count that would be returned without a global `LIMIT`. The conditions for use of `SQL_CALC_FOUND_ROWS` with `UNION` are:

- The `SQL_CALC_FOUND_ROWS` keyword must appear in the first `SELECT` of the `UNION`.
- The value of `FOUND_ROWS()` is exact only if `UNION ALL` is used. If `UNION` without `ALL` is used, duplicate removal occurs and the value of `FOUND_ROWS()` is only approximate.
- If no `LIMIT` is present in the `UNION`, `SQL_CALC_FOUND_ROWS` is ignored and returns the number of rows in the temporary table that is created to process the `UNION`.

Beyond the cases described here, the behavior of `FOUND_ROWS()` is undefined (for example, its value following a `SELECT` statement that fails with an error).

**Important**

`FOUND_ROWS()` is not replicated reliably using statement-based replication. This function is automatically replicated using row-based replication.

- `ICU_VERSION()`

The version of the International Components for Unicode (ICU) library used to support regular expression operations (see Section 12.8.2, “Regular Expressions”). This function is primarily intended for use in test cases.

- `LAST_INSERT_ID(), LAST_INSERT_ID(expr)`

With no argument, `LAST_INSERT_ID()` returns a `BIGINT UNSIGNED` (64-bit) value representing the first automatically generated value successfully inserted for an `AUTO_INCREMENT` column as a result of the most recently executed `INSERT` statement. The value of `LAST_INSERT_ID()` remains unchanged if no rows are successfully inserted.

With an argument, `LAST_INSERT_ID()` returns an unsigned integer.

For example, after inserting a row that generates an `AUTO_INCREMENT` value, you can get the value like this:

```sql
mysql> SELECT LAST_INSERT_ID();
-> 195
```

The currently executing statement does not affect the value of `LAST_INSERT_ID()`. Suppose that you generate an `AUTO_INCREMENT` value with one statement, and then refer to `LAST_INSERT_ID()` in a multiple-row `INSERT` statement that inserts rows into a table with its own `AUTO_INCREMENT` column. The value of `LAST_INSERT_ID()` remains stable in the second statement; its value for the second and later rows is not affected by the earlier row insertions. (You should be aware that, if you mix references to `LAST_INSERT_ID()` and `LAST_INSERT_ID(expr)`, the effect is undefined.)

If the previous statement returned an error, the value of `LAST_INSERT_ID()` is undefined. For transactional tables, if the statement is rolled back due to an error, the value of `LAST_INSERT_ID()`...
is left undefined. For manual \texttt{ROLLBACK}, the value of \texttt{LAST_INSERT_ID()} is not restored to that before the transaction; it remains as it was at the point of the \texttt{ROLLBACK}.

Within the body of a stored routine (procedure or function) or a trigger, the value of \texttt{LAST_INSERT_ID()} changes the same way as for statements executed outside the body of these kinds of objects. The effect of a stored routine or trigger upon the value of \texttt{LAST_INSERT_ID()} that is seen by following statements depends on the kind of routine:

- If a stored procedure executes statements that change the value of \texttt{LAST_INSERT_ID()}, the changed value is seen by statements that follow the procedure call.

- For stored functions and triggers that change the value, the value is restored when the function or trigger ends, so statements coming after it do not see a changed value.

The ID that was generated is maintained in the server on a \textit{per-connection basis}. This means that the value returned by the function to a given client is the first \texttt{AUTO_INCREMENT} value generated for most recent statement affecting an \texttt{AUTO_INCREMENT} column \textit{by that client}. This value cannot be affected by other clients, even if they generate \texttt{AUTO_INCREMENT} values of their own. This behavior ensures that each client can retrieve its own ID without concern for the activity of other clients, and without the need for locks or transactions.

The value of \texttt{LAST_INSERT_ID()} is not changed if you set the \texttt{AUTO_INCREMENT} column of a row to a non-“magic” value (that is, a value that is not \texttt{NULL} and not \texttt{0}).

\begin{center}
\textbf{Important}
\end{center}

If you insert multiple rows using a single \texttt{INSERT} statement, \texttt{LAST_INSERT_ID()} returns the value generated for the \textit{first} inserted row only. The reason for this is to make it possible to reproduce easily the same \texttt{INSERT} statement against some other server.

For example:

\begin{verbatim}
mysql> USE test;

mysql> CREATE TABLE t (id INT AUTO_INCREMENT NOT NULL PRIMARY KEY,
                      name VARCHAR(10) NOT NULL);

mysql> INSERT INTO t VALUES (NULL, 'Bob');

mysql> SELECT * FROM t;
+----+------+
| id | name |
+----+------+
| 1  | Bob  |
+----+

mysql> SELECT LAST_INSERT_ID();
+------------------+
| LAST_INSERT_ID() |
| 1                |
+------------------+

mysql> INSERT INTO t VALUES (NULL, 'Mary'), (NULL, 'Jane'), (NULL, 'Lisa');

mysql> SELECT * FROM t;
+----+------+
| id | name |
+----+------+
| 1  | Bob  |
| 2  | Mary |
| 3  | Jane |

\end{verbatim}
Although the second `INSERT` statement inserted three new rows into `t`, the ID generated for the first of these rows was `2`, and it is this value that is returned by `LAST_INSERT_ID()` for the following `SELECT` statement.

If you use `INSERT IGNORE` and the row is ignored, the `LAST_INSERT_ID()` remains unchanged from the current value (or `0` is returned if the connection has not yet performed a successful `INSERT`) and, for non-transactional tables, the `AUTO_INCREMENT` counter is not incremented. For InnoDB tables, the `AUTO_INCREMENT` counter is incremented if `innodb_autoinc_lock_mode` is set to `1` or `2`, as demonstrated in the following example:
Information Functions

# is incremented for the ignored rows

mysql> SHOW CREATE TABLE t
*************************** 1. row ***************************
Table: t
Create Table: CREATE TABLE `t` (id int(11) NOT NULL AUTO_INCREMENT, val int(11) DEFAULT NULL, PRIMARY KEY (`id`), UNIQUE KEY `i1` (`val`)) ENGINE=InnoDB AUTO_INCREMENT=5 DEFAULT CHARSET=latin1

# The LAST_INSERT_ID is unchanged because the previous insert was unsuccessful

mysql> SELECT LAST_INSERT_ID();
+------------------+
| LAST_INSERT_ID() |
+------------------+
| 1                |
+------------------+

For more information, see Section 15.6.1.6, “AUTO_INCREMENT Handling in InnoDB”.

If \texttt{expr} is given as an argument to \texttt{LAST_INSERT_ID()}, the value of the argument is returned by the function and is remembered as the next value to be returned by \texttt{LAST_INSERT_ID()}. This can be used to simulate sequences:

1. Create a table to hold the sequence counter and initialize it:

   mysql> create table sequence (id int not null);
   mysql> insert into sequence values (0);

2. Use the table to generate sequence numbers like this:

   mysql> update sequence set id=last_insert_id(id+1);
   mysql> select last_insert_id();

   The \texttt{UPDATE} statement increments the sequence counter and causes the next call to \texttt{LAST_INSERT_ID()} to return the updated value. The \texttt{SELECT} statement retrieves that value. The \texttt{mysql_insert_id()} C API function can also be used to get the value. See \texttt{mysql_insert_id()}.

You can generate sequences without calling \texttt{LAST_INSERT_ID()}, but the utility of using the function this way is that the ID value is maintained in the server as the last automatically generated value. It is multi-user safe because multiple clients can issue the \texttt{UPDATE} statement and get their own sequence value with the \texttt{SELECT} statement (or \texttt{mysql_insert_id()}), without affecting or being affected by other clients that generate their own sequence values.

Note that \texttt{mysql_insert_id()} is only updated after \texttt{INSERT} and \texttt{UPDATE} statements, so you cannot use the C API function to retrieve the value for \texttt{LAST_INSERT_ID(expr)} after executing other SQL statements like \texttt{SELECT} or \texttt{SET}.

• \texttt{ROLES_GRAPHML()}

Returns a utf8 string containing a GraphML document representing memory role subgraphs. The \texttt{ROLE_ADMIN} privilege (or the deprecated \texttt{SUPER} privilege) is required to see content in the \texttt{<graphml>} element. Otherwise, the result shows only an empty element:

mysql> select roles_graphml();
+---------------------------------------------------+
| ROLES_GRAPHML()                                   |
+---------------------------------------------------+
| <?xml version="1.0" encoding="UTF-8"?><graphml /> |
+---------------------------------------------------+
• **ROW_COUNT()**

**ROW_COUNT()** returns a value as follows:

- **DDL statements**: 0. This applies to statements such as `CREATE TABLE` or `DROP TABLE`.
- **DML statements other than SELECT**: The number of affected rows. This applies to statements such as `UPDATE`, `INSERT`, or `DELETE` (as before), but now also to statements such as `ALTER TABLE` and `LOAD DATA`.
- **SELECT**: -1 if the statement returns a result set, or the number of rows “affected” if it does not. For example, for `SELECT * FROM t1`, `ROW_COUNT()` returns -1. For `SELECT * FROM t1 INTO OUTFILE 'file_name'`, `ROW_COUNT()` returns the number of rows written to the file.
- **SIGNAL statements**: 0.

For **UPDATE** statements, the affected-rows value by default is the number of rows actually changed. If you specify the `CLIENT_FOUND_ROWS` flag to `mysql_real_connect()` when connecting to `mysqld`, the affected-rows value is the number of rows “found”; that is, matched by the WHERE clause.

For **REPLACE** statements, the affected-rows value is 2 if the new row replaced an old row, because in this case, one row was inserted after the duplicate was deleted.

For **INSERT ... ON DUPLICATE KEY UPDATE** statements, the affected-rows value per row is 1 if the row is inserted as a new row, 2 if an existing row is updated, and 0 if an existing row is set to its current values. If you specify the `CLIENT_FOUND_ROWS` flag, the affected-rows value is 1 (not 0) if an existing row is set to its current values.

The **ROW_COUNT()** value is similar to the value from the `mysql_affected_rows()` C API function and the row count that the `mysql` client displays following statement execution.

```sql
mysql> INSERT INTO t VALUES(1),(2),(3);
Query OK, 3 rows affected (0.00 sec)
Records: 3  Duplicates: 0  Warnings: 0

mysql> SELECT ROW_COUNT();
+-------------+
| ROW_COUNT() |
+-------------+
| 3           |
+-------------+
1 row in set (0.00 sec)

mysql> DELETE FROM t WHERE i IN(1,2);
Query OK, 2 rows affected (0.00 sec)

mysql> SELECT ROW_COUNT();
+-------------+
| ROW_COUNT() |
+-------------+
| 2           |
+-------------+
1 row in set (0.00 sec)
```

---

**Important**

**ROW_COUNT()** is not replicated reliably using statement-based replication. This function is automatically replicated using row-based replication.

• **SCHEMA()**

This function is a synonym for `DATABASE()`.
• **SESSION_USER()**

  **SESSION_USER()** is a synonym for **USER()**.

• **SYSTEM_USER()**

  **SYSTEM_USER()** is a synonym for **USER()**.

  **Note**

  The **SYSTEM_USER()** function is distinct from the **SYSTEM_USER** privilege. The former returns the current MySQL account name. The latter distinguishes the system user and regular user account categories (see Section 6.2.11, “Account Categories”).

• **USER()**

  Returns the current MySQL user name and host name as a string in the utf8 character set.

  ```sql
  mysql> SELECT USER();
  -> 'davida@localhost'
  ```

  The value indicates the user name you specified when connecting to the server, and the client host from which you connected. The value can be different from that of **CURRENT_USER()**.

• **VERSION()**

  Returns a string that indicates the MySQL server version. The string uses the utf8 character set. The value might have a suffix in addition to the version number. See the description of the version system variable in Section 5.1.8, “Server System Variables”.

  This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to **STATEMENT**.

  ```sql
  mysql> SELECT VERSION();
  -> '8.0.27-standard'
  ```

### 12.17 Spatial Analysis Functions

MySQL provides functions to perform various operations on spatial data. These functions can be grouped into several major categories according to the type of operation they perform:

• Functions that create geometries in various formats (WKT, WKB, internal)

• Functions that convert geometries between formats

• Functions that access qualitative or quantitative properties of a geometry

• Functions that describe relations between two geometries

• Functions that create new geometries from existing ones

For general background about MySQL support for using spatial data, see Section 11.4, “Spatial Data Types”.

### 12.17.1 Spatial Function Reference

The following table lists each spatial function and provides a short description of each one.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Introduced</th>
</tr>
</thead>
<tbody>
<tr>
<td>GeomCollection()</td>
<td>Construct geometry collection from geometries</td>
<td></td>
</tr>
<tr>
<td>GeometryCollection()</td>
<td>Construct geometry collection from geometries</td>
<td></td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Introduced</td>
</tr>
<tr>
<td>-----------------------</td>
<td>--------------------------------------------------------------</td>
<td>------------</td>
</tr>
<tr>
<td>LineString()</td>
<td>Construct LineString from Point values</td>
<td></td>
</tr>
<tr>
<td>MBRContains()</td>
<td>Whether MBR of one geometry contains MBR of another</td>
<td></td>
</tr>
<tr>
<td>MBRCoveredBy()</td>
<td>Whether one MBR is covered by another</td>
<td></td>
</tr>
<tr>
<td>MBRCovers()</td>
<td>Whether one MBR covers another</td>
<td></td>
</tr>
<tr>
<td>MBRDisjoint()</td>
<td>Whether MBRs of two geometries are disjoint</td>
<td></td>
</tr>
<tr>
<td>MBREquals()</td>
<td>Whether MBRs of two geometries are equal</td>
<td></td>
</tr>
<tr>
<td>MBRIntersects()</td>
<td>Whether MBRs of two geometries intersect</td>
<td></td>
</tr>
<tr>
<td>MBROverlaps()</td>
<td>Whether MBRs of two geometries overlap</td>
<td></td>
</tr>
<tr>
<td>MBRTouches()</td>
<td>Whether MBRs of two geometries touch</td>
<td></td>
</tr>
<tr>
<td>MBRWithin()</td>
<td>Whether MBR of one geometry is within MBR of another</td>
<td></td>
</tr>
<tr>
<td>MultiLineString()</td>
<td>Construct MultiLineString from LineString values</td>
<td></td>
</tr>
<tr>
<td>MultiPoint()</td>
<td>Construct MultiPoint from Point values</td>
<td></td>
</tr>
<tr>
<td>MultiPolygon()</td>
<td>Construct MultiPolygon from Polygon values</td>
<td></td>
</tr>
<tr>
<td>Point()</td>
<td>Construct Point from coordinates</td>
<td></td>
</tr>
<tr>
<td>Polygon()</td>
<td>Construct Polygon from LineString arguments</td>
<td></td>
</tr>
<tr>
<td>ST_Area()</td>
<td>Return Polygon or MultiPolygon area</td>
<td></td>
</tr>
<tr>
<td>ST_AsBinary(),</td>
<td>Convert from internal geometry format to WKB</td>
<td></td>
</tr>
<tr>
<td>ST_AsWKB()</td>
<td></td>
<td></td>
</tr>
<tr>
<td>ST_AsGeoJSON()</td>
<td>Generate GeoJSON object from geometry</td>
<td></td>
</tr>
<tr>
<td>ST_AsText(),</td>
<td>Convert from internal geometry format to WKT</td>
<td></td>
</tr>
<tr>
<td>ST_AsWKT()</td>
<td></td>
<td></td>
</tr>
<tr>
<td>ST_Buffer()</td>
<td>Return geometry of points within given distance from geometry</td>
<td></td>
</tr>
<tr>
<td>ST_Buffer_Strategy()</td>
<td>Produce strategy option for ST_Buffer()</td>
<td></td>
</tr>
<tr>
<td>ST_Centroid()</td>
<td>Return centroid as a point</td>
<td></td>
</tr>
<tr>
<td>ST_Collect()</td>
<td>Aggregate spatial values into collection</td>
<td>8.0.24</td>
</tr>
<tr>
<td>ST_Contains()</td>
<td>Whether one geometry contains another</td>
<td></td>
</tr>
<tr>
<td>ST_ConvexHull()</td>
<td>Return convex hull of geometry</td>
<td></td>
</tr>
<tr>
<td>ST_Crosses()</td>
<td>Whether one geometry crosses another</td>
<td></td>
</tr>
<tr>
<td>ST_Difference()</td>
<td>Return point set difference of two geometries</td>
<td></td>
</tr>
<tr>
<td>ST_Dimension()</td>
<td>Dimension of geometry</td>
<td></td>
</tr>
<tr>
<td>ST_Disjoint()</td>
<td>Whether one geometry is disjoint from another</td>
<td></td>
</tr>
<tr>
<td>ST_Distance()</td>
<td>The distance of one geometry from another</td>
<td></td>
</tr>
<tr>
<td>ST_Distance_Sphere()</td>
<td>Minimum distance on earth between two geometries</td>
<td></td>
</tr>
<tr>
<td>ST_EndPoint()</td>
<td>End Point of LineString</td>
<td></td>
</tr>
<tr>
<td>ST_Envelope()</td>
<td>Return MBR of geometry</td>
<td></td>
</tr>
<tr>
<td>ST_Equals()</td>
<td>Whether one geometry is equal to another</td>
<td></td>
</tr>
<tr>
<td>ST_ExteriorRing()</td>
<td>Return exterior ring of Polygon</td>
<td></td>
</tr>
<tr>
<td>ST_FrechetDistance()</td>
<td>The discrete Fréchet distance of one geometry from another</td>
<td>8.0.23</td>
</tr>
<tr>
<td>ST_GeoHash()</td>
<td>Produce a geohash value</td>
<td></td>
</tr>
<tr>
<td>ST_GeomCollFromText()</td>
<td>Return geometry collection from WKT</td>
<td></td>
</tr>
<tr>
<td>ST_GeometryCollectionFromText()</td>
<td></td>
<td></td>
</tr>
<tr>
<td>ST_GeomCollFromTxt()</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Introduced</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
<td>------------</td>
</tr>
<tr>
<td>ST_GeomCollFromWKB(), ST_GeometryCollectionFromWKB()</td>
<td>Return geometry collection from WKB</td>
<td>8.0.23</td>
</tr>
<tr>
<td>ST_GeometryN()</td>
<td>Return N-th geometry from geometry collection</td>
<td>8.0.12</td>
</tr>
<tr>
<td>ST_GeometryType()</td>
<td>Return name of geometry type</td>
<td>8.0.12</td>
</tr>
<tr>
<td>ST_GeomFromGeoJSON()</td>
<td>Generate geometry from GeoJSON object</td>
<td>8.0.12</td>
</tr>
<tr>
<td>ST_GeomFromText(), ST_GeometryFromText()</td>
<td>Return geometry from WKT</td>
<td>8.0.12</td>
</tr>
<tr>
<td>ST_GeomFromWKB(), ST_GeometryFromWKB()</td>
<td>Return geometry from WKB</td>
<td>8.0.12</td>
</tr>
<tr>
<td>ST_HausdorffDistance()</td>
<td>The discrete Hausdorff distance of one geometry from another</td>
<td>8.0.12</td>
</tr>
<tr>
<td>ST_InteriorRingN()</td>
<td>Return N-th interior ring of Polygon</td>
<td>8.0.12</td>
</tr>
<tr>
<td>ST_Intersection()</td>
<td>Return point set intersection of two geometries</td>
<td>8.0.12</td>
</tr>
<tr>
<td>ST_Intersects()</td>
<td>Whether one geometry intersects another</td>
<td>8.0.12</td>
</tr>
<tr>
<td>ST_IsClosed()</td>
<td>Whether a geometry is closed and simple</td>
<td>8.0.12</td>
</tr>
<tr>
<td>ST_IsEmpty()</td>
<td>Whether a geometry is empty</td>
<td>8.0.12</td>
</tr>
<tr>
<td>ST_IsSimple()</td>
<td>Whether a geometry is simple</td>
<td>8.0.12</td>
</tr>
<tr>
<td>ST_IsValid()</td>
<td>Whether a geometry is valid</td>
<td>8.0.12</td>
</tr>
<tr>
<td>ST_LatFromGeoHash()</td>
<td>Return latitude from geohash value</td>
<td>8.0.12</td>
</tr>
<tr>
<td>ST_Latitude()</td>
<td>Return latitude of Point</td>
<td>8.0.12</td>
</tr>
<tr>
<td>ST_Length()</td>
<td>Return length of LineString</td>
<td>8.0.12</td>
</tr>
<tr>
<td>ST_LineFromText(), ST_LineStringFromText()</td>
<td>Construct LineString from WKT</td>
<td>8.0.12</td>
</tr>
<tr>
<td>ST_LineFromWKB(), ST_LineStringFromWKB()</td>
<td>Construct LineString from WKB</td>

### 12.17.2 Argument Handling by Spatial Functions

Spatial values, or geometries, have the properties described in Section 11.4.2.2, “Geometry Class”. The following discussion lists general spatial function argument-handling characteristics. Specific functions or groups of functions may have additional or different argument-handling characteristics, as discussed in the sections where those function descriptions occur. Where that is true, those descriptions take precedence over the general discussion here.

Spatial functions are defined only for valid geometry values. See Section 11.4.4, “Geometry Well-Formedness and Validity”.

Each geometry value is associated with a spatial reference system (SRS), which is a coordinate-based system for geographic locations. See Section 11.4.5, “Spatial Reference System Support”.

The spatial reference identifier (SRID) of a geometry identifies the SRS in which the geometry is defined. In MySQL, the SRID value is an integer associated with the geometry value. The maximum usable SRID value is $2^{32} - 1$. If a larger value is given, only the lower 32 bits are used.

SRID 0 represents an infinite flat Cartesian plane with no units assigned to its axes. To ensure SRID 0 behavior, create geometry values using SRID 0. SRID 0 is the default for new geometry values if no SRID is specified.

For computations on multiple geometry values, all values must be in the same SRS or an error occurs. Thus, spatial functions that take multiple geometry arguments require those arguments to be in the same SRS. If a spatial function returns `ER_GIS_DIFFERENT_SRIDS`, it means that the geometry arguments were not all in the same SRS. You must modify them to have the same SRS.

</tbody>
</table>
A geometry returned by a spatial function is in the SRS of the geometry arguments because geometry values produced by any spatial function inherit the SRID of the geometry arguments.

The Open Geospatial Consortium guidelines require that input polygons already be closed, so unclosed polygons are rejected as invalid rather than being closed.

In MySQL, the only valid empty geometry is represented in the form of an empty geometry collection. Empty geometry collection handling is as follows: An empty WKT input geometry collection may be specified as `GEOMETRYCOLLECTION()`. This is also the output WKT resulting from a spatial operation that produces an empty geometry collection.

During parsing of a nested geometry collection, the collection is flattened and its basic components are used in various GIS operations to compute results. This provides additional flexibility to users because it is unnecessary to be concerned about the uniqueness of geometry data. Nested geometry collections may be produced from nested GIS function calls without having to be explicitly flattened first.

### 12.17.3 Functions That Create Geometry Values from WKT Values

These functions take as arguments a Well-Known Text (WKT) representation and, optionally, a spatial reference system identifier (SRID). They return the corresponding geometry. For a description of WKT format, see Well-Known Text (WKT) Format.

Functions in this section detect arguments in either Cartesian or geographic spatial reference systems (SRSs), and return results appropriate to the SRS.

**ST_GeomFromText()** accepts a WKT value of any geometry type as its first argument. Other functions provide type-specific construction functions for construction of geometry values of each geometry type.

Functions such as **ST_MPointFromText()** and **ST_GeomFromText()** that accept WKT-format representations of MultiPoint values permit individual points within values to be surrounded by parentheses. For example, both of the following function calls are valid:

```sql
ST_MPointFromText('MULTIPOINT (1 1, 2 2, 3 3)')
ST_MPointFromText('MULTIPOINT ((1 1), (2 2), (3 3))')
```

Functions such as **ST_GeomFromText()** that accept WKT geometry collection arguments understand both OpenGIS 'GEOMETRYCOLLECTION EMPTY' standard syntax and MySQL 'GEOMETRYCOLLECTION()' nonstandard syntax. Functions such as **ST_AsWKT()** that produce WKT values produce 'GEOMETRYCOLLECTION EMPTY' standard syntax:

```sql
mysql> SET @s1 = ST_GeomFromText('GEOMETRYCOLLECTION()');
mysql> SET @s2 = ST_GeomFromText('GEOMETRYCOLLECTION EMPTY');
mysql> SELECT ST_AsWKT(@s1), ST_AsWKT(@s2);
```

<table>
<thead>
<tr>
<th>ST_AsWKT(@s1)</th>
<th>ST_AsWKT(@s2)</th>
</tr>
</thead>
<tbody>
<tr>
<td>GEOMETRYCOLLECTION EMPTY</td>
<td>GEOMETRYCOLLECTION EMPTY</td>
</tr>
</tbody>
</table>

Unless otherwise specified, functions in this section handle their geometry arguments as follows:

- If any geometry argument is **NULL** or is not a syntactically well-formed geometry, or if the SRID argument is **NULL**, the return value is **NULL**.

- By default, geographic coordinates (latitude, longitude) are interpreted as in the order specified by the spatial reference system of geometry arguments. An optional **options** argument may be given to override the default axis order. **options** consists of a list of comma-separated `key=value`. The only permitted `key` value is `axis-order`, with permitted values of `lat-long`, `long-lat` and `srid-defined` (the default).

  If the **options** argument is **NULL**, the return value is **NULL**. If the **options** argument is invalid, an error occurs to indicate why.
• If an SRID argument refers to an undefined spatial reference system (SRS), an `ER_SRS_NOT_FOUND` error occurs.

• For geographic SRS geometry arguments, if any argument has a longitude or latitude that is out of range, an error occurs:
  • If a longitude value is not in the range \((-180, 180]\), an `ER_LONGITUDE_OUT_OF_RANGE` error occurs.
  • If a latitude value is not in the range \([-90, 90]\), an `ER_LATITUDE_OUT_OF_RANGE` error occurs.

Ranges shown are in degrees. If an SRS uses another unit, the range uses the corresponding values in its unit. The exact range limits deviate slightly due to floating-point arithmetic.

These functions are available for creating geometries from WKT values:

• `ST_GeomCollFromText(wkt [, srid [, options]]), ST_GeometryCollectionFromText(wkt [, srid [, options]]), ST_GeomCollFromTxt(wkt [, srid [, options]])`
  
  Constructs a `GeometryCollection` value using its WKT representation and SRID.

  These functions handle their arguments as described in the introduction to this section.

```sql
mysql> SET @g = "MULTILINESTRING((10 10, 11 11), (9 9, 10 10))";
mysql> SELECT ST_AsText(ST_GeomCollFromText(@g));
+--------------------------------------------+
| ST_AsText(ST_GeomCollFromText(@g))         |
+--------------------------------------------+
| MULTILINESTRING((10 10,11 11),(9 9,10 10)) |
+--------------------------------------------+
```

• `ST_GeomFromText(wkt [, srid [, options]]), ST_GeometryFromText(wkt [, srid [, options]])`
  
  Constructs a `Geometry` value of any type using its WKT representation and SRID.

  These functions handle their arguments as described in the introduction to this section.

• `ST_LineFromText(wkt [, srid [, options]]), ST_LineStringFromText(wkt [, srid [, options]])`
  
  Constructs a `LineString` value using its WKT representation and SRID.

  These functions handle their arguments as described in the introduction to this section.

• `ST_MLineFromText(wkt [, srid [, options]]), ST_MultiLineStringFromText(wkt [, srid [, options]])`
  
  Constructs a `MultiLineString` value using its WKT representation and SRID.

  These functions handle their arguments as described in the introduction to this section.

• `ST_MPointFromText(wkt [, srid [, options]]), ST_MultiPointFromText(wkt [, srid [, options]])`
  
  Constructs a `MultiPoint` value using its WKT representation and SRID.

  These functions handle their arguments as described in the introduction to this section.

• `ST_MPolyFromText(wkt [, srid [, options]]), ST_MultiPolygonFromText(wkt [, srid [, options]])`
  
  Constructs a `MultiPolygon` value using its WKT representation and SRID.
Functions That Create Geometry Values from WKB Values

These functions handle their arguments as described in the introduction to this section.

- **ST_PointFromText**(wkt [, srid [, options]])
  Constructs a *Point* value using its WKT representation and SRID.

**ST_PointFromText()** handles its arguments as described in the introduction to this section.

- **ST_PolyFromText**(wkt [, srid [, options]]), **ST_PolygonFromText**(wkt [, srid [, options]])
  Constructs a *Polygon* value using its WKT representation and SRID.

These functions handle their arguments as described in the introduction to this section.

### 12.17.4 Functions That Create Geometry Values from WKB Values

These functions take as arguments a *BLOB* containing a Well-Known Binary (WKB) representation and, optionally, a spatial reference system identifier (SRID). They return the corresponding geometry. For a description of WKB format, see *Well-Known Binary (WKB) Format*.

Functions in this section detect arguments in either Cartesian or geographic spatial reference systems (SRSs), and return results appropriate to the SRS.

**ST_GeomFromWKB()** accepts a WKB value of any geometry type as its first argument. Other functions provide type-specific construction functions for construction of geometry values of each geometry type.

Prior to MySQL 8.0, these functions also accepted geometry objects as returned by the functions in Section 12.17.5, “MySQL-Specific Functions That Create Geometry Values”. Geometry arguments are no longer permitted and produce an error. To migrate calls from using geometry arguments to using WKB arguments, follow these guidelines:

- Rewrite constructs such as `ST_GeomFromWKB(Point(0, 0))` as `Point(0, 0)`.
- Rewrite constructs such as `ST_GeomFromWKB(Point(0, 0), 4326)` as `ST_SRID(Point(0, 0), 4326)` or `ST_GeomFromWKB(ST_AsWKB(Point(0, 0)), 4326)`.

Unless otherwise specified, functions in this section handle their geometry arguments as follows:

- If the WKB or SRID argument is **NULL**, the return value is **NULL**.

- By default, geographic coordinates (latitude, longitude) are interpreted as in the order specified by the spatial reference system of geometry arguments. An optional **options** argument may be given to override the default axis order. **options** consists of a list of comma-separated **key=value**. The only permitted **key** value is **axis-order**, with permitted values of **lat-long**, **long-lat** and **srid-defined** (the default).

  If the **options** argument is **NULL**, the return value is **NULL**. If the **options** argument is invalid, an error occurs to indicate why.

- If an SRID argument refers to an undefined spatial reference system (SRS), an **ER_SRS_NOT_FOUND** error occurs.

- For geographic SRS geometry arguments, if any argument has a longitude or latitude that is out of range, an error occurs:
  - If a longitude value is not in the range (−180, 180], an **ER_LONGITUDE_OUT_OF_RANGE** error occurs.
  - If a latitude value is not in the range [−90, 90], an **ER_LATITUDE_OUT_OF_RANGE** error occurs.
Ranges shown are in degrees. If an SRS uses another unit, the range uses the corresponding values in its unit. The exact range limits deviate slightly due to floating-point arithmetic.

These functions are available for creating geometries from WKB values:

- `ST_GeomCollFromWKB(wkb [, srid [, options]])`, `ST_GeometryCollectionFromWKB(wkb [, srid [, options]])`

  Constructs a `GeometryCollection` value using its WKB representation and SRID.

  These functions handle their arguments as described in the introduction to this section.

- `ST_GeomFromWKB(wkb [, srid [, options]])`, `ST_GeometryFromWKB(wkb [, srid [, options]])`

  Constructs a geometry value of any type using its WKB representation and SRID.

  These functions handle their arguments as described in the introduction to this section.

- `ST_LineFromWKB(wkb [, srid [, options]])`, `ST_LineStringFromWKB(wkb [, srid [, options]])`

  Constructs a `LineString` value using its WKB representation and SRID.

  These functions handle their arguments as described in the introduction to this section.

- `ST_MLineFromWKB(wkb [, srid [, options]])`, `ST_MultiLineStringFromWKB(wkb [, srid [, options]])`

  Constructs a `MultiLineString` value using its WKB representation and SRID.

  These functions handle their arguments as described in the introduction to this section.

- `ST_MPointFromWKB(wkb [, srid [, options]])`, `ST_MultiPointFromWKB(wkb [, srid [, options]])`

  Constructs a `MultiPoint` value using its WKB representation and SRID.

  These functions handle their arguments as described in the introduction to this section.

- `ST_MPolyFromWKB(wkb [, srid [, options]])`, `ST_MultiPolygonFromWKB(wkb [, srid [, options]])`

  Constructs a `MultiPolygon` value using its WKB representation and SRID.

  These functions handle their arguments as described in the introduction to this section.

- `ST_PointFromWKB(wkb [, srid [, options]])`

  Constructs a `Point` value using its WKB representation and SRID.

  `ST_PointFromWKB()` handles its arguments as described in the introduction to this section.

- `ST_PolyFromWKB(wkb [, srid [, options]])`, `ST_PolygonFromWKB(wkb [, srid [, options]])`

  Constructs a `Polygon` value using its WKB representation and SRID.

  These functions handle their arguments as described in the introduction to this section.
12.17.5 MySQL-Specific Functions That Create Geometry Values

MySQL provides a set of useful nonstandard functions for creating geometry values. The functions described in this section are MySQL extensions to the OpenGIS specification.

These functions produce geometry objects from either WKB values or geometry objects as arguments. If any argument is not a proper WKB or geometry representation of the proper object type, the return value is NULL.

For example, you can insert the geometry return value from `Point()` directly into a `POINT` column:

```sql
INSERT INTO t1 (pt_col) VALUES(Point(1,2));
```

- **GeomCollection( \( g \), \( g \) ...)**
  
  Constructs a `GeomCollection` value from the geometry arguments.

  `GeomCollection()` returns all the proper geometries contained in the arguments even if a nonsupported geometry is present.

  `GeomCollection()` with no arguments is permitted as a way to create an empty geometry. Also, functions such as `ST_GeomFromText()` that accept WKT geometry collection arguments understand both OpenGIS 'GEOMETRYCOLLECTION EMPTY' standard syntax and MySQL 'GEOMETRYCOLLECTION()' nonstandard syntax.

  `GeomCollection()` and `GeometryCollection()` are synonymous, with `GeomCollection()` the preferred function.

- **GeometryCollection( \( g \), \( g \) ...)**
  
  Constructs a `GeometryCollection` value from the geometry arguments.

  `GeometryCollection()` returns all the proper geometries contained in the arguments even if a nonsupported geometry is present.

  `GeometryCollection()` with no arguments is permitted as a way to create an empty geometry. Also, functions such as `ST_GeomFromText()` that accept WKT geometry collection arguments understand both OpenGIS 'GEOMETRYCOLLECTION EMPTY' standard syntax and MySQL 'GEOMETRYCOLLECTION()' nonstandard syntax.

  `GeomCollection()` and `GeometryCollection()` are synonymous, with `GeomCollection()` the preferred function.

- **LineString( \( pt \), \( pt \) ...)**
  
  Constructs a `LineString` value from a number of `Point` or WKB `Point` arguments. If the number of arguments is less than two, the return value is NULL.

- **MultiLineString( \( ls \), \( ls \) ...)**
  
  Constructs a `MultiLineString` value using `LineString` or WKB `LineString` arguments.

- **MultiPoint( \( pt \), \( pt2 \) ...)**
  
  Constructs a `MultiPoint` value using `Point` or WKB `Point` arguments.

- **MultiPolygon( \( poly \), \( poly \) ...)**
  
  Constructs a `MultiPolygon` value from a set of `Polygon` or WKB `Polygon` arguments.

- **Point( \( x \), \( y \)**
  
  Constructs a `Point` using its coordinates.
Geometry Format Conversion Functions

- **Polygon(ls [, ls] ...)**
  Constructs a Polygon value from a number of LineString or WKB LineString arguments. If any argument does not represent a LinearRing (that is, not a closed and simple LineString), the return value is NULL.

### 12.17.6 Geometry Format Conversion Functions

MySQL supports the functions listed in this section for converting geometry values from internal geometry format to WKT or WKB format, or for swapping the order of X and Y coordinates.

There are also functions to convert a string from WKT or WKB format to internal geometry format. See Section 12.17.3, "Functions That Create Geometry Values from WKT Values", and Section 12.17.4, "Functions That Create Geometry Values from WKB Values".

Functions such as `ST_GeomFromText()` that accept WKT geometry collection arguments understand both OpenGIS 'GEOMETRYCOLLECTION EMPTY' standard syntax and MySQL 'GEOMETRYCOLLECTION()' nonstandard syntax. Another way to produce an empty geometry collection is by calling `GeometryCollection()` with no arguments. Functions such as `ST_AsWKT()` that produce WKT values produce 'GEOMETRYCOLLECTION EMPTY' standard syntax:

```sql
mysql> SET @s1 = ST_GeomFromText('GEOMETRYCOLLECTION()');
mysql> SET @s2 = ST_GeomFromText('GEOMETRYCOLLECTION EMPTY');
mysql> SELECT ST_AsWKT(@s1), ST_AsWKT(@s2);
+--------------------------+--------------------------+
| ST_AsWKT(@s1)            | ST_AsWKT(@s2)            |
| GEOMETRYCOLLECTION EMPTY | GEOMETRYCOLLECTION EMPTY |
+--------------------------+--------------------------+
mysql> SELECT ST_AsWKT(GeomCollection());
+----------------------------+
| ST_AsWKT(GeomCollection()) |
| GEOMETRYCOLLECTION EMPTY   |
+----------------------------+
```

Unless otherwise specified, functions in this section handle their geometry arguments as follows:

- If any argument is NULL, the return value is NULL.
- If any geometry argument is not a syntactically well-formed geometry, an ER_GIS_INVALID_DATA error occurs.
- If any geometry argument is in an undefined spatial reference system, the axes are output in the order they appear in the geometry and an ER_WARN_SRS_NOT_FOUND_AXIS_ORDER warning occurs.
- By default, geographic coordinates (latitude, longitude) are interpreted as in the order specified by the spatial reference system of geometry arguments. An optional options argument may be given to override the default axis order. options consists of a list of comma-separated key=value. The only permitted key value is axis-order, with permitted values of lat-long, long-lat and srid-defined (the default).

If the options argument is NULL, the return value is NULL. If the options argument is invalid, an error occurs to indicate why.

- Otherwise, the return value is non-NULL.

These functions are available for format conversions or coordinate swapping:

- `ST_AsBinary(g [, options]), ST_AsWKB(g [, options])`
  Converts a value in internal geometry format to its WKB representation and returns the binary result.
The function return value has geographic coordinates (latitude, longitude) in the order specified by the spatial reference system that applies to the geometry argument. An optional *options* argument may be given to override the default axis order.

**ST_AsBinary()** and **ST_AsWKB()** handle their arguments as described in the introduction to this section.

```sql
mysql> SET @g = ST_LineFromText('LINESTRING(0 5,5 10,10 15)', 4326);
mysql> SELECT ST_AsText(ST_GeomFromWKB(ST_AsWKB(@g)));
+-----------------------------------------+
| ST_AsText(ST_GeomFromWKB(ST_AsWKB(@g))) |
+-----------------------------------------+
| LINESTRING(5,0,10,5,15,10)              |
+-----------------------------------------+
```

```sql
mysql> SELECT ST_AsText(ST_GeomFromWKB(ST_AsWKB(@g, 'axis-order=long-lat')));
+----------------------------------------------------------------+
| ST_AsText(ST_GeomFromWKB(ST_AsWKB(@g, 'axis-order=long-lat'))) |
+----------------------------------------------------------------+
| LINESTRING(0,5,10,10,15)                                     |
+----------------------------------------------------------------+
```

```sql
mysql> SELECT ST_AsText(ST_GeomFromWKB(ST_AsWKB(@g, 'axis-order=lat-long')));
+----------------------------------------------------------------+
| ST_AsText(ST_GeomFromWKB(ST_AsWKB(@g, 'axis-order=lat-long'))) |
+----------------------------------------------------------------+
| LINESTRING(5,0,10,5,15,10)                                     |
+----------------------------------------------------------------+
```

**ST_AsText( g [, options])**, **ST_AsWKT( g [, options])**

Converts a value in internal geometry format to its WKT representation and returns the string result.

The function return value has geographic coordinates (latitude, longitude) in the order specified by the spatial reference system that applies to the geometry argument. An optional *options* argument may be given to override the default axis order.

**ST_AsText()** and **ST_AsWKT()** handle their arguments as described in the introduction to this section.

```sql
mysql> SET @g = 'LineString(1 1,2 2,3 3)';
mysql> SELECT ST_AsText(ST_GeomFromText(@g));
+--------------------------------+
| ST_AsText(ST_GeomFromText(@g)) |
| LINESTRING(1,1,2,2,3,3)        |
+--------------------------------+
```

Output for **MultiPoint** values includes parentheses around each point. For example:

```sql
mysql> SELECT ST_AsText(ST_GeomFromText(@mp));
+-----------------------------------------------+
| ST_AsText(ST_GeomFromText(@mp))               |
| MULTIPOINT((1,1),(2,2),(3,3))                 |
+-----------------------------------------------+
```

**ST_SwapXY( g)**

Accepts an argument in internal geometry format, swaps the X and Y values of each coordinate pair within the geometry, and returns the result.

**ST_SwapXY()** handles its arguments as described in the introduction to this section.

```sql
mysql> SET @g = ST_LineFromText('LINESTRING(0 5,5 10,10 15)');
mysql> SELECT ST_AsText(@g);
+----------------------------+
| ST_AsText(@g)              |
| LINESTRING(0,5,10,10,15,0) |
+----------------------------+
```
12.17.7 Geometry Property Functions

Each function that belongs to this group takes a geometry value as its argument and returns some quantitative or qualitative property of the geometry. Some functions restrict their argument type. Such functions return NULL if the argument is of an incorrect geometry type. For example, the ST_Area() polygon function returns NULL if the object type is neither Polygon nor MultiPolygon.

12.17.7.1 General Geometry Property Functions

The functions listed in this section do not restrict their argument and accept a geometry value of any type.

Unless otherwise specified, functions in this section handle their geometry arguments as follows:

• If any argument is NULL, the return value is NULL.

• If any geometry argument is not a syntactically well-formed geometry, an ER_GIS_INVALID_DATA error occurs.

• If any geometry argument is a syntactically well-formed geometry in an undefined spatial reference system (SRS), an ER_SRS_NOT_FOUND error occurs.

• If any SRID argument is not within the range of a 32-bit unsigned integer, an ER_DATA_OUT_OF_RANGE error occurs.

• If any SRID argument refers to an undefined SRS, an ER_SRS_NOT_FOUND error occurs.

• Otherwise, the return value is non-NULL.

These functions are available for obtaining geometry properties:

• **ST_Dimension(g)**
  
  Returns the inherent dimension of the geometry value g. The dimension can be −1, 0, 1, or 2. The meaning of these values is given in Section 11.4.2.2, “Geometry Class”.

  ST_Dimension() handles its arguments as described in the introduction to this section.

  ```sql
  mysql> SELECT ST_Dimension(ST_GeomFromText('LineString(1 1,2 2)'));
  +------------------------------------------------------+
  | ST_Dimension(ST_GeomFromText('LineString(1 1,2 2)')) |
  +------------------------------------------------------+
  |                                                    1 |
  +------------------------------------------------------+
  ```

• **ST_Envelope(g)**

  Returns the minimum bounding rectangle (MBR) for the geometry value g. The result is returned as a Polygon value that is defined by the corner points of the bounding box:

  POLYGON((MINX MINY, MAXX MINY, MAXX MAXY, MINX MAXY, MINX MINY))

  ```sql
  mysql> SELECT ST_AsText(ST_Envelope(ST_GeomFromText('LineString(1 1,2 2)')));
  +----------------------------------------------------------------+
  | ST_AsText(ST_Envelope(ST_GeomFromText('LineString(1 1,2 2)'))) |
  +----------------------------------------------------------------+
  | POLYGON((1 1,2 1,2 2,1 2,1 1))                                 |
  +----------------------------------------------------------------+
  ```

...
If the argument is a point or a vertical or horizontal line segment, \texttt{ST_Envelope()} returns the point or the line segment as its MBR rather than returning an invalid polygon:

```
mysql> SELECT ST_AsText(ST_Envelope(ST_GeomFromText('LineString(1 1,1 2)')));
```

\texttt{ST_Envelope()} handles its arguments as described in the introduction to this section, with this exception:

- If the geometry has an SRID value for a geographic spatial reference system (SRS), an \texttt{ER_NOT_IMPLEMENTED_FOR_GEOGRAPHIC_SRS} error occurs.

- \texttt{ST_GeometryType(}g\texttt{)}

Returns a binary string indicating the name of the geometry type of which the geometry instance \texttt{g} is a member. The name corresponds to one of the instantiable \texttt{Geometry} subclasses.

\texttt{ST_GeometryType()} handles its arguments as described in the introduction to this section.

```
mysql> SELECT ST_GeometryType(ST_GeomFromText('POINT(1 1)'));
```

- \texttt{ST_IsEmpty(}g\texttt{)}

This function is a placeholder that returns 1 for an empty geometry collection value or 0 otherwise.

The only valid empty geometry is represented in the form of an empty geometry collection value. MySQL does not support GIS \texttt{EMPTY} values such as \texttt{POINT EMPTY}.

\texttt{ST_IsEmpty()} handles its arguments as described in the introduction to this section.
Geometry Property Functions

• **ST_IsSimple**(*g*)

Returns 1 if the geometry value *g* is simple according to the ISO SQL/MM Part 3: Spatial standard. **ST_IsSimple**() returns 0 if the argument is not simple.

The descriptions of the instantiable geometric classes given under Section 11.4.2, “The OpenGIS Geometry Model” include the specific conditions that cause class instances to be classified as not simple.

**ST_IsSimple**() handles its arguments as described in the introduction to this section, with this exception:

• If the geometry has a geographic SRS with a longitude or latitude that is out of range, an error occurs:
  
  • If a longitude value is not in the range (-180, 180], an **ER_GEOMETRY_PARAM_LONGITUDE_OUT_OF_RANGE** error occurs *(**ER_LONGITUDE_OUT_OF_RANGE** prior to MySQL 8.0.12).*
  
  • If a latitude value is not in the range [-90, 90], an **ER_GEOMETRY_PARAM_LATITUDE_OUT_OF_RANGE** error occurs *(**ER_LATITUDE_OUT_OF_RANGE** prior to MySQL 8.0.12).*

Ranges shown are in degrees. The exact range limits deviate slightly due to floating-point arithmetic.

• **ST_SRID**(*g*, [, *srid]*)

With a single argument representing a valid geometry object *g*, **ST_SRID**() returns an integer indicating the ID of the spatial reference system (SRS) associated with *g*.

With the optional second argument representing a valid SRID value, **ST_SRID**() returns an object with the same type as its first argument with an SRID value equal to the second argument. This only sets the SRID value of the object; it does not perform any transformation of coordinate values.

**ST_SRID**() handles its arguments as described in the introduction to this section, with this exception:

• For the single-argument syntax, **ST_SRID**() returns the geometry SRID even if it refers to an undefined SRS. An **ER_SRS_NOT_FOUND** error does not occur.

**ST_SRID**(*g*, *target_srid*) and **ST_Transform**(*g*, *target_srid*) differ as follows:

• **ST_SRID**() changes the geometry SRID value without transforming its coordinates.

• **ST_Transform**() transforms the geometry coordinates in addition to changing its SRID value.

```sql
mysql> SET @g = ST_GeomFromText('LineString(1 1,2 2)', 0);
mysql> SELECT ST_SRID(@g);
+-------------+
| ST_SRID(@g) |
+-------------+
|           0 |
+-------------+
mysql> SET @g = ST_SRID(@g, 4326);
mysql> SELECT ST_SRID(@g);
+-------------+
| ST_SRID(@g) |
+-------------+
|        4326 |
```
### Geometry Property Functions

It is possible to create a geometry in a particular SRID by passing to `ST_SRID()` the result of one of the MySQL-specific functions for creating spatial values, along with an SRID value. For example:

```sql
SET @g1 = ST_SRID(Point(1, 1), 4326);
```

However, that method creates the geometry in SRID 0, then casts it to SRID 4326 (WGS 84). A preferable alternative is to create the geometry with the correct spatial reference system to begin with. For example:

```sql
SET @g1 = ST_PointFromText('POINT(1 1)', 4326);
SET @g1 = ST_GeomFromText('POINT(1 1)', 4326);
```

The two-argument form of `ST_SRID()` is useful for tasks such as correcting or changing the SRS of geometries that have an incorrect SRID.

#### 12.17.7.2 Point Property Functions

A `Point` consists of X and Y coordinates, which may be obtained using the `ST_X()` and `ST_Y()` functions, respectively. These functions also permit an optional second argument that specifies an X or Y coordinate value, in which case the function result is the `Point` object from the first argument with the appropriate coordinate modified to be equal to the second argument.

For `Point` objects that have a geographic spatial reference system (SRS), the longitude and latitude may be obtained using the `ST_Longitude()` and `ST_Latitude()` functions, respectively. These functions also permit an optional second argument that specifies a longitude or latitude value, in which case the function result is the `Point` object from the first argument with the longitude or latitude modified to be equal to the second argument.

Unless otherwise specified, functions in this section handle their geometry arguments as follows:

- If any argument is `NULL`, the return value is `NULL`.
- If any geometry argument is a valid geometry but not a `Point` object, an `ER_UNEXPECTED_GEOMETRY_TYPE` error occurs.
- If any geometry argument is not a syntactically well-formed geometry, an `ER_GIS_INVALID_DATA` error occurs.
- If any geometry argument is a syntactically well-formed geometry in an undefined spatial reference system (SRS), an `ER_SRS_NOT_FOUND` error occurs.
- If an X or Y coordinate argument is provided and the value is `-inf`, `+inf`, or `NaN`, an `ER_DATA_OUT_OF_RANGE` error occurs.
- If a longitude or latitude value is out of range, an error occurs:
  - If a longitude value is not in the range `[-180, 180]`, an `ER_LONGITUDE_OUT_OF_RANGE` error occurs.
  - If a latitude value is not in the range `[-90, 90]`, an `ER_LATITUDE_OUT_OF_RANGE` error occurs.

Ranges shown are in degrees. The exact range limits deviate slightly due to floating-point arithmetic.

- Otherwise, the return value is non-`NULL`.

These functions are available for obtaining point properties:

- `ST_Latitude(p [, new_latitude_val])`

  With a single argument representing a valid `Point` object `p` that has a geographic spatial reference system (SRS), `ST_Latitude()` returns the latitude value of `p` as a double-precision number.
With the optional second argument representing a valid latitude value, \texttt{ST\_Latitude()} returns a \texttt{Point} object like the first argument with its latitude equal to the second argument.

\texttt{ST\_Latitude()} handles its arguments as described in the introduction to this section, with the addition that if the \texttt{Point} object is valid but does not have a geographic SRS, an \texttt{ER\_SRS\_NOT\_GEOGRAPHIC} error occurs.

\begin{verbatim}
mysql> SET @pt = ST_GeomFromText('POINT(45 90)', 4326);
mysql> SELECT ST_Latitude(@pt);
+------------------+
<table>
<thead>
<tr>
<th>ST_Latitude(@pt)</th>
</tr>
</thead>
<tbody>
<tr>
<td>45</td>
</tr>
</tbody>
</table>
+------------------+

mysql> SELECT ST_AsText(ST_Latitude(@pt, 10));
+---------------------------------+
<table>
<thead>
<tr>
<th>ST_AsText(ST_Latitude(@pt, 10))</th>
</tr>
</thead>
<tbody>
<tr>
<td>POINT(10 90)</td>
</tr>
</tbody>
</table>
+---------------------------------+
\end{verbatim}

This function was added in MySQL 8.0.12.

\textbullet{} \texttt{ST\_Longitude(p [, new_longitude_val])}

With a single argument representing a valid \texttt{Point} object \texttt{p} that has a geographic spatial reference system (SRS), \texttt{ST\_Longitude()} returns the longitude value of \texttt{p} as a double-precision number.

With the optional second argument representing a valid longitude value, \texttt{ST\_Longitude()} returns a \texttt{Point} object like the first argument with its longitude equal to the second argument.

\texttt{ST\_Longitude()} handles its arguments as described in the introduction to this section, with the addition that if the \texttt{Point} object is valid but does not have a geographic SRS, an \texttt{ER\_SRS\_NOT\_GEOGRAPHIC} error occurs.

\begin{verbatim}
mysql> SET @pt = ST_GeomFromText('POINT(45 90)', 4326);
mysql> SELECT ST_Longitude(@pt);
+-------------------+
<table>
<thead>
<tr>
<th>ST_Longitude(@pt)</th>
</tr>
</thead>
<tbody>
<tr>
<td>90</td>
</tr>
</tbody>
</table>
+-------------------+

mysql> SELECT ST_AsText(ST_Longitude(@pt, 10));
+----------------------------------+
<table>
<thead>
<tr>
<th>ST_AsText(ST_Longitude(@pt, 10))</th>
</tr>
</thead>
<tbody>
<tr>
<td>POINT(45 10)</td>
</tr>
</tbody>
</table>
+----------------------------------+
\end{verbatim}

This function was added in MySQL 8.0.12.

\textbullet{} \texttt{ST\_X(p [, new_x_val])}

With a single argument representing a valid \texttt{Point} object \texttt{p}, \texttt{ST\_X()} returns the X-coordinate value of \texttt{p} as a double-precision number. As of MySQL 8.0.12, the X coordinate is considered to refer to the axis that appears first in the \texttt{Point} spatial reference system (SRS) definition.

With the optional second argument, \texttt{ST\_X()} returns a \texttt{Point} object like the first argument with its X coordinate equal to the second argument. As of MySQL 8.0.12, if the \texttt{Point} object has a geographic SRS, the second argument must be in the proper range for longitude or latitude values.

\texttt{ST\_X()} handles its arguments as described in the introduction to this section.

\begin{verbatim}
mysql> SELECT ST_X(Point(56.7, 53.34));
+--------------------------+
|                        2128 |
+--------------------------+
\end{verbatim}
Geometry Property Functions

• **ST_X(Point, new_x_val)**

With a single argument representing a valid `Point` object `p`, `ST_X()` returns the X-coordinate value of `p` as a double-precision number. As of MySQL 8.0.12, the X coordinate is considered to refer to the axis that appears second in the `Point` spatial reference system (SRS) definition.

With the optional second argument, `ST_X()` returns a `Point` object like the first argument with its X coordinate equal to the second argument. As of MySQL 8.0.12, if the `Point` object has a geographic SRS, the second argument must be in the proper range for longitude or latitude values.

`ST_X()` handles its arguments as described in the introduction to this section.

mysql> SELECT ST_X(Point(56.7, 53.34));
+--------------------------+
<table>
<thead>
<tr>
<th>ST_X(Point(56.7, 53.34))</th>
</tr>
</thead>
<tbody>
<tr>
<td>56.7</td>
</tr>
</tbody>
</table>
+--------------------------+

12.17.7.3 LineString and MultiLineString Property Functions

A `LineString` consists of `Point` values. You can extract particular points of a `LineString`, count the number of points that it contains, or obtain its length.

Some functions in this section also work for `MultiLineString` values.

Unless otherwise specified, functions in this section handle their geometry arguments as follows:

• If any argument is `NULL` or any geometry argument is an empty geometry, the return value is `NULL`.

• If any geometry argument is not a syntactically well-formed geometry, an `ER_GIS_INVALID_DATA` error occurs.

• If any geometry argument is a syntactically well-formed geometry in an undefined spatial reference system (SRS), an `ER_SRS_NOT_FOUND` error occurs.

• Otherwise, the return value is non-`NULL`.

These functions are available for obtaining linestring properties:

• **ST_EndPoint(ls)**

Returns the `Point` that is the endpoint of the `LineString` value `ls`.

`ST_EndPoint()` handles its arguments as described in the introduction to this section.

mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT ST_AsText(ST_EndPoint(ST_GeomFromText(@ls)));
+----------------------------------------------+
<table>
<thead>
<tr>
<th>ST_AsText(ST_EndPoint(ST_GeomFromText(@ls)))</th>
</tr>
</thead>
<tbody>
<tr>
<td>POINT(3 3)</td>
</tr>
</tbody>
</table>
+----------------------------------------------+
ST_IsClosed()

For a LineString value 1s, ST_IsClosed() returns 1 if 1s is closed (that is, its ST_StartPoint() and ST_EndPoint() values are the same).

For a MultiLineString value 1s, ST_IsClosed() returns 1 if 1s is closed (that is, the ST_StartPoint() and ST_EndPoint() values are the same for each LineString in 1s).

ST_IsClosed() returns 0 if 1s is not closed, and NULL if 1s is NULL.

ST_IsClosed() handles its arguments as described in the introduction to this section, with this exception:

- If the geometry has an SRID value for a geographic spatial reference system (SRS), an ER_NOT_IMPLEMENTED_FOR_GEOGRAPHIC_SRS error occurs.

```sql
mysql> SET @ls1 = 'LineString(1 1,2 2,3 3,2 2)';
mysql> SET @ls2 = 'LineString(1 1,2 2,3 3,1 1)';
mysql> SELECT ST_IsClosed(ST_GeomFromText(@ls1));
<table>
<thead>
<tr>
<th>ST_IsClosed(ST_GeomFromText(@ls1))</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
</tr>
</tbody>
</table>
mysql> SELECT ST_IsClosed(ST_GeomFromText(@ls2));
<table>
<thead>
<tr>
<th>ST_IsClosed(ST_GeomFromText(@ls2))</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
</tr>
</tbody>
</table>
mysql> SET @ls3 = 'MultiLineString((1 1,2 2,3 3),(4 4,5 5))';
mysql> SELECT ST_IsClosed(ST_GeomFromText(@ls3));
<table>
<thead>
<tr>
<th>ST_IsClosed(ST_GeomFromText(@ls3))</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
</tr>
</tbody>
</table>
```
Geometry Property Functions

- **ST_Length(ls [, unit])**

  Returns a double-precision number indicating the length of the `LineString` or `MultiLineString` value `ls` in its associated spatial reference system. The length of a `MultiLineString` value is equal to the sum of the lengths of its elements.

  **ST_Length()** computes a result as follows:

  - If the geometry is a valid `LineString` in a Cartesian SRS, the return value is the Cartesian length of the geometry.
  - If the geometry is a valid `MultiLineString` in a Cartesian SRS, the return value is the sum of the Cartesian lengths of its elements.
  - If the geometry is a valid `LineString` in a geographic SRS, the return value is the geodetic length of the geometry in that SRS, in meters.
  - If the geometry is a valid `MultiLineString` in a geographic SRS, the return value is the sum of the geodetic lengths of its elements in that SRS, in meters.

  **ST_Length()** handles its arguments as described in the introduction to this section, with these exceptions:

  - If the geometry is not a `LineString` or `MultiLineString`, the return value is `NULL`.
  - If the geometry is geometrically invalid, either the result is an undefined length (that is, it can be any number), or an error occurs.
  - If the length computation result is `+inf`, an `ER_DATA_OUT_OF_RANGE` error occurs.
  - If the geometry has a geographic SRS with a longitude or latitude that is out of range, an error occurs:
    - If a longitude value is not in the range `(-180, 180]`, an `ER_GEOMETRY_PARAM_LONGITUDE_OUT_OF_RANGE` error occurs (`ER_LONGITUDE_OUT_OF_RANGE` prior to MySQL 8.0.12).
    - If a latitude value is not in the range `[-90, 90]`, an `ER_GEOMETRY_PARAM_LATITUDE_OUT_OF_RANGE` error occurs (`ER_LATITUDE_OUT_OF_RANGE` prior to MySQL 8.0.12).

  Ranges shown are in degrees. The exact range limits deviate slightly due to floating-point arithmetic.

  As of MySQL 8.0.16, **ST_Length()** permits an optional `unit` argument that specifies the linear unit for the returned length value. These rules apply:

  - If a unit is specified but not supported by MySQL, an `ER_UNIT_NOT_FOUND` error occurs.
  - If a supported linear unit is specified and the SRID is 0, an `ER_GEOMETRY_IN_UNKNOWN_LENGTH_UNIT` error occurs.
  - If a supported linear unit is specified and the SRID is not 0, the result is in that unit.
  - If a unit is not specified, the result is in the unit of the SRS of the geometries, whether Cartesian or geographic. Currently, all MySQL SRSs are expressed in meters.

  A unit is supported if it is found in the `INFORMATION_SCHEMA ST_UNITS_OF_MEASURE` table. See Section 26.3.37, “The INFORMATION_SCHEMA ST_UNITS_OF_MEASURE Table”.

  ```sql
  mysql> SET @ls = ST_GeomFromText('LineString(1 1,2 2,3 3)');
  mysql> SELECT ST_Length(@ls);
  ```
• **ST_NumPoints**(ls)

  Returns the number of Point objects in the LineString value *ls*.

  **ST_NumPoints()** handles its arguments as described in the introduction to this section.

  

```sql
mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT ST_NumPoints(ST_GeomFromText(@ls));

+------------------------------------+
<table>
<thead>
<tr>
<th>ST_NumPoints(ST_GeomFromText(@ls))</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
</tr>
</tbody>
</table>
+------------------------------------+
```

• **ST_PointN**(ls, *N*)

  Returns the *N*-th Point in the Linestring value *ls*. Points are numbered beginning with 1.

  **ST_PointN()** handles its arguments as described in the introduction to this section.

  

```sql
mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT ST_AsText(ST_PointN(ST_GeomFromText(@ls),2));

+----------------------------------------------+
<table>
<thead>
<tr>
<th>ST_AsText(ST_PointN(ST_GeomFromText(@ls),2))</th>
</tr>
</thead>
<tbody>
<tr>
<td>POINT(2 2)</td>
</tr>
</tbody>
</table>
+----------------------------------------------+
```

• **ST_StartPoint**(ls)

  Returns the Point that is the start point of the LineString value *ls*.

  **ST_StartPoint()** handles its arguments as described in the introduction to this section.

  

```sql
mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT ST_AsText(ST_StartPoint(ST_GeomFromText(@ls)));
12.17.7.4 Polygon and MultiPolygon Property Functions

Functions in this section return properties of Polygon or MultiPolygon values.

Unless otherwise specified, functions in this section handle their geometry arguments as follows:

- If any argument is NULL or any geometry argument is an empty geometry, the return value is NULL.
- If any geometry argument is not a syntactically well-formed geometry, an ER_GIS_INVALID_DATA error occurs.
- If any geometry argument is a syntactically well-formed geometry in an undefined spatial reference system (SRS), an ER_SRS_NOT_FOUND error occurs.
- For functions that take multiple geometry arguments, if those arguments are not in the same SRS, an ER_GIS_DIFFERENT_SRIDS error occurs.
- Otherwise, the return value is non-NULL.

These functions are available for obtaining polygon properties:

- \texttt{ST\_Area(poly|mpoly)}

Returns a double-precision number indicating the area of the Polygon or MultiPolygon argument, as measured in its spatial reference system.

As of MySQL 8.0.13, \texttt{ST\_Area()} handles its arguments as described in the introduction to this section, with these exceptions:

- If the geometry is geometrically invalid, either the result is an undefined area (that is, it can be any number), or an error occurs.
- If the geometry is valid but is not a Polygon or MultiPolygon object, an ER_UNEXPECTED_GEOMETRY_TYPE error occurs.
- If the geometry is a valid Polygon in a Cartesian SRS, the result is the Cartesian area of the polygon.
- If the geometry is a valid MultiPolygon in a Cartesian SRS, the result is the sum of the Cartesian area of the polygons.
- If the geometry is a valid Polygon in a geographic SRS, the result is the geodetic area of the polygon in that SRS, in square meters.
- If the geometry is a valid MultiPolygon in a geographic SRS, the result is the sum of geodetic area of the polygons in that SRS, in square meters.
- If an area computation results in \(+\text{inf}\), an ER_DATA_OUT_OF_RANGE error occurs.
- If the geometry has a geographic SRS with a longitude or latitude that is out of range, an error occurs:
  - If a longitude value is not in the range \([-180, 180]\], an ER GEOMETRY PARAM LONGITUDE OUT OF RANGE error occurs (ER\_LONGITUDE\_OUT\_OF\_RANGE prior to MySQL 8.0.12).
Geometry Property Functions

- If a latitude value is not in the range \([-90, 90]\), an \texttt{ER GEOMETRY PARAM_LATITUDE_OUT_OF_RANGE} error occurs (\texttt{ER_LATITUDE_OUT_OF_RANGE} prior to MySQL 8.0.12).

Ranges shown are in degrees. The exact range limits deviate slightly due to floating-point arithmetic.

Prior to MySQL 8.0.13, \texttt{ST_Area()} handles its arguments as described in the introduction to this section, with these exceptions:

- For arguments of dimension 0 or 1, the result is 0.
- If a geometry is empty, the return value is 0 rather than \texttt{NULL}.
- For a geometry collection, the result is the sum of the area values of all components. If the geometry collection is empty, its area is returned as 0.
- If the geometry has an SRID value for a geographic spatial reference system (SRS), an \texttt{ER NOT_IMPLEMENTED_FOR_GEOGRAPHIC_SRS} error occurs.

```
mysql> SET @poly = 'Polygon((0 0,0 3,3 0,0 0),(1 1,1 2,2 1,1 1))';
mysql> SELECT ST_Area(ST_GeomFromText(@poly));
+---------------------------------+
| ST_Area(ST_GeomFromText(@poly)) |
+---------------------------------+
|                               4 |
+---------------------------------+
mysql> SET @mpoly = 'MultiPolygon(((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 2,2 1,1 1)))';
mysql> SELECT ST_Area(ST_GeomFromText(@mpoly));
+----------------------------------+
| ST_Area(ST_GeomFromText(@mpoly)) |
+----------------------------------+
|                                8 |
+----------------------------------+
```

- \texttt{ST_Centroid({poly|mpoly})}

Returns the mathematical centroid for the \texttt{Polygon} or \texttt{MultiPolygon} argument as a \texttt{Point}. The result is not guaranteed to be on the \texttt{MultiPolygon}.

This function processes geometry collections by computing the centroid point for components of highest dimension in the collection. Such components are extracted and made into a single \texttt{MultiPolygon}, \texttt{MultiLineString}, or \texttt{MultiPoint} for centroid computation.

\texttt{ST_Centroid()} handles its arguments as described in the introduction to this section, with these exceptions:

- The return value is \texttt{NULL} for the additional condition that the argument is an empty geometry collection.
- If the geometry has an SRID value for a geographic spatial reference system (SRS), an \texttt{ER NOT_IMPLEMENTED_FOR_GEOGRAPHIC_SRS} error occurs.

```
mysql> SET @poly = ST_GeomFromText('POLYGON((0 0,10 0,10 10,0 10,0 0),(5 5,7 5,7 7,5 7,5 5))');
mysql> SELECT ST_GeometryType(@poly),ST_AsText(ST_Centroid(@poly));
+------------------------+--------------------------------------------+
| ST_GeometryType(@poly) | ST_AsText(ST_Centroid(@poly))              |
+------------------------+--------------------------------------------+
| POLYGON                | POINT(4.958333333333333 4.958333333333333) |
+------------------------+--------------------------------------------+
```
Geometry Property Functions

- **ST_ExteriorRing(poly)**

  Returns the exterior ring of the **Polygon** value `poly` as a **LineString**.

  **ST_ExteriorRing()** handles its arguments as described in the introduction to this section.

  ```
  mysql> SET @poly = 'Polygon((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 2,2 1,1 1))';
  mysql> SELECT ST_AsText(ST_ExteriorRing(ST_GeomFromText(@poly)));
  +----------------------------------------------------+
  | ST_AsText(ST_ExteriorRing(ST_GeomFromText(@poly))) |
  +----------------------------------------------------+
  | LINESTRING(0 0,0 3,3 3,3 0,0 0)                    |
  +----------------------------------------------------+
  ```

- **ST_InteriorRingN(poly, N)**

  Returns the `N`-th interior ring for the **Polygon** value `poly` as a **LineString**. Rings are numbered beginning with 1.

  **ST_InteriorRingN()** handles its arguments as described in the introduction to this section.

  ```
  mysql> SET @poly = 'Polygon((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 2,2 1,1 1))';
  mysql> SELECT ST_AsText(ST_InteriorRingN(ST_GeomFromText(@poly),1));
  +-------------------------------------------------------+
  | ST_AsText(ST_InteriorRingN(ST_GeomFromText(@poly),1)) |
  +-------------------------------------------------------+
  | LINESTRING(1 1,1 2,2 2,2 1,1 1)                       |
  +-------------------------------------------------------+
  ```

- **ST_NumInteriorRing(poly), ST_NumInteriorRings(poly)**

  Returns the number of interior rings in the **Polygon** value `poly`.

  **ST_NumInteriorRing()** and **ST_NumInteriorRings()** handle their arguments as described in the introduction to this section.

  ```
  mysql> SET @poly = 'Polygon((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 2,2 1,1 1))';
  mysql> SELECT ST_NumInteriorRings(ST_GeomFromText(@poly));
  +---------------------------------------------+
  | ST_NumInteriorRings(ST_GeomFromText(@poly))  |
  +---------------------------------------------+
  |                                           1 |
  +---------------------------------------------+
  ```

12.17.7.5 GeometryCollection Property Functions

These functions return properties of **GeometryCollection** values.

Unless otherwise specified, functions in this section handle their geometry arguments as follows:

- If any argument is **NULL** or any geometry argument is an empty geometry, the return value is **NULL**.
- If any geometry argument is not a syntactically well-formed geometry, an **ER_GIS_INVALID_DATA** error occurs.
- If any geometry argument is a syntactically well-formed geometry in an undefined spatial reference system (SRS), an **ER_SRS_NOT_FOUND** error occurs.
- Otherwise, the return value is non-**NULL**.

These functions are available for obtaining geometry collection properties:

- **ST_GeometryN(gc, N)**
Spatial Operator Functions

Returns the \( N \)-th geometry in the \texttt{GeometryCollection} value \( gc \). Geometries are numbered beginning with 1.

\texttt{ST_GeometryN()} handles its arguments as described in the introduction to this section.

```
mysql> SET @gc = 'GeometryCollection(Point(1 1),LineString(2 2, 3 3))';
mysql> SELECT ST_AsText(ST_GeometryN(ST_GeomFromText(@gc),1));
+-------------------------------------------------+
| ST_AsText(ST_GeometryN(ST_GeomFromText(@gc),1)) |
| POINT(1 1)                                      |
+-------------------------------------------------+
```

\texttt{ST_NumGeometries(gc)}

Returns the number of geometries in the \texttt{GeometryCollection} value \( gc \).

\texttt{ST_NumGeometries()} handles its arguments as described in the introduction to this section.

```
mysql> SET @gc = 'GeometryCollection(Point(1 1),LineString(2 2, 3 3))';
mysql> SELECT ST_NumGeometries(ST_GeomFromText(@gc));
+----------------------------------------+
| ST_NumGeometries(ST_GeomFromText(@gc)) |
|                                      2 |
+----------------------------------------+
```

### 12.17.8 Spatial Operator Functions

OpenGIS proposes a number of functions that can produce geometries. They are designed to implement spatial operators. These functions support all argument type combinations except those that are inapplicable according to the Open Geospatial Consortium specification.

MySQL also implements certain functions that are extensions to OpenGIS, as noted in the function descriptions. In addition, Section 12.17.7, “Geometry Property Functions”, discusses several functions that construct new geometries from existing ones. See that section for descriptions of these functions:

- \texttt{ST_Envelope(\( g \))}
- \texttt{ST_StartPoint(\( ls \))}
- \texttt{ST_EndPoint(\( ls \))}
- \texttt{ST_PointN(\( ls, N \))}
- \texttt{ST_ExteriorRing(\( poly \))}
- \texttt{ST_InteriorRingN(\( poly, N \))}
- \texttt{ST_GeometryN(\( gc, N \))}

Unless otherwise specified, functions in this section handle their geometry arguments as follows:

- If any argument is \texttt{NULL}, the return value is \texttt{NULL}.
- If any geometry argument is not a syntactically well-formed geometry, an \texttt{ER_GIS_INVALID_DATA} error occurs.
- If any geometry argument is a syntactically well-formed geometry in an undefined spatial reference system (SRS), an \texttt{ER_SRS_NOT_FOUND} error occurs.
- For functions that take multiple geometry arguments, if those arguments are not in the same SRS, an \texttt{ER_GIS_DIFFERENT_SRIDS} error occurs.
Spatial Operator Functions

- If any geometry argument has an SRID value for a geographic SRS and the function does not handle geographic geometries, an `ER_NOT_IMPLEMENTED_FOR_GEOGRAPHIC_SRS` error occurs.

- For geographic SRS geometry arguments, if any argument has a longitude or latitude that is out of range, an error occurs:
  - If a longitude value is not in the range \((-180, 180]\), an `ER_GEOMETRY_PARAM_LONGITUDE_OUT_OF_RANGE` error occurs (prior to MySQL 8.0.12).
  - If a latitude value is not in the range \([-90, 90]\), an `ER_GEOMETRY_PARAM_LATITUDE_OUT_OF_RANGE` error occurs (prior to MySQL 8.0.12).

Ranges shown are in degrees. If an SRS uses another unit, the range uses the corresponding values in its unit. The exact range limits deviate slightly due to floating-point arithmetic.

- Otherwise, the return value is non-NULL.

These spatial operator functions are available:

- `ST_Buffer(g, d [, strategy1 [, strategy2 [, strategy3]]]])`

  Returns a geometry that represents all points whose distance from the geometry value `g` is less than or equal to a distance of `d`. The result is in the same SRS as the geometry argument.

  If the geometry argument is empty, `ST_Buffer()` returns an empty geometry.
  If the distance is 0, `ST_Buffer()` returns the geometry argument unchanged:

  ```
  mysql> SET @pt = ST_GeomFromText('POINT(0 0)');
  mysql> SELECT ST_AsText(ST_Buffer(@pt, 0));
  +------------------------------+
  | ST_AsText(ST_Buffer(@pt, 0)) |
  | POINT(0 0)                   |
  +------------------------------+
  ```

  If the geometry argument is in a Cartesian SRS:

  - `ST_Buffer()` supports negative distances for `Polygon` and `MultiPolygon` values, and for geometry collections containing `Polygon` or `MultiPolygon` values.
  - If the result is reduced so much that that it disappears, the result is an empty geometry.
  - An `ER_WRONG_ARGUMENTS` error occurs for `ST_Buffer()` with a negative distance for `Point`, `MultiPoint`, `LineString`, and `MultiLineString` values, and for geometry collections not containing any `Polygon` or `MultiPolygon` values.

  If the geometry argument is in a geographic SRS:

  - Prior to MySQL 8.0.26, an `ER_NOT_IMPLEMENTED_FOR_GEOGRAPHIC_SRS` error occurs.
  - As of MySQL 8.0.26, `Point` geometries in a geographic SRS are permitted. For non-`Point` geometries, an `ER_NOT_IMPLEMENTED_FOR_GEOGRAPHIC_SRS` error still occurs.

  For MySQL versions that permit geographic `Point` geometries:

  - If the distance is not negative and no strategies are specified, the function returns the geographic buffer of the `Point` in its SRS. The distance argument must be in the SRS distance unit (currently always meters).
Spatial Operator Functions

• If the distance is negative or any strategy (except NULL) is specified, an ER_WRONG_ARGUMENTS error occurs.

**ST_Buffer()** permits up to three optional strategy arguments following the distance argument. Strategies influence buffer computation. These arguments are byte string values produced by the \texttt{ST_Buffer_Strategy()} function, to be used for point, join, and end strategies:

• Point strategies apply to \texttt{Point} and \texttt{MultiPoint} geometries. If no point strategy is specified, the default is \texttt{ST_Buffer_Strategy('point\_circle', 32)}.

• Join strategies apply to \texttt{LineString}, \texttt{MultiLineString}, \texttt{Polygon}, and \texttt{MultiPolygon} geometries. If no join strategy is specified, the default is \texttt{ST_Buffer_Strategy('join\_round', 32)}.

• End strategies apply to \texttt{LineString} and \texttt{MultiLineString} geometries. If no end strategy is specified, the default is \texttt{ST_Buffer_Strategy('end\_round', 32)}.

Up to one strategy of each type may be specified, and they may be given in any order.

If the buffer strategies are invalid, an ER_WRONG_ARGUMENTS error occurs. Strategies are invalid under any of these circumstances:

• Multiple strategies of a given type (point, join, or end) are specified.

• A value that is not a strategy (such as an arbitrary binary string or a number) is passed as a strategy.

• A Point strategy is passed and the geometry contains no Point or MultiPoint values.

• An end or join strategy is passed and the geometry contains no LineString, Polygon, MultiLineString or MultiPolygon values.

```sql
mysql> SET @pt = ST_GeomFromText('POINT(0 0)');
mysql> SET @pt_strategy = ST_Buffer_Strategy('point_square');
mysql> SELECT ST_AsText(ST_Buffer(@pt, 2, @pt_strategy));
+--------------------------------------------+
| ST_AsText(ST_Buffer(@pt, 2, @pt_strategy)) |
| POLYGON((-2 -2,2 -2,2 2,-2 2,-2 -2))       |
+--------------------------------------------+
mysql> SET @ls = ST_GeomFromText('LINESTRING(0 0,0 5,5 5)');
mysql> SET @end_strategy = ST_Buffer_Strategy('end\_flat');
mysql> SET @join_strategy = ST_Buffer_Strategy('join\_round', 10);
mysql> SELECT ST_AsText(ST_Buffer(@ls, 5, @end_strategy, @join_strategy))
+---------------------------------------------------------------+
| ST_AsText(ST_Buffer(@ls, 5, @end_strategy, @join_strategy))   |
| POLYGON((5 5,10,0,10,-3.5355339059327373 8.535533905932738, |
| -5 5,-5 0,0,5 0,5 5))                                       |
+---------------------------------------------------------------+
```

• \texttt{ST_Buffer\_Strategy(strategy [, points\_per\_circle])}

This function returns a strategy byte string for use with \texttt{ST_Buffer()} to influence buffer computation.

Information about strategies is available at Boost.org.

The first argument must be a string indicating a strategy option:

• For point strategies, permitted values are 'point\_circle' and 'point\_square'.

• For join strategies, permitted values are 'join\_round' and 'join\_miter'.

2138
• For end strategies, permitted values are 'end_round' and 'end_flat'.

If the first argument is 'point_circle', 'join_round', 'join_miter', or 'end_round', the points_per_circle argument must be given as a positive numeric value. The maximum points_per_circle value is the value of the max_points_in_geometry system variable.

For examples, see the description of ST_Buffer().

ST_Buffer_Strategy() handles its arguments as described in the introduction to this section, with these exceptions:

• If any argument is invalid, an ER_WRONG_ARGUMENTS error occurs.

• If the first argument is 'point_square' or 'end_flat', the points_per_circle argument must not be given or an ER_WRONG_ARGUMENTS error occurs.

• ST_ConvexHull(g)

Returns a geometry that represents the convex hull of the geometry value g.

This function computes a geometry’s convex hull by first checking whether its vertex points are colinear. The function returns a linear hull if so, a polygon hull otherwise. This function processes geometry collections by extracting all vertex points of all components of the collection, creating a MultiPoint value from them, and computing its convex hull.

ST_ConvexHull() handles its arguments as described in the introduction to this section, with this exception:

• The return value is NULL for the additional condition that the argument is an empty geometry collection.

```
mysql> SET @g = 'MULTIPOINT(5 0,25 0,15 10,15 25)';
mysql> SELECT ST_AsText(ST_ConvexHull(ST_GeomFromText(@g)));
+-----------------------------------------------+
| ST_AsText(ST_ConvexHull(ST_GeomFromText(@g))) |
+-----------------------------------------------+
| POLYGON((5 0,25 0,15 25,5 0))                 |
+-----------------------------------------------+
```

• ST_Difference(g1, g2)

Returns a geometry that represents the point set difference of the geometry values g1 and g2. The result is in the same SRS as the geometry arguments.

As of MySQL 8.0.26, ST_Difference() permits arguments in either a Cartesian or a geographic SRS. Prior to MySQL 8.0.26, ST_Difference() permits arguments in a Cartesian SRS only; for arguments in a geographic SRS, an ER_NOT_IMPLEMENTED_FOR_GEOGRAPHIC_SRS error occurs.

ST_Difference() handles its arguments as described in the introduction to this section.

```
mysql> SET @g1 = Point(1,1), @g2 = Point(2,2);
mysql> SELECT ST_AsText(ST_Difference(@g1, @g2));
+------------------------------------+
| ST_AsText(ST_Difference(@g1, @g2)) |
+------------------------------------+
| POINT(1 1)                         |
+------------------------------------+
```
• **ST_Intersection**(g1, g2)

Returns a geometry that represents the point set intersection of the geometry values g1 and g2.

**ST_Intersection()** handles its arguments as described in the introduction to this section.

```sql
mysql> SET @g1 = ST_GeomFromText('LineString(1 1, 3 3)');
mysql> SET @g2 = ST_GeomFromText('LineString(1 3, 3 1)');
mysql> SELECT ST_AsText(ST_Intersection(@g1, @g2));
+--------------------------------------+
| ST_AsText(ST_Intersection(@g1, @g2)) |
+--------------------------------------+
| POINT(2 2)                           |
+--------------------------------------+
```

• **ST_LineInterpolatePoint**(ls, fractional_distance)

This function takes a LineString geometry and a fractional distance in the range [0.0, 1.0] and returns the Point along the LineString at the given fraction of the distance from its start point to its endpoint. It can be used to answer questions such as which Point lies halfway along the road described by the geometry argument.

The function is implemented for LineString geometries in all spatial reference systems, both Cartesian and geographic.

If the fractional_distance argument is 1.0, the result may not be exactly the last point of the LineString argument but a point close to it due to numerical inaccuracies in approximate-value computations.

A related function, **ST_LineInterpolatePoints()**, takes similar arguments but returns a MultiPoint consisting of Point values along the LineString at each fraction of the distance from its start point to its endpoint. For examples of both functions, see the **ST_LineInterpolatePoints()** description.

**ST_LineInterpolatePoint()** handles its arguments as described in the introduction to this section, with these exceptions:

- If the geometry argument is not a LineString, an ER_UNEXPECTED_GEOMETRY_TYPE error occurs.
- If the fractional distance argument is outside the range [0.0, 1.0], an ER_DATA_OUT_OF_RANGE error occurs.

**ST_LineInterpolatePoint()** is a MySQL extension to OpenGIS. This function was added in MySQL 8.0.24.

• **ST_LineInterpolatePoints**(ls, fractional_distance)

This function takes a LineString geometry and a fractional distance in the range (0.0, 1.0] and returns the MultiPoint consisting of the LineString start point, plus Point values along the LineString at each fraction of the distance from its start point to its endpoint. It can be used to
answer questions such as which `Point` values lie every 10% of the way along the road described by the geometry argument.

The function is implemented for `LineString` geometries in all spatial reference systems, both Cartesian and geographic.

If the `fractional_distance` argument divides 1.0 with zero remainder the result may not contain the last point of the `LineString` argument but a point close to it due to numerical inaccuracies in approximate-value computations.

A related function, `ST_LineInterpolatePoint()`, takes similar arguments but returns the `Point` along the `LineString` at the given fraction of the distance from its start point to its endpoint.

`ST_LineInterpolatePoints()` handles its arguments as described in the introduction to this section, with these exceptions:

- If the geometry argument is not a `LineString`, an `ER_UNEXPECTED_GEOMETRY_TYPE` error occurs.
- If the fractional distance argument is outside the range [0.0, 1.0], an `ER_DATA_OUT_OF_RANGE` error occurs.

```sql
mysql> SET @ls1 = ST_GeomFromText('LINESTRING(0 0,0 5,5 5)');
mysql> SELECT ST_AsText(ST_LineInterpolatePoint(@ls1, .5));
+----------------------------------------------+
| ST_AsText(ST_LineInterpolatePoint(@ls1, .5)) |
| POINT(0 5)                                   |
+----------------------------------------------+
mysql> SELECT ST_AsText(ST_LineInterpolatePoint(@ls1, .75));
+-----------------------------------------------+
| ST_AsText(ST_LineInterpolatePoint(@ls1, .75)) |
| POINT(2.5 5)                                  |
+-----------------------------------------------+
mysql> SELECT ST_AsText(ST_LineInterpolatePoint(@ls1, 1));
+---------------------------------------------+
| ST_AsText(ST_LineInterpolatePoint(@ls1, 1))  |
| POINT(5 5)                                   |
+---------------------------------------------+
mysql> SELECT ST_AsText(ST_LineInterpolatePoints(@ls1, .25));
+------------------------------------------------+
| ST_AsText(ST_LineInterpolatePoints(@ls1, .25)) |
| MULTIPOINT((0 2.5),(0 5),(2.5 5),(5 5))       |
+------------------------------------------------+
```

`ST_LineInterpolatePoints()` is a MySQL extension to OpenGIS. This function was added in MySQL 8.0.24.

- `ST_PointAtDistance(ls, distance)`

This function takes a `LineString` geometry and a distance in the range [0.0, `ST_Length(ls)`] measured in the unit of the spatial reference system (SRS) of the `LineString`, and returns the `Point` along the `LineString` at that distance from its start point. It can be used to answer
questions such as which Point value is 400 meters from the start of the road described by the geometry argument.

The function is implemented for LineString geometries in all spatial reference systems, both Cartesian and geographic.

ST_PointAtDistance() handles its arguments as described in the introduction to this section, with these exceptions:

- If the geometry argument is not a LineString, an ER_UNEXPECTED_GEOMETRY_TYPE error occurs.
- If the fractional distance argument is outside the range [0.0, ST_Length(ls)], an ER_DATA_OUT_OF_RANGE error occurs.

ST_PointAtDistance() is a MySQL extension to OpenGIS. This function was added in MySQL 8.0.24.

- ST_SymDifference(g1, g2)

Returns a geometry that represents the point set symmetric difference of the geometry values g1 and g2, which is defined as:

\[ g1 \text{ symdifference } g2 := (g1 \text{ union } g2) \text{ difference } (g1 \text{ intersection } g2) \]

Or, in function call notation:

\[ \text{ST_SymDifference}(g1, g2) = \text{ST_Difference}(\text{ST_Union}(g1, g2), \text{ST_Intersection}(g1, g2)) \]

ST_SymDifference() handles its arguments as described in the introduction to this section.

mysql> SET @g1 = Point(1,1), @g2 = Point(2,2);
mysql> SELECT ST_AsText(ST_SymDifference(@g1, @g2));
+---------------------------------------+
| ST_AsText(ST_SymDifference(@g1, @g2)) |
| MULTIPOINT((1 1),(2 2)) |
+---------------------------------------+

- ST_Transform(g, target_srid)

Transforms a geometry from one spatial reference system (SRS) to another. The return value is a geometry of the same type as the input geometry with all coordinates transformed to the target SRID, target_srid. Transformation support is limited to geographic SRSs, unless the SRID of the
geometry argument is the same as the target SRID value, in which case the return value is the input geometry for any valid SRS.

`ST_Transform()` handles its arguments as described in the introduction to this section, with these exceptions:

- Geometry arguments that have an SRID value for a geographic SRS do not produce an error.
- If the geometry or target SRID argument has an SRID value that refers to an undefined spatial reference system (SRS), an **ER_SRS_NOT_FOUND** error occurs.
- If the geometry is in an SRS that `ST_Transform()` cannot transform from, an **ER_TRANSFORM_SOURCE_SRS_NOT_SUPPORTED** error occurs.
- If the target SRID is in an SRS that `ST_Transform()` cannot transform to, an **ER_TRANSFORM_TARGET_SRS_NOT_SUPPORTED** error occurs.
- If the geometry is in an SRS that is not WGS 84 and has no TOWGS84 clause, an **ER_TRANSFORM_SOURCE_SRS_MISSING_TOWGS84** error occurs.
- If the target SRID is in an SRS that is not WGS 84 and has no TOWGS84 clause, an **ER_TRANSFORM_TARGET_SRS_MISSING_TOWGS84** error occurs.

`ST_SRID(g, target_srid)` and `ST_Transform(g, target_srid)` differ as follows:

- **ST_SRID()** changes the geometry SRID value without transforming its coordinates.
- **ST_Transform()** transforms the geometry coordinates in addition to changing its SRID value.

```sql
mysql> SET @p = ST_GeomFromText('POINT(52.381389 13.064444)', 4326);
mysql> SELECT ST_AsText(@p);
+----------------------------+
| ST_AsText(@p)              |
+----------------------------+
| POINT(52.381389 13.064444) |
+----------------------------+
mysql> SET @p = ST_Transform(@p, 4230);
mysql> SELECT ST_AsText(@p);
+---------------------------------------------+
| ST_AsText(@p)                               |
| POINT(52.38208611407426 13.065520672345304) |
+---------------------------------------------+
```

• **ST_Union(g1, g2)**

Returns a geometry that represents the point set union of the geometry values `g1` and `g2`. The result is in the same SRS as the geometry arguments.

As of MySQL 8.0.26, **ST_Union()** permits arguments in either a Cartesian or a geographic SRS. Prior to MySQL 8.0.26, **ST_Union()** permits arguments in a Cartesian SRS only; for arguments in a geographic SRS, an **ER_NOT_IMPLEMENTED_FOR_GEOGRAPHIC_SRS** error occurs.

`ST_Union()` handles its arguments as described in the introduction to this section.

```sql
mysql> SET @g1 = ST_GeomFromText('LineString(1 1, 3 3)');
mysql> SET @g2 = ST_GeomFromText('LineString(1 3, 3 1)');
mysql> SELECT ST_AsText(ST_Union(@g1, @g2));
+--------------------------------------+
| ST_AsText(ST_Union(@g1, @g2))        |
+--------------------------------------+
| MULTILINESTRING((1 1,3 3),(1 3,3 1)) |
```
12.17.9 Functions That Test Spatial Relations Between Geometry Objects

The functions described in this section take two geometries as arguments and return a qualitative or quantitative relation between them.

MySQL implements two sets of functions using function names defined by the OpenGIS specification. One set tests the relationship between two geometry values using precise object shapes, the other set uses object minimum bounding rectangles (MBRs).

12.17.9.1 Spatial Relation Functions That Use Object Shapes

The OpenGIS specification defines the following functions to test the relationship between two geometry values \( g_1 \) and \( g_2 \), using precise object shapes. The return values 1 and 0 indicate true and false, respectively, except that distance functions return distance values.

Functions in this section detect arguments in either Cartesian or geographic spatial reference systems (SRSs), and return results appropriate to the SRS.

Unless otherwise specified, functions in this section handle their geometry arguments as follows:

- If any argument is NULL or any geometry argument is an empty geometry, the return value is NULL.
- If any geometry argument is not a syntactically well-formed geometry, an ER_GIS_INVALID_DATA error occurs.
- If any geometry argument is a syntactically well-formed geometry in an undefined spatial reference system (SRS), an ER_SRS_NOT_FOUND error occurs.
- For functions that take multiple geometry arguments, if those arguments are not in the same SRS, an ER_GIS_DIFFERENT_SRIDS error occurs.
- If any geometry argument is geometrically invalid, either the result is true or false (it is undefined which), or an error occurs.
- For geographic SRS geometry arguments, if any argument has a longitude or latitude that is out of range, an error occurs:
  - If a longitude value is not in the range \((-180, 180]\), an ER_GEOMETRY_PARAM_LONGITUDE_OUT_OF_RANGE error occurs (ER_LONGITUDE_OUT_OF_RANGE prior to MySQL 8.0.12).
  - If a latitude value is not in the range \([-90, 90]\), an ER_GEOMETRY_PARAM_LATITUDE_OUT_OF_RANGE error occurs (ER_LATITUDE_OUT_OF_RANGE prior to MySQL 8.0.12).

Ranges shown are in degrees. If an SRS uses another unit, the range uses the corresponding values in its unit. The exact range limits deviate slightly due to floating-point arithmetic.

- Otherwise, the return value is non-NULL.

Some functions in this section permit a unit argument that specifies the length unit for the return value. Unless otherwise specified, functions handle their unit argument as follows:

- A unit is supported if it is found in the INFORMATION_SCHEMA ST_UNITS_OF_MEASURE table. See Section 26.3.37, "The INFORMATION_SCHEMA ST_UNITS_OF_MEASURE Table".
- If a unit is specified but not supported by MySQL, an ER_UNIT_NOT_FOUND error occurs.
- If a supported linear unit is specified and the SRID is 0, an ER_GEOMETRY_IN_UNKNOWN_LENGTH_UNIT error occurs.
- If a supported linear unit is specified and the SRID is not 0, the result is in that unit.
Functions That Test Spatial Relations Between Geometry Objects

- If a unit is not specified, the result is in the unit of the SRS of the geometries, whether Cartesian or geographic. Currently, all MySQL SRSs are expressed in meters.

These object-shape functions are available for testing geometry relationships:

- **ST_Contains**(g1, g2)

  Returns 1 or 0 to indicate whether g1 completely contains g2. This tests the opposite relationship as **ST_Within()

  ST_Contains() handles its arguments as described in the introduction to this section.

- **ST_Crosses**(g1, g2)

  Two geometries spatially cross if their spatial relation has the following properties:
  - Unless g1 and g2 are both of dimension 1: g1 crosses g2 if the interior of g2 has points in common with the interior of g1, but g2 does not cover the entire interior of g1.
  - If both g1 and g2 are of dimension 1: If the lines cross each other in a finite number of points (that is, no common line segments, only single points in common).

  This function returns 1 or 0 to indicate whether g1 spatially crosses g2.

  ST_Crosses() handles its arguments as described in the introduction to this section except that the return value is NULL for these additional conditions:
  - g1 is of dimension 2 (Polygon or MultiPolygon).
  - g2 is of dimension 1 (Point or MultiPoint).

- **ST_Disjoint**(g1, g2)

  Returns 1 or 0 to indicate whether g1 is spatially disjoint from (does not intersect) g2.

  ST_Disjoint() handles its arguments as described in the introduction to this section.

- **ST_Distance**(g1, g2 [, unit])

  Returns the distance between g1 and g2, measured in the length unit of the spatial reference system (SRS) of the geometry arguments, or in the unit of the optional unit argument if that is specified.

  This function processes geometry collections by returning the shortest distance among all combinations of the components of the two geometry arguments.

  ST_Distance() handles its geometry arguments as described in the introduction to this section, with these exceptions:
  - ST_Distance() detects arguments in a geographic (ellipsoidal) spatial reference system and returns the geodetic distance on the ellipsoid. As of MySQL 8.0.18, ST_Distance() supports distance calculations for geographic SRS arguments of all geometry types. Prior to MySQL 8.0.18, the only permitted geographic argument types are Point and Point, or Point and MultiPoint (in any argument order). If called with other geometry type argument combinations in a geographic SRS, an ER_NOT_IMPLEMENTED_FOR_GEOGRAPHIC_SRS error occurs.
  - If any argument is geometrically invalid, either the result is an undefined distance (that is, it can be any number), or an error occurs.
  - If an intermediate or final result produces NaN or a negative number, an ER_GIS_INVALID_DATA error occurs.
As of MySQL 8.0.14, \texttt{ST\_Distance()} permits an optional \texttt{unit} argument that specifies the linear unit for the returned distance value. \texttt{ST\_Distance()} handles its \texttt{unit} argument as described in the introduction to this section.

\begin{verbatim}
mysql> SET @g1 = ST_GeomFromText('POINT(1 1)');
mysql> SET @g2 = ST_GeomFromText('POINT(2 2)');
mysql> SELECT ST\_Distance(@g1, @g2);
+-----------------------+
| ST\_Distance(@g1, @g2) |
+-----------------------+
| 1.4142135623730951     |
+-----------------------+
mysql> SET @g1 = ST_GeomFromText('POINT(1 1)', 4326);
mysql> SET @g2 = ST_GeomFromText('POINT(2 2)', 4326);
mysql> SELECT ST\_Distance(@g1, @g2);
+-----------------------+
| ST\_Distance(@g1, @g2) |
+-----------------------+
| 156874.3859490455      |
+-----------------------+
mysql> SELECT ST\_Distance(@g1, @g2, 'metre');
+--------------------------------+
| ST\_Distance(@g1, @g2, 'metre') |
+--------------------------------+
| 156874.3859490455          |
+--------------------------------+
mysql> SELECT ST\_Distance(@g1, @g2, 'foot');
+-------------------------------+
| ST\_Distance(@g1, @g2, 'foot') |
+-------------------------------+
| 514679.7439273146            |
+-------------------------------+
\end{verbatim}

For the special case of distance calculations on a sphere, see the \texttt{ST\_Distance\_Sphere()} function.

- \texttt{ST\_Equals(g1, g2)}

  Returns 1 or 0 to indicate whether \texttt{g1} is spatially equal to \texttt{g2}.

  \texttt{ST\_Equals()} handles its arguments as described in the introduction to this section, except that it does not return \texttt{NULL} for empty geometry arguments.

\begin{verbatim}
mysql> SET @g1 = Point(1,1), @g2 = Point(2,2);
mysql> SELECT ST\_Equals(@g1, @g1), ST\_Equals(@g1, @g2);
+---------------------+---------------------+
| ST\_Equals(@g1, @g1) | ST\_Equals(@g1, @g2) |
+---------------------+---------------------+
|                   1 |                   0 |
+---------------------+---------------------+
\end{verbatim}

- \texttt{ST\_FrechetDistance(g1, g2 [, unit])}

  Returns the discrete Fréchet distance between two geometries, reflecting how similar the geometries are. The result is a double-precision number measured in the length unit of the spatial reference system (SRS) of the geometry arguments, or in the length unit of the \texttt{unit} argument if that argument is given.

  This function implements the discrete Fréchet distance, which means it is restricted to distances between the points of the geometries. For example, given two \texttt{LineString} arguments, only the
Functions That Test Spatial Relations Between Geometry Objects

Points explicitly mentioned in the geometries are considered. Points on the line segments between these points are not considered.

**ST_FrechetDistance()** handles its geometry arguments as described in the introduction to this section, with these exceptions:

- The geometries may have a Cartesian or geographic SRS, but only **LineString** values are supported. If the arguments are in the same Cartesian or geographic SRS, but either is not a **LineString**, an **ER_NOTIMPLEMENTED_FOR_CARTESIAN_SRS** or **ER_NOTIMPLEMENTED_FOR_GEOGRAPHIC_SRS** error occurs, depending on the SRS type.

**ST_FrechetDistance()** handles its optional **unit** argument as described in the introduction to this section.

```mysql
mysql> SET @ls1 = ST_GeomFromText('LINESTRING(0 0,0 5,5 5)');
mysql> SET @ls2 = ST_GeomFromText('LINESTRING(0 1,0 6,3 3,5 6)');
mysql> SELECT ST_FrechetDistance(@ls1, @ls2);
+--------------------------------+
| ST_FrechetDistance(@ls1, @ls2) |
+--------------------------------+
|             2.8284271247461903 |
+--------------------------------+
mysql> SET @ls1 = ST_GeomFromText('LINESTRING(0 0,0 5,5 5)', 4326);
mysql> SET @ls2 = ST_GeomFromText('LINESTRING(0 1,0 6,3 3,5 6)', 4326);
mysql> SELECT ST_FrechetDistance(@ls1, @ls2);
+-----------------------------------+
| ST_FrechetDistance(@ls1, @ls2)   |
| 313421.1999416798                |
+-----------------------------------+
mysql> SELECT ST_FrechetDistance(@ls1, @ls2, 'foot');
+-------------------------------+
| ST_FrechetDistance(@ls1, @ls2, 'foot') |
| 1028284.7767115477             |
+-------------------------------+
```

This function was added in MySQL 8.0.23.

**ST_HausdorffDistance**(g1, g2 [, unit])

Returns the discrete Hausdorff distance between two geometries, reflecting how similar the geometries are. The result is a double-precision number measured in the length unit of the spatial reference system (SRS) of the geometry arguments, or in the length unit of the **unit** argument if that argument is given.

This function implements the discrete Hausdorff distance, which means it is restricted to distances between the points of the geometries. For example, given two **LineString** arguments, only the points explicitly mentioned in the geometries are considered. Points on the line segments between these points are not considered.

**ST_HausdorffDistance()** handles its geometry arguments as described in the introduction to this section, with these exceptions:

- If the geometry arguments are in the same Cartesian or geographic SRS, but are not in a supported combination, an **ER_NOTIMPLEMENTED_FOR_CARTESIAN_SRS** or **ER_NOTIMPLEMENTED_FOR_GEOGRAPHIC_SRS** error occurs, depending on the SRS type. These combinations are supported:
  - **LineString** and **LineString**
  - **Point** and **MultiPoint**
  - **LineString** and **MultiLineString**
Functions That Test Spatial Relations Between Geometry Objects

- **MultiPoint and MultiPoint**
- **MultiLineString and MultiLineString**

`ST_HausdorffDistance()` handles its optional *unit* argument as described in the introduction to this section.

```sql
mysql> SET @ls1 = ST_GeomFromText('LINESTRING(0 0,0 5,5 5)');
mysql> SET @ls2 = ST_GeomFromText('LINESTRING(0 1,0 6,3 3,5 6)');
mysql> SELECT ST_HausdorffDistance(@ls1, @ls2);
+----------------------------------+
| ST_HausdorffDistance(@ls1, @ls2) |
+----------------------------------+
|                                1 |
+----------------------------------+
```

```sql
mysql> SET @ls1 = ST_GeomFromText('LINESTRING(0 0,0 5,5 5)', 4326);
mysql> SET @ls2 = ST_GeomFromText('LINESTRING(0 1,0 6,3 3,5 6)', 4326);
mysql> SELECT ST_HausdorffDistance(@ls1, @ls2);
+----------------------------------+
<table>
<thead>
<tr>
<th>ST_HausdorffDistance(@ls1, @ls2)</th>
</tr>
</thead>
<tbody>
<tr>
<td>111319.49079326246</td>
</tr>
</tbody>
</table>
+----------------------------------+
mysql> SELECT ST_HausdorffDistance(@ls1, @ls2, 'foot');
+------------------------------------------+
<table>
<thead>
<tr>
<th>ST_HausdorffDistance(@ls1, @ls2, 'foot')</th>
</tr>
</thead>
<tbody>
<tr>
<td>365221.4264870815</td>
</tr>
</tbody>
</table>
+------------------------------------------+
```

This function was added in MySQL 8.0.23.

- **ST_Intersects(\(g_1, g_2\))**

  Returns 1 or 0 to indicate whether \(g_1\) spatially intersects \(g_2\).

  `ST_Intersects()` handles its arguments as described in the introduction to this section.

- **ST_Overlaps(\(g_1, g_2\))**

  Two geometries *spatially overlap* if they intersect and their intersection results in a geometry of the same dimension but not equal to either of the given geometries.

  This function returns 1 or 0 to indicate whether \(g_1\) spatially overlaps \(g_2\).

  `ST_Overlaps()` handles its arguments as described in the introduction to this section except that the return value is *NULL* for the additional condition that the dimensions of the two geometries are not equal.

- **ST_Touches(\(g_1, g_2\))**

  Two geometries *spatially touch* if their interiors do not intersect, but the boundary of one of the geometries intersects either the boundary or the interior of the other.

  This function returns 1 or 0 to indicate whether \(g_1\) spatially touches \(g_2\).

  `ST_Touches()` handles its arguments as described in the introduction to this section except that the return value is *NULL* for the additional condition that both geometries are of dimension 0 (*Point* or *MultiPoint*).

- **ST_Within(\(g_1, g_2\))**

  Returns 1 or 0 to indicate whether \(g_1\) is spatially within \(g_2\). This tests the opposite relationship as `ST_Contains()`.
Functions That Test Spatial Relations Between Geometry Objects

ST_Within() handles its arguments as described in the introduction to this section.

12.17.9.2 Spatial Relation Functions That Use Minimum Bounding Rectangles

MySQL provides several MySQL-specific functions that test the relationship between minimum bounding rectangles (MBRs) of two geometries $g_1$ and $g_2$. The return values 1 and 0 indicate true and false, respectively.

The bounding box of a point is interpreted as a point that is both boundary and interior.

The bounding box of a straight horizontal or vertical line is interpreted as a line where the interior of the line is also boundary. The endpoints are boundary points.

If any of the parameters are geometry collections, the interior, boundary, and exterior of those parameters are those of the union of all elements in the collection.

Functions in this section detect arguments in either Cartesian or geographic spatial reference systems (SRSs), and return results appropriate to the SRS.

Unless otherwise specified, functions in this section handle their geometry arguments as follows:

- If any argument is NULL or an empty geometry, the return value is NULL.
- If any geometry argument is not a syntactically well-formed geometry, an ER_GIS_INVALID_DATA error occurs.
- If any geometry argument is a syntactically well-formed geometry in an undefined spatial reference system (SRS), an ER_SRS_NOT_FOUND error occurs.
- For functions that take multiple geometry arguments, if those arguments are not in the same SRS, an ER_GIS_DIFFERENT_SRIDS error occurs.
- If any argument is geometrically invalid, either the result is true or false (it is undefined which), or an error occurs.
- For geographic SRS geometry arguments, if any argument has a longitude or latitude that is out of range, an error occurs:
  - If a longitude value is not in the range $(-180, 180]$, an ER_GEOMETRY_PARAM_LONGITUDE_OUT_OF_RANGE error occurs (ER_LONGITUDE_OUT_OF_RANGE prior to MySQL 8.0.12).
  - If a latitude value is not in the range $[-90, 90]$, an ER_GEOMETRY_PARAM_LATITUDE_OUT_OF_RANGE error occurs (ER_LATITUDE_OUT_OF_RANGE prior to MySQL 8.0.12).

Ranges shown are in degrees. If an SRS uses another unit, the range uses the corresponding values in its unit. The exact range limits deviate slightly due to floating-point arithmetic.

- Otherwise, the return value is non-NULL.

These MBR functions are available for testing geometry relationships:

- **MBRContains($g_1$, $g_2$)**
  Returns 1 or 0 to indicate whether the minimum bounding rectangle of $g_1$ contains the minimum bounding rectangle of $g_2$. This tests the opposite relationship as **MBRWithin()**.

MBRContains() handles its arguments as described in the introduction to this section.

```sql
mysql> SET @g1 = ST_GeomFromText('Polygon((0 0,0 3,3 3,3 0,0 0))');
mysql> SET @g2 = ST_GeomFromText('Point(1 1)');
```
Functions That Test Spatial Relations Between Geometry Objects

- **MBRCoveredBy\((g_1, g_2)\)**
  
  Returns 1 or 0 to indicate whether the minimum bounding rectangle of \(g_1\) is covered by the minimum bounding rectangle of \(g_2\). This tests the opposite relationship as MBRCovers().

  MBRCoveredBy() handles its arguments as described in the introduction to this section.

- **MBRCovers\((g_1, g_2)\)**
  
  Returns 1 or 0 to indicate whether the minimum bounding rectangle of \(g_1\) covers the minimum bounding rectangle of \(g_2\). This tests the opposite relationship as MBRCoveredBy(). See the description of MBRCoveredBy() for examples.

  MBRCovers() handles its arguments as described in the introduction to this section.

- **MBRDisjoint\((g_1, g_2)\)**
  
  Returns 1 or 0 to indicate whether the minimum bounding rectangles of the two geometries \(g_1\) and \(g_2\) are disjoint (do not intersect).

  MBRDisjoint() handles its arguments as described in the introduction to this section.

- **MBREquals\((g_1, g_2)\)**
  
  Returns 1 or 0 to indicate whether the minimum bounding rectangles of the two geometries \(g_1\) and \(g_2\) are the same.

  MBREquals() handles its arguments as described in the introduction to this section, except that it does not return NULL for empty geometry arguments.

- **MBRIntersects\((g_1, g_2)\)**
  
  Returns 1 or 0 to indicate whether the minimum bounding rectangles of the two geometries \(g_1\) and \(g_2\) intersect.

  MBRIntersects() handles its arguments as described in the introduction to this section.

- **MBROverlaps\((g_1, g_2)\)**
  
  Two geometries spatially overlap if they intersect and their intersection results in a geometry of the same dimension but not equal to either of the given geometries.

  This function returns 1 or 0 to indicate whether the minimum bounding rectangles of the two geometries \(g_1\) and \(g_2\) overlap.
MBROverlaps() handles its arguments as described in the introduction to this section.

- MBRTouches($g1$, $g2$)

Two geometries spatially touch if their interiors do not intersect, but the boundary of one of the geometries intersects either the boundary or the interior of the other.

This function returns 1 or 0 to indicate whether the minimum bounding rectangles of the two geometries $g1$ and $g2$ touch.

MBRTouches() handles its arguments as described in the introduction to this section.

- MBRWithin($g1$, $g2$)

Returns 1 or 0 to indicate whether the minimum bounding rectangle of $g1$ is within the minimum bounding rectangle of $g2$. This tests the opposite relationship as MBRContains().

MBRWithin() handles its arguments as described in the introduction to this section.

```
mysql> SET @g1 = ST_GeomFromText('Polygon((0 0,0 3,3 3,3 0,0 0))');
mysql> SET @g2 = ST_GeomFromText('Polygon((0 0,0 5,5 5,5 0,0 0))');
mysql> SELECT MBRWithin(@g1,@g2), MBRWithin(@g2,@g1);
+--------------------+--------------------+
<table>
<thead>
<tr>
<th>MBRWithin(@g1,@g2)</th>
<th>MBRWithin(@g2,@g1)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>
+--------------------+--------------------+
```

### 12.17.10 Spatial Geohash Functions

Geohash is a system for encoding latitude and longitude coordinates of arbitrary precision into a text string. Geohash values are strings that contain only characters chosen from "$0123456789bcdefghjkmnpqrstuvwxyz$".

The functions in this section enable manipulation of geohash values, which provides applications the capabilities of importing and exporting geohash data, and of indexing and searching geohash values.

Unless otherwise specified, functions in this section handle their geometry arguments as follows:

- If any argument is **NULL**, the return value is **NULL**.
- If any argument is invalid, an error occurs.
- If any argument has a longitude or latitude that is out of range, an error occurs:
  - If a longitude value is not in the range $(-180, 180]$, an
    **ER_GEOMETRY_PARAM_LONGITUDE_OUT_OF_RANGE** error occurs
    (**ER_LONGITUDE_OUT_OF_RANGE** prior to MySQL 8.0.12).
  - If a latitude value is not in the range $[-90, 90]$, an
    **ER_GEOMETRY_PARAM_LATITUDE_OUT_OF_RANGE** error occurs
    (**ER_LATITUDE_OUT_OF_RANGE** prior to MySQL 8.0.12).

Ranges shown are in degrees. The exact range limits deviate slightly due to floating-point arithmetic.

- If any point argument does not have SRID 0 or 4326, an **ER_SRS_NOT_FOUND** error occurs. **point** argument SRID validity is not checked.
- If any SRID argument refers to an undefined spatial reference system (SRS), an
  **ER_SRS_NOT_FOUND** error occurs.
- If any SRID argument is not within the range of a 32-bit unsigned integer, an
  **ER_DATA_OUT_OF_RANGE** error occurs.
• Otherwise, the return value is non-NULL.

These geohash functions are available:

• **ST_GeoHash(longitude, latitude, max_length)**, **ST_GeoHash(point, max_length)**

Returns a geohash string in the connection character set and collation.

For the first syntax, the *longitude* must be a number in the range \([-180, 180]\), and the *latitude* must be a number in the range \([-90, 90]\). For the second syntax, a **POINT** value is required, where the X and Y coordinates are in the valid ranges for longitude and latitude, respectively.

The resulting string is no longer than *max_length* characters, which has an upper limit of 100. The string might be shorter than *max_length* characters because the algorithm that creates the geohash value continues until it has created a string that is either an exact representation of the location or *max_length* characters, whichever comes first.

**ST_GeoHash()** handles its arguments as described in the introduction to this section.

```sql
mysql> SELECT ST_GeoHash(180, 0, 10), ST_GeoHash(-180, -90, 15);
+----------------------+-------------------------+
| ST_GeoHash(180, 0, 10) | ST_GeoHash(-180, -90, 15) |
| xbpbpbpbpb           | 000000000000000         |
+----------------------+-------------------------+
```

• **ST_LatFromGeoHash(geohash_str)**

Returns the latitude from a geohash string value, as a double-precision number in the range \([-90, 90]\).

The **ST_LatFromGeoHash()** decoding function reads no more than 433 characters from the *geohash_str* argument. That represents the upper limit on information in the internal representation of coordinate values. Characters past the 433rd are ignored, even if they are otherwise illegal and produce an error.

**ST_LatFromGeoHash()** handles its arguments as described in the introduction to this section.

```sql
mysql> SELECT ST_LatFromGeoHash(ST_GeoHash(45, -20, 10));
+------------------------------------------+
| ST_LatFromGeoHash(ST_GeoHash(45, -20, 10)) |
|                                      -20 |
+------------------------------------------+
```

• **ST_LongFromGeoHash(geohash_str)**

Returns the longitude from a geohash string value, as a double-precision number in the range \([-180, 180]\).

The remarks in the description of **ST_LatFromGeoHash()** regarding the maximum number of characters processed from the *geohash_str* argument also apply to **ST_LongFromGeoHash()**.

**ST_LongFromGeoHash()** handles its arguments as described in the introduction to this section.

```sql
mysql> SELECT ST_LongFromGeoHash(ST_GeoHash(45, -20, 10));
+-------------------------------------------+
| ST_LongFromGeoHash(ST_GeoHash(45, -20, 10)) |
|                                        45 |
+-------------------------------------------+
```

• **ST_PointFromGeoHash(geohash_str, srid)**

Returns a **POINT** value containing the decoded geohash value, given a geohash string value.
The X and Y coordinates of the point are the longitude in the range \([-180, 180]\) and the latitude in the range \([-90, 90]\), respectively.

The \textit{srid} argument is a 32-bit unsigned integer.

The remarks in the description of \texttt{ST_LatFromGeoHash()} regarding the maximum number of characters processed from the \texttt{geohash\_str} argument also apply to \texttt{ST\_PointFromGeoHash()}.

\texttt{ST\_PointFromGeoHash()} handles its arguments as described in the introduction to this section.

\begin{verbatim}
mysql> SET @gh = ST_GeoHash(45,-20,10);
mysql> SELECT ST_AsText(ST_PointFromGeoHash(@gh,0));
+---------------------------------------+
| ST_AsText(ST_PointFromGeoHash(@gh,0)) |
| POINT(45 -20)                         |
+---------------------------------------+
\end{verbatim}

\section*{12.17.11 Spatial GeoJSON Functions}

This section describes functions for converting between GeoJSON documents and spatial values. GeoJSON is an open standard for encoding geometric/geographical features. For more information, see http://geojson.org. The functions discussed here follow GeoJSON specification revision 1.0.

GeoJSON supports the same geometric/geographic data types that MySQL supports. Feature and FeatureCollection objects are not supported, except that geometry objects are extracted from them. CRS support is limited to values that identify an SRID.

MySQL also supports a native \textit{JSON} data type and a set of SQL functions to enable operations on JSON values. For more information, see Section 11.5, “The JSON Data Type”, and Section 12.18, “JSON Functions”.

\begin{itemize}
  \item \texttt{ST\_AsGeoJSON(g [, max\_dec\_digits [, options]])}
\end{itemize}

Generates a GeoJSON object from the geometry \textit{g}. The object string has the connection character set and collation.

If any argument is \texttt{NULL}, the return value is \texttt{NULL}. If any non-\texttt{NULL} argument is invalid, an error occurs.

\texttt{max\_dec\_digits}, if specified, limits the number of decimal digits for coordinates and causes rounding of output. If not specified, this argument defaults to its maximum value of \(2^{32} - 1\). The minimum is 0.

\texttt{options}, if specified, is a bitmask. The following table shows the permitted flag values. If the geometry argument has an SRID of 0, no CRS object is produced even for those flag values that request one.

\begin{table}
<table>
<thead>
<tr>
<th>Flag Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No options. This is the default if \texttt{options} is not specified.</td>
</tr>
<tr>
<td>1</td>
<td>Add a bounding box to the output.</td>
</tr>
<tr>
<td>2</td>
<td>Add a short-format CRS URN to the output. The default format is a short format (\textit{EPSG:srid}).</td>
</tr>
<tr>
<td>4</td>
<td>Add a long-format CRS URN (\texttt{urn:ogc:def:crs:EPSG::srid}). This flag overrides flag 2. For example, option values of 5 and 7 mean the same (add a bounding box and a long-format CRS URN).</td>
</tr>
</tbody>
</table>
\end{table}

\begin{verbatim}
mysql> SELECT ST_AsGeoJSON(ST_GeomFromText('POINT(11.11111 12.22222)'),2);
\end{verbatim}
Spatial GeoJSON Functions

| ST_AsGeoJSON(ST_GeomFromText('POINT(11.11111 12.22222)'),2) |
| {"type": "Point", "coordinates": [11.11, 12.22]} |

- **ST_GeomFromGeoJSON**(str [, options [, srid]])

  Parses a string str representing a GeoJSON object and returns a geometry.

  If any argument is NULL, the return value is NULL. If any non-NULL argument is invalid, an error occurs.

  options, if given, describes how to handle GeoJSON documents that contain geometries with coordinate dimensions higher than 2. The following table shows the permitted options values.

<table>
<thead>
<tr>
<th>Option Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Reject the document and produce an error. This is the default if options is not specified.</td>
</tr>
<tr>
<td>2, 3, 4</td>
<td>Accept the document and strip off the coordinates for higher coordinate dimensions.</td>
</tr>
</tbody>
</table>

options values of 2, 3, and 4 currently produce the same effect. If geometries with coordinate dimensions higher than 2 are supported in the future, you can expect these values to produce different effects.

The srid argument, if given, must be a 32-bit unsigned integer. If not given, the geometry return value has an SRID of 4326.

If srid refers to an undefined spatial reference system (SRS), an ER_SRS_NOT_FOUND error occurs.

For geographic SRS geometry arguments, if any argument has a longitude or latitude that is out of range, an error occurs:

- If a longitude value is not in the range (-180, 180], an ER_LONGITUDE_OUT_OF_RANGE error occurs.
- If a latitude value is not in the range [-90, 90], an ER_LATITUDE_OUT_OF_RANGE error occurs.

Ranges shown are in degrees. If an SRS uses another unit, the range uses the corresponding values in its unit. The exact range limits deviate slightly due to floating-point arithmetic.

GeoJSON geometry, feature, and feature collection objects may have a crs property. The parsing function parses named CRS URNs in the urn:ogc:def:crs:EPSG::srid and EPSG:srid namespaces, but not CRSs given as link objects. Also, urn:ogc:def:crs:OGC:1.3:CRS84 is recognized as SRID 4326. If an object has a CRS that is not understood, an error occurs, with the exception that if the optional srid argument is given, any CRS is ignored even if it is invalid.

If a crs member that specifies an SRID different from the top-level object SRID is found at a lower level of the GeoJSON document, an ER_INVALID_GEOJSON_CRS_NOT_TOP_LEVEL error occurs.

As specified in the GeoJSON specification, parsing is case-sensitive for the type member of the GeoJSON input (Point, LineString, and so forth). The specification is silent regarding case sensitivity for other parsing, which in MySQL is not case-sensitive.

This example shows the parsing result for a simple GeoJSON object. Observe that the order of coordinates depends on the SRID used.

```
mysql> SET @json = '{ "type": "Point", "coordinates": [102.0, 0.0]}';
mysql> SELECT ST_AsText(ST_GeomFromGeoJSON(@json));
+-------------------------------------------------------------+
| ST_AsText(ST_GeomFromGeoJSON(@json))                       |
+-------------------------------------------------------------+
| 2154                                                        |
```
SPATIAL AGGREGATE FUNCTIONS

mysql> SELECT ST_SRID(ST_GeomFromGeoJSON(@json));
+-----------------------------+
| ST_SRID(ST_GeomFromGeoJSON(@json)) |
+-----------------------------+
| 4326                        |
+-----------------------------+

mysql> SELECT ST_AsText(ST_SRID(ST_GeomFromGeoJSON(@json),0));
+----------------------------------------------------------------------------------+
| ST_AsText(ST_SRID(ST_GeomFromGeoJSON(@json),0))                                   |
+----------------------------------------------------------------------------------+
| POINT(102 0)                                                                     |
+----------------------------------------------------------------------------------+

12.17.12 Spatial Aggregate Functions

MySQL supports aggregate functions that perform a calculation on a set of values. For general information about these functions, see Section 12.20.1, “Aggregate Function Descriptions”. This section describes the ST_Collect() spatial aggregate function.

ST_Collect() can be used as a window function, as signified in its syntax description by [over_clause], representing an optional OVER clause. over_clause is described in Section 12.21.2, “Window Function Concepts and Syntax”, which also includes other information about window function usage.

- ST_Collect([DISTINCT] g) [over_clause]

Aggregates geometry values and returns a single geometry collection value. With the DISTINCT option, returns the aggregation of the distinct geometry arguments.

As with other aggregate functions, GROUP BY may be used to group arguments into subsets. ST_Collect() returns an aggregate value for each subset.

This function executes as a window function if over_clause is present. over_clause is as described in Section 12.21.2, “Window Function Concepts and Syntax”. In contrast to most aggregate functions that support windowing, ST_Collect() permits use of over_clause together with DISTINCT.

ST_Collect() handles its arguments as follows:

- NULL arguments are ignored.
- If all arguments are NULL or the aggregate result is empty, the return value is NULL.
- If any geometry argument is not a syntactically well-formed geometry, an ER_GIS_INVALID_DATA error occurs.
- If any geometry argument is a syntactically well-formed geometry in an undefined spatial reference system (SRS), an ER_SRS_NOT_FOUND error occurs.
- If there are multiple geometry arguments and those arguments are in the same SRS, the return value is in that SRS. If those arguments are not in the same SRS, an ER_GIS_DIFFERENT_SRIDS_AGGREGATION error occurs.
- The result is the narrowest MultiXxx or GeometryCollection value possible, with the result type determined from the non-NULL geometry arguments as follows:
  - If all arguments are Point values, the result is a MultiPoint value.
  - If all arguments are LineString values, the result is a MultilineString value.
  - If all arguments are Polygon values, the result is a MultiPolygon value.
• Otherwise, the arguments are a mix of geometry types and the result is a 
  `GeometryCollection` value.

This example data set shows hypothetical products by year and location of manufacture:

```sql
CREATE TABLE product (  
  year INTEGER,  
  product VARCHAR(256),  
  location Geometry
);

INSERT INTO product  
(year, product, location) VALUES  
(2000, "Calculator", ST_GeomFromText('point(60 -24)',4326)),  
(2000, "Computer", ST_GeomFromText('point(28 -77)',4326)),  
(2000, "Abacus", ST_GeomFromText('point(28 -77)',4326)),  
(2000, "TV", ST_GeomFromText('point(38 60)',4326)),  
(2001, "Calculator", ST_GeomFromText('point(60 -24)',4326)),  
(2001, "Computer", ST_GeomFromText('point(28 -77)',4326));
```

Some sample queries using `ST_Collect()` on the data set:

```sql
mysql> SELECT ST_AsText(ST_Collect(location)) AS result  
           FROM product;
+------------------------------------------------------------------+
| result                                                           |
+------------------------------------------------------------------+
| MULTIPOINT((60 -24),(28 -77),(28 -77),(38 60),(60 -24),(28 -77)) |
+------------------------------------------------------------------+

mysql> SELECT ST_AsText(ST_Collect(DISTINCT location)) AS result  
           FROM product;
+---------------------------------------+
| result                                |
+---------------------------------------+
| MULTIPOINT((60 -24),(28 -77),(38 60)) |
+---------------------------------------+

mysql> SELECT year, ST_AsText(ST_Collect(location)) AS result  
           FROM product GROUP BY year;
+------+------------------------------------------------+
| year | result                                         |
+------+------------------------------------------------+
| 2000 | MULTIPOINT((60 -24),(28 -77),(28 -77),(38 60)) |

This function was added in MySQL 8.0.24.

12.17.13 Spatial Convenience Functions

The functions in this section provide convenience operations on geometry values.

Unless otherwise specified, functions in this section handle their geometry arguments as follows:

- If any argument is **NULL**, the return value is **NULL**.
- If any geometry argument is not a syntactically well-formed geometry, an **ER_GIS_INVALID_DATA** error occurs.
- If any geometry argument is a syntactically well-formed geometry in an undefined spatial reference system (SRS), an **ER_SRS_NOT_FOUND** error occurs.
- For functions that take multiple geometry arguments, if those arguments are not in the same SRS, an **ER_GIS_DIFFERENT_SRIDS** error occurs.
- Otherwise, the return value is non-**NULL**.

These convenience functions are available:

- **ST_Distance_Sphere(g1, g2 [, radius])**

  Returns the minimum spherical distance between Point or MultiPoint arguments on a sphere, in meters. (For general-purpose distance calculations, see the **ST_Distance()** function.) The optional **radius** argument should be given in meters.

  If both geometry parameters are valid Cartesian Point or MultiPoint values in SRID 0, the return value is shortest distance between the two geometries on a sphere with the provided radius. If omitted, the default radius is 6,370,986 meters, Point X and Y coordinates are interpreted as longitude and latitude, respectively, in degrees.

  If both geometry parameters are valid Point or MultiPoint values in a geographic spatial reference system (SRS), the return value is the shortest distance between the two geometries on a sphere with the provided radius. If omitted, the default radius is equal to the mean radius, defined as \((2a+b)/3\), where \(a\) is the semi-major axis and \(b\) is the semi-minor axis of the SRS.

  **ST_Distance_Sphere()** handles its arguments as described in the introduction to this section, with these exceptions:

- Supported geometry argument combinations are Point and Point, or Point and MultiPoint (in any argument order). If at least one of the geometries is neither Point nor MultiPoint, and its SRID is 0, an **ER_NOT_IMPLEMENTED_FOR_CARTESIAN_SRIS** error occurs. If at least one of the geometries is neither Point nor MultiPoint, and its SRID refers to a geographic SRS, an **ER_NOT_IMPLEMENTED_FOR_GEOGRAPHIC_SRIS** error occurs. If any geometry refers to a projected SRS, an **ER_NOT_IMPLEMENTED_FOR_PROJECTED_SRIS** error occurs.

- If any argument has a longitude or latitude that is out of range, an error occurs:

  - If a longitude value is not in the range \((-180, 180]\), an **ER_GEOMETRY_PARAM_LONGITUDE_OUT_OF_RANGE** error occurs (**ER_LONGITUDE_OUT_OF_RANGE** prior to MySQL 8.0.12).
Spatial Convenience Functions

- If a latitude value is not in the range \([-90, 90]\), an
  \texttt{ER\_GEOMETRY\_PARAM\_LATITUDE\_OUT\_OF\_RANGE} error occurs
  \texttt{(ER\_LATITUDE\_OUT\_OF\_RANGE prior to MySQL 8.0.12)}.

Ranges shown are in degrees. If an SRS uses another unit, the range uses the corresponding
values in its unit. The exact range limits deviate slightly due to floating-point arithmetic.

- If the \texttt{radius} argument is present but not positive, an \texttt{ER\_NONPOSITIVE\_RADIUS} error occurs.

- If the distance exceeds the range of a double-precision number, an \texttt{ER\_STD\_OVERFLOW\_ERROR} error occurs.

```sql
mysql> SET @pt1 = ST_GeomFromText('POINT(0 0)');
mysql> SET @pt2 = ST_GeomFromText('POINT(180 0)');
mysql> SELECT ST_Distance_Sphere(@pt1, @pt2);
+----------------------------------+
<table>
<thead>
<tr>
<th>ST_Distance_Sphere(@pt1, @pt2)</th>
</tr>
</thead>
<tbody>
<tr>
<td>20015042.813723423</td>
</tr>
<tr>
<td>----------------------------------</td>
</tr>
</tbody>
</table>
```

- \texttt{ST\_IsValid(g)}

Returns 1 if the argument is geometrically valid, 0 if the argument is not geometrically valid.
Geometry validity is defined by the OGC specification.

The only valid empty geometry is represented in the form of an empty geometry collection value.
\texttt{ST\_IsValid()} returns 1 in this case. MySQL does not support GIS \texttt{EMPTY} values such as \texttt{POINT EMPTY}.

\texttt{ST\_IsValid()} handles its arguments as described in the introduction to this section, with this exception:

- If the geometry has a geographic SRS with a longitude or latitude that is out of range, an error occurs:

  - If a longitude value is not in the range \((-180, 180]\), an
    \texttt{ER\_GEOMETRY\_PARAM\_LONGITUDE\_OUT\_OF\_RANGE} error occurs
    \texttt{(ER\_LONGITUDE\_OUT\_OF\_RANGE prior to MySQL 8.0.12)}.

  - If a latitude value is not in the range \([-90, 90]\), an
    \texttt{ER\_GEOMETRY\_PARAM\_LATITUDE\_OUT\_OF\_RANGE} error occurs
    \texttt{(ER\_LATITUDE\_OUT\_OF\_RANGE prior to MySQL 8.0.12)}.

Ranges shown are in degrees. If an SRS uses another unit, the range uses the corresponding
values in its unit. The exact range limits deviate slightly due to floating-point arithmetic.

```sql
mysql> SET @ls1 = ST_GeomFromText('LINESTRING(0 0,-0.00 0,0.0 0)');
mysql> SET @ls2 = ST_GeomFromText('LINESTRING(0 0, 1 1)');
mysql> SELECT ST_IsValid(@ls1);
+------------------+
<table>
<thead>
<tr>
<th>ST_IsValid(@ls1)</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
</tr>
</tbody>
</table>
+------------------+
mysql> SELECT ST_IsValid(@ls2);
+------------------+
<table>
<thead>
<tr>
<th>ST_IsValid(@ls2)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
</tr>
</tbody>
</table>
+------------------+
```
Spatial Convenience Functions

- **ST_MakeEnvelope**(pt1, pt2)

Returns the rectangle that forms the envelope around two points, as a `Point`, `LineString`, or `Polygon`.

Calculations are done using the Cartesian coordinate system rather than on a sphere, spheroid, or on earth.

Given two points `pt1` and `pt2`, `ST_MakeEnvelope()` creates the result geometry on an abstract plane like this:

- If `pt1` and `pt2` are equal, the result is the point `pt1`.
- Otherwise, if `(pt1, pt2)` is a vertical or horizontal line segment, the result is the line segment `(pt1, pt2)`.
- Otherwise, the result is a polygon using `pt1` and `pt2` as diagonal points.

The result geometry has an SRID of 0.

`ST_MakeEnvelope()` handles its arguments as described in the introduction to this section, with these exceptions:

- If the arguments are not `Point` values, an `ER_WRONG_ARGUMENTS` error occurs.
- An `ER_GIS_INVALID_DATA` error occurs for the additional condition that any coordinate value of the two points is infinite or NaN.
- If any geometry has an SRID value for a geographic spatial reference system (SRS), an `ER_NOTIMPLEMENTED_FOR_GEOGRAPHIC_SRS` error occurs.

```sql
mysql> SET @pt1 = ST_GeomFromText('POINT(0 0)');
mysql> SET @pt2 = ST_GeomFromText('POINT(1 1)');
mysql> SELECT ST_AsText(ST_MakeEnvelope(@pt1, @pt2));
+----------------------------------------+
| ST_AsText(ST_MakeEnvelope(@pt1, @pt2)) |
+----------------------------------------+
| POLYGON((0 0,1 0,1 1,0 1,0 0))         |
+----------------------------------------+
```

- **ST_Simplify**(g, max_distance)

Simplifies a geometry using the Douglas-Peucker algorithm and returns a simplified value of the same type.

The geometry may be any geometry type, although the Douglas-Peucker algorithm may not actually process every type. A geometry collection is processed by giving its components one by one to the simplification algorithm, and the returned geometries are put into a geometry collection as result.

The `max_distance` argument is the distance (in units of the input coordinates) of a vertex to other segments to be removed. Vertices within this distance of the simplified linestring are removed.

According to Boost.Geometry, geometries might become invalid as a result of the simplification process, and the process might create self-intersections. To check the validity of the result, pass it to `ST_IsValid()`.

`ST_Simplify()` handles its arguments as described in the introduction to this section, with this exception:

- If the `max_distance` argument is not positive, or is `NaN`, an `ER_WRONG_ARGUMENTS` error occurs.

```sql
mysql> SET @g = ST_GeomFromText('LINESTRING(0 0,0 1,1 1,1 2,2 2,2 3,3 3)');
mysql> SELECT ST_AsText(ST_Simplify(@g, 0.5));
```
Spatial Convenience Functions

| ST_AsText(ST_Simplify(@g, 0.5)) |
| LINESTRING(0 0, 1 1, 2 3, 3 3) |

\[
\text{mysql}> \text{SELECT ST_AsText(ST_Simplify(@g, 1.0));}
\]

| ST_AsText(ST_Simplify(@g, 1.0)) |
| LINESTRING(0 0, 3 3) |

- **ST_Validate\((g)\)**

Validates a geometry according to the OGC specification. A geometry can be syntactically well-formed (WKB value plus SRID) but geometrically invalid. For example, this polygon is geometrically invalid: \(\text{POLYGON((0 0, 0 0, 0 0, 0 0, 0 0))}\)

\(\text{ST_Validate()}\) returns the geometry if it is syntactically well-formed and is geometrically valid, NULL if the argument is not syntactically well-formed or is not geometrically valid or is NULL. \(\text{ST_Validate()}\) can be used to filter out invalid geometry data, although at a cost. For applications that require more precise results not tainted by invalid data, this penalty may be worthwhile.

If the geometry argument is valid, it is returned as is, except that if an input Polygon or MultiPolygon has clockwise rings, those rings are reversed before checking for validity. If the geometry is valid, the value with the reversed rings is returned.

The only valid empty geometry is represented in the form of an empty geometry collection value. \(\text{ST_Validate()}\) returns it directly without further checks in this case.

As of MySQL 8.0.13, \(\text{ST_Validate()}\) handles its arguments as described in the introduction to this section, with these exceptions:

- If the geometry has a geographic SRS with a longitude or latitude that is out of range, an error occurs:
  - If a longitude value is not in the range \((-180, 180]\), an \(\text{ER_GEOMETRY_PARAM_LONGITUDE_OUT_OF_RANGE}\) error occurs \(\text{(ER_LONGITUDE_OUT_OF_RANGE prior to MySQL 8.0.12)}\).
  - If a latitude value is not in the range \([-90, 90]\), an \(\text{ER_GEOMETRY_PARAM_LATITUDE_OUT_OF_RANGE}\) error occurs \(\text{(ER_LATITUDE_OUT_OF_RANGE prior to MySQL 8.0.12)}\).

Ranges shown are in degrees. The exact range limits deviate slightly due to floating-point arithmetic.

Prior to MySQL 8.0.13, \(\text{ST_Validate()}\) handles its arguments as described in the introduction to this section, with these exceptions:

- If the geometry is not syntactically well-formed, the return value is NULL. An \(\text{ER_GIS_INVALID_DATA}\) error does not occur.

- If the geometry has an SRID value for a geographic spatial reference system (SRS), an \(\text{ER_NOT_IMPLEMENTED_FOR_GEOGRAPHIC_SRS}\) error occurs.

\[
\text{mysql> SET @ls1 = ST_GeomFromText('LINESTRING(0 0)');}
\]
\[
\text{mysql> SET @ls2 = ST_GeomFromText('LINESTRING(0 0, 1 1)');}
\]
\[
\text{mysql> SELECT ST_AsText(ST_Validate(@ls1));}
\]

| ST_AsText(ST_Validate(@ls1)) |
| NULL |

2160
12.18 JSON Functions

The functions described in this section perform operations on JSON values. For discussion of the JSON data type and additional examples showing how to use these functions, see Section 11.5, “The JSON Data Type”.

For functions that take a JSON argument, an error occurs if the argument is not a valid JSON value. Arguments parsed as JSON are indicated by `json_doc`; arguments indicated by `val` are not parsed.

A set of spatial functions for operating on GeoJSON values is also available. See Section 12.17.11, “Spatial GeoJSON Functions”.

MySQL supports two aggregate JSON functions **JSON_ARRAYAGG()** and **JSON_OBJECTAGG()**. See Section 12.20, "Aggregate Functions", for descriptions of these.

MySQL also supports “pretty-printing” of JSON values in an easy-to-read format, using the **JSONPRETTY()** function. You can see how much storage space a given JSON value takes up, and how much space remains for additional storage, using **JSON_STORAGE_SIZE()** and **JSON_STORAGE_FREE()**, respectively. For complete descriptions of these functions, see Section 12.18.8, "JSON Utility Functions".

### 12.18.2 Functions That Create JSON Values

The functions listed in this section compose JSON values from component elements.

- **JSON_ARRAY([val[, val] ...])**

  Evaluates a (possibly empty) list of values and returns a JSON array containing those values.

  ```sql
  mysql> SELECT JSON_ARRAY(1, "abc", NULL, true, CURTIME());
  +---------------------------------------------+
  | JSON_ARRAY(1, "abc", null, true, "11:30:24.000000") |
  +---------------------------------------------+
  ```

- **JSON_OBJECT([key, val[, key, val] ...])**

  Evaluates a (possibly empty) list of key-value pairs and returns a JSON object containing those pairs. An error occurs if any key name is **NULL** or the number of arguments is odd.
Functions That Search JSON Values

- **JSON_QUOTE(string)**
  Quotes a string as a JSON value by wrapping it with double quote characters and escaping interior quote and other characters, then returning the result as a `utf8mb4` string. Returns `NULL` if the argument is `NULL`.

This function is typically used to produce a valid JSON string literal for inclusion within a JSON document.

Certain special characters are escaped with backslashes per the escape sequences shown in Table 12.23, “JSON_UNQUOTE() Special Character Escape Sequences”.

To check only whether any data exists at the path, use `JSON_CONTAINS_PATH()` instead.

The following rules define containment:

- A candidate scalar is contained in a target scalar if and only if they are comparable and are equal. Two scalar values are comparable if they have the same `JSON_TYPE()` types, with the exception that values of types `INTEGER` and `DECIMAL` are also comparable to each other.

- A candidate array is contained in a target array if and only if every element in the candidate is contained in some element of the target.
Functions That Search JSON Values

- A candidate nonarray is contained in a target array if and only if the candidate is contained in some element of the target.

- A candidate object is contained in a target object if and only if for each key in the candidate there is a key with the same name in the target and the value associated with the candidate key is contained in the value associated with the target key.

Otherwise, the candidate value is not contained in the target document.

Starting with MySQL 8.0.17, queries using `JSON_CONTAINS()` on InnoDB tables can be optimized using multi-valued indexes; see Multi-Valued Indexes, for more information.

```sql
mysql> SET @j = '({"a": 1, "b": 2, "c": {"d": 4}});
mysql> SELECT JSON_CONTAINS(@j, @j2, '$.a');
+-------------------------------+
| JSON_CONTAINS(@j, @j2, '$.a') |
+-------------------------------+
|                             1 |
+-------------------------------+
mysql> SELECT JSON_CONTAINS(@j, @j2, '$.b');
+-------------------------------+
| JSON_CONTAINS(@j, @j2, '$.b') |
+-------------------------------+
|                             0 |
+-------------------------------+
```

```sql
mysql> SET @j2 = ('d': 4);
mysql> SELECT JSON_CONTAINS(@j, @j2, '$.a');
+-------------------------------+
| JSON_CONTAINS(@j, @j2, '$.a') |
+-------------------------------+
|                             0 |
+-------------------------------+
mysql> SELECT JSON_CONTAINS(@j, @j2, '$.c');
+-------------------------------+
| JSON_CONTAINS(@j, @j2, '$.c') |
+-------------------------------+
|                             1 |
+-------------------------------+
```

- `JSON_CONTAINS_PATH(json_doc, one_or_all, path[, path] ...)`

Returns 0 or 1 to indicate whether a JSON document contains data at a given path or paths. Returns `NULL` if any argument is `NULL`. An error occurs if the `json_doc` argument is not a valid JSON document, any `path` argument is not a valid path expression, or `one_or_all` is not 'one' or 'all'.

To check for a specific value at a path, use `JSON_CONTAINS()` instead.

The return value is 0 if no specified path exists within the document. Otherwise, the return value depends on the `one_or_all` argument:

- 'one': 1 if at least one path exists within the document, 0 otherwise.
- 'all': 1 if all paths exist within the document, 0 otherwise.
Functions That Search JSON Values

+---------------------------------------------+ 0 |
mysql> SELECT JSON_CONTAINS_PATH(@j, 'one', '$.c.d'); |
| JSON_CONTAINS_PATH(@j, 'one', '$.c.d') | 1 |
mysql> SELECT JSON_CONTAINS_PATH(@j, 'one', '$.a.d'); |
| JSON_CONTAINS_PATH(@j, 'one', '$.a.d') | 0 |

• JSON_EXTRACT(json_doc, path[, path] ...)
Returns data from a JSON document, selected from the parts of the document matched by the path arguments. Returns NULL if any argument is NULL or no paths locate a value in the document. An error occurs if the json_doc argument is not a valid JSON document or any path argument is not a valid path expression.

The return value consists of all values matched by the path arguments. If it is possible that those arguments could return multiple values, the matched values are autowrapped as an array, in the order corresponding to the paths that produced them. Otherwise, the return value is the single matched value.

mysql> SELECT JSON_EXTRACT('[10, 20, [30, 40]]', '$[1]'); |
| JSON_EXTRACT('[10, 20, [30, 40]]', '$[1]') | 20 |
mysql> SELECT JSON_EXTRACT('[10, 20, [30, 40]]', '$[1]', '$[0]'); |
| JSON_EXTRACT('[10, 20, [30, 40]]', '$[1]', '$[0]') | [20, 10] |
mysql> SELECT JSON_EXTRACT('[10, 20, [30, 40]]', '$[2][*]'); |
| JSON_EXTRACT('[10, 20, [30, 40]]', '$[2][*]') | [30, 40] |

MySQL supports the -> operator as shorthand for this function as used with 2 arguments where the left hand side is a JSON column identifier (not an expression) and the right hand side is the JSON path to be matched within the column.

• column->path
The -> operator serves as an alias for the JSON_EXTRACT() function when used with two arguments, a column identifier on the left and a JSON path on the right that is evaluated against the JSON document (the column value). You can use such expressions in place of column identifiers wherever they occur in SQL statements.

The two SELECT statements shown here produce the same output:

mysql> SELECT c, JSON_EXTRACT(c, "$.id"), g > FROM jemp > WHERE JSON_EXTRACT(c, "$.id") > 1 > ORDER BY JSON_EXTRACT(c, "$.name"); |
| c | c->"$.id" | g |
| {"id": "3", "name": "Barney"} | 3 |
Functions That Search JSON Values

| {"id": "4", "name": "Betty"} | "4"
|
4 |
| {"id": "2", "name": "Wilma"} | "2"
|
2 |
+-------------------------------+-----------+------+
3 rows in set (0.00 sec)
mysql> SELECT c, c->"$.id", g
> FROM jemp
> WHERE c->"$.id" > 1
> ORDER BY c->"$.name";
+-------------------------------+-----------+------+
| c
| c->"$.id" | g
|
+-------------------------------+-----------+------+

3 | NULL |
| {"id": "4", "name": "Betty"} | "4"
|
4 |
1 |
| {"id": "2", "name": "Wilma"} | "2"
|
2 | NULL |
+-------------------------------+-----------+------+------+
3 rows in set (0.00 sec)
mysql> DELETE FROM jemp WHERE c->"$.id" = "4";
Query OK, 1 row affected (0.04 sec)
mysql> SELECT c, c->"$.id", g, n
> FROM jemp
> WHERE JSON_EXTRACT(c, "$.id") > 1
> ORDER BY c->"$.name";
+-------------------------------+-----------+------+------+
| c
| c->"$.id" | g
| n
|
+-------------------------------+-----------+------+------+
| {"id": "3", "name": "Barney"} | "3"
|
3 | NULL |
| {"id": "2", "name": "Wilma"} | "2"
|
2 | NULL |
+-------------------------------+-----------+------+------+
2 rows in set (0.00 sec)

(See Indexing a Generated Column to Provide a JSON Column Index, for the statements used to
create and populate the table just shown.)
This also works with JSON array values, as shown here:
mysql> CREATE TABLE tj10 (a JSON, b INT);
Query OK, 0 rows affected (0.26 sec)
mysql> INSERT INTO tj10
> VALUES ("[3,10,5,17,44]", 33), ("[3,10,5,17,[22,44,66]]", 0);
Query OK, 1 row affected (0.04 sec)
mysql> SELECT a->"$[4]" FROM tj10;
+--------------+
| a->"$[4]"
|

2166


Functions That Search JSON Values

```sql
mysql> SELECT * FROM tj10 WHERE a->"$[0]" = 3;
+-------------------+------+
| a                 | b    |
| [3, 10, 5, 17, 44]| 33   |
| [3, 10, 5, 17, [22, 44, 66]] | 0    |
+-------------------+------+
2 rows in set (0.00 sec)
```

Nested arrays are supported. An expression using `->` evaluates as `NULL` if no matching key is found in the target JSON document, as shown here:

```sql
mysql> SELECT * FROM tj10 WHERE a->"$[4][1]" IS NOT NULL;
+-------------------+------+
| a                 | b    |
| [3, 10, 5, 17, [22, 44, 66]] | 0    |
+-------------------+------+
```

```sql
mysql> SELECT a->"$[4][1]" FROM tj10;
+--------------+
| a->"$[4][1]" |
| NULL         |
| 44           |
+--------------+
```

This is the same behavior as seen in such cases when using `JSON_EXTRACT()`:

```sql
mysql> SELECT JSON_EXTRACT(a, "$[4][1]") FROM tj10;
+----------------------------+
| JSON_EXTRACT(a, "$[4][1]") |
| NULL                       |
| 44                         |
+----------------------------+
```

• `column->>path`

This is an improved, unquoting extraction operator. Whereas the `->` operator simply extracts a value, the `->>` operator in addition unquotes the extracted result. In other words, given a JSON column value `column` and a path expression `path`, the following three expressions return the same value:

• `JSON_UNQUOTE(JSON_EXTRACT(column, path))`

• `JSON_UNQUOTE(column->path)`

• `column->>path`

The `->>` operator can be used wherever `JSON_UNQUOTE(JSON_EXTRACT())` would be allowed. This includes (but is not limited to) `SELECT` lists, `WHERE` and `HAVING` clauses, and `ORDER BY` and `GROUP BY` clauses.

The next few statements demonstrate some `->>` operator equivalences with other expressions in the `mysql` client:

```sql
mysql> SELECT * FROM jemp WHERE g > 2;
+-------------------+------+
| c                 | g    |
+-------------------+------+
```

2167
Functions That Search JSON Values

See Indexing a Generated Column to Provide a JSON Column Index, for the SQL statements used to create and populate the `jemp` table in the set of examples just shown.

This operator can also be used with JSON arrays, as shown here:

As with `->`, the `->>` operator is always expanded in the output of `EXPLAIN`, as the following example demonstrates:

```sql
mysql> EXPLAIN SELECT c->'$.name' AS name
```
Functions That Search JSON Values

```
FROM jemp WHERE g > 2
```

This is similar to how MySQL expands the `->` operator in the same circumstances.

- **JSON_KEYS(json_doc[, path])**

  Returns the keys from the top-level value of a JSON object as a JSON array, or, if a `path` argument is given, the top-level keys from the selected path. Returns NULL if any argument is NULL, the `json_doc` argument is not an object, or `path`, if given, does not locate an object. An error occurs if the `json_doc` argument is not a valid JSON document or the `path` argument is not a valid path expression or contains a `*` or `**` wildcard.

  The result array is empty if the selected object is empty. If the top-level value has nested subobjects, the return value does not include keys from those subobjects.

- **JSON_OVERLAPS(json_doc1, json_doc2)**

  Compares two JSON documents. Returns true (1) if the two document have any key-value pairs or array elements in common. If both arguments are scalars, the function performs a simple equality test.

  This function serves as counterpart to `JSON_CONTAINS()`, which requires all elements of the array searched for to be present in the array searched in. Thus, `JSON_CONTAINS()` performs an AND operation on search keys, while `JSON_OVERLAPS()` performs an OR operation.

  Queries on JSON columns of InnoDB tables using `JSON_OVERLAPS()` in the `WHERE` clause can be optimized using multi-valued indexes. Multi-Valued Indexes, provides detailed information and examples.

  When comparing two arrays, `JSON_OVERLAPS()` returns true if they share one or more array elements in common, and false if they do not:
Functions That Search JSON Values

```
mysql> SELECT JSON_OVERLAPS('[1,3,5,7]', '[2,5,7]');
+-----------------------------+
| JSON_OVERLAPS('[1,3,5,7]', '[2,5,7]') |
| 1                           |
+-----------------------------+
1 row in set (0.00 sec)

mysql> SELECT JSON_OVERLAPS('[1,3,5,7]', '[2,6,7]');
+-----------------------------+
| JSON_OVERLAPS('[1,3,5,7]', '[2,6,7]') |
| 1                           |
+-----------------------------+
1 row in set (0.00 sec)

mysql> SELECT JSON_OVERLAPS('[1,3,5,7]', '[2,6,8]');
+-----------------------------+
| JSON_OVERLAPS('[1,3,5,7]', '[2,6,8]') |
| 0                           |
+-----------------------------+
1 row in set (0.00 sec)

Partial matches are treated as no match, as shown here:
```
mysql> SELECT JSON_OVERLAPS('[\[[1,2], [3,4], 5\]]', '[1, [2,3], [4,5]]');
+-----------------------------------------------------+
| JSON_OVERLAPS('[\[[1,2], [3,4], 5\]]', '[1, [2,3], [4,5]]') |
| 0                                                     |
+-----------------------------------------------------+
1 row in set (0.00 sec)

When comparing objects, the result is true if they have at least one key-value pair in common.
```
mysql> SELECT JSON_OVERLAPS('{"a":1,"b":10,"d":10}', '{"c":1,"e":10,"f":1,"d":10}');
+-----------------------------------------------------------------------+
| JSON_OVERLAPS('{"a":1,"b":10,"d":10}', '{"c":1,"e":10,"f":1,"d":10}') |
| 1                                                                     |
+-----------------------------------------------------------------------+
1 row in set (0.00 sec)

mysql> SELECT JSON_OVERLAPS('{"a":1,"b":10,"d":10}', '{"a":5,"e":10,"f":1,"d":20}');
+-----------------------------------------------------------------------+
| JSON_OVERLAPS('{"a":1,"b":10,"d":10}', '{"a":5,"e":10,"f":1,"d":20}') |
| 0                                                                     |
+-----------------------------------------------------------------------+
1 row in set (0.00 sec)

If two scalars are used as the arguments to the function, JSON_OVERLAPS() performs a simple test for equality:
```
mysql> SELECT JSON_OVERLAPS('5', '5');
+-------------------------+
| JSON_OVERLAPS('5', '5') |
| 1                      |
+-------------------------+
1 row in set (0.00 sec)

mysql> SELECT JSON_OVERLAPS('5', '6');
+-------------------------+
| JSON_OVERLAPS('5', '6') |
| 0                      |
+-------------------------+

```

2170
When comparing a scalar with an array, `JSON_OVERLAPS()` attempts to treat the scalar as an array element. In this example, the second argument 6 is interpreted as [6], as shown here:

```sql
mysql> SELECT JSON_OVERLAPS('[4,5,6,7]', '6');
+---------------------------------+
| JSON_OVERLAPS('[4,5,6,7]', '6') |
+---------------------------------+
|                               1 |
+---------------------------------+
1 row in set (0.00 sec)
```

The function does not perform type conversions:

```sql
mysql> SELECT JSON_OVERLAPS('[4,5,"6",7]', '6');
+-----------------------------------+
| JSON_OVERLAPS('[4,5,"6",7]', '6') |
+-----------------------------------+
|                                0 |
+-----------------------------------+
1 row in set (0.00 sec)

mysql> SELECT JSON_OVERLAPS('[4,5,6,7]', '"6"');
+-----------------------------------+
| JSON_OVERLAPS('[4,5,6,7]', '"6"') |
+-----------------------------------+
|                                0 |
+-----------------------------------+
1 row in set (0.00 sec)
```

`JSON_OVERLAPS()` was added in MySQL 8.0.17.

- `JSON_SEARCH(json_doc, one_or_all, search_str[, escape_char[, path] ...])`

  Returns the path to the given string within a JSON document. Returns NULL if any of the `json_doc`, `search_str`, or `path` arguments are NULL; no `path` exists within the document; or `search_str` is not found. An error occurs if the `json_doc` argument is not a valid JSON document, any `path` argument is not a valid path expression, `one_or_all` is not 'one' or 'all', or `escape_char` is not a constant expression.

  The `one_or_all` argument affects the search as follows:

  - 'one': The search terminates after the first match and returns one path string. It is undefined which match is considered first.

  - 'all': The search returns all matching path strings such that no duplicate paths are included. If there are multiple strings, they are autowrapped as an array. The order of the array elements is undefined.

Within the `search_str` search string argument, the % and _ characters work as for the LIKE operator: % matches any number of characters (including zero characters), and _ matches exactly one character.

To specify a literal % or _ character in the search string, precede it by the escape character. The default is \ if the `escape_char` argument is missing or NULL. Otherwise, `escape_char` must be a constant that is empty or one character.

For more information about matching and escape character behavior, see the description of `LIKE` in Section 12.8.1, "String Comparison Functions and Operators". For escape character handling, a difference from the LIKE behavior is that the escape character for `JSON_SEARCH()` must evaluate to a constant at compile time, not just at execution time. For example, if `JSON_SEARCH()` is used
in a prepared statement and the escape_char argument is supplied using a ? parameter, the parameter value might be constant at execution time, but is not at compile time.

search_str and path are always interpreted as utf8mb4 strings, regardless of their actual encoding. This is a known issue which is fixed in MySQL 8.0.24 (Bug #32449181).

```sql
mysql> SET @j = '\{"abc", [{"k": "10"}, "def"},{"x":"abc"},{"y":"bcd"}]\';
mysql> SELECT JSON_SEARCH(@j, 'one', 'abc');
+-----------------------------------------+
| JSON_SEARCH(@j, 'one', 'abc')          |
| +-------------------------------+    |
| "$[0]"                          |
| +-------------------------------+    |
mysql> SELECT JSON_SEARCH(@j, 'all', 'abc');
+-----------------------------------------+
| JSON_SEARCH(@j, 'all', 'abc')          |
| +-------------------------------+    |
| ["$[0]", "$[2].x"]                |
| +-------------------------------+    |
mysql> SELECT JSON_SEARCH(@j, 'all', 'ghi');
+-----------------------------------------+
| JSON_SEARCH(@j, 'all', 'ghi')          |
| +-------------------------------+    |
| NULL                          |
| +-------------------------------+    |
mysql> SELECT JSON_SEARCH(@j, 'all', '10');
+-----------------------------------------+
| JSON_SEARCH(@j, 'all', '10')          |
| +-------------------------------+    |
| "$[1][0].k"                      |
| +-------------------------------+    |
mysql> SELECT JSON_SEARCH(@j, 'all', '10', NULL, '$');
+-----------------------------------------+
| JSON_SEARCH(@j, 'all', '10', NULL, '$') |
| +-------------------------------+    |
| "$[1][0].k"                             |
| +-------------------------------+    |
mysql> SELECT JSON_SEARCH(@j, 'all', '10', NULL, '$[*]');
+-----------------------------------------+
| JSON_SEARCH(@j, 'all', '10', NULL, '$[*]') |
| +-------------------------------+    |
| "$[1][0].k"                                |
| +-------------------------------+    |
mysql> SELECT JSON_SEARCH(@j, 'all', '10', NULL, '$**.k');
+-----------------------------------------+
| JSON_SEARCH(@j, 'all', '10', NULL, '$**.k') |
| +-------------------------------+    |
| "$[1][0].k"                                 |
| +-------------------------------+    |
mysql> SELECT JSON_SEARCH(@j, 'all', '10', NULL, '$[*][0].k');
+-----------------------------------------+
| JSON_SEARCH(@j, 'all', '10', NULL, '$[*][0].k') |
| +-------------------------------+    |
| "$[1][0].k"                                     |
| +-------------------------------+    |
mysql> SELECT JSON_SEARCH(@j, 'all', '10', NULL, '$[1]');
+-----------------------------------------+
| JSON_SEARCH(@j, 'all', '10', NULL, '$[1]') |
| +-------------------------------+    |
| "$[1][0].k"                          |
| +-------------------------------+    |
```
Functions That Search JSON Values

mysql> SELECT JSON_SEARCH(@j, 'all', '10', NULL, '$[1][0]');
+-----------------------------------------------+
| JSON_SEARCH(@j, 'all', '10', NULL, '$[1][0]') |
+-----------------------------------------------+

| JSON_SEARCH(@j, 'all', '%b%', '', '$[1]') |
+-------------------------------------------+
| NULL                                      |
+-------------------------------------------+

mysql> SELECT JSON_SEARCH(@j, 'all', '%b%', '', '$[3]');
+-------------------------------------------+
| JSON_SEARCH(@j, 'all', '%b%', '', '$[3]') |
+-------------------------------------------+
| "$[3].y"                                  |
+-------------------------------------------+

For more information about the JSON path syntax supported by MySQL, including rules governing the wildcard operators * and **, see JSON Path Syntax.
Functions That Search JSON Values

- **JSON_VALUE(json_doc, path)**

Extracts a value from a JSON document at the path given in the specified document, and returns the extracted value, optionally converting it to a desired type. The complete syntax is shown here:

```
JSON_VALUE(json_doc, path [RETURNING type] [on_empty] [on_error])
```

- **on_empty**: {null | error | default value} on empty
- **on_error**: {null | error | default value} on error

`json_doc` is a valid JSON document.

`path` is a JSON path pointing to a location in the document.

`type` is one of the following data types:

- float
- double
- decimal
- signed
- unsigned
- date
- time
- datetime
- year (MySQL 8.0.22 and later)

YEAR values of one or two digits are not supported.

- char
- json

The types just listed are the same as the (non-array) types supported by the **CAST()** function.

If not specified by a **RETURNING** clause, the **JSON_VALUE()** function's return type is **VARCHAR(512)**. When no character set is specified for the return type, **JSON_VALUE()** uses **utf8mb4** with the binary collation, which is case-sensitive; if **utf8mb4** is specified as the character...
Functions That Search JSON Values

set for the result, the server uses the default collation for this character set, which is not casesensitive.
When the data at the specified path consists of or resolves to a JSON null literal, the function returns
SQL NULL.
on_empty, if specified, determines how JSON_VALUE() behaves when no data is found at the path
given; this clause takes one of the following values:
• NULL ON EMPTY: The function returns NULL; this is the default ON EMPTY behavior.
• DEFAULT value ON EMPTY: the provided value is returned. The value's type must match that
of the return type.
• ERROR ON EMPTY: The function throws an error.
If used, on_error takes one of the following values with the corresponding outcome when an error
occurs, as listed here:
• NULL ON ERROR: JSON_VALUE() returns NULL; this is the default behavior if no ON ERROR
clause is used.
• DEFAULT value ON ERROR: This is the value returned; its value must match that of the return
type.
• ERROR ON ERROR: An error is thrown.
ON EMPTY, if used, must precede any ON ERROR clause. Specifying them in the wrong order results
in a syntax error.
Error handling.

In general, errors are handled by JSON_VALUE() as follows:

• All JSON input (document and path) is checked for validity. If any of it is not valid, an SQL error is
thrown without triggering the ON ERROR clause.
• ON ERROR is triggered whenever any of the following events occur:
• Attempting to extract an object or an array, such as that resulting from a path that resolves to
multiple locations within the JSON document
• Conversion errors, such as attempting to convert 'asdf' to an UNSIGNED value
• Truncation of values
• A conversion error always triggers a warning even if NULL ON ERROR or DEFAULT ... ON
ERROR is specified.
• The ON EMPTY clause is triggered when the source JSON document (expr) contains no data at
the specified location (path).
JSON_VALUE() was introduced in MySQL 8.0.21.
Examples.

Two simple examples are shown here:

mysql> SELECT JSON_VALUE('{"fname": "Joe", "lname": "Palmer"}', '$.fname');
+--------------------------------------------------------------+
| JSON_VALUE('{"fname": "Joe", "lname": "Palmer"}', '$.fname') |
+--------------------------------------------------------------+
| Joe
|
+--------------------------------------------------------------+
mysql> SELECT JSON_VALUE('{"item": "shoes", "price": "49.95"}', '$.price'
-> RETURNING DECIMAL(4,2)) AS price;

2175


Functions That Search JSON Values

+-------+  
| price |  
| 49.95 |  

The statement `SELECT JSON_VALUE(json_doc, path RETURNING type)` is equivalent to the following statement:

```
SELECT CAST(
    JSON_UNQUOTE(JSON_EXTRACT(json_doc, path))
AS type);
```

`JSON_VALUE()` simplifies creating indexes on JSON columns by making it unnecessary in many cases to create a generated column and then an index on the generated column. You can do this when creating a table `t1` that has a JSON column by creating an index on an expression that uses `JSON_VALUE()` operating on that column (with a path that matches a value in that column), as shown here:

```
CREATE TABLE t1(
    j JSON,
    INDEX i1 ( (JSON_VALUE(j, '$.id' RETURNING UNSIGNED)) )
);
```

The following `EXPLAIN` output shows that a query against `t1` employing the index expression in the `WHERE` clause uses the index thus created:

```
mysql> EXPLAIN SELECT * FROM t1
    -> WHERE JSON_VALUE(j, '$.id' RETURNING UNSIGNED) = 123;
```

```
*************************** 1. row ***************************
id: 1
select_type: SIMPLE
table: t1
partitions: NULL
type: ref
possible_keys: i1
key: i1
key_len: 9
ref: const
rows: 1
filtered: 100.00
Extra: NULL
```

This achieves much the same effect as creating a table `t2` with an index on a generated column (see `Indexing a Generated Column to Provide a JSON Column Index`), like this one:

```
CREATE TABLE t2 (
    j JSON,
    g INT GENERATED ALWAYS AS (j->'$.id'),
    INDEX i1 (j)
);
```

The `EXPLAIN` output for a query against this table, referencing the generated column, shows that the index is used in the same way as for the previous query against table `t1`:

```
mysql> EXPLAIN SELECT * FROM t2 WHERE g = 123;
```

```
*************************** 1. row ***************************
id: 1
select_type: SIMPLE
table: t2
partitions: NULL
type: ref
possible_keys: i1
key: i1
key_len: 5
ref: const
rows: 1
filtered: 100.00
```
For information about using indexes on generated columns for indirect indexing of JSON columns, see Indexing a Generated Column to Provide a JSON Column Index.

- `value MEMBER OF(json_array)`

Returns true (1) if `value` is an element of `json_array`, otherwise returns false (0). `value` must be a scalar or a JSON document; if it is a scalar, the operator attempts to treat it as an element of a JSON array.

Queries using `MEMBER OF()` on JSON columns of InnoDB tables in the `WHERE` clause can be optimized using multi-valued indexes. See Multi-Valued Indexes, for detailed information and examples.

Simple scalars are treated as array values, as shown here:

```sql
mysql> SELECT 17 MEMBER OF('[23, "abc", 17, "ab", 10]');
+-------------------------------------------+
| 17 MEMBER OF('[23, "abc", 17, "ab", 10]') |
| 1 |
+-------------------------------------------+
1 row in set (0.00 sec)

mysql> SELECT 'ab' MEMBER OF('[23, "abc", 17, "ab", 10]');
+---------------------------------------------+
| 'ab' MEMBER OF('[23, "abc", 17, "ab", 10]') |
| 1 |
+---------------------------------------------+
1 row in set (0.00 sec)
```

Partial matches of array element values do not match:

```sql
mysql> SELECT 7 MEMBER OF('[23, "abc", 17, "ab", 10]');
+------------------------------------------+
| 7 MEMBER OF('[23, "abc", 17, "ab", 10]') |
| 0 |
+------------------------------------------+
1 row in set (0.00 sec)

mysql> SELECT 'a' MEMBER OF('[23, "abc", 17, "ab", 10]');
+--------------------------------------------+
| 'a' MEMBER OF('[23, "abc", 17, "ab", 10]') |
| 0 |
+--------------------------------------------+
1 row in set (0.00 sec)
```

Conversions to and from string types are not performed:

```sql
mysql> SELECT CAST('[4,5]' AS JSON) MEMBER OF('[3,4],[4,5]');
+----------------------------------+
| CAST('[4,5]' AS JSON) MEMBER OF('[3,4],[4,5]') |
| 0 |
+----------------------------------+
1 row in set (0.00 sec)
```

To use this operator with a value which itself an array, it is necessary to cast it explicitly as a JSON array. You can do this with `CAST(... AS JSON)`:

```sql
mysql> SELECT CAST('[4,5]' AS JSON) MEMBER OF('[3,4],[4,5]');
+----------------------------------+
| CAST('[4,5]' AS JSON) MEMBER OF('[3,4],[4,5]') |
| 0 |
+----------------------------------+
1 row in set (0.00 sec)
```
Functions That Modify JSON Values

|
1 |
+--------------------------------------------------+
1 row in set (0.00 sec)

It is also possible to perform the necessary cast using the JSON_ARRAY() function, like this:
mysql> SELECT JSON_ARRAY(4,5) MEMBER OF('[[3,4],[4,5]]');
+--------------------------------------------+
| JSON_ARRAY(4,5) MEMBER OF('[[3,4],[4,5]]') |
+--------------------------------------------+
|
1 |
+--------------------------------------------+
1 row in set (0.00 sec)

Any JSON objects used as values to be tested or which appear in the target array must be coerced
to the correct type using CAST(... AS JSON) or JSON_OBJECT(). In addition, a target array
containing JSON objects must itself be cast using JSON_ARRAY. This is demonstrated in the
following sequence of statements:
mysql> SET @a = CAST('{"a":1}' AS JSON);
Query OK, 0 rows affected (0.00 sec)
mysql> SET @b = JSON_OBJECT("b", 2);
Query OK, 0 rows affected (0.00 sec)
mysql> SET @c = JSON_ARRAY(17, @b, "abc", @a, 23);
Query OK, 0 rows affected (0.00 sec)
mysql> SELECT @a MEMBER OF(@c), @b MEMBER OF(@c);
+------------------+------------------+
| @a MEMBER OF(@c) | @b MEMBER OF(@c) |
+------------------+------------------+
|
1 |
1 |
+------------------+------------------+
1 row in set (0.00 sec)

The MEMBER OF() operator was added in MySQL 8.0.17.

12.18.4 Functions That Modify JSON Values
The functions in this section modify JSON values and return the result.
• JSON_ARRAY_APPEND(json_doc, path, val[, path, val] ...)
Appends values to the end of the indicated arrays within a JSON document and returns the result.
Returns NULL if any argument is NULL. An error occurs if the json_doc argument is not a valid
JSON document or any path argument is not a valid path expression or contains a * or ** wildcard.
The path-value pairs are evaluated left to right. The document produced by evaluating one pair
becomes the new value against which the next pair is evaluated.
If a path selects a scalar or object value, that value is autowrapped within an array and the new value
is added to that array. Pairs for which the path does not identify any value in the JSON document are
ignored.
mysql> SET @j = '["a", ["b", "c"], "d"]';
mysql> SELECT JSON_ARRAY_APPEND(@j, '$[1]', 1);
+----------------------------------+
| JSON_ARRAY_APPEND(@j, '$[1]', 1) |
+----------------------------------+
| ["a", ["b", "c", 1], "d"]
|
+----------------------------------+
mysql> SELECT JSON_ARRAY_APPEND(@j, '$[0]', 2);
+----------------------------------+
| JSON_ARRAY_APPEND(@j, '$[0]', 2) |
+----------------------------------+
| [["a", 2], ["b", "c"], "d"]
|
+----------------------------------+

2178


In MySQL 5.7, this function was named `JSON_APPEND()`. That name is no longer supported in MySQL 8.0.

- **JSON_ARRAY_INSERT(json_doc, path, val[, path, val] ...)**

Updates a JSON document, inserting into an array within the document and returning the modified document. Returns **NULL** if any argument is **NULL**. An error occurs if the `json_doc` argument is not a valid JSON document or any `path` argument is not a valid path expression or contains a `*` or `**` wildcard or does not end with an array element identifier.

The path-value pairs are evaluated left to right. The document produced by evaluating one pair becomes the new value against which the next pair is evaluated.

Pairs for which the path does not identify any array in the JSON document are ignored. If a path identifies an array element, the corresponding value is inserted at that element position, shifting any following values to the right. If a path identifies an array position past the end of an array, the value is inserted at the end of the array.
Functions That Modify JSON Values

Earlier modifications affect the positions of the following elements in the array, so subsequent paths in the same `JSON_ARRAY_INSERT()` call should take this into account. In the final example, the second path inserts nothing because the path no longer matches anything after the first insert.

- `JSON_INSERT(json_doc, path, val[, path, val] ...)`
  Inserts data into a JSON document and returns the result. Returns `NULL` if any argument is `NULL`. An error occurs if the `json_doc` argument is not a valid JSON document or any `path` argument is not a valid path expression or contains a `*` or `**` wildcard.

  The path-value pairs are evaluated left to right. The document produced by evaluating one pair becomes the new value against which the next pair is evaluated.

  A path-value pair for an existing path in the document is ignored and does not overwrite the existing document value. A path-value pair for a nonexisting path in the document adds the value to the document if the path identifies one of these types of values:

  - A member not present in an existing object. The member is added to the object and associated with the new value.
  - A position past the end of an existing array. The array is extended with the new value. If the existing value is not an array, it is autowrapped as an array, then extended with the new value.

  Otherwise, a path-value pair for a nonexisting path in the document is ignored and has no effect.

  For a comparison of `JSON_INSERT()`, `JSON_REPLACE()`, and `JSON_SET()`, see the discussion of `JSON_SET()`.

- `JSON_MERGE(json_doc, json_doc[, json_doc] ...)`
  Merges two or more JSON documents. Synonym for `JSON_MERGE_PRESERVE()`; deprecated in MySQL 8.0.3 and subject to removal in a future release.
For additional examples, see the entry for `JSON_MERGE_PRESERVE()`.

- `JSON_MERGE_PATCH(json_doc, json_doc[, json_doc] ...)`

Performs an RFC 7396 compliant merge of two or more JSON documents and returns the merged result, without preserving members having duplicate keys. Raises an error if at least one of the documents passed as arguments to this function is not valid.

**Note**

For an explanation and example of the differences between this function and `JSON_MERGE_PRESERVE()`, see `JSON_MERGE_PATCH()` compared with `JSON_MERGE_PRESERVE()`.

`JSON_MERGE_PATCH()` performs a merge as follows:

1. If the first argument is not an object, the result of the merge is the same as if an empty object had been merged with the second argument.

2. If the second argument is not an object, the result of the merge is the second argument.

3. If both arguments are objects, the result of the merge is an object with the following members:
   
   - All members of the first object which do not have a corresponding member with the same key in the second object.
   
   - All members of the second object which do not have a corresponding key in the first object, and whose value is not the JSON `null` literal.
   
   - All members with a key that exists in both the first and the second object, and whose value in the second object is not the JSON `null` literal. The values of these members are the results of recursively merging the value in the first object with the value in the second object.

For additional information, see Normalization, Merging, and Autowrapping of JSON Values.
Functions That Modify JSON Values

| true
|
+-------------------------------+
mysql> SELECT JSON_MERGE_PATCH('[1, 2]', '{"id": 47}');
+------------------------------------------+
| JSON_MERGE_PATCH('[1, 2]', '{"id": 47}') |
+------------------------------------------+
| {"id": 47}
|
+------------------------------------------+
mysql> SELECT JSON_MERGE_PATCH('{ "a": 1, "b":2 }',
>
'{ "a": 3, "c":4 }');
+-----------------------------------------------------------+
| JSON_MERGE_PATCH('{ "a": 1, "b":2 }','{ "a": 3, "c":4 }') |
+-----------------------------------------------------------+
| {"a": 3, "b": 2, "c": 4}
|
+-----------------------------------------------------------+
mysql> SELECT JSON_MERGE_PATCH('{ "a": 1, "b":2 }','{ "a": 3, "c":4 }',
>
'{ "a": 5, "d":6 }');
+-------------------------------------------------------------------------------+
| JSON_MERGE_PATCH('{ "a": 1, "b":2 }','{ "a": 3, "c":4 }','{ "a": 5, "d":6 }') |
+-------------------------------------------------------------------------------+
| {"a": 5, "b": 2, "c": 4, "d": 6}
|
+-------------------------------------------------------------------------------+

You can use this function to remove a member by specifying null as the value of the same member
in the seond argument, as shown here:
mysql> SELECT JSON_MERGE_PATCH('{"a":1, "b":2}', '{"b":null}');
+--------------------------------------------------+
| JSON_MERGE_PATCH('{"a":1, "b":2}', '{"b":null}') |
+--------------------------------------------------+
| {"a": 1}
|
+--------------------------------------------------+

This example shows that the function operates in a recursive fashion; that is, values of members are
not limited to scalars, but rather can themselves be JSON documents:
mysql> SELECT JSON_MERGE_PATCH('{"a":{"x":1}}', '{"a":{"y":2}}');
+----------------------------------------------------+
| JSON_MERGE_PATCH('{"a":{"x":1}}', '{"a":{"y":2}}') |
+----------------------------------------------------+
| {"a": {"x": 1, "y": 2}}
|
+----------------------------------------------------+

JSON_MERGE_PATCH() is supported in MySQL 8.0.3 and later.
JSON_MERGE_PATCH() compared with JSON_MERGE_PRESERVE().
The behavior of
JSON_MERGE_PATCH() is the same as that of JSON_MERGE_PRESERVE(), with the following two
exceptions:
• JSON_MERGE_PATCH() removes any member in the first object with a matching key in the second
object, provided that the value associated with the key in the second object is not JSON null.
• If the second object has a member with a key matching a member in the first object,
JSON_MERGE_PATCH() replaces the value in the first object with the value in the second object,
whereas JSON_MERGE_PRESERVE() appends the second value to the first value.
This example compares the results of merging the same 3 JSON objects, each having a matching
key "a", with each of these two functions:
mysql> SET @x = '{ "a": 1, "b": 2 }',
>
@y = '{ "a": 3, "c": 4 }',
>
@z = '{ "a": 5, "d": 6 }';
mysql> SELECT
->

2182

JSON_MERGE_PATCH(@x, @y, @z)
AS Patch,
JSON_MERGE_PRESERVE(@x, @y, @z) AS Preserve\G


Functions That Modify JSON Values

*************************** 1. row ***************************
Patch: {"a": 5, "b": 2, "c": 4, "d": 6}
Preserve: {"a": [1, 3, 5], "b": 2, "c": 4, "d": 6}

• JSON_MERGE_PRESERVE(json_doc, json_doc[, json_doc] ...)
Merges two or more JSON documents and returns the merged result. Returns NULL if any argument
is NULL. An error occurs if any argument is not a valid JSON document.
Merging takes place according to the following rules. For additional information, see Normalization,
Merging, and Autowrapping of JSON Values.
• Adjacent arrays are merged to a single array.
• Adjacent objects are merged to a single object.
• A scalar value is autowrapped as an array and merged as an array.
• An adjacent array and object are merged by autowrapping the object as an array and merging the
two arrays.
mysql> SELECT JSON_MERGE_PRESERVE('[1, 2]', '[true, false]');

| {"a": [1, 3, 5], "b": 2, "c": 4, "d": 6}
|

2183


This function was added in MySQL 8.0.3 as a synonym for `JSON_MERGE()`. The `JSON_MERGE()` function is now deprecated, and is subject to removal in a future release of MySQL.

This function is similar to but differs from `JSON_MERGE_PATCH()` in significant respects; see `JSON_MERGE_PATCH()` compared with `JSON_MERGE_PRESERVE()`, for more information.

- **JSON_REMOVE(json_doc, path[, path] ...)**

Removes data from a JSON document and returns the result. Returns `NULL` if any argument is `NULL`. An error occurs if the `json_doc` argument is not a valid JSON document or any `path` argument is not a valid path expression or is `$` or contains a `*` or `**` wildcard.

The `path` arguments are evaluated left to right. The document produced by evaluating one path becomes the new value against which the next path is evaluated.

It is not an error if the element to be removed does not exist in the document; in that case, the path does not affect the document.

```sql
mysql> SET @j = '["a", ["b", "c"], "d"]';
mysql> SELECT JSON_REMOVE(@j, '$[1]');
+-------------------------+
| JSON_REMOVE(@j, '$[1]') |
+-------------------------+
| ["a", "d"]            |
+-------------------------+
```

- **JSON_REPLACE(json_doc, path, val[, path, val] ...)**

Replaces existing values in a JSON document and returns the result. Returns `NULL` if any argument is `NULL`. An error occurs if the `json_doc` argument is not a valid JSON document or any `path` argument is not a valid path expression or contains a `*` or `**` wildcard.

The `path-value` pairs are evaluated left to right. The document produced by evaluating one pair becomes the new value against which the next pair is evaluated.

A `path-value` pair for an existing path in the document overwrites the existing document value with the new value. A `path-value` pair for a nonexisting path in the document is ignored and has no effect.

In MySQL 8.0.4, the optimizer can perform a partial, in-place update of a JSON column instead of removing the old document and writing the new document in its entirety to the column. This optimization can be performed for an update statement that uses the `JSON_REPLACE()` function and meets the conditions outlined in Partial Updates of JSON Values.

For a comparison of `JSON_INSERT()`, `JSON_REPLACE()`, and `JSON_SET()`, see the discussion of `JSON_SET()`.

```sql
mysql> SET @j = '{ "a": 1, "b": [2, 3]}';
mysql> SELECT JSON_REPLACE(@j, '$.a', 10, '$.c', '[true, false]');
+-----------------------------------------------------+
| JSON_REPLACE(@j, '$.a', 10, '$.c', '[true, false]') |
| ["a": 10, "b": [2, 3]]                             |
+-----------------------------------------------------+
```

- **JSON_SET(json_doc, path, val[, path, val] ...)**

Inserts or updates data in a JSON document and returns the result. Returns `NULL` if any argument is `NULL` or `path`, if given, does not locate an object. An error occurs if the `json_doc` argument is not
a valid JSON document or any path argument is not a valid path expression or contains a * or ** wildcard.

The path-value pairs are evaluated left to right. The document produced by evaluating one pair becomes the new value against which the next pair is evaluated.

A path-value pair for an existing path in the document overwrites the existing document value with the new value. A path-value pair for a nonexisting path in the document adds the value to the document if the path identifies one of these types of values:

- A member not present in an existing object. The member is added to the object and associated with the new value.
- A position past the end of an existing array. The array is extended with the new value. If the existing value is not an array, it is autowrapped as an array, then extended with the new value.

Otherwise, a path-value pair for a nonexisting path in the document is ignored and has no effect.

In MySQL 8.0.4, the optimizer can perform a partial, in-place update of a JSON column instead of removing the old document and writing the new document in its entirety to the column. This optimization can be performed for an update statement that uses the JSON_SET() function and meets the conditions outlined in Partial Updates of JSON Values.

The JSON_SET(), JSON_INSERT(), and JSON_REPLACE() functions are related:

- JSON_SET() replaces existing values and adds nonexisting values.
- JSON_INSERT() inserts values without replacing existing values.
- JSON_REPLACE() replaces only existing values.

The following examples illustrate these differences, using one path that does exist in the document (`.a`) and another that does not exist (`.c`):

```sql
mysql> SET @j = '{ "a": 1, "b": [2, 3] }';
mysql> SELECT JSON_SET(@j, '$.a', 10, '$.c', '[true, false]');
+-------------------------------------------------+
| JSON_SET(@j, '$.a', 10, '$.c', '[true, false]') |
+-------------------------------------------------+
| {"a": 10, "b": [2, 3], "c": [true, false]}    |
+-------------------------------------------------+
mysql> SELECT JSON_INSERT(@j, '$.a', 10, '$.c', '[true, false]');
+----------------------------------------------------+
| JSON_INSERT(@j, '$.a', 10, '$.c', '[true, false]') |
+----------------------------------------------------+
| {"a": 1, "b": [2, 3], "c": [true, false]}        |
+----------------------------------------------------+
mysql> SELECT JSON_REPLACE(@j, '$.a', 10, '$.c', '[true, false]');
+-----------------------------------------------------+
| JSON_REPLACE(@j, '$.a', 10, '$.c', '[true, false]') |
+-----------------------------------------------------+
| {"a": 10, "b": [2, 3]}                              |
+-----------------------------------------------------+
```

- JSON_UNQUOTE(json_val)

Unquotes JSON value and returns the result as a utf8mb4 string. Returns NULL if the argument is NULL. An error occurs if the value starts and ends with double quotes but is not a valid JSON string literal.

Within a string, certain sequences have special meaning unless the NO_BACKSLASH_ESCAPES SQL mode is enabled. Each of these sequences begins with a backslash (\), known as the escape character. MySQL recognizes the escape sequences shown in Table 12.23, “JSON_UNQUOTE() Special Character Escape Sequences”.

For all other escape sequences, backslash is ignored. That
is, the escaped character is interpreted as if it was not escaped. For example, \x is just x. These sequences are case-sensitive. For example, \b is interpreted as a backspace, but \B is interpreted as B.

### Table 12.23 JSON_UNQUOTE() Special Character Escape Sequences

<table>
<thead>
<tr>
<th>Escape Sequence</th>
<th>Character Represented by Sequence</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;</td>
<td>A double quote (&quot; ) character</td>
</tr>
<tr>
<td>\b</td>
<td>A backspace character</td>
</tr>
<tr>
<td>\f</td>
<td>A formfeed character</td>
</tr>
<tr>
<td>\n</td>
<td>A newline (linefeed) character</td>
</tr>
<tr>
<td>\r</td>
<td>A carriage return character</td>
</tr>
<tr>
<td>\t</td>
<td>A tab character</td>
</tr>
<tr>
<td>\xXXXX</td>
<td>UTF-8 bytes for Unicode value XXXX</td>
</tr>
</tbody>
</table>

Two simple examples of the use of this function are shown here:

```
mysql> SET @j = '"abc"';
mysql> SELECT @j, JSON_UNQUOTE(@j);
+-------+------------------+
| @j    | JSON_UNQUOTE(@j) |
+-------+------------------+
| "abc" | abc              |
+-------+------------------+
mysql> SET @j = '[1, 2, 3]';
mysql> SELECT @j, JSON_UNQUOTE(@j);
+-----------+------------------+
| @j        | JSON_UNQUOTE(@j) |
+-----------+------------------+
| [1, 2, 3] | [1, 2, 3]        |
+-----------+------------------+
```

The following set of examples shows how JSON_UNQUOTE handles escapes with NO_BACKSLASH_ESCAPES disabled and enabled:

```
mysql> SELECT @@sql_mode;
+------------+
| @@sql_mode |
+------------+
|            |
+------------+
mysql> SELECT JSON_UNQUOTE('"\t\u0032"');
+------------------+
| JSON_UNQUOTE('"\t\u0032"') |
+------------------+
|       2          |
+------------------+
mysql> SET @@sql_mode = 'NO_BACKSLASH_ESCAPES';
mysql> SELECT JSON_UNQUOTE('"\t\u0032"');
+------------------+
| JSON_UNQUOTE('"\t\u0032"') |
+------------------+
| \t\u0032        |
+------------------+
mysql> SELECT JSON_UNQUOTE('"\t\u0032"');
+------------------+
| JSON_UNQUOTE('"\t\u0032"') |
+------------------+
| 2                |
+------------------+
```
12.18.5 Functions That Return JSON Value Attributes

The functions in this section return attributes of JSON values.

- **JSON_DEPTH(json_doc)**

  Returns the maximum depth of a JSON document. Returns `NULL` if the argument is `NULL`. An error occurs if the argument is not a valid JSON document.

  An empty array, empty object, or scalar value has depth 1. A nonempty array containing only elements of depth 1 or nonempty object containing only member values of depth 1 has depth 2. Otherwise, a JSON document has depth greater than 2.

- **JSON_LENGTH(json_doc[, path])**

  Returns the length of a JSON document, or, if a `path` argument is given, the length of the value within the document identified by the path. Returns `NULL` if any argument is `NULL` or the `path` argument does not identify a value in the document. An error occurs if the `json_doc` argument is not a valid JSON document or the `path` argument is not a valid path expression or contains a `*` or `**` wildcard.

  The length of a document is determined as follows:

  - The length of a scalar is 1.
  - The length of an array is the number of array elements.
  - The length of an object is the number of object members.
  - The length does not count the length of nested arrays or objects.

```sql
mysql> SELECT JSON_DEPTH('{}'), JSON_DEPTH('[]'), JSON_DEPTH('true');
+------------------+------------------+-
| JSON_DEPTH('{}') | JSON_DEPTH('[]')  | JSON_DEPTH('true') |
+------------------+------------------+-
|                   1 |                   1 |                1  |
+------------------+------------------+-

mysql> SELECT JSON_DEPTH('[10, 20]'), JSON_DEPTH('[[[], {}]]');
+------------------------+------------------------+
| JSON_DEPTH('[10, 20]') | JSON_DEPTH('[[[], {}]]') |
+------------------------+------------------------+
|                      2 |                      2  |
+------------------------+------------------------+

mysql> SELECT JSON_DEPTH('[10, {"a": 20}]');
+-----------------------------------+
| JSON_DEPTH('[10, {"a": 20}]')    |
+-----------------------------------+
|                                 3 |
+-----------------------------------+

mysql> SELECT JSON_LENGTH('[1, 2, {"a": 3}]');
+-------------------------------------------+
| JSON_LENGTH('[1, 2, {"a": 3}]')         |
+-------------------------------------------+
|                                      3    |
+-------------------------------------------+

mysql> SELECT JSON_LENGTH('{"a": 1, "b": {"c": 30}}');
+-------------------------------------------+
| JSON_LENGTH('{"a": 1, "b": {"c": 30}}') |
+-------------------------------------------+
|                                      2    |
+-------------------------------------------+

mysql> SELECT JSON_LENGTH('{"a": 1, "b": {"c": 30}}', '$.b');
+-------------------------------------------+
| JSON_LENGTH('{"a": 1, "b": {"c": 30}}', '$.b') |
+-------------------------------------------+
|                                         2    |
+-------------------------------------------+
Functions That Return JSON Value Attributes

+------------------------------------------------+
|
1 |
+------------------------------------------------+

• JSON_TYPE(json_val)
Returns a utf8mb4 string indicating the type of a JSON value. This can be an object, an array, or a
scalar type, as shown here:
mysql> SET @j = '{"a": [10, true]}';
mysql> SELECT JSON_TYPE(@j);
+---------------+
| JSON_TYPE(@j) |
+---------------+
| OBJECT
|
+---------------+
mysql> SELECT JSON_TYPE(JSON_EXTRACT(@j, '$.a'));
+------------------------------------+
| JSON_TYPE(JSON_EXTRACT(@j, '$.a')) |
+------------------------------------+
| ARRAY
|
+------------------------------------+
mysql> SELECT JSON_TYPE(JSON_EXTRACT(@j, '$.a[0]'));
+---------------------------------------+
| JSON_TYPE(JSON_EXTRACT(@j, '$.a[0]')) |
+---------------------------------------+
| INTEGER
|
+---------------------------------------+
mysql> SELECT JSON_TYPE(JSON_EXTRACT(@j, '$.a[1]'));
+---------------------------------------+
| JSON_TYPE(JSON_EXTRACT(@j, '$.a[1]')) |
+---------------------------------------+
| BOOLEAN
|
+---------------------------------------+

JSON_TYPE() returns NULL if the argument is NULL:
mysql> SELECT JSON_TYPE(NULL);
+-----------------+
| JSON_TYPE(NULL) |
+-----------------+
| NULL
|
+-----------------+

An error occurs if the argument is not a valid JSON value:
mysql> SELECT JSON_TYPE(1);
ERROR 3146 (22032): Invalid data type for JSON data in argument 1
to function json_type; a JSON string or JSON type is required.

For a non-NULL, non-error result, the following list describes the possible JSON_TYPE() return
values:
• Purely JSON types:
• OBJECT: JSON objects
• ARRAY: JSON arrays
• BOOLEAN: The JSON true and false literals
• NULL: The JSON null literal

2188


JSON Table Functions

• Numeric types:
• INTEGER: MySQL TINYINT, SMALLINT, MEDIUMINT and INT and BIGINT scalars
• DOUBLE: MySQL DOUBLE FLOAT scalars
• DECIMAL: MySQL DECIMAL and NUMERIC scalars
• Temporal types:
• DATETIME: MySQL DATETIME and TIMESTAMP scalars
• DATE: MySQL DATE scalars
• TIME: MySQL TIME scalars
• String types:
• STRING: MySQL utf8 character type scalars: CHAR, VARCHAR, TEXT, ENUM, and SET
• Binary types:
• BLOB: MySQL binary type scalars including BINARY, VARBINARY, BLOB, and BIT
• All other types:
• OPAQUE (raw bits)
• JSON_VALID(val)
Returns 0 or 1 to indicate whether a value is valid JSON. Returns NULL if the argument is NULL.
mysql> SELECT JSON_VALID('{"a": 1}');
+------------------------+
| JSON_VALID('{"a": 1}') |
+------------------------+
|
1 |
+------------------------+
mysql> SELECT JSON_VALID('hello'), JSON_VALID('"hello"');
+---------------------+-----------------------+

12.18.6 JSON Table Functions
This section contains information about JSON functions that convert JSON data to tabular data. In
MySQL 8.0.4 and later, one such function—JSON_TABLE()—is supported.
• JSON_TABLE(expr, path COLUMNS (column_list) [AS] alias)
Extracts data from a JSON document and returns it as a relational table having the specified
columns. The complete syntax for this function is shown here:
JSON_TABLE(
expr,
path COLUMNS (column_list)
)
[AS] alias
column_list:
column[, column][, ...]
column:
name FOR ORDINALITY

2189


### JSON Table Functions

A JSON path expression, which is applied to the data source. We refer to the JSON value matching the path as the **row source**; this is used to generate a row of relational data. The `COLUMNS` clause evaluates the row source, finds specific JSON values within the row source, and returns those JSON values as SQL values in individual columns of a row of relational data.

The **alias** is required. The usual rules for table aliases apply (see Section 9.2, “Schema Object Names”).

Beginning with MySQL 8.0.27, this function compares column names in case-insensitive fashion.

**JSON_TABLE()** supports four types of columns, described in the following list:

1. **name FOR ORDINALITY**: This type enumerates rows in the `COLUMNS` clause; the column named `name` is a counter whose type is `UNSIGNED INT`, and whose initial value is 1. This is equivalent to specifying a column as `AUTO_INCREMENT` in a `CREATE TABLE` statement, and can be used to distinguish parent rows with the same value for multiple rows generated by a `NESTED [PATH]` clause.

2. **name type PATH string_path [on_empty] [on_error]**: Columns of this type are used to extract values specified by `string_path` in MySQL scalar data type (that is, it cannot be an object or array).

3. **name type EXISTS PATH path**

4. **NESTED [PATH] path COLUMNS (column_list)**: This flattens nested objects or arrays in JSON data into a single row along with the JSON values from the parent object or array. Using multiple `PATH` options allows projection of JSON values from multiple levels of nesting into a single row.

The **path** is relative to the parent path row path of `JSON_TABLE()`, or the path of the parent `NESTED [PATH]` clause in the event of nested paths.

**on empty**, if specified, determines what `JSON_TABLE()` does in the event that data is missing (depending on type). This clause is also triggered on a column in a `NESTED PATH` clause when the latter has no match and a `NULL` complemented row is produced for it. `on empty` takes one of the following values:

- **NULL ON EMPTY**: The column is set to `NULL`; this is the default behavior.

- **DEFAULT json_string ON EMPTY**: the provided `json_string` is parsed as JSON, as long as it is valid, and stored instead of the missing value. Column type rules also apply to the default value.

<table>
<thead>
<tr>
<th>name type PATH string path</th>
<th>on_empty</th>
<th>on_error</th>
</tr>
</thead>
<tbody>
<tr>
<td>name type EXISTS PATH string path</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>on_empty:</th>
</tr>
</thead>
<tbody>
<tr>
<td>{NULL</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>on_error:</th>
</tr>
</thead>
<tbody>
<tr>
<td>{NULL</td>
</tr>
</tbody>
</table>

**expr**: This is an expression that returns JSON data. This can be a constant (`"a":1`), a column (`t1.json_data`, given table `t1` specified prior to `JSON_TABLE()` in the FROM clause), or a function call (`JSON_EXTRACT(t1.json_data,'$.post.comments')`).

**path**: A JSON path expression, which is applied to the data source. We refer to the JSON value matching the path as the **row source**; this is used to generate a row of relational data. The `COLUMNS` clause evaluates the row source, finds specific JSON values within the row source, and returns those JSON values as SQL values in individual columns of a row of relational data.

The **alias** is required. The usual rules for table aliases apply (see Section 9.2, “Schema Object Names”).

Beginning with MySQL 8.0.27, this function compares column names in case-insensitive fashion.

**JSON_TABLE()** supports four types of columns, described in the following list:

1. **name FOR ORDINALITY**: This type enumerates rows in the `COLUMNS` clause; the column named `name` is a counter whose type is `UNSIGNED INT`, and whose initial value is 1. This is equivalent to specifying a column as `AUTO_INCREMENT` in a `CREATE TABLE` statement, and can be used to distinguish parent rows with the same value for multiple rows generated by a `NESTED [PATH]` clause.

2. **name type PATH string_path [on_empty] [on_error]**: Columns of this type are used to extract values specified by `string_path` in MySQL scalar data type (that is, it cannot be an object or array). `JSON_TABLE()` extracts data as JSON then coerces it to the column type, using the regular automatic type conversion applying to JSON data in MySQL. A missing value triggers the `on_empty` clause. Saving an object or array triggers the optional `on_error` clause; this also occurs when an error takes place during coercion from the value saved as JSON to the table column, such as trying to save the string `asd` to an integer column.

3. **name type EXISTS PATH path**: This column returns 1 if any data is present at the location specified by `path`, and 0 otherwise. `type` can be any valid MySQL data type, but should normally be specified as some variety of `INT`.

4. **NESTED [PATH] path COLUMNS (column_list)**: This flattens nested objects or arrays in JSON data into a single row along with the JSON values from the parent object or array. Using multiple `PATH` options allows projection of JSON values from multiple levels of nesting into a single row.

The **path** is relative to the parent path row path of `JSON_TABLE()`, or the path of the parent `NESTED [PATH]` clause in the event of nested paths.

**on empty**, if specified, determines what `JSON_TABLE()` does in the event that data is missing (depending on type). This clause is also triggered on a column in a `NESTED PATH` clause when the latter has no match and a `NULL` complemented row is produced for it. **on empty** takes one of the following values:

- **NULL ON EMPTY**: The column is set to `NULL`; this is the default behavior.

- **DEFAULT json_string ON EMPTY**: the provided `json_string` is parsed as JSON, as long as it is valid, and stored instead of the missing value. Column type rules also apply to the default value.
• **ERROR ON EMPTY**: An error is thrown.

If used, `on_error` takes one of the following values with the corresponding result as shown here:

• **NULL ON ERROR**: The column is set to NULL; this is the default behavior.

• **DEFAULT json string ON ERROR**: The `json_string` is parsed as JSON (provided that it is valid) and stored instead of the object or array.

• **ERROR ON ERROR**: An error is thrown.

Prior to MySQL 8.0.20, a warning was thrown if a type conversion error occurred with `NULL ON ERROR` or `DEFAULT ... ON ERROR` was specified or implied. In MySQL 8.0.20 and later, this is no longer the case. (Bug #30628330)

Previously, it was possible to specify `ON EMPTY` and `ON ERROR` clauses in either order. This runs counter to the SQL standard, which stipulates that `ON EMPTY`, if specified, must precede any `ON ERROR` clause. For this reason, beginning with MySQL 8.0.20, specifying `ON ERROR` before `ON EMPTY` is deprecated; trying to do so causes the server to issue a warning. Expect support for the nonstandard syntax to be removed in a future version of MySQL.

When a value saved to a column is truncated, such as saving 3.14159 in a `DECIMAL(10,1)` column, a warning is issued independently of any `ON ERROR` option. When multiple values are truncated in a single statement, the warning is issued only once.

Prior to MySQL 8.0.21, when the expression and path passed to this function resolved to JSON null, `JSON_TABLE()` raised an error. In MySQL 8.0.21 and later, it returns `SQL NULL` in such cases, in accordance with the SQL standard, as shown here (Bug #31345503, Bug #99557):

```
mysql> SELECT *
-> FROM
-> JSON_TABLE(
-> '['{"cl": null} '],
-> '[$*]' COLUMNS( cl INT PATH '*.cl' ERROR ON ERROR )
-> ) as jt;
+------+
| cl   |
+------+
| NULL |
1 row in set (0.00 sec)
```

The following query demonstrates the use of `ON EMPTY` and `ON ERROR`. The row corresponding to `{"b":1}` is empty for the path `"$.a"`, and attempting to save `[1,2]` as a scalar produces an error; these rows are highlighted in the output shown.

```
mysql> SELECT *
-> FROM
-> JSON_TABLE(
-> '['{"a":"3"},{"a":2},{"b":1},{"a":0},{"a":[1,2]}'],
-> '[$*]'
-> COLUMNS(
-> rowid FOR ORDINALITY,
-> ac VARCHAR(100) PATH "$.a" DEFAULT '111' ON EMPTY DEFAULT '999' ON ERROR,
-> aj JSON PATH "$.a" DEFAULT '{"x": 333}' ON EMPTY,
-> bx INT EXISTS PATH "$.b"
-> )
-> ) AS tt;
+-------+------+------------+------+
| rowid | ac   | aj         | bx   |
|-------+------+------------+------|
|     1 | 3    | "3"        |    0 |
|     2 | 2    | 2          |    0 |
|     3 | 111  | {"x": 333} |    1 |
+-------+------+------------+------+
```

mysql> SELECT *
-> FROM
-> JSON_TABLE(
-> '{"a":3},{"a":2},{"b":1},{"a":0},{"a":[1,2]} 
-> '[$*]'
-> COLUMNS(
-> rowid FOR ORDINALITY,
-> ac VARCHAR(100) PATH "$.a" DEFAULT '111' ON EMPTY DEFAULT '999' ON ERROR,
-> aj JSON PATH "$.a" DEFAULT '{"x": 333}' ON EMPTY,
-> bx INT EXISTS PATH "$.b"
-> )
-> ) AS tt;
+-------+------+------------+------+
| rowid | ac   | aj         | bx   |
|-------+------+------------+------|
|     1 | 3    | "3"        |    0 |
|     2 | 2    | 2          |    0 |
|     3 | 111  | {"x": 333} |    1 |
+-------+------+------------+------+
Column names are subject to the usual rules and limitations governing table column names. See Section 9.2, “Schema Object Names”.

All JSON and JSON path expressions are checked for validity; an invalid expression of either type causes an error.

Each match for the \textit{path} preceding the \texttt{COLUMNS} keyword maps to an individual row in the result table. For example, the following query gives the result shown here:

\begin{verbatim}
mysql> SELECT * FROM JSON_TABLE(  
    -> '[["x":2,"y":"8"],{"x":"3","y":"7"},{"x":"4","y":6}]',  
    -> "[*]" COLUMNS(  
    -> xval VARCHAR(100) PATH ".x",  
    -> yval VARCHAR(100) PATH ".y"  
    -> ) AS jt1;

+------+------+
| xval | yval |
+------+------+
| 2    | 8    |
| 3    | 7    |
| 4    | 6    |
+------+------+
\end{verbatim}

The expression \texttt{"[*]"} matches each element of the array. You can filter the rows in the result by modifying the path. For example, using \texttt{"[1]"} limits extraction to the second element of the JSON array used as the source, as shown here:

\begin{verbatim}
mysql> SELECT * FROM JSON_TABLE(  
    -> '[["a": 1, "b": [11,111]},{"a": 2, "b": [22,222]},{"a":3}]',  
    -> "[*]" COLUMNS(  
    -> a INT PATH ".a",  
    -> NESTED PATH ".b[*]" COLUMNS (b INT PATH ".b")
    -> ) AS jt1;

+-----+-----+
| a   | b    |
+-----+-----+
| 1   | 11  |
| 2   | 22  |
| 3   | 111 |
+-----+-----+
\end{verbatim}

Within a column definition, \texttt{"\$"} passes the entire match to the column; \texttt{"\$.x"} and \texttt{"\$.y"} pass only the values corresponding to the keys \texttt{x} and \texttt{y}, respectively, within that match. For more information, see \texttt{JSON Path Syntax}.

\texttt{NESTED PATH} (or simply \texttt{NESTED}; \texttt{PATH} is optional) produces a set of records for each match in the \texttt{COLUMNS} clause to which it belongs. If there is no match, all columns of the nested path are set to \texttt{NULL}. This implements an outer join between the topmost clause and \texttt{NESTED \{PATH\}}. An inner join can be emulated by applying a suitable condition in the \texttt{WHERE} clause, as shown here:
Sibling nested paths—that is, two or more instances of `NESTED [PATH]` in the same `COLUMNS` clause—are processed one after another, one at a time. While one nested path is producing records, columns of any sibling nested path expressions are set to `NULL`. This means that the total number of records for a single match within a single containing `COLUMNS` clause is the sum and not the product of all records produced by `NESTED [PATH]` modifiers, as shown here:

```sql
mysql> SELECT *
    -> FROM
    -> JSON_TABLE(
    ->   '[["a": 1, "b": [11,111]], ("a": 2, "b": [22,222])]','
    ->   '$[*]' COLUMNS(
    ->     a INT PATH '$.a',
    ->     NESTED PATH '$.b[*]' COLUMNS (b1 INT PATH '$'),
    ->     NESTED PATH '$.b[*]' COLUMNS (b2 INT PATH '$'),
    ->   )
    ->   ) AS jt;
```

<table>
<thead>
<tr>
<th>a</th>
<th>b1</th>
<th>b2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>11</td>
<td>NULL</td>
</tr>
<tr>
<td>1</td>
<td>111</td>
<td>NULL</td>
</tr>
<tr>
<td>1</td>
<td>NULL</td>
<td>11</td>
</tr>
<tr>
<td>1</td>
<td>NULL</td>
<td>111</td>
</tr>
<tr>
<td>2</td>
<td>22</td>
<td>NULL</td>
</tr>
<tr>
<td>2</td>
<td>222</td>
<td>NULL</td>
</tr>
<tr>
<td>2</td>
<td>NULL</td>
<td>22</td>
</tr>
<tr>
<td>2</td>
<td>NULL</td>
<td>222</td>
</tr>
</tbody>
</table>

A `FOR ORDINALITY` column enumerates records produced by the `COLUMNS` clause, and can be used to distinguish parent records of a nested path, especially if values in parent records are the same, as can be seen here:

```sql
mysql> SELECT *
    -> FROM
    -> JSON_TABLE(
    ->   '(["a": "a_val", "b": [({"c": "c_val","l": [1,2]}),
    ->     ("a": "a_val", "b": [{"c": "c_val","l": [11]}], "c": "c_val","l": [22])])',
    ->   '$[*]' COLUMNS(
    ->     top_ord FOR ORDINALITY,
    ->     apath VARCHAR(10) PATH '$.a',
    ->     NESTED PATH '$.b[*]' COLUMNS (bpath VARCHAR(10) PATH '$.c',
    ->     ord FOR ORDINALITY,
    ->     NESTED PATH '$.l[*]' COLUMNS (lpath varchar(10) PATH '$')
    ->   )
    ->   ) AS jt;
```

<table>
<thead>
<tr>
<th>top_ord</th>
<th>apath</th>
<th>bpath</th>
<th>ord</th>
<th>lpath</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>a_val</td>
<td>c_val</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>a_val</td>
<td>c_val</td>
<td>1</td>
<td>2</td>
</tr>
</tbody>
</table>
The source document contains an array of two elements; each of these elements produces two rows. The values of `apath` and `bpath` are the same over the entire result set; this means that they cannot be used to determine whether `lpath` values came from the same or different parents. The value of the `ord` column remains the same as the set of records having `top_ord` equal to 1, so these two values are from a single object. The remaining two values are from different objects, since they have different values in the `ord` column.

### 12.18.7 JSON Schema Validation Functions

Beginning with MySQL 8.0.17, MySQL supports validation of JSON documents against JSON schemas conforming to [Draft 4 of the JSON Schema specification](https://json-schema.org/draft-04/). This can be done using either of the functions detailed in this section, both of which take two arguments, a JSON schema, and a JSON document which is validated against the schema. `JSON_SCHEMA_VALID()` returns true if the document validates against the schema, and false if it does not; `JSON_SCHEMA_VALIDATION_REPORT()` provides a report in JSON format on the validation.

Both functions handle null or invalid input as follows:

- If at least one of the arguments is `NULL`, the function returns `NULL`.
- If at least one of the arguments is not valid JSON, the function raises an error (`ER_INVALID_TYPE_FOR_JSON`)
- In addition, if the schema is not a valid JSON object, the function returns `ER_INVALID_JSON_TYPE`.

MySQL supports the `required` attribute in JSON schemas to enforce the inclusion of required properties (see the examples in the function descriptions).

MySQL supports the `id`, `$schema`, `description`, and `type` attributes in JSON schemas but does not require any of these.

MySQL does not support external resources in JSON schemas; using the `$ref` keyword causes `JSON_SCHEMA_VALID()` to fail with `ER_NOT_SUPPORTED_YET`.

**Note**

MySQL supports regular expression patterns in JSON schema, which supports but silently ignores invalid patterns (see the description of `JSON_SCHEMA_VALID()` for an example).

These functions are described in detail in the following list:

- **`JSON_SCHEMA_VALID(schema, document)`**

  Validates a JSON document against a JSON schema. Both `schema` and `document` are required. The schema must be a valid JSON object; the document must be a valid JSON document. Provided that these conditions are met: If the document validates against the schema, the function returns true (1); otherwise, it returns false (0).

  In this example, we set a user variable `@schema` to the value of a a JSON schema for geographical coordinates, and another one `@document` to the value of a JSON document containing one such coordinate. We then verify that `@document` validates according to `@schema` by using them as the arguments to `JSON_SCHEMA_VALID()`:

```sql
mysql> SET @schema = '{
  > "id": "http://json-schema.org/geo",
  > "$schema": "http://json-schema.org/draft-04/schema#",
  > "description": "A geographical coordinate",
  > "type": "object",
  > "properties": {
```
Since `@schema` contains the required attribute, we can set `@document` to a value that is otherwise valid but does not contain the required properties, then test it against `@schema`, like this:

```sql
mysql> SET @document = '{}';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT JSON_SCHEMA_VALID(@schema, @document);
+---------------------------------------+
<table>
<thead>
<tr>
<th>JSON_SCHEMA_VALID(@schema, @document)</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
</tr>
</tbody>
</table>
+---------------------------------------+
1 row in set (0.00 sec)
```

If we now set the value of `@schema` to the same JSON schema but without the required attribute, `@document` validates because it is a valid JSON object, even though it contains no properties, as shown here:

```sql
mysql> SET @schema = '{
  "id": "http://json-schema.org/geo",
  "$schema": "http://json-schema.org/draft-04/schema#",
  "description": "A geographical coordinate",
  "type": "object",
  "properties": {
    "latitude": {
      "type": "number",
      "minimum": -90,
      "maximum": 90
    },
    "longitude": {
      "type": "number",
      "minimum": -180,
      "maximum": 180
    }
  }
}';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT JSON_SCHEMA_VALID(@schema, @document);
+---------------------------------------+
<table>
<thead>
<tr>
<th>JSON_SCHEMA_VALID(@schema, @document)</th>
</tr>
</thead>
</table>
+---------------------------------------|
|                                     1 |
+---------------------------------------+
1 row in set (0.00 sec)
```
JSON Schema Validation Functions

<table>
<thead>
<tr>
<th>1</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 row in set (0.00 sec)</td>
</tr>
</tbody>
</table>

**JSON_SCHEMA_VALID() and CHECK constraints.**  
`JSON_SCHEMA_VALID()` can also be used to enforce `CHECK` constraints.

Consider the table `geo` created as shown here, with a JSON column `coordinate` representing a point of latitude and longitude on a map, governed by the JSON schema used as an argument in a `JSON_SCHEMA_VALID()` call which is passed as the expression for a `CHECK` constraint on this table:

```sql
mysql> CREATE TABLE geo (  
-> coordinate JSON,  
-> CHECK(  
-> JSON_SCHEMA_VALID(  
-> '{  
->   "type": "object",  
->   "properties": {  
->     "latitude": {"type": "number", "minimum": -90, "maximum": 90},  
->     "longitude": {"type": "number", "minimum": -180, "maximum": 180}  
->   },  
->   "required": ["latitude", "longitude"]  
->   coordinate  
-> )  
-> );
```

Query OK, 0 rows affected (0.45 sec)

**Note**

Because a MySQL `CHECK` constraint cannot contain references to variables, you must pass the JSON schema to `JSON_SCHEMA_VALID()` inline when using it to specify such a constraint for a table.

We assign JSON values representing coordinates to three variables, as shown here:

```sql
mysql> SET @point1 = '{"latitude":59, "longitude":18}';
```

Query OK, 0 rows affected (0.00 sec)

```sql
mysql> SET @point2 = '{"latitude":91, "longitude":0}';
```

Query OK, 0 rows affected (0.00 sec)

```sql
mysql> SET @point3 = '{"longitude":120}';
```

Query OK, 0 rows affected (0.00 sec)

The first of these values is valid, as can be seen in the following `INSERT` statement:

```sql
mysql> INSERT INTO geo VALUES(@point1);
```

Query OK, 1 row affected (0.05 sec)

The second JSON value is invalid and so fails the constraint, as shown here:

```sql
mysql> INSERT INTO geo VALUES(@point2);
ERROR 3819 (HY000): Check constraint 'geo_chk_1' is violated.
```

In MySQL 8.0.19 and later, you can obtain precise information about the nature of the failure—in this case, that the `latitude` value exceeds the maximum defined in the schema—by issuing a `SHOW WARNINGS` statement:

```sql
mysql> SHOW WARNINGS\G
```

```
*************************** 1. row ***************************
Level: Error
Code: 3934
Message: The JSON document location '#/latitude' failed requirement 'maximum' at
```

2196
JSON Schema Validation Functions

JSON Schema location '#/properties/latitude'.
*************************** 2. row ***************************
Level: Error
Code: 3819
Message: Check constraint 'geo_chk_1' is violated.
2 rows in set (0.00 sec)

The third coordinate value defined above is also invalid, since it is missing the required latitude
property. As before, you can see this by attempting to insert the value into the geo table, then issuing
SHOW WARNINGS afterwards:
mysql> INSERT INTO geo VALUES(@point3);
ERROR 3819 (HY000): Check constraint 'geo_chk_1' is violated.
mysql> SHOW WARNINGS\G
*************************** 1. row ***************************
Level: Error
Code: 3934
Message: The JSON document location '#' failed requirement 'required' at JSON
Schema location '#'.
*************************** 2. row ***************************
Level: Error
Code: 3819
Message: Check constraint 'geo_chk_1' is violated.
2 rows in set (0.00 sec)

See Section 13.1.20.6, “CHECK Constraints”, for more information.
JSON Schema has support for specifying regular expression patterns for strings, but
the implementation used by MySQL silently ignores invalid patterns. This means that
JSON_SCHEMA_VALID() can return true even when a regular expression pattern is invalid, as
shown here:
mysql> SELECT JSON_SCHEMA_VALID('{"type":"string","pattern":"("}', '"abc"');
+---------------------------------------------------------------+
| JSON_SCHEMA_VALID('{"type":"string","pattern":"("}', '"abc"') |
+---------------------------------------------------------------+
|
1 |
+---------------------------------------------------------------+
1 row in set (0.04 sec)

• JSON_SCHEMA_VALIDATION_REPORT(schema,document)
Validates a JSON document against a JSON schema. Both schema and document are required.
As with JSON_VALID_SCHEMA(), the schema must be a valid JSON object, and the document
must be a valid JSON document. Provided that these conditions are met, the function returns a
report, as a JSON document, on the outcome of the validation. If the JSON document is considered
valid according to the JSON Schema, the function returns a JSON object with one property valid
having the value "true". If the JSON document fails validation, the function returns a JSON object
which includes the properties listed here:
• valid: Always "false" for a failed schema validation
• reason: A human-readable string containing the reason for the failure
• schema-location: A JSON pointer URI fragment identifier indicating where in the JSON
schema the validation failed (see Note following this list)
• document-location: A JSON pointer URI fragment identifier indicating where in the JSON
document the validation failed (see Note following this list)

2197


• **schema-failed-keyword**: A string containing the name of the keyword or property in the JSON schema that was violated

**Note**

JSON pointer URI fragment identifiers are defined in RFC 6901 - JavaScript Object Notation (JSON) Pointer. (These are not the same as the JSON path notation used by `JSON_EXTRACT()` and other MySQL JSON functions.) In this notation, `#` represents the entire document, and `#/myprop` represents the portion of the document included in the top-level property named `myprop`. See the specification just cited and the examples shown later in this section for more information.

In this example, we set a user variable `@schema` to the value of a a JSON schema for geographical coordinates, and another one `@document` to the value of a JSON document containing one such coordinate. We then verify that `@document` validates according to `@schema` by using them as the arguments to `JSON_SCHEMA_VALIDATION_REPORT()`:

```sql
mysql> SET @schema = '{
  
    "id": "http://json-schema.org/geo",
    "$schema": "http://json-schema.org/draft-04/schema#",
    "description": "A geographical coordinate",
    "type": "object",
    "properties": {
      "latitude": {
        "type": "number",
        "minimum": -90,
        "maximum": 90
      },
      "longitude": {
        "type": "number",
        "minimum": -180,
        "maximum": 180
      }
    },
    "required": ["latitude", "longitude"]
  }';
Query OK, 0 rows affected (0.01 sec)

mysql> SET @document = '{
    "latitude": 63.444697,
    "longitude": 10.445118
  }';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT JSON_SCHEMA_VALIDATION_REPORT(@schema, @document);
+---------------------------------------------------+
| JSON_SCHEMA_VALIDATION_REPORT(@schema, @document) |
+---------------------------------------------------+
| { "valid": true }                                 |
+---------------------------------------------------+
1 row in set (0.00 sec)
```

Now we set `@document` such that it specifies an illegal value for one of its properties, like this:

```sql
mysql> SET @document = '{
    "latitude": 63.444697,
    "longitude": 310.445118
  }';
Query OK, 0 rows affected (0.01 sec)
```

Validation of `@document` now fails when tested with `JSON_SCHEMA_VALIDATION_REPORT()`. The output from the function call contains detailed information about the failure (with the function wrapped by `JSON_PRETTY()` to provide better formatting), as shown here:

```sql
mysql> SELECT JSON_SCHEMA_VALIDATION_REPORT(@schema, @document));
+---------------------------------------------------------------------------+
| JSON_SCHEMA_VALIDATION_REPORT(@schema, @document)                         |
| { "valid": true }                                                        |
+---------------------------------------------------------------------------+
1 row in set (0.00 sec)
```

mysql> SELECT JSON_SCHEMA_VALIDATION_REPORT(@schema, @document))
```
Since @schema contains the required attribute, we can set @document to a value that is otherwise valid but does not contain the required properties, then test it against @schema. The output of JSON_SCHEMA_VALIDATION_REPORT() shows that validation fails due to lack of a required element, like this:

```sql
mysql> SET @document = '{}';
Query OK, 0 rows affected (0.00 sec)
```

If we now set the value of @schema to the same JSON schema but without the required attribute, @document validates because it is a valid JSON object, even though it contains no properties, as shown here:

```sql
mysql> SET @schema = '{
  "id": "http://json-schema.org/geo",
  "$schema": "http://json-schema.org/draft-04/schema#",
  "description": "A geographical coordinate",
  "type": "object",
  "properties": {
    "latitude": {
      "type": "number",
      "minimum": -90,
      "maximum": 90
    },
    "longitude": {
      "type": "number",
      "minimum": -180,
      "maximum": 180
    }
  }
}';
Query OK, 0 rows affected (0.00 sec)
```

12.18.8 JSON Utility Functions

This section documents utility functions that act on JSON values, or strings that can be parsed as JSON values. JSON_PRETTY() prints out a JSON value in a format that is easy to read. JSON_STORAGE_SIZE() and JSON_STORAGE_FREE() show, respectively, the amount of storage space used by a given JSON value and the amount of space remaining in a JSON column following a partial update.
• **JSON_PRETTY(json_val)**

Provides pretty-printing of JSON values similar to that implemented in PHP and by other languages and database systems. The value supplied must be a JSON value or a valid string representation of a JSON value. Extraneous whitespaces and newlines present in this value have no effect on the output. For a NULL value, the function returns NULL. If the value is not a JSON document, or if it cannot be parsed as one, the function fails with an error.

Formatting of the output from this function adheres to the following rules:

- Each array element or object member appears on a separate line, indented by one additional level as compared to its parent.

- Each level of indentation adds two leading spaces.

- A comma separating individual array elements or object members is printed before the newline that separates the two elements or members.

- The key and the value of an object member are separated by a colon followed by a space (' : ').

- An empty object or array is printed on a single line. No space is printed between the opening and closing brace.

- Special characters in string scalars and key names are escaped employing the same rules used by the JSON_QUOTE() function.

```sql
mysql> SELECT JSON_PRETTY('123');  # scalar
+--------------------+
| JSON_PRETTY('123') |
+--------------------+
| 123                |
+--------------------+

mysql> SELECT JSON_PRETTY('"[1,3,5]"');  # array
+------------------------+
| JSON_PRETTY('"[1,3,5]"') |
+------------------------+
| [1, 3, 5]              |
+------------------------+

mysql> SELECT JSON_PRETTY('{"a":"10","b":"15","x":"25"}');  # object
+---------------------------------------------+
| JSON_PRETTY('{"a":"10","b":"15","x":"25"}') |
+---------------------------------------------+
| { "a": "10", "b": "15", "x": "25" } |
+---------------------------------------------+

mysql> SELECT JSON_PRETTY('"["a",1,"key1": "value1"],["key2":{"value3","valueX","valueY"}],j,2"
<<<<<<<<<')
G  # nested arrays and objects
+--------------------------------------------------------------------+
| JSON_PRETTY('"["a",1,"key1": "value1"],["key2":{"value3","valueX","valueY"}],j,2"
<<<<<<<<<') |
+--------------------------------------------------------------------+
| [ "a", 1, { "key1": "value1" } ] |
+--------------------------------------------------------------------+
```
JSON Utility Functions

For a JSON column value, this function shows how much storage space was freed in its binary representation after it was updated in place using JSON_SET(), JSON_REPLACE(), or JSON_REMOVE(). The argument can also be a valid JSON document or a string which can be parsed as one—either as a literal value or as the value of a user variable—in which case the function returns 0. It returns a positive, nonzero value if the argument is a JSON column value which has been updated as described previously, such that its binary representation takes up less space than it did prior to the update. For a JSON column which has been updated such that its binary representation is the same as or larger than before, or if the update was not able to take advantage of a partial update, it returns 0; it returns NULL if the argument is NULL.

If json_val is not NULL, and neither is a valid JSON document nor can be successfully parsed as one, an error results.

In this example, we create a table containing a JSON column, then insert a row containing a JSON object:

```sql
mysql> CREATE TABLE jtable (jcol JSON);
Query OK, 0 rows affected (0.38 sec)

mysql> INSERT INTO jtable VALUES
-> ("{"a": 10, "b": "wxyz", "c": "[true, false]"}");
Query OK, 1 row affected (0.04 sec)

mysql> SELECT * FROM jtable;
+----------------------------------------------+
| jcol                                         |
+----------------------------------------------+
| {"a": 10, "b": "wxyz", "c": "[true, false]"} |
+----------------------------------------------+
1 row in set (0.00 sec)

Now we update the column value using JSON_SET() such that a partial update can be performed; in this case, we replace the value pointed to by the c key (the array [true, false]) with one that takes up less space (the integer 1):

```sql
mysql> UPDATE jtable
-> SET jcol = JSON_SET(jcol, "$a", 10, "$b", "wxyz", "$c", 1);
Query OK, 1 row affected (0.03 sec)
Rows matched: 1  Changed: 1  Warnings: 0

mysql> SELECT * FROM jtable;
+----------------------------------+
| jcol                             |
+----------------------------------+
| {"a": 10, "b": "wxyz", "c": 1}  |
+----------------------------------+
1 row in set (0.00 sec)

mysql> SELECT JSON_STORAGE_FREE(jcol) FROM jtable;
+-------------------------+
| JSON_STORAGE_FREE(jcol) |
+-------------------------+
| 2201                   |
+-------------------------+
```
JSON Utility Functions

|
14 |
+-------------------------+
1 row in set (0.00 sec)

The effects of successive partial updates on this free space are cumulative, as shown in this
example using JSON_SET() to reduce the space taken up by the value having key b (and making no
other changes):
mysql> UPDATE jtable
->
SET jcol = JSON_SET(jcol, "$.a", 10, "$.b", "wx", "$.c", 1);
Query OK, 1 row affected (0.03 sec)
Rows matched: 1 Changed: 1 Warnings: 0
mysql> SELECT JSON_STORAGE_FREE(jcol) FROM jtable;
+-------------------------+
| JSON_STORAGE_FREE(jcol) |
+-------------------------+
|
16 |
+-------------------------+
1 row in set (0.00 sec)

Updating the column without using JSON_SET(), JSON_REPLACE(), or JSON_REMOVE() means
that the optimizer cannot perform the update in place; in this case, JSON_STORAGE_FREE() returns
0, as shown here:
mysql> UPDATE jtable SET jcol = '{"a": 10, "b": 1}';
Query OK, 1 row affected (0.05 sec)
Rows matched: 1 Changed: 1 Warnings: 0
mysql> SELECT JSON_STORAGE_FREE(jcol) FROM jtable;
+-------------------------+
| JSON_STORAGE_FREE(jcol) |
+-------------------------+
|
0 |
+-------------------------+
1 row in set (0.00 sec)

Partial updates of JSON documents can be performed only on column values. For a user variable
that stores a JSON value, the value is always completely replaced, even when the update is
performed using JSON_SET():
mysql> SET @j = '{"a": 10, "b": "wxyz", "c": "[true, false]"}';
Query OK, 0 rows affected (0.00 sec)
mysql> SET @j = JSON_SET(@j, '$.a', 10, '$.b', 'wxyz', '$.c', '1');
Query OK, 0 rows affected (0.00 sec)
mysql> SELECT @j, JSON_STORAGE_FREE(@j) AS Free;
+----------------------------------+------+
| @j
| Free |
+----------------------------------+------+
| {"a": 10, "b": "wxyz", "c": "1"} |
0 |
+----------------------------------+------+
1 row in set (0.00 sec)

For a JSON literal, this function always returns 0:
mysql> SELECT JSON_STORAGE_FREE('{"a": 10, "b": "wxyz", "c": "1"}') AS Free;
+------+
| Free |
+------+
|
0 |
+------+
1 row in set (0.00 sec)

• JSON_STORAGE_SIZE(json_val)
This function returns the number of bytes used to store the binary representation of a JSON
document. When the argument is a JSON column, this is the space used to store the JSON

2202


document as it was inserted into the column, prior to any partial updates that may have been performed on it afterwards. \texttt{json\_val} must be a valid JSON document or a string which can be parsed as one. In the case where it is string, the function returns the amount of storage space in the JSON binary representation that is created by parsing the string as JSON and converting it to binary. It returns \texttt{NULL} if the argument is \texttt{NULL}.

An error results when \texttt{json\_val} is not \texttt{NULL}, and is not—or cannot be successfully parsed as—a JSON document.

To illustrate this function's behavior when used with a JSON column as its argument, we create a table named \texttt{jtable} containing a JSON column \texttt{jcol}, insert a JSON value into the table, then obtain the storage space used by this column with \texttt{JSON\_STORAGE\_SIZE()}, as shown here:

```sql
mysql> CREATE TABLE jtable (jcol JSON);
Query OK, 0 rows affected (0.42 sec)

mysql> INSERT INTO jtable VALUES
    -> ('{"a": 1000, "b": "wxyz", "c": "[1, 3, 5, 7]"}')
Query OK, 1 row affected (0.04 sec)

mysql> SELECT
    -> jcol,
    -> JSON\_STORAGE\_SIZE(jcol) AS Size,
    -> JSON\_STORAGE\_FREE(jcol) AS Free
    -> FROM jtable;
+-----------------------------------------------+------+------+
| jcol                                          | Size | Free |
+-----------------------------------------------+------+------+
| {"a": 1000, "b": "wxyz", "c": "[1, 3, 5, 7]"} |   47 |    0 |
+-----------------------------------------------+------+------+
1 row in set (0.00 sec)
```

According to the output of \texttt{JSON\_STORAGE\_SIZE()}, the JSON document inserted into the column takes up 47 bytes. We also checked the amount of space freed by any previous partial updates of the column using \texttt{JSON\_STORAGE\_FREE()}; since no updates have yet been performed, this is 0, as expected.

Next we perform an \texttt{UPDATE} on the table that should result in a partial update of the document stored in \texttt{jcol}, and then test the result as shown here:

```sql
mysql> UPDATE jtable SET jcol =
    -> JSON\_SET(jcol, "$\cdot b", "a");
Query OK, 1 row affected (0.04 sec)
Rows matched: 1  Changed: 1  Warnings: 0

mysql> SELECT
    -> jcol,
    -> JSON\_STORAGE\_SIZE(jcol) AS Size,
    -> JSON\_STORAGE\_FREE(jcol) AS Free
    -> FROM jtable;
+-----------------------------------------------+------+------+
| jcol                                         | Size | Free |
+-----------------------------------------------+------+------+
| {"a": 1000, "b": "a", "c": "[1, 3, 5, 7]"} |   47 |    3 |
+-----------------------------------------------+------+------+
1 row in set (0.00 sec)
```

The value returned by \texttt{JSON\_STORAGE\_FREE()} in the previous query indicates that a partial update of the JSON document was performed, and that this freed 3 bytes of space used to store it. The result returned by \texttt{JSON\_STORAGE\_SIZE()} is unchanged by the partial update.

Partial updates are supported for updates using \texttt{JSON\_SET()}, \texttt{JSON\_REPLACE()} or \texttt{JSON\_REMOVE()}. The direct assignment of a value to a JSON column cannot be partially updated;
JSON Utility Functions

following such an update, JSON_STORAGE_SIZE() always shows the storage used for the newlyset value:
mysql> UPDATE jtable
mysql>
SET jcol = '{"a": 4.55, "b": "wxyz", "c": "[true, false]"}';
Query OK, 1 row affected (0.04 sec)
Rows matched: 1 Changed: 1 Warnings: 0
mysql> SELECT
->
jcol,
->
JSON_STORAGE_SIZE(jcol) AS Size,
->
JSON_STORAGE_FREE(jcol) AS Free
-> FROM jtable;
+------------------------------------------------+------+------+
| jcol
| Size | Free |
+------------------------------------------------+------+------+
| {"a": 4.55, "b": "wxyz", "c": "[true, false]"} |
56 |
0 |
+------------------------------------------------+------+------+
1 row in set (0.00 sec)

A JSON user variable cannot be partially updated. This means that this function always shows the
space currently used to store a JSON document in a user variable:
mysql> SET @j = '[100, "sakila", [1, 3, 5], 425.05]';
Query OK, 0 rows affected (0.00 sec)
mysql> SELECT @j, JSON_STORAGE_SIZE(@j) AS Size;
+------------------------------------+------+
| @j
| Size |
+------------------------------------+------+
| [100, "sakila", [1, 3, 5], 425.05] |
45 |
+------------------------------------+------+
1 row in set (0.00 sec)
mysql> SET @j = JSON_SET(@j, '$[1]', "json");
Query OK, 0 rows affected (0.00 sec)
mysql> SELECT @j, JSON_STORAGE_SIZE(@j) AS Size;
+----------------------------------+------+
| @j
| Size |
+----------------------------------+------+
| [100, "json", [1, 3, 5], 425.05] |
43 |
+----------------------------------+------+
1 row in set (0.00 sec)
mysql> SET @j = JSON_SET(@j, '$[2][0]', JSON_ARRAY(10, 20, 30));
Query OK, 0 rows affected (0.00 sec)
mysql> SELECT @j, JSON_STORAGE_SIZE(@j) AS Size;
+---------------------------------------------+------+
| @j
| Size |
+---------------------------------------------+------+
| [100, "json", [[10, 20, 30], 3, 5], 425.05] |
56 |
+---------------------------------------------+------+
1 row in set (0.00 sec)

For a JSON literal, this function always returns the current storage space used:
mysql> SELECT
->
JSON_STORAGE_SIZE('[100,
->
JSON_STORAGE_SIZE('{"a":
->
JSON_STORAGE_SIZE('{"a":
->
JSON_STORAGE_SIZE('[100,
+----+----+----+----+
| A | B | C | D |
+----+----+----+----+
| 45 | 44 | 47 | 56 |
+----+----+----+----+
1 row in set (0.00 sec)

2204

"sakila", [1, 3, 5], 425.05]') AS A,
1000, "b": "a", "c": "[1, 3, 5, 7]"}') AS B,
1000, "b": "wxyz", "c": "[1, 3, 5, 7]"}') AS C,
"json", [[10, 20, 30], 3, 5], 425.05]') AS D;


12.19 Functions Used with Global Transaction Identifiers (GTIDs)

The functions described in this section are used with GTID-based replication. It is important to keep in mind that all of these functions take string representations of GTID sets as arguments. As such, the GTID sets must always be quoted when used with them. See GTID Sets for more information.

The union of two GTID sets is simply their representations as strings, joined together with an interposed comma. In other words, you can define a very simple function for obtaining the union of two GTID sets, similar to that created here:

```sql
CREATE FUNCTION GTID_UNION(g1 TEXT, g2 TEXT) RETURNS TEXT DETERMINISTIC
RETURN CONCAT(g1,',',g2);
```

For more information about GTIDs and how these GTID functions are used in practice, see Section 17.1.3, “Replication with Global Transaction Identifiers”.

### Table 12.24 GTID Functions

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Deprecated</th>
</tr>
</thead>
<tbody>
<tr>
<td>GTID_SUBSET()</td>
<td>Return true if all GTIDs in subset are also in set; otherwise false.</td>
<td></td>
</tr>
<tr>
<td>GTID_SUBTRACT()</td>
<td>Return all GTIDs in set that are not in subset.</td>
<td></td>
</tr>
<tr>
<td>WAIT_FOR_EXECUTED_GTID_SET()</td>
<td>Wait until the given GTIDs have executed on the replica.</td>
<td>8.0.18</td>
</tr>
<tr>
<td>WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS</td>
<td>Use WAIT_FOR_EXECUTED_GTID_SET().</td>
<td></td>
</tr>
</tbody>
</table>

- **GTID_SUBSET(set1, set2)**

Given two sets of global transaction identifiers `set1` and `set2`, returns true if all GTIDs in `set1` are also in `set2`. Returns false otherwise.

The GTID sets used with this function are represented as strings, as shown in the following examples:

```sql
mysql> SELECT GTID_SUBSET('3E11FA47-71CA-11E1-9E33-C80AA9429562:23',
                           '3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57');
+---------------------------------------------+
| GTID_SUBSET('3E11FA47-71CA-11E1-9E33-C80AA9429562:23',
  '3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57'): 1 |
+---------------------------------------------+
```

- **GTID_SUBTRACT(set1, set2)**

Given two sets of global transaction identifiers `set1` and `set2`, returns only those GTIDs from `set1` that are not in `set2`.

All GTID sets used with this function are represented as strings and must be quoted, as shown in these examples:
Aggregate Functions

12.20 Aggregate Functions

Aggregate functions operate on sets of values. They are often used with a `GROUP BY` clause to group values into subsets. This section describes most aggregate functions. For information about aggregate functions that operate on geometry values, see Section 12.17.12, “Spatial Aggregate Functions”.

 WAIT_FOR_EXECUTED_GTID_SET(gtid_set[, timeout])

Wait until the server has applied all of the transactions whose global transaction identifiers are contained in `gtid_set`; that is, until the condition GTID_SUBSET(`gtid_subset`, @@GLOBAL.gtid_executed) holds. See Section 17.1.3.1, “GTID Format and Storage” for a definition of GTID sets.

If a timeout is specified, and `timeout` seconds elapse before all of the transactions in the GTID set have been applied, the function stops waiting. `timeout` is optional, and the default timeout is 0 seconds, in which case the function always waits until all of the transactions in the GTID set have been applied.

`WAIT_FOR_EXECUTED_GTID_SET()` monitors all the GTIDs that are applied on the server, including transactions that arrive from all replication channels and user clients. It does not take into account whether replication channels have been started or stopped.

For more information, see Section 17.1.3, “Replication with Global Transaction Identifiers”.

GTID sets used with this function are represented as strings and so must be quoted as shown in the following example:

```sql
mysql> SELECT WAIT_FOR_EXECUTED_GTID_SET('3E11FA47-71CA-11E1-9E33-C80AA9429562:1-5');
-> 0
```

For a syntax description for GTID sets, see Section 17.1.3.1, “GTID Format and Storage”.

For `WAIT_FOR_EXECUTED_GTID_SET()`, the return value is the state of the query, where 0 represents success, and 1 represents timeout. Any other failures generate an error.

`gtid_mode` cannot be changed to OFF while any client is using this function to wait for GTIDs to be applied.

 WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS(gtid_set[, timeout][,channel])

`WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS()` is deprecated. Use `WAIT_FOR_EXECUTED_GTID_SET()` instead, which works regardless of the replication channel or user client through which the specified transactions arrive on the server.
12.20.1 Aggregate Function Descriptions

This section describes aggregate functions that operate on sets of values. They are often used with a GROUP BY clause to group values into subsets.

### Table 12.25 Aggregate Functions

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AVG()</td>
<td>Return the average value of the argument</td>
</tr>
<tr>
<td>BIT_AND()</td>
<td>Return bitwise AND</td>
</tr>
<tr>
<td>BIT_OR()</td>
<td>Return bitwise OR</td>
</tr>
<tr>
<td>BIT_XOR()</td>
<td>Return bitwise XOR</td>
</tr>
<tr>
<td>COUNT()</td>
<td>Return a count of the number of rows returned</td>
</tr>
<tr>
<td>COUNT(DISTINCT)</td>
<td>Return the count of a number of different values</td>
</tr>
<tr>
<td>GROUP_CONCAT()</td>
<td>Return a concatenated string</td>
</tr>
<tr>
<td>JSON_ARRAYAGG()</td>
<td>Return result set as a single JSON array</td>
</tr>
<tr>
<td>JSON_OBJECTAGG()</td>
<td>Return result set as a single JSON object</td>
</tr>
<tr>
<td>MAX()</td>
<td>Return the maximum value</td>
</tr>
<tr>
<td>MIN()</td>
<td>Return the minimum value</td>
</tr>
<tr>
<td>STD()</td>
<td>Return the population standard deviation</td>
</tr>
<tr>
<td>STDDEV()</td>
<td>Return the population standard deviation</td>
</tr>
<tr>
<td>STDDEV_POP()</td>
<td>Return the population standard deviation</td>
</tr>
<tr>
<td>STDDEV_SAMP()</td>
<td>Return the sample standard deviation</td>
</tr>
<tr>
<td>SUM()</td>
<td>Return the sum</td>
</tr>
<tr>
<td>VAR_POP()</td>
<td>Return the population standard variance</td>
</tr>
<tr>
<td>VAR_SAMP()</td>
<td>Return the sample variance</td>
</tr>
<tr>
<td>VARIANCE()</td>
<td>Return the population standard variance</td>
</tr>
</tbody>
</table>

Unless otherwise stated, aggregate functions ignore NULL values.

If you use an aggregate function in a statement containing no GROUP BY clause, it is equivalent to grouping on all rows. For more information, see Section 12.20.3, “MySQL Handling of GROUP BY”.

Most aggregate functions can be used as window functions. Those that can be used this way are signified in their syntax description by \[over_clause\], representing an optional OVER clause. over_clause is described in Section 12.21.2, “Window Function Concepts and Syntax”, which also includes other information about window function usage.

For numeric arguments, the variance and standard deviation functions return a DOUBLE value. The SUM() and AVG() functions return a DECIMAL value for exact-value arguments (integer or DECIMAL), and a DOUBLE value for approximate-value arguments (FLOAT or DOUBLE).

The SUM() and AVG() aggregate functions do not work with temporal values. (They convert the values to numbers, losing everything after the first nonnumeric character.) To work around this problem, convert to numeric units, perform the aggregate operation, and convert back to a temporal value. Examples:

```sql
SELECT SEC_TO_TIME(SUM(TIME_TO_SEC(time_col))) FROM tbl_name;
SELECT FROM_DAYS(SUM(TO_DAYS(date_col))) FROM tbl_name;
```

Functions such as SUM() or AVG() that expect a numeric argument cast the argument to a number if necessary. For SET or ENUM values, the cast operation causes the underlying numeric value to be used.
The `BIT_AND()`, `BIT_OR()`, and `BIT_XOR()` aggregate functions perform bit operations. Prior to MySQL 8.0, bit functions and operators required `BIGINT` (64-bit integer) arguments and returned `BIGINT` values, so they had a maximum range of 64 bits. Non-`BIGINT` arguments were converted to `BIGINT` prior to performing the operation and truncation could occur.

In MySQL 8.0, bit functions and operators permit binary string type arguments (`BINARY`, `VARBINARY`, and the `BLOB` types) and return a value of like type, which enables them to take arguments and produce return values larger than 64 bits. For discussion about argument evaluation and result types for bit operations, see the introductory discussion in Section 12.13, "Bit Functions and Operators".

- **AVG([DISTINCT] expr) [over_clause]**

  Returns the average value of `expr`. The `DISTINCT` option can be used to return the average of the distinct values of `expr`.

  If there are no matching rows, `AVG()` returns `NULL`.

  This function executes as a window function if `over_clause` is present. `over_clause` is as described in Section 12.21.2, "Window Function Concepts and Syntax"; it cannot be used with `DISTINCT`.

  ```sql
  mysql> SELECT student_name, AVG(test_score)
                 FROM student
                 GROUP BY student_name;
  ```

- **BIT_AND(expr) [over_clause]**

  Returns the bitwise `AND` of all bits in `expr`.

  The result type depends on whether the function argument values are evaluated as binary strings or numbers:

  - Binary-string evaluation occurs when the argument values have a binary string type, and the argument is not a hexadecimal literal, bit literal, or `NULL` literal. Numeric evaluation occurs otherwise, with argument value conversion to unsigned 64-bit integers as necessary.

  - Binary-string evaluation produces a binary string of the same length as the argument values. If argument values have unequal lengths, an `ER_INVALID_BITWISE_OPERANDS_SIZE` error occurs. If the argument size exceeds 511 bytes, an `ER_INVALID_BITWISE_AGGREGATE_OPERANDS_SIZE` error occurs. Numeric evaluation produces an unsigned 64-bit integer.

  If there are no matching rows, `BIT_AND()` returns a neutral value (all bits set to 1) having the same length as the argument values.

  `NULL` values do not affect the result unless all values are `NULL`. In that case, the result is a neutral value having the same length as the argument values.

  For more information discussion about argument evaluation and result types, see the introductory discussion in Section 12.13, "Bit Functions and Operators".

  As of MySQL 8.0.12, this function executes as a window function if `over_clause` is present. `over_clause` is as described in Section 12.21.2, "Window Function Concepts and Syntax".

- **BIT_OR(expr) [over_clause]**

  Returns the bitwise `OR` of all bits in `expr`.

  The result type depends on whether the function argument values are evaluated as binary strings or numbers:
• Binary-string evaluation occurs when the argument values have a binary string type, and the argument is not a hexadecimal literal, bit literal, or NULL literal. Numeric evaluation occurs otherwise, with argument value conversion to unsigned 64-bit integers as necessary.

• Binary-string evaluation produces a binary string of the same length as the argument values. If argument values have unequal lengths, an ER_INVALID_BITWISE_OPERANDS_SIZE error occurs. If the argument size exceeds 511 bytes, an ER_INVALID_BITWISE_AGGREGATE_OPERANDS_SIZE error occurs. Numeric evaluation produces an unsigned 64-bit integer.

If there are no matching rows, BIT_OR() returns a neutral value (all bits set to 0) having the same length as the argument values.

NULL values do not affect the result unless all values are NULL. In that case, the result is a neutral value having the same length as the argument values.

For more information discussion about argument evaluation and result types, see the introductory discussion in Section 12.13, “Bit Functions and Operators”.

As of MySQL 8.0.12, this function executes as a window function if over_clause is present. over_clause is as described in Section 12.21.2, “Window Function Concepts and Syntax”.

• BIT_XOR(expr) [over_clause]

Returns the bitwise XOR of all bits in expr.

The result type depends on whether the function argument values are evaluated as binary strings or numbers:

• Binary-string evaluation occurs when the argument values have a binary string type, and the argument is not a hexadecimal literal, bit literal, or NULL literal. Numeric evaluation occurs otherwise, with argument value conversion to unsigned 64-bit integers as necessary.

• Binary-string evaluation produces a binary string of the same length as the argument values. If argument values have unequal lengths, an ER_INVALID_BITWISE_OPERANDS_SIZE error occurs. If the argument size exceeds 511 bytes, an ER_INVALID_BITWISE_AGGREGATE_OPERANDS_SIZE error occurs. Numeric evaluation produces an unsigned 64-bit integer.

If there are no matching rows, BIT_XOR() returns a neutral value (all bits set to 0) having the same length as the argument values.

NULL values do not affect the result unless all values are NULL. In that case, the result is a neutral value having the same length as the argument values.

For more information discussion about argument evaluation and result types, see the introductory discussion in Section 12.13, “Bit Functions and Operators”.

As of MySQL 8.0.12, this function executes as a window function if over_clause is present. over_clause is as described in Section 12.21.2, “Window Function Concepts and Syntax”.

• `COUNT(expr) [over_clause]`

Returns a count of the number of non-NULL values of `expr` in the rows retrieved by a `SELECT` statement. The result is a `BIGINT` value.

If there are no matching rows, `COUNT()` returns 0.

This function executes as a window function if `over_clause` is present. `over_clause` is as described in Section 12.21.2, "Window Function Concepts and Syntax".

```sql
mysql> SELECT student.student_name,COUNT(*)
    FROM student,course
    WHERE student.student_id=course.student_id
    GROUP BY student_name;
```

`COUNT(*)` is somewhat different in that it returns a count of the number of rows retrieved, whether or not they contain NULL values.

For transactional storage engines such as InnoDB, storing an exact row count is problematic. Multiple transactions may be occurring at the same time, each of which may affect the count.

InnoDB does not keep an internal count of rows in a table because concurrent transactions might "see" different numbers of rows at the same time. Consequently, `SELECT COUNT(*)` statements only count rows visible to the current transaction.

As of MySQL 8.0.13, `SELECT COUNT(*)` from tbl_name query performance for InnoDB tables is optimized for single-threaded workloads if there are no extra clauses such as `WHERE` or `GROUP BY`.

InnoDB processes `SELECT COUNT(*)` statements by traversing the smallest available secondary index unless an index or optimizer hint directs the optimizer to use a different index. If a secondary index is not present, InnoDB processes `SELECT COUNT(*)` statements by scanning the clustered index.

Processing `SELECT COUNT(*)` statements takes some time if index records are not entirely in the buffer pool. For a faster count, create a counter table and let your application update it according to the inserts and deletes it does. However, this method may not scale well in situations where thousands of concurrent transactions are initiating updates to the same counter table. If an approximate row count is sufficient, use `SHOW TABLE STATUS`.

InnoDB handles `SELECT COUNT(*)` and `SELECT COUNT(1)` operations in the same way. There is no performance difference.

For MyISAM tables, `COUNT(*)` is optimized to return very quickly if the `SELECT` retrieves from one table, no other columns are retrieved, and there is no `WHERE` clause. For example:

```sql
mysql> SELECT COUNT(*) FROM student;
```

This optimization only applies to MyISAM tables, because an exact row count is stored for this storage engine and can be accessed very quickly. `COUNT(1)` is only subject to the same optimization if the first column is defined as NOT NULL.
• **COUNT(DISTINCT expr,[expr...])**

Returns a count of the number of rows with different non-NULL expr values.

If there are no matching rows, **COUNT(DISTINCT)** returns 0.

```
mysql> SELECT COUNT(DISTINCT results) FROM student;
```

In MySQL, you can obtain the number of distinct expression combinations that do not contain NULL by giving a list of expressions. In standard SQL, you would have to do a concatenation of all expressions inside **COUNT(DISTINCT ...)**.

• **GROUP_CONCAT(expr)**

This function returns a string result with the concatenated non-NULL values from a group. It returns NULL if there are no non-NULL values. The full syntax is as follows:

```
GROUP_CONCAT([DISTINCT] expr [,expr ...] [ORDER BY {unsigned_integer | col_name | expr} [ASC | DESC] [,col_name ...]] [SEPARATOR str_val])
```

```
mysql> SELECT student_name,
    GROUP_CONCAT(test_score)
FROM student
GROUP BY student_name;
```

Or:

```
mysql> SELECT student_name,
    GROUP_CONCAT(DISTINCT test_score ORDER BY test_score DESC SEPARATOR ' ')
FROM student
GROUP BY student_name;
```

In MySQL, you can get the concatenated values of expression combinations. To eliminate duplicate values, use the **DISTINCT** clause. To sort values in the result, use the **ORDER BY** clause. To sort in reverse order, add the **DESC** (descending) keyword to the name of the column you are sorting by in the **ORDER BY** clause. The default is ascending order; this may be specified explicitly using the **ASC** keyword. The default separator between values in a group is comma (,). To specify a separator explicitly, use **SEPARATOR** followed by the string literal value that should be inserted between group values. To eliminate the separator altogether, specify **SEPARATOR ''**.

The result is truncated to the maximum length that is given by the **group_concat_max_len** system variable, which has a default value of 1024. The value can be set higher, although the effective maximum length of the return value is constrained by the value of **max_allowed_packet**. The syntax to change the value of **group_concat_max_len** at runtime is as follows, where **val** is an unsigned integer:

```
SET [GLOBAL | SESSION] group_concat_max_len = val;
```

The return value is a nonbinary or binary string, depending on whether the arguments are nonbinary or binary strings. The result type is **TEXT** or **BLOB** unless **group_concat_max_len** is less than or equal to 512, in which case the result type is **VARCHAR** or **VARBINARY**.

See also **CONCAT()** and **CONCAT_WS()**: [Section 12.8, “String Functions and Operators”](#).
• **JSON_ARRAYAGG**(col_or_expr) [over_clause]

Aggregates a result set as a single JSON array whose elements consist of the rows. The order of elements in this array is undefined. The function acts on a column or an expression that evaluates to a single value. Returns NULL if the result contains no rows, or in the event of an error.

As of MySQL 8.0.14, this function executes as a window function if over_clause is present. over_clause is as described in Section 12.21.2, “Window Function Concepts and Syntax”.

```
mysql> SELECT o_id, attribute, value FROM t3;
+------+-----------+-------+
<table>
<thead>
<tr>
<th>o_id</th>
<th>attribute</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>color</td>
<td>red</td>
</tr>
<tr>
<td>2</td>
<td>fabric</td>
<td>silk</td>
</tr>
<tr>
<td>3</td>
<td>color</td>
<td>green</td>
</tr>
<tr>
<td>3</td>
<td>shape</td>
<td>square</td>
</tr>
</tbody>
</table>
+------+-----------+-------+
4 rows in set (0.00 sec)
```

```
mysql> SELECT o_id, JSON_ARRAYAGG(attribute) AS attributes FROM t3 GROUP BY o_id;
+------+---------------------+
<table>
<thead>
<tr>
<th>o_id</th>
<th>attributes</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>[&quot;color&quot;, &quot;fabric&quot;]</td>
</tr>
<tr>
<td>3</td>
<td>[&quot;color&quot;, &quot;shape&quot;]</td>
</tr>
</tbody>
</table>
+------+---------------------+
2 rows in set (0.00 sec)
```

• **JSON_OBJECTAGG**(key, value) [over_clause]

Takes two column names or expressions as arguments, the first of these being used as a key and the second as a value, and returns a JSON object containing key-value pairs. Returns NULL if the result contains no rows, or in the event of an error. An error occurs if any key name is NULL or the number of arguments is not equal to 2.

As of MySQL 8.0.14, this function executes as a window function if over_clause is present. over_clause is as described in Section 12.21.2, “Window Function Concepts and Syntax”.

```
mysql> SELECT o_id, attribute, value FROM t3;
+------+-----------+-------+
<table>
<thead>
<tr>
<th>o_id</th>
<th>attribute</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>color</td>
<td>red</td>
</tr>
<tr>
<td>2</td>
<td>fabric</td>
<td>silk</td>
</tr>
<tr>
<td>3</td>
<td>color</td>
<td>green</td>
</tr>
<tr>
<td>3</td>
<td>shape</td>
<td>square</td>
</tr>
</tbody>
</table>
+------+-----------+-------+
4 rows in set (0.00 sec)
```

```
mysql> SELECT o_id, JSON_OBJECTAGG(attribute, value) FROM t3 GROUP BY o_id;
+------+---------------------------------------+
<table>
<thead>
<tr>
<th>o_id</th>
<th>JSON_OBJECTAGG(attribute, value)</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>{&quot;color&quot;: &quot;red&quot;, &quot;fabric&quot;: &quot;silk&quot;}</td>
</tr>
<tr>
<td>3</td>
<td>{&quot;color&quot;: &quot;green&quot;, &quot;shape&quot;: &quot;square&quot;}</td>
</tr>
</tbody>
</table>
+------+---------------------------------------+
2 rows in set (0.00 sec)
```

**Duplicate key handling.** When the result of this function is normalized, values having duplicate keys are discarded. In keeping with the MySQL JSON data type specification that does not permit duplicate keys, only the last value encountered is used with that key in the returned object ("last
Aggregate Function Descriptions

duplicate key wins”). This means that the result of using this function on columns from a SELECT can
depend on the order in which the rows are returned, which is not guaranteed.
When used as a window function, if there are duplicate keys within a frame, only the last value for
the key is present in the result. The value for the key from the last row in the frame is deterministic
if the ORDER BY specification guarantees that the values have a specific order. If not, the resulting
value of the key is nondeterministic.
Consider the following:
mysql> CREATE TABLE t(c VARCHAR(10), i INT);
Query OK, 0 rows affected (0.33 sec)
mysql> INSERT INTO t VALUES ('key', 3), ('key', 4), ('key', 5);
Query OK, 3 rows affected (0.10 sec)
Records: 3 Duplicates: 0 Warnings: 0
mysql> SELECT c, i FROM t;
+------+------+
| c
| i
|
+------+------+
| key |
3 |
| key |
4 |
| key |
5 |
+------+------+
3 rows in set (0.00 sec)
mysql> SELECT JSON_OBJECTAGG(c, i) FROM t;
+----------------------+
| JSON_OBJECTAGG(c, i) |
+----------------------+
| {"key": 5}
|
+----------------------+
1 row in set (0.00 sec)
mysql> DELETE FROM t;
Query OK, 3 rows affected (0.08 sec)
mysql> INSERT INTO t VALUES ('key', 3), ('key', 5), ('key', 4);
Query OK, 3 rows affected (0.06 sec)
Records: 3 Duplicates: 0 Warnings: 0
mysql> SELECT c, i FROM t;
+------+------+
| c
| i
|
+------+------+
| key |
3 |
| key |
5 |
| key |
4 |
+------+------+
3 rows in set (0.00 sec)
mysql> SELECT JSON_OBJECTAGG(c, i) FROM t;
+----------------------+
| JSON_OBJECTAGG(c, i) |
+----------------------+
| {"key": 4}
|
+----------------------+
1 row in set (0.00 sec)

The key chosen from the last query is nondeterministic. If you prefer a particular key ordering, you
can invoke JSON_OBJECTAGG() as a window function by including an OVER clause with an ORDER
BY specification to impose a particular order on frame rows. The following examples show what
happens with and without ORDER BY for a few different frame specifications.
Without ORDER BY, the frame is the entire partition:
mysql> SELECT JSON_OBJECTAGG(c, i)
OVER () AS json_object FROM t;

2213


With `ORDER BY`, where the frame is the default of `RANGE BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW` (in both ascending and descending order):

```sql
mysql> SELECT JSON_OBJECTAGG(c, i)
OVER (ORDER BY i) AS json_object FROM t;
+-------------+
| json_object |
| {"key": 3}  |
| {"key": 4}  |
| {"key": 5}  |
+-------------+

mysql> SELECT JSON_OBJECTAGG(c, i)
OVER (ORDER BY i DESC) AS json_object FROM t;
+-------------+
| json_object |
| {"key": 5}  |
| {"key": 4}  |
| {"key": 3}  |
+-------------+
```

With `ORDER BY` and an explicit frame of the entire partition:

```sql
mysql> SELECT JSON:ObjectAGG(c, i)
OVER (ORDER BY i ROWS BETWEEN UNBOUNDED PRECEDING AND UNBOUNDED FOLLOWING) AS json_object FROM t;
+-------------+
| json_object |
| {"key": 5}  |
| {"key": 5}  |
| {"key": 5}  |
+-------------+
```

To return a particular key value (such as the smallest or largest), include a `LIMIT` clause in the appropriate query. For example:

```sql
mysql> SELECT JSON_OBJECTAGG(c, i)
OVER (ORDER BY i) AS json_object FROM t LIMIT 1;
+-------------+
| json_object |
| {"key": 3}  |
+-------------+

mysql> SELECT JSON_OBJECTAGG(c, i)
OVER (ORDER BY i DESC) AS json_object FROM t LIMIT 1;
+-------------+
| json_object |
| {"key": 5}  |
+-------------+
```

See Normalization, Merging, and Autowrapping of JSON Values, for additional information and examples.
• \texttt{MAX([DISTINCT] \ expr \ [over\_clause])}

Returns the maximum value of \texttt{expr}. \texttt{MAX()} may take a string argument; in such cases, it returns the maximum string value. See Section 8.3.1, “How MySQL Uses Indexes”. The \texttt{DISTINCT} keyword can be used to find the maximum of the distinct values of \texttt{expr}, however, this produces the same result as omitting \texttt{DISTINCT}.

If there are no matching rows, \texttt{MAX()} returns \texttt{NULL}.

This function executes as a window function if \texttt{over\_clause} is present. \texttt{over\_clause} is as described in Section 12.21.2, “Window Function Concepts and Syntax”; it cannot be used with \texttt{DISTINCT}.

\begin{verbatim}
mysql> SELECT student_name, MIN(test_score), MAX(test_score)
      FROM student
      GROUP BY student_name;
\end{verbatim}

For \texttt{MAX()}, MySQL currently compares \texttt{ENUM} and \texttt{SET} columns by their string value rather than by the string’s relative position in the set. This differs from how \texttt{ORDER BY} compares them.

• \texttt{MIN([DISTINCT] \ expr \ [over\_clause])}

Returns the minimum value of \texttt{expr}. \texttt{MIN()} may take a string argument; in such cases, it returns the minimum string value. See Section 8.3.1, “How MySQL Uses Indexes”. The \texttt{DISTINCT} keyword can be used to find the minimum of the distinct values of \texttt{expr}, however, this produces the same result as omitting \texttt{DISTINCT}.

If there are no matching rows, \texttt{MIN()} returns \texttt{NULL}.

This function executes as a window function if \texttt{over\_clause} is present. \texttt{over\_clause} is as described in Section 12.21.2, “Window Function Concepts and Syntax”; it cannot be used with \texttt{DISTINCT}.

\begin{verbatim}
mysql> SELECT student_name, MIN(test_score), MAX(test_score)
      FROM student
      GROUP BY student_name;
\end{verbatim}

For \texttt{MIN()}, MySQL currently compares \texttt{ENUM} and \texttt{SET} columns by their string value rather than by the string’s relative position in the set. This differs from how \texttt{ORDER BY} compares them.

• \texttt{STD(\ expr \ [over\_clause])}

Returns the population standard deviation of \texttt{expr}. \texttt{STD()} is a synonym for the standard SQL function \texttt{STDDEV\_POP()}, provided as a MySQL extension.

If there are no matching rows, \texttt{STD()} returns \texttt{NULL}.

This function executes as a window function if \texttt{over\_clause} is present. \texttt{over\_clause} is as described in Section 12.21.2, “Window Function Concepts and Syntax”.

• \texttt{STDDEV(\ expr \ [over\_clause])}

Returns the population standard deviation of \texttt{expr}. \texttt{STDDEV()} is a synonym for the standard SQL function \texttt{STDDEV\_POP()}, provided for compatibility with Oracle.

If there are no matching rows, \texttt{STDDEV()} returns \texttt{NULL}.

This function executes as a window function if \texttt{over\_clause} is present. \texttt{over\_clause} is as described in Section 12.21.2, “Window Function Concepts and Syntax”. 
GROUP BY Modifiers

- **STDDEV_POP(expr) [over_clause]**

  Returns the population standard deviation of `expr` (the square root of `VAR_POP()`). You can also use `STD()` or `STDDEV()`, which are equivalent but not standard SQL.

  If there are no matching rows, `STDDEV_POP()` returns `NULL`.

  This function executes as a window function if `over_clause` is present. `over_clause` is as described in Section 12.21.2, “Window Function Concepts and Syntax”.

- **STDDEV_SAMP(expr) [over_clause]**

  Returns the sample standard deviation of `expr` (the square root of `VAR_SAMP()`).

  If there are no matching rows, `STDDEV_SAMP()` returns `NULL`.

  This function executes as a window function if `over_clause` is present. `over_clause` is as described in Section 12.21.2, “Window Function Concepts and Syntax”.

- **SUM([DISTINCT] expr [over_clause])**

  Returns the sum of `expr`. If the return set has no rows, `SUM()` returns `NULL`. The `DISTINCT` keyword can be used to sum only the distinct values of `expr`.

  If there are no matching rows, `SUM()` returns `NULL`.

  This function executes as a window function if `over_clause` is present. `over_clause` is as described in Section 12.21.2, “Window Function Concepts and Syntax”; it cannot be used with `DISTINCT`.

- **VAR_POP(expr) [over_clause]**

  Returns the population standard variance of `expr`. It considers rows as the whole population, not as a sample, so it has the number of rows as the denominator. You can also use `VARIANCE()`, which is equivalent but is not standard SQL.

  If there are no matching rows, `VAR_POP()` returns `NULL`.

  This function executes as a window function if `over_clause` is present. `over_clause` is as described in Section 12.21.2, “Window Function Concepts and Syntax”.

- **VAR_SAMP(expr) [over_clause]**

  Returns the sample variance of `expr`. That is, the denominator is the number of rows minus one.

  If there are no matching rows, `VAR_SAMP()` returns `NULL`.

  This function executes as a window function if `over_clause` is present. `over_clause` is as described in Section 12.21.2, “Window Function Concepts and Syntax”.

- **VARIANCE(expr) [over_clause]**

  Returns the population standard variance of `expr`. `VARIANCE()` is a synonym for the standard SQL function `VAR_POP()`, provided as a MySQL extension.

  If there are no matching rows, `VARIANCE()` returns `NULL`.

  This function executes as a window function if `over_clause` is present. `over_clause` is as described in Section 12.21.2, “Window Function Concepts and Syntax”.
The `GROUP BY` clause permits a `WITH ROLLUP` modifier that causes summary output to include extra rows that represent higher-level (that is, super-aggregate) summary operations. `ROLLUP` thus enables you to answer questions at multiple levels of analysis with a single query. For example, `ROLLUP` can be used to provide support for OLAP (Online Analytical Processing) operations.

Suppose that a `sales` table has `year`, `country`, `product`, and `profit` columns for recording sales profitability:

```sql
CREATE TABLE sales
(
    year INT,
    country VARCHAR(20),
    product VARCHAR(32),
    profit INT
);
```

To summarize table contents per year, use a simple `GROUP BY` like this:

```sql
mysql> SELECT year, SUM(profit) AS profit
FROM sales
GROUP BY year;
```

<table>
<thead>
<tr>
<th>year</th>
<th>profit</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000</td>
<td>4525</td>
</tr>
<tr>
<td>2001</td>
<td>3010</td>
</tr>
</tbody>
</table>

The output shows the total (aggregate) profit for each year. To also determine the total profit summed over all years, you must add up the individual values yourself or run an additional query. Or you can use `ROLLUP`, which provides both levels of analysis with a single query. Adding a `WITH ROLLUP` modifier to the `GROUP BY` clause causes the query to produce another (super-aggregate) row that shows the grand total over all year values:

```sql
mysql> SELECT year, SUM(profit) AS profit
FROM sales
GROUP BY year WITH ROLLUP;
```

<table>
<thead>
<tr>
<th>year</th>
<th>profit</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000</td>
<td>4525</td>
</tr>
<tr>
<td>2001</td>
<td>3010</td>
</tr>
<tr>
<td>NULL</td>
<td>7535</td>
</tr>
</tbody>
</table>

The `NULL` value in the `year` column identifies the grand total super-aggregate line.

`ROLLUP` has a more complex effect when there are multiple `GROUP BY` columns. In this case, each time there is a change in value in any but the last grouping column, the query produces an extra super-aggregate summary row.

For example, without `ROLLUP`, a summary of the `sales` table based on `year`, `country`, and `product` might look like this, where the output indicates summary values only at the year/country/product level of analysis:

```sql
mysql> SELECT year, country, product, SUM(profit) AS profit
FROM sales
GROUP BY year, country, product;
```

<table>
<thead>
<tr>
<th>year</th>
<th>country</th>
<th>product</th>
<th>profit</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000</td>
<td>Finland</td>
<td>Computer</td>
<td>1500</td>
</tr>
<tr>
<td>2000</td>
<td>Finland</td>
<td>Phone</td>
<td>100</td>
</tr>
<tr>
<td>2000</td>
<td>India</td>
<td>Calculator</td>
<td>150</td>
</tr>
<tr>
<td>2000</td>
<td>India</td>
<td>Computer</td>
<td>1200</td>
</tr>
<tr>
<td>2000</td>
<td>USA</td>
<td>Calculator</td>
<td>75</td>
</tr>
<tr>
<td>2000</td>
<td>USA</td>
<td>Computer</td>
<td>1500</td>
</tr>
<tr>
<td>2001</td>
<td>Finland</td>
<td>Phone</td>
<td>10</td>
</tr>
</tbody>
</table>
With \texttt{ROLLUP} added, the query produces several extra rows:

\begin{verbatim}
mysql> SELECT year, country, product, SUM(profit) AS profit
    > FROM sales
    > GROUP BY year, country, product WITH ROLLUP;
\end{verbatim}

\begin{verbatim}
+------+---------+------------+--------+
| year | country | product    | profit |
+------+---------+------------+--------+
| 2000 | Finland | Computer   | 1500   |
| 2000 | Finland | Phone      | 100    |
| 2000 | Finland | NULL       | 1600   |
| 2000 | India   | Calculator | 150    |
| 2000 | India   | Computer   | 1200   |
| 2000 | India   | NULL       | 1350   |
| 2000 | USA     | Calculator | 75     |
| 2000 | USA     | Computer   | 1500   |
| 2000 | USA     | NULL       | 1575   |
| 2000 | NULL    | NULL       | 4525   |
| 2001 | Finland | Phone      | 10     |
| 2001 | Finland | NULL       | 10     |
| 2001 | USA     | Calculator | 50     |
| 2001 | USA     | Computer   | 2700   |
| 2001 | USA     | TV         | 250    |
| 2001 | USA     | NULL       | 3000   |
| 2001 | NULL    | NULL       | 3010   |
| NULL | NULL    | NULL       | 7535   |
+------+---------+------------+--------+
\end{verbatim}

Now the output includes summary information at four levels of analysis, not just one:

- Following each set of product rows for a given year and country, an extra super-aggregate summary row appears showing the total for all products. These rows have the \texttt{product} column set to \texttt{NULL}.

- Following each set of rows for a given year, an extra super-aggregate summary row appears showing the total for all countries and products. These rows have the \texttt{country} and \texttt{products} columns set to \texttt{NULL}.

- Finally, following all other rows, an extra super-aggregate summary row appears showing the grand total for all years, countries, and products. This row has the \texttt{year}, \texttt{country}, and \texttt{products} columns set to \texttt{NULL}.

The \texttt{NULL} indicators in each super-aggregate row are produced when the row is sent to the client. The server looks at the columns named in the \texttt{GROUP BY} clause following the leftmost one that has changed value. For any column in the result set with a name that matches any of those names, its value is set to \texttt{NULL}. (If you specify grouping columns by column position, the server identifies which columns to set to \texttt{NULL} by position.)

Because the \texttt{NULL} values in the super-aggregate rows are placed into the result set at such a late stage in query processing, you can test them as \texttt{NULL} values only in the select list or the \texttt{HAVING} clause. You cannot test them as \texttt{NULL} values in join conditions or the \texttt{WHERE} clause to determine which rows to select. For example, you cannot add \texttt{WHERE product IS NULL} to the query to eliminate from the output all but the super-aggregate rows.

The \texttt{NULL} values do appear as \texttt{NULL} on the client side and can be tested as such using any MySQL client programming interface. However, at this point, you cannot distinguish whether a \texttt{NULL} represents a regular grouped value or a super-aggregate value. To test the distinction, use the \texttt{GROUPING()} function, described later.

Previously, MySQL did not allow the use of \texttt{DISTINCT} or \texttt{ORDER BY} in a query having a \texttt{WITH ROLLUP} option. This restriction is lifted in MySQL 8.0.12 and later. (Bug \#87450, Bug \#86311, Bug \#26640100, Bug \#26073513)
For `GROUP BY ... WITH ROLLUP` queries, to test whether `NULL` values in the result represent super-aggregate values, the `GROUPING()` function is available for use in the select list, having clause, and (as of MySQL 8.0.12) order by clause. For example, `GROUPING(year)` returns 1 when `NULL` in the `year` column occurs in a super-aggregate row, and 0 otherwise. Similarly, `GROUPING(country)` and `GROUPING(product)` return 1 for super-aggregate `NULL` values in the `country` and `product` columns, respectively:

```sql
mysql> SELECT
    
    
    | year | country | product    | profit | grp_year | grp_country | grp_product |
    |
    | 2000 | Finland | Computer   | 1500   | 0        | 0           | 0           |
    | 2000 | Finland | Phone      | 100    | 0        | 0           | 0           |
    | 2000 | Finland | NULL       | 1600   | 0        | 0           | 1           |
    | 2000 | India   | Calculator | 150    | 0        | 0           | 0           |
    | 2000 | India   | Computer   | 1200   | 0        | 0           | 0           |
    | 2000 | India   | NULL       | 1350   | 0        | 0           | 1           |
    | 2000 | USA     | Calculator | 75     | 0        | 0           | 0           |
    | 2000 | USA     | Computer   | 1500   | 0        | 0           | 0           |
    | 2000 | USA     | NULL       | 1575   | 0        | 0           | 1           |
    | 2000 | NULL    | NULL       | 4525   | 0        | 1           | 1           |
    | 2001 | Finland | Phone      | 10     | 0        | 0           | 0           |
    | 2001 | Finland | NULL       | 3010   | 0        | 1           | 1           |
    | 2001 | USA     | Calculator | 50     | 0        | 0           | 0           |
    | 2001 | USA     | Computer   | 2700   | 0        | 0           | 0           |
    | 2001 | USA     | TV         | 250    | 0        | 0           | 0           |
    | 2001 | USA     | NULL       | 3000   | 0        | 0           | 1           |
    | 2001 | NULL    | NULL       | 7535   | 1        | 1           | 1           |
    | NULL | NULL    | NULL       | 7535   | 1        | 1           | 1           |
```

Instead of displaying the `GROUPING()` results directly, you can use `GROUPING()` to substitute labels for super-aggregate `NULL` values:

```sql
mysql> SELECT
    
    
    | year | country | product    | profit |
    |
    | 2000 | Finland | Computer   | 1500   |
    | 2000 | Finland | Phone      | 100    |
    | 2000 | Finland | All products | 1600  |
    | 2000 | India   | Calculator | 150    |
    | 2000 | India   | Computer   | 1200   |
    | 2000 | India   | All products | 1350  |
    | 2000 | USA     | Calculator | 75     |
    | 2000 | USA     | Computer   | 1500   |
    | 2000 | USA     | All products | 1575  |
    | 2000 | All countries | All products | 4525  |
    | 2001 | Finland | Phone      | 10     |
    | 2001 | Finland | All products | 10    |
    | 2001 | USA     | Calculator | 50     |
    | 2001 | USA     | Computer   | 2700   |
    | 2001 | USA     | TV         | 250    |
    | 2001 | USA     | All products | 3000  |
    | 2001 | All countries | All products | 3010  |
    | All years | All countries | All products | 7535  |
```
With multiple expression arguments, \texttt{GROUPING()} returns a result representing a bitmask that combines the results for each expression, with the lowest-order bit corresponding to the result for the rightmost expression. For example, \texttt{GROUPING(year, country, product)} is evaluated like this:

\begin{verbatim}
result for \texttt{GROUPING(product)}
+ result for \texttt{GROUPING(country)} << 1
+ result for \texttt{GROUPING(year)} << 2
\end{verbatim}

The result of such a \texttt{GROUPING()} is nonzero if any of the expressions represents a super-aggregate \texttt{NULL}, so you can return only the super-aggregate rows and filter out the regular grouped rows like this:

\begin{verbatim}
mysql> SELECT year, country, product, SUM(profit) AS profit
FROM sales
GROUP BY year, country, product WITH ROLLUP
HAVING GROUPING(year, country, product) <> 0;
\end{verbatim}

\texttt{GROUPING()} enables these to be distinguished. Suppose that table \texttt{t1} contains a simple data set with two grouping factors for a set of quantity values, where \texttt{NULL} indicates something like “other” or “unknown”:

\begin{verbatim}
mysql> SELECT * FROM t1;
\end{verbatim}

A simple \texttt{ROLLUP} operation produces these results, in which it is not so easy to distinguish \texttt{NULL} values in super-aggregate rows from \texttt{NULL} values in regular grouped rows:

\begin{verbatim}
mysql> SELECT name, size, SUM(quantity) AS quantity
FROM t1
GROUP BY name, size WITH ROLLUP;
\end{verbatim}

Using \texttt{GROUPING()} to substitute labels for the super-aggregate \texttt{NULL} values makes the result easier to interpret:

\begin{verbatim}
mysql> SELECT
GROUP BY Modifiers

IF (GROUPING(name) = 1, 'All items', name) AS name,
IF (GROUPING(size) = 1, 'All sizes', size) AS size,
SUM(quantity) AS quantity
FROM t1
GROUP BY name, size WITH ROLLUP;

+-----------+-----------+----------+
<table>
<thead>
<tr>
<th>name</th>
<th>size</th>
<th>quantity</th>
</tr>
</thead>
<tbody>
<tr>
<td>ball</td>
<td>NULL</td>
<td>5</td>
</tr>
<tr>
<td>ball</td>
<td>large</td>
<td>20</td>
</tr>
<tr>
<td>ball</td>
<td>small</td>
<td>10</td>
</tr>
<tr>
<td>ball</td>
<td>All sizes</td>
<td>35</td>
</tr>
<tr>
<td>hoop</td>
<td>NULL</td>
<td>3</td>
</tr>
<tr>

<td>large</td>
<td>5</td>
</tr>
<tr>
<td>hoop</td>
<td>small</td>
<td>15</td>
</tr>
<tr>
<td>hoop</td>
<td>All sizes</td>
<td>23</td>
</tr>
<tr>
<td>All items</td>
<td>All sizes</td>
<td>58</td>
</tr>
</tbody>
</table>
+-----------+-----------+----------+

Other Considerations When using ROLLUP

The following discussion lists some behaviors specific to the MySQL implementation of ROLLUP.

Prior to MySQL 8.0.12, when you use ROLLUP, you cannot also use an ORDER BY clause to sort the results. In other words, ROLLUP and ORDER BY were mutually exclusive in MySQL. However, you still have some control over sort order. To work around the restriction that prevents using ROLLUP with ORDER BY and achieve a specific sort order of grouped results, generate the grouped result set as a derived table and apply ORDER BY to it. For example:

```sql
mysql> SELECT * FROM (SELECT year, SUM(profit) AS profit
FROM sales GROUP BY year WITH ROLLUP) AS dt
ORDER BY year DESC;
```

<table>
<thead>
<tr>
<th>year</th>
<th>profit</th>
</tr>
</thead>
<tbody>
<tr>
<td>2001</td>
<td>3010</td>
</tr>
<tr>
<td>2000</td>
<td>4525</td>
</tr>
<tr>
<td>NULL</td>
<td>7535</td>
</tr>
</tbody>
</table>

As of MySQL 8.0.12, ORDER BY and ROLLUP can be used together, which enables the use of ORDER BY and GROUPING() to achieve a specific sort order of grouped results. For example:

```sql
mysql> SELECT year, SUM(profit) AS profit
FROM sales
GROUP BY year WITH ROLLUP
ORDER BY GROUPING(year) DESC;
```

<table>
<thead>
<tr>
<th>year</th>
<th>profit</th>
</tr>
</thead>
<tbody>
<tr>
<td>NULL</td>
<td>7535</td>
</tr>
<tr>
<td>2000</td>
<td>4525</td>
</tr>
<tr>
<td>2001</td>
<td>3010</td>
</tr>
</tbody>
</table>

In both cases, the super-aggregate summary rows sort with the rows from which they are calculated, and their placement depends on sort order (at the end for ascending sort, at the beginning for descending sort).

LIMIT can be used to restrict the number of rows returned to the client. LIMIT is applied after ROLLUP, so the limit applies against the extra rows added by ROLLUP. For example:

```sql
mysql> SELECT year, country, product, SUM(profit) AS profit
FROM sales
GROUP BY year, country, product WITH ROLLUP
LIMIT 5;
```

<table>
<thead>
<tr>
<th>year</th>
<th>country</th>
<th>product</th>
<th>profit</th>
</tr>
</thead>
</table>

2221
Using `LIMIT` with `ROLLUP` may produce results that are more difficult to interpret, because there is less context for understanding the super-aggregate rows.

A MySQL extension permits a column that does not appear in the `GROUP BY` list to be named in the select list. (For information about nonaggregated columns and `GROUP BY`, see Section 12.20.3, “MySQL Handling of GROUP BY.”) In this case, the server is free to choose any value from this nonaggregated column in summary rows, and this includes the extra rows added by `WITH ROLLUP`. For example, in the following query, `country` is a nonaggregated column that does not appear in the `GROUP BY` list and values chosen for this column are nondeterministic:

```sql
mysql> SELECT year, country, SUM(profit) AS profit
    -> FROM sales
    -> GROUP BY year WITH ROLLUP;
```

This behavior is permitted when the `ONLY_FULL_GROUP_BY` SQL mode is not enabled. If that mode is enabled, the server rejects the query as illegal because `country` is not listed in the `GROUP BY` clause. With `ONLY_FULL_GROUP_BY` enabled, you can still execute the query by using the `ANY_VALUE()` function for nondeterministic-value columns:

```sql
mysql> SELECT year, ANY_VALUE(country) AS country, SUM(profit) AS profit
    -> FROM sales
    -> GROUP BY year WITH ROLLUP;
```

### 12.20.3 MySQL Handling of GROUP BY

SQL-92 and earlier does not permit queries for which the select list, `HAVING` condition, or `ORDER BY` list refer to nonaggregated columns that are not named in the `GROUP BY` clause. For example, this query is illegal in standard SQL-92 because the nonaggregated `name` column in the select list does not appear in the `GROUP BY`:

```sql
SELECT o.custid, c.name, MAX(o.payment)
FROM orders AS o, customers AS c
WHERE o.custid = c.custid
GROUP BY o.custid;
```

For the query to be legal in SQL-92, the `name` column must be omitted from the select list or named in the `GROUP BY` clause.

SQL:1999 and later permits such nonaggregates per optional feature T301 if they are functionally dependent on `GROUP BY` columns: If such a relationship exists between `name` and `custid`, the query is legal. This would be the case, for example, were `custid` a primary key of `customers`.

MySQL implements detection of functional dependence. If the `ONLY_FULL_GROUP_BY` SQL mode is enabled (which it is by default), MySQL rejects queries for which the select list, `HAVING` condition, or
MySQL Handling of GROUP BY

ORDER BY list refer to nonaggregated columns that are neither named in the GROUP BY clause nor are functionally dependent on them.

MySQL also permits a nonaggregate column not named in a GROUP BY clause when SQL ONLY_FULL_GROUP_BY mode is enabled, provided that this column is limited to a single value, as shown in the following example:

```
mysql> CREATE TABLE mytable (id INT UNSIGNED NOT NULL PRIMARY KEY, a VARCHAR(10), b INT);
mysql> INSERT INTO mytable VALUES (1, 'abc', 1000), (2, 'abc', 2000), (3, 'def', 4000);
mysql> SET SESSION sql_mode = sys.list_add(@@session.sql_mode, 'ONLY_FULL_GROUP_BY');
mysql> SELECT a, SUM(b) FROM mytable WHERE a = 'abc';
+------+--------+
| a    | SUM(b) |
+------+--------+
| abc  |   3000 |
+------+--------+
```

It is also possible to have more than one nonaggregate column in the SELECT list when employing ONLY_FULL_GROUP_BY. In this case, every such column must be limited to a single value in the WHERE clause, and all such limiting conditions must be joined by logical AND, as shown here:

```
mysql> CREATE TABLE mytable (id INT UNSIGNED NOT NULL PRIMARY KEY, a VARCHAR(10), b VARCHAR(10), c INT);
mysql> INSERT INTO mytable VALUES (1, 'abc', 'qrs', 1000), (2, 'abc', 'tuv', 2000), (3, 'def', 'qrs', 4000), (4, 'def', 'tuv', 8000), (5, 'abc', 'qrs', 16000), (6, 'def', 'tuv', 32000);
mysql> SELECT @@session.sql_mode;
+---------------------------------------------------------------+
| @@session.sql_mode                                            |
+---------------------------------------------------------------+
| ONLY_FULL_GROUP_BY,STRICT_TRANS_TABLES,NO_ENGINE_SUBSTITUTION |
+---------------------------------------------------------------+
mysql> SELECT a, b, SUM(c) FROM mytable WHERE a = 'abc' AND b = 'qrs';
+------+------+--------+
| a    | b    | SUM(c) |
+------+------+--------+
| abc  | qrs  |  17000 |
+------+------+--------+
```

If ONLY_FULL_GROUP_BY is disabled, a MySQL extension to the standard SQL use of GROUP BY permits the select list, HAVING condition, or ORDER BY list to refer to nonaggregated columns even if the columns are not functionally dependent on GROUP BY columns. This causes MySQL to accept the preceding query. In this case, the server is free to choose any value from each group, so unless they are the same, the values chosen are nondeterministic, which is probably not what you want. Furthermore, the selection of values from each group cannot be influenced by adding an ORDER BY
MySQL Handling of GROUP BY

clause. Result set sorting occurs after values have been chosen, and ORDER BY does not affect which value within each group the server chooses. Disabling ONLY_FULL_GROUP_BY is useful primarily when you know that, due to some property of the data, all values in each nonaggregated column not named in the GROUP BY are the same for each group.

You can achieve the same effect without disabling ONLY_FULL_GROUP_BY by using ANY_VALUE() to refer to the nonaggregated column.

The following discussion demonstrates functional dependence, the error message MySQL produces when functional dependence is absent, and ways of causing MySQL to accept a query in the absence of functional dependence.

This query might be invalid with ONLY_FULL_GROUP_BY enabled because the nonaggregated address column in the select list is not named in the GROUP BY clause:

```
SELECT name, address, MAX(age) FROM t GROUP BY name;
```

The query is valid if name is a primary key of t or is a unique NOT NULL column. In such cases, MySQL recognizes that the selected column is functionally dependent on a grouping column. For example, if name is a primary key, its value determines the value of address because each group has only one value of the primary key and thus only one row. As a result, there is no randomness in the choice of address value in a group and no need to reject the query.

The query is invalid if name is not a primary key of t or a unique NOT NULL column. In this case, no functional dependency can be inferred and an error occurs:

```
mysql> SELECT name, address, MAX(age) FROM t GROUP BY name;
ERROR 1055 (42000): Expression #2 of SELECT list is not in GROUP BY clause and contains nonaggregated column 'mydb.t.address' which is not functionally dependent on columns in GROUP BY clause; this is incompatible with sql_mode=only_full_group_by
```

If you know that, for a given data set, each name value in fact uniquely determines the address value, address is effectively functionally dependent on name. To tell MySQL to accept the query, you can use the ANY_VALUE() function:

```
SELECT name, ANY_VALUE(address), MAX(age) FROM t GROUP BY name;
```

Alternatively, disable ONLY_FULL_GROUP_BY.

The preceding example is quite simple, however. In particular, it is unlikely you would group on a single primary key column because every group would contain only one row. For additional examples demonstrating functional dependence in more complex queries, see Section 12.20.4, “Detection of Functional Dependence”.

If a query has aggregate functions and no GROUP BY clause, it cannot have nonaggregated columns in the select list, HAVING condition, or ORDER BY list with ONLY_FULL_GROUP_BY enabled:

```
mysql> SELECT name, MAX(age) FROM t;
ERROR 1140 (42000): In aggregated query without GROUP BY, expression #1 of SELECT list contains nonaggregated column 'mydb.t.name'; this is incompatible with sql_mode=only_full_group_by
```

Without GROUP BY, there is a single group and it is nondeterministic which name value to choose for the group. Here, too, ANY_VALUE() can be used, if it is immaterial which name value MySQL chooses:

```
SELECT ANY_VALUE(name), MAX(age) FROM t;
```

ONLY_FULL_GROUP_BY also affects handling of queries that use DISTINCT and ORDER BY. Consider the case of a table t with three columns c1, c2, and c3 that contains these rows:

```
c1 c2 c3
1 2 A
3 4 B
1 2 C
```

If you know that, for a given data set, each (c1, c2) value in fact uniquely determines the c3 value, c3 is effectively functionally dependent on (c1, c2). To tell MySQL to accept the query, you can use the ANY_VALUE() function:

```
SELECT ANY_VALUE((c1, c2)), MAX(c3) FROM t;
```

Alternatively, disable ONLY_FULL_GROUP_BY.

The preceding example is quite simple, however. In particular, it is unlikely you would group on a single primary key column because every group would contain only one row. For additional examples demonstrating functional dependence in more complex queries, see Section 12.20.4, “Detection of Functional Dependence”.

If a query has aggregate functions and no GROUP BY clause, it cannot have nonaggregated columns in the select list, HAVING condition, or ORDER BY list with ONLY_FULL_GROUP_BY enabled:

```
mysql> SELECT name, MAX(age) FROM t;
ERROR 1140 (42000): In aggregated query without GROUP BY, expression #1 of SELECT list contains nonaggregated column 'mydb.t.name'; this is incompatible with sql_mode=only_full_group_by
```

Without GROUP BY, there is a single group and it is nondeterministic which name value to choose for the group. Here, too, ANY_VALUE() can be used, if it is immaterial which name value MySQL chooses:

```
SELECT ANY_VALUE(name), MAX(age) FROM t;
```

ONLY_FULL_GROUP_BY also affects handling of queries that use DISTINCT and ORDER BY. Consider the case of a table t with three columns c1, c2, and c3 that contains these rows:

```
c1 c2 c3
1 2 A
3 4 B
1 2 C
```
Suppose that we execute the following query, expecting the results to be ordered by \(c_3\):

```
SELECT DISTINCT c1, c2 FROM t ORDER BY c3;
```

To order the result, duplicates must be eliminated first. But to do so, should we keep the first row or the third? This arbitrary choice influences the retained value of \(c_3\), which in turn influences ordering and makes it arbitrary as well. To prevent this problem, a query that has `DISTINCT` and `ORDER BY` expression does not satisfy at least one of these conditions:

- The expression is equal to one in the select list
- All columns referenced by the expression and belonging to the query’s selected tables are elements of the select list

Another MySQL extension to standard SQL permits references in the `HAVING` clause to aliased expressions in the select list. For example, the following query returns `name` values that occur only once in table `orders`:

```
SELECT name, COUNT(name) FROM orders
GROUP BY name
HAVING COUNT(name) = 1;
```

The MySQL extension permits the use of an alias in the `HAVING` clause for the aggregated column:

```
SELECT name, COUNT(name) AS c FROM orders
GROUP BY name
HAVING c = 1;
```

Standard SQL permits only column expressions in `GROUP BY` clauses, so a statement such as this is invalid because `FLOOR(value/100)` is a noncolumn expression:

```
SELECT id, FLOOR(value/100)
FROM tbl_name
GROUP BY id, FLOOR(value/100);
```

MySQL extends standard SQL to permit noncolumn expressions in `GROUP BY` clauses and considers the preceding statement valid.

Standard SQL also does not permit aliases in `GROUP BY` clauses. MySQL extends standard SQL to permit aliases, so another way to write the query is as follows:

```
SELECT id, FLOOR(value/100) AS val
FROM tbl_name
GROUP BY id, val;
```

The alias `val` is considered a column expression in the `GROUP BY` clause.

In the presence of a noncolumn expression in the `GROUP BY` clause, MySQL recognizes equality between that expression and expressions in the select list. This means that with `ONLY_FULL_GROUP_BY` SQL mode enabled, the query containing `GROUP BY id, FLOOR(value/100)` is valid because that same `FLOOR()` expression occurs in the select list. However, MySQL does not try to recognize functional dependence on `GROUP BY` noncolumn expressions, so the following query is invalid with `ONLY_FULL_GROUP_BY` enabled, even though the third selected expression is a simple formula of the `id` column and the `FLOOR()` expression in the `GROUP BY` clause:

```
SELECT id, FLOOR(value/100), id+FLOOR(value/100)
FROM tbl_name
GROUP BY id, FLOOR(value/100);
```

A workaround is to use a derived table:

```
SELECT id, F, id+F
FROM
  (SELECT id, FLOOR(value/100) AS F
   FROM tbl_name
   GROUP BY id, FLOOR(value/100)) AS dt;
```
12.20.4 Detection of Functional Dependence

The following discussion provides several examples of the ways in which MySQL detects functional dependencies. The examples use this notation:

\[
\{X\} \rightarrow \{Y\}
\]

Understand this as "\(X\) uniquely determines \(Y\)," which also means that \(Y\) is functionally dependent on \(X\).

The examples use the world database, which can be downloaded from https://dev.mysql.com/doc/index-other.html. You can find details on how to install the database on the same page.

- Functional Dependencies Derived from Keys
- Functional Dependencies Derived from Multiple-Column Keys and from Equalities
- Functional Dependency Special Cases
- Functional Dependencies and Views
- Combinations of Functional Dependencies

**Functional Dependencies Derived from Keys**

The following query selects, for each country, a count of spoken languages:

```sql
SELECT co.Name, COUNT(*)
FROM countrylanguage cl, country co
GROUP BY co.Code;
```

co.Code is a primary key of co, so all columns of co are functionally dependent on it, as expressed using this notation:

\[
\{co.Code\} \rightarrow \{co.*\}
\]

Thus, co.name is functionally dependent on GROUP BY columns and the query is valid.

A UNIQUE index over a NOT NULL column could be used instead of a primary key and the same functional dependence would apply. (This is not true for a UNIQUE index that permits NULL values because it permits multiple NULL values and in that case uniqueness is lost.)

**Functional Dependencies Derived from Multiple-Column Keys and from Equalities**

This query selects, for each country, a list of all spoken languages and how many people speak them:

```sql
SELECT co.Name, cl.Language,
cl.Percentage * co.Population / 100.0 AS SpokenBy
FROM countrylanguage cl, country co
GROUP BY cl.CountryCode, cl.Language;
```

The pair \((cl.CountryCode, cl.Language)\) is a two-column composite primary key of cl, so that column pair uniquely determines all columns of cl:

\[
\{cl.CountryCode, cl.Language\} \rightarrow \{cl.*,co.*\}
\]

Moreover, because of the equality in the WHERE clause:

\[
\{cl.CountryCode\} \rightarrow \{co.Code\}
\]

And, because co.Code is primary key of co:

\[
\{co.Code\} \rightarrow \{co.*\}
\]

"Uniquely determines" relationships are transitive, therefore:

\[
\{cl.CountryCode, cl.Language\} \rightarrow \{cl.*,co.*\}
As a result, the query is valid.

As with the previous example, a **UNIQUE** key over **NOT NULL** columns could be used instead of a primary key.

An **INNER JOIN** condition can be used instead of **WHERE**. The same functional dependencies apply:

```sql
SELECT co.Name, cl.Language, 
  cl.Percentage * co.Population/100.0 AS SpokenBy 
FROM countrylanguage cl INNER JOIN country co 
GROUP BY cl.CountryCode, cl.Language;
```

### Functional Dependency Special Cases

Whereas an equality test in a **WHERE** condition or **INNER JOIN** condition is symmetric, an equality test in an outer join condition is not, because tables play different roles.

Assume that referential integrity has been accidentally broken and there exists a row of `countrylanguage` without a corresponding row in `country`. Consider the same query as in the previous example, but with a **LEFT JOIN**:

```sql
SELECT co.Name, cl.Language, 
  cl.Percentage * co.Population/100.0 AS SpokenBy 
FROM countrylanguage cl LEFT JOIN country co 
GROUP BY cl.CountryCode, cl.Language;
```

For a given value of `cl.CountryCode`, the value of `co.Code` in the join result is either found in a matching row (determined by `cl.CountryCode`) or is **NULL**-complemented if there is no match (also determined by `cl.CountryCode`). In each case, this relationship applies:

```plaintext
```

`cl.CountryCode` is itself functionally dependent on `{cl.CountryCode, cl.Language}` which is a primary key.

If in the join result `co.Code` is **NULL**-complemented, `co.Name` is as well. If `co.Code` is not **NULL**-complemented, then because `co.Code` is a primary key, it determines `co.Name`. Therefore, in all cases:

```plaintext
[co.Code] -> [co.Name]
```

Which yields:

```plaintext
{cl.CountryCode, cl.Language} -> {cl.*, co.*}
```

As a result, the query is valid.

However, suppose that the tables are swapped, as in this query:

```sql
SELECT co.Name, cl.Language, 
  cl.Percentage * co.Population/100.0 AS SpokenBy 
FROM country co LEFT JOIN countrylanguage cl 
GROUP BY cl.CountryCode, cl.Language;
```

Now this relationship does **not** apply:

```plaintext
{cl.CountryCode, cl.Language} -> {cl.*, co.*}
```

Indeed, all **NULL**-complemented rows made for `cl` is put into a single group (they have both `GROUP BY` columns equal to **NULL**), and inside this group the value of `co.Name` can vary. The query is invalid and MySQL rejects it.

Functional dependence in outer joins is thus linked to whether determinant columns belong to the left or right side of the **LEFT JOIN**. Determination of functional dependence becomes more complex if there are nested outer joins or the join condition does not consist entirely of equality comparisons.
Window Functions

Functional Dependencies and Views

Suppose that a view on countries produces their code, their name in uppercase, and how many different official languages they have:

```sql
CREATE VIEW country2 AS
SELECT co.Code, UPPER(co.Name) AS UpperName,
COUNT(cl.Language) AS OfficialLanguages
FROM country AS co JOIN countrylanguage AS cl
WHERE cl.isOfficial = 'T'
GROUP BY co.Code;
```

This definition is valid because:

```
{co.Code} -> {co.*}
```

In the view result, the first selected column is `co.Code`, which is also the group column and thus determines all other selected expressions:

```
{country2.Code} -> {country2.*}
```

MySQL understands this and uses this information, as described following.

This query displays countries, how many different official languages they have, and how many cities they have, by joining the view with the `city` table:

```sql
SELECT co2.Code, co2.UpperName, co2.OfficialLanguages,
COUNT(*) AS Cities
FROM country2 AS co2 JOIN city ci
GROUP BY co2.Code;
```

This query is valid because, as seen previously:

```
{co2.Code} -> {co2.*}
```

MySQL is able to discover a functional dependency in the result of a view and use that to validate a query which uses the view. The same would be true if `country2` were a derived table (or common table expression), as in:

```sql
SELECT co2.Code, co2.UpperName, co2.OfficialLanguages,
COUNT(*) AS Cities
FROM
(
SELECT co.Code, UPPER(co.Name) AS UpperName,
COUNT(cl.Language) AS OfficialLanguages
FROM country AS co JOIN countrylanguage AS cl
WHERE cl.isOfficial = 'T'
GROUP BY co.Code
) AS co2
GROUP BY co2.Code;
```

Combinations of Functional Dependencies

MySQL is able to combine all of the preceding types of functional dependencies (key based, equality based, view based) to validate more complex queries.

12.21 Window Functions

MySQL supports window functions that, for each row from a query, perform a calculation using rows related to that row. The following sections discuss how to use window functions, including descriptions of the `OVER` and `WINDOW` clauses. The first section provides descriptions of the nonaggregate window
functions. For descriptions of the aggregate window functions, see Section 12.20.1, “Aggregate Function Descriptions”.

For information about optimization and window functions, see Section 8.2.1.21, “Window Function Optimization”.

12.21.1 Window Function Descriptions

This section describes nonaggregate window functions that, for each row from a query, perform a calculation using rows related to that row. Most aggregate functions also can be used as window functions; see Section 12.20.1, “Aggregate Function Descriptions”.

For window function usage information and examples, and definitions of terms such as the \texttt{OVER}\ clause, window, partition, frame, and peer, see Section 12.21.2, “Window Function Concepts and Syntax”.

Table 12.26 Window Functions

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{CUME_DIST()}</td>
<td>Cumulative distribution value</td>
</tr>
<tr>
<td>\texttt{DENSE_RANK()}</td>
<td>Rank of current row within its partition, without gaps</td>
</tr>
<tr>
<td>\texttt{FIRST_VALUE()}</td>
<td>Value of argument from first row of window frame</td>
</tr>
<tr>
<td>\texttt{LAG()}</td>
<td>Value of argument from row lagging current row within partition</td>
</tr>
<tr>
<td>\texttt{LAST_VALUE()}</td>
<td>Value of argument from last row of window frame</td>
</tr>
<tr>
<td>\texttt{LEAD()}</td>
<td>Value of argument from row leading current row within partition</td>
</tr>
<tr>
<td>\texttt{NTH_VALUE()}</td>
<td>Value of argument from N-th row of window frame</td>
</tr>
<tr>
<td>\texttt{NTILE()}</td>
<td>Bucket number of current row within its partition.</td>
</tr>
<tr>
<td>\texttt{PERCENT_RANK()}</td>
<td>Percentage rank value</td>
</tr>
<tr>
<td>\texttt{RANK()}</td>
<td>Rank of current row within its partition, with gaps</td>
</tr>
<tr>
<td>\texttt{ROW_NUMBER()}</td>
<td>Number of current row within its partition</td>
</tr>
</tbody>
</table>

In the following function descriptions, \texttt{over\_clause} represents the \texttt{OVER} clause, described in Section 12.21.2, “Window Function Concepts and Syntax”. Some window functions permit a \texttt{null\_treatment} clause that specifies how to handle \texttt{NULL} values when calculating results. This clause is optional. It is part of the SQL standard, but the MySQL implementation permits only \texttt{RESPECT NULLS} (which is also the default). This means that \texttt{NULL} values are considered when calculating results. \texttt{IGNORE NULLS} is parsed, but produces an error.

- \texttt{CUME\_DIST()} \texttt{over\_clause}

  Returns the cumulative distribution of a value within a group of values; that is, the percentage of partition values less than or equal to the value in the current row. This represents the number of rows preceding or peer with the current row in the window ordering of the window partition divided by the total number of rows in the window partition. Return values range from 0 to 1.

  This function should be used with \texttt{ORDER BY} to sort partition rows into the desired order. Without \texttt{ORDER BY}, all rows are peers and have value \(N/N = 1\), where \(N\) is the partition size.

  \texttt{over\_clause} is as described in Section 12.21.2, “Window Function Concepts and Syntax”.

The following query shows, for the set of values in the \texttt{val} column, the \texttt{CUME\_DIST()} value for each row, as well as the percentage rank value returned by the similar \texttt{PERCENT\_RANK()} function. For reference, the query also displays row numbers using \texttt{ROW\_NUMBER()}:

```sql
mysql> SELECT
    val,
    ROW\_NUMBER() OVER w AS 'row\_number',
```
Window Function Descriptions

cume_dist(), percent_rank()

FROM numbers
WINDOW w AS (ORDER BY val);

<table>
<thead>
<tr>
<th>val</th>
<th>row_number</th>
<th>cume_dist</th>
<th>percent_rank</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>0.2222222222222222</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>0.2222222222222222</td>
<td>0</td>
</tr>
<tr>
<td>2</td>

<td>0.75</td>
</tr>
<tr>
<td>4</td>
<td>8</td>
<td>0.8888888888888889</td>
<td>0.75</td>
</tr>
<tr>
<td>5</td>
<td>9</td>
<td>1.000000000000000</td>
<td>1</td>
</tr>
</tbody>
</table>

- **DENSE_RANK() over_clause**

  Returns the rank of the current row within its partition, without gaps. Peers are considered ties and receive the same rank. This function assigns consecutive ranks to peer groups; the result is that groups of size greater than one do not produce noncontiguous rank numbers. For an example, see the RANK() function description.

  This function should be used with ORDER BY to sort partition rows into the desired order. Without ORDER BY, all rows are peers.

  over_clause is as described in Section 12.21.2, “Window Function Concepts and Syntax”.

- **FIRST_VALUE(expr) [null_treatment] over_clause**

  Returns the value of expr from the first row of the window frame.

  over_clause is as described in Section 12.21.2, “Window Function Concepts and Syntax”. null_treatment is as described in the section introduction.

  The following query demonstrates FIRST_VALUE(), LAST_VALUE(), and two instances of NTH_VALUE():

  ```sql
  mysql> SELECT
  time, subject, val,
  FIRST_VALUE(val) OVER w AS 'first',
  LAST_VALUE(val) OVER w AS 'last',
  NTH_VALUE(val, 2) OVER w AS 'second',
  NTH_VALUE(val, 4) OVER w AS 'fourth'
  FROM observations
  WINDOW w AS (PARTITION BY subject ORDER BY time
  ROWS UNBOUNDED PRECEDING);
  ```

<table>
<thead>
<tr>
<th>time</th>
<th>subject</th>
<th>val</th>
<th>first</th>
<th>last</th>
<th>second</th>
<th>fourth</th>
</tr>
</thead>
<tbody>
<tr>
<td>07:00:00</td>
<td>st113</td>
<td>10</td>
<td>10</td>
<td>10</td>
<td>NULL</td>
<td>NULL</td>
</tr>
<tr>
<td>07:15:00</td>
<td>st113</td>
<td>10</td>
<td>10</td>
<td>9</td>
<td>9</td>
<td>NULL</td>
</tr>
<tr>
<td>07:30:00</td>
<td>st113</td>
<td>25</td>
<td>10</td>
<td>25</td>
<td>9</td>
<td>NULL</td>
</tr>
<tr>
<td>07:45:00</td>
<td>st113</td>
<td>20</td>
<td>10</td>
<td>20</td>
<td>9</td>
<td>20</td>
</tr>
<tr>
<td>07:00:00</td>
<td>xh458</td>

<td>0</td>
<td>0</td>
<td>NULL</td>
<td>NULL</td>
</tr>
<tr>
<td>07:15:00</td>
<td>xh458</td>
<td>10</td>
<td>0</td>
<td>10</td>
<td>10</td>
<td>NULL</td>
</tr>
<tr>
<td>07:30:00</td>
<td>xh458</td>
<td>5</td>
<td>0</td>
<td>5</td>
<td>10</td>
<td>NULL</td>
</tr>
<tr>
<td>07:45:00</td>
<td>xh458</td>
<td>30</td>
<td>0</td>
<td>30</td>
<td>10</td>
<td>30</td>
</tr>
<tr>
<td>08:00:00</td>
<td>xh458</td>
<td>25</td>
<td>0</td>
<td>25</td>
<td>10</td>
<td>30</td>
</tr>
</tbody>
</table>

  Each function uses the rows in the current frame, which, per the window definition shown, extends from the first partition row to the current row. For the NTH_VALUE() calls, the current frame does not always include the requested row; in such cases, the return value is NULL.

- **LAG(expr [, N[, default]]) [null_treatment] over_clause**
Returns the value of `expr` from the row that lags (precedes) the current row by \( N \) rows within its partition. If there is no such row, the return value is `default`. For example, if \( N \) is 3, the return value is `default` for the first two rows. If \( N \) or `default` are missing, the defaults are 1 and `NULL`, respectively.

\( N \) must be a literal nonnegative integer. If \( N \) is 0, `expr` is evaluated for the current row.

Beginning with MySQL 8.0.22, \( N \) cannot be `NULL`. In addition, it must now be an integer in the range 1 to \( 2^{63} \), inclusive, in any of the following forms:

- an unsigned integer constant literal
- a positional parameter marker (`?`)
- a user-defined variable
- a local variable in a stored routine

`over_clause` is as described in Section 12.21.2, “Window Function Concepts and Syntax”. `null_treatment` is as described in the section introduction.

`LAG()` (and the similar `LEAD()` function) are often used to compute differences between rows. The following query shows a set of time-ordered observations and, for each one, the `LAG()` and `LEAD()` values from the adjoining rows, as well as the differences between the current and adjoining rows:

```sql
mysql> SELECT t, val, LAG(val) OVER w AS 'lag', LEAD(val) OVER w AS 'lead', val - LAG(val) OVER w AS 'lag diff', val - LEAD(val) OVER w AS 'lead diff'
FROM series WINDOW w AS (ORDER BY t);
```

| t        | val | lag  | lead | lag diff | lead diff |
|----------+-----+------+------|---------+-----------|
| 12:00:00 | 100 | NULL | 125  | NULL    | -25       |
| 13:00:00 | 125 | 100  | 132  | 25       | -7        |
| 14:00:00 | 132 | 125  | 145  | 7        | -13       |
| 15:00:00 | 145 | 132  | 140  | 13       | -10       |
| 16:00:00 | 140 | 145  | 150  | -5       | 10        |
| 17:00:00 | 150 | 140  | 200  | 10       | -50       |
| 18:00:00 | 200 | 150  | NULL | 50       | NULL      |

In the example, the `LAG()` and `LEAD()` calls use the default \( N \) and `default` values of 1 and `NULL`, respectively.

The first row shows what happens when there is no previous row for `LAG()`: The function returns the `default` value (in this case, `NULL`). The last row shows the same thing when there is no next row for `LEAD()`.

`LAG()` and `LEAD()` also serve to compute sums rather than differences. Consider this data set, which contains the first few numbers of the Fibonacci series:

```sql
mysql> SELECT n FROM fib ORDER BY n;
```

<table>
<thead>
<tr>
<th>n</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
</tr>
<tr>
<td>2</td>
</tr>
<tr>
<td>3</td>
</tr>
<tr>
<td>5</td>
</tr>
<tr>
<td>8</td>
</tr>
</tbody>
</table>
The following query shows the `LAG()` and `LEAD()` values for the rows adjacent to the current row. It also uses those functions to add to the current row value the values from the preceding and following rows. The effect is to generate the next number in the Fibonacci series, and the next number after that:

```sql
mysql> SELECT
    n,
    LAG(n, 1, 0) OVER w AS 'lag',
    LEAD(n, 1, 0) OVER w AS 'lead',
    n + LAG(n, 1, 0) OVER w AS 'next_n',
    n + LEAD(n, 1, 0) OVER w AS 'next_next_n'
FROM fib
WINDOW w AS (ORDER BY n);
```

<table>
<thead>
<tr>
<th>n</th>
<th>lag</th>
<th>lead</th>
<th>next_n</th>
<th>next_next_n</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0</td>
<td>1</td>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>2</td>
<td>2</td>
<td>3</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
<td>3</td>
<td>3</td>
<td>5</td>
</tr>
<tr>
<td>3</td>
<td>2</td>
<td>5</td>
<td>5</td>
<td>8</td>
</tr>
<tr>
<td>5</td>
<td>3</td>
<td>8</td>
<td>8</td>
<td>13</td>
</tr>
<tr>
<td>8</td>
<td>5</td>
<td>0</td>
<td>13</td>
<td>8</td>
</tr>
</tbody>
</table>

One way to generate the initial set of Fibonacci numbers is to use a recursive common table expression. For an example, see Fibonacci Series Generation.

Beginning with MySQL 8.0.22, you cannot use a negative value for the rows argument of this function.

- **LAST_VALUE(expr) [null_treatment] over_clause**
  
  Returns the value of `expr` from the last row of the window frame.

  `over_clause` is as described in Section 12.21.2, “Window Function Concepts and Syntax”.

  `null_treatment` is as described in the section introduction.

  For an example, see the FIRST_VALUE() function description.

- **LEAD(expr [, N[, default]]) [null_treatment] over_clause**
  
  Returns the value of `expr` from the row that leads (follows) the current row by `N` rows within its partition. If there is no such row, the return value is `default`. For example, if `N` is 3, the return value is `default` for the last two rows. If `N` or `default` are missing, the defaults are 1 and NULL, respectively.

  `N` must be a literal nonnegative integer. If `N` is 0, `expr` is evaluated for the current row.

  Beginning with MySQL 8.0.22, `N` cannot be NULL. In addition, it must now be an integer in the range 1 to $2^{31}$, inclusive, in any of the following forms:

  - an unsigned integer constant literal
  - a positional parameter marker (?)
  - a user-defined variable
  - a local variable in a stored routine

  `over_clause` is as described in Section 12.21.2, “Window Function Concepts and Syntax”.

  `null_treatment` is as described in the section introduction.

  For an example, see the LAG() function description.
In MySQL 8.0.22 and later, use of a negative value for the rows argument of this function is not permitted.

- **NTH_VALUE**(expr, N) [from_first_last][null_treatment] over_clause

Returns the value of expr from the N-th row of the window frame. If there is no such row, the return value is NULL.

N must be a literal positive integer.

from_first_last is part of the SQL standard, but the MySQL implementation permits only FROM FIRST (which is also the default). This means that calculations begin at the first row of the window. FROM LAST is parsed, but produces an error. To obtain the same effect as FROM LAST (begin calculations at the last row of the window), use ORDER BY to sort in reverse order.

over_clause is as described in Section 12.21.2, “Window Function Concepts and Syntax”. null_treatment is as described in the section introduction.

For an example, see the FIRST_VALUE() function description.

In MySQL 8.0.22 and later, you cannot use NULL for the row argument of this function.

- **NTILE**(N) over_clause

Divides a partition into N groups (buckets), assigns each row in the partition its bucket number, and returns the bucket number of the current row within its partition. For example, if N is 4, NTILE() divides rows into four buckets. If N is 100, NTILE() divides rows into 100 buckets.

N must be a literal positive integer. Bucket number return values range from 1 to N.

Beginning with MySQL 8.0.22, N cannot be NULL. In addition, it must be an integer in the range 1 to 2^63, inclusive, in any of the following forms:

- an unsigned integer constant literal
- a positional parameter marker (?)
- a user-defined variable
- a local variable in a stored routine

This function should be used with ORDER BY to sort partition rows into the desired order.

over_clause is as described in Section 12.21.2, “Window Function Concepts and Syntax”.

The following query shows, for the set of values in the val column, the percentile values resulting from dividing the rows into two or four groups. For reference, the query also displays row numbers using ROW_NUMBER():

```plaintext
mysql> SELECT val, ROW_NUMBER() OVER w AS 'row_number', NTILE(2) OVER w AS 'ntile2', NTILE(4) OVER w AS 'ntile4' FROM numbers WINDOW w AS (ORDER BY val);
```

<table>
<thead>
<tr>
<th>val</th>
<th>row_number</th>
<th>ntile2</th>
<th>ntile4</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>2</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>3</td>
<td>4</td>
<td>1</td>
<td>2</td>
</tr>
</tbody>
</table>
Beginning with MySQL 8.0.22, the construct `NTILE(NULL)` is no longer permitted.

- **PERCENT_RANK() `over_clause`**

  Returns the percentage of partition values less than the value in the current row, excluding the highest value. Return values range from 0 to 1 and represent the row relative rank, calculated as the result of this formula, where \( \text{rank} \) is the row rank and \( \text{rows} \) is the number of partition rows:

  \[
  \frac{\text{rank} - 1}{\text{rows} - 1}
  \]

  This function should be used with `ORDER BY` to sort partition rows into the desired order. Without `ORDER BY`, all rows are peers.

  `over_clause` is as described in Section 12.21.2, “Window Function Concepts and Syntax”.

  For an example, see the `CUME_DIST()` function description.

- **RANK() `over_clause`**

  Returns the rank of the current row within its partition, with gaps. Peers are considered ties and receive the same rank. This function does not assign consecutive ranks to peer groups if groups of size greater than one exist; the result is noncontiguous rank numbers.

  This function should be used with `ORDER BY` to sort partition rows into the desired order. Without `ORDER BY`, all rows are peers.

  `over_clause` is as described in Section 12.21.2, “Window Function Concepts and Syntax”.

  The following query shows the difference between `RANK()`, which produces ranks with gaps, and `DENSE_RANK()`, which produces ranks without gaps. The query shows rank values for each member of a set of values in the `val` column, which contains some duplicates. `RANK()` assigns peers (the duplicates) the same rank value, and the next greater value has a rank higher by the number of peers minus one. `DENSE_RANK()` also assigns peers the same rank value, but the next higher value has a rank one greater. For reference, the query also displays row numbers using `ROW_NUMBER()`:

  ```sql
  mysql> SELECT val, ROW_NUMBER() OVER w AS 'row_number', RANK() OVER w AS 'rank', DENSE_RANK() OVER w AS 'dense_rank'
  FROM numbers WINDOW w AS (ORDER BY val);
  +-----+----------+------+------------------+
  | val | row_number | rank | dense_rank      |
  |-----+----------+------+------------------+
  | 1   |          1 |    1 |          1      |
  | 1   |          2 |    1 |          1      |
  | 2   |          3 |    3 |          2      |
  | 3   |          4 |    4 |          3      |
  | 3   |          5 |    4 |          3      |
  | 3   |          6 |    4 |          3      |
  | 4   |          7 |    7 |          4      |
  | 4   |          8 |    7 |          4      |
  | 5   |          9 |    9 |          5      |
  +-----+----------+------+------------------+
  ```

  2234
• **ROW_NUMBER() over_clause**

Returns the number of the current row within its partition. Rows numbers range from 1 to the number of partition rows.

*ORDER BY* affects the order in which rows are numbered. Without *ORDER BY*, row numbering is nondeterministic.

*ROW_NUMBER()* assigns peers different row numbers. To assign peers the same value, use *RANK()* or *DENSE_RANK()* . For an example, see the *RANK()* function description.

*over_clause* is as described in Section 12.21.2, “Window Function Concepts and Syntax”.

### 12.21.2 Window Function Concepts and Syntax

This section describes how to use window functions. Examples use the same sales information data set as found in the discussion of the *GROUPING()* function in Section 12.20.2, “GROUP BY Modifiers”:

```sql
mysql> SELECT * FROM sales ORDER BY country, year, product;
+------+---------+------------+--------+
| year | country | product    | profit |
+------+---------+------------+--------+
| 2000 | Finland | Computer   |   1500 |
| 2000 | Finland | Phone      |    100 |
| 2001 | Finland | Phone      |     10 |
| 2000 | India   | Calculator |     75 |
| 2000 | India   | Calculator |     75 |
| 2000 | India   | Computer   |   1200 |
| 2000 | USA     | Calculator |     75 |
| 2000 | USA     | Computer   |   1500 |
| 2000 | USA     | Computer   |   1200 |
| 2001 | USA     | Calculator |     50 |
| 2001 | USA     | Computer   |   1500 |
| 2001 | USA     | Computer   |   1200 |
| 2001 | USA     | TV         |    150 |
| 2001 | USA     | TV         |    100 |
+------+---------+------------+--------+
```

A window function performs an aggregate-like operation on a set of query rows. However, whereas an aggregate operation groups query rows into a single result row, a window function produces a result for each query row:

• The row for which function evaluation occurs is called the current row.

• The query rows related to the current row over which function evaluation occurs comprise the window for the current row.

For example, using the sales information table, these two queries perform aggregate operations that produce a single global sum for all rows taken as a group, and sums grouped per country:

```sql
mysql> SELECT SUM(profit) AS total_profit
    FROM sales;
+------------------+
| total_profit     |
+------------------+
| 7535             |
+------------------+

mysql> SELECT country, SUM(profit) AS country_profit
    FROM sales
    GROUP BY country
    ORDER BY country;
+---------+------------------+
| country | country_profit   |
+---------+------------------+
| Finland | 1610             |
| India   | 1350             |
| USA     | 4575             |
+---------+------------------+
```
By contrast, window operations do not collapse groups of query rows to a single output row. Instead, they produce a result for each row. Like the preceding queries, the following query uses `SUM()`, but this time as a window function:

```sql
SELECT year, country, product, profit,
       SUM(profit) OVER() AS total_profit,
       SUM(profit) OVER(PARTITION BY country) AS country_profit
FROM sales
ORDER BY country, year, product, profit;
```

Each window operation in the query is signified by inclusion of an `OVER` clause that specifies how to partition query rows into groups for processing by the window function:

- The first `OVER` clause is empty, which treats the entire set of query rows as a single partition. The window function thus produces a global sum, but does so for each row.

- The second `OVER` clause partitions rows by country, producing a sum per partition (per country). The function produces this sum for each partition row.

Window functions are permitted only in the select list and `ORDER BY` clause. Query result rows are determined from the `FROM` clause, after `WHERE`, `GROUP BY`, and `HAVING` processing, and windowing execution occurs before `ORDER BY`, `LIMIT`, and `SELECT DISTINCT`.

The `OVER` clause is permitted for many aggregate functions, which therefore can be used as window or nonwindow functions, depending on whether the `OVER` clause is present or absent:

```sql
AVG()  
BIT_AND()  
BIT_OR()  
BIT_XOR()  
COUNT()  
JSON_ARRAYAGG()  
JSON_OBJECTAGG()  
MAX()  
MIN()  
STDDEV_POP(), STDDEV(), STD()  
STDDEV_SAMP()  
SUM()  
VAR_POP(), VARIANCE()  
VAR_SAMP()  
```

For details about each aggregate function, see Section 12.20.1, “Aggregate Function Descriptions”.

MySQL also supports nonaggregate functions that are used only as window functions. For these, the `OVER` clause is mandatory:

```sql
CUME_DIST()  
```
Window Function Concepts and Syntax

DENSE_RANK()
FIRST_VALUE()
LAG()
LAST_VALUE()
LEAD()
NTH_VALUE()
NTILE()
PERCENT_RANK()
RANK()
ROW_NUMBER()

For details about each nonaggregate function, see Section 12.21.1, “Window Function Descriptions”.

As an example of one of those nonaggregate window functions, this query uses ROW_NUMBER(), which produces the row number of each row within its partition. In this case, rows are numbered per country. By default, partition rows are unordered and row numbering is nondeterministic. To sort partition rows, include an ORDER BY clause within the window definition. The query uses unordered and ordered partitions (the row_num1 and row_num2 columns) to illustrate the difference between omitting and including ORDER BY:

```sql
mysql> SELECT year, country, product, profit,
ROW_NUMBER() OVER(PARTITION BY country) AS row_num1,
ROW_NUMBER() OVER(PARTITION BY country ORDER BY year, product) AS row_num2
FROM sales;
```

<table>

</table>

As mentioned previously, to use a window function (or treat an aggregate function as a window function), include an OVER clause following the function call. The OVER clause has two forms:

```sql
over_clause:
{OVER (window_spec) | OVER window_name}
```

Both forms define how the window function should process query rows. They differ in whether the window is defined directly in the OVER clause, or supplied by a reference to a named window defined elsewhere in the query:

- In the first case, the window specification appears directly in the OVER clause, between the parentheses.
- In the second case, window_name is the name for a window specification defined by a WINDOW clause elsewhere in the query. For details, see Section 12.21.4, “Named Windows”.

For OVER (window_spec) syntax, the window specification has several parts, all optional:

```sql
window_spec:
[window_name] [partition_clause] [order_clause] [frame_clause]
```

If OVER () is empty, the window consists of all query rows and the window function computes a result using all rows. Otherwise, the clauses present within the parentheses determine which query rows are used to compute the function result and how they are partitioned and ordered.
• window_name: The name of a window defined by a WINDOW clause elsewhere in the query. If window_name appears by itself within the OVER clause, it completely defines the window. If partitioning, ordering, or framing clauses are also given, they modify interpretation of the named window. For details, see Section 12.21.4, “Named Windows”.

• partition_clause: A PARTITION BY clause indicates how to divide the query rows into groups. The window function result for a given row is based on the rows of the partition that contains the row. If PARTITION BY is omitted, there is a single partition consisting of all query rows.

Note
Partitioning for window functions differs from table partitioning. For information about table partitioning, see Chapter 24, Partitioning.

partition_clause has this syntax:

```
partition_clause:
  PARTITION BY expr [, expr] ...
```

Standard SQL requires PARTITION BY to be followed by column names only. A MySQL extension is to permit expressions, not just column names. For example, if a table contains a TIMESTAMP column named ts, standard SQL permits PARTITION BY ts but not PARTITION BY HOUR(ts), whereas MySQL permits both.

• order_clause: An ORDER BY clause indicates how to sort rows in each partition. Partition rows that are equal according to the ORDER BY clause are considered peers. If ORDER BY is omitted, partition rows are unordered, with no processing order implied, and all partition rows are peers.

order_clause has this syntax:

```
order_clause:
  ORDER BY expr [ASC|DESC] [, expr [ASC|DESC]] ...
```

Each ORDER BY expression optionally can be followed by ASC or DESC to indicate sort direction. The default is ASC if no direction is specified. NULL values sort first for ascending sorts, last for descending sorts.

An ORDER BY in a window definition applies within individual partitions. To sort the result set as a whole, include an ORDER BY at the query top level.

• frame_clause: A frame is a subset of the current partition and the frame clause specifies how to define the subset. The frame clause has many subclauses of its own. For details, see Section 12.21.3, “Window Function Frame Specification”.

12.21.3 Window Function Frame Specification

The definition of a window used with a window function can include a frame clause. A frame is a subset of the current partition and the frame clause specifies how to define the subset.

Frames are determined with respect to the current row, which enables a frame to move within a partition depending on the location of the current row within its partition. Examples:

• By defining a frame to be all rows from the partition start to the current row, you can compute running totals for each row.

• By defining a frame as extending \( N \) rows on either side of the current row, you can compute rolling averages.

The following query demonstrates the use of moving frames to compute running totals within each group of time-ordered level values, as well as rolling averages computed from the current row and the rows that immediately precede and follow it:

```
mysql> SELECT ...
```
Window Function Frame Specification

```
time, subject, val,
SUM(val) OVER (PARTITION BY subject ORDER BY time
ROWS UNBOUNDED PRECEDING)
AS running_total,
AVG(val) OVER (PARTITION BY subject ORDER BY time
ROWS BETWEEN 1 PRECEDING AND 1 FOLLOWING)
AS running_average
FROM observations;
```

<table>
<thead>
<tr>
<th>time</th>
<th>subject</th>
<th>val</th>
<th>running_total</th>
<th>running_average</th>
</tr>
</thead>
<tbody>
<tr>
<td>07:00:00</td>
<td>st113</td>
<td>10</td>
<td>10</td>
<td>9.5000</td>
</tr>
<tr>
<td>07:15:00</td>
<td>st113</td>
<td>9</td>
<td>19</td>
<td>14.6667</td>
</tr>
<tr>
<td>07:30:00</td>
<td>st113</td>
<td>25</td>
<td>44</td>
<td>18.0000</td>
</tr>
<tr>
<td>07:45:00</td>
<td>st113</td>
<td>20</td>
<td>64</td>
<td>22.5000</td>
</tr>
<tr>
<td>07:00:00</td>
<td>xh458</td>
<td>0</td>
<td>0</td>
<td>5.0000</td>
</tr>
<tr>
<td>07:15:00</td>
<td>xh458</td>
<td>10</td>
<td>10</td>
<td>5.0000</td>
</tr>
<tr>
<td>07:30:00</td>
<td>xh458</td>
<td>5</td>
<td>15</td>
<td>15.0000</td>
</tr>
<tr>
<td>07:45:00</td>
<td>xh458</td>
<td>30</td>
<td>45</td>
<td>20.0000</td>
</tr>
<tr>
<td>08:00:00</td>
<td>xh458</td>
<td>25</td>
<td>70</td>
<td>27.5000</td>
</tr>
</tbody>
</table>

For the running_average column, there is no frame row preceding the first one or following the last. In these cases, AVG() computes the average of the rows that are available.

Aggregate functions used as window functions operate on rows in the current row frame, as do these nonaggregate window functions:

```
FIRST_VALUE()
LAST_VALUE()
NTH_VALUE()
```

Standard SQL specifies that window functions that operate on the entire partition should have no frame clause. MySQL permits a frame clause for such functions but ignores it. These functions use the entire partition even if a frame is specified:

```
CUME_DIST()
DENSE_RANK()
LAG()
LEAD()
NTILE()
PERCENT_RANK()
RANK()
ROW_NUMBER()
```

The frame clause, if given, has this syntax:

```
frame_clause:
    frame_units frame_extent

frame_units:
    {ROWS | RANGE}
```

In the absence of a frame clause, the default frame depends on whether an ORDER BY clause is present, as described later in this section.

The frame_units value indicates the type of relationship between the current row and frame rows:

- **ROWS**: The frame is defined by beginning and ending row positions. Offsets are differences in row numbers from the current row number.
- **RANGE**: The frame is defined by rows within a value range. Offsets are differences in row values from the current row value.

The frame_extent value indicates the start and end points of the frame. You can specify just the start of the frame (in which case the current row is implicitly the end) or use BETWEEN to specify both frame endpoints:
Window Function Frame Specification

[frame_extent]:
{frame_start | frame_between}

[frame_between]:
BETWEEN frame_start AND frame_end

[frame_start, frame_end]:
{CURRENT ROW | UNBOUNDED PRECEDING | UNBOUNDED FOLLOWING | expr PRECEDING | expr FOLLOWING}

With BETWEEN syntax, frame_start must not occur later than frame_end.

The permitted frame_start and frame_end values have these meanings:

- CURRENT ROW: For ROWS, the bound is the current row. For RANGE, the bound is the peers of the current row.

- UNBOUNDED PRECEDING: The bound is the first partition row.

- UNBOUNDED FOLLOWING: The bound is the last partition row.

- expr PRECEDING: For ROWS, the bound is expr rows before the current row. For RANGE, the bound is the rows with values equal to the current row value minus expr; if the current row value is NULL, the bound is the peers of the row.

For expr PRECEDING (and expr FOLLOWING), expr can be a ? parameter marker (for use in a prepared statement), a nonnegative numeric literal, or a temporal interval of the form INTERVAL val unit. For INTERVAL expressions, val specifies nonnegative interval value, and unit is a keyword indicating the units in which the value should be interpreted. (For details about the permitted units specifiers, see the description of the DATE_ADD() function in Section 12.7, “Date and Time Functions”.)

RANGE on a numeric or temporal expr requires ORDER BY on a numeric or temporal expression, respectively.

Examples of valid expr PRECEDING and expr FOLLOWING indicators:

10 PRECEDING
INTERVAL 5 DAY PRECEDING
5 FOLLOWING
INTERVAL '2:30' MINUTE_SECOND FOLLOWING

- expr FOLLOWING: For ROWS, the bound is expr rows after the current row. For RANGE, the bound is the rows with values equal to the current row value plus expr; if the current row value is NULL, the bound is the peers of the row.

For permitted values of expr, see the description of expr PRECEDING.

The following query demonstrates FIRST_VALUE(), LAST_VALUE(), and two instances of NTH_VALUE():

mysql> SELECT
    time, subject, val,
    FIRST_VALUE(val) OVER w AS 'first',
    LAST_VALUE(val) OVER w AS 'last',
    NTH_VALUE(val, 2) OVER w AS 'second',
    NTH_VALUE(val, 4) OVER w AS 'fourth'
FROM observations
WINDOW w AS (PARTITION BY subject ORDER BY time
    ROWS UNBOUNDED PRECEDING);

+----------+---------+------+-------+------+--------+--------+
| time     | subject | val  | first | last | second | fourth |
|-----------+---------+------|-------+------|-------+--------+
| 2240      | 35      | 25   | NULL | NULL | NULL   | NULL   |
Each function uses the rows in the current frame, which, per the window definition shown, extends from
the first partition row to the current row. For the \texttt{NTH\_VALUE()} calls, the current frame does not always
include the requested row; in such cases, the return value is \texttt{NULL}.

In the absence of a frame clause, the default frame depends on whether an \texttt{ORDER BY} clause is
present:

- With \texttt{ORDER BY}: The default frame includes rows from the partition start through the current row,
  including all peers of the current row (rows equal to the current row according to the \texttt{ORDER BY}
  clause). The default is equivalent to this frame specification:

  \texttt{RANGE BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW}

- Without \texttt{ORDER BY}: The default frame includes all partition rows (because, without \texttt{ORDER BY}, all
  partition rows are peers). The default is equivalent to this frame specification:

  \texttt{RANGE BETWEEN UNBOUNDED PRECEDING AND UNBOUNDED FOLLOWING}

Because the default frame differs depending on presence or absence of \texttt{ORDER BY}, adding \texttt{ORDER BY}
to a query to get deterministic results may change the results. (For example, the values produced by
\texttt{SUM()} might change.) To obtain the same results but ordered per \texttt{ORDER BY}, provide an explicit frame
specification to be used regardless of whether \texttt{ORDER BY} is present.

The meaning of a frame specification can be nonobvious when the current row value is \texttt{NULL}.
Assuming that to be the case, these examples illustrate how various frame specifications apply:

- \texttt{ORDER BY X ASC RANGE BETWEEN 10 FOLLOWING AND 15 FOLLOWING}

  The frame starts at \texttt{NULL} and stops at \texttt{NULL}, thus includes only rows with value \texttt{NULL}.

- \texttt{ORDER BY X ASC RANGE BETWEEN 10 FOLLOWING AND UNBOUNDED FOLLOWING}

  The frame starts at \texttt{NULL} and stops at the end of the partition. Because an \texttt{ASC} sort puts \texttt{NULL}
  values first, the frame is the entire partition.

- \texttt{ORDER BY X DESC RANGE BETWEEN 10 FOLLOWING AND UNBOUNDED FOLLOWING}

  The frame starts at \texttt{NULL} and stops at the end of the partition. Because a \texttt{DESC} sort puts \texttt{NULL}
  values last, the frame is only the \texttt{NULL} values.

- \texttt{ORDER BY X ASC RANGE BETWEEN 10 PRECEDING AND UNBOUNDED FOLLOWING}

  The frame starts at \texttt{NULL} and stops at the end of the partition. Because an \texttt{ASC} sort puts \texttt{NULL}
  values first, the frame is the entire partition.

- \texttt{ORDER BY X ASC RANGE BETWEEN 10 PRECEDING AND 10 FOLLOWING}

  The frame starts at \texttt{NULL} and stops at \texttt{NULL}, thus includes only rows with value \texttt{NULL}.

- \texttt{ORDER BY X ASC RANGE BETWEEN 10 PRECEDING AND 1 PRECEDING}

  The frame starts at \texttt{NULL} and stops at \texttt{NULL}, thus includes only rows with value \texttt{NULL}.
12.21.4 Named Windows

Windows can be defined and given names by which to refer to them in OVER clauses. To do this, use a WINDOW clause. If present in a query, the WINDOW clause falls between the positions of the HAVING and ORDER BY clauses, and has this syntax:

```
WINDOW window_name AS (window_spec)
    [, window_name AS (window_spec)] ...
```

For each window definition, window_name is the window name, and window_spec is the same type of window specification as given between the parentheses of an OVER clause, as described in Section 12.21.2, "Window Function Concepts and Syntax":

```
window_spec:
    [window_name] [partition_clause] [order_clause] [frame_clause]
```

A WINDOW clause is useful for queries in which multiple OVER clauses would otherwise define the same window. Instead, you can define the window once, give it a name, and refer to the name in the OVER clauses. Consider this query, which defines the same window multiple times:

```
SELECT val,
    ROW_NUMBER() OVER (ORDER BY val) AS 'row_number',
    RANK()       OVER (ORDER BY val) AS 'rank',
    DENSE_RANK() OVER (ORDER BY val) AS 'dense_rank'
FROM numbers;
```

The query can be written more simply by using WINDOW to define the window once and referring to the window by name in the OVER clauses:

```
SELECT val,
    ROW_NUMBER() OVER w AS 'row_number',
    RANK()       OVER w AS 'rank',
    DENSE_RANK() OVER w AS 'dense_rank'
FROM numbers
WINDOW w AS (ORDER BY val);
```

A named window also makes it easier to experiment with the window definition to see the effect on query results. You need only modify the window definition in the WINDOW clause, rather than multiple OVER clause definitions.

If an OVER clause uses OVER (window_name ...) rather than OVER window_name, the named window can be modified by the addition of other clauses. For example, this query defines a window that includes partitioning, and uses ORDER BY in the OVER clauses to modify the window in different ways:

```
SELECT DISTINCT year, country,
    FIRST_VALUE(year) OVER (w ORDER BY year ASC) AS first,
    FIRST_VALUE(year) OVER (w ORDER BY year DESC) AS last
FROM sales
WINDOW w AS (PARTITION BY country);
```

An OVER clause can only add properties to a named window, not modify them. If the named window definition includes a partitioning, ordering, or framing property, the OVER clause that refers to the window name cannot also include the same kind of property or an error occurs:

- This construct is permitted because the window definition and the referring OVER clause do not contain the same kind of properties:
Window Function Restrictions

Window Function Restrictions

OVER (w ORDER BY country)
... WINDOW w AS (PARTITION BY country)

- This construct is not permitted because the OVER clause specifies PARTITION BY for a named window that already has PARTITION BY:

OVER (w PARTITION BY year)
... WINDOW w AS (PARTITION BY country)

The definition of a named window can itself begin with a window_name. In such cases, forward and backward references are permitted, but not cycles:

- This is permitted; it contains forward and backward references but no cycles:

  WINDOW w1 AS (w2), w2 AS (), w3 AS (w1)

- This is not permitted because it contains a cycle:

  WINDOW w1 AS (w2), w2 AS (w3), w3 AS (w1)

12.21.5 Window Function Restrictions

The SQL standard imposes a constraint on window functions that they cannot be used in UPDATE or DELETE statements to update rows. Using such functions in a subquery of these statements (to select rows) is permitted.

MySQL does not support these window function features:

- DISTINCT syntax for aggregate window functions.
- Nested window functions.
- Dynamic frame endpoints that depend on the value of the current row.

The parser recognizes these window constructs which nevertheless are not supported:

- The GROUPS frame units specifier is parsed, but produces an error. Only ROWS and RANGE are supported.
- The EXCLUDE clause for frame specification is parsed, but produces an error.
- IGNORE NULLS is parsed, but produces an error. Only RESPECT NULLS is supported.
- FROM LAST is parsed, but produces an error. Only FROM FIRST is supported.

12.22 Performance Schema Functions

As of MySQL 8.0.16, MySQL includes built-in SQL functions that format or retrieve Performance Schema data, and that may be used as equivalents for the corresponding sys schema stored functions. The built-in functions can be invoked in any schema and require no qualifier, unlike the sys functions, which require either a sys.schema qualifier or that sys be the current schema.

Table 12.27 Performance Schema Functions

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Introduced</th>
</tr>

</tr>
</tbody>
</table>
### Performance Schema Functions

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Introduced</th>
</tr>
</thead>
<tbody>
<tr>
<td>PS_THREAD_ID()</td>
<td>Performance Schema thread ID for given thread</td>
<td>8.0.16</td>
</tr>
</tbody>
</table>

The built-in functions supersede the corresponding `sys` functions, which are deprecated; expect them to be removed in a future version of MySQL. Applications that use the `sys` functions should be adjusted to use the built-in functions instead, keeping in mind some minor differences between the `sys` functions and the built-in functions. For details about these differences, see the function descriptions in this section.

- **FORMAT_BYTES(count)**

  Given a numeric byte count, converts it to human-readable format and returns a string consisting of a value and a units indicator. The string contains the number of bytes rounded to 2 decimal places and a minimum of 3 significant digits. Numbers less than 1024 bytes are represented as whole numbers and are not rounded.

  The units indicator depends on the size of the byte-count argument as shown in the following table.

<table>
<thead>
<tr>
<th>Argument Value</th>
<th>Result Units</th>
<th>Result Units Indicator</th>
</tr>
</thead>
<tbody>
<tr>
<td>Up to 1023</td>
<td>bytes</td>
<td>bytes</td>
</tr>
<tr>
<td>Up to 1024² − 1</td>
<td>kibibytes</td>
<td>KiB</td>
</tr>
<tr>
<td>Up to 1024³ − 1</td>
<td>mebibytes</td>
<td>MiB</td>
</tr>
<tr>
<td>Up to 1024⁴ − 1</td>
<td>gibibytes</td>
<td>GiB</td>
</tr>
<tr>
<td>Up to 1024⁵ − 1</td>
<td>tebibytes</td>
<td>TiB</td>
</tr>
<tr>
<td>Up to 1024⁶ − 1</td>
<td>pebibytes</td>
<td>PiB</td>
</tr>
<tr>
<td>1024⁶ and up</td>
<td>exbibytes</td>
<td>EiB</td>
</tr>
</tbody>
</table>

  ```sql
  mysql> SELECT FORMAT_BYTES(512), FORMAT_BYTES(18446644073709551615);
  +-------------------+------------------------------------+
  | FORMAT_BYTES(512) | FORMAT_BYTES(18446644073709551615) |
  +-------------------+------------------------------------+
  |  512 bytes        | 16.00 EiB                          |
  +-------------------+------------------------------------+
  ```

  **FORMAT_BYTES()** was added in MySQL 8.0.16. It may be used instead of the `sys` schema `format_bytes()` function, keeping in mind this difference:

  - **FORMAT_BYTES()** uses the EiB units indicator. `sys.format_bytes()` does not.

- **FORMAT_PICO_TIME(time_val)**

  Given a numeric Performance Schema latency or wait time in picoseconds, converts it to human-readable format and returns a string consisting of a value and a units indicator. The string contains the decimal time rounded to 2 decimal places and a minimum of 3 significant digits. Times under 1 nanosecond are represented as whole numbers and are not rounded.

  The units indicator depends on the size of the time-value argument as shown in the following table.

<table>
<thead>
<tr>
<th>Argument Value</th>
<th>Result Units</th>
<th>Result Units Indicator</th>
</tr>
</thead>
<tbody>
<tr>
<td>Up to 10³ − 1</td>
<td>picoseconds</td>
<td>ps</td>
</tr>
<tr>
<td>Up to 10⁶ − 1</td>
<td>nanoseconds</td>
<td>ns</td>
</tr>
<tr>
<td>Up to 10⁹ − 1</td>
<td>microseconds</td>
<td>us</td>
</tr>
<tr>
<td>Up to 10¹² − 1</td>
<td>milliseconds</td>
<td>ms</td>
</tr>
<tr>
<td>Up to 60×10¹² − 1</td>
<td>seconds</td>
<td>s</td>
</tr>
<tr>
<td>Up to 3.6×10¹⁵ − 1</td>
<td>minutes</td>
<td>min</td>
</tr>
</tbody>
</table>

---

2244
### Performance Schema Functions

<table>
<thead>
<tr>
<th>Argument Value</th>
<th>Result Units</th>
<th>Result Units Indicator</th>
</tr>
</thead>
<tbody>
<tr>
<td>Up to 8.64×10^{16} − 1</td>
<td>hours</td>
<td>h</td>
</tr>
<tr>
<td>8.64×10^{16} and up</td>
<td>days</td>
<td>d</td>
</tr>
</tbody>
</table>

MySQL> `SELECT FORMAT_PICO_TIME(3501), FORMAT_PICO_TIME(188732396662000);`

<table>
<thead>
<tr>
<th>FORMAT_PICO_TIME(3501)</th>
<th>FORMAT_PICO_TIME(188732396662000)</th>
</tr>
</thead>
<tbody>
<tr>
<td>3.50 ns</td>
<td>3.15 min</td>
</tr>
</tbody>
</table>

`FORMAT_PICO_TIME()` was added in MySQL 8.0.16. It may be used instead of the `sys` schema `format_time()` function, keeping in mind these differences:

- To indicate minutes, `sys.format_time()` uses the `m` units indicator, whereas `FORMAT_PICO_TIME()` uses `min`.
- `sys.format_time()` uses the `w` (weeks) units indicator. `FORMAT_PICO_TIME()` does not.

**PS_CURRENT_THREAD_ID()**

Returns a `BIGINT UNSIGNED` value representing the Performance Schema thread ID assigned to the current connection.

The thread ID return value is a value of the type given in the `THREAD_ID` column of Performance Schema tables.

Performance Schema configuration affects `PS_CURRENT_THREAD_ID()` the same way as for `PS_THREAD_ID()`. For details, see the description of that function.

MySQL> `SELECT PS_CURRENT_THREAD_ID();`

<table>
<thead>
<tr>
<th>PS_CURRENT_THREAD_ID()</th>
</tr>
</thead>
<tbody>
<tr>
<td>52</td>
</tr>
</tbody>
</table>

MySQL> `SELECT PS_THREAD_ID(CONNECTION_ID());`

<table>
<thead>
<tr>
<th>PS_THREAD_ID(CONNECTION_ID())</th>
</tr>
</thead>
<tbody>
<tr>
<td>52</td>
</tr>
</tbody>
</table>

`PS_CURRENT_THREAD_ID()` was added in MySQL 8.0.16. It may be used as a shortcut for invoking the `sys` schema `ps_thread_id()` function with an argument of `NULL` or `CONNECTION_ID()`.

---

2245
• **PS_THREAD_ID(connection_id)**

  Given a connection ID, returns a **BIGINT UNSIGNED** value representing the Performance Schema thread ID assigned to the connection ID, or **NULL** if no thread ID exists for the connection ID. The latter can occur for threads that are not instrumented.

  The connection ID argument is a value of the type given in the `PROCESSLIST_ID` column of the Performance Schema `threads` table or the `Id` column of `SHOW PROCESSLIST` output.

  The thread ID return value is a value of the type given in the `THREAD_ID` column of Performance Schema tables.

  Performance Schema configuration affects `PS_THREAD_ID()` operation as follows. (These remarks also apply to `PS_CURRENT_THREAD_ID()`.)

  • Disabling the `thread_instrumentation` consumer disables statistics from being collected and aggregated at the thread level, but has no effect on `PS_THREAD_ID()`.

  • If `performance_schema_max_thread_instances` is not 0, the Performance Schema allocates memory for thread statistics and assigns an internal ID to each thread for which instance memory is available. If there are threads for which instance memory is not available, `PS_THREAD_ID()` returns **NULL**; in this case, `Performance_schema_thread_instances_lost` is nonzero.

  • If `performance_schema_max_thread_instances` is 0, the Performance Schema allocates no thread memory and `PS_THREAD_ID()` returns **NULL**.

  • If the Performance Schema itself is disabled, `PS_THREAD_ID()` produces an error.

```sql
mysql> SELECT PS_THREAD_ID(6);
+-----------------+
| PS_THREAD_ID(6) |
+-----------------+
|              45  |
+-----------------+
```

`PS_THREAD_ID()` was added in MySQL 8.0.16. It may be used instead of the `sys` schema `ps_thread_id()` function, keeping in mind this difference:

• With an argument of **NULL**, `sys.ps_thread_id()` returns the thread ID for the current connection, whereas `PS_THREAD_ID()` returns **NULL**. To obtain the current connection thread ID, use `PS_CURRENT_THREAD_ID()` instead.

### 12.23 Internal Functions

**Table 12.28 Internal Functions**

</table>

- `ANY_VALUE(arg)`

  This function is useful for GROUP BY queries when the ONLY_FULL_GROUP_BY SQL mode is enabled, for cases when MySQL rejects a query that you know is valid for reasons that MySQL
Miscellaneous Functions

cannot determine. The function return value and type are the same as the return value and type of its argument, but the function result is not checked for the `ONLY_FULL_GROUP_BY` SQL mode.

For example, if `name` is a nonindexed column, the following query fails with `ONLY_FULL_GROUP_BY` enabled:

```
mysql> SELECT name, address, MAX(age) FROM t GROUP BY name;
ERROR 1055 (42000): Expression #2 of SELECT list is not in GROUP BY clause and contains nonaggregated column 'mydb.t.address' which is not functionally dependent on columns in GROUP BY clause; this is incompatible with sql_mode=only_full_group_by
```

The failure occurs because `address` is a nonaggregated column that is neither named among `GROUP BY` columns nor functionally dependent on them. As a result, the `address` value for rows within each `name` group is nondeterministic. There are multiple ways to cause MySQL to accept the query:

- Alter the table to make `name` a primary key or a unique NOT NULL column. This enables MySQL to determine that `address` is functionally dependent on `name`; that is, `address` is uniquely determined by `name`. (This technique is inapplicable if NULL must be permitted as a valid `name` value.)

- Use `ANY_VALUE()` to refer to `address`:

  ```
  SELECT name, ANY_VALUE(address), MAX(age) FROM t GROUP BY name;
  ```

  In this case, MySQL ignores the nondeterminism of `address` values within each `name` group and accepts the query. This may be useful if you simply do not care which value of a nonaggregated column is chosen for each group. `ANY_VALUE()` is not an aggregate function, unlike functions such as `SUM()` or `COUNT()`. It simply acts to suppress the test for nondeterminism.

- Disable `ONLY_FULL_GROUP_BY`. This is equivalent to using `ANY_VALUE()` with `ONLY_FULL_GROUP_BY` enabled, as described in the previous item.

`ANY_VALUE()` is also useful if functional dependence exists between columns but MySQL cannot determine it. The following query is valid because `age` is functionally dependent on the grouping column `age-1`, but MySQL cannot tell that and rejects the query with `ONLY_FULL_GROUP_BY` enabled:

```
SELECT age FROM t GROUP BY age-1;
```

To cause MySQL to accept the query, use `ANY_VALUE()`:

```
SELECT ANY_VALUE(age) FROM t GROUP BY age-1;
```

`ANY_VALUE()` can be used for queries that refer to aggregate functions in the absence of a `GROUP BY` clause:

```
mysql> SELECT name, MAX(age) FROM t;
ERROR 1140 (42000): In aggregated query without GROUP BY, expression #1 of SELECT list contains nonaggregated column 'mydb.t.name'; this is incompatible with sql_mode=only_full_group_by
```

Without `GROUP BY`, there is a single group and it is nondeterministic which `name` value to choose for the group. `ANY_VALUE()` tells MySQL to accept the query:

```
SELECT ANY_VALUE(name), MAX(age) FROM t;
```

It may be that, due to some property of a given data set, you know that a selected nonaggregated column is effectively functionally dependent on a `GROUP BY` column. For example, an application
may enforce uniqueness of one column with respect to another. In this case, using `ANY_VALUE()` for the effectively functionally dependent column may make sense.

For additional discussion, see Section 12.20.3, “MySQL Handling of GROUP BY”.

- **BIN_TO_UUID(binary_uuid), BIN_TO_UUID(binary_uuid, swap_flag)**

  `BIN_TO_UUID()` is the inverse of `UUID_TO_BIN()`. It converts a binary UUID to a string UUID and returns the result. The binary value should be a UUID as a `VARBINARY(16)` value. The return value is a `utf8` string of five hexadecimal numbers separated by dashes. (For details about this format, see the `UUID()` function description.) If the UUID argument is `NULL`, the return value is `NULL`. If any argument is invalid, an error occurs.

  `BIN_TO_UUID()` takes one or two arguments:

  - The one-argument form takes a binary UUID value. The UUID value is assumed not to have its time-low and time-high parts swapped. The string result is in the same order as the binary argument.

  - The two-argument form takes a binary UUID value and a swap-flag value:
    - If `swap_flag` is 0, the two-argument form is equivalent to the one-argument form. The string result is in the same order as the binary argument.
    - If `swap_flag` is 1, the UUID value is assumed to have its time-low and time-high parts swapped. These parts are swapped back to their original position in the result value.

  For usage examples and information about time-part swapping, see the `UUID_TO_BIN()` function description.

- **DEFAULT(col_name)**

  Returns the default value for a table column. An error results if the column has no default value.

  The use of `DEFAULT(col_name)` to specify the default value for a named column is permitted only for columns that have a literal default value, not for columns that have an expression default value.

```
mysql> UPDATE t SET i = DEFAULT(i)+1 WHERE id < 100;
```

- **FORMAT(X, D)**

  Formats the number `X` to a format like `'#,###,###.##'`, rounded to `D` decimal places, and returns the result as a string. For details, see Section 12.8, “String Functions and Operators”.

- **GROUPING(expr [, expr] ...)**

  For `GROUP BY` queries that include a `WITH ROLLUP` modifier, the `ROLLUP` operation produces super-aggregate output rows where `NULL` represents the set of all values. The `GROUPING()` function enables you to distinguish `NULL` values for super-aggregate rows from `NULL` values in regular grouped rows.

  `GROUPING()` is permitted only in the select list or `HAVING` clause.

  Each argument to `GROUPING()` must be an expression that exactly matches an expression in the `GROUP BY` clause. The expression cannot be a positional specifier. For each expression, `GROUPING()` produces 1 if the expression value in the current row is a `NULL` representing a super-
aggregate value. Otherwise, \texttt{GROUPING()} produces 0, indicating that the expression value is a \texttt{NULL} for a regular result row or is not \texttt{NULL}.

Suppose that table \texttt{t1} contains these rows, where \texttt{NULL} indicates something like “other” or “unknown”:

```sql
mysql> SELECT * FROM t1;
+------+-------+----------+
| name | size  | quantity |
+------+-------+----------+
| ball | small | 10       |
| ball | large | 20       |
| ball | NULL  | 5        |
| hoop | small | 15       |
| hoop | large | 5        |
| hoop | NULL  | 3        |
+------+-------+----------+
```

A summary of the table without \texttt{WITH ROLLUP} looks like this:

```sql
mysql> SELECT name, size, SUM(quantity) AS quantity FROM t1 GROUP BY name, size;
+------+-------+----------+
| name | size  | quantity |
+------+-------+----------+
| ball | small | 10       |
| ball | large | 20       |
| ball | NULL  | 5        |
| hoop | small | 15       |
| hoop | large | 5        |
+------+-------+----------+
```

The result contains \texttt{NULL} values, but those do not represent super-aggregate rows because the query does not include \texttt{WITH ROLLUP}.

Adding \texttt{WITH ROLLUP} produces super-aggregate summary rows containing additional \texttt{NULL} values. However, without comparing this result to the previous one, it is not easy to see which \texttt{NULL} values occur in super-aggregate rows and which occur in regular grouped rows:

```sql
mysql> SELECT name, size, SUM(quantity) AS quantity FROM t1 GROUP BY name, size WITH ROLLUP;
+------+-------+----------+
| name | size  | quantity |
+------+-------+----------+
| ball | NULL  | 5        |
| ball | large | 20       |
| ball | small | 10       |
| ball | NULL  | 35       |
| hoop | NULL  | 3        |
| hoop | large | 5        |
| hoop | small | 15       |
| hoop | NULL  | 23       |
| NULL | NULL  | 58       |
+------+-------+----------+
```

To distinguish \texttt{NULL} values in super-aggregate rows from those in regular grouped rows, use \texttt{GROUPING()}, which returns 1 only for super-aggregate \texttt{NULL} values:

```sql
mysql> SELECT name, size, SUM(quantity) AS quantity, GROUPING(name) AS grp_name, GROUPING(size) AS grp_size FROM t1 GROUP BY name, size WITH ROLLUP;
+------+-------+----------+----------+----------+
| name | size  | quantity | grp_name | grp_size |
+------+-------+----------+----------+----------+
| ball | NULL  | 5        | 1        | 0        |
| ball | large | 20       | 0        | 1        |
| ball | small | 10       | 0        | 0        |
| ball | NULL  | 35       | 1        | 0        |
| hoop | NULL  | 3        | 0        | 1        |
| hoop | large | 5        | 0        | 0        |
| hoop | small | 15       | 0        | 0        |
| hoop | NULL  | 23       | 1        | 0        |
| NULL | NULL  | 58       | 0        | 0        |
+------+-------+----------+----------+----------+
```
Common uses for GROUPING():

- Substitute a label for super-aggregate NULL values:

```sql
mysql> SELECT
    IF(GROUPING(name) = 1, 'All items', name) AS name,
    IF(GROUPING(size) = 1, 'All sizes', size) AS size,
    SUM(quantity) AS quantity
FROM t1
GROUP BY name, size WITH ROLLUP;
```

```
<table>
<thead>
<tr>
<th>name</th>
<th>size</th>
<th>quantity</th>
</tr>
</thead>
<tbody>
<tr>
<td>ball</td>
<td>NULL</td>
<td>5</td>
</tr>
<tr>
<td>ball</td>
<td>large</td>
<td>20</td>
</tr>
<tr>
<td>ball</td>
<td>small</td>
<td>10</td>
</tr>
<tr>
<td>ball</td>
<td>All sizes</td>
<td>35</td>
</tr>
<tr>
<td>hoop</td>
<td>NULL</td>
<td>3</td>
</tr>
<tr>
<td>hoop</td>
<td>large</td>
<td>5</td>
</tr>
<tr>
<td>hoop</td>
<td>small</td>
<td>15</td>
</tr>
<tr>
<td>hoop</td>
<td>All sizes</td>
<td>23</td>
</tr>
<tr>
<td>All items</td>
<td>All sizes</td>
<td>58</td>
</tr>
</tbody>
</table>
```

- Return only super-aggregate lines by filtering out the regular grouped lines:

```sql
mysql> SELECT name, size, SUM(quantity) AS quantity
FROM t1
GROUP BY name, size WITH ROLLUP
HAVING GROUPING(name) = 1 OR GROUPING(size) = 1;
```

```
<table>
<thead>
<tr>
<th>name</th>
<th>size</th>
<th>quantity</th>
</tr>
</thead>
<tbody>
<tr>
<td>ball</td>
<td>NULL</td>
<td>35</td>
</tr>
<tr>
<td>hoop</td>
<td>NULL</td>
<td>23</td>
</tr>
<tr>
<td>NULL</td>
<td>NULL</td>
<td>58</td>
</tr>
</tbody>
</table>
```

GROUPING() permits multiple expression arguments. In this case, the GROUPING() return value represents a bitmask combined from the results for each expression, where the lowest-order bit corresponds to the result for the rightmost expression. For example, with three expression arguments, GROUPING(expr1, expr2, expr3) is evaluated like this:

result for GROUPING(expr3)
+ result for GROUPING(expr2) << 1
+ result for GROUPING(expr1) << 2

The following query shows how GROUPING() results for single arguments combine for a multiple-argument call to produce a bitmask value:

```sql
mysql> SELECT
    name, size, SUM(quantity) AS quantity,
    GROUPING(name) AS grp_name,
    GROUPING(size) AS grp_size,
    GROUPING(name, size) AS grp_all
FROM t1
GROUP BY name, size WITH ROLLUP;
```

```
<table>
<thead>
<tr>
<th>name</th>
<th>size</th>
<th>quantity</th>
<th>grp_name</th>
<th>grp_size</th>
<th>grp_all</th>
</tr>
</thead>
<tbody>
<tr>
<td>ball</td>
<td>NULL</td>
<td>5</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>ball</td>
<td>large</td>
<td>20</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>ball</td>
<td>small</td>
<td>10</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>ball</td>
<td>All sizes</td>
<td>35</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>hoop</td>
<td>NULL</td>
<td>3</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>hoop</td>
<td>large</td>
<td>5</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>hoop</td>
<td>small</td>
<td>15</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>hoop</td>
<td>All sizes</td>
<td>23</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>NULL</td>
<td>NULL</td>
<td>58</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```
With multiple expression arguments, the `GROUPING()` return value is nonzero if any expression represents a super-aggregate value. Multiple-argument `GROUPING()` syntax thus provides a simpler way to write the earlier query that returned only super-aggregate rows, by using a single multiple-argument `GROUPING()` call rather than multiple single-argument calls:

```sql
mysql> SELECT name, size, SUM(quantity) AS quantity
    FROM t1
    GROUP BY name, size WITH ROLLUP
    HAVING GROUPING(name, size) <> 0;
```

<table>
<thead>
<tr>
<th>name</th>
<th>size</th>
<th>quantity</th>
</tr>
</thead>
<tbody>
<tr>
<td>ball</td>
<td>NULL</td>
<td>35</td>
</tr>
<tr>
<td>hoop</td>
<td>NULL</td>
<td>23</td>
</tr>
<tr>
<td>NULL</td>
<td>NULL</td>
<td>58</td>
</tr>
</tbody>
</table>

Use of `GROUPING()` is subject to these limitations:

- Do not use subquery `GROUP BY` expressions as `GROUPING()` arguments because matching might fail. For example, matching fails for this query:

```sql
mysql> SELECT GROUPING((SELECT MAX(name) FROM t1))
    FROM t1
    GROUP BY (SELECT MAX(name) FROM t1) WITH ROLLUP;
```

ERROR 3580 (HY000): Argument #1 of GROUPING function is not in GROUP BY

- `GROUP BY` literal expressions should not be used within a `HAVING` clause as `GROUPING()` arguments. Due to differences between when the optimizer evaluates `GROUP BY` and `HAVING`, matching may succeed but `GROUPING()` evaluation does not produce the expected result. Consider this query:

```sql
SELECT a AS f1, 'w' AS f2
    FROM t
    GROUP BY f1, f2 WITH ROLLUP
    HAVING GROUPING(f2) = 1;
```

`GROUPING()` is evaluated earlier for the literal constant expression than for the `HAVING` clause as a whole and returns 0. To check whether a query such as this is affected, use `EXPLAIN` and look for `Impossible having` in the Extra column.

For more information about `WITH ROLLUP` and `GROUPING()`, see Section 12.20.2, “GROUP BY Modifiers”.

- `INET_ATON(expr)`

Given the dotted-quad representation of an IPv4 network address as a string, returns an integer that represents the numeric value of the address in network byte order (big endian). `INET_ATON()` returns `NULL` if it does not understand its argument.

```sql
mysql> SELECT INET_ATON('10.0.5.9');
-> 167773449
```

For this example, the return value is calculated as $10 \times 256^3 + 0 \times 256^2 + 5 \times 256 + 9$. 

---

**INET_ATON**

<table>
<thead>
<tr>
<th>name</th>
<th>size</th>
<th>quantity</th>
<th>grp_name</th>
<th>grp_size</th>
<th>grp_all</th>
</tr>
</thead>
<tbody>
<tr>
<td>ball</td>
<td>NULL</td>
<td>5</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>ball</td>
<td>large</td>
<td>20</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>ball</td>
<td>small</td>
<td>10</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>ball</td>
<td>NULL</td>
<td>35</td>
<td>0</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>hoop</td>
<td>NULL</td>
<td>3</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>hoop</td>
<td>large</td>
<td>5</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>hoop</td>
<td>small</td>
<td>15</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>hoop</td>
<td>NULL</td>
<td>23</td>
<td>0</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>NULL</td>
<td>NULL</td>
<td>58</td>
<td>1</td>
<td>1</td>
<td>3</td>
</tr>
</tbody>
</table>
**INET_ATON()** may or may not return a non-**NULL** result for short-form IP addresses (such as '127.1' as a representation of '127.0.0.1'). Because of this, **INET_ATON()** a should not be used for such addresses.

**Note**
To store values generated by **INET_ATON()**, use an **INT UNSIGNED** column rather than **INT**, which is signed. If you use a signed column, values corresponding to IP addresses for which the first octet is greater than 127 cannot be stored correctly. See Section 11.1.7, “Out-of-Range and Overflow Handling”.

- **INET_NTOA(expr)**
  Given a numeric IPv4 network address in network byte order, returns the dotted-quad string representation of the address as a string in the connection character set. **INET_NTOA()** returns **NULL** if it does not understand its argument.

  ```sql
  mysql> SELECT INET_NTOA(167773449);
  -> '10.0.5.9'
  ```

- **INET6_ATON(expr)**
  Given an IPv6 or IPv4 network address as a string, returns a binary string that represents the numeric value of the address in network byte order (big endian). Because numeric-format IPv6 addresses require more bytes than the largest integer type, the representation returned by this function has the **VARBINARY** data type: **VARBINARY(16)** for IPv6 addresses and **VARBINARY(4)** for IPv4 addresses. If the argument is not a valid address, **INET6_ATON()** returns **NULL**.

  The following examples use **HEX()** to display the **INET6_ATON()** result in printable form:

  ```sql
  mysql> SELECT HEX(INET6_ATON('fdfe::5a55:caff:fefa:9089'));
  -> 'FDFE0000000000005A55CAFFFEFA9089'
  mysql> SELECT HEX(INET6_ATON('10.0.5.9'));
  -> '0A000509'
  ```

**INET6_ATON()** observes several constraints on valid arguments. These are given in the following list along with examples.

- A trailing zone ID is not permitted, as in **fe80::3%1** or **fe80::3%eth0**.
- A trailing network mask is not permitted, as in **2001:45f:3:ba::/64** or **198.51.100.0/24**.
- For values representing IPv4 addresses, only classless addresses are supported. Classful addresses such as **198.51.1** are rejected. A trailing port number is not permitted, as in **198.51.100.2:8080**. Hexadecimal numbers in address components are not permitted, as in **198.0xa0.1.2**. Octal numbers are not supported: **198.51.010.1** is treated as **198.51.10.1**, not **198.51.8.1**. These IPv4 constraints also apply to IPv6 addresses that have IPv4 address parts, such as IPv6-compatible or IPv4-mapped addresses.

  To convert an IPv4 address **expr** represented in numeric form as an **INT** value to an IPv6 address represented in numeric form as a **VARBINARY** value, use this expression:

  ```sql
  INET6_ATON(INET_NTOA(expr))
  ```

  For example:

  ```sql
  mysql> SELECT HEX(INET6_ATON(INET_NTOA(167773449)));
  -> '0A000509'
  ```
• **INET6_NTOA(expr)**

  Given an IPv6 or IPv4 network address represented in numeric form as a binary string, returns the string representation of the address as a string in the connection character set. If the argument is not a valid address, **INET6_NTOA()** returns NULL.

  **INET6_NTOA()** has these properties:

  • It does not use operating system functions to perform conversions, thus the output string is platform independent.

  • The return string has a maximum length of 39 (4 x 8 + 7). Given this statement:

    ```
    CREATE TABLE t AS SELECT INET6_NTOA(expr) AS c1;
    ```

    The resulting table would have this definition:

    ```
    CREATE TABLE t (c1 VARCHAR(39) CHARACTER SET utf8 DEFAULT NULL);
    ```

  • The return string uses lowercase letters for IPv6 addresses.

    ```
    mysql> SELECT INET6_NTOA(INET6_ATON('fdfe::5a55:caff:fefa:9089'));
    -> 'fdfe::5a55:caff:fefa:9089'
    ```

    ```
    mysql> SELECT INET6_NTOA(INET6_ATON('10.0.5.9'));
    -> '10.0.5.9'
    ```

    ```
    mysql> SELECT INET6_NTOA(UNHEX('FDFE0000000000005A55CAFFFEFA9089'));
    -> 'fdfe::5a55:caff:fefa:9089'
    ```

    ```
    mysql> SELECT INET6_NTOA(UNHEX('0A000509'));
    -> '10.0.5.9'
    ```

• **IS_IPV4(expr)**

  Returns 1 if the argument is a valid IPv4 address specified as a string, 0 otherwise.

    ```
    mysql> SELECT IS_IPV4('10.0.5.9'), IS_IPV4('10.0.5.256');
    -> 1, 0
    ```

  For a given argument, if **IS_IPV4()** returns 1, **INET_ATON()** (and **INET6_ATON()**) returns non-NULL. The converse statement is not true: In some cases, **INET_ATON()** returns non-NULL when **IS_IPV4()** returns 0.

  As implied by the preceding remarks, **IS_IPV4()** is more strict than **INET_ATON()** about what constitutes a valid IPv4 address, so it may be useful for applications that need to perform strong checks against invalid values. Alternatively, use **INET6_ATON()** to convert IPv4 addresses to internal form and check for a NULL result (which indicates an invalid address). **INET6_ATON()** is equally strong as **IS_IPV4()** about checking IPv4 addresses.

• **IS_IPV4_COMPAT(expr)**

  This function takes an IPv6 address represented in numeric form as a binary string, as returned by **INET6_ATON()**. It returns 1 if the argument is a valid IPv4-compatible IPv6 address, 0 otherwise. IPv4-compatible addresses have the form ::ipv4_address.

    ```
    mysql> SELECT IS_IPV4_COMPAT(INET6_ATON('::10.0.5.9'));
    -> 1
    ```

    ```
    mysql> SELECT IS_IPV4_COMPAT(INET6_ATON('::ffff:10.0.5.9'));
    -> 0
    ```

  The IPv4 part of an IPv4-compatible address can also be represented using hexadecimal notation. For example, 198.51.100.1 has this raw hexadecimal value:

    ```
    mysql> SELECT HEX(INET6_ATON('198.51.100.1'));
    ```
Expressed in IPv4-compatible form, ::198.51.100.1 is equivalent to ::c0a8:0001 or (without leading zeros) ::c0a8:1

mysql> SELECT
    -> IS_IPV4_COMPAT(INET6_ATON('::198.51.100.1')),
    -> IS_IPV4_COMPAT(INET6_ATON('::c0a8:0001')),
    -> IS_IPV4_COMPAT(INET6_ATON('::c0a8:1'));
-> 1, 1, 1

• IS_IPV4_MAPPED(expr)

This function takes an IPv6 address represented in numeric form as a binary string, as returned by INET6_ATON(). It returns 1 if the argument is a valid IPv4-mapped IPv6 address, 0 otherwise. IPv4-mapped addresses have the form ::ffff:ipv4_address.

mysql> SELECT IS_IPV4_MAPPED(INET6_ATON('::10.0.5.9'));
-> 0
mysql> SELECT IS_IPV4_MAPPED(INET6_ATON('::ffff:10.0.5.9'));
-> 1

As with IS_IPV4_COMPAT() the IPv4 part of an IPv4-mapped address can also be represented using hexadecimal notation:

mysql> SELECT
    -> IS_IPV4_MAPPED(INET6_ATON('::ffff:198.51.100.1')),
    -> IS_IPV4_MAPPED(INET6_ATON('::ffff:c0a8:0001')),
    -> IS_IPV4_MAPPED(INET6_ATON('::ffff:c0a8:1'));
-> 1, 1, 1

• IS_IPV6(expr)

Returns 1 if the argument is a valid IPv6 address specified as a string, 0 otherwise. This function does not consider IPv4 addresses to be valid IPv6 addresses.

mysql> SELECT IS_IPV6('10.0.5.9'), IS_IPV6('::1');
-> 0, 1

For a given argument, if IS_IPV6() returns 1, INET6_ATON() returns non-NULL.

• IS_UUID(string_uuid)

Returns 1 if the argument is a valid string-format UUID, 0 if the argument is not a valid UUID, and NULL if the argument is NULL.

“Valid” means that the value is in a format that can be parsed. That is, it has the correct length and contains only the permitted characters (hexadecimal digits in any lettercase and, optionally, dashes and curly braces). This format is most common:

aaaaaaaa-bbbb-cccc-dddd-eeeeeeeeeeee

These other formats are also permitted:

aaaaaaaaabbbbbccccdddeeewnriugimplify
{|aaaaaa-bbbb-cccc-dddd-eeeeeeeeeeee|

For the meanings of fields within the value, see the UUID() function description.

mysql> SELECT IS_UUID('6ccd780c-baba-1026-9564-5b8c656024db');
+--------------------------+
| IS_UUID('6ccd780c-baba-1026-9564-5b8c656024db') | 1 |
+--------------------------+
mysql> SELECT IS_UUID('6CCD780C-BABA-1026-9564-5B8C656024DB');
• **MASTER_POS_WAIT(log_name, log_pos[, timeout][, channel])**

This function is useful for control of source/replica synchronization. It blocks until the replica has read and applied all updates up to the specified position in the source's binary log. The return value is the number of log events the replica had to wait for to advance to the specified position. The function returns `NULL` if the replication SQL thread is not started, the replica's source information is not initialized, the arguments are incorrect, or an error occurs. It returns `-1` if the timeout has been exceeded. If the replication SQL thread stops while `MASTER_POS_WAIT()` is waiting, the function returns `NULL`. If the replica is past the specified position, the function returns immediately.

On a multithreaded replica, the function waits until expiry of the limit set by the `slave_checkpoint_group` or `slave_checkpoint_period` system variable, when the checkpoint operation is called to update the status of the replica. Depending on the setting for the system variables, the function might therefore return some time after the specified position was reached.

If binary log transaction compression is in use and the transaction payload at the specified position is compressed (as a `Transaction_payload_event`), the function waits until the whole transaction has been read and applied, and the positions have updated.

If a `timeout` value is specified, `MASTER_POS_WAIT()` stops waiting when `timeout` seconds have elapsed. `timeout` must be greater than 0; a zero or negative `timeout` means no timeout.

The optional `channel` value enables you to name which replication channel the function applies to. See Section 17.2.2, “Replication Channels” for more information.

This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

• **NAME_CONST(name, value)**

Returns the given value. When used to produce a result set column, `NAME_CONST()` causes the column to have the given name. The arguments should be constants.
This function is for internal use only. The server uses it when writing statements from stored programs that contain references to local program variables, as described in Section 25.7, “Stored Program Binary Logging”. You might see this function in the output from `mysqlbinlog`.

For your applications, you can obtain exactly the same result as in the example just shown by using simple aliasing, like this:

```
mysql> SELECT 14 AS myname;
+--------+
| myname |
+--------+
|     14 |
+--------+
1 row in set (0.00 sec)
```

See Section 13.2.10, “SELECT Statement”, for more information about column aliases.

- **SLEEP (duration)**

  Sleeps (pauses) for the number of seconds given by the `duration` argument, then returns 0. The duration may have a fractional part. If the argument is `NULL` or negative, `SLEEP()` produces a warning, or an error in strict SQL mode.

  When `SLEEP()` returns normally (without interruption), it returns 0:

  ```
  mysql> SELECT SLEEP(1000);
  +-------------+
  | SLEEP(1000) |
  +-------------+
  |           0 |
  +-------------+
  ```

  When `SLEEP()` is the only thing invoked by a query that is interrupted, it returns 1 and the query itself returns no error. This is true whether the query is killed or times out:

  - This statement is interrupted using `KILL QUERY` from another session:
    ```
    mysql> SELECT SLEEP(1000);
    +-------------+
    | SLEEP(1000) |
    +-------------+
    |           1 |
    +-------------+
    ```

  - This statement is interrupted by timing out:
    ```
    mysql> SELECT /*+ MAX_EXECUTION_TIME(1) */ SLEEP(1000);
    +-------------+
    | SLEEP(1000) |
    +-------------+
    |           1 |
    +-------------+
    ```

  When `SLEEP()` is only part of a query that is interrupted, the query returns an error:

  - This statement is interrupted using `KILL QUERY` from another session:
    ```
    mysql> SELECT 1 FROM t1 WHERE SLEEP(1000);
    ERROR 1317 (70100): Query execution was interrupted
    ```

  - This statement is interrupted by timing out:
    ```
    mysql> SELECT /*+ MAX_EXECUTION_TIME(1000) */ 1 FROM t1 WHERE SLEEP(1000);
    ```
This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

- **UUID()**

Returns a Universal Unique Identifier (UUID) generated according to RFC 4122, “A Universally Unique IDentifier (UUID) URN Namespace” (http://www.ietf.org/rfc/rfc4122.txt).

A UUID is designed as a number that is globally unique in space and time. Two calls to `UUID()` are expected to generate two different values, even if these calls are performed on two separate devices not connected to each other.

**Warning**

Although `UUID()` values are intended to be unique, they are not necessarily unguessable or unpredictable. If unpredictability is required, UUID values should be generated some other way.

`UUID()` returns a value that conforms to UUID version 1 as described in RFC 4122. The value is a 128-bit number represented as a `utf8` string of five hexadecimal numbers in `aaaaaaaa-bbbb-cccc-dddd-eeeeeeeeeee` format:

- The first three numbers are generated from the low, middle, and high parts of a timestamp. The high part also includes the UUID version number.
- The fourth number preserves temporal uniqueness in case the timestamp value loses monotonicity (for example, due to daylight saving time).
- The fifth number is an IEEE 802 node number that provides spatial uniqueness. A random number is substituted if the latter is not available (for example, because the host device has no Ethernet card, or it is unknown how to find the hardware address of an interface on the host operating system). In this case, spatial uniqueness cannot be guaranteed. Nevertheless, a collision should have very low probability.

The MAC address of an interface is taken into account only on FreeBSD, Linux, and Windows. On other operating systems, MySQL uses a randomly generated 48-bit number.

```
mysql> SELECT UUID();
-> '6ccd780c-baba-1026-9564-5b8c656024db'
```

To convert between string and binary UUID values, use the `UUID_TO_BIN()` and `BIN_TO_UUID()` functions. To check whether a string is a valid UUID value, use the `IS_UUID()` function.

This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

- **UUID_SHORT()**

Returns a "short" universal identifier as a 64-bit unsigned integer. Values returned by `UUID_SHORT()` differ from the string-format 128-bit identifiers returned by the `UUID()` function and
have different uniqueness properties. The value of \texttt{UUID\_SHORT()} is guaranteed to be unique if the following conditions hold:

- The \texttt{server\_id} value of the current server is between 0 and 255 and is unique among your set of source and replica servers
- You do not set back the system time for your server host between \texttt{mysqld} restarts
- You invoke \texttt{UUID\_SHORT()} on average fewer than 16 million times per second between \texttt{mysqld} restarts

The \texttt{UUID\_SHORT()} return value is constructed this way:

```
(server\_id & 255) \texttt{\ll} 56
+ (server\_startup\_time\_in\_seconds \texttt{\ll} 24)
+ incremented\_variable++;
```

```
mysql> SELECT UUID\_SHORT();
-> 92395783831158784
```

\textbf{Note}

\texttt{UUID\_SHORT()} does not work with statement-based replication.

- \texttt{UUID\_TO\_BIN(string\_uuid)}, \texttt{UUID\_TO\_BIN(string\_uuid, swap\_flag)}

Converts a string UUID to a binary UUID and returns the result. (The \texttt{IS\_UUID()} function description lists the permitted string UUID formats.) The return binary UUID is a \texttt{VARBINARY(16)} value. If the UUID argument is \texttt{NULL}, the return value is \texttt{NULL}. If any argument is invalid, an error occurs.

\texttt{UUID\_TO\_BIN()} takes one or two arguments:

- The one-argument form takes a string UUID value. The binary result is in the same order as the string argument.
- The two-argument form takes a string UUID value and a flag value:
  - If \texttt{swap\_flag} is 0, the two-argument form is equivalent to the one-argument form. The binary result is in the same order as the string argument.
  - If \texttt{swap\_flag} is 1, the format of the return value differs: The time-low and time-high parts (the first and third groups of hexadecimal digits, respectively) are swapped. This moves the more rapidly varying part to the right and can improve indexing efficiency if the result is stored in an indexed column.

Time-part swapping assumes the use of UUID version 1 values, such as are generated by the \texttt{UUID()} function. For UUID values produced by other means that do not follow version 1 format, time-part swapping provides no benefit. For details about version 1 format, see the \texttt{UUID()} function description.

Suppose that you have the following string UUID value:

```
mysql> SET @uuid = '6ccd780c-baba-1026-9564-5b8c656024db';
```

To convert the string UUID to binary with or without time-part swapping, use \texttt{UUID\_TO\_BIN()}:

```
mysql> SELECT HEX(UUID\_TO\_BIN(@uuid));
+----------------------------------+
| HEX(UUID\_TO\_BIN(@uuid))        |
| 6CCD780CBA8A102695645B8C656024DB |
```
To convert a binary UUID returned by `UUID_TO_BIN()` to a string UUID, use `BIN_TO_UUID()`. If you produce a binary UUID by calling `UUID_TO_BIN()` with a second argument of 1 to swap time parts, you should also pass a second argument of 1 to `BIN_TO_UUID()` to unswap the time parts when converting the binary UUID back to a string UUID:

```
mysql> SELECT BIN_TO_UUID(UUID_TO_BIN(@uuid));
+--------------------------------------+
| BIN_TO_UUID(UUID_TO_BIN(@uuid))      |
| 6ccd780c-baba-1026-9564-5b8c656024db |
+--------------------------------------+
mysql> SELECT BIN_TO_UUID(UUID_TO_BIN(@uuid),0);
+--------------------------------------+
| BIN_TO_UUID(UUID_TO_BIN(@uuid),0)    |
| 6ccd780c-baba-1026-9564-5b8c656024db |
+--------------------------------------+
mysql> SELECT BIN_TO_UUID(UUID_TO_BIN(@uuid,0),1);
| BIN_TO_UUID(UUID_TO_BIN(@uuid,0),1) |
| baba1026-780c-6ccd-9564-5b8c656024db |
+--------------------------------------+
mysql> SELECT BIN_TO_UUID(UUID_TO_BIN(@uuid,1),1);
| BIN_TO_UUID(UUID_TO_BIN(@uuid,1),1)  |
| 6ccd780c-baba-1026-9564-5b8c656024db |
+--------------------------------------+
```

If the use of time-part swapping is not the same for the conversion in both directions, the original UUID is not recovered properly:

```
mysql> SELECT BIN_TO_UUID(UUID_TO_BIN(@uuid,0),1);
+--------------------------------------+
| BIN_TO_UUID(UUID_TO_BIN(@uuid,0),1)  |
| baba1026-780c-6ccd-9564-5b8c656024db |
+--------------------------------------+
mysql> SELECT BIN_TO_UUID(UUID_TO_BIN(@uuid,1),0);
+--------------------------------------+
| BIN_TO_UUID(UUID_TO_BIN(@uuid,1),0)  |
| 1026baba-6ccd-780c-9564-5b8c656024db |
+--------------------------------------+
```

• **VALUES**(col_name)

In an `INSERT ... ON DUPLICATE KEY UPDATE` statement, you can use the `VALUES`(col_name) function in the `UPDATE` clause to refer to column values from the `INSERT` portion of the statement. In other words, `VALUES`(col_name) in the `UPDATE` clause refers to the value of col_name that would be inserted, had no duplicate-key conflict occurred. This function is especially useful in multiple-row inserts. The `VALUES()` function is meaningful only in the `ON DUPLICATE KEY UPDATE` clause of `INSERT` statements and returns `NULL` otherwise. See Section 13.2.6.2, “INSERT ... ON DUPLICATE KEY UPDATE Statement”.

```
mysql> INSERT INTO table (a,b,c) VALUES (1,2,3),(4,5,6)
```
12.25 Precision Math

MySQL provides support for precision math: numeric value handling that results in extremely accurate results and a high degree control over invalid values. Precision math is based on these two features:

- SQL modes that control how strict the server is about accepting or rejecting invalid data.
- The MySQL library for fixed-point arithmetic.

These features have several implications for numeric operations and provide a high degree of compliance with standard SQL:

- **Precise calculations**: For exact-value numbers, calculations do not introduce floating-point errors. Instead, exact precision is used. For example, MySQL treats a number such as \( .0001 \) as an exact value rather than as an approximation, and summing it 10,000 times produces a result of exactly 1, not a value that is merely “close” to 1.

- **Well-defined rounding behavior**: For exact-value numbers, the result of \( \text{ROUND}() \) depends on its argument, not on environmental factors such as how the underlying C library works.

- **Platform independence**: Operations on exact numeric values are the same across different platforms such as Windows and Unix.

- **Control over handling of invalid values**: Overflow and division by zero are detectable and can be treated as errors. For example, you can treat a value that is too large for a column as an error rather than having the value truncated to lie within the range of the column's data type. Similarly, you can treat division by zero as an error rather than as an operation that produces a result of \( \text{NULL} \). The choice of which approach to take is determined by the setting of the server SQL mode.

The following discussion covers several aspects of how precision math works, including possible incompatibilities with older applications. At the end, some examples are given that demonstrate how MySQL handles numeric operations precisely. For information about controlling the SQL mode, see Section 5.1.11, “Server SQL Modes”.

12.25.1 Types of Numeric Values

The scope of precision math for exact-value operations includes the exact-value data types (integer and \textit{DECIMAL} types) and exact-value numeric literals. Approximate-value data types and numeric literals are handled as floating-point numbers.

Exact-value numeric literals have an integer part or fractional part, or both. They may be signed. Examples: 1, .2, 3.4, -5, -6.78, +9.10.

Approximate-value numeric literals are represented in scientific notation with a mantissa and exponent. Either or both parts may be signed. Examples: 1.2E3, 1.2E-3, -1.2E3, -1.2E-3.

Two numbers that look similar may be treated differently. For example, 2.34 is an exact-value (fixed-point) number, whereas \( 2.34E0 \) is an approximate-value (floating-point) number.

The \textit{DECIMAL} data type is a fixed-point type and calculations are exact. In MySQL, the \textit{DECIMAL} type has several synonyms: NUMERIC, DEC, FIXED. The integer types also are exact-value types.
The FLOAT and DOUBLE data types are floating-point types and calculations are approximate. In MySQL, types that are synonymous with FLOAT or DOUBLE are DOUBLE PRECISION and REAL.

### 12.25.2 DECIMAL Data Type Characteristics

This section discusses the characteristics of the DECIMAL data type (and its synonyms), with particular regard to the following topics:

- Maximum number of digits
- Storage format
- Storage requirements
- The nonstandard MySQL extension to the upper range of DECIMAL columns

The declaration syntax for a DECIMAL column is DECIMAL(M, D). The ranges of values for the arguments are as follows:

- **M** is the maximum number of digits (the precision). It has a range of 1 to 65.
- **D** is the number of digits to the right of the decimal point (the scale). It has a range of 0 to 30 and must be no larger than M.

If D is omitted, the default is 0. If M is omitted, the default is 10.

The maximum value of 65 for M means that calculations on DECIMAL values are accurate up to 65 digits. This limit of 65 digits of precision also applies to exact-value numeric literals, so the maximum range of such literals differs from before. (There is also a limit on how long the text of DECIMAL literals can be; see Section 12.25.3, “Expression Handling”.)

Values for DECIMAL columns are stored using a binary format that packs nine decimal digits into 4 bytes. The storage requirements for the integer and fractional parts of each value are determined separately. Each multiple of nine digits requires 4 bytes, and any remaining digits left over require some fraction of 4 bytes. The storage required for remaining digits is given by the following table.

<table>
<thead>
<tr>
<th>Leftover Digits</th>
<th>Number of Bytes</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>1–2</td>
<td>1</td>
</tr>
<tr>
<td>3–4</td>
<td>2</td>
</tr>
<tr>
<td>5–6</td>
<td>3</td>
</tr>
<tr>
<td>7–9</td>
<td>4</td>
</tr>
</tbody>
</table>

For example, a DECIMAL(18, 9) column has nine digits on either side of the decimal point, so the integer part and the fractional part each require 4 bytes. A DECIMAL(20, 6) column has fourteen integer digits and six fractional digits. The integer digits require four bytes for nine of the digits and 3 bytes for the remaining five digits. The six fractional digits require 3 bytes.

DECIMAL columns do not store a leading + character or – character or leading 0 digits. If you insert +0003.1 into a DECIMAL(5, 1) column, it is stored as 3.1. For negative numbers, a literal – character is not stored.

DECIMAL columns do not permit values larger than the range implied by the column definition. For example, a DECIMAL(3, 0) column supports a range of −999 to 999. A DECIMAL(M, D) column permits up to M − D digits to the left of the decimal point.

The SQL standard requires that the precision of NUMERIC(M, D) be exactly M digits. For DECIMAL(M, D), the standard requires a precision of at least M digits but permits more. In MySQL, DECIMAL(M, D) and NUMERIC(M, D) are the same, and both have a precision of exactly M digits.
For a full explanation of the internal format of DECIMAL values, see the file `strings/decimal.c` in a MySQL source distribution. The format is explained (with an example) in the `decimal2bin()` function.

### 12.25.3 Expression Handling

With precision math, exact-value numbers are used as given whenever possible. For example, numbers in comparisons are used exactly as given without a change in value. In strict SQL mode, for `INSERT` into a column with an exact data type (DECIMAL or integer), a number is inserted with its exact value if it is within the column range. When retrieved, the value should be the same as what was inserted. (If strict SQL mode is not enabled, truncation for `INSERT` is permissible.)

Handling of a numeric expression depends on what kind of values the expression contains:

- If any approximate values are present, the expression is approximate and is evaluated using floating-point arithmetic.

- If no approximate values are present, the expression contains only exact values. If any exact value contains a fractional part (a value following the decimal point), the expression is evaluated using DECIMAL exact arithmetic and has a precision of 65 digits. The term “exact” is subject to the limits of what can be represented in binary. For example, `1.0/3.0` can be approximated in decimal notation as `.333...`, but not written as an exact number, so `(1.0/3.0)*3.0` does not evaluate to exactly `1.0`.

- Otherwise, the expression contains only integer values. The expression is exact and is evaluated using integer arithmetic and has a precision the same as BIGINT (64 bits).

If a numeric expression contains any strings, they are converted to double-precision floating-point values and the expression is approximate.

Inserts into numeric columns are affected by the SQL mode, which is controlled by the `sql_mode` system variable. (See Section 5.1.11, “Server SQL Modes”.) The following discussion mentions strict mode (selected by the `STRICT_ALL_TABLES` or `STRICT_TRANS_TABLES` mode values) and `ERROR_FOR_DIVISION_BY_ZERO`. To turn on all restrictions, you can simply use TRADITIONAL mode, which includes both strict mode values and `ERROR_FOR_DIVISION_BY_ZERO`:

```sql
SET sql_mode='TRADITIONAL';
```

If a number is inserted into an exact type column (DECIMAL or integer), it is inserted with its exact value if it is within the column range and precision.

If the value has too many digits in the fractional part, rounding occurs and a note is generated. Rounding is done as described in Section 12.25.4, “Rounding Behavior”. Truncation due to rounding of the fractional part is not an error, even in strict mode.

If the value has too many digits in the integer part, it is too large (out of range) and is handled as follows:

- If strict mode is not enabled, the value is truncated to the nearest legal value and a warning is generated.

- If strict mode is enabled, an overflow error occurs.

For DECIMAL literals, in addition to the precision limit of 65 digits, there is a limit on how long the text of the literal can be. If the value exceeds approximately 80 characters, unexpected results can occur. For example:

```sql
mysql> SELECT CAST('0000000000000000000000000000000000000000000000000000000000000000000000000000000020.01' AS DECIMAL(15,2)) as val;
+------------------+
| val              |
+------------------+
```

```sql
2264
```
9999999999999.99
+------------------+
1 row in set, 2 warnings (0.00 sec)

mysql> SHOW WARNINGS;
+---------+------+----------------------------------------------+
| Level   | Code | Message                                      |
+---------+------+----------------------------------------------+
| Warning | 1292 | Truncated incorrect DECIMAL value: '20'      |
| Warning | 1264 | Out of range value for column 'val' at row 1 |
+---------+------+----------------------------------------------+
2 rows in set (0.00 sec)

Underflow is not detected, so underflow handling is undefined.

For inserts of strings into numeric columns, conversion from string to number is handled as follows if the string has nonnumeric contents:

- A string that does not begin with a number cannot be used as a number and produces an error in strict mode, or a warning otherwise. This includes the empty string.

- A string that begins with a number can be converted, but the trailing nonnumeric portion is truncated. If the truncated portion contains anything other than spaces, this produces an error in strict mode, or a warning otherwise.

By default, division by zero produces a result of NULL and no warning. By setting the SQL mode appropriately, division by zero can be restricted.

With the **ERROR_FOR_DIVISION_BY_ZERO** SQL mode enabled, MySQL handles division by zero differently:

- If strict mode is not enabled, a warning occurs.

- If strict mode is enabled, inserts and updates involving division by zero are prohibited, and an error occurs.

In other words, inserts and updates involving expressions that perform division by zero can be treated as errors, but this requires **ERROR_FOR_DIVISION_BY_ZERO** in addition to strict mode.

Suppose that we have this statement:

```
INSERT INTO t SET i = 1/0;
```

This is what happens for combinations of strict and **ERROR_FOR_DIVISION_BY_ZERO** modes.

<table>
<thead>
<tr>
<th>sql_mode</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>'' (Default)</td>
<td>No warning, no error; i is set to NULL.</td>
</tr>
<tr>
<td>strict</td>
<td>No warning, no error; i is set to NULL.</td>
</tr>
<tr>
<td>ERROR_FOR_DIVISION_BYZERO</td>
<td>Warning, no error; i is set to NULL.</td>
</tr>
<tr>
<td>strict,ERROR_FOR_DIVISION_BYZERO</td>
<td>Error condition; no row is inserted.</td>
</tr>
</tbody>
</table>

### 12.25.4 Rounding Behavior

This section discusses precision math rounding for the **ROUND()** function and for inserts into columns with exact-value types (**DECIMAL** and integer).

The **ROUND()** function rounds differently depending on whether its argument is exact or approximate:

- For exact-value numbers, **ROUND()** uses the “round half up” rule: A value with a fractional part of .5 or greater is rounded up to the next integer if positive or down to the next integer if negative. (In other
words, it is rounded away from zero.) A value with a fractional part less than .5 is rounded down to the next integer if positive or up to the next integer if negative. (In other words, it is rounded toward zero.)

- For approximate-value numbers, the result depends on the C library. On many systems, this means that `ROUND()` uses the “round to nearest even” rule: A value with a fractional part exactly half way between two integers is rounded to the nearest even integer.

The following example shows how rounding differs for exact and approximate values:

```sql
mysql> SELECT ROUND(2.5), ROUND(25E-1);
+------------+--------------+
| ROUND(2.5) | ROUND(25E-1) |
+------------+--------------+
| 3          | 2            |
+------------+--------------+
```

For inserts into a `DECIMAL` or integer column, the target is an exact data type, so rounding uses “round half away from zero,” regardless of whether the value to be inserted is exact or approximate:

```sql
mysql> CREATE TABLE t (d DECIMAL(10,0));
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t VALUES(2.5),(2.5E0);
Query OK, 2 rows affected, 2 warnings (0.00 sec)
Records: 2  Duplicates: 0  Warnings: 2

mysql> SHOW WARNINGS;
+-------+------+----------------------------------------+
| Level | Code | Message                                |
|-------|------|----------------------------------------+
| Note  | 1265 | Data truncated for column 'd' at row 1 |
| Note  | 1265 | Data truncated for column 'd' at row 2 |
+-------+------+----------------------------------------+

mysql> SELECT d FROM t;
+------+
| d    |
+------+
| 3    |
| 3    |
+------+
```

The `SHOW WARNINGS` statement displays the notes that are generated by truncation due to rounding of the fractional part. Such truncation is not an error, even in strict SQL mode (see Section 12.25.3, “Expression Handling”).

### 12.25.5 Precision Math Examples

This section provides some examples that show precision math query results in MySQL. These examples demonstrate the principles described in Section 12.25.3, “Expression Handling”, and Section 12.25.4, “Rounding Behavior”.

**Example 1.** Numbers are used with their exact value as given when possible:

```sql
mysql> SELECT (.1 + .2) = .3;
+----------------+
| (.1 + .2) = .3 |
+----------------+
|              1  |
+----------------+
```

For floating-point values, results are inexact:

```sql
mysql> SELECT (.1E0 + .2E0) = .3E0;
```
Another way to see the difference in exact and approximate value handling is to add a small number to a sum many times. Consider the following stored procedure, which adds \( .0001 \) to a variable 1,000 times.

```sql
CREATE PROCEDURE p ()
BEGIN
  DECLARE i INT DEFAULT 0;
  DECLARE d DECIMAL(10,4) DEFAULT 0;
  DECLARE f FLOAT DEFAULT 0;
  WHILE i < 10000 DO
    SET d = d + .0001;
    SET f = f + .0001E0;
    SET i = i + 1;
  END WHILE;
  SELECT d, f;
END;
```

The sum for both \( d \) and \( f \) logically should be 1, but that is true only for the decimal calculation. The floating-point calculation introduces small errors:

| d      | f                |
|--------+------------------|
| 1.0000 | 0.99999999999991 |

### Example 2
Multiplication is performed with the scale required by standard SQL. That is, for two numbers \( X_1 \) and \( X_2 \) that have scale \( S_1 \) and \( S_2 \), the scale of the result is \( S_1 + S_2 \):

```sql
mysql> SELECT .01 * .01;
+------------------+
| .01 * .01        |
| 0.0001           |
+------------------+
```

### Example 3
Rounding behavior for exact-value numbers is well-defined:

Rounding behavior (for example, with the `ROUND()` function) is independent of the implementation of the underlying C library, which means that results are consistent from platform to platform.

- Rounding for exact-value columns (DECIMAL and integer) and exact-valued numbers uses the "round half away from zero" rule. A value with a fractional part of .5 or greater is rounded away from zero to the nearest integer, as shown here:

```sql
mysql> SELECT ROUND(2.5), ROUND(-2.5);
+------------+-------------+
| ROUND(2.5) | ROUND(-2.5) |
| 3          | -3          |
+------------+-------------+
```

- Rounding for floating-point values uses the C library, which on many systems uses the "round to nearest even" rule. A value with a fractional part exactly half way between two integers is rounded to the nearest even integer:

```sql
mysql> SELECT ROUND(2.5E0), ROUND(-2.5E0);
+--------------+---------------+
| ROUND(2.5E0) | ROUND(-2.5E0) |
| 2            | -2            |
+--------------+---------------+
```
**Example 4.** In strict mode, inserting a value that is out of range for a column causes an error, rather than truncation to a legal value.

When MySQL is not running in strict mode, truncation to a legal value occurs:

```sql
mysql> SET sql_mode='';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO t SET i = 128;
Query OK, 1 row affected, 1 warning (0.00 sec)

mysql> SELECT i FROM t;
+----+
| i  |
+----+
| 127|
+----+
1 row in set (0.00 sec)
```

However, an error occurs if strict mode is in effect:

```sql
mysql> SET sql_mode='STRICT_ALL_TABLES';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t SET i = 128;
ERROR 1264 (22003): Out of range value adjusted for column 'i' at row 1

mysql> SELECT i FROM t;
Empty set (0.00 sec)
```

**Example 5:** In strict mode and with `ERROR_FOR_DIVISION_BY_ZERO` set, division by zero causes an error, not a result of `NULL`.

In nonstrict mode, division by zero has a result of `NULL`:

```sql
mysql> SET sql_mode='';
Query OK, 0 rows affected (0.01 sec)

mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t SET i = 1 / 0;
Query OK, 1 row affected (0.00 sec)

mysql> SELECT i FROM t;
+----+
| i  |
+----+
| NULL|
+----+
1 row in set (0.03 sec)
```

However, division by zero is an error if the proper SQL modes are in effect:

```sql
mysql> SET sql_mode='STRICT_ALL_TABLES,ERROR_FOR_DIVISION_BY_ZERO';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t SET i = 1 / 0;
ERROR 1365 (22012): Division by 0

mysql> SELECT i FROM t;
```
Example 6. Exact-value literals are evaluated as exact values.

Approximate-value literals are evaluated using floating point, but exact-value literals are handled as `DECIMAL`:

```sql
mysql> CREATE TABLE t SELECT 2.5 AS a, 25E-1 AS b;
Query OK, 1 row affected (0.01 sec)
Records: 1  Duplicates: 0  Warnings: 0
``` 

```sql
mysql> DESCRIBE t;
+-------+-----------------------+------+-----+---------+-------+
| Field | Type                  | Null | Key | Default | Extra |
+-------+-----------------------+------+-----+---------+-------+
| a     | decimal(2,1) unsigned | NO   |     | 0.0     |       |
| b     | double                | NO   |     | 0       |       |
+-------+-----------------------+------+-----+---------+-------+
2 rows in set (0.01 sec)
```

Example 7. If the argument to an aggregate function is an exact numeric type, the result is also an exact numeric type, with a scale at least that of the argument.

Consider these statements:

```sql
mysql> CREATE TABLE t (i INT, d DECIMAL, f FLOAT);
mysql> INSERT INTO t VALUES(1,1,1);
mysql> CREATE TABLE y SELECT AVG(i), AVG(d), AVG(f) FROM t;
``` 

The result is a double only for the floating-point argument. For exact type arguments, the result is also an exact type:

```sql
mysql> DESCRIBE y;
+--------+---------------+------+-----+---------+-------+
| Field  | Type          | Null | Key | Default | Extra |
+--------+---------------+------+-----+---------+-------+
| AVG(i) | decimal(14,4) | YES  |     | NULL    |       |
| AVG(d) | decimal(14,4) | YES  |     | NULL    |       |
| AVG(f) | double        | YES  |     | NULL    |       |
+--------+---------------+------+-----+---------+-------+
```

The result is a double only for the floating-point argument. For exact type arguments, the result is also an exact type.

Data Definition Statements

13.1 Data Definition Statements

13.1.1 Atomic Data Definition Statement Support

MySQL 8.0 supports atomic Data Definition Language (DDL) statements. This feature is referred to as atomic DDL. An atomic DDL statement combines the data dictionary updates, storage engine operations, and binary log writes associated with a DDL operation into a single, atomic operation. The operation is either committed, with applicable changes persisted to the data dictionary, storage engine, and binary log, or is rolled back, even if the server halts during the operation.
Atomic Data Definition Statement Support

Note

Atomic DDL is not transactional DDL. DDL statements, atomic or otherwise, implicitly end any transaction that is active in the current session, as if you had done a COMMIT before executing the statement. This means that DDL statements cannot be performed within another transaction, within transaction control statements such as START TRANSACTION ... COMMIT, or combined with other statements within the same transaction.

Atomic DDL is made possible by the introduction of the MySQL data dictionary in MySQL 8.0. In earlier MySQL versions, metadata was stored in metadata files, nontransactional tables, and storage engine-specific dictionaries, which necessitated intermediate commits. Centralized, transactional metadata storage provided by the MySQL data dictionary removed this barrier, making it possible to restructure DDL statement operations to be atomic.

The atomic DDL feature is described under the following topics in this section:

• Supported DDL Statements
• Atomic DDL Characteristics
• Changes in DDL Statement Behavior
• Storage Engine Support
• Viewing DDL Logs

Supported DDL Statements

The atomic DDL feature supports both table and non-table DDL statements. Table-related DDL operations require storage engine support, whereas non-table DDL operations do not. Currently, only the InnoDB storage engine supports atomic DDL.

• Supported table DDL statements include CREATE, ALTER, and DROP statements for databases, tablespaces, tables, and indexes, and the TRUNCATE TABLE statement.

• Supported non-table DDL statements include:
  • CREATE and DROP statements, and, if applicable, ALTER statements for stored programs, triggers, views, and user-defined functions (UDFs).
  • Account management statements: CREATE, ALTER, DROP, and, if applicable, RENAME statements for users and roles, as well as GRANT and REVOKE statements.

The following statements are not supported by the atomic DDL feature:

• Table-related DDL statements that involve a storage engine other than InnoDB.
• INSTALL PLUGIN and UNINSTALL PLUGIN statements.
• INSTALL COMPONENT and UNINSTALL COMPONENT statements.
• CREATE SERVER, ALTER SERVER, and DROP SERVER statements.

Atomic DDL Characteristics

The characteristics of atomic DDL statements include the following:

• Metadata updates, binary log writes, and storage engine operations, where applicable, are combined into a single atomic operation.

• There are no intermediate commits at the SQL layer during the DDL operation.

• Where applicable:
• The state of data dictionary, routine, event, and UDF caches is consistent with the status of the DDL operation, meaning that caches are updated to reflect whether or not the DDL operation was completed successfully or rolled back.

• The storage engine methods involved in a DDL operation do not perform intermediate commits, and the storage engine registers itself as part of the DDL operation.

• The storage engine supports redo and rollback of DDL operations, which is performed in the Post-DDL phase of the DDL operation.

• The visible behaviour of DDL operations is atomic, which changes the behavior of some DDL statements. See Changes in DDL Statement Behavior.

Changes in DDL Statement Behavior

This section describes changes in DDL statement behavior due to the introduction of atomic DDL support.

• DROP TABLE operations are fully atomic if all named tables use an atomic DDL-supported storage engine. The statement either drops all tables successfully or is rolled back.

  DROP TABLE fails with an error if a named table does not exist, and no changes are made, regardless of the storage engine. This change in behavior is demonstrated in the following example, where the DROP TABLE statement fails because a named table does not exist:

  mysql> CREATE TABLE t1 (c1 INT);
  mysql> DROP TABLE t1, t2;
  ERROR 1051 (42S02): Unknown table 'test.t2'
  mysql> SHOW TABLES;
  +----------------+
  | Tables_in_test |
  +----------------+
  | t1             |
  +----------------+

Prior to the introduction of atomic DDL, DROP TABLE reports an error for the named table that does not exist but succeeds for the named table that does exist:

  mysql> CREATE TABLE t1 (c1 INT);
  mysql> DROP TABLE t1, t2;
  ERROR 1051 (42S02): Unknown table 'test.t2'
  mysql> SHOW TABLES;
  Empty set (0.00 sec)

Note

Due to this change in behavior, a partially completed DROP TABLE statement on a MySQL 5.7 replication source server fails when replicated on a MySQL 8.0 replica. To avoid this failure scenario, use IF EXISTS syntax in DROP TABLE statements to prevent errors from occurring for tables that do not exist.

• DROP DATABASE is atomic if all tables use an atomic DDL-supported storage engine. The statement either drops all objects successfully or is rolled back. However, removal of the database directory from the file system occurs last and is not part of the atomic operation. If removal of the database directory fails due to a file system error or server halt, the DROP DATABASE transaction is not rolled back.

• For tables that do not use an atomic DDL-supported storage engine, table deletion occurs outside of the atomic DROP TABLE or DROP DATABASE transaction. Such table deletions are written to the binary log individually, which limits the discrepancy between the storage engine, data dictionary, and binary log to one table at most in the case of an interrupted DROP TABLE or DROP DATABASE operation. For operations that drop multiple tables, the tables that do not use an atomic DDL-supported storage engine are dropped before tables that do.
Atomic Data Definition Statement Support

- **CREATE TABLE, ALTER TABLE, RENAME TABLE, TRUNCATE TABLE, CREATE TABLESPACE, and DROP TABLESPACE** operations for tables that use an atomic DDL-supported storage engine are either fully committed or rolled back if the server halts during their operation. In earlier MySQL releases, interruption of these operations could cause discrepancies between the storage engine, data dictionary, and binary log, or leave behind orphan files. **RENAME TABLE** operations are only atomic if all named tables use an atomic DDL-supported storage engine.

- As of MySQL 8.0.21, on storage engines that support atomic DDL, the **CREATE TABLE ... SELECT** statement is logged as one transaction in the binary log when row-based replication is in use. Previously, it was logged as two transactions, one to create the table, and the other to insert data. A server failure between the two transactions or while inserting data could result in replication of an empty table. With the introduction of atomic DDL support, **CREATE TABLE ... SELECT** statements are now safe for row-based replication and permitted for use with GTID-based replication.

On storage engines that support both atomic DDL and foreign key constraints, creation of foreign keys is not permitted in **CREATE TABLE ... SELECT** statements when row-based replication is in use. Foreign key constraints can be added later using **ALTER TABLE**.

When **CREATE TABLE ... SELECT** is applied as an atomic operation, a metadata lock is held on the table while data is inserted, which prevents concurrent access to the table for the duration of the operation.

- **DROP VIEW** fails if a named view does not exist, and no changes are made. The change in behavior is demonstrated in this example, where the **DROP VIEW** statement fails because a named view does not exist:

```
mysql> CREATE VIEW test.viewA AS SELECT * FROM t;
mysql> DROP VIEW test.viewA, test.viewB;
ERROR 1051 (42S02): Unknown table 'test.viewB'
mysql> SHOW FULL TABLES IN test WHERE TABLE_TYPE LIKE 'VIEW';
+----------------+------------+
<table>
<thead>
<tr>
<th>Tables_in_test</th>
<th>Table_type</th>
</tr>
</thead>
<tbody>
<tr>
<td>viewA</td>
<td>VIEW</td>
</tr>
</tbody>
</table>
+----------------+------------+
```

Prior to the introduction of atomic DDL, **DROP VIEW** returns an error for the named view that does not exist but succeeds for the named view that does exist:

```
mysql> CREATE VIEW test.viewA AS SELECT * FROM t;
mysql> DROP VIEW test.viewA, test.viewB;
ERROR 1051 (42S02): Unknown table 'test.viewB'
mysql> SHOW FULL TABLES IN test WHERE TABLE_TYPE LIKE 'VIEW';
Empty set (0.00 sec)
```

**Note**
Due to this change in behavior, a partially completed **DROP VIEW** operation on a MySQL 5.7 replication source server fails when replicated on a MySQL 8.0 replica. To avoid this failure scenario, use **IF EXISTS** syntax in **DROP VIEW** statements to prevent an error from occurring for views that do not exist.

- Partial execution of account management statements is no longer permitted. Account management statements either succeed for all named users or roll back and have no effect if an error occurs. In earlier MySQL versions, account management statements that name multiple users could succeed for some users and fail for others.

The change in behavior is demonstrated in this example, where the second **CREATE USER** statement returns an error but fails because it cannot succeed for all named users.

```
mysql> CREATE USER userA;
```
Prior to the introduction of atomic DDL, the second `CREATE USER` statement returns an error for the named user that does not exist but succeeds for the named user that does exist:

```sql
mysql> CREATE USER userA, userB;
ERROR 1396 (HY000): Operation CREATE USER failed for 'userA'@'%
mysql> CREATE USER userA, userB;
ERROR 1396 (HY000): Operation CREATE USER failed for 'userA'@'%
```

<table>
<thead>
<tr>
<th>User</th>
</tr>
</thead>
<tbody>
<tr>
<td>userA</td>
</tr>
<tr>
<td>userB</td>
</tr>
</tbody>
</table>

Note
---

Due to this change in behavior, partially completed account management statements on a MySQL 5.7 replication source server fail when replicated on a MySQL 8.0 replica. To avoid this failure scenario, use `IF EXISTS` or `IF NOT EXISTS` syntax, as appropriate, in account management statements to prevent errors related to named users.

Storage Engine Support
---

Currently, only the InnoDB storage engine supports atomic DDL. Storage engines that do not support atomic DDL are exempted from DDL atomicity. DDL operations involving exempted storage engines remain capable of introducing inconsistencies that can occur when operations are interrupted or only partially completed.

To support redo and rollback of DDL operations, InnoDB writes DDL logs to the `mysql.innodb_ddl_log` table, which is a hidden data dictionary table that resides in the `mysql.ibd` data dictionary tablespace.

To view DDL logs that are written to the `mysql.innodb_ddl_log` table during a DDL operation, enable the `innodb_print_ddl_logs` configuration option. For more information, see Viewing DDL Logs.

Note
---

The redo logs for changes to the `mysql.innodb_ddl_log` table are flushed to disk immediately regardless of the `innodb_flush_log_at_trx_commit` setting. Flushing the redo logs immediately avoids situations where data files are modified by DDL operations but the redo logs for changes to the `mysql.innodb_ddl_log` table resulting from those operations are not persisted to disk. Such a situation could cause errors during rollback or recovery.

The InnoDB storage engine executes DDL operations in phases. DDL operations such as `ALTER TABLE` may perform the `Prepare` and `Perform` phases multiple times prior to the `Commit` phase.

1. **Prepare**: Create the required objects and write the DDL logs to the `mysql.innodb_ddl_log` table. The DDL logs define how to roll forward and roll back the DDL operation.

2. **Perform**: Perform the DDL operation. For example, perform a create routine for a `CREATE TABLE` operation.
3. **Commit**: Update the data dictionary and commit the data dictionary transaction.

4. **Post-DDL**: Replay and remove DDL logs from the `mysql.innodb_ddl_log` table. To ensure that rollback can be performed safely without introducing inconsistencies, file operations such as renaming or removing data files are performed in this final phase. This phase also removes dynamic metadata from the `mysql.innodb_dynamic_metadata` data dictionary table for `DROP TABLE`, `TRUNCATE TABLE`, and other DDL operations that rebuild the table.

DDL logs are replayed and removed from the `mysql.innodb_ddl_log` table during the Post-DDL phase, regardless of whether the DDL operation is committed or rolled back. DDL logs should only remain in the `mysql.innodb_ddl_log` table if the server is halted during a DDL operation. In this case, the DDL logs are replayed and removed after recovery.

In a recovery situation, a DDL operation may be committed or rolled back when the server is restarted. If the data dictionary transaction that was performed during the Commit phase of a DDL operation is present in the redo log and binary log, the operation is considered successful and is rolled forward. Otherwise, the incomplete data dictionary transaction is rolled back when InnoDB replays data dictionary redo logs, and the DDL operation is rolled back.

**Viewing DDL Logs**

To view DDL logs that are written to the `mysql.innodb_ddl_log` data dictionary table during atomic DDL operations that involve the InnoDB storage engine, enable `innodb_print_dml_logs` to have MySQL write the DDL logs to `stderr`. Depending on the host operating system and MySQL configuration, `stderr` may be the error log, terminal, or console window. See Section 5.4.2.2, “Default Error Log Destination Configuration”.

InnoDB writes DDL logs to the `mysql.innodb_ddl_log` table to support redo and rollback of DDL operations. The `mysql.innodb_ddl_log` table is a hidden data dictionary table that resides in the `mysql.ibd` data dictionary tablespace. Like other hidden data dictionary tables, the `mysql.innodb_ddl_log` table cannot be accessed directly in non-debug versions of MySQL. (See Section 14.1, “Data Dictionary Schema.”) The structure of the `mysql.innodb_ddl_log` table corresponds to this definition:

```sql
CREATE TABLE mysql.innodb_ddl_log (
    id BIGINT UNSIGNED NOT NULL AUTO_INCREMENT PRIMARY KEY,
    thread_id BIGINT UNSIGNED NOT NULL,
    type INT UNSIGNED NOT NULL,
    space_id INT UNSIGNED,
    page_no INT UNSIGNED,
    index_id BIGINT UNSIGNED,
    table_id BIGINT UNSIGNED,
    old_file_path VARCHAR(512) COLLATE UTF8_BIN,
    new_file_path VARCHAR(512) COLLATE UTF8_BIN,
    KEY(thread_id)
);
```

- **id**: A unique identifier for a DDL log record.
- **thread_id**: Each DDL log record is assigned a `thread_id`, which is used to replay and remove DDL logs that belong to a particular DDL operation. DDL operations that involve multiple data file operations generate multiple DDL log records.
- **type**: The DDL operation type. Types include `FREE` (drop an index tree), `DELETE` (delete a file), `RENAME` (rename a file), or `DROP` (drop metadata from the `mysql.innodb_dynamic_metadata` data dictionary table).
- **space_id**: The tablespace ID.
- **page_no**: A page that contains allocation information; an index tree root page, for example.
- **index_id**: The index ID.
- **table_id**: The table ID.
• **old_file_path**: The old tablespace file path. Used by DDL operations that create or drop tablespace files; also used by DDL operations that rename a tablespace.

• **new_file_path**: The new tablespace file path. Used by DDL operations that rename tablespace files.

This example demonstrates enabling `innodb_print_ddl_logs` to view DDL logs written to `strderr` for a `CREATE TABLE` operation.

```sql
mysql> SET GLOBAL innodb_print_ddl_logs=1;
mysql> CREATE TABLE t1 (c1 INT) ENGINE = InnoDB;

[Note] [000000] InnoDB: DDL log insert : [DDL record: DELETE SPACE, id=18, thread_id=7, space_id=5, old_file_path=./test/t1.ibd]
[Note] [000000] InnoDB: DDL log delete : by id 18
[Note] [000000] InnoDB: DDL log insert : [DDL record: REMOVE CACHE, id=19, thread_id=7, table_id=1058, new_file_path=test/t1]
[Note] [000000] InnoDB: DDL log delete : by id 19
[Note] [000000] InnoDB: DDL log insert : [DDL record: FREE, id=20, thread_id=7, space_id=5, index_id=132, page_no=4]
[Note] [000000] InnoDB: DDL log delete : by id 20
[Note] [000000] InnoDB: DDL log post ddl : begin for thread id : 7
[Note] [000000] InnoDB: DDL log post ddl : end for thread id : 7
```

13.1.2 ALTER DATABASE Statement

```sql
ALTER {DATABASE | SCHEMA} [db_name]
alter_option ...
alter_option: [
    [DEFAULT] CHARACTER SET [=] charset_name
    | [DEFAULT] COLLATE [=] collation_name
    | [DEFAULT] ENCRYPTION [=] {'Y' | 'N'}
    | READ ONLY [=] {DEFAULT | 0 | 1}
]
```

**ALTER DATABASE** enables you to change the overall characteristics of a database. These characteristics are stored in the data dictionary. This statement requires the **ALTER** privilege on the database. **ALTER SCHEMA** is a synonym for **ALTER DATABASE**.

If the database name is omitted, the statement applies to the default database. In that case, an error occurs if there is no default database.

For any **alter_option** omitted from the statement, the database retains its current option value, with the exception that changing the character set may change the collation and vice versa.

• **Character Set and Collation Options**

• **Encryption Option**

• **Read Only Option**

**Character Set and Collation Options**

The **CHARACTER SET** option changes the default database character set. The **COLLATE** option changes the default database collation. For information about character set and collation names, see Chapter 10, **Character Sets, Collations, Unicode**.

To see the available character sets and collations, use the **SHOW CHARACTER SET** and **SHOW COLLATION** statements, respectively. See Section 13.7.7.3, “SHOW CHARACTER SET Statement”, and Section 13.7.7.4, “SHOW COLLATION Statement”.

A stored routine that uses the database defaults when the routine is created includes those defaults as part of its definition. (In a stored routine, variables with character data types use the database defaults if the character set or collation are not specified explicitly. See Section 13.1.17, “CREATE PROCEDURE and CREATE FUNCTION Statements”.) If you change the default character set or
ALTER DATABASE Statement

collation for a database, any stored routines that are to use the new defaults must be dropped and recreated.

Encryption Option

The **ENCRYPTION** option, introduced in MySQL 8.0.16, defines the default database encryption, which is inherited by tables created in the database. The permitted values are 'Y' (encryption enabled) and 'N' (encryption disabled). Only newly created tables inherit the default database encryption. For existing tables associated with the database, their encryption remains unchanged. If the **table_encryption_privilege_check** system variable is enabled, the **TABLE_ENCRYPTION_ADMIN** privilege is required to specify a default encryption setting that differs from the value of the **default_table_encryption** system variable. For more information, see [Defining an Encryption Default for Schemas and General Tablespaces](#).

Read Only Option

The **READ ONLY** option, introduced in MySQL 8.0.22, controls whether to permit modification of the database and objects within it. The permitted values are **DEFAULT** or 0 (not read only) and 1 (read only). This option is useful for database migration because a database for which **READ ONLY** is enabled can be migrated to another MySQL instance without concern that the database might be changed during the operation.

With NDB Cluster, making a database read only on one **mysqld** server is synchronized to other **mysqld** servers in the same cluster, so that the database becomes read only on all **mysqld** servers.

The **READ ONLY** option, if enabled, is displayed in the **INFORMATION_SCHEMA SCHEMATA_EXTENSIONS** table. See [Section 26.3.32, “The INFORMATION_SCHEMA SCHEMATA_EXTENSIONS Table”](#).

The **READ ONLY** option cannot be enabled for these system schemas: mysql, information_schema, performance_schema.

In **ALTER DATABASE** statements, the **READ ONLY** option interacts with other instances of itself and with other options as follows:

- An error occurs if multiple instances of **READ ONLY** conflict (for example, **READ ONLY** = 1 **READ ONLY** = 0).
- An **ALTER DATABASE** statement that contains only (nonconflicting) **READ ONLY** options is permitted even for a read-only database.
- A mix of (nonconflicting) **READ ONLY** options with other options is permitted if the read-only state of the database either before or after the statement permits modifications. If the read-only state both before and after prohibits changes, an error occurs.

This statement succeeds whether or not the database is read only:

```
ALTER DATABASE mydb READ ONLY = 0 DEFAULT COLLATE utf8mb4_bin;
```

This statement succeeds if the database is not read only, but fails if it is already read only:

```
ALTER DATABASE mydb READ ONLY = 1 DEFAULT COLLATE utf8mb4_bin;
```

Enabling **READ ONLY** affects all users of the database, with these exceptions that are not subject to read-only checks:

- Statements executed by the server as part of server initialization, restart, upgrade, or replication.
- Statements in a file named at server startup by the **init_file** system variable.
- **TEMPORARY** tables; it is possible to create, alter, drop, and write to **TEMPORARY** tables in a read-only database.
• NDB Cluster non-SQL inserts and updates.

Other than for the excepted operations just listed, enabling READ ONLY prohibits write operations to the database and its objects, including their definitions, data, and metadata. The following list details affected SQL statements and operations:

• The database itself:
  • CREATE DATABASE
  • ALTER DATABASE (except to change the READ ONLY option)
  • DROP DATABASE

• Views:
  • CREATE VIEW
  • ALTER VIEW
  • DROP VIEW

• Selecting from views that invoke functions with side effects.

• Updating updatable views.

• Statements that create or drop objects in a writable database are rejected if they affect metadata of a view in a read-only database (for example, by making the view valid or invalid).

• Stored routines:
  • CREATE PROCEDURE
  • DROP PROCEDURE
  • CALL (of procedures with side effects)
  • CREATE FUNCTION
  • DROP FUNCTION
  • SELECT (of functions with side effects)

• For procedures and functions, read-only checks follow prelocking behavior. For CALL statements, read-only checks are done on a per-statement basis, so if some conditionally executed statement writing to a read-only database does not actually execute, the call still succeeds. On the other hand, for a function called within a SELECT, execution of the function body happens in prelocked mode. As long as a some statement within the function writes to a read-only database, execution of the function fails with an error regardless of whether the statement actually executes.

• Triggers:
  • CREATE TRIGGER
  • DROP TRIGGER
  • Trigger invocation.

• Events:
  • CREATE EVENT
  • ALTER EVENT
• DROP EVENT

• Event execution:
  • Executing an event in the database fails because that would change the last-execution
    timestamp, which is event metadata stored in the data dictionary. Failure of event execution also
    has the effect of causing the event scheduler to stop.
  • If an event writes to an object in a read-only database, execution of the event fails with an error,
    but the event scheduler is not stopped.

• Tables:
  • CREATE TABLE
  • ALTER TABLE
  • CREATE INDEX
  • DROP INDEX
  • RENAME TABLE
  • TRUNCATE TABLE
  • DROP TABLE
  • DELETE
  • INSERT
  • IMPORT TABLE
  • LOAD DATA
  • LOAD XML
  • REPLACE
  • UPDATE

  • For cascading foreign keys where the child table is in a read-only database, updates and deletes
    on the parent are rejected even if the child table is not directly affected.

  • For a MERGE table such as CREATE TABLE s1.t(i int) ENGINE MERGE UNION (s2.t, s3.t), INSERT_METHOD=..., the following behavior applies:
    • Inserting into the MERGE table (INSERT into s1.t) fails if at least one of s1, s2, s3 is read
      only, regardless of insert method. The insert is refused even if it would actually end up in a
      writable table.
    • Dropping the MERGE table (DROP TABLE s1.t) succeeds as long as s1 is not read only. It is
      permitted to drop a MERGE table that refers to a read-only database.

An ALTER DATABASE statement blocks until all concurrent transactions that have already accessed
an object in the database being altered have committed. Conversely, a write transaction accessing
an object in a database being altered in a concurrent ALTER DATABASE blocks until the ALTER
DATABASE has committed.

If the Clone plugin is used to clone a local or remote data directory, the databases in the clone retain
the read-only state they had in the source data directory. The read-only state does not affect the
cloning process itself. If it is not desirable to have the same database read-only state in the clone, the option must be changed explicitly for the clone after the cloning process has finished, using `ALTER DATABASE` operations on the clone.

When cloning from a donor to a recipient, if the recipient has a user database that is read only, cloning fails with an error message. Cloning may be retried after making the database writable.

`READ ONLY` is permitted for `ALTER DATABASE`, but not for `CREATE DATABASE`. However, for a read-only database, the statement produced by `SHOW CREATE DATABASE` does include `READ ONLY=1` within a comment to indicate its read-only status:

```
mysql> ALTER DATABASE mydb READ ONLY = 1;
```
```
+-----------------------------+---------------------------------------+
| Database                   | Create Database: CREATE DATABASE `mydb` |
|                            | /*40100 DEFAULT CHARACTER SET utf8mb4  |
|                            | COLLATE utf8mb4_0900_ai_ci */          |
|                            | /*80016 DEFAULT ENCRYPTION='N' */      |
|                            | /* READ ONLY = 1 */                    |
```

If the server executes a `CREATE DATABASE` statement containing such a comment, the server ignores the comment and the `READ ONLY` option is not processed. This has implications for `mysqldump` and `mysqlpump`, which use `SHOW CREATE DATABASE` to produce `CREATE DATABASE` statements in dump output:

- In a dump file, the `CREATE DATABASE` statement for a read-only database contains the commented `READ ONLY` option.
- The dump file can be restored as usual, but because the server ignores the commented `READ ONLY` option, the restored database is not read only. If the database is to be read only after being restored, you must execute `ALTER DATABASE` manually to make it so.

Suppose that `mydb` is read only and you dump it as follows:

```
shell> mysqldump --databases mydb > mydb.sql
```

A restore operation later must be followed by `ALTER DATABASE` if `mydb` should still be read only:

```
shell> mysql
mysql> SOURCE mydb.sql;
mysql> ALTER DATABASE mydb READ ONLY = 1;
```

MySQL Enterprise Backup is not subject to this issue. It backs up and restores a read-only database like any other, but enables the `READ ONLY` option at restore time if it was enabled at backup time.

`ALTER DATABASE` is written to the binary log, so a change to the `READ ONLY` option on a replication source server also affects replicas. To prevent this from happening, binary logging must be disabled prior to execution of the `ALTER DATABASE` statement. For example, to prepare for migrating a database without affecting replicas, perform these operations:

1. Within a single session, disable binary logging and enable `READ ONLY` for the database:

```
 mysql> SET sql_log_bin = OFF;
 mysql> ALTER DATABASE mydb READ ONLY = 1;
```

2. Dump the database, for example, with `mysqldump` or `mysqlpump`:

```
shell> mysqldump --databases mydb > mydb.sql
```

3. Within a single session, disable binary logging and disable `READ ONLY` for the database:

```
 mysql> SET sql_log_bin = OFF;
 mysql> ALTER DATABASE mydb READ ONLY = 0;
```
13.1.3 ALTER EVENT Statement

ALTER
    [DEFINER = user]
    EVENT event_name
    [ON SCHEDULE schedule]
    [ON COMPLETION [NOT] PRESERVE]
    [RENAME TO new_event_name]
    [ENABLE | DISABLE | DISABLE ON SLAVE]
    [COMMENT 'string']
    [DO event_body]

The ALTER EVENT statement changes one or more of the characteristics of an existing event without the need to drop and recreate it. The syntax for each of the DEFINER, ON SCHEDULE, ON COMPLETION, COMMENT, ENABLE / DISABLE, and DO clauses is exactly the same as when used with CREATE EVENT. (See Section 13.1.13, “CREATE EVENT Statement”.)

Any user can alter an event defined on a database for which that user has the EVENT privilege. When a user executes a successful ALTER EVENT statement, that user becomes the definer for the affected event.

ALTER EVENT works only with an existing event:

mysql> ALTER EVENT no_such_event
    > ON SCHEDULE
    > EVERY '2:3' DAY_HOUR;
ERROR 1517 (HY000): Unknown event 'no_such_event'

In each of the following examples, assume that the event named myevent is defined as shown here:

CREATE EVENT myevent
    ON SCHEDULE
    EVERY 6 HOUR
    COMMENT 'A sample comment.'
    DO
        UPDATE myschema.mytable SET mycol = mycol + 1;

The following statement changes the schedule for myevent from once every six hours starting immediately to once every twelve hours, starting four hours from the time the statement is run:

ALTER EVENT myevent
    ON SCHEDULE
    EVERY 12 HOUR
    STARTS CURRENT_TIMESTAMP + INTERVAL 4 HOUR;

It is possible to change multiple characteristics of an event in a single statement. This example changes the SQL statement executed by myevent to one that deletes all records from mytable; it also changes the schedule for the event such that it executes once, one day after this ALTER EVENT statement is run.

ALTER EVENT myevent
    ON SCHEDULE
    AT CURRENT_TIMESTAMP + INTERVAL 1 DAY
    DO
        TRUNCATE TABLE myschema.mytable;

Specify the options in an ALTER EVENT statement only for those characteristics that you want to change; omitted options keep their existing values. This includes any default values for CREATE EVENT such as ENABLE.

To disable myevent, use this ALTER EVENT statement:

ALTER EVENT myevent
    DISABLE;
The `ON SCHEDULE` clause may use expressions involving built-in MySQL functions and user variables to obtain any of the `timestamp` or `interval` values which it contains. You cannot use stored routines or user-defined functions in such expressions, and you cannot use any table references; however, you can use `SELECT FROM DUAL`. This is true for both `ALTER EVENT` and `CREATE EVENT` statements. References to stored routines, user-defined functions, and tables in such cases are specifically not permitted, and fail with an error (see Bug #22830).

Although an `ALTER EVENT` statement that contains another `ALTER EVENT` statement in its `DO` clause appears to succeed, when the server attempts to execute the resulting scheduled event, the execution fails with an error.

To rename an event, use the `ALTER EVENT` statement's `RENAME TO` clause. This statement renames the event `myevent` to `yourevent`:

```
ALTER EVENT myevent
    RENAME TO yourevent;
```

You can also move an event to a different database using `ALTER EVENT ... RENAME TO ...` and `db_name.event_name` notation, as shown here:

```
ALTER EVENT olddb.myevent
    RENAME TO newdb.myevent;
```

To execute the previous statement, the user executing it must have the `EVENT` privilege on both the `oldbb` and `newdb` databases.

- **Note**
  - There is no `RENAME EVENT` statement.

The value `DISABLE ON SLAVE` is used on a replica instead of `ENABLE` or `DISABLE` to indicate an event that was created on the replication source server and replicated to the replica, but that is not executed on the replica. Normally, `DISABLE ON SLAVE` is set automatically as required; however, there are some circumstances under which you may want or need to change it manually. See Section 17.5.1.16, “Replication of Invoked Features”, for more information.

### 13.1.4 ALTER FUNCTION Statement

```
ALTER FUNCTION func_name [characteristic ...]
    characteristic: {
        COMMENT 'string'
        LANGUAGE SQL
        { CONTAINS SQL | NO SQL | READS SQL DATA | MODIFIES SQL DATA }
        SQL SECURITY { DEFINER | INVOKER }
    }
```

This statement can be used to change the characteristics of a stored function. More than one change may be specified in an `ALTER FUNCTION` statement. However, you cannot change the parameters or body of a stored function using this statement; to make such changes, you must drop and re-create the function using `DROP FUNCTION` and `CREATE FUNCTION`.

You must have the `ALTER ROUTINE` privilege for the function. (That privilege is granted automatically to the function creator.) If binary logging is enabled, the `ALTER FUNCTION` statement might also require the `SUPER` privilege, as described in Section 25.7, “Stored Program Binary Logging”.

### 13.1.5 ALTER INSTANCE Statement

```
ALTER INSTANCE instance_action
    instance_action: {
        | [ENABLE|DISABLE] INNODB REDO_LOG
    }
```
ALTER INSTANCE Statement

ALTER INSTANCE defines actions applicable to a MySQL server instance. The statement supports these actions:

• **ALTER INSTANCE (ENABLE | DISABLE) INNODB REDO_LOG**

  This action enables or disables InnoDB redo logging. Redo logging is enabled by default. This feature is intended only for loading data into a new MySQL instance. The statement is not written to the binary log. This action was introduced in MySQL 8.0.21.

  **Warning**

  *Do not disable redo logging on a production system.* While it is permitted to shutdown and restart the server while redo logging is disabled, an unexpected server stoppage while redo logging is disabled can cause data loss and instance corruption.

  An **ALTER INSTANCE [ENABLE|DISABLE] INNODB REDO_LOG** operation requires an exclusive backup lock, which prevents other **ALTER INSTANCE** operations from executing concurrently. Other **ALTER INSTANCE** operations must wait for the lock to be released before executing.

  For more information, see Disabling Redo Logging.

• **ALTER INSTANCE ROTATE INNODB MASTER KEY**

  This action rotates the master encryption key used for InnoDB tablespace encryption. Key rotation requires the **ENCRYPTION_KEY_ADMIN** or **SUPER** privilege. To perform this action, a keyring plugin must be installed and configured. For instructions, see Section 6.4.4, “The MySQL Keyring”.

  **ALTER INSTANCE ROTATE INNODB MASTER KEY** actions are not written to the binary log and are not executed on replicas. Binary log master key rotation can therefore be carried out in replication environments including a mix of MySQL versions. To schedule regular rotation of the binary log master key on all applicable source and replica servers, you can enable the MySQL Event Scheduler on each server and issue the **ALTER INSTANCE ROTATE BINLOG MASTER KEY** statement using a **CREATE EVENT** statement. If you rotate the binary log master key because you suspect that the
current or any of the previous binary log master keys might have been compromised, issue the statement on every applicable source and replica server, which enables you to verify immediate compliance.

For additional ALTER INSTANCE ROTATE BINLOG MASTER KEY usage information, including what to do if the process does not complete correctly or is interrupted by an unexpected server halt, see Section 17.3.2, “Encrypting Binary Log Files and Relay Log Files”.

• ALTER INSTANCE RELOAD TLS

This action reconfigures a TLS context from the current values of the system variables that define the context. It also updates the status variables that reflect the active context values. This action requires the CONNECTION_ADMIN privilege. For additional information about reconfiguring the TLS context, including which system and status variables are context-related, see Server-Side Runtime Configuration and Monitoring for Encrypted Connections.

By default, the statement reloads the TLS context for the main connection interface. If the FOR CHANNEL clause (available as of MySQL 8.0.21) is given, the statement reloads the TLS context for the named channel: mysql_main for the main connection interface, mysql_admin for the administrative connection interface. For information about the different interfaces, see Section 5.1.12.1, “Connection Interfaces”. The updated TLS context properties are exposed in the Performance Schema tls_channel_status table. See Section 27.12.21.7, “The tls_channel_status Table”.

Updating the TLS context for the main interface may also affect the administrative interface because unless some nondefault TLS value is configured for that interface, it uses the same TLS context as the main interface.

By default, the RELOAD TLS action rolls back with an error and has no effect if the configuration values do not permit creation of the new TLS context. The previous context values continue to be used for new connections. If the optional NO ROLLBACK ON ERROR clause is given and the new context cannot be created, rollback does not occur. Instead, a warning is generated and encryption is disabled for new connections on the interface to which the statement applies.

ALTER INSTANCE RELOAD TLS statements are not written to the binary log (and thus are not replicated). TLS configuration is local and depends on local files not necessarily present on all servers involved.

• ALTER INSTANCE RELOAD KEYRING

If a keyring component is installed, this action tells the component to re-read its configuration file and reinitialize any keyring in-memory data. If you modify the component configuration at runtime, the new configuration does not take effect until you perform this action. Keyring reloading requires the ENCRYPTION_KEY_ADMIN privilege. This action was added in MySQL 8.0.24.

This action enables reconfiguring only the currently installed keyring component. It does not enable changing which component is installed. For example, if you change the configuration for the installed keyring component, ALTER INSTANCE RELOAD KEYRING causes the new configuration to take effect. On the other hand, if you change the keyring component named in the server manifest file, ALTER INSTANCE RELOAD KEYRING has no effect and the current component remains installed.

ALTER INSTANCE RELOAD KEYRING statements are not written to the binary log (and thus are not replicated).

13.1.6 ALTER LOGFILE GROUP Statement

```
ALTER LOGFILE GROUP logfile_group
ADD UNDOFILE 'file_name'
[INITIAL_SIZE [=] size]
[WAIT]
ENGINE [=] engine_name
```
This statement adds an UNDO file named ‘file_name’ to an existing log file group logfile_group. An ALTER LOGFILE GROUP statement has one and only one ADD UNDOFILE clause. No DROP UNDOFILE clause is currently supported.

Note
All NDB Cluster Disk Data objects share the same namespace. This means that each Disk Data object must be uniquely named (and not merely each Disk Data object of a given type). For example, you cannot have a tablespace and an undo log file with the same name, or an undo log file and a data file with the same name.

The optional INITIAL_SIZE parameter sets the UNDO file’s initial size in bytes; if not specified, the initial size defaults to 134217728 (128 MB). You may optionally follow size with a one-letter abbreviation for an order of magnitude, similar to those used in my.cnf. Generally, this is one of the letters M (megabytes) or G (gigabytes). (Bug #13116514, Bug #16104705, Bug #62858)

On 32-bit systems, the maximum supported value for INITIAL_SIZE is 4294967296 (4 GB). (Bug #29186)

The minimum allowed value for INITIAL_SIZE is 1048576 (1 MB). (Bug #29574)

Note
WAIT is parsed but otherwise ignored. This keyword currently has no effect, and is intended for future expansion.

The ENGINE parameter (required) determines the storage engine which is used by this log file group, with engine_name being the name of the storage engine. Currently, the only accepted values for engine_name are “NDBCLUSTER” and “NDB”. The two values are equivalent.

Here is an example, which assumes that the log file group lg_3 has already been created using CREATE LOGFILE GROUP (see Section 13.1.16, “CREATE LOGFILE GROUP Statement”):

```
ALTER LOGFILE GROUP lg_3
  ADD UNDOFILE 'undo_10.dat'
  INITIAL_SIZE=32M,
  ENGINE=NDBCLUSTER;
```

When ALTER LOGFILE GROUP is used with ENGINE = NDBCLUSTER (alternatively, ENGINE = NDB), an UNDO log file is created on each NDB Cluster data node. You can verify that the UNDO files were created and obtain information about them by querying the INFORMATION_SCHEMA.FILES table. For example:

```
mysql> SELECT FILE_NAME, LOGFILE_GROUP_NUMBER, EXTRA
    -> FROM INFORMATION_SCHEMA.FILES
    -> WHERE LOGFILE_GROUP_NAME = 'lg_3';
+-------------+----------------------+----------------+
<table>
<thead>
<tr>
<th>FILE_NAME</th>
<th>LOGFILE_GROUP_NUMBER</th>
<th>EXTRA</th>
</tr>
</thead>
<tbody>
<tr>
<td>newdata.dat</td>
<td>0</td>
<td>CLUSTER_NODE=3</td>
</tr>
<tr>
<td>newdata.dat</td>
<td>0</td>
<td>CLUSTER_NODE=4</td>
</tr>
<tr>
<td>undo_10.dat</td>
<td>11</td>
<td>CLUSTER_NODE=3</td>
</tr>
<tr>
<td>undo_10.dat</td>
<td>11</td>
<td>CLUSTER_NODE=4</td>
</tr>
</tbody>
</table>
+-------------+----------------------|----------------+
4 rows in set (0.01 sec)
```

(See Section 26.3.15, “The INFORMATION_SCHEMA.FILES Table”.)

Memory used for UNDO_BUFFER_SIZE comes from the global pool whose size is determined by the value of the SharedGlobalMemory data node configuration parameter. This includes any default value implied for this option by the setting of the InitialLogFileGroup data node configuration parameter.
ALTER LOGFILE GROUP is useful only with Disk Data storage for NDB Cluster. For more information, see Section 23.5.10, “NDB Cluster Disk Data Tables”.

### 13.1.7 ALTER PROCEDURE Statement

```sql
ALTER PROCEDURE proc_name [characteristic ...]
```

**characteristic:**

- `COMMENT 'string'`
- `LANGUAGE SQL`
- `CONTAINS SQL | NO SQL | READS SQL DATA | MODIFIES SQL DATA`
- `SQL SECURITY { DEFINER | INVOKER }

This statement can be used to change the characteristics of a stored procedure. More than one change may be specified in an `ALTER PROCEDURE` statement. However, you cannot change the parameters or body of a stored procedure using this statement; to make such changes, you must drop and re-create the procedure using `DROP PROCEDURE` and `CREATE PROCEDURE`.

You must have the `ALTER ROUTINE` privilege for the procedure. By default, that privilege is granted automatically to the procedure creator. This behavior can be changed by disabling the `automatic_sp_privileges` system variable. See Section 25.2.2, “Stored Routines and MySQL Privileges”.

### 13.1.8 ALTER SERVER Statement

```sql
ALTER SERVER server_name OPTIONS (option [, option] ...)
```

Alters the server information for `server_name`, adjusting any of the options permitted in the `CREATE SERVER` statement. The corresponding fields in the `mysql.servers` table are updated accordingly.

This statement requires the `SUPER` privilege.

For example, to update the `USER` option:

```sql
ALTER SERVER s OPTIONS (USER 'sally');
```

`ALTER SERVER` causes an implicit commit. See Section 13.3.3, “Statements That Cause an Implicit Commit”.

`ALTER SERVER` is not written to the binary log, regardless of the logging format that is in use.

### 13.1.9 ALTER TABLE Statement

```sql
ALTER TABLE tbl_name
   [alter_option [, alter_option] ...]
   [partition_options]
```

**alter_option:**

- `table_options`
- `ADD [COLUMN] col_name column_definition [FIRST | AFTER col_name]`
- `ADD [COLUMN] (col_name column_definition, ...)`
- `ADD [INDEX | KEY] [index_name] [index_type] (key_part, ...)
  [index_option] ...`
- `ADD [FULLTEXT | SPATIAL] [INDEX | KEY] [index_name]
  (key_part, ...) [index_option] ...`
- `ADD [CONSTRAINT [symbol]] PRIMARY KEY [index_type]
  (key_part, ...)
  [index_option] ...`
- `ADD [CONSTRAINT [symbol]] UNIQUE [INDEX | KEY]
  [index_name] [index_type] (key_part, ...)
  [index_option] ...`
- `ADD [CONSTRAINT [symbol]] FOREIGN KEY [index_name]
  (col_name, ...)
  reference_definition`
- `ADD [CONSTRAINT [symbol]] CHECK (expr) [NOT] ENFORCED`
- `DROP [CHECK | CONSTRAINT] symbol`
ALTER TABLE Statement

| ALTER (CHECK | CONSTRAINT) symbol (NOT) ENFORCED
| ALGORITHM [=] (DEFAULT | INSTANT | INPLACE | COPY)
| ALTER [COLUMN] col_name {
  | SET DEFAULT {literal | (expr)}
  | SET {VISIBLE | INVISIBLE}
  | DROP DEFAULT
}
| ALTER INDEX index_name {VISIBLE | INVISIBLE}
| CHANGE [COLUMN] old_col_name new_col_name column_definition
  | [FIRST | AFTER col_name]
| [DEFAULT] CHARACTER SET [=] charset_name [COLLATE [=] collation_name]
| CONVERT TO CHARACTER SET charset_name [COLLATE collation_name]
| {DISABLE | ENABLE} KEYS
| {DISCARD | IMPORT} TABLESPACE
| DROP [COLUMN] col_name
| DROP [INDEX | KEY] index_name
| DROP PRIMARY KEY
| DROP FOREIGN KEY fk_symbol
| FORCE

  | AUTO_INCREMENT [=] value
  | AVG_ROW_LENGTH [=] value
  | [DEFAULT] CHARACTER SET [=] charset_name
  | CHECKSUM [=] {0 | 1}
  | [DEFAULT] COLLATE [=] collation_name

### ALTER TABLE Statement

**ALTER TABLE** changes the structure of a table. For example, you can add or delete columns, create or destroy indexes, change the type of existing columns, or rename columns or the table itself. You can also change characteristics such as the storage engine used for the table or the table comment.

- To use **ALTER TABLE**, you need **ALTER**, **CREATE**, and **INSERT** privileges for the table. Renaming a table requires **ALTER** and **DROP** on the old table, **ALTER**, **CREATE**, and **INSERT** on the new table.

- Following the table name, specify the alterations to be made. If none are given, **ALTER TABLE** does nothing.

- The syntax for many of the permissible alterations is similar to clauses of the **CREATE TABLE** statement. **column_definition** clauses use the same syntax for **ADD** and **CHANGE** as for **CREATE TABLE**. For more information, see Section 13.1.20, “CREATE TABLE Statement”.

- The word **COLUMN** is optional and can be omitted, except for **RENAME COLUMN** (to distinguish a column-renaming operation from the **RENAME** table-renaming operation).

- Multiple **ADD**, **ALTER**, **DROP**, and **CHANGE** clauses are permitted in a single **ALTER TABLE** statement, separated by commas. This is a MySQL extension to standard SQL, which permits only one of each clause per **ALTER TABLE** statement. For example, to drop multiple columns in a single statement, do this:

```sql
ALTER TABLE t2 DROP COLUMN c, DROP COLUMN d;
```

- If a storage engine does not support an attempted **ALTER TABLE** operation, a warning may result. Such warnings can be displayed with **SHOW WARNINGS**. See Section 13.7.7.42, “SHOW WARNINGS Statement”. For information on troubleshooting **ALTER TABLE**, see Section B.3.6.1, “Problems with **ALTER TABLE**”.

- For information about generated columns, see Section 13.1.9.2, “**ALTER TABLE** and Generated Columns”.

- For usage examples, see Section 13.1.9.3, “**ALTER TABLE** Examples”.

- **InnoDB** in MySQL 8.0.17 and later supports addition of multi-valued indexes on JSON columns using a **key_part** specification can take the form `(CAST json_path AS type ARRAY)`. See Multi-Valued Indexes, for detailed information regarding multi-valued index creation and usage of, as well as restrictions and limitations on multi-valued indexes.

- With the **mysql_info()** C API function, you can find out how many rows were copied by **ALTER TABLE**. See **mysql_info()**.
There are several additional aspects to the `ALTER TABLE` statement, described under the following topics in this section:

- Table Options
- Performance and Space Requirements
- Concurrency Control
- Adding and Dropping Columns
- Renaming, Redefining, and Reordering Columns
- Primary Keys and Indexes
- Foreign Keys and Other Constraints
- Changing the Character Set
- Importing InnoDB Tables
- Row Order for MyISAM Tables
- Partitioning Options

**Table Options**

`table_options` signifies table options of the kind that can be used in the `CREATE TABLE` statement, such as `ENGINE`, `AUTO_INCREMENT`, `AVG_ROW_LENGTH`, `MAX_ROWS`, `ROW_FORMAT`, or `TABLESPACE`.

For descriptions of all table options, see Section 13.1.20, “CREATE TABLE Statement”. However, `ALTER TABLE` ignores `DATA DIRECTORY` and `INDEX DIRECTORY` when given as table options. `ALTER TABLE` permits them only as partitioning options, and requires that you have the `FILE` privilege.

Use of table options with `ALTER TABLE` provides a convenient way of altering single table characteristics. For example:

- If `t1` is currently not an InnoDB table, this statement changes its storage engine to InnoDB:

  ```sql
  ALTER TABLE t1 ENGINE = InnoDB;
  ```

- See Section 15.6.1.5, “Converting Tables from MyISAM to InnoDB” for considerations when switching tables to the InnoDB storage engine.

- When you specify an `ENGINE` clause, `ALTER TABLE` rebuilds the table. This is true even if the table already has the specified storage engine.

- Running `ALTER TABLE tbl_name ENGINE=INNODB` on an existing InnoDB table performs a “null” `ALTER TABLE` operation, which can be used to defragment an InnoDB table, as described in Section 15.11.4, “Defragmenting a Table”. Running `ALTER TABLE tbl_name FORCE` on an InnoDB table performs the same function.

- `ALTER TABLE tbl_name ENGINE=INNODB` and `ALTER TABLE tbl_name FORCE` use online DDL. For more information, see Section 15.12, “InnoDB and Online DDL”.

- The outcome of attempting to change the storage engine of a table is affected by whether the desired storage engine is available and the setting of the `NO_ENGINE_SUBSTITUTION` SQL mode, as described in Section 5.1.11, “Server SQL Modes”.

- To prevent inadvertent loss of data, `ALTER TABLE` cannot be used to change the storage engine of a table to `MERGE` or `BLACKHOLE`.

- To change the InnoDB table to use compressed row-storage format:
ALTER TABLE t1 ROW_FORMAT = COMPRESSED;

- The `ENCRYPTION` clause enables or disables page-level data encryption for an InnoDB table. A keyring plugin must be installed and configured to enable encryption.

  If the `table_encryption_privilege_check` variable is enabled, the `TABLE_ENCRYPTION_ADMIN` privilege is required to use an `ENCRYPTION` clause with a setting that differs from the default schema encryption setting.

  Prior to MySQL 8.0.16, the `ENCRYPTION` clause was only supported when altering tables residing in file-per-table tablespaces. As of MySQL 8.0.16, the `ENCRYPTION` clause is also supported for tables residing in general tablespaces.

  For tables that reside in general tablespaces, table and tablespace encryption must match.

  Altering table encryption by moving a table to a different tablespace or changing the storage engine is not permitted without explicitly specifying an `ENCRYPTION` clause.

  As of MySQL 8.0.16, specifying an `ENCRYPTION` clause with a value other than 'N' or '' is not permitted if the table uses a storage engine that does not support encryption. Previously, the clause was accepted. Attempting to create a table without an `ENCRYPTION` clause in an encryption-enabled schema using a storage engine that does not support encryption is also not permitted.

  For more information, see Section 15.13, “InnoDB Data-at-Rest Encryption”.

- To reset the current auto-increment value:

  ```
  ALTER TABLE t1 AUTO_INCREMENT = 13;
  ```

  You cannot reset the counter to a value less than or equal to the value that is currently in use. For both InnoDB and MyISAM, if the value is less than or equal to the maximum value currently in the `AUTO_INCREMENT` column, the value is reset to the current maximum `AUTO_INCREMENT` column value plus one.

- To change the default table character set:

  ```
  ALTER TABLE t1 CHARACTER SET = utf8;
  ```

  See also Changing the Character Set.

- To add (or change) a table comment:

  ```
  ALTER TABLE t1 COMMENT = 'New table comment';
  ```

- Use `ALTER TABLE` with the `TABLESPACE` option to move InnoDB tables between existing general tablespaces, file-per-table tablespaces, and the system tablespace. See Moving Tables Between Tablespaces Using ALTER TABLE.

  - `ALTER TABLE ... TABLESPACE` operations always cause a full table rebuild, even if the `TABLESPACE` attribute has not changed from its previous value.

  - `ALTER TABLE ... TABLESPACE` syntax does not support moving a table from a temporary tablespace to a persistent tablespace.

  - The `DATA DIRECTORY` clause, which is supported with `CREATE TABLE ... TABLESPACE`, is not supported with `ALTER TABLE ... TABLESPACE`, and is ignored if specified.

  - For more information about the capabilities and limitations of the `TABLESPACE` option, see `CREATE TABLE`.

- MySQL NDB Cluster 8.0 supports setting `NDB_TABLE` options for controlling a table's partition balance (fragment count type), read-from-any-replica capability, full replication, or any combination...
of these, as part of the table comment for an ALTER TABLE statement in the same manner as for CREATE TABLE, as shown in this example:

```sql
ALTER TABLE t1 COMMENT = "NDB_TABLE=READ_BACKUP=0,PARTITION_BALANCE=FOR_RA_BY_NODE";
```

Bear in mind that ALTER TABLE ... COMMENT ... discards any existing comment for the table. See Setting NDB_TABLE options, for additional information and examples.

- ENGINE_ATTRIBUTE and SECONDARY_ENGINE_ATTRIBUTE options (available as of MySQL 8.0.21) are used to specify table, column, and index attributes for primary and secondary storage engines. The options are reserved for future use. Index attributes cannot be altered. An index must be dropped and added back with the desired change, which can be performed in a single ALTER TABLE statement.

To verify that the table options were changed as intended, use `SHOW CREATE TABLE`, or query the INFORMATION_SCHEMA.TABLES table.

### Performance and Space Requirements

ALTER TABLE operations are processed using one of the following algorithms:

- **COPY**: Operations are performed on a copy of the original table, and table data is copied from the original table to the new table row by row. Concurrent DML is not permitted.

- **INPLACE**: Operations avoid copying table data but may rebuild the table in place. An exclusive metadata lock on the table may be taken briefly during preparation and execution phases of the operation. Typically, concurrent DML is supported.

- **INSTANT**: Operations only modify metadata in the data dictionary. No exclusive metadata locks are taken on the table during preparation and execution, and table data is unaffected, making operations instantaneous. Concurrent DML is permitted. (Introduced in MySQL 8.0.12)

The ALGORITHM clause is optional. If the ALGORITHM clause is omitted, MySQL uses ALGORITHM=INSTANT for storage engines and ALTER TABLE clauses that support it. Otherwise, ALGORITHM=INPLACE is used. If ALGORITHM=INPLACE is not supported, ALGORITHM=COPY is used.

Specifying an ALGORITHM clause requires the operation to use the specified algorithm for clauses and storage engines that support it, or fail with an error otherwise. Specifying ALGORITHM=DEFAULT is the same as omitting the ALGORITHM clause.

ALTER TABLE operations that use the COPY algorithm wait for other operations that are modifying the table to complete. After alterations are applied to the table copy, data is copied over, the original table is deleted, and the table copy is renamed to the name of the original table. While the ALTER TABLE operation executes, the original table is readable by other sessions (with the exception noted shortly). Updates and writes to the table started after the ALTER TABLE operation begins are stalled until the new table is ready, then are automatically redirected to the new table. The temporary copy of the table is created in the database directory of the original table unless it is a RENAME TO operation that moves the table to a database that resides in a different directory.

The exception referred to earlier is that ALTER TABLE blocks reads (not just writes) at the point where it is ready to clear outdated table structures from the table and table definition caches. At this point, it must acquire an exclusive lock. To do so, it waits for current readers to finish, and blocks new reads and writes.

An ALTER TABLE operation that uses the COPY algorithm prevents concurrent DML operations. Concurrent queries are still allowed. That is, a table-copying operation always includes at least the concurrency restrictions of LOCK=SHARED (allow queries but not DML). You can further restrict concurrency for operations that support the LOCK clause by specifying LOCK=EXCLUSIVE, which prevents DML and queries. For more information, see Concurrency Control.

To force use of the COPY algorithm for an ALTER TABLE operation that would otherwise not use it, specify ALGORITHM=COPY or enable the old_alter_table system variable. If there is a conflict
between the `old_alter_table` setting and an `ALGORITHM` clause with a value other than `DEFAULT`, the `ALGORITHM` clause takes precedence.

For InnoDB tables, an `ALTER TABLE` operation that uses the `COPY` algorithm on a table that resides in a `shared tablespace` can increase the amount of space used by the tablespace. Such operations require as much additional space as the data in the table plus indexes. For a table residing in a shared tablespace, the additional space used during the operation is not released back to the operating system as it is for a table that resides in a `file-per-table` tablespace.

For information about space requirements for online DDL operations, see Section 15.12.3, “Online DDL Space Requirements”.

`ALTER TABLE` operations that support the `INPLACE` algorithm include:

- `ALTER TABLE` operations supported by the InnoDB online DDL feature. See Section 15.12.1, “Online DDL Operations”.

- Renaming a table. MySQL renames files that correspond to the table `tbl_name` without making a copy. (You can also use the `RENAME TABLE` statement to rename tables. See Section 13.1.36, “RENAME TABLE Statement”.) Privileges granted specifically for the renamed table are not migrated to the new name. They must be changed manually.

- Operations that only modify table metadata. These operations are immediate because the server does not touch table contents. Metadata-only operations include:
  - Renaming a column. In NDB Cluster 8.0.18 and later, this operation can also be performed online.
  - Changing the default value of a column (except for NDB tables).
  - Modifying the definition of an `ENUM` or `SET` column by adding new enumeration or set members to the `end` of the list of valid member values, as long as the storage size of the data type does not change. For example, adding a member to a `SET` column that has 8 members changes the required storage per value from 1 byte to 2 bytes; this requires a table copy. Adding members in the middle of the list causes renumbering of existing members, which requires a table copy.
  - Changing the definition of a spatial column to remove the `SRID` attribute. (Adding or changing an `SRID` attribute does require a rebuild and cannot be done in place because the server must verify that all values have the specified SRID value.)
  - As of MySQL 8.0.14, changing a column character set, when these conditions apply:
    - The column data type is `CHAR`, `VARCHAR`, a `TEXT` type, or `ENUM`.
    - The character set change is from `utf8mb3` to `utf8mb4`, or any character set to `binary`.
    - There is no index on the column.
  - As of MySQL 8.0.14, changing a generated column, when these conditions apply:
    - For InnoDB tables, statements that modify generated stored columns but do not change their type, expression, or nullability.
    - For non-InnoDB tables, statements that modify generated stored or virtual columns but do not change their type, expression, or nullability.
    - An example of such a change is a change to the column comment.
  - Renaming an index.
  - Adding or dropping a secondary index, for InnoDB and NDB tables. See Section 15.12.1, “Online DDL Operations”.

2294
For NDB tables, operations that add and drop indexes on variable-width columns. These operations occur online, without table copying and without blocking concurrent DML actions for most of their duration. See Section 23.5.11, “Online Operations with ALTER TABLE in NDB Cluster”.

Modifying index visibility with an ALTER_INDEX operation.

Column modifications of tables containing generated columns that depend on columns with a DEFAULT value if the modified columns are not involved in the generated column expressions. For example, changing the NULL property of a separate column can be done in place without a table rebuild.

ALTER_TABLE operations that support the INSTANT algorithm include:

- Adding a column. This feature is referred to as “Instant ADD COLUMN”. Limitations apply. See Section 15.12.1, “Online DDL Operations”.
- Adding or dropping a virtual column.
- Adding or dropping a column default value.
- Modifying the definition of an ENUM or SET column. The same restrictions apply as described above for ALGORITHM=INSTANT.
- Changing the index type.
- Renaming a table. The same restrictions apply as described above for ALGORITHM=INSTANT.

For more information about operations that support ALGORITHM=INSTANT, see Section 15.12.1, “Online DDL Operations”.

ALTER_TABLE upgrades MySQL 5.5 temporal columns to 5.6 format for ADD_COLUMN, CHANGE COLUMN, MODIFY COLUMN, ADD_INDEX, and FORCE operations. This conversion cannot be done using the INPLACE algorithm because the table must be rebuilt, so specifying ALGORITHM=INPLACE in these cases results in an error. Specify ALGORITHM=COPY if necessary.

If an ALTER_TABLE operation on a multicolumn index used to partition a table by KEY changes the order of the columns, it can only be performed using ALGORITHM=COPY.

The WITHOUT VALIDATION and WITH VALIDATION clauses affect whether ALTER_TABLE performs an in-place operation for virtual generated column modifications. See Section 13.1.9.2, “ALTER_TABLE and Generated Columns”.

NDB Cluster 8.0 supports online operations using the same ALGORITHM=INPLACE syntax used with the standard MySQL Server. NDB does not support changing a tablespace online; beginning with NDB 8.0.21, it is disallowed. See Section 23.5.11, “Online Operations with ALTER_TABLE in NDB Cluster”, for more information.

ALTER_TABLE with DISCARD ... PARTITION ... TABLESPACE or IMPORT ... PARTITION ... TABLESPACE does not create any temporary tables or temporary partition files.

ALTER_TABLE with ADD_PARTITION, DROP_PARTITION, COALESCE_PARTITION, REBUILD_PARTITION, or REORGANIZE_PARTITION does not create temporary tables (except when used with NDB tables); however, these operations can and do create temporary partition files.

ADD or DROP operations for RANGE or LIST partitions are immediate operations or nearly so. ADD or COALESCE operations for HASH or KEY partitions copy data between all partitions, unless LINEAR_HASH or LINEAR_KEY was used; this is effectively the same as creating a new table, although the ADD or COALESCE operation is performed partition by partition. REORGANIZE operations copy only changed partitions and do not touch unchanged ones.

For MyISAM tables, you can speed up index re-creation (the slowest part of the alteration process) by setting the myisam_sort_buffer_size system variable to a high value.
Concurreny Control

For ALTER TABLE operations that support it, you can use the LOCK clause to control the level of concurrent reads and writes on a table while it is being altered. Specifying a non-default value for this clause enables you to require a certain amount of concurrent access or exclusivity during the alter operation, and halts the operation if the requested degree of locking is not available.

Only LOCK = DEFAULT is permitted for operations that use ALGORITHM=INSTANT. The other LOCK clause parameters are not applicable.

The parameters for the LOCK clause are:

- **LOCK = DEFAULT**
  Maximum level of concurrency for the given ALGORITHM clause (if any) and ALTER TABLE operation: Permit concurrent reads and writes if supported. If not, permit concurrent reads if supported. If not, enforce exclusive access.

- **LOCK = NONE**
  If supported, permit concurrent reads and writes. Otherwise, an error occurs.

- **LOCK = SHARED**
  If supported, permit concurrent reads but block writes. Writes are blocked even if concurrent writes are supported by the storage engine for the given ALGORITHM clause (if any) and ALTER TABLE operation. If concurrent reads are not supported, an error occurs.

- **LOCK = EXCLUSIVE**
  Enforce exclusive access. This is done even if concurrent reads/writes are supported by the storage engine for the given ALGORITHM clause (if any) and ALTER TABLE operation.

Adding and Dropping Columns

Use ADD to add new columns to a table, and DROP to remove existing columns. DROP col_name is a MySQL extension to standard SQL.

To add a column at a specific position within a table row, use FIRST or AFTER col_name. The default is to add the column last.

If a table contains only one column, the column cannot be dropped. If what you intend is to remove the table, use the DROP TABLE statement instead.

If columns are dropped from a table, the columns are also removed from any index of which they are a part. If all columns that make up an index are dropped, the index is dropped as well. If you use CHANGE or MODIFY to shorten a column for which an index exists on the column, and the resulting column length is less than the index length, MySQL shortens the index automatically.

For ALTER TABLE ... ADD, if the column has an expression default value that uses a nondeterministic function, the statement may produce a warning or error. For further information, see Section 11.6, “Data Type Default Values”, and Section 17.1.3.7, “Restrictions on Replication with GTIDs”.

Renaming, Redefining, and Reordering Columns

The CHANGE, MODIFY, RENAME COLUMN, and ALTER clauses enable the names and definitions of existing columns to be altered. They have these comparative characteristics:

- **CHANGE**:

  - Can rename a column and change its definition, or both.
ALTER TABLE Statement

- Has more capability than MODIFY or RENAME COLUMN, but at the expense of convenience for some operations. CHANGE requires naming the column twice if not renaming it, and requires respecifying the column definition if only renaming it.
- With FIRST or AFTER, can reorder columns.
- MODIFY:
  - Can change a column definition but not its name.
  - More convenient than CHANGE to change a column definition without renaming it.
- With FIRST or AFTER, can reorder columns.
- RENAME COLUMN:
  - Can change a column name but not its definition.
  - More convenient than CHANGE to rename a column without changing its definition.
- ALTER: Used only to change a column default value.

CHANGE is a MySQL extension to standard SQL. MODIFY and RENAME COLUMN are MySQL extensions for Oracle compatibility.

To alter a column to change both its name and definition, use CHANGE, specifying the old and new names and the new definition. For example, to rename an INT NOT NULL column from a to b and change its definition to use the BIGINT data type while retaining the NOT NULL attribute, do this:

```
ALTER TABLE t1 CHANGE a b BIGINT NOT NULL;
```

To change a column definition but not its name, use CHANGE or MODIFY. With CHANGE, the syntax requires two column names, so you must specify the same name twice to leave the name unchanged. For example, to change the definition of column b, do this:

```
ALTER TABLE t1 CHANGE b b INT NOT NULL;
```

MODIFY is more convenient to change the definition without changing the name because it requires the column name only once:

```
ALTER TABLE t1 MODIFY b INT NOT NULL;
```

To change a column name but not its definition, use CHANGE or RENAME COLUMN. With CHANGE, the syntax requires a column definition, so to leave the definition unchanged, you must respecify the definition the column currently has. For example, to rename an INT NOT NULL column from b to a, do this:

```
ALTER TABLE t1 CHANGE b a INT NOT NULL;
```

RENAME COLUMN is more convenient to change the name without changing the definition because it requires only the old and new names:

```
ALTER TABLE t1 RENAME COLUMN b TO a;
```

In general, you cannot rename a column to a name that already exists in the table. However, this is sometimes not the case, such as when you swap names or move them through a cycle. If a table has columns named a, b, and c, these are valid operations:

```
-- swap a and b
ALTER TABLE t1 RENAME COLUMN a TO b,
    RENAME COLUMN b TO a;
-- "rotate" a, b, c through a cycle
ALTER TABLE t1 RENAME COLUMN a TO b,
    RENAME COLUMN b TO c,
```
ALTER TABLE Statement

RENAME COLUMN c TO a;

For column definition changes using CHANGE or MODIFY, the definition must include the data type and all attributes that should apply to the new column, other than index attributes such as PRIMARY KEY or UNIQUE. Attributes present in the original definition but not specified for the new definition are not carried forward. Suppose that a column `col1` is defined as `INT UNSIGNED DEFAULT 1 COMMENT 'my column'` and you modify the column as follows, intending to change only `INT` to `BIGINT`:

```
ALTER TABLE t1 MODIFY col1 BIGINT;
```

That statement changes the data type from `INT` to `BIGINT`, but it also drops the `UNSIGNED`, `DEFAULT`, and `COMMENT` attributes. To retain them, the statement must include them explicitly:

```
ALTER TABLE t1 MODIFY col1 BIGINT UNSIGNED DEFAULT 1 COMMENT 'my column';
```

For data type changes using CHANGE or MODIFY, MySQL tries to convert existing column values to the new type as well as possible.

**Warning**

This conversion may result in alteration of data. For example, if you shorten a string column, values may be truncated. To prevent the operation from succeeding if conversions to the new data type would result in loss of data, enable strict SQL mode before using ALTER TABLE (see Section 5.1.11, “Server SQL Modes”).

If you use CHANGE or MODIFY to shorten a column for which an index exists on the column, and the resulting column length is less than the index length, MySQL shortens the index automatically.

For columns renamed by CHANGE or RENAME COLUMN, MySQL automatically renames these references to the renamed column:

- Indexes that refer to the old column, including invisible indexes and disabled MyISAM indexes.
- Foreign keys that refer to the old column.

For columns renamed by CHANGE or RENAME COLUMN, MySQL does not automatically rename these references to the renamed column:

- Generated column and partition expressions that refer to the renamed column. You must use CHANGE to redefine such expressions in the same ALTER TABLE statement as the one that renames the column.
- Views and stored programs that refer to the renamed column. You must manually alter the definition of these objects to refer to the new column name.

To reorder columns within a table, use FIRST and AFTER in CHANGE or MODIFY operations.

```
ALTER ... SET DEFAULT or ALTER ... DROP DEFAULT specify a new default value for a column or remove the old default value, respectively. If the old default is removed and the column can be NULL, the new default is NULL. If the column cannot be NULL, MySQL assigns a default value as described in Section 11.6, “Data Type Default Values”.
```

As of MySQL 8.0.23, ALTER ... SET VISIBLE and ALTER ... SET INVISIBLE enable column visibility to be changed. See Section 13.1.20.10, “Invisible Columns”.

**Primary Keys and Indexes**

```
DROP PRIMARY KEY drops the primary key. If there is no primary key, an error occurs. For information about the performance characteristics of primary keys, especially for InnoDB tables, see Section 8.3.2, “Primary Key Optimization”.
```

If the sql_require_primary_key system variable is enabled, attempting to drop a primary key produces an error.
If you add a `UNIQUE INDEX` or `PRIMARY KEY` to a table, MySQL stores it before any nonunique index to permit detection of duplicate keys as early as possible.

`DROP INDEX` removes an index. This is a MySQL extension to standard SQL. See Section 13.1.27, “DROP INDEX Statement”. To determine index names, use `SHOW INDEX FROM tbl_name`.

Some storage engines permit you to specify an index type when creating an index. The syntax for the `index_type` specifier is `USING type_name`. For details about `USING`, see Section 13.1.15, “CREATE INDEX Statement”. The preferred position is after the column list. Expect support for use of the option before the column list to be removed in a future MySQL release.

`index_option` values specify additional options for an index. `USING` is one such option. For details about permissible `index_option` values, see Section 13.1.15, “CREATE INDEX Statement”.

`RENAME INDEX old_index_name TO new_index_name` renames an index. This is a MySQL extension to standard SQL. The content of the table remains unchanged. `old_index_name` must be the name of an existing index in the table that is not dropped by the same `ALTER TABLE` statement. `new_index_name` is the new index name, which cannot duplicate the name of an index in the resulting table after changes have been applied. Neither index name can be `PRIMARY`.

If you use `ALTER TABLE` on a `MyISAM` table, all nonunique indexes are created in a separate batch (as for `REPAIR TABLE`). This should make `ALTER TABLE` much faster when you have many indexes.

For `MyISAM` tables, key updating can be controlled explicitly. Use `ALTER TABLE ... DISABLE KEYS` to tell MySQL to stop updating nonunique indexes. Then use `ALTER TABLE ... ENABLE KEYS` to re-create missing indexes. `MyISAM` does this with a special algorithm that is much faster than inserting keys one by one, so disabling keys before performing bulk insert operations should give a considerable speedup. Using `ALTER TABLE ... DISABLE KEYS` requires the `INDEX` privilege in addition to the privileges mentioned earlier.

While the nonunique indexes are disabled, they are ignored for statements such as `SELECT` and `EXPLAIN` that otherwise would use them.

After an `ALTER TABLE` statement, it may be necessary to run `ANALYZE TABLE` to update index cardinality information. See Section 13.7.7.22, “SHOW INDEX Statement”.

The `ALTER INDEX` operation permits an index to be made visible or invisible. An invisible index is not used by the optimizer. Modification of index visibility applies to indexes other than primary keys (either explicit or implicit). This feature is storage engine neutral (supported for any engine). For more information, see Section 8.3.12, “Invisible Indexes”.

### Foreign Keys and Other Constraints

The `FOREIGN KEY` and `REFERENCES` clauses are supported by the `InnoDB` and `NDB` storage engines, which implement [ADD [CONSTRAINT [symbol]] FOREIGN KEY [index_name] (...) REFERENCES ... (...)]. See Section 13.1.20.5, “FOREIGN KEY Constraints”. For other storage engines, the clauses are parsed but ignored.

For `ALTER TABLE`, unlike `CREATE TABLE`, `ADD FOREIGN KEY` ignores `index_name` if given and uses an automatically generated foreign key name. As a workaround, include the `CONSTRAINT` clause to specify the foreign key name:

```
ADD CONSTRAINT name FOREIGN KEY (.....) ... 
```

**Important**

MySQL silently ignores inline `REFERENCES` specifications, where the references are defined as part of the column specification. MySQL accepts only `REFERENCES` clauses defined as part of a separate `FOREIGN KEY` specification.
My SQL Server and NDB Cluster both support the use of \texttt{ALTER TABLE} to drop foreign keys:

\begin{verbatim}
ALTER TABLE tbl_name DROP FOREIGN KEY fk_symbol;
\end{verbatim}

Adding and dropping a foreign key in the same \texttt{ALTER TABLE} statement is supported for \texttt{ALTER TABLE ... ALGORITHM=INPLACE} but not for \texttt{ALTER TABLE ... ALGORITHM=COPY}.

The server prohibits changes to foreign key columns that have the potential to cause loss of referential integrity. A workaround is to use \texttt{ALTER TABLE ... DROP FOREIGN KEY} before changing the column definition and \texttt{ALTER TABLE ... ADD FOREIGN KEY} afterward. Examples of prohibited changes include:

\begin{itemize}
  \item Changes to the data type of foreign key columns that may be unsafe. For example, changing \texttt{VARCHAR(20)} to \texttt{VARCHAR(30)} is permitted, but changing it to \texttt{VARCHAR(1024)} is not because that alters the number of length bytes required to store individual values.
  \item Changing a \texttt{NULL} column to \texttt{NOT NULL} in non-strict mode is prohibited to prevent converting \texttt{NULL} values to default non-\texttt{NULL} values, for which there are no corresponding values in the referenced table. The operation is permitted in strict mode, but an error is returned if any such conversion is required.
\end{itemize}

\texttt{ALTER TABLE tbl_name RENAME new_tbl_name} changes internally generated foreign key constraint names and user-defined foreign key constraint names that begin with the string “\texttt{tbl_name}_ibfk_” to reflect the new table name. InnoDB interprets foreign key constraint names that begin with the string “\texttt{tbl_name}_ibfk_” as internally generated names.

Prior to MySQL 8.0.16, \texttt{ALTER TABLE} permits only the following limited version of \texttt{CHECK} constraint-adding syntax, which is parsed and ignored:

\begin{verbatim}
ADD CHECK (expr)
\end{verbatim}

As of MySQL 8.0.16, \texttt{ALTER TABLE} permits \texttt{CHECK} constraints for existing tables to be added, dropped, or altered:

\begin{itemize}
  \item Add a new \texttt{CHECK} constraint:
    \begin{verbatim}
    ALTER TABLE tbl_name
    ADD CONSTRAINT [symbol] CHECK (expr) [[NOT] ENFORCED];
    \end{verbatim}
    The meaning of constraint syntax elements is the same as for \texttt{CREATE TABLE}. See Section 13.1.20.6, “CHECK Constraints”.
  \item Drop an existing \texttt{CHECK} constraint named \texttt{symbol}:
    \begin{verbatim}
    ALTER TABLE tbl_name
    DROP CHECK symbol;
    \end{verbatim}
  \item Alter whether an existing \texttt{CHECK} constraint named \texttt{symbol} is enforced:
    \begin{verbatim}
    ALTER TABLE tbl_name
    ALTER CHECK symbol [NOT] ENFORCED;
    \end{verbatim}
\end{itemize}

The \texttt{DROP CHECK} and \texttt{ALTER CHECK} clauses are MySQL extensions to standard SQL.

As of MySQL 8.0.19, \texttt{ALTER TABLE} permits more general (and SQL standard) syntax for dropping and altering existing constraints of any type, where the constraint type is determined from the constraint name:
• Drop an existing constraint named `symbol`:

```
ALTER TABLE tbl_name
  DROP CONSTRAINT symbol;
```

If the `sql_require_primary_key` system variable is enabled, attempting to drop a primary key produces an error.

• Alter whether an existing constraint named `symbol` is enforced:

```
ALTER TABLE tbl_name
  ALTER CONSTRAINT symbol [NOT] ENFORCED;
```

Only `CHECK` constraints can be altered to be unenforced. All other constraint types are always enforced.

The SQL standard specifies that all types of constraints (primary key, unique index, foreign key, check) belong to the same namespace. In MySQL, each constraint type has its own namespace per schema. Consequently, names for each type of constraint must be unique per schema, but constraints of different types can have the same name. When multiple constraints have the same name, `DROP CONSTRAINT` and `ADD CONSTRAINT` are ambiguous and an error occurs. In such cases, constraint-specific syntax must be used to modify the constraint. For example, use `DROP PRIMARY KEY` or `DROP FOREIGN KEY` to drop a primary key or foreign key.

If a table alteration causes a violation of an enforced `CHECK` constraint, an error occurs and the table is not modified. Examples of operations for which an error occurs:

• Attempts to add the `AUTO_INCREMENT` attribute to a column that is used in a `CHECK` constraint.

• Attempts to add an enforced `CHECK` constraint or enforce a nonenforced `CHECK` constraint for which existing rows violate the constraint condition.

• Attempts to modify, rename, or drop a column that is used in a `CHECK` constraint, unless that constraint is also dropped in the same statement. Exception: If a `CHECK` constraint refers only to a single column, dropping the column automatically drops the constraint.

```
ALTER TABLE tbl_name RENAME new_tbl_name
```

changes internally generated and user-defined `CHECK` constraint names that begin with the string “`tbl_name_chk_” to reflect the new table name. MySQL interprets `CHECK` constraint names that begin with the string “`tbl_name_chk_” as internally generated names.

### Changing the Character Set

To change the table default character set and all character columns (`CHAR`, `VARCHAR`, `TEXT`) to a new character set, use a statement like this:

```
ALTER TABLE tbl_name CONVERT TO CHARACTER SET charset_name;
```

The statement also changes the collation of all character columns. If you specify no `COLLATE` clause to indicate which collation to use, the statement uses default collation for the character set. If this collation is inappropriate for the intended table use (for example, if it would change from a case-sensitive collation to a case-insensitive collation), specify a collation explicitly.

For a column that has a data type of `VARCHAR` or one of the `TEXT` types, `CONVERT TO CHARACTER SET` changes the data type as necessary to ensure that the new column is long enough to store as many characters as the original column. For example, a `TEXT` column has two length bytes, which store the byte-length of values in the column, up to a maximum of 65,535. For a `latin1 TEXT` column, each character requires a single byte, so the column can store up to 65,535 characters. If the column is converted to `utf8`, each character might require up to three bytes, for a maximum possible length of $3 \times 65,535 = 196,605$ bytes. That length does not fit in a `TEXT` column's length bytes, so MySQL converts the data type to `MEDIUMTEXT`, which is the smallest string type for which the length bytes can record a value of 196,605. Similarly, a `VARCHAR` column might be converted to `MEDIUMTEXT`. 
To avoid data type changes of the type just described, do not use `CONVERT TO CHARACTER SET`. Instead, use `MODIFY` to change individual columns. For example:

```
ALTER TABLE t MODIFY latin1_text_col TEXT CHARACTER SET utf8;
ALTER TABLE t MODIFY latin1_varchar_col VARCHAR(M) CHARACTER SET utf8;
```

If you specify `CONVERT TO CHARACTER SET binary`, the `CHAR`, `VARCHAR`, and `TEXT` columns are converted to their corresponding binary string types (`BINARY`, `VARBINARY`, `BLOB`). This means that the columns no longer have a character set and a subsequent `CONVERT TO` operation does not apply to them.

If `charset_name` is `DEFAULT` in a `CONVERT TO CHARACTER SET` operation, the character set named by the `character_set_database` system variable is used.

**Warning**
The `CONVERT TO` operation converts column values between the original and named character sets. This is *not* what you want if you have a column in one character set (like `latin1`) but the stored values actually use some other, incompatible character set (like `utf8`). In this case, you have to do the following for each such column:

```
ALTER TABLE t1 CHANGE c1 c1 BLOB;
ALTER TABLE t1 CHANGE c1 c1 TEXT CHARACTER SET utf8;
```

The reason this works is that there is no conversion when you convert to or from `BLOB` columns.

To change only the `default` character set for a table, use this statement:

```
ALTER TABLE tbl_name DEFAULT CHARACTER SET charset_name;
```

The word `DEFAULT` is optional. The default character set is the character set that is used if you do not specify the character set for columns that you add to a table later (for example, with `ALTER TABLE ... ADD column`).

When the `foreign_key_checks` system variable is enabled, which is the default setting, character set conversion is not permitted on tables that include a character string column used in a foreign key constraint. The workaround is to disable `foreign_key_checks` before performing the character set conversion. You must perform the conversion on both tables involved in the foreign key constraint before re-enabling `foreign_key_checks`. If you re-enable `foreign_key_checks` after converting only one of the tables, an `ON DELETE CASCADE` or `ON UPDATE CASCADE` operation could corrupt data in the referencing table due to implicit conversion that occurs during these operations (Bug #45290, Bug #74816).

**Importing InnoDB Tables**

An InnoDB table created in its own `file-per-table` tablespace can be imported from a backup or from another MySQL server instance using `DISCARD TABLESPACE` and `IMPORT TABLESPACE` clauses. See Section 15.6.1.3, “Importing InnoDB Tables”.

**Row Order for MyISAM Tables**

`ORDER BY` enables you to create the new table with the rows in a specific order. This option is useful primarily when you know that you query the rows in a certain order most of the time. By using this option after major changes to the table, you might be able to get higher performance. In some cases, it might make sorting easier for MySQL if the table is in order by the column that you want to order it by later.

**Note**
The table does not remain in the specified order after inserts and deletes.
ALTER TABLE Statement

ORDER BY syntax permits one or more column names to be specified for sorting, each of which optionally can be followed by ASC or DESC to indicate ascending or descending sort order, respectively. The default is ascending order. Only column names are permitted as sort criteria; arbitrary expressions are not permitted. This clause should be given last after any other clauses.

ORDER BY does not make sense for InnoDB tables because InnoDB always orders table rows according to the clustered index.

When used on a partitioned table, ALTER TABLE ... ORDER BY orders rows within each partition only.

Partitioning Options

partition_options signifies options that can be used with partitioned tables for repartitioning, to add, drop, discard, import, merge, and split partitions, and to perform partitioning maintenance.

It is possible for an ALTER TABLE statement to contain a PARTITION BY or REMOVE PARTITIONING clause in an addition to other alter specifications, but the PARTITION BY or REMOVE PARTITIONING clause must be specified last after any other specifications. The ADD PARTITION, DROP PARTITION, DISCARD PARTITION, IMPORT PARTITION, COALESCE PARTITION, REORGANIZE PARTITION, EXCHANGE PARTITION, ANALYZE PARTITION, CHECK PARTITION, and REPAIR PARTITION options cannot be combined with other alter specifications in a single ALTER TABLE, since the options just listed act on individual partitions.

For more information about partition options, see Section 13.1.20, “CREATE TABLE Statement”, and Section 13.1.9.1, “ALTER TABLE Partition Operations”. For information about and examples of ALTER TABLE ... EXCHANGE PARTITION statements, see Section 24.3.3, “Exchanging Partitions and Subpartitions with Tables”.

13.1.9.1 ALTER TABLE Partition Operations

Partitioning-related clauses for ALTER TABLE can be used with partitioned tables for repartitioning, to add, drop, discard, import, merge, and split partitions, and to perform partitioning maintenance.

• Simply using a partition_options clause with ALTER TABLE on a partitioned table repartitions the table according to the partitioning scheme defined by the partition_options. This clause always begins with PARTITION BY, and follows the same syntax and other rules as apply to the partition_options clause for CREATE TABLE (for more detailed information, see Section 13.1.20, “CREATE TABLE Statement”), and can also be used to partition an existing table that is not already partitioned. For example, consider a (nonpartitioned) table defined as shown here:

```sql
CREATE TABLE t1 (
    id INT,
    year_col INT
);
```

This table can be partitioned by HASH, using the id column as the partitioning key, into 8 partitions by means of this statement:

```sql
ALTER TABLE t1
    PARTITION BY HASH(id)
    PARTITIONS 8;
```

MySQL supports an ALGORITHM option with [SUB]PARTITION BY [LINEAR] KEY. ALGORITHM=1 causes the server to use the same key-hashing functions as MySQL 5.1 when computing the placement of rows in partitions; ALGORITHM=2 means that the server employs the key-hashing functions implemented and used by default for new KEY partitioned tables in MySQL 5.5 and later. (Partitioned tables created with the key-hashing functions employed in MySQL 5.5 and later cannot be used by a MySQL 5.1 server.) Not specifying the option has the same effect as using ALGORITHM=2. This option is intended for use chiefly when upgrading or downgrading [LINEAR] KEY partitioned tables between MySQL 5.1 and later MySQL versions, or for creating
tables partitioned by `KEY` or `LINEAR KEY` on a MySQL 5.5 or later server which can be used on a MySQL 5.1 server.

The table that results from using an `ALTER TABLE ... PARTITION BY` statement must follow the same rules as one created using `CREATE TABLE ... PARTITION BY`. This includes the rules governing the relationship between any unique keys (including any primary key) that the table might have, and the column or columns used in the partitioning expression, as discussed in Section 24.6.1, “Partitioning Keys, Primary Keys, and Unique Keys”. The `CREATE TABLE ... PARTITION BY` rules for specifying the number of partitions also apply to `ALTER TABLE ... PARTITION BY`.

The `partition_definition` clause for `ALTER TABLE ADD PARTITION` supports the same options as the clause of the same name for the `CREATE TABLE` statement. (See Section 13.1.20, “CREATE TABLE Statement”, for the syntax and description.) Suppose that you have the partitioned table created as shown here:

```sql
CREATE TABLE t1 {
    id INT,
    year_col INT
} PARTITION BY RANGE (year_col) {
    PARTITION p0 VALUES LESS THAN (1991),
    PARTITION p1 VALUES LESS THAN (1995),
    PARTITION p2 VALUES LESS THAN (1999)
};
```

You can add a new partition `p3` to this table for storing values less than 2002 as follows:

```sql
ALTER TABLE t1 ADD PARTITION (PARTITION p3 VALUES LESS THAN (2002));
```

`DROP PARTITION` can be used to drop one or more `RANGE` or `LIST` partitions. This statement cannot be used with `HASH` or `KEY` partitions; instead, use `COALESCE PARTITION` (see later in this section). Any data that was stored in the dropped partitions named in the `partition_names` list is discarded. For example, given the table `t1` defined previously, you can drop the partitions named `p0` and `p1` as shown here:

```sql
ALTER TABLE t1 DROP PARTITION p0, p1;
```

Note

`DROP PARTITION` does not work with tables that use the NDB storage engine. See Section 24.3.1, “Management of RANGE and LIST Partitions”, and Section 23.1.7, “Known Limitations of NDB Cluster”.

`ADD PARTITION` and `DROP PARTITION` do not currently support `IF [NOT] EXISTS`.

The `DISCARD PARTITION ... TABLESPACE` and `IMPORT PARTITION ... TABLESPACE` options extend the Transportable Tablespace feature to individual InnoDB table partitions. Each InnoDB table partition has its own tablespace file (.ibd file). The Transportable Tablespace feature makes it easy to copy the tablespaces from a running MySQL server instance to another running
instance, or to perform a restore on the same instance. Both options take a comma-separated list of one or more partition names. For example:

```sql
ALTER TABLE t1 DISCARD PARTITION p2, p3 TABLESPACE;
ALTER TABLE t1 IMPORT PARTITION p2, p3 TABLESPACE;
```

When running `DISCARD PARTITION ... TABLESPACE` and `IMPORT PARTITION ... TABLESPACE` on subpartitioned tables, both partition and subpartition names are allowed. When a partition name is specified, subpartitions of that partition are included.

Renames of partitioned tables are supported. You can rename individual partitions indirectly using `ALTER TABLE ... REORGANIZE PARTITION`; however, this operation copies the partition's data.

To delete rows from selected partitions, use the `TRUNCATE PARTITION` option. This option takes a list of one or more comma-separated partition names. Consider the table `t1` created by this statement:

```sql
CREATE TABLE t1 (  
id INT,  
year_col INT
)  
PARTITION BY RANGE (year_col) (  
PARTITION p0 VALUES LESS THAN (1991),  
PARTITION p1 VALUES LESS THAN (1995),  
PARTITION p2 VALUES LESS THAN (1999),  
PARTITION p3 VALUES LESS THAN (2003),  
PARTITION p4 VALUES LESS THAN (2007)
);
```

To delete all rows from partition `p0`, use the following statement:

```sql
ALTER TABLE t1 TRUNCATE PARTITION p0;
```

The statement just shown has the same effect as the following `DELETE` statement:

```sql
DELETE FROM t1 WHERE year_col < 1991;
```

When truncating multiple partitions, the partitions do not have to be contiguous: This can greatly simplify delete operations on partitioned tables that would otherwise require very complex `WHERE` conditions if done with `DELETE` statements. For example, this statement deletes all rows from partitions `p1` and `p3`:

```sql
ALTER TABLE t1 TRUNCATE PARTITION p1, p3;
```

An equivalent `DELETE` statement is shown here:

```sql
DELETE FROM t1 WHERE  
    (year_col >= 1991 AND year_col < 1995)  
    OR  
    (year_col >= 2003 AND year_col < 2007);
```

If you use the `ALL` keyword in place of the list of partition names, the statement acts on all table partitions.

`TRUNCATE PARTITION` merely deletes rows; it does not alter the definition of the table itself, or of any of its partitions.

To verify that the rows were dropped, check the `INFORMATION_SCHEMA.PARTITIONS` table, using a query such as this one:

```sql
SELECT PARTITION_NAME, TABLE_ROWS
```
COALESCE PARTITION can be used with a table that is partitioned by HASH or KEY to reduce the number of partitions by number. Suppose that you have created table t2 as follows:

```sql
CREATE TABLE t2 (
    name VARCHAR (30),
    started DATE
) PARTITION BY HASH(YEAR(started)) PARTITIONS 6;
```

To reduce the number of partitions used by t2 from 6 to 4, use the following statement:

```sql
ALTER TABLE t2 COALESCE PARTITION 2;
```

The data contained in the last number partitions is merged into the remaining partitions. In this case, partitions 4 and 5 are merged into the first 4 partitions (the partitions numbered 0, 1, 2, and 3).

To change some but not all the partitions used by a partitioned table, you can use REORGANIZE PARTITION. This statement can be used in several ways:

- To merge a set of partitions into a single partition. This is done by naming several partitions in the partition_names list and supplying a single definition for partition_definition.

- To split an existing partition into several partitions. Accomplish this by naming a single partition for partition_names and providing multiple partition_definitions.

- To change the ranges for a subset of partitions defined using VALUES LESS THAN or the value lists for a subset of partitions defined using VALUES IN.

Note
For partitions that have not been explicitly named, MySQL automatically provides the default names p0, p1, p2, and so on. The same is true with regard to subpartitions.

For more detailed information about and examples of ALTER TABLE ... REORGANIZE PARTITION statements, see Section 24.3.1, “Management of RANGE and LIST Partitions”.

- To exchange a table partition or subpartition with a table, use the ALTER TABLE ... EXCHANGE PARTITION statement—that is, to move any existing rows in the partition or subpartition to the nonpartitioned table, and any existing rows in the nonpartitioned table to the table partition or subpartition.

For usage information and examples, see Section 24.3.3, “Exchanging Partitions and Subpartitions with Tables”.

- Several options provide partition maintenance and repair functionality analogous to that implemented for nonpartitioned tables by statements such as CHECK TABLE and REPAIR TABLE (which are also supported for partitioned tables; for more information, see Section 13.7.3, “Table Maintenance Statements”). These include ANALYZE PARTITION, CHECK PARTITION, OPTIMIZE PARTITION, REBUILD PARTITION, and REPAIR PARTITION. Each of these options takes a partition_names clause consisting of one or more names of partitions, separated by commas. The partitions must already exist in the target table. You can also use the ALL keyword in place of partition_names, in which case the statement acts on all table partitions. For more information and examples, see Section 24.3.4, “Maintenance of Partitions”.

InnoDB does not currently support per-partition optimization; ALTER TABLE ... OPTIMIZE PARTITION causes the entire table to be rebuilt and analyzed, and an appropriate warning to be
issued. (Bug #11751825, Bug #42822) To work around this problem, use `ALTER TABLE ... REBUILD PARTITION` and `ALTER TABLE ... ANALYZE PARTITION` instead.

The `ANALYZE PARTITION`, `CHECK PARTITION`, `OPTIMIZE PARTITION`, and `REPAIR PARTITION` options are not supported for tables which are not partitioned.

- `REMOVE PARTITIONING` enables you to remove a table’s partitioning without otherwise affecting the table or its data. This option can be combined with other `ALTER TABLE` options such as those used to add, drop, or rename columns or indexes.

- Using the `ENGINE` option with `ALTER TABLE` changes the storage engine used by the table without affecting the partitioning. The target storage engine must provide its own partitioning handler. Only the InnoDB and NDB storage engines have native partitioning handlers; NDB is not currently supported in MySQL 8.0.

It is possible for an `ALTER TABLE` statement to contain a `PARTITION BY` or `REMOVE PARTITIONING` clause in an addition to other alter specifications, but the `PARTITION BY` or `REMOVE PARTITIONING` clause must be specified last after any other specifications.

The `ADD PARTITION`, `DROP PARTITION`, `COALESCE PARTITION`, `REORGANIZE PARTITION`, `ANALYZE PARTITION`, `CHECK PARTITION`, and `REPAIR PARTITION` options cannot be combined with other alter specifications in a single `ALTER TABLE`, since the options just listed act on individual partitions. For more information, see Section 13.1.9.1, “ALTER TABLE Partition Operations”.

Only a single instance of any one of the following options can be used in a given `ALTER TABLE` statement: `PARTITION BY`, `ADD PARTITION`, `DROP PARTITION`, `TRUNCATE PARTITION`, `EXCHANGE PARTITION`, `REORGANIZE PARTITION`, or `COALESCE PARTITION`, `ANALYZE PARTITION`, `CHECK PARTITION`, `OPTIMIZE PARTITION`, `REBUILD PARTITION`, `REMOVE PARTITIONING`.

For example, the following two statements are invalid:

```
ALTER TABLE t1 ANALYZE PARTITION p1, ANALYZE PARTITION p2;
ALTER TABLE t1 ANALYZE PARTITION p1, CHECK PARTITION p2;
```

In the first case, you can analyze partitions `p1` and `p2` of table `t1` concurrently using a single statement with a single `ANALYZE PARTITION` option that lists both of the partitions to be analyzed, like this:

```
ALTER TABLE t1 ANALYZE PARTITION p1, p2;
```

In the second case, it is not possible to perform `ANALYZE` and `CHECK` operations on different partitions of the same table concurrently. Instead, you must issue two separate statements, like this:

```
ALTER TABLE t1 ANALYZE PARTITION p1;
ALTER TABLE t1 CHECK PARTITION p2;
```

`REBUILD` operations are currently unsupported for subpartitions. The `REBUILD` keyword is expressly disallowed with subpartitions, and causes `ALTER TABLE` to fail with an error if so used.

`CHECK PARTITION` and `REPAIR PARTITION` operations fail when the partition to be checked or repaired contains any duplicate key errors.

For more information about these statements, see Section 24.3.4, “Maintenance of Partitions”.

### 13.1.9.2 ALTER TABLE and Generated Columns

`ALTER TABLE` operations permitted for generated columns are `ADD`, `MODIFY`, and `CHANGE`.

- Generated columns can be added.

```sql
CREATE TABLE t1 (c1 INT);
ALTER TABLE t1 ADD COLUMN c2 INT GENERATED ALWAYS AS (c1 + 1) STORED;
```
ALTER TABLE Statement

- The data type and expression of generated columns can be modified.

```
CREATE TABLE t1 (c1 INT, c2 INT GENERATED ALWAYS AS (c1 + 1) STORED);
ALTER TABLE t1 MODIFY COLUMN c2 TINYINT GENERATED ALWAYS AS (c1 + 5) STORED;
```

- Generated columns can be renamed or dropped, if no other column refers to them.

```
CREATE TABLE t1 (c1 INT, c2 INT GENERATED ALWAYS AS (c1 + 1) STORED);
ALTER TABLE t1 CHANGE c2 c3 INT GENERATED ALWAYS AS (c1 + 1) STORED;
ALTER TABLE t1 DROP COLUMN c3;
```

- Virtual generated columns cannot be altered to stored generated columns, or vice versa. To work around this, drop the column, then add it with the new definition.

```
CREATE TABLE t1 (c1 INT, c2 INT GENERATED ALWAYS AS (c1 + 1) VIRTUAL);
ALTER TABLE t1 DROP COLUMN c2;
ALTER TABLE t1 ADD COLUMN c2 INT GENERATED ALWAYS AS (c1 + 1) STORED;
```

- Nongenerated columns can be altered to stored but not virtual generated columns.

```
CREATE TABLE t1 (c1 INT, c2 INT);
ALTER TABLE t1 MODIFY COLUMN c2 INT GENERATED ALWAYS AS (c1 + 1) STORED;
```

- Stored but not virtual generated columns can be altered to nongenerated columns. The stored generated values become the values of the nongenerated column.

```
CREATE TABLE t1 (c1 INT, c2 INT GENERATED ALWAYS AS (c1 + 1) STORED);
ALTER TABLE t1 MODIFY COLUMN c2 INT;
```

- `ADD COLUMN` is not an in-place operation for stored columns (done without using a temporary table) because the expression must be evaluated by the server. For stored columns, indexing changes are done in place, and expression changes are not done in place. Changes to column comments are done in place.

- For non-partitioned tables, `ADD COLUMN` and `DROP COLUMN` are in-place operations for virtual columns. However, adding or dropping a virtual column cannot be performed in place in combination with other `ALTER TABLE` operations. For partitioned tables, `ADD COLUMN` and `DROP COLUMN` are not in-place operations for virtual columns.

- `InnoDB` supports secondary indexes on virtual generated columns. Adding or dropping a secondary index on a virtual generated column is an in-place operation. For more information, see Section 13.1.20.9, “Secondary Indexes and Generated Columns”.

- When a `VIRTUAL` generated column is added to a table or modified, it is not ensured that data being calculated by the generated column expression is be out of range for the column. This can lead to inconsistent data being returned and unexpectedly failed statements. To permit control over whether validation occurs for such columns, `ALTER TABLE` supports `WITHOUT VALIDATION` and `WITH VALIDATION` clauses:

  - With `WITHOUT VALIDATION` (the default if neither clause is specified), an in-place operation is performed (if possible), data integrity is not checked, and the statement finishes more quickly. However, later reads from the table might report warnings or errors for the column if values are out of range.

  - With `WITH VALIDATION`, `ALTER TABLE` copies the table. If an out-of-range or any other error occurs, the statement fails. Because a table copy is performed, the statement takes longer.

`WITHOUT VALIDATION` and `WITH VALIDATION` are permitted only with `ADD COLUMN`, `CHANGE COLUMN`, and `MODIFY COLUMN` operations. Otherwise, an `ER_WRONG_USAGE` error occurs.

- If expression evaluation causes truncation or provides incorrect input to a function, the `ALTER TABLE` statement terminates with an error and the DDL operation is rejected.
ALTER TABLE Statement

• An **ALTER TABLE** statement that changes the default value of a column `col_name` may also change the value of a generated column expression that refers to the column using `col_name`, which may change the value of a generated column expression that refers to the column using `DEFAULT(col_name)`. For this reason, **ALTER TABLE** operations that change the definition of a column cause a table rebuild if any generated column expression uses `DEFAULT()`.

### 13.1.9.3 ALTER TABLE Examples

Begin with a table `t1` created as shown here:

```sql
CREATE TABLE t1 (a INTEGER, b CHAR(10));
```

To rename the table from `t1` to `t2`:

```sql
ALTER TABLE t1 RENAME t2;
```

To change column `a` from `INTEGER` to `TINYINT NOT NULL` (leaving the name the same), and to change column `b` from `CHAR(10)` to `CHAR(20)` as well as renaming it from `b` to `c`:

```sql
ALTER TABLE t2 MODIFY a TINYINT NOT NULL, CHANGE b c CHAR(20);
```

To add a new `TIMESTAMP` column named `d`:

```sql
ALTER TABLE t2 ADD d TIMESTAMP;
```

To add an index on column `d` and a `UNIQUE` index on column `a`:

```sql
ALTER TABLE t2 ADD INDEX (d), ADD UNIQUE (a);
```

To remove column `c`:

```sql
ALTER TABLE t2 DROP COLUMN c;
```

To add a new `AUTO_INCREMENT` integer column named `c`:

```sql
ALTER TABLE t2 ADD c INT UNSIGNED NOT NULL AUTO_INCREMENT,
ADD PRIMARY KEY (c);
```

We indexed `c` (as a `PRIMARY KEY`) because `AUTO_INCREMENT` columns must be indexed, and we declare `c` as `NOT NULL` because primary key columns cannot be `NULL`.

For NDB tables, it is also possible to change the storage type used for a table or column. For example, consider an NDB table created as shown here:

```sql
mysql> CREATE TABLE t1 (c1 INT) TABLESPACE ts_1 ENGINE NDB;
Query OK, 0 rows affected (1.27 sec)
```

To convert this table to disk-based storage, you can use the following **ALTER TABLE** statement:

```sql
mysql> ALTER TABLE t1 TABLESPACE ts_1 STORAGE DISK;
Query OK, 0 rows affected (2.99 sec)
Records: 0  Duplicates: 0  Warnings: 0
```

It is not necessary that the tablespace was referenced when the table was originally created; however, the tablespace must be referenced by the **ALTER TABLE**:

```sql
mysql> CREATE TABLE t2 (c1 INT) ts_1 ENGINE NDB;
Query OK, 0 rows affected (1.00 sec)
```
To change the storage type of an individual column, you can use `ALTER TABLE ... MODIFY [COLUMN]`. For example, suppose you create an NDB Cluster Disk Data table with two columns, using this `CREATE TABLE` statement:

```
CREATE TABLE t3 (c1 INT, c2 INT)
  TABLESPACE ts_1 STORAGE DISK ENGINE NDB;
```

To change column `c2` from disk-based to in-memory storage, include a `STORAGE MEMORY` clause in the column definition used by the `ALTER TABLE` statement, as shown here:

```
ALTER TABLE t3 MODIFY c2 INT STORAGE MEMORY;
```

You can make an in-memory column into a disk-based column by using `STORAGE DISK` in a similar fashion.

Column `c1` uses disk-based storage, since this is the default for the table (determined by the table-level `STORAGE DISK` clause in the `CREATE TABLE` statement). However, column `c2` uses in-memory storage, as can be seen here in the output of `SHOW CREATE TABLE`:

```
SHOW CREATE TABLE t3\G
*************************** 1. row ***************************
Table: t3
Create Table: CREATE TABLE `t3` (  
  `c1` int(11) DEFAULT NULL,  
  `c2` int(11) /*!50120 STORAGE MEMORY */ DEFAULT NULL  
) /*!50100 TABLESPACE ts_1 STORAGE DISK */ ENGINE=ndbcluster DEFAULT CHARSET=latin1  
1 row in set (0.02 sec)
```

When you add an `AUTO_INCREMENT` column, column values are filled in with sequence numbers automatically. For `MyISAM` tables, you can set the first sequence number by executing `SET INSERT_ID=value` before `ALTER TABLE` or by using the `AUTO_INCREMENT=value` table option.

With `MyISAM` tables, if you do not change the `AUTO_INCREMENT` column, the sequence number is not affected. If you drop an `AUTO_INCREMENT` column and then add another `AUTO_INCREMENT` column, the numbers are resequenced beginning with 1.

When replication is used, adding an `AUTO_INCREMENT` column to a table might not produce the same ordering of the rows on the replica and the source. This occurs because the order in which the rows are numbered depends on the specific storage engine used for the table and the order in which the rows were inserted. If it is important to have the same order on the source and replica, the rows must be ordered before assigning an `AUTO_INCREMENT` number. Assuming that you want to add an `AUTO_INCREMENT` column to the table `t1`, the following statements produce a new table `t2` identical to `t1` but with an `AUTO_INCREMENT` column:

```
CREATE TABLE t2 (id INT AUTO_INCREMENT PRIMARY KEY)
SELECT * FROM t1 ORDER BY col1, col2;
```

This assumes that the table `t1` has columns `col1` and `col2`. 
This set of statements also produces a new table `t2` identical to `t1`, with the addition of an `AUTO_INCREMENT` column:

```
CREATE TABLE t2 LIKE t1;
ALTER TABLE t2 ADD id INT AUTO_INCREMENT PRIMARY KEY;
INSERT INTO t2 SELECT * FROM t1 ORDER BY col1, col2;
```

Important

To guarantee the same ordering on both source and replica, all columns of `t1` must be referenced in the `ORDER BY` clause.

Regardless of the method used to create and populate the copy having the `AUTO_INCREMENT` column, the final step is to drop the original table and then rename the copy:

```
DROP TABLE t1;
ALTER TABLE t2 RENAME t1;
```

### 13.1.10 ALTER TABLESPACE Statement

```
ALTER [UNDO] TABLESPACE `tablespace_name`
NDB only:
  {ADD | DROP} DATAFILE `file_name`
  [INITIAL_SIZE [=] size]
  [WAIT]
InnoDB and NDB:
  [RENAME TO `tablespace_name`]
InnoDB only:
  [AUTOEXTEND_SIZE [=] 'value']
  [SET {ACTIVE | INACTIVE}]
  [ENCRYPTION [=] {'Y' | 'N'}]
InnoDB and NDB:
  [ENGINE [=] `engine_name`]
Reserved for future use:
  [ENGINE_ATTRIBUTE [=] 'string']
```

This statement is used with NDB and InnoDB tablespaces. It can be used to add a new data file to, or to drop a data file from an NDB tablespace. It can also be used to rename an NDB Cluster Disk Data tablespace, rename an InnoDB general tablespace, encrypt an InnoDB general tablespace, or mark an InnoDB undo tablespace as active or inactive.

The `UNDO` keyword, introduced in MySQL 8.0.14, is used with the `SET {ACTIVE | INACTIVE}` clause to mark an InnoDB undo tablespace as active or inactive. For more information, see Section 15.6.3.4, “Undo Tablespaces”.

The `ADD DATAFILE` variant enables you to specify an initial size for an NDB Disk Data tablespace using an `INITIAL_SIZE` clause, where `size` is measured in bytes; the default value is 134217728 (128 MB). You may optionally follow `size` with a one-letter abbreviation for an order of magnitude, similar to those used in `my.cnf`. Generally, this is one of the letters `M` (megabytes) or `G` (gigabytes).

On 32-bit systems, the maximum supported value for `INITIAL_SIZE` is 4294967296 (4 GB). (Bug #29186)

`INITIAL_SIZE` is rounded, explicitly, as for `CREATE TABLESPACE`.

Once a data file has been created, its size cannot be changed; however, you can add more data files to an NDB tablespace using additional `ALTER TABLESPACE ... ADD DATAFILE` statements.

When `ALTER TABLESPACE ... ADD DATAFILE` is used with `ENGINE = NDB`, a data file is created on each Cluster data node, but only one row is generated in the `INFORMATION_SCHEMA.FILES` table. See the description of this table, as well as Section 23.5.10.1, “NDB Cluster Disk Data Objects”, for more information. `ADD DATAFILE` is not supported with InnoDB tablespaces.

Using `DROP DATAFILE` with `ALTER TABLESPACE` drops the data file `file_name` from an NDB tablespace. You cannot drop a data file from a tablespace which is in use by any table; in other
ALTER TABLESPACE Statement

words, the data file must be empty (no extents used). See Section 23.5.10.1, “NDB Cluster Disk Data Objects”. In addition, any data file to be dropped must previously have been added to the tablespace with CREATE TABLESPACE or ALTER TABLESPACE. DROP DATAFILE is not supported with InnoDB tablespaces.

WAIT is parsed but otherwise ignored. It is intended for future expansion.

The ENGINE clause, which specifies the storage engine used by the tablespace, is deprecated; expect it to be removed in a future release. The tablespace storage engine is known by the data dictionary, making the ENGINE clause obsolete. If the storage engine is specified, it must match the tablespace storage engine defined in the data dictionary. The only values for engine_name compatible with NDB tablespaces are NDB and NDBCLUSTER.

RENAME TO operations are implicitly performed in autocommit mode, regardless of the autocommit setting.

A RENAME TO operation cannot be performed while LOCK TABLES or FLUSH TABLES WITH READ LOCK is in effect for tables that reside in the tablespace.

Exclusive metadata locks are taken on tables that reside in a general tablespace while the tablespace is renamed, which prevents concurrent DDL. Concurrent DML is supported.

The CREATE TABLESPACE privilege is required to rename an InnoDB general tablespace.

The AUTOEXTEND_SIZE option defines the amount by which InnoDB extends the size of a tablespace when it becomes full. Introduced in MySQL 8.0.23. The setting must be a multiple of 4MB. The default setting is 0, which causes the tablespace to be extended according to the implicit default behavior. For more information, see Section 15.6.3.9, “Tablespace AUTOEXTEND_SIZE Configuration”.

The ENCRYPTION clause enables or disables page-level data encryption for an InnoDB general tablespace or the mysql system tablespace. Encryption support for general tablespaces was introduced in MySQL 8.0.13. Encryption support for the mysql system tablespace was introduced in MySQL 8.0.16.

A keyring plugin must be installed and configured before encryption can be enabled.

As of MySQL 8.0.16, if the table_encryption_privilege_check variable is enabled, the TABLE_ENCRYPTION_ADMIN privilege is required to alter a general tablespace with an ENCRYPTION clause setting that differs from the default_table_encryption setting.

Enabling encryption for a general tablespace fails if any table in the tablespace belongs to a schema defined with DEFAULT ENCRYPTION='N'. Similarly, disabling encryption fails if any table in the general tablespace belongs to a schema defined with DEFAULT ENCRYPTION='Y'. The DEFAULT ENCRYPTION schema option was introduced in MySQL 8.0.16.

If an ALTER TABLESPACE statement executed on a general tablespace does not include an ENCRYPTION clause, the tablespace retains its current encryption status, regardless of the default_table_encryption setting.

When a general tablespace or the mysql system tablespace is encrypted, all tables residing in the tablespace are encrypted. Likewise, a table created in an encrypted tablespace is encrypted.

The INPLACE algorithm is used when altering the ENCRYPTION attribute of a general tablespace or the mysql system tablespace. The INPLACE algorithm permits concurrent DML on tables that reside in the tablespace. Concurrent DDL is blocked.

For more information, see Section 15.13, “InnoDB Data-at-Rest Encryption”.

The ENGINE_ATTRIBUTE option (available as of MySQL 8.0.21) is used to specify tablespace attributes for primary storage engines. The option is reserved for future use.
ALTER VIEW Statement

Permitted values are a string literal containing a valid JSON document or an empty string (""). Invalid JSON is rejected.

```
ALTER TABLESPACE ts1 ENGINE_ATTRIBUTE='{"key":"value"}';
```

ENGINE_ATTRIBUTE values can be repeated without error. In this case, the last specified value is used.

ENGINE_ATTRIBUTE values are not checked by the server, nor are they cleared when the table’s storage engine is changed.

It is not permitted to alter an individual element of a JSON attribute value. You can only add or replace an attribute.

13.1.11 ALTER VIEW Statement

```
ALTER
  [ALGORITHM = {UNDEFINED | MERGE | TEMPTABLE}]
  [DEFINER = user]
  [SQL SECURITY { DEFINER | INVOKER }]
  VIEW view_name [(column_list)]
  AS select_statement
  [WITH [CASCADED | LOCAL] CHECK OPTION]
```

This statement changes the definition of a view, which must exist. The syntax is similar to that for CREATE VIEW see Section 13.1.23, “CREATE VIEW Statement”). This statement requires the CREATE VIEW and DROP privileges for the view, and some privilege for each column referred to in the SELECT statement. ALTER VIEW is permitted only to the definer or users with the SET_USER_ID privilege (or the deprecated SUPER privilege).

13.1.12 CREATE DATABASE Statement

```
CREATE {DATABASE | SCHEMA} [IF NOT EXISTS] db_name
  [create_option] ...
create_option: [DEFAULT] {
  CHARACTER SET [=] charset_name
  | COLLATE [=] collation_name
  | ENCRYPTION [=] {'Y' | 'N'}
}
```

CREATE DATABASE creates a database with the given name. To use this statement, you need the CREATE privilege for the database. CREATE_SCHEMA is a synonym for CREATE DATABASE.

An error occurs if the database exists and you did not specify IF NOT EXISTS.

CREATE DATABASE is not permitted within a session that has an active LOCK TABLES statement.

Each create_option specifies a database characteristic. Database characteristics are stored in the data dictionary.

- The CHARACTER SET option specifies the default database character set. The COLLATE option specifies the default database collation. For information about character set and collation names, see Chapter 10, Character Sets, Collations, Unicode.

To see the available character sets and collations, use the the SHOW CHARACTER SET and SHOW COLLATION statements, respectively. See Section 13.7.7.3, “SHOW CHARACTER SET Statement”, and Section 13.7.7.4, “SHOW COLLATION Statement”.

- The ENCRYPTION option, introduced in MySQL 8.0.16, defines the default database encryption, which is inherited by tables created in the database. The permitted values are 'Y' (encryption enabled) and 'N' (encryption disabled). If the ENCRYPTION option is not specified, the value of the default_table_encryption system variable defines the default database encryption. If the table_encryption_privilege_check system variable is enabled, the...
TABLE_ENCRYPTION_ADMIN privilege is required to specify a default encryption setting that differs from the default_table_encryption setting. For more information, see Defining an Encryption Default for Schemas and General Tablespaces.

A database in MySQL is implemented as a directory containing files that correspond to tables in the database. Because there are no tables in a database when it is initially created, the CREATE DATABASE statement creates only a directory under the MySQL data directory. Rules for permissible database names are given in Section 9.2, “Schema Object Names”. If a database name contains special characters, the name for the database directory contains encoded versions of those characters as described in Section 9.2.4, “Mapping of Identifiers to File Names”.

Creating a database directory by manually creating a directory under the data directory (for example, with mkdir) is unsupported in MySQL 8.0.

When you create a database, let the server manage the directory and the files in it. Manipulating database directories and files directly can cause inconsistencies and unexpected results.

MySQL has no limit on the number of databases. The underlying file system may have a limit on the number of directories.

You can also use the mysqladmin program to create databases. See Section 4.5.2, “mysqladmin — A MySQL Server Administration Program”.

### 13.1.13 CREATE EVENT Statement

```sql
CREATE [DEFINER = user] EVENT [IF NOT EXISTS] event_name ON SCHEDULE schedule [ON COMPLETION [NOT] PRESERVE] [ENABLE | DISABLE | DISABLE ON SLAVE] [COMMENT 'string'] DO event_body;
```

**schedule**: 
- `AT timestamp [+ INTERVAL interval] ...`
- `EVERY interval`
- `STARTS timestamp [+ INTERVAL interval] ...`
- `ENDS timestamp [+ INTERVAL interval] ...`

**interval**: 
- `quantity {YEAR | QUARTER | MONTH | DAY | HOUR | MINUTE | WEEK | SECOND | YEAR.MONTH | DAY.HOUR | DAY.MINUTE | DAY.SECOND | HOUR.MINUTE | HOUR.SECOND | MINUTE.SECOND}
```

This statement creates and schedules a new event. The event does not run unless the Event Scheduler is enabled. For information about checking Event Scheduler status and enabling it if necessary, see Section 25.4.2, “Event Scheduler Configuration”.

CREATE EVENT requires the EVENT privilege for the schema in which the event is to be created. If the DEFINER clause is present, the privileges required depend on the user value, as discussed in Section 25.6, “Stored Object Access Control”.

The minimum requirements for a valid CREATE EVENT statement are as follows:

- The keywords CREATE EVENT plus an event name, which uniquely identifies the event in a database schema.
- An ON SCHEDULE clause, which determines when and how often the event executes.
- A DO clause, which contains the SQL statement to be executed by an event.

This is an example of a minimal CREATE EVENT statement:
CREATE EVENT myevent
  ON SCHEDULE AT CURRENT_TIMESTAMP + INTERVAL 1 HOUR
  DO
    UPDATE myschema.mytable SET mycol = mycol + 1;

The previous statement creates an event named `myevent`. This event executes once—one hour following its creation—by running an SQL statement that increments the value of the `myschema.mytable` table's `mycol` column by 1.

The `event_name` must be a valid MySQL identifier with a maximum length of 64 characters. Event names are not case-sensitive, so you cannot have two events named `myevent` and `MyEvent` in the same schema. In general, the rules governing event names are the same as those for names of stored routines. See Section 9.2, “Schema Object Names”.

An event is associated with a schema. If no schema is indicated as part of `event_name`, the default (current) schema is assumed. To create an event in a specific schema, qualify the event name with a schema using `schema_name.event_name` syntax.

The `DEFINER` clause specifies the MySQL account to be used when checking access privileges at event execution time. If the `DEFINER` clause is present, the `user` value should be a MySQL account specified as `'user_name'@'host_name'`, `CURRENT_USER`, or `CURRENT_USER()`. The permitted `user` values depend on the privileges you hold, as discussed in Section 25.6, “Stored Object Access Control”. Also see that section for additional information about event security.

If the `DEFINER` clause is omitted, the default definer is the user who executes the `CREATE EVENT` statement. This is the same as specifying `DEFINER = CURRENT_USER` explicitly.

Within an event body, the `CURRENT_USER` function returns the account used to check privileges at event execution time, which is the `DEFINER` user. For information about user auditing within events, see Section 6.2.22, “SQL-Based Account Activity Auditing”.

`IF NOT EXISTS` has the same meaning for `CREATE EVENT` as for `CREATE TABLE`: If an event named `event_name` already exists in the same schema, no action is taken, and no error results. (However, a warning is generated in such cases.)

The `ON SCHEDULE` clause determines when, how often, and for how long the `event_body` defined for the event repeats. This clause takes one of two forms:

- **AT timestamp** is used for a one-time event. It specifies that the event executes one time only at the date and time given by `timestamp`, which must include both the date and time, or must be an expression that resolves to a datetime value. You may use a value of either the `DATETIME` or `TIMESTAMP` type for this purpose. If the date is in the past, a warning occurs, as shown here:

  ```sql
  mysql> SELECT NOW();
  +---------------------+
  | NOW()               |
  +---------------------+
  | 2006-02-10 23:59:01 |
  +---------------------+
  1 row in set (0.04 sec)
  mysql> CREATE EVENT e_totals
  -> ON SCHEDULE AT '2006-02-10 23:59:00'
  -> DO INSERT INTO test.totals VALUES (NOW());
  Query OK, 0 rows affected, 1 warning (0.00 sec)
  mysql> SHOW WARNINGS\G
  *************************** 1. row ***************************
  Level: Note
  Code: 1588
  Message: Event execution time is in the past and ON COMPLETION NOT PRESERVE is set. The event was dropped immediately after creation.
  ```

- **AT CURRENT_TIMESTAMP + INTERVAL 1 HOUR** is used for a periodic event that repeats every hour. It specifies that the event executes every hour, starting one hour after its creation.

`CREATE EVENT` statements which are themselves invalid—for whatever reason—fail with an error.
You may use `CURRENT_TIMESTAMP` to specify the current date and time. In such a case, the event acts as soon as it is created.

To create an event which occurs at some point in the future relative to the current date and time—such as that expressed by the phrase “three weeks from now”—you can use the optional clause `+ INTERVAL interval`. The `interval` portion consists of two parts, a quantity and a unit of time, and follows the syntax rules described in Temporal Intervals, except that you cannot use any units keywords that involving microseconds when defining an event. With some interval types, complex time units may be used. For example, “two minutes and ten seconds” can be expressed as `+ INTERVAL '2:10' MINUTE_SECOND`.

You can also combine intervals. For example, `AT CURRENT_TIMESTAMP + INTERVAL 3 WEEK + INTERVAL 2 DAY` is equivalent to “three weeks and two days from now”. Each portion of such a clause must begin with `+ INTERVAL`.

- To repeat actions at a regular interval, use an `EVERY` clause. The `EVERY` keyword is followed by an `interval` as described in the previous discussion of the `AT` keyword. (+ INTERVAL is not used with EVERY.) For example, `EVERY 6 WEEK` means “every six weeks”.

  Although `+ INTERVAL` clauses are not permitted in an `EVERY` clause, you can use the same complex time units permitted in a `+ INTERVAL`.

  An `EVERY` clause may contain an optional `STARTS` clause. `STARTS` is followed by a `timestamp` value that indicates when the action should begin repeating, and may also use `+ INTERVAL interval` to specify an amount of time “from now”. For example, `EVERY 3 MONTH STARTS CURRENT_TIMESTAMP + INTERVAL 1 WEEK` means “every three months, beginning one week from now”. Similarly, you can express “every two weeks, beginning six hours and fifteen minutes from now” as `EVERY 2 WEEK STARTS CURRENT_TIMESTAMP + INTERVAL '6:15' HOUR_MINUTE`. Not specifying `STARTS` is the same as using `STARTS CURRENT_TIMESTAMP`—that is, the action specified for the event begins repeating immediately upon creation of the event.

  An `EVERY` clause may contain an optional `ENDS` clause. The `ENDS` keyword is followed by a `timestamp` value that tells MySQL when the event should stop repeating. You may also use `+ INTERVAL interval` with `ENDS`; for instance, `EVERY 12 HOUR STARTS CURRENT_TIMESTAMP + INTERVAL 30 MINUTE ENDS CURRENT_TIMESTAMP + INTERVAL 4 WEEK` is equivalent to “every twelve hours, beginning thirty minutes from now, and ending four weeks from now”. Not using `ENDS` means that the event continues executing indefinitely.

  `ENDS` supports the same syntax for complex time units as `STARTS` does.

  You may use `STARTS`, `ENDS`, both, or neither in an `EVERY` clause.

  If a repeating event does not terminate within its scheduling interval, the result may be multiple instances of the event executing simultaneously. If this is undesirable, you should institute a mechanism to prevent simultaneous instances. For example, you could use the `GET_LOCK()` function, or row or table locking.

  The `ON SCHEDULE` clause may use expressions involving built-in MySQL functions and user variables to obtain any of the `timestamp` or `interval` values which it contains. You may not use stored functions or user-defined functions in such expressions, nor may you use any table references; however, you may use `SELECT FROM DUAL`. This is true for both `CREATE EVENT` and `ALTER EVENT` statements. References to stored functions, user-defined functions, and tables in such cases are specifically not permitted, and fail with an error (see Bug #22830).

  Times in the `ON SCHEDULE` clause are interpreted using the current session `time_zone` value. This becomes the event time zone; that is, the time zone that is used for event scheduling and is in effect within the event as it executes. These times are converted to UTC and stored along with the event time zone internally. This enables event execution to proceed as defined regardless of any subsequent changes to the server time zone or daylight saving time effects. For additional information about
representation of event times, see Section 25.4.4, “Event Metadata”. See also Section 13.7.7.18, “SHOW EVENTS Statement”, and Section 26.3.14, “The INFORMATION_SCHEMA EVENTS Table”.

Normally, once an event has expired, it is immediately dropped. You can override this behavior by specifying ON COMPLETION PRESERVE. Using ON COMPLETION NOT PRESERVE merely makes the default nonpersistent behavior explicit.

You can create an event but prevent it from being active using the DISABLE keyword. Alternatively, you can use ENABLE to make explicit the default status, which is active. This is most useful in conjunction with ALTER EVENT (see Section 13.1.3, “ALTER EVENT Statement”).

A third value may also appear in place of ENABLE or DISABLE; DISABLE ON SLAVE is set for the status of an event on a replica to indicate that the event was created on the replication source server and replicated to the replica, but is not executed on the replica. See Section 17.5.1.16, “Replication of Invoked Features”.

You may supply a comment for an event using a COMMENT clause. comment may be any string of up to 64 characters that you wish to use for describing the event. The comment text, being a string literal, must be surrounded by quotation marks.

The DO clause specifies an action carried by the event, and consists of an SQL statement. Nearly any valid MySQL statement that can be used in a stored routine can also be used as the action statement for a scheduled event. (See Section 25.8, “Restrictions on Stored Programs”.) For example, the following event e_hourly deletes all rows from the sessions table once per hour, where this table is part of the site_activity schema:

```sql
CREATE EVENT e_hourly
    ON SCHEDULE
        EVERY 1 HOUR
    COMMENT 'Clears out sessions table each hour.'
    DO
        DELETE FROM site_activity.sessions;
```

MySQL stores the sql_mode system variable setting in effect when an event is created or altered, and always executes the event with this setting in force, regardless of the current server SQL mode when the event begins executing.

A CREATE EVENT statement that contains an ALTER EVENT statement in its DO clause appears to succeed; however, when the server attempts to execute the resulting scheduled event, the execution fails with an error.

Note

Statements such as SELECT or SHOW that merely return a result set have no effect when used in an event; the output from these is not sent to the MySQL Monitor, nor is it stored anywhere. However, you can use statements such as SELECT ... INTO and INSERT INTO ... SELECT that store a result. (See the next example in this section for an instance of the latter.)

The schema to which an event belongs is the default schema for table references in the DO clause. Any references to tables in other schemas must be qualified with the proper schema name.

As with stored routines, you can use compound-statement syntax in the DO clause by using the BEGIN and END keywords, as shown here:

```sql
delimiter |
CREATE EVENT e_daily
    ON SCHEDULE
        EVERY 1 DAY
    COMMENT 'Saves total number of sessions then clears the table each day'
    BEGIN
        INSERT INTO site_activity.totals (time, total)
        SELECT CURRENT_TIMESTAMP, COUNT(*)
    END
```
CREATE FUNCTION Statement

FROM site_activity.sessions;
DELETE FROM site_activity.sessions;
END |
delimiter ;

This example uses the `delimiter` command to change the statement delimiter. See Section 25.1, “Defining Stored Programs”.

More complex compound statements, such as those used in stored routines, are possible in an event. This example uses local variables, an error handler, and a flow control construct:

delimiter |
CREATE EVENT e
ON SCHEDULE
EVERY 5 SECOND
DO
BEGIN
DECLARE v INTEGER;
DECLARE CONTINUE HANDLER FOR SQLEXCEPTION BEGIN END;
SET v = 0;
WHILE v < 5 DO
    INSERT INTO t1 VALUES (0);
    UPDATE t2 SET s1 = s1 + 1;
    SET v = v + 1;
END WHILE;
END |
delimiter ;

There is no way to pass parameters directly to or from events; however, it is possible to invoke a stored routine with parameters within an event:

CREATE EVENT e_call_myproc
ON SCHEDULE
    AT CURRENT_TIMESTAMP + INTERVAL 1 DAY
DO CALL myproc(5, 27);

If an event’s definer has privileges sufficient to set global system variables (see Section 5.1.9.1, “System Variable Privileges”), the event can read and write global variables. As granting such privileges entails a potential for abuse, extreme care must be taken in doing so.

Generally, any statements that are valid in stored routines may be used for action statements executed by events. For more information about statements permissible within stored routines, see Section 25.2.1, “Stored Routine Syntax”. You can create an event as part of a stored routine, but an event cannot be created by another event.

13.1.14 CREATE FUNCTION Statement

The CREATE FUNCTION statement is used to create stored functions and user-defined functions (UDFs):

- For information about creating stored functions, see Section 13.1.17, “CREATE PROCEDURE and CREATE FUNCTION Statements”.
- For information about creating user-defined functions, see Section 13.7.4.1, “CREATE FUNCTION Statement for User-Defined Functions”.

13.1.15 CREATE INDEX Statement

CREATE [UNIQUE | FULLTEXT | SPATIAL] INDEX index_name
[index_type]
ON tbl_name (key_part,...)
[index_option]
CREATE INDEX Statement

```
[algorithm_option | lock_option] ...
```

```
key_part: {col_name [(length)] | (expr)} [ASC | DESC]
```

```
index_option: {
    KEY_BLOCK_SIZE [=] value
    INDEX_TYPE
    WITH PARSER parser_name
    COMMENT 'string'
    {VISIBLE | INVISIBLE}
    ENGINE_ATTRIBUTE [=] 'string'
    SECONDARY_ENGINE_ATTRIBUTE [=] 'string'
}
```

```
index_type: USING {BTREE | HASH}
```

```
algorithm_option: ALGORITHM [=] {DEFAULT | INPLACE | COPY}
```

```
lock_option: LOCK [=] {DEFAULT | NONE | SHARED | EXCLUSIVE}
```

Normally, you create all indexes on a table at the time the table itself is created with CREATE TABLE. See Section 13.1.20, “CREATE TABLE Statement”. This guideline is especially important for InnoDB tables, where the primary key determines the physical layout of rows in the data file. CREATE INDEX enables you to add indexes to existing tables.

CREATE INDEX is mapped to an ALTER TABLE statement to create indexes. See Section 13.1.9, “ALTER TABLE Statement”. CREATE INDEX cannot be used to create a PRIMARY KEY; use ALTER TABLE instead. For more information about indexes, see Section 8.3.1, “How MySQL Uses Indexes”.

InnoDB supports secondary indexes on virtual columns. For more information, see Section 13.1.20.9, “Secondary Indexes and Generated Columns”.

When the innodb_stats_persistent setting is enabled, run the ANALYZE TABLE statement for an InnoDB table after creating an index on that table.

Beginning with MySQL 8.0.17, the expr for a key_part specification can take the form (CAST json_expression AS type ARRAY) to create a multi-valued index on a JSON column. See Multi-Valued Indexes.

An index specification of the form (key_part1, key_part2, ...) creates an index with multiple key parts. Index key values are formed by concatenating the values of the given key parts. For example (col1, col2, col3) specifies a multiple-column index with index keys consisting of values from col1, col2, and col3.

A key_part specification can end with ASC or DESC to specify whether index values are stored in ascending or descending order. The default is ascending if no order specifier is given. ASC and DESC are not permitted for HASH indexes. ASC and DESC are also not supported for multi-valued indexes. As of MySQL 8.0.12, ASC and DESC are not permitted for SPATIAL indexes.

The following sections describe different aspects of the CREATE INDEX statement:

- Column Prefix Key Parts
- Functional Key Parts
- Unique Indexes
- Full-Text Indexes
- Multi-Valued Indexes
- Spatial Indexes
- Index Options
Column Prefix Key Parts

For string columns, indexes can be created that use only the leading part of column values, using `col_name(length)` syntax to specify an index prefix length:

- Prefixes can be specified for `CHAR`, `VARCHAR`, `BINARY`, and `VARBINARY` key parts.
- Prefixes must be specified for `BLOB` and `TEXT` key parts. Additionally, `BLOB` and `TEXT` columns can be indexed only for `InnoDB`, `MyISAM`, and `BLACKHOLE` tables.
- Prefix limits are measured in bytes. However, prefix lengths for index specifications in `CREATE TABLE`, `ALTER TABLE`, and `CREATE INDEX` statements are interpreted as number of characters for nonbinary string types (`CHAR`, `VARCHAR`, `TEXT`) and number of bytes for binary string types (`BINARY`, `VARBINARY`, `BLOB`). Take this into account when specifying a prefix length for a nonbinary string column that uses a multibyte character set.

Prefix support and lengths of prefixes (where supported) are storage engine dependent. For example, a prefix can be up to 767 bytes long for `InnoDB` tables that use the `REDUNDANT` or `COMPACT` row format. The prefix length limit is 3072 bytes for `InnoDB` tables that use the `DYNAMIC` or `COMPRESSED` row format. For `MyISAM` tables, the prefix length limit is 1000 bytes. The `NDB` storage engine does not support prefixes (see Section 23.1.7.6, "Unsupported or Missing Features in NDB Cluster").

If a specified index prefix exceeds the maximum column data type size, `CREATE INDEX` handles the index as follows:

- For a nonunique index, either an error occurs (if strict SQL mode is enabled), or the index length is reduced to lie within the maximum column data type size and a warning is produced (if strict SQL mode is not enabled).
- For a unique index, an error occurs regardless of SQL mode because reducing the index length might enable insertion of nonunique entries that do not meet the specified uniqueness requirement.

The statement shown here creates an index using the first 10 characters of the `name` column (assuming that `name` has a nonbinary string type):

```
CREATE INDEX part_of_name ON customer (name(10));
```

If names in the column usually differ in the first 10 characters, lookups performed using this index should not be much slower than using an index created from the entire `name` column. Also, using column prefixes for indexes can make the index file much smaller, which could save a lot of disk space and might also speed up `INSERT` operations.

Functional Key Parts

A “normal” index indexes column values or prefixes of column values. For example, in the following table, the index entry for a given `t1` row includes the full `col1` value and a prefix of the `col2` value consisting of its first 10 characters:

```
CREATE TABLE t1 (  
  col1 VARCHAR(10),  
  col2 VARCHAR(20),  
  INDEX (col1, col2(10))  
);
```

MySQL 8.0.13 and higher supports functional key parts that index expression values rather than column or column prefix values. Use of functional key parts enables indexing of values not stored directly in the table. Examples:

```
CREATE TABLE t1 (col1 INT, col2 INT, INDEX func_index ((ABS(col1))));  
CREATE INDEX idx1 ON t1 ((col1 + col2));  
CREATE INDEX idx2 ON t1 ((col1 + col2), (col1 - col2), col1);  
ALTER TABLE t1 ADD INDEX ((col1 * 40) DESC);
```
CREATE INDEX Statement

An index with multiple key parts can mix nonfunctional and functional key parts. **ASC** and **DESC** are supported for functional key parts.

Functional key parts must adhere to the following rules. An error occurs if a key part definition contains disallowed constructs.

- In index definitions, enclose expressions within parentheses to distinguish them from columns or column prefixes. For example, this is permitted; the expressions are enclosed within parentheses:

  ```sql
  INDEX ((col1 + col2), (col3 - col4))
  ```

  This produces an error; the expressions are not enclosed within parentheses:

  ```sql
  INDEX (col1 + col2, col3 - col4)
  ```

- A functional key part cannot consist solely of a column name. For example, this is not permitted:

  ```sql
  INDEX ((col1), (col2))
  ```

  Instead, write the key parts as nonfunctional key parts, without parentheses:

  ```sql
  INDEX (col1, col2)
  ```

- A functional key part expression cannot refer to column prefixes. For a workaround, see the discussion of **SUBSTRING()** and **CAST()** later in this section.

- Functional key parts are not permitted in foreign key specifications.

For **CREATE TABLE ... LIKE**, the destination table preserves functional key parts from the original table.

Functional indexes are implemented as hidden virtual generated columns, which has these implications:

- Each functional key part counts against the limit on total number of table columns; see Section 8.4.7, “Limits on Table Column Count and Row Size”.

- Functional key parts inherit all restrictions that apply to generated columns. Examples:
  - Only functions permitted for generated columns are permitted for functional key parts.
  - Subqueries, parameters, variables, stored functions, and user-defined functions are not permitted.

For more information about applicable restrictions, see Section 13.1.20.8, “CREATE TABLE and Generated Columns”, and Section 13.1.9.2, “ALTER TABLE and Generated Columns”.

- The virtual generated column itself requires no storage. The index itself takes up storage space as any other index.

**UNIQUE** is supported for indexes that include functional key parts. However, primary keys cannot include functional key parts. A primary key requires the generated column to be stored, but functional key parts are implemented as virtual generated columns, not stored generated columns.

**SPATIAL** and **FULLTEXT** indexes cannot have functional key parts.

If a table contains no primary key, **InnoDB** automatically promotes the first **UNIQUE NOT NULL** index to the primary key. This is not supported for **UNIQUE NOT NULL** indexes that have functional key parts.

Nonfunctional indexes raise a warning if there are duplicate indexes. Indexes that contain functional key parts do not have this feature.

To remove a column that is referenced by a functional key part, the index must be removed first. Otherwise, an error occurs.
CREATE INDEX Statement

Although nonfunctional key parts support a prefix length specification, this is not possible for functional key parts. The solution is to use `SUBSTRING()` (or `CAST()`, as described later in this section). For a functional key part containing the `SUBSTRING()` function to be used in a query, the `WHERE` clause must contain `SUBSTRING()` with the same arguments. In the following example, only the second `SELECT` is able to use the index because that is the only query in which the arguments to `SUBSTRING()` match the index specification:

```sql
CREATE TABLE tbl (  
  col1 LONGTEXT,  
  INDEX idx1 ((SUBSTRING(col1, 1, 10))) 
)
SELECT * FROM tbl WHERE SUBSTRING(col1, 1, 9) = '123456789';  
SELECT * FROM tbl WHERE SUBSTRING(col1, 1, 10) = '1234567890';
```

Functional key parts enable indexing of values that cannot be indexed otherwise, such as `JSON` values. However, this must be done correctly to achieve the desired effect. For example, this syntax does not work:

```sql
CREATE TABLE employees (  
  data JSON,  
  INDEX ((data->>'$.name'))
)
```

The syntax fails because:

- The `->>` operator translates into `JSON_UNQUOTE(JSON_EXTRACT(...))`.
- `JSON_UNQUOTE()` returns a value with a data type of `LONGTEXT`, and the hidden generated column thus is assigned the same data type.
- MySQL cannot index `LONGTEXT` columns specified without a prefix length on the key part, and prefix lengths are not permitted in functional key parts.

To index the `JSON` column, you could try using the `CAST()` function as follows:

```sql
CREATE TABLE employees (  
  data JSON,  
  INDEX ((CAST(data->>'$.name' AS CHAR(30))))
)
```

The hidden generated column is assigned the `VARCHAR(30)` data type, which can be indexed. But this approach produces a new issue when trying to use the index:

- `CAST()` returns a string with the collation `utf8mb4_0900_ai_ci` (the server default collation).
- `JSON_UNQUOTE()` returns a string with the collation `utf8mb4_bin` (hard coded).

As a result, there is a collation mismatch between the indexed expression in the preceding table definition and the `WHERE` clause expression in the following query:

```sql
SELECT * FROM employees WHERE data->>'$.name' = 'James';
```

The index is not used because the expressions in the query and the index differ. To support this kind of scenario for functional key parts, the optimizer automatically strips `CAST()` when looking for an index to use, but only if the collation of the indexed expression matches that of the query expression. For an index with a functional key part to be used, either of the following two solutions work (although they differ somewhat in effect):

- **Solution 1.** Assign the indexed expression the same collation as `JSON_UNQUOTE()`:

  ```sql
  CREATE TABLE employees (  
    data JSON,  
    INDEX idx ((CAST(data->>'$.name' AS CHAR(30)) COLLATE utf8mb4_bin))
  );
  INSERT INTO employees VALUES  
  ({{ "name": "james", "salary": 9000 }}),  
  ({{ "name": "James", "salary": 10000 }}),
  ```

- **Solution 2.** Use `CAST()` with the right collation:

  ```sql
  CREATE TABLE employees (  
    data JSON,  
    INDEX idx ((CAST(data->>'$.name' AS CHAR(30)) COLLATE utf8mb4_bin))
  );
  INSERT INTO employees VALUES  
  ({{ "name": "james", "salary": 9000 }},  
  ({{ "name": "James", "salary": 10000 }},
  ```
CREATE INDEX Statement

('{ "name": "Mary", "salary": 12000 }'),
('{ "name": "Peter", "salary": 8000 }');
SELECT * FROM employees WHERE data->>'$.name' = 'James';

The ->> operator is the same as JSON_UNQUOTE(JSON_EXTRACT(...)), and JSON_UNQUOTE()
returns a string with collation utf8mb4_bin. The comparison is thus case-sensitive, and only one
row matches:
+------------------------------------+
| data
|
+------------------------------------+
| {"name": "James", "salary": 10000} |
+------------------------------------+

• Solution 2. Specify the full expression in the query:
CREATE TABLE employees (
data JSON,
INDEX idx ((CAST(data->>"$.name" AS CHAR(30))))
);
INSERT INTO employees VALUES
('{ "name": "james", "salary": 9000 }'),
('{ "name": "James", "salary": 10000 }'),
('{ "name": "Mary", "salary": 12000 }'),
('{ "name": "Peter", "salary": 8000 }');
SELECT * FROM employees WHERE CAST(data->>'$.name' AS CHAR(30)) = 'James';

CAST() returns a string with collation utf8mb4_0900_ai_ci, so the comparison case-insensitive
and two rows match:
+------------------------------------+
| data
|
+------------------------------------+
| {"name": "james", "salary": 9000} |
| {"name": "James", "salary": 10000} |
+------------------------------------+

Be aware that although the optimizer supports automatically stripping CAST() with indexed generated
columns, the following approach does not work because it produces a different result with and without
an index (Bug#27337092):
mysql> CREATE TABLE employees (
data JSON,
generated_col VARCHAR(30) AS (CAST(data->>'$.name' AS CHAR(30)))
);
Query OK, 0 rows affected, 1 warning (0.03 sec)
mysql> INSERT INTO employees (data)
VALUES ('{"name": "james"}'), ('{"name": "James"}');
Query OK, 2 rows affected, 1 warning (0.01 sec)
Records: 2 Duplicates: 0 Warnings: 1
mysql> SELECT * FROM employees WHERE data->>'$.name' = 'James';
+-------------------+---------------+
| data
| generated_col |
+-------------------+---------------+
| {"name": "James"} | James
|
+-------------------+---------------+
1 row in set (0.00 sec)
mysql> ALTER TABLE employees ADD INDEX idx (generated_col);
Query OK, 0 rows affected, 1 warning (0.03 sec)
Records: 0 Duplicates: 0 Warnings: 1
mysql> SELECT * FROM employees WHERE data->>'$.name' = 'James';
+-------------------+---------------+
| data
| generated_col |
+-------------------+---------------+
| {"name": "james"} | james
|
| {"name": "James"} | James
|

2323


Unique Indexes

A UNIQUE index creates a constraint such that all values in the index must be distinct. An error occurs if you try to add a new row with a key value that matches an existing row. If you specify a prefix value for a column in a UNIQUE index, the column values must be unique within the prefix length. A UNIQUE index permits multiple NULL values for columns that can contain NULL.

If a table has a PRIMARY KEY or UNIQUE NOT NULL index that consists of a single column that has an integer type, you can use _rowid to refer to the indexed column in SELECT statements, as follows:

- _rowid refers to the PRIMARY KEY column if there is a PRIMARY KEY consisting of a single integer column. If there is a PRIMARY KEY but it does not consist of a single integer column, _rowid cannot be used.
- Otherwise, _rowid refers to the column in the first UNIQUE NOT NULL index if that index consists of a single integer column. If the first UNIQUE NOT NULL index does not consist of a single integer column, _rowid cannot be used.

Full-Text Indexes

FULLTEXT indexes are supported only for InnoDB and MyISAM tables and can include only CHAR, VARCHAR, and TEXT columns. Indexing always happens over the entire column; column prefix indexing is not supported and any prefix length is ignored if specified. See Section 12.10, “Full-Text Search Functions”, for details of operation.

Multi-Valued Indexes

As of MySQL 8.0.17, InnoDB supports multi-valued indexes. A multi-valued index is a secondary index defined on a column that stores an array of values. A “normal” index has one index record for each data record (1:1). A multi-valued index can have multiple index records for a single data record (N:1). Multi-valued indexes are intended for indexing JSON arrays. For example, a multi-valued index defined on the array of zip codes in the following JSON document creates an index record for each zip code, with each index record referencing the same data record.

```json
{
    "user":"Bob",
    "user_id":31,
    "zipcode": [94477,94536]
}
```

Creating multi-valued Indexes

You can create a multi-valued index in a CREATE TABLE, ALTER TABLE, or CREATE INDEX statement. This requires using CAST(...) AS ... ARRAY in the index definition, which casts same-typed scalar values in a JSON array to an SQL data type array. A virtual column is then generated transparently with the values in the SQL data type array; finally, a functional index (also referred to as a virtual index) is created on the virtual column. It is the functional index defined on the virtual column of values from the SQL data type array that forms the multi-valued index.

The examples in the following list show the three different ways in which a multi-valued index zips can be created on an array $.zipcode on a JSON column custinfo in a table named customers. In each case, the JSON array is cast to an SQL data type array of UNSIGNED integer values.

- **CREATE TABLE** only:

```sql
CREATE TABLE customers {
    id BIGINT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    modified DATETIME DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
    custinfo JSON,
    INDEX zips( (CAST(custinfo->'$.zip' AS UNSIGNED ARRAY)) )
};
```
CREATE INDEX Statement

- CREATE TABLE plus ALTER TABLE:

```sql
CREATE TABLE customers {
  id BIGINT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  modified DATETIME DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
  custinfo JSON
};
ALTER TABLE customers ADD INDEX zips( (CAST(custinfo->'$.zip' AS UNSIGNED ARRAY)) );
```

- CREATE TABLE plus CREATE INDEX:

```sql
CREATE TABLE customers {
  id BIGINT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  modified DATETIME DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
  custinfo JSON
};
CREATE INDEX zips ON customers ( (CAST(custinfo->'$.zip' AS UNSIGNED ARRAY)) );
```

A multi-valued index can also be defined as part of a composite index. This example shows a composite index that includes two single-valued parts (for the id and modified columns), and one multi-valued part (for the custinfo column):

```sql
CREATE TABLE customers {
  id BIGINT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  modified DATETIME DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
  custinfo JSON
};
ALTER TABLE customers ADD INDEX comp(id, modified, (CAST(custinfo->'$.zipcode' AS UNSIGNED ARRAY)) );
```

Only one multi-valued key part can be used in a composite index. The multi-valued key part may be used in any order relative to the other parts of the key. In other words, the `ALTER TABLE` statement just shown could have used `comp(id, (CAST(custinfo->'$.zipcode' AS UNSIGNED ARRAY), modified))` (or any other ordering) and still have been valid.

Using multi-valued Indexes

The optimizer uses a multi-valued index to fetch records when the following functions are specified in a `WHERE` clause:

- `MEMBER OF()`
- `JSON_CONTAINS()`
- `JSON_OVERLAPS()`

We can demonstrate this by creating and populating the `customers` table using the following `CREATE TABLE` and `INSERT` statements:

```sql
mysql> CREATE TABLE customers {
  ->  id BIGINT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  ->  modified DATETIME DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
  ->  custinfo JSON
  -> };
Query OK, 0 rows affected (0.51 sec)

mysql> INSERT INTO customers VALUES
  ->  (NULL, NOW(), '{"user":"Jack","user_id":37,"zipcode":[94582,94536]}'),
  ->  (NULL, NOW(), '{"user":"Jill","user_id":22,"zipcode":[94568,94507,94582]}'),
  ->  (NULL, NOW(), '{"user":"Bob","user_id":31,"zipcode":[94477,94507]}'),
  ->  (NULL, NOW(), '{"user":"Mary","user_id":72,"zipcode":[94536]}'),
  ->  (NULL, NOW(), '{"user":"Ted","user_id":56,"zipcode":[94507,94582]}');
Query OK, 5 rows affected (0.07 sec)
Records: 5  Duplicates: 0  Warnings: 0
```
First we execute three queries on the customers table, one each using \texttt{MEMBER\_OF()}, \texttt{JSON\_CONTAINS()}, and \texttt{JSON\_OVERLAPS()}, with the result from each query shown here:

<table>
<thead>
<tr>
<th>id</th>
<th>modified</th>
<th>custinfo</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2019-06-29 22:23:12</td>
<td>{&quot;user&quot;: &quot;Jack&quot;, &quot;user_id&quot;: 37, &quot;zipcode&quot;: [94582, 94536]}</td>
</tr>
<tr>
<td>2</td>
<td>2019-06-29 22:23:12</td>
<td>{&quot;user&quot;: &quot;Jill&quot;, &quot;user_id&quot;: 22, &quot;zipcode&quot;: [94507, 94582]}</td>
</tr>
<tr>
<td>3</td>
<td>2019-06-29 22:23:12</td>
<td>{&quot;user&quot;: &quot;Bob&quot;, &quot;user_id&quot;: 31, &quot;zipcode&quot;: [94477, 94507]}</td>
</tr>
</tbody>
</table>

3 rows in set (0.00 sec)

Next, we run \texttt{EXPLAIN} on each of the previous three queries:

<table>
<thead>
<tr>
<th>id</th>
<th>select_type</th>
<th>table</th>
<th>partitions</th>
<th>type</th>
<th>possible_keys</th>
<th>key</th>
<th>key_len</th>
<th>ref</th>
<th>rows</th>
<th>filtered</th>
<th>Extra</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>SIMPLE</td>
<td>customers</td>
<td>NULL</td>
<td>ALL</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
<td>5</td>
<td>100.00</td>
<td>Using where</td>
</tr>
</tbody>
</table>

1 row in set, 1 warning (0.00 sec)

<table>
<thead>
<tr>
<th>id</th>
<th>select_type</th>
<th>table</th>
<th>partitions</th>
<th>type</th>
<th>possible_keys</th>
<th>key</th>
<th>key_len</th>
<th>ref</th>
<th>rows</th>
<th>filtered</th>
<th>Extra</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>SIMPLE</td>
<td>customers</td>
<td>NULL</td>
<td>ALL</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
<td>5</td>
<td>100.00</td>
<td>Using where</td>
</tr>
</tbody>
</table>

1 row in set, 1 warning (0.00 sec)

None of the three queries just shown are able to use any keys. To solve this problem, we can add a multi-valued index on the \texttt{zipcode} array in the \texttt{JSON} column (\texttt{custinfo}), like this:

\begin{verbatim}
mysql> ALTER TABLE customers
  -> ADD INDEX zips( (CAST(custinfo->'$.zipcode' AS UNSIGNED ARRAY)) );
Query OK, 0 rows affected (0.47 sec)
Records: 0  Duplicates: 0  Warnings: 0
\end{verbatim}
CREATE INDEX Statement

When we run the previous `EXPLAIN` statements again, we can now observe that the queries can (and do) use the index `zips` that was just created:

```sql
mysql> EXPLAIN SELECT * FROM customers
    -> WHERE 94507 MEMBER OF(custinfo->'$.zipcode');

+----+-------------+-----------+------------+------+---------------+------+---------+-------+------+----------+-------------+
| id | select_type | table     | partitions | type | possible_keys | key  | key_len | ref   | rows | filtered | Extra       |
|----|-------------|-----------|------------|------|---------------|------|---------|-------|------|----------|-------------+
|  1 | SIMPLE      | customers | NULL       | ref  | zips          | zips | 9       | const |  1   |   100.00 | Using where |
+----+-------------+-----------+------------+------+---------------+------+---------+-------+------+----------+-------------+
1 row in set, 1 warning (0.00 sec)
```

```sql
mysql> EXPLAIN SELECT * FROM customers
    -> WHERE JSON_CONTAINS(custinfo->'$.zipcode', CAST('[94507,94582]' AS JSON));

+----+-------------+-----------+------------+-------+---------------+------+---------+------+------+----------+-------------+
| id | select_type | table     | partitions | type  | possible_keys | key  | key_len | ref  | rows | filtered | Extra       |
|----|-------------|-----------|------------|-------|---------------|------|---------|------|------|----------|-------------+
|  1 | SIMPLE      | customers | NULL       | range | zips          | zips | 9       | NULL |  6   |   100.00 | Using where |
+----+-------------+-----------+------------+-------+---------------+------+---------+------+------+----------+-------------+
1 row in set, 1 warning (0.00 sec)
```

```sql
mysql> EXPLAIN SELECT * FROM customers
    -> WHERE JSON_OVERLAPS(custinfo->'$.zipcode', CAST('[94507,94582]' AS JSON));

+----+-------------+-----------+------------+-------+---------------+------+---------+------+------+----------+-------------+
| id | select_type | table     | partitions | type  | possible_keys | key  | key_len | ref  | rows | filtered | Extra       |
|----|-------------|-----------|------------|-------|---------------|------|---------|------|------|----------|-------------+
|  1 | SIMPLE      | customers | NULL       | range | zips          | zips | 9       | NULL |  6   |   100.00 | Using where |
+----+-------------+-----------+------------+-------+---------------+------+---------+------+------+----------+-------------+
1 row in set, 1 warning (0.01 sec)
```

A multi-valued index can be defined as a unique key. If defined as a unique key, attempting to insert a value already present in the multi-valued index returns a duplicate key error. If duplicate values are already present, attempting to add a unique multi-valued index fails, as shown here:

```sql
mysql> ALTER TABLE customers DROP INDEX zips;
Query OK, 0 rows affected (0.55 sec)
Records: 0  Duplicates: 0  Warnings: 0

mysql> ALTER TABLE customers
    -> ADD UNIQUE INDEX zips((CAST(custinfo->'$.zipcode' AS UNSIGNED ARRAY)));
ERROR 1062 (23000): Duplicate entry '94507,' for key 'customers.zips'

mysql> ALTER TABLE customers
    -> ADD INDEX zips((CAST(custinfo->'$.zipcode' AS UNSIGNED ARRAY)));
Query OK, 0 rows affected (0.36 sec)
Records: 0  Duplicates: 0  Warnings: 0
```

Characteristics of Multi-Valued Indexes

Multi-valued indexes have the additional characteristics listed here:

- DML operations that affect multi-valued indexes are handled in the same way as DML operations that affect a normal index, with the only difference being that there may be more than one insert or update for a single clustered index record.

- Nullability and multi-valued indexes:
  - If multi-valued key part has an empty array, no entries are added to the index, and the data record is not accessible by an index scan.
  - If multi-valued key part generation returns a `NULL` value, a single entry containing `NULL` is added to the multi-valued index. If the key part is defined as `NOT NULL`, an error is reported.
  - If the typed array column is set to `NULL`, the storage engine stores single record containing `NULL` that points to the data record.
  - `JSON` null values are not permitted in indexed arrays. If any returned value is `NULL`, it is treated as a `JSON` null and an `Invalid JSON value` error is reported.
CREATE INDEX Statement

- Because multi-valued indexes are virtual indexes on virtual columns, they must adhere to the same rules as secondary indexes on virtual generated columns.

- Index records are not added for empty arrays.

Limitations and Restrictions on Multi-valued Indexes

Multi-valued indexes are subject to the limitations and restrictions listed here:

- Only one multi-valued key part is permitted per multi-valued index. However, the `CAST(...) AS ... ARRAY)` expression can refer to multiple arrays within a JSON document, as shown here:

  ```sql
  CAST(data->'$.arr[*][*]' AS UNSIGNED ARRAY)
  ```

  In this case, all values matching the JSON expression are stored in the index as a single flat array.

- An index with a multi-valued key part does not support ordering and therefore cannot be used as a primary key. For the same reason, a multi-valued index cannot be defined using the `ASC` or `DESC` keyword.

- A multi-valued index cannot be a covering index.

- The maximum number of values per record for a multi-valued index is determined by the amount of data than can be stored on a single undo log page, which is 65221 bytes (64K minus 315 bytes for overhead), which means that the maximum total length of key values is also 65221 bytes. The maximum number of keys depends on various factors, which prevents defining a specific limit. Tests have shown a multi-valued index to permit as many as 1604 integer keys per record, for example. When the limit is reached, an error similar to the following is reported: `ERROR 3905 (HY000): Exceeded max number of values per record for multi-valued index ‘idx’ by 1 value(s).`

- The only type of expression that is permitted in a multi-valued key part is a JSON expression. The expression need not reference an existing element in a JSON document inserted into the indexed column, but must itself be syntactically valid.

- Because index records for the same clustered index record are dispersed throughout a multi-valued index, a multi-valued index does not support range scans or index-only scans.

- Multi-valued indexes are not permitted in foreign key specifications.

- Index prefixes cannot be defined for multi-valued indexes.

- Multi-valued indexes cannot be defined on data cast as `BINARY` (see the description of the `CAST()` function).

- Online creation of a multi-value index is not supported, which means the operation uses `ALGORITHM=COPY`. See Performance and Space Requirements.

- Character sets and collations other than the following two combinations of character set and collation are not supported for multi-valued indexes:
  1. The `binary` character set with the default `binary` collation
  2. The `utf8mb4` character set with the default `utf8mb4_0900_as_cs` collation.

- As with other indexes on columns of InnoDB tables, a multi-valued index cannot be created with `USING HASH`; attempting to do so results in a warning: This storage engine does not support the HASH index algorithm, storage engine default was used instead. (USING BTREE is supported as usual.)

Spatial Indexes

The MyISAM, InnoDB, NDB, and ARCHIVE storage engines support spatial columns such as `POINT` and `GEOMETRY`. (Section 11.4, “Spatial Data Types”, describes the spatial data types.) However,
support for spatial column indexing varies among engines. Spatial and nonspatial indexes on spatial columns are available according to the following rules.

Spatial indexes on spatial columns have these characteristics:

- Available only for InnoDB and MyISAM tables. Specifying SPATIAL INDEX for other storage engines results in an error.
- As of MySQL 8.0.12, an index on a spatial column must be a SPATIAL index. The SPATIAL keyword is thus optional but implicit for creating an index on a spatial column.
- Available for single spatial columns only. A spatial index cannot be created over multiple spatial columns.
- Indexed columns must be NOT NULL.
- Column prefix lengths are prohibited. The full width of each column is indexed.
- Not permitted for a primary key or unique index.

Nonspatial indexes on spatial columns (created with INDEX, UNIQUE, or PRIMARY KEY) have these characteristics:

- Permitted for any storage engine that supports spatial columns except ARCHIVE.
- Columns can be NULL unless the index is a primary key.
- The index type for a non-SPATIAL index depends on the storage engine. Currently, B-tree is used.
- Permitted for a column that can have NULL values only for InnoDB, MyISAM, and MEMORY tables.

Index Options

Following the key part list, index options can be given. An index_option value can be any of the following:

- KEY_BLOCK_SIZE [=] value
  
  For MyISAM tables, KEY_BLOCK_SIZE optionally specifies the size in bytes to use for index key blocks. The value is treated as a hint; a different size could be used if necessary. A KEY_BLOCK_SIZE value specified for an individual index definition overrides a table-level KEY_BLOCK_SIZE value.
  
  KEY_BLOCK_SIZE is not supported at the index level for InnoDB tables. See Section 13.1.20, “CREATE TABLE Statement”.

- index_type

Some storage engines permit you to specify an index type when creating an index. For example:

```
CREATE TABLE lookup (id INT) ENGINE = MEMORY;
CREATE INDEX id_index ON lookup (id) USING BTREE;
```

Table 13.1, “Index Types Per Storage Engine” shows the permissible index type values supported by different storage engines. Where multiple index types are listed, the first one is the default when no index type specifier is given. Storage engines not listed in the table do not support an index_type clause in index definitions.

Table 13.1 Index Types Per Storage Engine

<table>
<thead>
<tr>
<th>Storage Engine</th>
<th>Permissible Index Types</th>
</tr>
</thead>
<tbody>
<tr>
<td>InnoDB</td>
<td>BTREE</td>
</tr>
<tr>

</tbody>
</table>
CREATE INDEX Statement

### Storage Engine

<table>
<thead>
<tr>
<th>Permissible Index Types</th>
</tr>
</thead>
<tbody>
<tr>
<td>MEMORY/HEAP</td>
</tr>
<tr>
<td>HASH, BTREE</td>
</tr>
<tr>
<td>NDB</td>
</tr>
<tr>
<td>HASH, BTREE (see note in text)</td>
</tr>
</tbody>
</table>

The index_type clause cannot be used for FULLTEXT INDEX or (prior to MySQL 8.0.12) SPATIAL INDEX specifications. Full-text index implementation is storage engine dependent. Spatial indexes are implemented as R-tree indexes.

If you specify an index type that is not valid for a given storage engine, but another index type is available that the engine can use without affecting query results, the engine uses the available type. The parser recognizes RTREE as a type name. As of MySQL 8.0.12, this is permitted only for SPATIAL indexes. Prior to 8.0.12, RTREE cannot be specified for any storage engine.

**Note**

**BTREE** indexes are implemented by the **NDB** storage engine as T-tree indexes.

**Note**

For indexes on NDB table columns, the USING option can be specified only for a unique index or primary key. USING HASH prevents the creation of an ordered index; otherwise, creating a unique index or primary key on an NDB table automatically results in the creation of both an ordered index and a hash index, each of which indexes the same set of columns.

For unique indexes that include one or more NULL columns of an NDB table, the hash index can be used only to look up literal values, which means that IS [NOT] NULL conditions require a full scan of the table. One workaround is to make sure that a unique index using one or more NULL columns on such a table is always created in such a way that it includes the ordered index; that is, avoid employing USING HASH when creating the index.

If you specify an index type that is not valid for a given storage engine, but another index type is available that the engine can use without affecting query results, the engine uses the available type. The parser recognizes RTREE as a type name, but currently this cannot be specified for any storage engine.

**Note**

Use of the index_type option before the ON tbl_name clause is deprecated; expect support for use of the option in this position to be removed in a future MySQL release. If an index_type option is given in both the earlier and later positions, the final option applies.

**TYPE** type_name is recognized as a synonym for USING type_name. However, USING is the preferred form.

The following tables show index characteristics for the storage engines that support the index_type option.

### Table 13.2 InnoDB Storage Engine Index Characteristics

<table>
<thead>
<tr>
<th>Index Class</th>
<th>Index Type</th>
<th>Stores NULL VALUES</th>
<th>Permits Multiple NULL Values</th>
<th>IS NULL Scan Type</th>

</tr>
<tr>
<td>Key</td>
<td>HASH</td>
<td>Yes</td>
<td>Yes</td>
<td>Table (see note 1)</td>
<td>Table (see note 1)</td>
</tr>
</tbody>
</table>

Table note:

1. **USING HASH** prevents creation of an implicit ordered index.

- **WITH PARSER parser_name**

This option can be used only with **FULLTEXT** indexes. It associates a parser plugin with the index if full-text indexing and searching operations need special handling. **InnoDB** and **MyISAM** support full-text parser plugins. If you have a **MyISAM** table with an associated full-text parser plugin, you can convert the table to **InnoDB** using **ALTER TABLE**. See **Full-Text Parser Plugins** and **Writing Full-Text Parser Plugins** for more information.
CREATE LOGFILE GROUP Statement

Index definitions can include an optional comment of up to 1024 characters.

The `MERGE_THRESHOLD` for index pages can be configured for individual indexes using the `index_option COMMENT` clause of the `CREATE_INDEX` statement. For example:

```sql
CREATE TABLE t1 (id INT);
CREATE INDEX id_index ON t1 (id) COMMENT 'MERGE_THRESHOLD=40';
```

If the page-full percentage for an index page falls below the `MERGE_THRESHOLD` value when a row is deleted or when a row is shortened by an update operation, InnoDB attempts to merge the index page with a neighboring index page. The default `MERGE_THRESHOLD` value is 50, which is the previously hardcoded value.

`MERGE_THRESHOLD` can also be defined at the index level and table level using `CREATE TABLE` and `ALTER TABLE` statements. For more information, see Section 15.8.11, “Configuring the Merge Threshold for Index Pages”.

- **VISIBLE, INVISIBLE**

  Specify index visibility. Indexes are visible by default. An invisible index is not used by the optimizer. Specification of index visibility applies to indexes other than primary keys (either explicit or implicit). For more information, see Section 8.3.12, “Invisible Indexes”.

- **ENGINE_ATTRIBUTE and SECONDARY_ENGINE_ATTRIBUTE** options (available as of MySQL 8.0.21) are used to specify index attributes for primary and secondary storage engines. The options are reserved for future use.

  Permitted values are a string literal containing a valid JSON document or an empty string (""). Invalid JSON is rejected.

  ```sql
  CREATE INDEX i1 ON t1 (c1) ENGINE_ATTRIBUTE='{"key":"value"}';
  ```

  `ENGINE_ATTRIBUTE` and `SECONDARY_ENGINE_ATTRIBUTE` values can be repeated without error. In this case, the last specified value is used.

  `ENGINE_ATTRIBUTE` and `SECONDARY_ENGINE_ATTRIBUTE` values are not checked by the server, nor are they cleared when the table’s storage engine is changed.

Table Copying and Locking Options

`ALGORITHM` and `LOCK` clauses may be given to influence the table copying method and level of concurrency for reading and writing the table while its indexes are being modified. They have the same meaning as for the `ALTER TABLE` statement. For more information, see Section 13.1.9, “ALTER TABLE Statement”.

NDB Cluster supports online operations using the same `ALGORITHM=INPLACE` syntax used with the standard MySQL Server. See Section 23.5.11, “Online Operations with ALTER TABLE in NDB Cluster”, for more information.

13.1.16 CREATE LOGFILE GROUP Statement

```sql
CREATE LOGFILE GROUP logfile_group
  ADD UNDOFILE 'undo_file'
  [INITIAL_SIZE [=] initial_size]
  [UNDO_BUFFER_SIZE [=] undo_buffer_size]
  [REDO_BUFFER_SIZE [=] redo_buffer_size]
  [NODEGROUP [=] nodegroup_id]
  [WAIT]
  [COMMENT [=] 'string']
  ENGINE [=] engine_name
```
CREATE LOGFILE GROUP Statement

This statement creates a new log file group named `logfile_group` having a single UNDO file named `undo_file`. A CREATE LOGFILE GROUP statement has one and only one ADD UNDOFILE clause. For rules covering the naming of log file groups, see Section 9.2, “Schema Object Names”.

Note

All NDB Cluster Disk Data objects share the same namespace. This means that each Disk Data object must be uniquely named (and not merely each Disk Data object of a given type). For example, you cannot have a tablespace and a log file group with the same name, or a tablespace and a data file with the same name.

There can be only one log file group per NDB Cluster instance at any given time.

The optional INITIAL_SIZE parameter sets the UNDO file's initial size; if not specified, it defaults to 128M (128 megabytes). The optional UNDO_BUFFER_SIZE parameter sets the size used by the UNDO buffer for the log file group; The default value for UNDO_BUFFER_SIZE is 8M (eight megabytes); this value cannot exceed the amount of system memory available. Both of these parameters are specified in bytes. You may optionally follow either or both of these with a one-letter abbreviation for an order of magnitude, similar to those used in my.cnf. Generally, this is one of the letters M (for megabytes) or G (for gigabytes).

Memory used for UNDO_BUFFER_SIZE comes from the global pool whose size is determined by the value of the SharedGlobalMemory data node configuration parameter. This includes any default value implied for this option by the setting of the InitialLogFileGroup data node configuration parameter.

The maximum permitted for UNDO_BUFFER_SIZE is 629145600 (600 MB).

On 32-bit systems, the maximum supported value for INITIAL_SIZE is 4294967296 (4 GB). (Bug #29186)

The minimum allowed value for INITIAL_SIZE is 1048576 (1 MB).

The ENGINE option determines the storage engine to be used by this log file group, with engine_name being the name of the storage engine. In MySQL 8.0, this must be NDB (or NDBCLUSTER). If ENGINE is not set, MySQL tries to use the engine specified by the default_storage_engine server system variable (formerly storage_engine). In any case, if the engine is not specified as NDB or NDBCLUSTER, the CREATE LOGFILE GROUP statement appears to succeed but actually fails to create the log file group, as shown here:

```
mysql> CREATE LOGFILE GROUP lg1
    ->    ADD UNDOFILE 'undo.dat' INITIAL_SIZE = 10M;
Query OK, 0 rows affected, 1 warning (0.00 sec)

mysql> SHOW WARNINGS;
+-------+------+------------------------------------------------------------------------------------------------+
| Level | Code | Message                                                                                        |
+-------+------+------------------------------------------------------------------------------------------------+
| Error | 1478 | Table storage engine 'InnoDB' does not support the create option 'TABLESPACE or LOGFILE GROUP'  |
+-------+------+------------------------------------------------------------------------------------------------+
1 row in set (0.00 sec)

mysql> DROP LOGFILE GROUP lg1 ENGINE = NDB;
ERROR 1529 (HY000): Failed to drop LOGFILE GROUP

mysql> CREATE LOGFILE GROUP lg1
    ->    ADD UNDOFILE 'undo.dat' INITIAL_SIZE = 10M
    ->    ENGINE = NDB;
Query OK, 0 rows affected (2.97 sec)
```

The fact that the CREATE LOGFILE GROUP statement does not actually return an error when a non-NDB storage engine is named, but rather appears to succeed, is a known issue which we hope to address in a future release of NDB Cluster.
CREATE PROCEDURE and CREATE FUNCTION Statements

**REDO_BUFFER_SIZE**, **NODEGROUP**, **WAIT**, and **COMMENT** are parsed but ignored, and so have no effect in MySQL 8.0. These options are intended for future expansion.

When used with **ENGINE [ = ] NDB**, a log file group and associated **UNDO** log file are created on each Cluster data node. You can verify that the **UNDO** files were created and obtain information about them by querying the **INFORMATION_SCHEMA.FILES** table. For example:

```
mysql> SELECT LOGFILE_GROUP_NAME, LOGFILE_GROUP_NUMBER, EXTRA
    -> FROM INFORMATION_SCHEMA.FILES
    -> WHERE FILE_NAME = 'undo_10.dat';
```

<table>
<thead>
<tr>
<th>LOGFILE_GROUP_NAME</th>
<th>LOGFILE_GROUP_NUMBER</th>
<th>EXTRA</th>
</tr>
</thead>
<tbody>
<tr>
<td>lg_3</td>
<td>11</td>
<td>CLUSTER_NODE=3</td>
</tr>
<tr>
<td>lg_3</td>
<td>11</td>
<td>CLUSTER_NODE=4</td>
</tr>
</tbody>
</table>

2 rows in set (0.06 sec)

**CREATE LOGFILE GROUP** is useful only with Disk Data storage for NDB Cluster. See Section 23.5.10, "NDB Cluster Disk Data Tables".

### 13.1.17 CREATE PROCEDURE and CREATE FUNCTION Statements

**CREATE**

```sql
CREATE [DEFINER = user]
    PROCEDURE sp_name ([proc_parameter[, ...]])
    [characteristic ...] routine_body
```

**CREATE**

```sql
CREATE [DEFINER = user]
    FUNCTION sp_name ([func_parameter[, ...]])
    RETURNS type
    [characteristic ...] routine_body
```

**proc_parameter**:

- `IN | OUT | INOUT` `param_name` `type`

**func_parameter**:

- `param_name` `type`

**type**:

- Any valid MySQL data type

**characteristic**:

- `COMMENT 'string'
- `LANGUAGE SQL`
- `[NOT] DETERMINISTIC`
- `{ CONTAINS SQL | NO SQL | READS SQL DATA | MODIFIES SQL DATA }
- `SQL SECURITY { DEFINER | INVOKER }

**routine_body**:

- Valid SQL routine statement

These statements are used to create a stored routine (a stored procedure or function). That is, the specified routine becomes known to the server. By default, a stored routine is associated with the default database. To associate the routine explicitly with a given database, specify the name as `db_name.sp_name` when you create it.

The **CREATE FUNCTION** statement is also used in MySQL to support UDFs (user-defined functions). See Section 13.7.4.1, "CREATE FUNCTION Statement for User-Defined Functions". A UDF can be regarded as an external stored function. Stored functions share their namespace with UDFs. See Section 9.2.5, "Function Name Parsing and Resolution", for the rules describing how the server interprets references to different kinds of functions.

To invoke a stored procedure, use the **CALL** statement (see Section 13.2.1, "CALL Statement"). To invoke a stored function, refer to it in an expression. The function returns a value during expression evaluation.
CREATE PROCEDURE and CREATE FUNCTION Statements

CREATE PROCEDURE and CREATE FUNCTION require the CREATE ROUTINE privilege. If the DEFINER clause is present, the privileges required depend on the user value, as discussed in Section 25.6, “Stored Object Access Control”. If binary logging is enabled, CREATE FUNCTION might require the SUPER privilege, as discussed in Section 25.7, “Stored Program Binary Logging”.

By default, MySQL automatically grants the ALTER ROUTINE and EXECUTE privileges to the routine creator. This behavior can be changed by disabling the automatic_sp_privileges system variable. See Section 25.2.2, “Stored Routines and MySQL Privileges”.

The DEFINER and SQL SECURITY clauses specify the security context to be used when checking access privileges at routine execution time, as described later in this section.

If the routine name is the same as the name of a built-in SQL function, a syntax error occurs unless you use a space between the name and the following parenthesis when defining the routine or invoking it later. For this reason, avoid using the names of existing SQL functions for your own stored routines.

The IGNORE_SPACE SQL mode applies to built-in functions, not to stored routines. It is always permissible to have spaces after a stored routine name, regardless of whether IGNORE_SPACE is enabled.

The parameter list enclosed within parentheses must always be present. If there are no parameters, an empty parameter list of () should be used. Parameter names are not case-sensitive.

Each parameter is an IN parameter by default. To specify otherwise for a parameter, use the keyword OUT or INOUT before the parameter name.

Note

Specifying a parameter as IN, OUT, or INOUT is valid only for a PROCEDURE. For a FUNCTION, parameters are always regarded as IN parameters.

An IN parameter passes a value into a procedure. The procedure might modify the value, but the modification is not visible to the caller when the procedure returns. An OUT parameter passes a value from the procedure back to the caller. Its initial value is NULL within the procedure, and its value is visible to the caller when the procedure returns. An INOUT parameter is initialized by the caller, can be modified by the procedure, and any change made by the procedure is visible to the caller when the procedure returns.

For each OUT or INOUT parameter, pass a user-defined variable in the CALL statement that invokes the procedure so that you can obtain its value when the procedure returns. If you are calling the procedure from within another stored procedure or function, you can also pass a routine parameter or local routine variable as an OUT or INOUT parameter. If you are calling the procedure from within a trigger, you can also pass NEW.col_name as an OUT or INOUT parameter.

For information about the effect of unhandled conditions on procedure parameters, see Section 13.6.7.8, “Condition Handling and OUT or INOUT Parameters”.

Routine parameters cannot be referenced in statements prepared within the routine; see Section 25.8, “Restrictions on Stored Programs”.

The following example shows a simple stored procedure that, given a country code, counts the number of cities for that country that appear in the city table of the world database. The country code is passed using an IN parameter, and the city count is returned using an OUT parameter:

mysql> delimiter //
mysql> CREATE PROCEDURE citycount (IN country CHAR(3), OUT cities INT)
BEGIN
  SELECT COUNT(*) INTO cities FROM world.city
  WHERE CountryCode = country;
END//
Query OK, 0 rows affected (0.01 sec)
mysql> delimiter ;
CREATE PROCEDURE and CREATE FUNCTION Statements

The example uses the `mysql` client `delimiter` command to change the statement delimiter from `;` to `//` while the procedure is being defined. This enables the `;` delimiter used in the procedure body to be passed through to the server rather than being interpreted by `mysql` itself. See Section 25.1, “Defining Stored Programs”.

The `RETURNS` clause may be specified only for a `FUNCTION`, for which it is mandatory. It indicates the return type of the function, and the function body must contain a `RETURN` value statement. If the `RETURN` statement returns a value of a different type, the value is coerced to the proper type. For example, if a function specifies an `ENUM` or `SET` value in the `RETURNS` clause, but the `RETURN` statement returns an integer, the value returned from the function is the string for the corresponding `ENUM` member of set of `SET` members.

The following example function takes a parameter, performs an operation using an SQL function, and returns the result. In this case, it is unnecessary to use `delimiter` because the function definition contains no internal `;` statement delimiters:

```
mysql> CREATE FUNCTION hello (s CHAR(20))
    -> RETURNS CHAR(50) DETERMINISTIC
    -> RETURN CONCAT('Hello, ',s,'!');
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT hello('world');
+----------------+
| hello('world') |
+----------------+
| Hello, world!  |
+----------------+
1 row in set (0.00 sec)
```

Parameter types and function return types can be declared to use any valid data type. The `COLLATE` attribute can be used if preceded by a `CHARACTER` `SET` specification.

The `routine_body` consists of a valid SQL routine statement. This can be a simple statement such as `SELECT` or `INSERT`, or a compound statement written using `BEGIN` and `END`. Compound statements can contain declarations, loops, and other control structure statements. The syntax for these statements is described in Section 13.6, “Compound Statement Syntax”. In practice, stored functions tend to use compound statements, unless the body consists of a single `RETURN` statement.

MySQL permits routines to contain DDL statements, such as `CREATE` and `DROP`. MySQL also permits stored procedures (but not stored functions) to contain SQL transaction statements such as `COMMIT`. Stored functions may not contain statements that perform explicit or implicit commit or rollback. Support for these statements is not required by the SQL standard, which states that each DBMS vendor may decide whether to permit them.
CREATE PROCEDURE and CREATE FUNCTION Statements

Statements that return a result set can be used within a stored procedure but not within a stored function. This prohibition includes `SELECT` statements that do not have an `INTO var_list` clause and other statements such as `SHOW`, `EXPLAIN`, and `CHECK TABLE`. For statements that can be determined at function definition time to return a result set, a `Not allowed to return a result set from a function` error occurs (ER_SP_NO_RETSET). For statements that can be determined only at runtime to return a result set, a `PROCEDURE %s can't return a result set in the given context` error occurs (ER_SP_BADSELECT).

`USE` statements within stored routines are not permitted. When a routine is invoked, an implicit `USE db_name` is performed (and undone when the routine terminates). The causes the routine to have the given default database while it executes. References to objects in databases other than the routine default database should be qualified with the appropriate database name.

For additional information about statements that are not permitted in stored routines, see Section 25.8, “Restrictions on Stored Programs”.

For information about invoking stored procedures from within programs written in a language that has a MySQL interface, see Section 13.2.1, “CALL Statement”.

MySQL stores the `sql_mode` system variable setting in effect when a routine is created or altered, and always executes the routine with this setting in force, regardless of the current server SQL mode when the routine begins executing.

The switch from the SQL mode of the invoker to that of the routine occurs after evaluation of arguments and assignment of the resulting values to routine parameters. If you define a routine in strict SQL mode but invoke it in nonstrict mode, assignment of arguments to routine parameters does not take place in strict mode. If you require that expressions passed to a routine be assigned in strict SQL mode, you should invoke the routine with strict mode in effect.

The `COMMENT` characteristic is a MySQL extension, and may be used to describe the stored routine. This information is displayed by the `SHOW CREATE PROCEDURE` and `SHOW CREATE FUNCTION` statements.

The `LANGUAGE` characteristic indicates the language in which the routine is written. The server ignores this characteristic; only SQL routines are supported.

A routine is considered “deterministic” if it always produces the same result for the same input parameters, and “not deterministic” otherwise. If neither `DETERMINISTIC` nor `NOT DETERMINISTIC` is given in the routine definition, the default is `NOT DETERMINISTIC`. To declare that a function is deterministic, you must specify `DETERMINISTIC` explicitly.

Assessment of the nature of a routine is based on the “honesty” of the creator: MySQL does not check that a routine declared `DETERMINISTIC` is free of statements that produce nondeterministic results. However, misdeclaring a routine might affect results or affect performance. Declaring a nondeterministic routine as `DETERMINISTIC` might lead to unexpected results by causing the optimizer to make incorrect execution plan choices. Declaring a deterministic routine as `NONDETERMINISTIC` might diminish performance by causing available optimizations not to be used.

If binary logging is enabled, the `DETERMINISTIC` characteristic affects which routine definitions MySQL accepts. See Section 25.7, “Stored Program Binary Logging”.

A routine that contains the `NOW()` function (or its synonyms) or `RAND()` is nondeterministic, but it might still be replication-safe. For `NOW()`, the binary log includes the timestamp and replicates correctly. `RAND()` also replicates correctly as long as it is called only a single time during the execution of a routine. (You can consider the routine execution timestamp and random number seed as implicit inputs that are identical on the source and replica.)

Several characteristics provide information about the nature of data use by the routine. In MySQL, these characteristics are advisory only. The server does not use them to constrain what kinds of statements a routine is permitted to execute.
CREATE PROCEDURE and CREATE FUNCTION Statements

- **CONTAINS SQL** indicates that the routine does not contain statements that read or write data. This is the default if none of these characteristics is given explicitly. Examples of such statements are `SET @x = 1` or `DO RELEASE_LOCK('abc')`, which execute but neither read nor write data.

- **NO SQL** indicates that the routine contains no SQL statements.

- **READS SQL DATA** indicates that the routine contains statements that read data (for example, `SELECT`), but not statements that write data.

- **MODIFIES SQL DATA** indicates that the routine contains statements that may write data (for example, `INSERT` or `DELETE`).

The SQL SECURITY characteristic can be **DEFINER** or **INVOKER** to specify the security context; that is, whether the routine executes using the privileges of the account named in the routine **DEFINER** clause or the user who invokes it. This account must have permission to access the database with which the routine is associated. The default value is **DEFINER**. The user who invokes the routine must have the **EXECUTE** privilege for it, as must the **DEFINER** account if the routine executes in definer security context.

The **DEFINER** clause specifies the MySQL account to be used when checking access privileges at routine execution time for routines that have the SQL SECURITY **DEFINER** characteristic.

If the **DEFINER** clause is present, the **user** value should be a MySQL account specified as `'user_name'@'host_name'`, CURRENT_USER, or CURRENT_USER(). The permitted **user** values depend on the privileges you hold, as discussed in Section 25.6, “Stored Object Access Control”. Also see that section for additional information about stored routine security.

If the **DEFINER** clause is omitted, the default definer is the user who executes the **CREATE PROCEDURE** or **CREATE FUNCTION** statement. This is the same as specifying **DEFINER = CURRENT_USER** explicitly.

Within the body of a stored routine that is defined with the SQL SECURITY **DEFINER** characteristic, the **CURRENT_USER** function returns the routine's **DEFINER** value. For information about user auditing within stored routines, see Section 6.2.22, “SQL-Based Account Activity Auditing”.

Consider the following procedure, which displays a count of the number of MySQL accounts listed in the **mysql.user** system table:

```sql
CREATE DEFINER = 'admin'@'localhost' PROCEDURE account_count()
BEGIN
  SELECT 'Number of accounts:', COUNT(*) FROM mysql.user;
END;
```

The procedure is assigned a **DEFINER** account of 'admin'@'localhost' no matter which user defines it. It executes with the privileges of that account no matter which user invokes it (because the default security characteristic is **DEFINER**). The procedure succeeds or fails depending on whether the invoker has the **EXECUTE** privilege for it and 'admin'@'localhost' has the **SELECT** privilege for the **mysql.user** table.

Now suppose that the procedure is defined with the SQL SECURITY **INVOKER** characteristic:

```sql
CREATE DEFINER = 'admin'@'localhost' PROCEDURE account_count()
SQL SECURITY INVOKER
BEGIN
  SELECT 'Number of accounts:', COUNT(*) FROM mysql.user;
END;
```

The procedure still has a **DEFINER** of 'admin'@'localhost', but in this case, it executes with the privileges of the invoking user. Thus, the procedure succeeds or fails depending on whether the invoker has the **EXECUTE** privilege for it and the **SELECT** privilege for the **mysql.user** table.

The server handles the data type of a routine parameter, local routine variable created with **DECLARE**, or function return value as follows:
• Assignments are checked for data type mismatches and overflow. Conversion and overflow problems result in warnings, or errors in strict SQL mode.

• Only scalar values can be assigned. For example, a statement such as `SET x = (SELECT 1, 2)` is invalid.

• For character data types, if `CHARACTER_SET` is included in the declaration, the specified character set and its default collation is used. If the `COLLATE` attribute is also present, that collation is used rather than the default collation.

If `CHARACTER_SET` and `COLLATE` are not present, the database character set and collation in effect at routine creation time are used. To avoid having the server use the database character set and collation, provide an explicit `CHARACTER_SET` and a `COLLATE` attribute for character data parameters.

If you alter the database default character set or collation, stored routines that are to use the new database defaults must be dropped and recreated.

The database character set and collation are given by the value of the `character_set_database` and `collation_database` system variables. For more information, see Section 10.3.3, "Database Character Set and Collation".

### 13.1.18 CREATE SERVER Statement

```
CREATE SERVER server_name
    FOREIGN DATA WRAPPER wrapper_name
    OPTIONS (option [, option] ...)
```

This statement creates the definition of a server for use with the `FEDERATED` storage engine. The `CREATE SERVER` statement creates a new row in the `servers` table in the `mysql` database. This statement requires the `SUPER` privilege.

The `server_name` should be a unique reference to the server. Server definitions are global within the scope of the server, it is not possible to qualify the server definition to a specific database. `server_name` has a maximum length of 64 characters (names longer than 64 characters are silently truncated), and is case-insensitive. You may specify the name as a quoted string.

The `wrapper_name` is an identifier and may be quoted with single quotation marks.

For each `option` you must specify either a character literal or numeric literal. Character literals are UTF-8, support a maximum length of 64 characters and default to a blank (empty) string. String literals are silently truncated to 64 characters. Numeric literals must be a number between 0 and 9999, default value is 0.

**Note**

The `OWNER` option is currently not applied, and has no effect on the ownership or operation of the server connection that is created.

The `CREATE SERVER` statement creates an entry in the `mysql.servers` table that can later be used with the `CREATE TABLE` statement when creating a `FEDERATED` table. The options that you specify are used to populate the columns in the `mysql.servers` table. The table columns are `Server_name`, `Host`, `Db`, `Username`, `Password`, `Port` and `Socket`.
CREATE SPATIAL REFERENCE SYSTEM Statement

For example:

```sql
CREATE SERVER s
FOREIGN DATA WRAPPER mysql
OPTIONS (USER 'Remote', HOST '198.51.100.106', DATABASE 'test');
```

Be sure to specify all options necessary to establish a connection to the server. The user name, host name, and database name are mandatory. Other options might be required as well, such as password.

The data stored in the table can be used when creating a connection to a FEDERATED table:

```sql
CREATE TABLE t (s1 INT) ENGINE=FEDERATED CONNECTION='s';
```

For more information, see Section 16.8, "The FEDERATED Storage Engine".

CREATE SERVER causes an implicit commit. See Section 13.3.3, “Statements That Cause an Implicit Commit”.

CREATE SERVER is not written to the binary log, regardless of the logging format that is in use.

13.1.19 CREATE SPATIAL REFERENCE SYSTEM Statement

This statement creates a spatial reference system (SRS) definition and stores it in the data dictionary. It requires the SUPER privilege. The resulting data dictionary entry can be inspected using the INFORMATION_SCHEMA.ST_SPATIAL_REFERENCE_SYSTEMS table.

SRID values must be unique, so if neither OR REPLACE nor IF NOT EXISTS is specified, an error occurs if an SRS definition with the given SRID value already exists.

With CREATE OR REPLACE syntax, any existing SRS definition with the same SRID value is replaced, unless the SRID value is used by some column in an existing table. In that case, an error occurs. For example:

```sql
mysql> CREATE OR REPLACE SPATIAL REFERENCE SYSTEM 4326 ...;
ERROR 3716 (SR005): Can't modify SRID 4326. There is at least one column depending on it.
```

To identify which column or columns use the SRID, use this query, replacing 4326 with the SRID of the definition you are trying to create:

```sql
SELECT * FROM INFORMATION_SCHEMA.ST_GEOMETRY_COLUMNS WHERE SRS_ID=4326;
```

With CREATE ... IF NOT EXISTS syntax, any existing SRS definition with the same SRID value causes the new definition to be ignored and a warning occurs.

SRID values must be in the range of 32-bit unsigned integers, with these restrictions:

- SRID 0 is a valid SRID but cannot be used with CREATE SPATIAL REFERENCE SYSTEM.

- If the value is in a reserved SRID range, a warning occurs. Reserved ranges are [0, 32767] (reserved by EPSG), [60,000,000, 69,999,999] (reserved by EPSG), and [2,000,000,000, 2,147,483,647] (reserved by MySQL). EPSG stands for the European Petroleum Survey Group.
CREATE SPATIAL REFERENCE SYSTEM Statement

- Users should not create SRSs with SRIDs in the reserved ranges. Doing so runs the risk of the SRIDs conflicting with future SRS definitions distributed with MySQL, with the result that the new system-provided SRSs are not installed for MySQL upgrades or that the user-defined SRSs are overwritten.

Attributes for the statement must satisfy these conditions:

- Attributes can be given in any order, but no attribute can be given more than once.

- The `NAME` and `DEFINITION` attributes are mandatory.

- The `NAME srs_name` attribute value must be unique. The combination of the `ORGANIZATION org_name` and `org_id` attribute values must be unique.

- The `NAME srs_name` attribute value and `ORGANIZATION org_name` attribute value cannot be empty or begin or end with whitespace.

- String values in attribute specifications cannot contain control characters, including newline.

- The following table shows the maximum lengths for string attribute values.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Maximum Length (characters)</th>
</tr>
</thead>
<tbody>
<tr>
<td>NAME</td>
<td>80</td>
</tr>
<tr>
<td>DEFINITION</td>
<td>4096</td>
</tr>
<tr>
<td>ORGANIZATION</td>
<td>256</td>
</tr>
<tr>
<td>DESCRIPTION</td>
<td>2048</td>
</tr>
</tbody>
</table>

Here is an example `CREATE SPATIAL REFERENCE SYSTEM` statement. The `DEFINITION` value is reformatted across multiple lines for readability. (For the statement to be legal, the value actually must be given on a single line.)

```sql
CREATE SPATIAL REFERENCE SYSTEM 4120
  NAME 'Greek'
  ORGANIZATION 'EPSG' IDENTIFIED BY 4120
  DEFINITION
    'GEOGCS["Greek",DATUM["Greek",SPHEROID["Bessel 1841",
6377397.155,299.1528128,AUTHORITY["EPSG","7004"]],
AUTHORITY["EPSG","6120"]],PRIMEM["Greenwich",0,
AUTHORITY["EPSG","8901"]],UNIT["degree",0.017453292519943278,
AUTHORITY["EPSG","8901"]],AXIS["Lat",NORTH],AXIS["Lon",EAST],
AUTHORITY["EPSG","4120"]];
```

The grammar for SRS definitions is based on the grammar defined in OpenGIS Implementation Specification: Coordinate Transformation Services, Revision 1.00, OGC 01-009, January 12, 2001, Section 7.2. This specification is available at http://www.opengeospatial.org/standards/ct.

MySQL incorporates these changes to the specification:

- Only the `<horz cs>` production rule is implemented (that is, geographic and projected SRSs).

- There is an optional, nonstandard `<authority>` clause for `<parameter>`. This makes it possible to recognize projection parameters by authority instead of name.

- The specification does not make `AXIS` clauses mandatory in `GEOGCS` spatial reference system definitions. However, if there are no `AXIS` clauses, MySQL cannot determine whether a definition has axes in latitude-longitude order or longitude-latitude order. MySQL enforces the nonstandard requirement that each `GEOGCS` definition must include two `AXIS` clauses. One must be `NORTH` or `SOUTH`, and the other `EAST` or `WEST`. The `AXIS` clause order determines whether the definition has axes in latitude-longitude order or longitude-latitude order.

- SRS definitions may not contain newlines.
If an SRS definition specifies an authority code for the projection (which is recommended), an error occurs if the definition is missing mandatory parameters. In this case, the error message indicates what the problem is. The projection methods and mandatory parameters that MySQL supports are shown in Table 13.7, “Supported Spatial Reference System Projection Methods” and Table 13.8, “Spatial Reference System Projection Parameters”.

For additional information about writing SRS definitions for MySQL, see Geographic Spatial Reference Systems in MySQL 8.0 and Projected Spatial Reference Systems in MySQL 8.0.

The following table shows the projection methods that MySQL supports. MySQL permits unknown projection methods but cannot check the definition for mandatory parameters and cannot convert spatial data to or from an unknown projection. For detailed explanations of how each projection works, including formulas, see EPSG Guidance Note 7-2.

The following table shows the projection parameters that MySQL recognizes. Recognition occurs primarily by authority code. If there is no authority code, MySQL falls back to case-insensitive string matching on the parameter name. For details about each parameter, look it up by code in the EPSG Online Registry.

```
CREATE TABLE creates a table with the given name. You must have the CREATE privilege for the table.

By default, tables are created in the default database, using the InnoDB storage engine. An error occurs if the table exists, if there is no default database, or if the database does not exist.

MySQL has no limit on the number of tables. The underlying file system may have a limit on the number of files that represent tables. Individual storage engines may impose engine-specific constraints. InnoDB permits up to 4 billion tables.

For information about the physical representation of a table, see Section 13.1.20.1, “Files Created by CREATE TABLE”.

There are several aspects to the CREATE TABLE statement, described under the following topics in this section:

• Table Name
• Temporary Tables
• Table Cloning and Copying
• Column Data Types and Attributes
• Indexes, Foreign Keys, and CHECK Constraints
• Table Options
• Table Partitioning

Table Name

• tbl_name

The table name can be specified as db_name.tbl_name to create the table in a specific database. This works regardless of whether there is a default database, assuming that the database exists. If you use quoted identifiers, quote the database and table names separately. For example, write `mydb`.`mytbl`, not `mydb.mytbl`.

Rules for permissible table names are given in Section 9.2, “Schema Object Names”.

• IF NOT EXISTS

Prevents an error from occurring if the table exists. However, there is no verification that the existing table has a structure identical to that indicated by the CREATE TABLE statement.

Temporary Tables

You can use the TEMPORARY keyword when creating a table. A TEMPORARY table is visible only within the current session, and is dropped automatically when the session is closed. For more information, see Section 13.1.20.2, “CREATE TEMPORARY TABLE Statement”.

Table Cloning and Copying

• LIKE
CREATE TABLE Statement

Use `CREATE TABLE ... LIKE` to create an empty table based on the definition of another table, including any column attributes and indexes defined in the original table:

```
CREATE TABLE new_tbl LIKE orig_tbl;
```

For more information, see Section 13.1.20.3, “CREATE TABLE ... LIKE Statement”.

• `[AS] query_expression`  

To create one table from another, add a `SELECT` statement at the end of the `CREATE TABLE` statement:

```
CREATE TABLE new_tbl AS SELECT * FROM orig_tbl;
```

For more information, see Section 13.1.20.4, “CREATE TABLE ... SELECT Statement”.

• `IGNORE | REPLACE`  

The `IGNORE` and `REPLACE` options indicate how to handle rows that duplicate unique key values when copying a table using a `SELECT` statement.

For more information, see Section 13.1.20.4, “CREATE TABLE ... SELECT Statement”.

### Column Data Types and Attributes

There is a hard limit of 4096 columns per table, but the effective maximum may be less for a given table and depends on the factors discussed in Section 8.4.7, “Limits on Table Column Count and Row Size”.

• `data_type`  

`data_type` represents the data type in a column definition. For a full description of the syntax available for specifying column data types, as well as information about the properties of each type, see Chapter 11, Data Types.

• Some attributes do not apply to all data types. `AUTO_INCREMENT` applies only to integer and floating-point types. Prior to MySQL 8.0.13, `DEFAULT` does not apply to the `BLOB`, `TEXT`, `GEOMETRY`, and `JSON` types.

• Character data types (`CHAR`, `VARCHAR`, the `TEXT` types, `ENUM`, `SET`, and any synonyms) can include `CHARACTER SET` to specify the character set for the column. `CHARSET` is a synonym for `CHARACTER SET`. A collation for the character set can be specified with the `COLLATE` attribute, along with any other attributes. For details, see Chapter 10, Character Sets, Collations, Unicode. Example:

```
CREATE TABLE t (c CHAR(20) CHARACTER SET utf8 COLLATE utf8_bin);
```

MySQL 8.0 interprets length specifications in character column definitions in characters. Lengths for `BINARY` and `VARBINARY` are in bytes.

• For `CHAR`, `VARCHAR`, `BINARY`, and `VARBINARY` columns, indexes can be created that use only the leading part of column values, using `col_name(length)` syntax to specify an index prefix length. `BLOB` and `TEXT` columns also can be indexed, but a prefix length must be given. Prefix lengths are given in characters for nonbinary string types and in bytes for binary string types. That is, index entries consist of the first `length` characters of each column value for `CHAR`, `VARCHAR`, and `TEXT` columns, and the first `length` bytes of each column value for `BINARY`, `VARBINARY`, and `BLOB` columns. Indexing only a prefix of column values like this can make the index file much smaller. For additional information about index prefixes, see Section 13.1.15, “CREATE INDEX Statement”.

Only the `InnoDB` and `MyISAM` storage engines support indexing on `BLOB` and `TEXT` columns. For example:
CREATE TABLE test (blob_col BLOB, INDEX(blob_col(10)));

If a specified index prefix exceeds the maximum column data type size, `CREATE TABLE` handles the index as follows:

- For a nonunique index, either an error occurs (if strict SQL mode is enabled), or the index length is reduced to lie within the maximum column data type size and a warning is produced (if strict SQL mode is not enabled).
- For a unique index, an error occurs regardless of SQL mode because reducing the index length might enable insertion of nonunique entries that do not meet the specified uniqueness requirement.

- **JSON** columns cannot be indexed. You can work around this restriction by creating an index on a generated column that extracts a scalar value from the JSON column. See [Indexing a Generated Column to Provide a JSON Column Index](#), for a detailed example.

- **NOT NULL | NULL**

  If neither NULL nor NOT NULL is specified, the column is treated as though NULL had been specified.

  In MySQL 8.0, only the InnoDB, MyISAM, and MEMORY storage engines support indexes on columns that can have NULL values. In other cases, you must declare indexed columns as NOT NULL or an error results.

- **DEFAULT**

  Specifies a default value for a column. For more information about default value handling, including the case that a column definition includes no explicit DEFAULT value, see [Section 11.6, “Data Type Default Values”](#).

  If the NO_ZERO_DATE or NO_ZERO_IN_DATE SQL mode is enabled and a date-valued default is not correct according to that mode, `CREATE TABLE` produces a warning if strict SQL mode is not enabled and an error if strict mode is enabled. For example, with NO_ZERO_IN_DATE enabled, `c1 DATE DEFAULT '2010-00-00'` produces a warning.

- **VISIBLE, INVISIBLE**

  Specify column visibility. The default is VISIBLE if neither keyword is present. A table must have at least one visible column. Attempting to make all columns invisible produces an error. For more information, see [Section 13.1.20.10, “Invisible Columns”](#).

  The VISIBLE and INVISIBLE keywords are available as of MySQL 8.0.23. Prior to MySQL 8.0.23, all columns are visible.

- **AUTO_INCREMENT**

  An integer or floating-point column can have the additional attribute AUTO_INCREMENT. When you insert a value of NULL (recommended) or 0 into an indexed AUTO_INCREMENT column, the column
is set to the next sequence value. Typically this is value+1, where value is the largest value for the column currently in the table. AUTO_INCREMENT sequences begin with 1.

To retrieve an AUTO_INCREMENT value after inserting a row, use the LAST_INSERT_ID() SQL function or the mysql_insert_id() C API function. See Section 12.16, “Information Functions”, and mysql_insert_id().

If the NO_AUTO_VALUE_ON_ZERO SQL mode is enabled, you can store 0 in AUTO_INCREMENT columns as 0 without generating a new sequence value. See Section 5.1.11, “Server SQL Modes”.

There can be only one AUTO_INCREMENT column per table, it must be indexed, and it cannot have a DEFAULT value. An AUTO_INCREMENT column works properly only if it contains only positive values. Inserting a negative number is regarded as inserting a very large positive number. This is done to avoid precision problems when numbers “wrap” over from positive to negative and also to ensure that you do not accidentally get an AUTO_INCREMENT column that contains 0.

For MyISAM tables, you can specify an AUTO_INCREMENT secondary column in a multiple-column key. See Section 3.6.9, “Using AUTO_INCREMENT”.

To make MySQL compatible with some ODBC applications, you can find the AUTO_INCREMENT value for the last inserted row with the following query:

```
SELECT * FROM tbl_name WHERE auto_col IS NULL
```

This method requires that sql_auto_is_null variable is not set to 0. See Section 5.1.8, “Server System Variables”.

For information about InnoDB and AUTO_INCREMENT, see Section 15.6.1.6, “AUTO_INCREMENT Handling in InnoDB”. For information about AUTO_INCREMENT and MySQL Replication, see Section 17.5.1.1, “Replication and AUTO_INCREMENT”.

• COMMENT

A comment for a column can be specified with the COMMENT option, up to 1024 characters long. The comment is displayed by the SHOW CREATE TABLE and SHOW FULL COLUMNS statements.

• COLUMN_FORMAT

In NDB Cluster, it is also possible to specify a data storage format for individual columns of NDB tables using COLUMN_FORMAT. Permissible column formats are FIXED, DYNAMIC, and DEFAULT. FIXED is used to specify fixed-width storage, DYNAMIC permits the column to be variable-width, and DEFAULT causes the column to use fixed-width or variable-width storage as determined by the column's data type (possibly overridden by a ROW_FORMAT specifier).

For NDB tables, the default value for COLUMN_FORMAT is FIXED.

In NDB Cluster, the maximum possible offset for a column defined with COLUMN_FORMAT=FIXED is 8188 bytes. For more information and possible workarounds, see Section 23.1.7.5, “Limits Associated with Database Objects in NDB Cluster”.

COLUMN_FORMAT currently has no effect on columns of tables using storage engines other than NDB. MySQL 8.0 silently ignores COLUMN_FORMAT.
• **ENGINE_ATTRIBUTE** and **SECONDARY_ENGINE_ATTRIBUTE** options (available as of MySQL 8.0.21) are used to specify column attributes for primary and secondary storage engines. The options are reserved for future use.

Permitted values are a string literal containing a valid JSON document or an empty string (""). Invalid JSON is rejected.

```sql
CREATE TABLE t1 (c1 INT ENGINE_ATTRIBUTE='{"key":"value"}');
```

**ENGINE_ATTRIBUTE** and **SECONDARY_ENGINE_ATTRIBUTE** values can be repeated without error. In this case, the last specified value is used.

**ENGINE_ATTRIBUTE** and **SECONDARY_ENGINE_ATTRIBUTE** values are not checked by the server, nor are they cleared when the table's storage engine is changed.

• **STORAGE**

For NDB tables, it is possible to specify whether the column is stored on disk or in memory by using a **STORAGE** clause. **STORAGE DISK** causes the column to be stored on disk, and **STORAGE MEMORY** causes in-memory storage to be used. The **CREATE TABLE** statement used must still include a **TABLESPACE** clause:

```sql
mysql> CREATE TABLE t1 (  --> c1 INT STORAGE DISK,  --> c2 INT STORAGE MEMORY  --> ) ENGINE NDB;
ERROR 1005 (HY000): Can't create table 'c.t1' (errno: 140)
mysql> CREATE TABLE t1 (  --> c1 INT STORAGE DISK,  --> c2 INT STORAGE MEMORY  --> ) TABLESPACE ts_1 ENGINE NDB;
Query OK, 0 rows affected (1.06 sec)
```

For NDB tables, **STORAGE DEFAULT** is equivalent to **STORAGE MEMORY**.

The **STORAGE** clause has no effect on tables using storage engines other than NDB. The **STORAGE** keyword is supported only in the build of mysql that is supplied with NDB Cluster; it is not recognized in any other version of MySQL, where any attempt to use the **STORAGE** keyword causes a syntax error.

• **GENERATED ALWAYS**

Used to specify a generated column expression. For information about generated columns, see Section 13.1.20.8, “CREATE TABLE and Generated Columns”.

Stored generated columns can be indexed. InnoDB supports secondary indexes on virtual generated columns. See Section 13.1.20.9, “Secondary Indexes and Generated Columns”.

### Indexes, Foreign Keys, and CHECK Constraints

Several keywords apply to creation of indexes, foreign keys, and **CHECK** constraints. For general background in addition to the following descriptions, see Section 13.1.15, “CREATE INDEX Statement”, Section 13.1.20.5, “FOREIGN KEY Constraints”; and Section 13.1.20.6, “CHECK Constraints”.

• **CONSTRAINT symbol**

The **CONSTRAINT symbol** clause may be given to name a constraint. If the clause is not given, or a **symbol** is not included following the **CONSTRAINT** keyword, MySQL automatically generates a constraint name, with the exception noted below. The **symbol** value, if used, must be unique per schema (database), per constraint type. A duplicate **symbol** results in an error. See also the
discussion about length limits of generated constraint identifiers at Section 9.2.1, “Identifier Length Limits”.

Note

If the `CONSTRAINT symbol` clause is not given in a foreign key definition, or a `symbol` is not included following the `CONSTRAINT` keyword, MySQL uses the foreign key index name up to MySQL 8.0.15, and automatically generates a constraint name thereafter.

The SQL standard specifies that all types of constraints (primary key, unique index, foreign key, check) belong to the same namespace. In MySQL, each constraint type has its own namespace per schema. Consequently, names for each type of constraint must be unique per schema, but constraints of different types can have the same name.

- **PRIMARY KEY**

  A unique index where all key columns must be defined as `NOT NULL`. If they are not explicitly declared as `NOT NULL`, MySQL declares them so implicitly (and silently). A table can have only one PRIMARY KEY. The name of a PRIMARY KEY is always PRIMARY, which thus cannot be used as the name for any other kind of index.

  If you do not have a PRIMARY KEY and an application asks for the PRIMARY KEY in your tables, MySQL returns the first UNIQUE index that has no NULL columns as the PRIMARY KEY.

  In InnoDB tables, keep the PRIMARY KEY short to minimize storage overhead for secondary indexes. Each secondary index entry contains a copy of the primary key columns for the corresponding row. (See Section 15.6.2.1, “Clustered and Secondary Indexes”.)

  In the created table, a PRIMARY KEY is placed first, followed by all UNIQUE indexes, and then the nonunique indexes. This helps the MySQL optimizer to prioritize which index to use and also more quickly to detect duplicated UNIQUE keys.

  A PRIMARY KEY can be a multiple-column index. However, you cannot create a multiple-column index using the PRIMARY KEY key attribute in a column specification. Doing so only marks that single column as primary. You must use a separate `PRIMARY KEY(key_part, ...) clause`.

  If a table has a PRIMARY KEY or UNIQUE NOT NULL index that consists of a single column that has an integer type, you can use `_rowid` to refer to the indexed column in SELECT statements, as described in Unique Indexes.

  In MySQL, the name of a PRIMARY KEY is PRIMARY. For other indexes, if you do not assign a name, the index is assigned the same name as the first indexed column, with an optional suffix ( `_2`, `_3`, ...) to make it unique. You can see index names for a table using `SHOW INDEX FROM tbl_name`. See Section 13.7.7.22, “SHOW INDEX Statement”.

- **KEY | INDEX**

  KEY is normally a synonym for INDEX. The key attribute PRIMARY KEY can also be specified as just KEY when given in a column definition. This was implemented for compatibility with other database systems.

- **UNIQUE**

  A UNIQUE index creates a constraint such that all values in the index must be distinct. An error occurs if you try to add a new row with a key value that matches an existing row. For all engines, a UNIQUE index permits multiple NULL values for columns that can contain NULL. If you specify a
prefix value for a column in a UNIQUE index, the column values must be unique within the prefix length.

If a table has a PRIMARY KEY or UNIQUE NOT NULL index that consists of a single column that has an integer type, you can use _rowid to refer to the indexed column in SELECT statements, as described in Unique Indexes.

- **FULLTEXT**

A FULLTEXT index is a special type of index used for full-text searches. Only the InnoDB and MyISAM storage engines support FULLTEXT indexes. They can be created only from CHAR, VARCHAR, and TEXT columns. Indexing always happens over the entire column; column prefix indexing is not supported and any prefix length is ignored if specified. See Section 12.10, “Full-Text Search Functions”, for details of operation. A WITH PARSER clause can be specified as an index_option value to associate a parser plugin with the index if full-text indexing and searching operations need special handling. This clause is valid only for FULLTEXT indexes. InnoDB and MyISAM support full-text parser plugins. See Full-Text Parser Plugins and Writing Full-Text Parser Plugins for more information.

- **SPATIAL**

You can create SPATIAL indexes on spatial data types. Spatial types are supported only for InnoDB and MyISAM tables, and indexed columns must be declared as NOT NULL. See Section 11.4, “Spatial Data Types”.

- **FOREIGN KEY**

MySQL supports foreign keys, which let you cross-reference related data across tables, and foreign key constraints, which help keep this spread-out data consistent. For definition and option information, see reference_definition, and reference_option.

Partitioned tables employing the InnoDB storage engine do not support foreign keys. See Section 24.6, “Restrictions and Limitations on Partitioning”, for more information.

- **CHECK**

The CHECK clause enables the creation of constraints to be checked for data values in table rows. See Section 13.1.20.6, “CHECK Constraints”.

- **key_part**

A key_part specification can end with ASC or DESC to specify whether index values are stored in ascending or descending order. The default is ascending if no order specifier is given.

- Prefixes, defined by the length attribute, can be up to 767 bytes long for InnoDB tables that use the REDUNDANT or COMPACT row format. The prefix length limit is 3072 bytes for InnoDB tables that use the DYNAMIC or COMPRESSED row format. For MyISAM tables, the prefix length limit is 1000 bytes.

Prefix limits are measured in bytes. However, prefix lengths for index specifications in CREATE TABLE, ALTER TABLE, and CREATE INDEX statements are interpreted as number of characters for nonbinary string types (CHAR, VARCHAR, TEXT) and number of bytes for binary string types (BINARY, VARBINARY, BLOB). Take this into account when specifying a prefix length for a nonbinary string column that uses a multibyte character set.

- Beginning with MySQL 8.0.17, the expr for a key_part specification can take the form (CAST json_path AS type ARRAY) to create a multi-valued index on a JSON column. Multi-Valued Indexes, provides detailed information regarding creation of, usage of, and restrictions and limitations on multi-valued indexes.

- **index_type**
Some storage engines permit you to specify an index type when creating an index. The syntax for the `index_type` specifier is `USING type_name`.

Example:

```
CREATE TABLE lookup
(id INT, INDEX USING BTREE (id))
ENGINE = MEMORY;
```

The preferred position for `USING` is after the index column list. It can be given before the column list, but support for use of the option in that position is deprecated and you should expect it to be removed in a future MySQL release.

- `index_option`

  `index_option` values specify additional options for an index.

- `KEY_BLOCK_SIZE`

  For `MyISAM` tables, `KEY_BLOCK_SIZE` optionally specifies the size in bytes to use for index key blocks. The value is treated as a hint; a different size could be used if necessary. A `KEY_BLOCK_SIZE` value specified for an individual index definition overrides the table-level `KEY_BLOCK_SIZE` value.

  For information about the table-level `KEY_BLOCK_SIZE` attribute, see `Table Options`.

- `WITH PARSER`

  The `WITH PARSER` option can be used only with `FULLTEXT` indexes. It associates a parser plugin with the index if full-text indexing and searching operations need special handling. `InnoDB` and `MyISAM` support full-text parser plugins. If you have a `MyISAM` table with an associated full-text parser plugin, you can convert the table to `InnoDB` using `ALTER TABLE`.

- `COMMENT`

  Index definitions can include an optional comment of up to 1024 characters.

  You can set the `InnoDB MERGE_THRESHOLD` value for an individual index using the `index_option COMMENT` clause. See `Section 15.8.11, "Configuring the Merge Threshold for Index Pages"`.

- `VISIBLE, INVISIBLE`

  Specify index visibility. Indexes are visible by default. An invisible index is not used by the optimizer. Specification of index visibility applies to indexes other than primary keys (either explicit or implicit). For more information, see `Section 8.3.12, "Invisible Indexes"`.

- `ENGINE_ATTRIBUTE` and `SECONDARY_ENGINE_ATTRIBUTE` options (available as of MySQL 8.0.21) are used to specify index attributes for primary and secondary storage engines. The options are reserved for future use.

  For more information about permissible `index_option` values, see `Section 13.1.15, "CREATE INDEX Statement"`. For more information about indexes, see `Section 8.3.1, "How MySQL Uses Indexes"`. 
CREATE TABLE Statement

*reference_definition*

For *reference_definition* syntax details and examples, see Section 13.1.20.5, “FOREIGN KEY Constraints”.

*InnoDB* and *NDB* tables support checking of foreign key constraints. The columns of the referenced table must always be explicitly named. Both ON DELETE and ON UPDATE actions on foreign keys are supported. For more detailed information and examples, see Section 13.1.20.5, “FOREIGN KEY Constraints”.

For other storage engines, MySQL Server parses and ignores the FOREIGN KEY and REFERENCES syntax in CREATE TABLE statements. See Section 1.7.2.3, “FOREIGN KEY Constraint Differences”.

Important

For users familiar with the ANSI/ISO SQL Standard, please note that no storage engine, including *InnoDB*, recognizes or enforces the MATCH clause used in referential integrity constraint definitions. Use of an explicit MATCH clause does not have the specified effect, and also causes ON DELETE and ON UPDATE clauses to be ignored. For these reasons, specifying MATCH should be avoided.

The MATCH clause in the SQL standard controls how NULL values in a composite (multiple-column) foreign key are handled when comparing to a primary key. *InnoDB* essentially implements the semantics defined by MATCH SIMPLE, which permit a foreign key to be all or partially NULL. In that case, the (child table) row containing such a foreign key is permitted to be inserted, and does not match any row in the referenced (parent) table. It is possible to implement other semantics using triggers.

Additionally, MySQL requires that the referenced columns be indexed for performance. However, *InnoDB* does not enforce any requirement that the referenced columns be declared UNIQUE or NOT NULL. The handling of foreign key references to nonunique keys or keys that contain NULL values is not well defined for operations such as UPDATE or DELETE CASCADE. You are advised to use foreign keys that reference only keys that are both UNIQUE (or PRIMARY) and NOT NULL.

MySQL parses but ignores “inline REFERENCES specifications” (as defined in the SQL standard) where the references are defined as part of the column specification. MySQL accepts REFERENCES clauses only when specified as part of a separate FOREIGN KEY specification.

*reference_option*

For information about the RESTRICT, CASCADE, SET NULL, NO ACTION, and SET DEFAULT options, see Section 13.1.20.5, “FOREIGN KEY Constraints”.

Table Options

Table options are used to optimize the behavior of the table. In most cases, you do not have to specify any of them. These options apply to all storage engines unless otherwise indicated. Options that do not apply to a given storage engine may be accepted and remembered as part of the table definition. Such options then apply if you later use ALTER TABLE to convert the table to use a different storage engine.

*ENGINE*

Specifies the storage engine for the table, using one of the names shown in the following table. The engine name can be unquoted or quoted. The quoted name 'DEFAULT' is recognized but ignored.
CREATE TABLE Statement

<table>
<thead>
<tr>
<th>Storage Engine</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>InnoDB</td>
<td>Transaction-safe tables with row locking and foreign keys. The default storage engine for new tables. See Chapter 15, The InnoDB Storage Engine, and in particular Section 15.1, “Introduction to InnoDB” if you have MySQL experience but are new to InnoDB.</td>
</tr>
<tr>
<td>MyISAM</td>
<td>The binary portable storage engine that is primarily used for read-only or read-mostly workloads. See Section 16.2, “The MyISAM Storage Engine”.</td>
</tr>
<tr>
<td>MEMORY</td>
<td>The data for this storage engine is stored only in memory. See Section 16.3, “The MEMORY Storage Engine”.</td>
</tr>
<tr>
<td>CSV</td>
<td>Tables that store rows in comma-separated values format. See Section 16.4, “The CSV Storage Engine”.</td>
</tr>
<tr>
<td>ARCHIVE</td>
<td>The archiving storage engine. See Section 16.5, “The ARCHIVE Storage Engine”.</td>
</tr>
<tr>
<td>EXAMPLE</td>
<td>An example engine. See Section 16.9, “The EXAMPLE Storage Engine”.</td>
</tr>
<tr>
<td>FEDERATED</td>
<td>Storage engine that accesses remote tables. See Section 16.8, “The FEDERATED Storage Engine”.</td>
</tr>
<tr>
<td>HEAP</td>
<td>This is a synonym for MEMORY.</td>
</tr>
<tr>
<td>MERGE</td>
<td>A collection of MyISAM tables used as one table. Also known as MRG_MyISAM. See Section 16.7, “The MERGE Storage Engine”.</td>
</tr>
<tr>
<td>NDB</td>
<td>Clustered, fault-tolerant, memory-based tables, supporting transactions and foreign keys. Also known as NDBCLUSTER. See Chapter 23, MySQL NDB Cluster 8.0.</td>
</tr>
</tbody>
</table>

By default, if a storage engine is specified that is not available, the statement fails with an error. You can override this behavior by removing NO_ENGINE_SUBSTITUTION from the server SQL mode (see Section 5.1.11, “Server SQL Modes”) so that MySQL allows substitution of the specified engine with the default storage engine instead. Normally in such cases, this is InnoDB, which is the default value for the default_storage_engine system variable. When NO_ENGINE_SUBSTITUTION is disabled, a warning occurs if the storage engine specification is not honored.

- AUTOEXTEND_SIZE

Defines the amount by which InnoDB extends the size of the tablespace when it becomes full. Introduced in MySQL 8.0.23. The setting must be a multiple of 4MB. The default setting is 0, which causes the tablespace to be extended according to the implicit default behavior. For more information, see Section 15.6.3.9, “Tablespace AUTOEXTEND_SIZE Configuration”.

- AUTO_INCREMENT

The initial AUTO_INCREMENT value for the table. In MySQL 8.0.0, this works for MyISAM, MEMORY, InnoDB, and ARCHIVE tables. To set the first auto-increment value for engines that do not support the AUTO_INCREMENT table option, insert a “dummy” row with a value one less than the desired value after creating the table, and then delete the dummy row.

For engines that support the AUTO_INCREMENT table option in CREATE TABLE statements, you can also use ALTER TABLE tbl_name AUTO_INCREMENT = N to reset the AUTO_INCREMENT value. The value cannot be set lower than the maximum value currently in the column.
**AVG_ROW_LENGTH**

An approximation of the average row length for your table. You need to set this only for large tables with variable-size rows.

When you create a MyISAM table, MySQL uses the product of the MAX_ROWS and AVG_ROW_LENGTH options to decide how big the resulting table is. If you don't specify either option, the maximum size for MyISAM data and index files is 256TB by default. (If your operating system does not support files that large, table sizes are constrained by the file size limit.) If you want to keep down the pointer sizes to make the index smaller and faster and you don't really need big files, you can decrease the default pointer size by setting the myisam_data_pointer_size system variable. (See Section 5.1.8, “Server System Variables”.) If you want all your tables to be able to grow above the default limit and are willing to have your tables slightly slower and larger than necessary, you can increase the default pointer size by setting this variable. Setting the value to 7 permits table sizes up to 65,536TB.

**[DEFAULT] CHARACTER SET**

Specifies a default character set for the table. CHARSET is a synonym for CHARACTER SET. If the character set name is DEFAULT, the database character set is used.

**CHECKSUM**

Set this to 1 if you want MySQL to maintain a live checksum for all rows (that is, a checksum that MySQL updates automatically as the table changes). This makes the table a little slower to update, but also makes it easier to find corrupted tables. The CHECKSUM TABLE statement reports the checksum. (MyISAM only.)

**[DEFAULT] COLLATE**

Specifies a default collation for the table.

**COMMENT**

A comment for the table, up to 2048 characters long.

You can set the InnoDB MERGE_THRESHOLD value for a table using the table_option COMMENT clause. See Section 15.8.11, “Configuring the Merge Threshold for Index Pages”.

**Setting NDB_TABLE options.** The table comment in a CREATE TABLE that creates an NDB table or an ALTER TABLE statement which alters one can also be used to specify one to four of the NDB_TABLE options NOLOGGING, READ_BACKUP, PARTITION_BALANCE, or FULLY_REPLICATED as a set of name-value pairs, separated by commas if need be, immediately following the string NDB_TABLE= that begins the quoted comment text. An example statement using this syntax is shown here (emphasized text):

```sql
CREATE TABLE t1 (  
c1 INT NOT NULL AUTO_INCREMENT PRIMARY KEY,  
c2 VARCHAR(100),  
c3 VARCHAR(100) )  
ENGINE=NDB
```
CREATE TABLE Statement

COMMENT="NDB_TABLE=READ_BACKUP=0, PARTITION_BALANCE=FOR_RP_BY_NODE";

Spaces are not permitted within the quoted string. The string is case-insensitive.

The comment is displayed as part of the output of SHOW CREATE TABLE. The text of the comment is also available as the TABLE_COMMENT column of the MySQL Information Schema TABLES table.

This comment syntax is also supported with ALTER TABLE statements for NDB tables. Keep in mind that a table comment used with ALTER TABLE replaces any existing comment which the table might have had previously.

Setting the MERGE_THRESHOLD option in table comments is not supported for NDB tables (it is ignored).

For complete syntax information and examples, see Section 13.1.20.11, “Setting NDB_TABLE Options”.

• COMPRESSION

The compression algorithm used for page level compression for InnoDB tables. Supported values include Zlib, LZ4, and None. The COMPRESSION attribute was introduced with the transparent page compression feature. Page compression is only supported with InnoDB tables that reside in file-per-table tablespaces, and is only available on Linux and Windows platforms that support sparse files and hole punching. For more information, see Section 15.9.2, “InnoDB Page Compression”.

• CONNECTION

The connection string for a FEDERATED table.

Note
Older versions of MySQL used a COMMENT option for the connection string.

• DATA DIRECTORY, INDEX DIRECTORY

For InnoDB, the DATA DIRECTORY='directory' clause permits creating tables outside of the data directory. The innodb_file_per_table variable must be enabled to use the DATA DIRECTORY clause. The full directory path must be specified. As of MySQL 8.0.21, the directory specified must be known to InnoDB. For more information, see Section 15.6.1.2, “Creating Tables Externally”.

When creating MyISAM tables, you can use the DATA DIRECTORY='directory' clause, the INDEX DIRECTORY='directory' clause, or both. They specify where to put a MyISAM table’s data file and index file, respectively. Unlike InnoDB tables, MySQL does not create subdirectories that correspond to the database name when creating a MyISAM table with a DATA DIRECTORY or INDEX DIRECTORY option. Files are created in the directory that is specified.

You must have the FILE privilege to use the DATA DIRECTORY or INDEX DIRECTORY table option.

Important
Table-level DATA DIRECTORY and INDEX DIRECTORY options are ignored for partitioned tables. (Bug #32091)

These options work only when you are not using the --skip-symbolic-links option. Your operating system must also have a working, thread-safe realpath() call. See Section 8.12.2.2, “Using Symbolic Links for MyISAM Tables on Unix”, for more complete information.

If a MyISAM table is created with no DATA DIRECTORY option, the .MYD file is created in the database directory. By default, if MyISAM finds an existing .MYD file in this case, it overwrites it. The same applies to .MYI files for tables created with no INDEX DIRECTORY option. To suppress this
behavior, start the server with the `--keep_files_on_create` option, in which case MyISAM does not overwrite existing files and returns an error instead.

If a MyISAM table is created with a `DATA DIRECTORY` or `INDEX DIRECTORY` option and an existing `.MYD` or `.MYI` file is found, MyISAM always returns an error, and does not overwrite a file in the specified directory.

**Important**

You cannot use path names that contain the MySQL data directory with `DATA DIRECTORY` or `INDEX DIRECTORY`. This includes partitioned tables and individual table partitions. (See Bug #32167.)

- **DELAY_KEY_WRITE**

  Set this to 1 if you want to delay key updates for the table until the table is closed. See the description of the `delay_key_write` system variable in Section 5.1.8, “Server System Variables”. (MyISAM only.)

- **ENCRYPTION**

  The `ENCRYPTION` clause enables or disables page-level data encryption for an InnoDB table. A keyring plugin must be installed and configured before encryption can be enabled. Prior to MySQL 8.0.16, the `ENCRYPTION` clause can only be specified when creating a table in an a file-per-table tablespace. As of MySQL 8.0.16, the `ENCRYPTION` clause can also be specified when creating a table in a general tablespace.

  As of MySQL 8.0.16, a table inherits the default schema encryption if an `ENCRYPTION` clause is not specified. If the `table_encryption_privilege_check` variable is enabled, the `TABLE_ENCRYPTION_ADMIN` privilege is required to create a table with an `ENCRYPTION` clause setting that differs from the default schema encryption. When creating a table in a general tablespace, table and tablespace encryption must match.

  As of MySQL 8.0.16, specifying an `ENCRYPTION` clause with a value other than `'N'` or `''` is not permitted when using a storage engine that does not support encryption. Previously, the clause was accepted.

  For more information, see Section 15.13, “InnoDB Data-at-Rest Encryption”.

- **ENGINE_ATTRIBUTE** and **SECONDARY_ENGINE_ATTRIBUTE** options (available as of MySQL 8.0.21) are used to specify table attributes for primary and secondary storage engines. The options are reserved for future use.

  Permitted values are a string literal containing a valid JSON document or an empty string (""). Invalid JSON is rejected.

  ```
  CREATE TABLE t1 (c1 INT) ENGINE_ATTRIBUTE='{"key":"value"}';
  ```

  `ENGINE_ATTRIBUTE` and `SECONDARY_ENGINE_ATTRIBUTE` values can be repeated without error. In this case, the last specified value is used.

  `ENGINE_ATTRIBUTE` and `SECONDARY_ENGINE_ATTRIBUTE` values are not checked by the server, nor are they cleared when the table's storage engine is changed.

- **INSERT_METHOD**

  If you want to insert data into a MERGE table, you must specify with `INSERT_METHOD` the table into which the row should be inserted. `INSERT_METHOD` is an option useful for MERGE tables only. Use a value of `FIRST` or `LAST` to have inserts go to the first or last table, or a value of `NO` to prevent inserts. See Section 16.7, “The MERGE Storage Engine”.

- **KEY_BLOCK_SIZE**
For **MyISAM** tables, **KEY_BLOCK_SIZE** optionally specifies the size in bytes to use for index key blocks. The value is treated as a hint; a different size could be used if necessary. A **KEY_BLOCK_SIZE** value specified for an individual index definition overrides the table-level **KEY_BLOCK_SIZE** value.

For **InnoDB** tables, **KEY_BLOCK_SIZE** specifies the page size in kilobytes to use for compressed **InnoDB** tables. The **KEY_BLOCK_SIZE** value is treated as a hint; a different size could be used by **InnoDB** if necessary. **KEY_BLOCK_SIZE** can only be less than or equal to the **innodb_page_size** value. A value of 0 represents the default compressed page size, which is half of the **innodb_page_size** value. Depending on **innodb_page_size**, possible **KEY_BLOCK_SIZE** values include 0, 1, 2, 4, 8, and 16. See Section 15.9.1, “InnoDB Table Compression” for more information.

Oracle recommends enabling **innodb_strict_mode** when specifying **KEY_BLOCK_SIZE** for **InnoDB** tables. When **innodb_strict_mode** is enabled, specifying an invalid **KEY_BLOCK_SIZE** value returns an error. If **innodb_strict_mode** is disabled, an invalid **KEY_BLOCK_SIZE** value results in a warning, and the **KEY_BLOCK_SIZE** option is ignored.

The **Create_options** column in response to **SHOW TABLE STATUS** reports the actual **KEY_BLOCK_SIZE** used by the table, as does **SHOW CREATE TABLE**.

**InnoDB** only supports **KEY_BLOCK_SIZE** at the table level. **KEY_BLOCK_SIZE** is not supported with 32KB and 64KB **innodb_page_size** values. **InnoDB** table compression does not support these pages sizes.

**InnoDB** does not support the **KEY_BLOCK_SIZE** option when creating temporary tables.

- **MAX_ROWS**

  The maximum number of rows you plan to store in the table. This is not a hard limit, but rather a hint to the storage engine that the table must be able to store at least this many rows.

  **Important**

  The use of **MAX_ROWS** with **NDB** tables to control the number of table partitions is deprecated. It remains supported in later versions for backward compatibility, but is subject to removal in a future release. Use **PARTITION_BALANCE** instead; see Setting **NDB_TABLE** options.

  The **NDB** storage engine treats this value as a maximum. If you plan to create very large **NDB Cluster** tables (containing millions of rows), you should use this option to insure that **NDB** allocates sufficient number of index slots in the hash table used for storing hashes of the table's primary keys by setting **MAX_ROWS** = 2 * rows, where rows is the number of rows that you expect to insert into the table.

  The maximum **MAX_ROWS** value is 4294967295; larger values are truncated to this limit.

- **MIN_ROWS**

  The minimum number of rows you plan to store in the table. The **MEMORY** storage engine uses this option as a hint about memory use.

- **PACK_KEYS**

  Takes effect only with **MyISAM** tables. Set this option to 1 if you want to have smaller indexes. This usually makes updates slower and reads faster. Setting the option to 0 disables all packing of
CREATE TABLE Statement

keys. Setting it to DEFAULT tells the storage engine to pack only long CHAR, VARCHAR, BINARY, or VARBINARY columns.

If you do not use PACK_KEYS, the default is to pack strings, but not numbers. If you use PACK_KEYS=1, numbers are packed as well.

When packing binary number keys, MySQL uses prefix compression:

- Every key needs one extra byte to indicate how many bytes of the previous key are the same for the next key.
- The pointer to the row is stored in high-byte-first order directly after the key, to improve compression.

This means that if you have many equal keys on two consecutive rows, all following “same” keys usually only take two bytes (including the pointer to the row). Compare this to the ordinary case where the following keys takes storage_size_for_key + pointer_size (where the pointer size is usually 4). Conversely, you get a significant benefit from prefix compression only if you have many numbers that are the same. If all keys are totally different, you use one byte more per key, if the key is not a key that can have NULL values. (In this case, the packed key length is stored in the same byte that is used to mark if a key is NULL.)

- PASSWORD

This option is unused.

- ROW_FORMAT

Defines the physical format in which the rows are stored.

When creating a table with strict mode disabled, the storage engine's default row format is used if the specified row format is not supported. The actual row format of the table is reported in the Row_format column in response to SHOW TABLE STATUS. The Create_options column shows the row format that was specified in the CREATE TABLE statement, as does SHOW CREATE TABLE.

Row format choices differ depending on the storage engine used for the table.

For InnoDB tables:

- The default row format is defined by innodb_default_row_format, which has a default setting of DYNAMIC. The default row format is used when the ROW_FORMAT option is not defined or when ROW_FORMAT=DEFAULT is used.

  If the ROW_FORMAT option is not defined, or if ROW_FORMAT=DEFAULT is used, operations that rebuild a table also silently change the row format of the table to the default defined by innodb_default_row_format. For more information, see Defining the Row Format of a Table.

- For more efficient InnoDB storage of data types, especially BLOB types, use the DYNAMIC. See DYNAMIC Row Format for requirements associated with the DYNAMIC row format.

- To enable compression for InnoDB tables, specify ROW_FORMAT=COMPRESSED. The ROW_FORMAT=COMPRESSED option is not supported when creating temporary tables. See
CREATE TABLE Statement

Section 15.9, “InnoDB Table and Page Compression” for requirements associated with the COMPRESSED row format.

• The row format used in older versions of MySQL can still be requested by specifying the REDUNDANT row format.

• When you specify a non-default ROW_FORMAT clause, consider also enabling the innodb_strict_mode configuration option.

• ROW_FORMAT=FIXED is not supported. If ROW_FORMAT=FIXED is specified while innodb_strict_mode is disabled, InnoDB issues a warning and assumes ROW_FORMAT=DYNAMIC. If ROW_FORMAT=FIXED is specified while innodb_strict_mode is enabled, which is the default, InnoDB returns an error.

• For additional information about InnoDB row formats, see Section 15.10, “InnoDB Row Formats”.

For MyISAM tables, the option value can be FIXED or DYNAMIC for static or variable-length row format. myisampack sets the type to COMPRESSED. See Section 16.2.3, “MyISAM Table Storage Formats”.

For NDB tables, the default ROW_FORMAT is DYNAMIC.

• STATS_AUTO_RECALC

Specifies whether to automatically recalculate persistent statistics for an InnoDB table. The value DEFAULT causes the persistent statistics setting for the table to be determined by the innodb_stats_auto_recalc configuration option. The value 1 causes statistics to be recalculated when 10% of the data in the table has changed. The value 0 prevents automatic recalculation for this table; with this setting, issue an ANALYZE TABLE statement to recalculate the statistics after making substantial changes to the table. For more information about the persistent statistics feature, see Section 15.8.10.1, “Configuring Persistent Optimizer Statistics Parameters”.

• STATS_PERSISTENT

Specifies whether to enable persistent statistics for an InnoDB table. The value DEFAULT causes the persistent statistics setting for the table to be determined by the innodb_stats_persistent configuration option. The value 1 enables persistent statistics for the table, while the value 0 turns off this feature. After enabling persistent statistics through a CREATE TABLE or ALTER TABLE statement, issue an ANALYZE TABLE statement to calculate the statistics, after loading representative data into the table. For more information about the persistent statistics feature, see Section 15.8.10.1, “Configuring Persistent Optimizer Statistics Parameters”.

• STATS_SAMPLE_PAGES

The number of index pages to sample when estimating cardinality and other statistics for an indexed column, such as those calculated by ANALYZE TABLE. For more information, see Section 15.8.10.1, “Configuring Persistent Optimizer Statistics Parameters”.

• TABLESPACE

The TABLESPACE clause can be used to create a table in an existing general tablespace, a file-per-table tablespace, or the system tablespace.

CREATE TABLE tbl_name ... TABLESPACE [=] tablespace_name

The general tablespace that you specify must exist prior to using the TABLESPACE clause. For information about general tablespaces, see Section 15.6.3.3, “General Tablespaces”.

The tablespace_name is a case-sensitive identifier. It may be quoted or unquoted. The forward slash character ("/") is not permitted. Names beginning with "innodb_" are reserved for special use.

To create a table in the system tablespace, specify innodb_system as the tablespace name.
CREATE TABLE `tbl_name` ... TABLESPACE [=] innodb_system

Using TABLESPACE [=] innodb_system, you can place a table of any uncompressed row format in the system tablespace regardless of the innodb_file_per_table setting. For example, you can add a table with ROW_FORMAT=DYNAMIC to the system tablespace using TABLESPACE [=] innodb_system.

To create a table in a file-per-table tablespace, specify innodb_file_per_table as the tablespace name.

CREATE TABLE `tbl_name` ... TABLESPACE [=] innodb_file_per_table

Note

If innodb_file_per_table is enabled, you need not specify TABLESPACE=innodb_file_per_table to create an InnoDB file-per-table tablespace. InnoDB tables are created in file-per-table tablespaces by default when innodb_file_per_table is enabled.

The DATA DIRECTORY clause is permitted with CREATE TABLE ... TABLESPACE=innodb_file_per_table but is otherwise not supported for use in combination with the TABLESPACE clause. As of MySQL 8.0.21, the directory specified in a DATA DIRECTORY clause must be known to InnoDB. For more information, see Using the DATA DIRECTORY Clause.

Note

Support for TABLESPACE = innodb_file_per_table and TABLESPACE = innodb_temporary clauses with CREATE TEMPORARY TABLE is deprecated as of MySQL 8.0.13; expect it to be removed in a future version of MySQL.

The STORAGE table option is employed only with NDB tables. STORAGE determines the type of storage used (disk or memory), and can be either DISK or MEMORY.

TABLESPACE ... STORAGE DISK assigns a table to an NDB Cluster Disk Data tablespace. The tablespace must already have been created using CREATE TABLESPACE. See Section 23.5.10, “NDB Cluster Disk Data Tables”, for more information.

Important

A STORAGE clause cannot be used in a CREATE TABLE statement without a TABLESPACE clause.

• UNION

Used to access a collection of identical MyISAM tables as one. This works only with MERGE tables. See Section 16.7, “The MERGE Storage Engine”.

You must have SELECT, UPDATE, and DELETE privileges for the tables you map to a MERGE table.

Note

Formerly, all tables used had to be in the same database as the MERGE table itself. This restriction no longer applies.

Table Partitioning

`partition_options` can be used to control partitioning of the table created with CREATE TABLE.

Not all options shown in the syntax for `partition_options` at the beginning of this section are available for all partitioning types. Please see the listings for the following individual types for
information specific to each type, and see Chapter 24, Partitioning, for more complete information about the workings of and uses for partitioning in MySQL, as well as additional examples of table creation and other statements relating to MySQL partitioning.

Partitions can be modified, merged, added to tables, and dropped from tables. For basic information about the MySQL statements to accomplish these tasks, see Section 13.1.9, “ALTER TABLE Statement”. For more detailed descriptions and examples, see Section 24.3, “Partition Management”.

• **PARTITION BY**

If used, a `partition_options` clause begins with `PARTITION BY`. This clause contains the function that is used to determine the partition; the function returns an integer value ranging from 1 to `num`, where `num` is the number of partitions. (The maximum number of user-defined partitions which a table may contain is 1024; the number of subpartitions—discussed later in this section—is included in this maximum.)

Note

The expression `(expr)` used in a `PARTITION BY` clause cannot refer to any columns not in the table being created; such references are specifically not permitted and cause the statement to fail with an error. (Bug #29444)

• **HASH(expr)**

Hashes one or more columns to create a key for placing and locating rows. `expr` is an expression using one or more table columns. This can be any valid MySQL expression (including MySQL functions) that yields a single integer value. For example, these are both valid `CREATE TABLE` statements using `PARTITION BY HASH`:

```sql
CREATE TABLE t1 (col1 INT, col2 CHAR(5))
PARTITION BY HASH(col1);
CREATE TABLE t1 (col1 INT, col2 CHAR(5), col3 DATETIME)
PARTITION BY HASH ( YEAR(col3) );
```

You may not use either `VALUES LESS THAN` or `VALUES IN` clauses with `PARTITION BY HASH`. `PARTITION BY HASH` uses the remainder of `expr` divided by the number of partitions (that is, the modulus). For examples and additional information, see Section 24.2.4, “HASH Partitioning”.

The `LINEAR` keyword entails a somewhat different algorithm. In this case, the number of the partition in which a row is stored is calculated as the result of one or more logical `AND` operations. For discussion and examples of linear hashing, see Section 24.2.4.1, “LINEAR HASH Partitioning”.

• **KEY(column_list)**

This is similar to `HASH`, except that MySQL supplies the hashing function so as to guarantee an even data distribution. The `column_list` argument is simply a list of 1 or more table columns (maximum: 16). This example shows a simple table partitioned by key, with 4 partitions:

```sql
CREATE TABLE tk (col1 INT, col2 CHAR(5), col3 DATE)
PARTITION BY KEY(col3)
PARTITIONS 4;
```

For tables that are partitioned by key, you can employ linear partitioning by using the `LINEAR` keyword. This has the same effect as with tables that are partitioned by `HASH`. That is, the partition number is found using the `&` operator rather than the modulus (see Section 24.2.4.1, “LINEAR HASH Partitioning”, and Section 24.2.5, “KEY Partitioning”, for details). This example uses linear partitioning by key to distribute data between 5 partitions:

```sql
CREATE TABLE tk (col1 INT, col2 CHAR(5), col3 DATE)
PARTITION BY LINEAR KEY(col3)
PARTITIONS 5;
```
The **ALGORITHM=(1 | 2)** option is supported with **[SUB]PARTITION BY [LINEAR] KEY**. **ALGORITHM=1** causes the server to use the same key-hashing functions as MySQL 5.1; **ALGORITHM=2** means that the server employs the key-hashing functions implemented and used by default for new **KEY** partitioned tables in MySQL 5.5 and later. (Partitioned tables created with the key-hashing functions employed in MySQL 5.5 and later cannot be used by a MySQL 5.1 server.) Not specifying the option has the same effect as using **ALGORITHM=2**. This option is intended for use chiefly when upgrading or downgrading **[LINEAR] KEY** partitioned tables between MySQL 5.1 and later MySQL versions, or for creating tables partitioned by **KEY** or **LINEAR KEY** on a MySQL 5.5 or later server which can be used on a MySQL 5.1 server. For more information, see Section 13.1.9.1, “ALTER TABLE Partition Operations”.

**mysql dump** in MySQL 5.7 (and later) writes this option encased in versioned comments, like this:

```sql
CREATE TABLE t1 (a INT)
/*!50100 PARTITION BY KEY */
/*!50611 ALGORITHM = 1 */
/*!50100 () PARTITIONS 3 */
```

This causes MySQL 5.6.10 and earlier servers to ignore the option, which would otherwise cause a syntax error in those versions. If you plan to load a dump made on a MySQL 5.7 server where you use tables that are partitioned or subpartitioned by **KEY** into a MySQL 5.6 server previous to version 5.6.11, be sure to consult **Changes in MySQL 5.6**, before proceeding. (The information found there also applies if you are loading a dump containing **KEY** partitioned or subpartitioned tables made from a MySQL 5.7—actually 5.6.11 or later—server into a MySQL 5.5.30 or earlier server.)

Also in MySQL 5.6.11 and later, **ALGORITHM=1** is shown when necessary in the output of **SHOW CREATE TABLE** using versioned comments in the same manner as **mysql dump**. **ALGORITHM=2** is always omitted from **SHOW CREATE TABLE** output, even if this option was specified when creating the original table.

You may not use either **VALUES LESS THAN** or **VALUES IN** clauses with **PARTITION BY KEY**.

- **RANGE(expr)**

In this case, **expr** shows a range of values using a set of **VALUES LESS THAN** operators. When using range partitioning, you must define at least one partition using **VALUES LESS THAN**. You cannot use **VALUES IN** with range partitioning.

**Note**

For tables partitioned by **RANGE, VALUES LESS THAN** must be used with either an integer literal value or an expression that evaluates to a single integer value. In MySQL 8.0, you can overcome this limitation in a table that is defined using **PARTITION BY RANGE COLUMNS**, as described later in this section.

Suppose that you have a table that you wish to partition on a column containing year values, according to the following scheme:

<table>
<thead>
<tr>
<th>Partition Number</th>
<th>Years Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1990 and earlier</td>
</tr>
<tr>
<td>1</td>
<td>1991 to 1994</td>
</tr>
<tr>
<td>2</td>
<td>1995 to 1998</td>
</tr>
<tr>
<td>3</td>
<td>1999 to 2002</td>
</tr>
<tr>
<td>4</td>
<td>2003 to 2005</td>
</tr>
</tbody>
</table>
A table implementing such a partitioning scheme can be realized by the `CREATE TABLE` statement shown here:

```sql
CREATE TABLE t1 (  
  year_col INT,  
  some_data INT
)  
PARTITION BY RANGE (year_col) (  
  PARTITION p0 VALUES LESS THAN (1991),  
  PARTITION p1 VALUES LESS THAN (1995),  
  PARTITION p2 VALUES LESS THAN (1999),  
  PARTITION p3 VALUES LESS THAN (2002),  
  PARTITION p4 VALUES LESS THAN (2006),  
  PARTITION p5 VALUES LESS THAN MAXVALUE
);  
```

`PARTITION ... VALUES LESS THAN ...` statements work in a consecutive fashion. `VALUES LESS THAN MAXVALUE` works to specify “leftover” values that are greater than the maximum value otherwise specified.

`VALUES LESS THAN` clauses work sequentially in a manner similar to that of the `case` portions of a `switch ... case` block (as found in many programming languages such as C, Java, and PHP). That is, the clauses must be arranged in such a way that the upper limit specified in each successive `VALUES LESS THAN` is greater than that of the previous one, with the one referencing `MAXVALUE` coming last of all in the list.

- **RANGE COLUMNS(column_list)**

This variant on `RANGE` facilitates partition pruning for queries using range conditions on multiple columns (that is, having conditions such as `WHERE a = 1 AND b < 10` or `WHERE a = 1 AND b = 10 AND c < 10`). It enables you to specify value ranges in multiple columns by using a list of columns in the `COLUMNS` clause and a set of column values in each `PARTITION ... VALUES LESS THAN (value_list)` partition definition clause. (In the simplest case, this set consists of a single column.) The maximum number of columns that can be referenced in the `COLUMNS` and `value_list` is 16.

The `column_list` used in the `COLUMNS` clause may contain only names of columns; each column in the list must be one of the following MySQL data types: the integer types; the string types; and time or date column types. Columns using `BLOB`, `TEXT`, `SET`, `ENUM`, `BIT`, or spatial data types are not permitted; columns that use floating-point number types are also not permitted. You also may not use functions or arithmetic expressions in the `COLUMNS` clause.

The `VALUES LESS THAN` clause used in a partition definition must specify a literal value for each column that appears in the `COLUMNS()` clause; that is, the list of values used for each `VALUES LESS THAN` clause must contain the same number of values as there are columns listed in the `COLUMNS` clause. An attempt to use more or fewer values in a `VALUES LESS THAN` clause than there are in the `COLUMNS` clause causes the statement to fail with the error `Inconsistency in usage of column lists for partitioning...`. You cannot use `NULL` for any value appearing in `VALUES LESS THAN`. It is possible to use `MAXVALUE` more than once for a given column other than the first, as shown in this example:

```sql
CREATE TABLE rc (  
  a INT NOT NULL,  
  b INT NOT NULL
)  
PARTITION BY RANGE COLUMNS(a,b) (  
  PARTITION p0 VALUES LESS THAN (10,5),  
  PARTITION p1 VALUES LESS THAN (20,10),  
  PARTITION p2 VALUES LESS THAN (50,MAXVALUE),  
  PARTITION p3 VALUES LESS THAN (65,MAXVALUE),  
);  
```
Each value used in a VALUES LESS THAN value list must match the type of the corresponding column exactly; no conversion is made. For example, you cannot use the string '1' for a value that matches a column that uses an integer type (you must use the numeral 1 instead), nor can you use the numeral 1 for a value that matches a column that uses a string type (in such a case, you must use a quoted string: '1').

For more information, see Section 24.2.1, “RANGE Partitioning”, and Section 24.4, “Partition Pruning”.

- LIST(expr)

This is useful when assigning partitions based on a table column with a restricted set of possible values, such as a state or country code. In such a case, all rows pertaining to a certain state or country can be assigned to a single partition, or a partition can be reserved for a certain set of states or countries. It is similar to RANGE, except that only VALUES IN may be used to specify permissible values for each partition.

VALUES IN is used with a list of values to be matched. For instance, you could create a partitioning scheme such as the following:

```sql
CREATE TABLE client_firms (  
id INT,  
name VARCHAR(35)
)
PARTITION BY LIST (id) (  
  PARTITION r0 VALUES IN (1, 5, 9, 13, 17, 21),  
  PARTITION r1 VALUES IN (2, 6, 10, 14, 18, 22),  
  PARTITION r2 VALUES IN (3, 7, 11, 15, 19, 23),  
  PARTITION r3 VALUES IN (4, 8, 12, 16, 20, 24)
);
```

When using list partitioning, you must define at least one partition using VALUES IN. You cannot use VALUES LESS THAN with PARTITION BY LIST.

Note

For tables partitioned by LIST, the value list used with VALUES IN must consist of integer values only. In MySQL 8.0, you can overcome this limitation using partitioning by LIST COLUMNS, which is described later in this section.

- LIST COLUMNS(column_list)

This variant on LIST facilitates partition pruning for queries using comparison conditions on multiple columns (that is, having conditions such as WHERE a = 5 AND b = 5 or WHERE a = 1 AND b = 10 AND c = 5). It enables you to specify values in multiple columns by using a list of columns in the COLUMNS clause and a set of column values in each PARTITION ... VALUES IN (value_list) partition definition clause.

The rules governing regarding data types for the column list used in LIST COLUMNS(column_list) and the value list used in VALUES IN(value_list) are the same as those for the column list used in RANGE COLUMNS(column_list) and the value list used in VALUES LESS THAN(value_list), respectively, except that in the VALUES IN clause, MAXVALUE is not permitted, and you may use NULL.

There is one important difference between the list of values used for VALUES IN with PARTITION BY LIST COLUMNS as opposed to when it is used with PARTITION BY LIST. When used with PARTITION BY LIST COLUMNS, each element in the VALUES IN clause must be a set of column values; the number of values in each set must be the same as the number of columns used in the COLUMNS clause, and the data types of these values must match those of the columns (and occur in
the same order). In the simplest case, the set consists of a single column. The maximum number of
columns that can be used in the column_list and in the elements making up the value_list is 16.

The table defined by the following CREATE TABLE statement provides an example of a table using
LIST COLUMNS partitioning:

```sql
CREATE TABLE lc {
    a INT NULL,
    b INT NULL
}
PARTITION BY LIST COLUMNS(a,b) {
    PARTITION p0 VALUES IN( (0,0), (NULL,NULL) ),
    PARTITION p1 VALUES IN( (0,1), (0,2), (0,3), (1,1), (1,2) ),
    PARTITION p2 VALUES IN( (1,0), (2,0), (2,1), (3,0), (3,1) ),
    PARTITION p3 VALUES IN( (1,3), (2,2), (2,3), (3,2), (3,3) )
};
```

- **PARTITIONS num**

The number of partitions may optionally be specified with a PARTITIONS num clause, where num
is the number of partitions. If both this clause and any PARTITION clauses are used, num must be
equal to the total number of any partitions that are declared using PARTITION clauses.

**Note**

Whether or not you use a PARTITIONS clause in creating a table that is
partitioned by RANGE or LIST, you must still include at least one PARTITION VALUES clause in the table definition (see below).

- **SUBPARTITION BY**

A partition may optionally be divided into a number of subpartitions. This can be indicated by using
the optional SUBPARTITION BY clause. Subpartitioning may be done by HASH or KEY. Either of
these may be LINEAR. These work in the same way as previously described for the equivalent
partitioning types. (It is not possible to subpartition by LIST or RANGE.)

The number of subpartitions can be indicated using the SUBPARTITIONS keyword followed by an
integer value.

- Rigorous checking of the value used in PARTITIONS or SUBPARTITIONS clauses is applied and this
value must adhere to the following rules:
  - The value must be a positive, nonzero integer.
  - No leading zeros are permitted.
  - The value must be an integer literal, and cannot not be an expression. For example, PARTITIONS
    0.2E+01 is not permitted, even though 0.2E+01 evaluates to 2. (Bug #15890)

- **partition_definition**

Each partition may be individually defined using a partition_definition clause. The individual
parts making up this clause are as follows:

- PARTITION partition_name

  Specifies a logical name for the partition.

- **VALUES**

For range partitioning, each partition must include a VALUES LESS THAN clause; for list
partitioning, you must specify a VALUES IN clause for each partition. This is used to determine
which rows are to be stored in this partition. See the discussions of partitioning types in Chapter 24, Partitioning, for syntax examples.

- [STORAGE] ENGINE

MySQL accepts a [STORAGE] ENGINE option for both PARTITION and SUBPARTITION. Currently, the only way in which this option can be used is to set all partitions or all subpartitions to the same storage engine, and an attempt to set different storage engines for partitions or subpartitions in the same table raises the error ERROR 1469 (HY000): The mix of handlers in the partitions is not permitted in this version of MySQL.

- COMMENT

An optional COMMENT clause may be used to specify a string that describes the partition. Example:

```sql
COMMENT = 'Data for the years previous to 1999'
```

The maximum length for a partition comment is 1024 characters.

- DATA DIRECTORY and INDEX DIRECTORY

DATA DIRECTORY and INDEX DIRECTORY may be used to indicate the directory where, respectively, the data and indexes for this partition are to be stored. Both the data_dir and the index_dir must be absolute system path names.

As of MySQL 8.0.21, the directory specified in a DATA DIRECTORY clause must be known to InnoDB. For more information, see Using the DATA DIRECTORY Clause.

You must have the FILE privilege to use the DATA DIRECTORY or INDEX DIRECTORY partition option.

Example:

```sql
CREATE TABLE th (id INT, name VARCHAR(30), adate DATE)
PARTITION BY LIST(YEAR(adate))
(
    DATA DIRECTORY = '/var/appdata/95/data'
    INDEX DIRECTORY = '/var/appdata/95/idx',
    DATA DIRECTORY = '/var/appdata/96/data'
    INDEX DIRECTORY = '/var/appdata/96/idx',
    DATA DIRECTORY = '/var/appdata/97/data'
    INDEX DIRECTORY = '/var/appdata/97/idx',
    DATA DIRECTORY = '/var/appdata/98/data'
    INDEX DIRECTORY = '/var/appdata/98/idx'
);
```

DATA DIRECTORY and INDEX DIRECTORY behave in the same way as in the CREATE TABLE statement's table_option clause as used for MyISAM tables.

One data directory and one index directory may be specified per partition. If left unspecified, the data and indexes are stored by default in the table's database directory.

The DATA DIRECTORY and INDEX DIRECTORY options are ignored for creating partitioned tables if NO_DIR_IN_CREATE is in effect.

- MAX_ROWS and MIN_ROWS

May be used to specify, respectively, the maximum and minimum number of rows to be stored in the partition. The values for max_number_of_rows and min_number_of_rows must be positive
CREATE TABLE Statement

integers. As with the table-level options with the same names, these act only as “suggestions” to
the server and are not hard limits.

• TABLESPACE

May be used to designate an InnoDB file-per-table tablespace for the partition by specifying
TABLESPACE `innodb_file_per_table`. All partitions must belong to the same storage
engine.

Placing InnoDB table partitions in shared InnoDB tablespaces is not supported. Shared
tablespaces include the InnoDB system tablespace and general tablespaces.

• subpartition_definition

The partition definition may optionally contain one or more subpartition_definition clauses.
Each of these consists at a minimum of the SUBPARTITION name, where name is an identifier for
the subpartition. Except for the replacement of the PARTITION keyword with SUBPARTITION, the
syntax for a subpartition definition is identical to that for a partition definition.

Subpartitioning must be done by HASH or KEY, and can be done only on RANGE or LIST partitions. See Section 24.2.6, “Subpartitioning”.

Partitioning by Generated Columns

Partitioning by generated columns is permitted. For example:

CREATE TABLE t1 {
    s1 INT,
    s2 INT AS (EXP(s1)) STORED
} PARTITION BY LIST (s2) (
    PARTITION p1 VALUES IN (1)
);
You can use the `TEMPORARY` keyword when creating a table. A `TEMPORARY` table is visible only within the current session, and is dropped automatically when the session is closed. This means that two different sessions can use the same temporary table name without conflicting with each other or with an existing non-`TEMPORARY` table of the same name. (The existing table is hidden until the temporary table is dropped.)

`InnoDB` does not support compressed temporary tables. When `innodb_strict_mode` is enabled (the default), `CREATE TEMPORARY TABLE` returns an error if `ROW_FORMAT=COMPRESSED` or `KEY_BLOCK_SIZE` is specified. If `innodb_strict_mode` is disabled, warnings are issued and the temporary table is created using a non-compressed row format. The `innodb_file_per_table` option does not affect the creation of `InnoDB` temporary tables.

`CREATE TABLE` causes an implicit commit, except when used with the `TEMPORARY` keyword. See Section 13.3.3, "Statements That Cause an Implicit Commit".

`TEMPORARY` tables have a very loose relationship with databases (schemas). Dropping a database does not automatically drop any `TEMPORARY` tables created within that database.

To create a temporary table, you must have the `CREATE TEMPORARY TABLES` privilege. After a session has created a temporary table, the server performs no further privilege checks on the table. The creating session can perform any operation on the table, such as `DROP TABLE`, `INSERT`, `UPDATE`, or `SELECT`.

One implication of this behavior is that a session can manipulate its temporary tables even if the current user has no privilege to create them. Suppose that the current user does not have the `CREATE TEMPORARY TABLES` privilege but is able to execute a definer-context stored procedure that executes with the privileges of a user who does have `CREATE TEMPORARY TABLES` and that creates a temporary table. While the procedure executes, the session uses the privileges of the defining user. After the procedure returns, the effective privileges revert to those of the current user, which can still see the temporary table and perform any operation on it.

You cannot use `CREATE TEMPORARY TABLE ... LIKE` to create an empty table based on the definition of a table that resides in the `mysql` tablespace, `InnoDB` system tablespace (`innodb_system`), or a general tablespace. The tablespace definition for such a table includes a `TABLESPACE` attribute that defines the tablespace where the table resides, and the aforementioned tablespaces do not support temporary tables. To create a temporary table based on the definition of such a table, use this syntax instead:

```
CREATE TEMPORARY TABLE new_tbl SELECT * FROM orig_tbl LIMIT 0;
```

**Note**

Support for `TABLESPACE = innodb_file_per_table` and `TABLESPACE = innodb_temporary` clauses with `CREATE TEMPORARY TABLE` is deprecated as of MySQL 8.0.13; expect it be removed in a future version of MySQL.

### 13.1.20.3 CREATE TABLE ... LIKE Statement

Use `CREATE TABLE ... LIKE` to create an empty table based on the definition of another table, including any column attributes and indexes defined in the original table:

```
CREATE TABLE new_tbl LIKE orig_tbl;
```

The copy is created using the same version of the table storage format as the original table. The `SELECT` privilege is required on the original table.

`LIKE` works only for base tables, not for views.

**Important**

You cannot execute `CREATE TABLE` or `CREATE TABLE ... LIKE` while a `LOCK TABLES` statement is in effect.
CREATE TABLE ... LIKE makes the same checks as CREATE TABLE. This means that if the current SQL mode is different from the mode in effect when the original table was created, the table definition might be considered invalid for the new mode and cause the statement to fail.

For CREATE TABLE ... LIKE, the destination table preserves generated column information from the original table.

For CREATE TABLE ... LIKE, the destination table preserves expression default values from the original table.

For CREATE TABLE ... LIKE, the destination table preserves CHECK constraints from the original table, except that all the constraint names are generated.

CREATE TABLE ... LIKE does not preserve any DATA DIRECTORY or INDEX DIRECTORY table options that were specified for the original table, or any foreign key definitions.

If the original table is a TEMPORARY table, CREATE TABLE ... LIKE does not preserve TEMPORARY. To create a TEMPORARY destination table, use CREATE TEMPORARY TABLE ... LIKE.

Tables created in the mysql tablespace, the InnoDB system tablespace (innodb_system), or general tablespaces include a TABLESPACE attribute in the table definition, which defines the tablespace where the table resides. Due to a temporary regression, CREATE TABLE ... LIKE preserves the TABLESPACE attribute and creates the table in the defined tablespace regardless of the innodb_file_per_table setting. To avoid the TABLESPACE attribute when creating an empty table based on the definition of such a table, use this syntax instead:

```
CREATE TABLE new_tbl SELECT * FROM orig_tbl LIMIT 0;
```

CREATE TABLE ... LIKE operations apply all ENGINE_ATTRIBUTE and SECONDARY_ENGINE_ATTRIBUTE values to the new table.

### 13.1.20.4 CREATE TABLE ... SELECT Statement

You can create one table from another by adding a SELECT statement at the end of the CREATE TABLE statement:

```
CREATE TABLE new_tbl [AS] SELECT * FROM orig_tbl;
```

MySQL creates new columns for all elements in the SELECT. For example:

```
mysql> CREATE TABLE test (a INT NOT NULL AUTO_INCREMENT,
-> PRIMARY KEY (a), KEY(b))
-> ENGINE=InnoDB SELECT b,c FROM test2;
```

This creates an InnoDB table with three columns, a, b, and c. The ENGINE option is part of the CREATE TABLE statement, and should not be used following the SELECT; this would result in a syntax error. The same is true for other CREATE TABLE options such as CHARSET.

Notice that the columns from the SELECT statement are appended to the right side of the table, not overlapped onto it. Take the following example:

```
mysql> SELECT * FROM foo;
+----+
| n  |
+----+
| 1  |
+----+
mysql> CREATE TABLE bar (m INT) SELECT n FROM foo;
Query OK, 1 row affected (0.02 sec)
```
CREATE TABLE Statement

For each row in table `foo`, a row is inserted in `bar` with the values from `foo` and default values for the new columns.

In a table resulting from `CREATE TABLE ... SELECT`, columns named only in the `CREATE TABLE` part come first. Columns named in both parts or only in the `SELECT` part come after that. The data type of `SELECT` columns can be overridden by also specifying the column in the `CREATE TABLE` part.

If errors occur while copying data to the table, the table is automatically dropped and not created. However, prior to MySQL 8.0.21, when row-based replication is in use, a `CREATE TABLE ... SELECT` statement is recorded in the binary log as two transactions, one to create the table, and the other to insert data. When the statement applied from the binary log, a failure between the two transactions or while copying data can result in replication of an empty table. That limitation is removed in MySQL 8.0.21. On storage engines that support atomic DDL, `CREATE TABLE ... SELECT` is now recorded and applied as one transaction when row-based replication is in use. For more information, see Section 13.1.1, "Atomic Data Definition Statement Support".

As of MySQL 8.0.21, on storage engines that support both atomic DDL and foreign key constraints, creation of foreign keys is not permitted in `CREATE TABLE ... SELECT` statements when row-based replication is in use. Foreign key constraints can be added later using `ALTER TABLE`.

You can precede the `SELECT` by `IGNORE` or `REPLACE` to indicate how to handle rows that duplicate unique key values. With `IGNORE`, rows that duplicate an existing row on a unique key value are discarded. With `REPLACE`, new rows replace rows that have the same unique key value. If neither `IGNORE` nor `REPLACE` is specified, duplicate unique key values result in an error. For more information, see The Effect of `IGNORE` on Statement Execution.

In MySQL 8.0.19 and later, you can also use a `VALUES` statement in the `SELECT` part of `CREATE TABLE ... SELECT`; the `VALUES` portion of the statement must include a table alias using an `AS` clause. To name the columns coming from `VALUES`, supply column aliases with the table alias; otherwise, the default column names `column_0`, `column_1`, `column_2`, ..., are used.

Otherwise, naming of columns in the table thus created follows the same rules as described previously in this section. Examples:

```sql
mysql> CREATE TABLE tv1
    -> SELECT * FROM (VALUES ROW(1,3,5), ROW(2,4,6)) AS v;

mysql> TABLE tv1;
+----------+----------+----------+
| column_0 | column_1 | column_2 |
+----------+----------+----------+
|        1 |        3 |        5 |
|        2 |        4 |        6 |
+----------+----------+----------+

mysql> CREATE TABLE tv2
    -> SELECT * FROM (VALUES ROW(1,3,5), ROW(2,4,6)) AS v(x,y,z);

mysql> TABLE tv2;
+---+---+---+
| x | y | z |
+---+---+---+
| 1 | 3 | 5 |
| 2 | 4 | 6 |
+---+---+---+

mysql> CREATE TABLE tv3 (a INT, b INT, c INT)
```

2373
When selecting all columns and using the default column names, you can omit `SELECT *`, so the statement just used to create table `tv1` can also be written as shown here:

```sql
mysql> CREATE TABLE tv1 VALUES ROW(1,3,5), ROW(2,4,6);
mysql> TABLE tv1;
+----------+----------+----------+
| column_0 | column_1 | column_2 |
+----------+----------+----------+
|        1 |        3 |        5 |
|        2 |        4 |        6 |
+----------+----------+----------+
```

When using `VALUES` as the source of the `SELECT`, all columns are always selected into the new table, and individual columns cannot be selected as they can be when selecting from a named table; each of the following statements produces an error (`ER_OPERAND_COLUMNS`):

```sql
CREATE TABLE tvx
SELECT (x,z) FROM (VALUES ROW(1,3,5), ROW(2,4,6)) AS v(x,y,z);
CREATE TABLE tvx (a INT, c INT)
SELECT (x,z) FROM (VALUES ROW(1,3,5), ROW(2,4,6)) AS v(a,b,c);
```

Similarly, you can use a `TABLE` statement in place of the `SELECT`. This follows the same rules as with `VALUES`; all columns of the source table and their names in the source table are always inserted into the new table. Examples:

```sql
mysql> TABLE t1;
+----+----+
| a  | b  |
+----+----+
| 1  | 2  |
| 6  | 7  |
| 10 | -4 |
| 14 | 6  |
+----+----+
```

```sql
mysql> CREATE TABLE tt1 TABLE t1;
mysql> TABLE tt1;
+----+----+
| a  | b  |
+----+----+
2374
+----+----+
```
CREATE TABLE Statement

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>6</td>
<td>7</td>
</tr>
<tr>
<td>10</td>
<td>-4</td>
</tr>
<tr>
<td>14</td>
<td>6</td>
</tr>
</tbody>
</table>

mysql> CREATE TABLE tt2 (x INT) TABLE t1;
mysql> TABLE tt2;

<table>
<thead>
<tr>
<th>x</th>
<th>a</th>
<th>b</th>
</tr>
</thead>
<tbody>
<tr>
<td>NULL</td>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>NULL</td>
<td>6</td>
<td>7</td>
</tr>
<tr>
<td>NULL</td>
<td>10</td>
<td>-4</td>
</tr>
<tr>
<td>NULL</td>
<td>14</td>
<td>6</td>
</tr>
</tbody>
</table>

Because the ordering of the rows in the underlying SELECT statements cannot always be determined, CREATE TABLE ... IGNORE SELECT and CREATE TABLE ... REPLACE SELECT statements are flagged as unsafe for statement-based replication. Such statements produce a warning in the error log when using statement-based mode and are written to the binary log using the row-based format when using MIXED mode. See also Section 17.2.1.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”.

CREATE TABLE ... SELECT does not automatically create any indexes for you. This is done intentionally to make the statement as flexible as possible. If you want to have indexes in the created table, you should specify these before the SELECT statement:

mysql> CREATE TABLE bar (UNIQUE (n)) SELECT n FROM foo;

For CREATE TABLE ... SELECT, the destination table does not preserve information about whether columns in the selected-from table are generated columns. The SELECT part of the statement cannot assign values to generated columns in the destination table.

For CREATE TABLE ... SELECT, the destination table does preserve expression default values from the original table.

Some conversion of data types might occur. For example, the AUTO_INCREMENT attribute is not preserved, and VARCHAR columns can become CHAR columns. Retained attributes are NULL (or NOT NULL) and, for those columns that have them, CHARACTER SET, COLLATION, COMMENT, and the DEFAULT clause.

When creating a table with CREATE TABLE ... SELECT, make sure to alias any function calls or expressions in the query. If you do not, the CREATE statement might fail or result in undesirable column names.

CREATE TABLE artists_and_works
   SELECT artist.name, COUNT(work.artist_id) AS number_of_works
   FROM artist LEFT JOIN work ON artist.id = work.artist_id
   GROUP BY artist.id;

You can also explicitly specify the data type for a column in the created table:

CREATE TABLE foo (a TINYINT NOT NULL) SELECT b+1 AS a FROM bar;

For CREATE TABLE ... SELECT, if IF NOT EXISTS is given and the target table exists, nothing is inserted into the destination table, and the statement is not logged.

To ensure that the binary log can be used to re-create the original tables, MySQL does not permit concurrent inserts during CREATE TABLE ... SELECT. However, prior to MySQL 8.0.21, when a CREATE TABLE ... SELECT operation is applied from the binary log when row-based replication is in use, concurrent inserts are permitted on the replicated table while copying data. That limitation is removed in MySQL 8.0.21 on storage engines that support atomic DDL. For more information, see Section 13.1.1, “Atomic Data Definition Statement Support”.

2375
CREATE TABLE Statement

You cannot use `FOR UPDATE` as part of the `SELECT` in a statement such as `CREATE TABLE new_table SELECT ... FROM old_table ...`. If you attempt to do so, the statement fails.

`CREATE TABLE ... SELECT` operations apply `ENGINE_ATTRIBUTE` and `SECONDARY_ENGINE_ATTRIBUTE` values to columns only. Table and index `ENGINE_ATTRIBUTE` and `SECONDARY_ENGINE_ATTRIBUTE` values are not applied to the new table unless specified explicitly.

13.1.20.5 FOREIGN KEY Constraints

MySQL supports foreign keys, which permit cross-referencing related data across tables, and foreign key constraints, which help keep the related data consistent.

A foreign key relationship involves a parent table that holds the initial column values, and a child table with column values that reference the parent column values. A foreign key constraint is defined on the child table.

The essential syntax for defining a foreign key constraint in a `CREATE TABLE` or `ALTER TABLE` statement includes the following:

```sql
[CONSTRAINT [symbol]] FOREIGN KEY
[index_name] (col_name, ...)
REFERENCES tbl_name (col_name, ...)
[ON DELETE reference_option]
[ON UPDATE reference_option]
```

reference_option:
- `RESTRICT` | `CASCADE` | `SET NULL` | `NO ACTION` | `SET DEFAULT`

Foreign key constraint usage is described under the following topics in this section:

- Identifiers
- Conditions and Restrictions
- Referential Actions
- Foreign Key Constraint Examples
- Adding Foreign Key Constraints
- Dropping Foreign Key Constraints
- Foreign Key Checks
- Locking
- Foreign Key Definitions and Metadata
- Foreign Key Errors

Identifiers

Foreign key constraint naming is governed by the following rules:

- The `CONSTRAINT symbol` value is used, if defined.

- If the `CONSTRAINT symbol` clause is not defined, or a symbol is not included following the `CONSTRAINT` keyword, a constraint name name is generated automatically.

Prior to MySQL 8.0.16, if the `CONSTRAINT symbol` clause was not defined, or a symbol was not included following the `CONSTRAINT` keyword, both InnoDB and NDB storage engines would use the `FOREIGN_KEY index_name` if defined. In MySQL 8.0.16 and higher, the `FOREIGN_KEY index_name` is ignored.
CREATE TABLE Statement

- The `CONSTRAINT symbol` value, if defined, must be unique in the database. A duplicate `symbol` results in an error similar to: `ERROR 1005 (HY000): Can't create table 'test.fk1' (errno: 121).

- NDB Cluster stores foreign names using the same lettercase with which they are created. Prior to version 8.0.20, when processing `SELECT` and other SQL statements, NDB compared the names of foreign keys in such statements with the names as stored in a case-sensitive fashion when `lower_case_table_names` was equal to 0. In NDB 8.0.20 and later, this value no longer has any effect on how such comparisons are made, and they are always done without regard to lettercase. (Bug #30512043)

  Table and column identifiers in a `FOREIGN KEY ... REFERENCES` clause can be quoted within backticks (``). Alternatively, double quotation marks (") can be used if the `ANSI_QUOTES` SQL mode is enabled. The `lower_case_table_names` system variable setting is also taken into account.

Conditions and Restrictions

Foreign key constraints are subject to the following conditions and restrictions:

- Parent and child tables must use the same storage engine, and they cannot be defined as temporary tables.

- Creating a foreign key constraint requires the `REFERENCES` privilege on the parent table.

- Corresponding columns in the foreign key and the referenced key must have similar data types. The size and sign of fixed precision types such as `INTEGER` and `DECIMAL` must be the same. The length of string types need not be the same. For nonbinary (character) string columns, the character set and collation must be the same.

- MySQL supports foreign key references between one column and another within a table. (A column cannot have a foreign key reference to itself.) In these cases, a “child table record” refers to a dependent record within the same table.

- MySQL requires indexes on foreign keys and referenced keys so that foreign key checks can be fast and not require a table scan. In the referencing table, there must be an index where the foreign key columns are listed as the first columns in the same order. Such an index is created on the referencing table automatically if it does not exist. This index might be silently dropped later if you create another index that can be used to enforce the foreign key constraint. `index_name`, if given, is used as described previously.

- InnoDB permits a foreign key to reference any index column or group of columns. However, in the referenced table, there must be an index where the referenced columns are the first columns in the same order. Hidden columns that InnoDB adds to an index are also considered (see Section 15.6.2.1, “Clustered and Secondary Indexes”).

  NDB requires an explicit unique key (or primary key) on any column referenced as a foreign key. InnoDB does not, which is an extension of standard SQL.

- Index prefixes on foreign key columns are not supported. Consequently, `BLOB` and `TEXT` columns cannot be included in a foreign key because indexes on those columns must always include a prefix length.

- InnoDB does not currently support foreign keys for tables with user-defined partitioning. This includes both parent and child tables.

  This restriction does not apply for NDB tables that are partitioned by `KEY` or `LINEAR KEY` (the only user partitioning types supported by the NDB storage engine); these may have foreign key references or be the targets of such references.

- A table in a foreign key relationship cannot be altered to use another storage engine. To change the storage engine, you must drop any foreign key constraints first.
A foreign key constraint cannot reference a virtual generated column.

For information about how the MySQL implementation of foreign key constraints differs from the SQL standard, see Section 1.7.2.3, “FOREIGN KEY Constraint Differences”.

Referential Actions

When an `UPDATE` or `DELETE` operation affects a key value in the parent table that has matching rows in the child table, the result depends on the referential action specified by `ON UPDATE` and `ON DELETE` subclauses of the `FOREIGN KEY` clause. Referential actions include:

- **CASCADE**: Delete or update the row from the parent table and automatically delete or update the matching rows in the child table. Both `ON DELETE CASCADE` and `ON UPDATE CASCADE` are supported. Between two tables, do not define several `ON UPDATE CASCADE` clauses that act on the same column in the parent table or in the child table.

  If a `FOREIGN KEY` clause is defined on both tables in a foreign key relationship, making both tables a parent and child, an `ON UPDATE CASCADE` or `ON DELETE CASCADE` subclause defined for one `FOREIGN KEY` clause must be defined for the other in order for cascading operations to succeed. If an `ON UPDATE CASCADE` or `ON DELETE CASCADE` subclause is only defined for one `FOREIGN KEY` clause, cascading operations fail with an error.

  **Note**
  
  Cascaded foreign key actions do not activate triggers.

- **SET NULL**: Delete or update the row from the parent table and set the foreign key column or columns in the child table to `NULL`. Both `ON DELETE SET NULL` and `ON UPDATE SET NULL` clauses are supported.

  If you specify a `SET NULL` action, make sure that you have not declared the columns in the child table as `NOT NULL`.

- **RESTRICT**: Rejects the delete or update operation for the parent table. Specifying `RESTRICT` (or `NO ACTION`) is the same as omitting the `ON DELETE` or `ON UPDATE` clause.

- **NO ACTION**: A keyword from standard SQL. In MySQL, equivalent to `RESTRICT`. The MySQL Server rejects the delete or update operation for the parent table if there is a related foreign key value in the referenced table. Some database systems have deferred checks, and `NO ACTION` is a deferred check. In MySQL, foreign key constraints are checked immediately, so `NO ACTION` is the same as `RESTRICT`.

- **SET DEFAULT**: This action is recognized by the MySQL parser, but both InnoDB and NDB reject table definitions containing `ON DELETE SET DEFAULT` or `ON UPDATE SET DEFAULT` clauses.

  For storage engines that support foreign keys, MySQL rejects any `INSERT` or `UPDATE` operation that attempts to create a foreign key value in a child table if there is no matching candidate key value in the parent table.

  For an `ON DELETE` or `ON UPDATE` that is not specified, the default action is always `NO ACTION`.

  As the default, an `ON DELETE NO ACTION` or `ON UPDATE NO ACTION` clause that is specified explicitly does not appear in `SHOW CREATE TABLE` output or in tables dumped with `mysqldump`. `RESTRICT`, which is an equivalent non-default keyword, appears in `SHOW CREATE TABLE` output and in tables dumped with `mysqldump`.

  For NDB tables, `ON UPDATE CASCADE` is not supported where the reference is to the parent table’s primary key.

  As of NDB 8.0.16: For NDB tables, `ON DELETE CASCADE` is not supported where the child table contains one or more columns of any of the `TEXT` or `BLOB` types. (Bug #89511, Bug #27484882)
InnoDB performs cascading operations using a depth-first search algorithm on the records of the index that corresponds to the foreign key constraint.

A foreign key constraint on a stored generated column cannot use `CASCADE`, `SET NULL`, or `SET DEFAULT` as `ON UPDATE` referential actions, nor can it use `SET NULL` or `SET DEFAULT` as `ON DELETE` referential actions.

A foreign key constraint on the base column of a stored generated column cannot use `CASCADE`, `SET NULL`, or `SET DEFAULT` as `ON UPDATE` or `ON DELETE` referential actions.

**Foreign Key Constraint Examples**

This simple example relates `parent` and `child` tables through a single-column foreign key:

```sql
CREATE TABLE parent (
  id INT NOT NULL,
  PRIMARY KEY (id)
) ENGINE=INNODB;

CREATE TABLE child (
  id INT,
  parent_id INT,
  INDEX par_ind (parent_id),
  FOREIGN KEY (parent_id)
    REFERENCES parent(id)
    ON DELETE CASCADE
) ENGINE=INNODB;
```

This is a more complex example in which a `product_order` table has foreign keys for two other tables. One foreign key references a two-column index in the `product` table. The other references a single-column index in the `customer` table:

```sql
CREATE TABLE product (
  category INT NOT NULL, id INT NOT NULL,
  price DECIMAL,
  PRIMARY KEY(category, id)
) ENGINE=INNODB;

CREATE TABLE customer (
  id INT NOT NULL,
  PRIMARY KEY (id)
) ENGINE=INNODB;

CREATE TABLE product_order (
  no INT NOT NULL AUTO_INCREMENT,
  product_category INT NOT NULL,
  product_id INT NOT NULL,
  customer_id INT NOT NULL,
  PRIMARY KEY(no),
  INDEX (product_category, product_id),
  INDEX (customer_id),
  FOREIGN KEY (product_category, product_id)
    REFERENCES product(category, id)
    ON UPDATE CASCADE ON DELETE RESTRICT,
  FOREIGN KEY (customer_id)
    REFERENCES customer(id)
) ENGINE=INNODB;
```

**Adding Foreign Key Constraints**

You can add a foreign key constraint to an existing table using the following `ALTER TABLE` syntax:

```sql
ALTER TABLE tbl_name
  ADD [CONSTRAINT [symbol]] FOREIGN KEY
```
CREATE TABLE Statement

The foreign key can be self referential (referring to the same table). When you add a foreign key constraint to a table using `ALTER TABLE`, remember to first create an index on the column(s) referenced by the foreign key.

**Dropping Foreign Key Constraints**

You can drop a foreign key constraint using the following `ALTER TABLE` syntax:

```sql
ALTER TABLE tbl_name DROP FOREIGN KEY fk_symbol;
```

If the `FOREIGN KEY` clause defined a `CONSTRAINT` name when you created the constraint, you can refer to that name to drop the foreign key constraint. Otherwise, a constraint name was generated internally, and you must use that value. To determine the foreign key constraint name, use `SHOW CREATE TABLE`:

```
mysql> SHOW CREATE TABLE child\G
*************************** 1. row ***************************
Table: child
Create Table: CREATE TABLE `child` (
  `id` int DEFAULT NULL,
  `parent_id` int DEFAULT NULL,
  KEY `par_ind` (`parent_id`),
  CONSTRAINT `child_ibfk_1` FOREIGN KEY (`parent_id`) REFERENCES `parent` (`id`) ON DELETE CASCADE
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_0900_ai_ci
mysql>
```

Adding and dropping a foreign key in the same `ALTER TABLE` statement is supported for `ALTER TABLE ... ALGORITHM=INPLACE`. It is not supported for `ALTER TABLE ... ALGORITHM=COPY`.

**Foreign Key Checks**

Foreign key checking is controlled by the `foreign_key_checks` variable, which is enabled by default. Typically, you leave this variable enabled during normal operation to enforce referential integrity. The `foreign_key_checks` variable has the same effect on NDB tables as it does for InnoDB tables.

The `foreign_key_checks` variable is dynamic and supports both global and session scopes. For information about using system variables, see Section 5.1.9, "Using System Variables".

Disabling foreign key checking is useful when:

- Dropping a table that is referenced by a foreign key constraint. A referenced table can only be dropped after `foreign_key_checks` is disabled. When you drop a table, constraints defined on the table are also dropped.
- Reloading tables in different order than required by their foreign key relationships. For example, `mysqldump` produces correct definitions of tables in the dump file, including foreign key constraints for child tables. To make it easier to reload dump files for tables with foreign key relationships, `mysqldump` automatically includes a statement in the dump output that disables `foreign_key_checks`. This enables you to import the tables in any order in case the dump file contains tables that are not correctly ordered for foreign keys. Disabling `foreign_key_checks` also speeds up the import operation by avoiding foreign key checks.
- Executing `LOAD DATA` operations, to avoid foreign key checking.
- Performing an `ALTER TABLE` operation on a table that has a foreign key relationship.
When `foreign_key_checks` is disabled, foreign key constraints are ignored, with the following exceptions:

- Recreating a table that was previously dropped returns an error if the table definition does not conform to the foreign key constraints that reference the table. The table must have the correct column names and types. It must also have indexes on the referenced keys. If these requirements are not satisfied, MySQL returns Error 1005 that refers to errno: 150 in the error message, which means that a foreign key constraint was not correctly formed.

- Altering a table returns an error (errno: 150) if a foreign key definition is incorrectly formed for the altered table.

- Dropping an index required by a foreign key constraint. The foreign key constraint must be removed before dropping the index.

- Creating a foreign key constraint where a column references a nonmatching column type.

Disabling `foreign_key_checks` has these additional implications:

- It is permitted to drop a database that contains tables with foreign keys that are referenced by tables outside the database.

- It is permitted to drop a table with foreign keys referenced by other tables.

- Enabling `foreign_key_checks` does not trigger a scan of table data, which means that rows added to a table while `foreign_key_checks` is disabled are not checked for consistency when `foreign_key_checks` is re-enabled.

### Locking

MySQL extends metadata locks, as necessary, to tables that are related by a foreign key constraint. Extending metadata locks prevents conflicting DML and DDL operations from executing concurrently on related tables. This feature also enables updates to foreign key metadata when a parent table is modified. In earlier MySQL releases, foreign key metadata, which is owned by the child table, could not be updated safely.

If a table is locked explicitly with `LOCK TABLES`, any tables related by a foreign key constraint are opened and locked implicitly. For foreign key checks, a shared read-only lock (`LOCK TABLES READ`) is taken on related tables. For cascading updates, a shared-nothing write lock (`LOCK TABLES WRITE`) is taken on related tables that are involved in the operation.

### Foreign Key Definitions and Metadata

To view a foreign key definition, use `SHOW CREATE TABLE`:

```
mysql> SHOW CREATE TABLE child;
```

```sql
CREATE TABLE `child` (  `id` int DEFAULT NULL,  `parent_id` int DEFAULT NULL,  KEY `par_ind` (`parent_id`),  CONSTRAINT `child_ibfk_1` FOREIGN KEY (`parent_id`)  REFERENCES `parent` (`id`) ON DELETE CASCADE) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_0900_ai_ci
```

You can obtain information about foreign keys from the `INFORMATION_SCHEMA.KEY_COLUMN_USAGE` table. An example of a query against this table is shown here:

```
mysql> SELECT TABLE_SCHEMA, TABLE_NAME, COLUMN_NAME, CONSTRAINT_NAME  FROM INFORMATION_SCHEMA.KEY_COLUMN_USAGE  WHERE REFERENCED_TABLE_SCHEMA IS NOT NULL;
```

<table>
<thead>
<tr>
<th>TABLE_SCHEMA</th>
<th>TABLE_NAME</th>
<th>COLUMN_NAME</th>
<th>CONSTRAINT_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>2381</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
CREATE TABLE Statement

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>test</td>
<td>child</td>
<td>parent_id</td>
<td>child_ibfk_1</td>
</tr>
<tr>
<td>--------------</td>
<td>------------</td>
<td>-------------</td>
<td>-----------------</td>
</tr>
</tbody>
</table>

You can obtain information specific to InnoDB foreign keys from the INNODB_FOREIGN and INNODB_FOREIGN_COLS tables. Example queries are show here:

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FOREIGN \G
*************************** 1. row ***************************
ID: test/child_ibfk_1
FOR_NAME: test/child
REF_NAME: test/parent
N_COLS: 1
TYPE: 1
mysql>
```

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FOREIGN_COLS \G
*************************** 1. row ***************************
ID: test/child_ibfk_1
FOR_COL_NAME: parent_id
REF_COL_NAME: id
POS: 0
```

Foreign Key Errors

In the event of a foreign key error involving InnoDB tables (usually Error 150 in the MySQL Server), information about the latest foreign key error can be obtained by checking SHOW ENGINE INNODB STATUS output.

```sql
mysql> SHOW ENGINE INNODB STATUS\G
...  
LATEST FOREIGN KEY ERROR
------------------------
2018-04-12 14:57:24 0x7f97a9c91700 Transaction:
TRANSACTION 7717, ACTIVE 0 sec inserting
mysql tables in use 1, locked 1
4 lock struct(s), heap size 1136, 3 row lock(s), undo log entries 3
MySQL thread id 8, OS thread handle 140289365317376, query id 14 localhost root update
INSERT INTO child VALUES (NULL, 1), (NULL, 2), (NULL, 3), (NULL, 4), (NULL, 5), (NULL, 6)
Foreign key constraint fails for table `test`.`child`:
 CONSTRAINT `child_ibfk_1` FOREIGN KEY (`parent_id`) REFERENCES `parent` (`id`) ON DELETE CASCADE ON UPDATE CASCADE
Trying to add in child table, in index par_ind tuple:
DATA TUPLE: 2 fields;
  0: len 4; hex 80000003; asc     ;;
  1: len 4; hex 80000003; asc     ;;

But in parent table `test`.`parent`, in index PRIMARY, the closest match we can find is record:
PHYSICAL RECORD: n_fields 3; compact format; info bits 0
  0: len 4; hex 80000004; asc     ;;
  1: len 6; hex 000000001e19; asc 7;;
  2: len 7; hex 81000001110137; asc 7;;
```

Warning

If a user has table-level privileges for all parent tables, ER_NO_REFERENCED_ROW_2 and ER_ROW_IS_REFERENCED_2 error messages for foreign key operations expose information about parent tables. If a user does not have table-level privileges for all parent tables, more generic error messages are displayed instead (ER_NO_REFERENCED_ROW and ER_ROW_IS_REFERENCED).

An exception is that, for stored programs defined to execute with DEFINER privileges, the user against which privileges are assessed is the user in the program DEFINER clause, not the invoking user. If that user has table-level
CREATE TABLE Statement

parent table privileges, parent table information is still displayed. In this case, it is the responsibility of the stored program creator to hide the information by including appropriate condition handlers.

13.1.20.6 CHECK Constraints

Prior to MySQL 8.0.16, `CREATE TABLE` permits only the following limited version of table `CHECK` constraint syntax, which is parsed and ignored:

```
CHECK (expr)
```

As of MySQL 8.0.16, `CREATE TABLE` permits the core features of table and column `CHECK` constraints, for all storage engines. `CREATE TABLE` permits the following `CHECK` constraint syntax, for both table constraints and column constraints:

```
[CONSTRAINT [symbol]] CHECK (expr) [NOT] ENFORCED
```

The optional `symbol` specifies a name for the constraint. If omitted, MySQL generates a name from the table name, a literal `_chk_`, and an ordinal number (1, 2, 3, ...). Constraint names have a maximum length of 64 characters. They are case-sensitive, but not accent-sensitive.

`expr` specifies the constraint condition as a boolean expression that must evaluate to `TRUE` or `UNKNOWN` (for `NULL` values) for each row of the table. If the condition evaluates to `FALSE`, it fails and a constraint violation occurs. The effect of a violation depends on the statement being executed, as described later in this section.

The optional enforcement clause indicates whether the constraint is enforced:

- If omitted or specified as `ENFORCED`, the constraint is created and enforced.
- If specified as `NOT ENFORCED`, the constraint is created but not enforced.

A `CHECK` constraint is specified as either a table constraint or column constraint:

- A table constraint does not appear within a column definition and can refer to any table column or columns. Forward references are permitted to columns appearing later in the table definition.

- A column constraint appears within a column definition and can refer only to that column.

Consider this table definition:

```
CREATE TABLE t1
(
  CHECK (c1 <> c2),
  c1 INT CHECK (c1 > 10),
  c2 INT CONSTRAINT c2_positive CHECK (c2 > 0),
  c3 INT CHECK (c3 < 100),
  CONSTRAINT c1_nonzero CHECK (c1 <> 0),
  CHECK (c1 > c3)
);
```

The definition includes table constraints and column constraints, in named and unnamed formats:

- The first constraint is a table constraint: It occurs outside any column definition, so it can (and does) refer to multiple table columns. This constraint contains forward references to columns not defined yet. No constraint name is specified, so MySQL generates a name.

- The next three constraints are column constraints: Each occurs within a column definition, and thus can refer only to the column being defined. One of the constraints is named explicitly. MySQL generates a name for each of the other two.

- The last two constraints are table constraints. One of them is named explicitly. MySQL generates a name for the other one.
As mentioned, MySQL generates a name for any \texttt{CHECK} constraint specified without one. To see the names generated for the preceding table definition, use \texttt{SHOW CREATE TABLE}:

```
mysql> SHOW CREATE TABLE t1
                    +-------------------------------+
                    | CREATE TABLE `t1` (          |
                    |   `c1` int(11) DEFAULT NULL, |
                    |   `c2` int(11) DEFAULT NULL, |
                    |   `c3` int(11) DEFAULT NULL, |
                    |   CONSTRAINT `c1_nonzero` CHECK (\textbackslash`c1` <> 0), |
                    |   CONSTRAINT `c2_positive` CHECK (\textbackslash`c2` > 0), |
                    |   CONSTRAINT `t1_chk_1` CHECK (\textbackslash`c1` <> \textbackslash`c2`), |
                    |   CONSTRAINT `t1_chk_2` CHECK (\textbackslash`c1` > 10), |
                    |   CONSTRAINT `t1_chk_3` CHECK (\textbackslash`c3` < 100), |
                    |   CONSTRAINT `t1_chk_4` CHECK (\textbackslash`c1` > \textbackslash`c3`) |
                    | ) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_0900_ai_ci |
```

The SQL standard specifies that all types of constraints (primary key, unique index, foreign key, check) belong to the same namespace. In MySQL, each constraint type has its own namespace per schema (database). Consequently, \texttt{CHECK} constraint names must be unique per schema; no two tables in the same schema can share a \texttt{CHECK} constraint name. (Exception: A \texttt{TEMPORARY} table hides a non-\texttt{TEMPORARY} table of the same name, so it can have the same \texttt{CHECK} constraint names as well.)

Beginning generated constraint names with the table name helps ensure schema uniqueness because table names also must be unique within the schema.

\texttt{CHECK} condition expressions must adhere to the following rules. An error occurs if an expression contains disallowed constructs.

- Nongenerated and generated columns are permitted, except columns with the \texttt{AUTO_INCREMENT} attribute and columns in other tables.
- Literals, deterministic built-in functions, and operators are permitted. A function is deterministic if, given the same data in tables, multiple invocations produce the same result, independently of the connected user. Examples of functions that are nondeterministic and fail this definition: \texttt{CONNECTION_ID()}, \texttt{CURRENT_USER()}, \texttt{NOW()}.
- Stored functions and user-defined functions are not permitted.
- Stored procedure and function parameters are not permitted.
- Variables (system variables, user-defined variables, and stored program local variables) are not permitted.
- Subqueries are not permitted.

Foreign key referential actions (\texttt{ON UPDATE}, \texttt{ON DELETE}) are prohibited on columns used in \texttt{CHECK} constraints. Likewise, \texttt{CHECK} constraints are prohibited on columns used in foreign key referential actions.

\texttt{CHECK} constraints are evaluated for \texttt{INSERT}, \texttt{UPDATE}, \texttt{REPLACE}, \texttt{LOAD DATA}, and \texttt{LOAD XML} statements and an error occurs if a constraint evaluates to \texttt{FALSE}. If an error occurs, handling of changes already applied differs for transactional and nontransactional storage engines, and also depends on whether strict SQL mode is in effect, as described in \texttt{Strict SQL Mode}.

\texttt{CHECK} constraints are evaluated for \texttt{INSERT IGNORE}, \texttt{UPDATE IGNORE}, \texttt{LOAD DATA ... IGNORE}, and \texttt{LOAD XML ... IGNORE} statements and a warning occurs if a constraint evaluates to \texttt{FALSE}. The insert or update for any offending row is skipped.

If the constraint expression evaluates to a data type that differs from the declared column type, implicit coercion to the declared type occurs according to the usual MySQL type-conversion rules. See \texttt{Section 12.3, "Type Conversion in Expression Evaluation"}. If type conversion fails or results in a loss of precision, an error occurs.
Note
Constraint expression evaluation uses the SQL mode in effect at evaluation
time. If any component of the expression depends on the SQL mode, different
results may occur for different uses of the table unless the SQL mode is the
same during all uses.

The INFORMATION_SCHEMA.CHECK_CONSTRAINTS table provides information about
CHECK constraints defined on tables. See Section 26.3.5, “The INFORMATION_SCHEMA
CHECK_CONSTRAINTS Table”.

13.1.20.7 Silent Column Specification Changes

In some cases, MySQL silently changes column specifications from those given in a CREATE TABLE or
ALTER TABLE statement. These might be changes to a data type, to attributes associated with a data
type, or to an index specification.

All changes are subject to the internal row-size limit of 65,535 bytes, which may cause some attempts
at data type changes to fail. See Section 8.4.7, “Limits on Table Column Count and Row Size”.

- Columns that are part of a PRIMARY KEY are made NOT NULL even if not declared that way.
- Trailing spaces are automatically deleted from ENUM and SET member values when the table is
  created.
- MySQL maps certain data types used by other SQL database vendors to MySQL types. See
  Section 11.9, “Using Data Types from Other Database Engines”.
- If you include a USING clause to specify an index type that is not permitted for a given storage
  engine, but there is another index type available that the engine can use without affecting query
  results, the engine uses the available type.
- If strict SQL mode is not enabled, a VARCHAR column with a length specification greater than 65535
  is converted to TEXT, and a VARBINARY column with a length specification greater than 65535 is
  converted to BLOB. Otherwise, an error occurs in either of these cases.
- Specifying the CHARACTER SET binary attribute for a character data type causes the column
to be created as the corresponding binary data type: CHAR becomes BINARY, VARCHAR becomes
VARBINARY, and TEXT becomes BLOB. For the ENUM and SET data types, this does not occur; they
are created as declared. Suppose that you specify a table using this definition:

```sql
CREATE TABLE t
|
| c1 VARCHAR(10) CHARACTER SET binary,
| c2 TEXT CHARACTER SET binary,
| c3 ENUM('a','b','c') CHARACTER SET binary
|
```

The resulting table has this definition:

```sql
CREATE TABLE t
|
| c1 VARBINARY(10),
| c2 BLOB,
| c3 ENUM('a','b','c') CHARACTER SET binary
|
```

To see whether MySQL used a data type other than the one you specified, issue a DESCRIBE or SHOW
CREATE TABLE statement after creating or altering the table.

Certain other data type changes can occur if you compress a table using myisampack. See
Section 16.2.3.3, “Compressed Table Characteristics”.

13.1.20.8 CREATE TABLE and Generated Columns
CREATE TABLE supports the specification of generated columns. Values of a generated column are computed from an expression included in the column definition.

Generated columns are also supported by the NDB storage engine.

The following simple example shows a table that stores the lengths of the sides of right triangles in the sidea and sideb columns, and computes the length of the hypotenuse in sidec (the square root of the sums of the squares of the other sides):

```sql
CREATE TABLE triangle (
  sidea DOUBLE,
  sideb DOUBLE,
  sidec DOUBLE AS (SQRT(sidea * sidea + sideb * sideb))
);
INSERT INTO triangle (sidea, sideb) VALUES(1,1),(3,4),(6,8);
```

Selecting from the table yields this result:

```
mysql> SELECT * FROM triangle;
+-------+-------+--------------------+
| sidea | sideb | sidec              |
+-------+-------+--------------------+
|     1 |     1 | 1.4142135623730951 |
|     3 |     4 |                  5 |
|     6 |     8 |                 10 |
+-------+-------+--------------------+
```

Any application that uses the `triangle` table has access to the hypotenuse values without having to specify the expression that calculates them.

Generated column definitions have this syntax:

```
col_name data_type [GENERATED ALWAYS] AS (expr) [VIRTUAL | STORED] [NOT NULL | NULL] [UNIQUE [KEY]] [PRIMARY KEY] [COMMENT 'string']
```

`AS (expr)` indicates that the column is generated and defines the expression used to compute column values. `AS` may be preceded by `GENERATED ALWAYS` to make the generated nature of the column more explicit. Constructs that are permitted or prohibited in the expression are discussed later.

The `VIRTUAL` or `STORED` keyword indicates how column values are stored, which has implications for column use:

- **VIRTUAL**: Column values are not stored, but are evaluated when rows are read, immediately after any BEFORE triggers. A virtual column takes no storage.

  InnoDB supports secondary indexes on virtual columns. See Section 13.1.20.9, “Secondary Indexes and Generated Columns”.

- **STORED**: Column values are evaluated and stored when rows are inserted or updated. A stored column does require storage space and can be indexed.

The default is `VIRTUAL` if neither keyword is specified.

It is permitted to mix `VIRTUAL` and `STORED` columns within a table.

Other attributes may be given to indicate whether the column is indexed or can be `NULL`, or provide a comment.

Generated column expressions must adhere to the following rules. An error occurs if an expression contains disallowed constructs.

- Literals, deterministic built-in functions, and operators are permitted. A function is deterministic if, given the same data in tables, multiple invocations produce the same result, independently
CREATE TABLE Statement

of the connected user. Examples of functions that are nondeterministic and fail this definition:
CONNECTION_ID(), CURRENT_USER(), NOW().

• Stored functions and user-defined functions are not permitted.
• Stored procedure and function parameters are not permitted.
• Variables (system variables, user-defined variables, and stored program local variables) are not
  permitted.
• Subqueries are not permitted.
• A generated column definition can refer to other generated columns, but only those occurring earlier
  in the table definition. A generated column definition can refer to any base (nongenerated) column in
  the table whether its definition occurs earlier or later.
• The AUTO_INCREMENT attribute cannot be used in a generated column definition.
• An AUTO_INCREMENT column cannot be used as a base column in a generated column definition.
• If expression evaluation causes truncation or provides incorrect input to a function, the CREATE
  TABLE statement terminates with an error and the DDL operation is rejected.

If the expression evaluates to a data type that differs from the declared column type, implicit coercion to
the declared type occurs according to the usual MySQL type-conversion rules. See Section 12.3, “Type
Conversion in Expression Evaluation”.

If a generated column uses the TIMESTAMP data type, the setting for
explicit_defaults_for_timestamp is ignored. In such cases, if this variable is disabled then
NULL is not converted to CURRENT_TIMESTAMP. In MySQL 8.0.22 and later, if the column is also
declared as NOT NULL, attempting to insert NULL is explicitly rejected with ER_BAD_NULL_ERROR.

Note
Expression evaluation uses the SQL mode in effect at evaluation time. If any
component of the expression depends on the SQL mode, different results may
occur for different uses of the table unless the SQL mode is the same during all
uses.

For CREATE TABLE ... LIKE, the destination table preserves generated column information from
the original table.

For CREATE TABLE ... SELECT, the destination table does not preserve information about whether
columns in the selected-from table are generated columns. The SELECT part of the statement cannot
assign values to generated columns in the destination table.

Partitioning by generated columns is permitted. See Table Partitioning.

A foreign key constraint on a stored generated column cannot use CASCADE, SET NULL, or SET
DEFAULT as ON UPDATE referential actions, nor can it use SET NULL or SET DEFAULT as ON
DELETE referential actions.

A foreign key constraint on the base column of a stored generated column cannot use CASCADE, SET
NULL, or SET DEFAULT as ON UPDATE or ON DELETE referential actions.

A foreign key constraint cannot reference a virtual generated column.

Triggers cannot use NEW.col_name or use OLD.col_name to refer to generated columns.

For INSERT, REPLACE, and UPDATE, if a generated column is inserted into, replaced, or updated
explicitly, the only permitted value is DEFAULT.
A generated column in a view is considered updatable because it is possible to assign to it. However, if such a column is updated explicitly, the only permitted value is DEFAULT.

Generated columns have several use cases, such as these:

- Virtual generated columns can be used as a way to simplify and unify queries. A complicated condition can be defined as a generated column and referred to from multiple queries on the table to ensure that all of them use exactly the same condition.
- Stored generated columns can be used as a materialized cache for complicated conditions that are costly to calculate on the fly.
- Generated columns can simulate functional indexes: Use a generated column to define a functional expression and index it. This can be useful for working with columns of types that cannot be indexed directly, such as JSON columns; see Indexing a Generated Column to Provide a JSON Column Index, for a detailed example.

For stored generated columns, the disadvantage of this approach is that values are stored twice; once as the value of the generated column and once in the index.

- If a generated column is indexed, the optimizer recognizes query expressions that match the column definition and uses indexes from the column as appropriate during query execution, even if a query does not refer to the column directly by name. For details, see Section 8.3.11, “Optimizer Use of Generated Column Indexes”.

Example:

Suppose that a table `t1` contains `first_name` and `last_name` columns and that applications frequently construct the full name using an expression like this:

```sql
SELECT CONCAT(first_name,' ',last_name) AS full_name FROM t1;
```

One way to avoid writing out the expression is to create a view `v1` on `t1`, which simplifies applications by enabling them to select `full_name` directly without using an expression:

```sql
CREATE VIEW v1 AS
    SELECT *, CONCAT(first_name,' ',last_name) AS full_name FROM t1;
SELECT full_name FROM v1;
```

A generated column also enables applications to select `full_name` directly without the need to define a view:

```sql
CREATE TABLE t1 (  
    first_name VARCHAR(10),  
    last_name VARCHAR(10),  
    full_name VARCHAR(255) AS (CONCAT(first_name,' ',last_name))  
);
SELECT full_name FROM t1;
```

### 13.1.20.9 Secondary Indexes and Generated Columns

**InnoDB** supports secondary indexes on virtual generated columns. Other index types are not supported. A secondary index defined on a virtual column is sometimes referred to as a “virtual index”.

A secondary index may be created on one or more virtual columns or on a combination of virtual columns and regular columns or stored generated columns. Secondary indexes that include virtual columns may be defined as UNIQUE.

When a secondary index is created on a virtual generated column, generated column values are materialized in the records of the index. If the index is a covering index (one that includes all the
columns retrieved by a query), generated column values are retrieved from materialized values in the index structure instead of computed “on the fly”.

There are additional write costs to consider when using a secondary index on a virtual column due to computation performed when materializing virtual column values in secondary index records during INSERT and UPDATE operations. Even with additional write costs, secondary indexes on virtual columns may be preferable to generated stored columns, which are materialized in the clustered index, resulting in larger tables that require more disk space and memory. If a secondary index is not defined on a virtual column, there are additional costs for reads, as virtual column values must be computed each time the column's row is examined.

Values of an indexed virtual column are MVCC-logged to avoid unnecessary recomputation of generated column values during rollback or during a purge operation. The data length of logged values is limited by the index key limit of 767 bytes for COMPACT and REDUNDANT row formats, and 3072 bytes for DYNAMIC and COMPRESSED row formats.

Adding or dropping a secondary index on a virtual column is an in-place operation.

**Indexing a Generated Column to Provide a JSON Column Index**

As noted elsewhere, JSON columns cannot be indexed directly. To create an index that references such a column indirectly, you can define a generated column that extracts the information that should be indexed, then create an index on the generated column, as shown in this example:

```
mysql> CREATE TABLE jemp (  
    ->     c JSON,  
    ->     g INT GENERATED ALWAYS AS (c->"$.id"),  
    ->     INDEX i (g)  
    -> );
Query OK, 0 rows affected (0.28 sec)

mysql> INSERT INTO jemp (c) VALUES  
    -> ('{"id": "1", "name": "Fred"}'), ('{"id": "2", "name": "Wilma"}'),  
    -> ('{"id": "3", "name": "Barney"}'), ('{"id": "4", "name": "Betty"}');
Query OK, 4 rows affected (0.04 sec)
Records: 4  Duplicates: 0  Warnings: 0

mysql> SELECT c->"$.name" AS name  
    -> FROM jemp WHERE g > 2;
+--------+
<table>
<thead>
<tr>
<th>name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Barney</td>
</tr>
<tr>
<td>Betty</td>
</tr>
</tbody>
</table>
+--------+
2 rows in set (0.00 sec)

mysql> EXPLAIN SELECT c->"$.name" AS name  
    -> FROM jemp WHERE g > 2;
*************************** 1. row ***************************
| id: 1 |
| select_type: SIMPLE |
| table: jemp |
| partitions: NULL |
| type: range |
| possible_keys: i |
| key: i |
| key_len: 5 |
| ref: NULL |
| rows: 2 |
| filtered: 100.00 |
| Extra: Using where |
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS;
```

2389
When you use \texttt{EXPLAIN} on a \texttt{SELECT} or other SQL statement containing one or more expressions that use the \texttt{->} or \texttt{->>} operator, these expressions are translated into their equivalents using \texttt{JSON\_EXTRACT()} and (if needed) \texttt{JSON\_UNQUOTE()} instead, as shown here in the output from \texttt{SHOW WARNINGS} immediately following this \texttt{EXPLAIN} statement:

\begin{verbatim}
mysql> \texttt{EXPLAIN SELECT c->"$.name"}
FROM jemp WHERE g > 2 ORDER BY c->"$.name"
G
*************************** 1. row ***************************
id: 1
select_type: SIMPLE
table: jemp
partitions: NULL
type: range
possible_keys: i
key: i
key_len: 5
ref: NULL
rows: 2
filtered: 100.00
Extra: Using where; Using filesort
1 row in set, 1 warning (0.00 sec)
mysql> \texttt{SHOW WARNINGS}
G
*************************** 1. row ***************************
Level: Note
Code: 1003
Message: /* select#1 */ \texttt{select json\_unquote(json\_extract(`test`.`jemp`.`c`,'$.name')) AS `name` from `test`.`jemp` where (`test`.`jemp`.`g` > 2) order by json\_extract(`test`.`jemp`.`c`,'$.name')} 1 row in set (0.00 sec)
\end{verbatim}

See the descriptions of the \texttt{->} and \texttt{->>} operators, as well as those of the \texttt{JSON\_EXTRACT()} and \texttt{JSON\_UNQUOTE()} functions, for additional information and examples.

This technique also can be used to provide indexes that indirectly reference columns of other types that cannot be indexed directly, such as \texttt{GEOMETRY} columns.

In MySQL 8.0.21 and later, it is also possible to create an index on a \texttt{JSON} column using the \texttt{JSON\_VALUE()} function with an expression that can be used to optimize queries employing the expression. See the description of that function for more information and examples.

**JSON columns and indirect indexing in NDB Cluster**

It is also possible to use indirect indexing of JSON columns in MySQL NDB Cluster, subject to the following conditions:

1. **NDB** handles a \texttt{JSON} column value internally as a \texttt{BLOB}. This means that any **NDB** table having one or more JSON columns must have a primary key, else it cannot be recorded in the binary log.

2. The **NDB** storage engine does not support indexing of virtual columns. Since the default for generated columns is \texttt{VIRTUAL}, you must specify explicitly the generated column to which to apply the indirect index as \texttt{STORED}.

The \texttt{CREATE TABLE} statement used to create the table \texttt{jempn} shown here is a version of the \texttt{jemp} table shown previously, with modifications making it compatible with **NDB**:

\begin{verbatim}
CREATE TABLE jempn
(a BIGINT(20) NOT NULL AUTO_INCREMENT PRIMARY KEY,
\end{verbatim}
CREATE TABLE Statement
c JSON DEFAULT NULL,
g INT GENERATED ALWAYS AS (c->"$.name") STORED,
INDEX i (g)
) ENGINE=NDB;

We can populate this table using the following INSERT statement:

```
INSERT INTO jempn (a, c) VALUES
(NULL, '{"id": "1", "name": "Fred"}'),
(NULL, '{"id": "2", "name": "Wilma"}'),
(NULL, '{"id": "3", "name": "Barney"}'),
(NULL, '{"id": "4", "name": "Betty"}');
```

Now NDB can use index i, as shown here:

```
mysql>
```
```
EXPLAIN SELECT c->"$.name" AS name
FROM jempn WHERE g > 2
```
```
*************************** 1. row ***************************
id: 1
select_type: SIMPLE
table: jempn
partitions: p0,p1
type: range
possible_keys: i
key: i
key_len: 5
ref: NULL
rows: 3
filtered: 100.00
Extra: Using where with pushed condition (`test`.`jempn`.`g` > 2)
1 row in set, 1 warning (0.00 sec)
```
```
mysql>
```
```

You should keep in mind that a stored generated column uses DataMemory, and that an index on such a column uses IndexMemory.

13.1.20.10 Invisible Columns

MySQL supports invisible columns as of MySQL 8.0.23. An invisible column is normally hidden to queries, but can be accessed if explicitly referenced. Prior to MySQL 8.0.23, all columns are visible.

As an illustration of when invisible columns may be useful, suppose that an application uses SELECT * queries to access a table, and must continue to work without modification even if the table is altered to add a new column that the application does not expect to be there. In a SELECT * query, the * evaluates to all table columns, except those that are invisible, so the solution is to add the new column as an invisible column. The column remains “hidden” from SELECT * queries, and the application continues to work as previously. A newer version of the application can refer to the invisible column if necessary by explicitly referencing it.

The following sections detail how MySQL treats invisible columns.

- DDL Statements and Invisible Columns
- DML Statements and Invisible Columns
- Invisible Column Metadata
- The Binary Log and Invisible Columns
DDL Statements and Invisible Columns

Columns are visible by default. To explicitly specify visibility for a new column, use a VISIBLE or INVISIBLE keyword as part of the column definition for CREATE TABLE or ALTER TABLE:

```sql
CREATE TABLE t1 (
  i INT,
  j DATE INVISIBLE
) ENGINE = InnoDB;
ALTER TABLE t1 ADD COLUMN k INT INVISIBLE;
```

To alter the visibility of an existing column, use a VISIBLE or INVISIBLE keyword with one of the ALTER TABLE column-modification clauses:

```sql
ALTER TABLE t1 CHANGE COLUMN j j DATE VISIBLE;
ALTER TABLE t1 MODIFY COLUMN j DATE INVISIBLE;
ALTER TABLE t1 ALTER COLUMN j SET VISIBLE;
```

A table must have at least one visible column. Attempting to make all columns invisible produces an error.

Invisible columns support the usual column attributes: NULL, NOT NULL, AUTO_INCREMENT, and so forth.

Generated columns can be invisible.

Index definitions can name invisible columns, including definitions for PRIMARY KEY and UNIQUE indexes. Although a table must have at least one visible column, an index definition need not have any visible columns.

An invisible column dropped from a table is dropped in the usual way from any index definition that names the column.

Foreign key constraints can be defined on invisible columns, and foreign key constraints can reference invisible columns.

CHECK constraints can be defined on invisible columns. For new or modified rows, violation of a CHECK constraint on an invisible column produces an error.

CREATE TABLE ... LIKE includes invisible columns, and they are invisible in the new table.

CREATE TABLE ... SELECT does not include invisible columns, unless they are explicitly referenced in the SELECT part. However, even if explicitly referenced, a column that is invisible in the existing table is visible in the new table:

```sql
mysql> CREATE TABLE t1 (col1 INT, col2 INT INVISIBLE);
mysql> CREATE TABLE t2 AS SELECT col1, col2 FROM t1;
mysql> SHOW CREATE TABLE t2\G
```

If invisibility should be preserved, provide a definition for the invisible column in the CREATE TABLE part of the CREATE TABLE ... SELECT statement:

```sql
mysql> CREATE TABLE t1 (col1 INT, col2 INT INVISIBLE);
mysql> CREATE TABLE t2 (col1 INT INVISIBLE) AS SELECT col1, col2 FROM t1;
mysql> SHOW CREATE TABLE t2\G
```
CREATE TABLE Statement

`col2` int DEFAULT NULL /*!80023 INVISIBLE */
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_0900_ai_ci

Views can refer to invisible columns by explicitly referencing them in the SELECT statement that defines the view. Changing a column’s visibility subsequent to defining a view that references the column does not change view behavior.

DML Statements and Invisible Columns

For SELECT statements, an invisible column is not part of the result set unless explicitly referenced in the select list. In a select list, the * and tbl_name.* shorthands do not include invisible columns. Natural joins do not include invisible columns.

Consider the following statement sequence:

```sql
mysql> CREATE TABLE t1 (col1 INT, col2 INT INVISIBLE);
mysql> INSERT INTO t1 (col1, col2) VALUES(1, 2), (3, 4);
mysql> SELECT * FROM t1;
+------+
| col1 |
+------+
|    1 |
|    3 |
+------+
mysql> SELECT col1, col2 FROM t1;
+-----+-----+
| col1 | col2 |
|-----+-----+
|    1 |    2 |
|    3 |    4 |
+-----+-----+
```

The first SELECT does not reference the invisible column col2 in the select list (because * does not include invisible columns), so col2 does not appear in the statement result. The second SELECT does reference col2, so it does appear in the result.

For statements that create new rows, an invisible column is assigned its implicit default value unless explicitly referenced and assigned a value. For information about implicit defaults, see Implicit Default Handling.

For INSERT (and REPLACE, for non-replaced rows), implicit default assignment occurs with a missing column list, an empty column list, or a nonempty column list that does not include the invisible column:

```sql
CREATE TABLE t1 (col1 INT, col2 INT INVISIBLE);
INSERT INTO t1 VALUES(1, 2), (3, 4);
```

For the first two INSERT statements, the VALUES() list must provide a value for each visible column and no invisible column. For the third INSERT statement, the VALUES() list must provide the same number of values as the number of named columns.

For LOAD DATA and LOAD XML, implicit default assignment occurs with a missing column list or a nonempty column list that does not include the invisible column. Input rows should not include a value for the invisible column.

To assign a value other than the implicit default for the preceding statements, explicitly name the invisible column in the column list and provide a value for it.

```sql
INSERT INTO ... SELECT * and REPLACE INTO ... SELECT * do not include invisible columns because * does not include invisible columns. Implicit default assignment occurs as described previously.
```
For statements that insert or ignore new rows, or that replace or modify existing rows, based on values in a PRIMARY KEY or UNIQUE index, MySQL treats invisible columns the same as visible columns: Invisible columns participate in key value comparisons. Specifically, if a new row has the same value as an existing row for a unique key value, these behaviors occur whether the index columns are visible or invisible:

• With the IGNORE modifier, INSERT, LOAD DATA, and LOAD XML ignore the new row.
• REPLACE replaces the existing row with the new row. With the REPLACE modifier, LOAD DATA and LOAD XML do the same.
• INSERT ... ON DUPLICATE KEY UPDATE updates the existing row.

To update invisible columns for UPDATE statements, name them and assign a value, just as for visible columns.

Invisible Column Metadata

Information about whether a column is visible or invisible is available from the EXTRA column of the INFORMATION_SCHEMA.COLUMNS table or SHOW COLUMNS output. For example:

```
mysql> SELECT TABLE_NAME, COLUMN_NAME, EXTRA
          FROM INFORMATION_SCHEMA.COLUMNS
         WHERE TABLE_SCHEMA = 'test' AND TABLE_NAME = 't1';
+------------+-------------+-----------+
| TABLE_NAME | COLUMN_NAME | EXTRA     |
+------------+-------------+-----------+
| t1         | i           |           |
| t1         | j           |           |
| t1         | k           | INVISIBLE |
+------------+-------------+-----------+
```

Columns are visible by default, so in that case, EXTRA displays no visibility information. For invisible columns, EXTRA displays INVISIBLE.

SHOW CREATE TABLE displays invisible columns in the table definition, with the INVISIBLE keyword in a version-specific comment:

```
mysql> SHOW CREATE TABLE t1\G
*************************** 1. row ***************************
Table: t1
Create Table: CREATE TABLE `t1` (
  `i` int DEFAULT NULL,
  `j` int DEFAULT NULL,
  `k` int DEFAULT NULL /*!80023 INVISIBLE */
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_0900_ai_ci
```

mysqldump and mysqlpump use SHOW CREATE TABLE, so they include invisible columns in dumped table definitions. They also include invisible column values in dumped data.

Reloading a dump file into an older version of MySQL that does not support invisible columns causes the version-specific comment to be ignored, which creates any invisible columns as visible.

The Binary Log and Invisible Columns

MySQL treats invisible columns as follows with respect to events in the binary log:

• Table-creation events include the INVISIBLE attribute for invisible columns.
• Invisible columns are treated like visible columns in row events. They are included if needed according to the binlog_row_image system variable setting.
• When row events are applied, invisible columns are treated like visible columns in row events. In particular, the algorithm and index to use are chosen according to the slave_rows_search_algorithms system variable setting.
CREATE TABLE Statement

- Invisible columns are treated like visible columns when computing writesets. In particular, writesets include indexes defined on invisible columns.

- The `mysqlbinlog` command includes visibility in column metadata.

### 13.1.20.11 Setting NDB_TABLE Options

In MySQL NDB Cluster, the table comment in a `CREATE TABLE` or `ALTER TABLE` statement can also be used to specify an `NDB_TABLE` option, which consists of one or more name-value pairs, separated by commas if need be, following the string `NDB_TABLE=`. Complete syntax for names and values syntax is shown here:

```sql
COMMENT="NDB_TABLE=ndb_table_option[,ndb_table_option][,...]"
```

```sql
ndb_table_option: {  
  NOLOGGING={1 | 0};  
  READ_BACKUP={1 | 0};  
  PARTITION_BALANCE={FOR_RP_BY_NODE | FOR_RA_BY_NODE | FOR_RP_BY_LDM |  
  FOR_RA_BY_LDM | FOR_RA_BY_LDM_X_2 | FOR_RA_BY_LDM_X_3 | FOR_RA_BY_LDM_X_4};  
  FULLY_REPLICATED={1 | 0};  
}
```

Spaces are not permitted within the quoted string. The string is case-insensitive.

The four `NDB` table options that can be set as part of a comment in this way are described in more detail in the next few paragraphs.

- **NOLOGGING**: Using 1 corresponds to having `ndb_table_no_logging` enabled, but has no actual effect. Provided as a placeholder, mostly for completeness of `ALTER TABLE` statements.

- **READ_BACKUP**: Setting this option to 1 has the same effect as though `ndb_read_backup` were enabled; enables reading from any replica. Doing so greatly improves the performance of reads from the table at a relatively small cost to write performance. Beginning with NDB 8.0.19, 1 is the default for `READ_BACKUP`, and the default for `ndb_read_backup` is ON (previously, read from any replica was disabled by default).

You can set `READ_BACKUP` for an existing table online, using an `ALTER TABLE` statement similar to one of those shown here:

```sql
ALTER TABLE ... ALGORITHM=INPLACE, COMMENT="NDB_TABLE=READ_BACKUP=1";
```

```sql
ALTER TABLE ... ALGORITHM=INPLACE, COMMENT="NDB_TABLE=READ_BACKUP=0";
```

For more information about the `ALGORITHM` option for `ALTER TABLE`, see Section 23.5.11, “Online Operations with ALTER TABLE in NDB Cluster”.

- **PARTITION_BALANCE**: Provides additional control over assignment and placement of partitions. The following four schemes are supported:

  1. **FOR_RP_BY_NODE**: One partition per node.

     Only one LDM on each node stores a primary partition. Each partition is stored in the same LDM (same ID) on all nodes.

  2. **FOR_RA_BY_NODE**: One partition per node group.

     Each node stores a single partition, which can be either a primary replica or a backup replica. Each partition is stored in the same LDM on all nodes.

  3. **FOR_RP_BY_LDM**: One partition for each LDM on each node; the default.

     This is the setting used if `READ_BACKUP` is set to 1.
4. **FOR_RA_BY_LDM**: One partition per LDM in each node group. 
   These partitions can be primary or backup partitions.

5. **FOR_RA_BY_LDM_X_2**: Two partitions per LDM in each node group. 
   These partitions can be primary or backup partitions.

6. **FOR_RA_BY_LDM_X_3**: Three partitions per LDM in each node group. 
   These partitions can be primary or backup partitions.

7. **FOR_RA_BY_LDM_X_4**: Four partitions per LDM in each node group. 
   These partitions can be primary or backup partitions.

**PARTITION_BALANCE** is the preferred interface for setting the number of partitions per table. Using **MAX_ROWS** to force the number of partitions is deprecated but continues to be supported for backward compatibility; it is subject to removal in a future release of MySQL NDB Cluster. (Bug #81759, Bug #23544301)

**FULLY_REPLICATED** controls whether the table is fully replicated, that is, whether each data node has a complete copy of the table. To enable full replication of the table, use **FULLY_REPLICATED=1**.

This setting can also be controlled using the **ndb_fully_replicated** system variable. Setting it to **ON** enables the option by default for all new **NDB** tables; the default is **OFF**. The **ndb_data_node_neighbour** system variable is also used for fully replicated tables, to ensure that when a fully replicated table is accessed, we access the data node which is local to this MySQL Server.

An example of a **CREATE TABLE** statement using such a comment when creating an **NDB** table is shown here:

```sql
mysql> CREATE TABLE t1 (  
>  c1 INT NOT NULL AUTO_INCREMENT PRIMARY KEY,  
>  c2 VARCHAR(100),  
>  c3 VARCHAR(100) )  
>  ENGINE=NDB  
>  COMMENT="NDB_TABLE=READ_BACKUP=0,PARTITION_BALANCE=FOR_RP_BY_NODE";
```

The comment is displayed as part of the output of **SHOW CREATE TABLE**. The text of the comment is also available from querying the MySQL Information Schema **TABLES** table, as in this example:

```sql
mysql> SELECT TABLE_NAME, TABLE_SCHEMA, TABLE_COMMENT  
> FROM INFORMATION_SCHEMA.TABLES WHERE TABLE_NAME="t1"\G
```

```sql
*************************** 1. row ***************************
TABLE_NAME: t1
TABLE_SCHEMA: test
TABLE_COMMENT: NDB_TABLE=READ_BACKUP=0,PARTITION_BALANCE=FOR_RP_BY_NODE
1 row in set (0.01 sec)
```

This comment syntax is also supported with **ALTER TABLE** statements for **NDB** tables, as shown here:

```sql
mysql> ALTER TABLE t1 COMMENT="NDB_TABLE=PARTITION_BALANCE=FOR_RA_BY_NODE";
Query OK, 0 rows affected (0.40 sec)
Records: 0  Duplicates: 0  Warnings: 0
```

Beginning with NDB 8.0.21, the **TABLE_COMMENT** column displays the comment that is required to recreate the table as it is following the **ALTER TABLE** statement, like this:

```sql
mysql> SELECT TABLE_NAME, TABLE_SCHEMA, TABLE_COMMENT  
> FROM INFORMATION_SCHEMA.TABLES WHERE TABLE_NAME="t1"\G
```

```sql
*************************** 1. row ***************************
TABLE_NAME: t1
```

Beginning with NDB 8.0.21, the **TABLE_COMMENT** column displays the comment that is required to recreate the table as it is following the **ALTER TABLE** statement, like this:
TABLE_SCHEMA: test
TABLE_COMMENT: NDB_TABLE=READ_BACKUP=0,PARTITION_BALANCE=FOR_RP_BY_NODE
1 row in set (0.01 sec)

mysql> SELECT TABLE_NAME, TABLE_SCHEMA, TABLE_COMMENT
    > FROM INFORMATION_SCHEMA.TABLES WHERE TABLE_NAME="t1";

<table>
<thead>
<tr>
<th>TABLE_NAME</th>
<th>TABLE_SCHEMA</th>
<th>TABLE_COMMENT</th>
</tr>
</thead>
<tbody>
<tr>
<td>t1</td>
<td>c</td>
<td>NDB_TABLE=PARTITION_BALANCE=FOR_RA_BY_NODE</td>
</tr>
<tr>
<td>t1</td>
<td>d</td>
<td></td>
</tr>
<tr>
<td>t1</td>
<td>d</td>
<td></td>
</tr>
</tbody>
</table>
2 rows in set (0.01 sec)

Keep in mind that a table comment used with ALTER TABLE replaces any existing comment which the table might have.

Prior to NDB 8.0.21, the table comment used with ALTER TABLE replaced any existing comment which the table might have had. This meant that (for example) the READ_BACKUP value was not carried over to the new comment set by the ALTER TABLE statement, and that any unspecified values reverted to their defaults. (BUG#30428829) There was thus no longer any way using SQL to retrieve the value previously set for the comment. To keep comment values from reverting to their defaults, it was necessary to preserve any such values from the existing comment string and include them in the comment passed to ALTER TABLE.

You can also see the value of the PARTITION_BALANCE option in the output of ndb_desc. ndb_desc also shows whether the READ_BACKUP and FULLY_REPLICATED options are set for the table. See the description of this program for more information.

13.1.21 CREATE TABLESPACE Statement

CREATE [UNDO] TABLESPACE tablespace_name

InnoDB and NDB:
[ADD DATAFILE 'file_name']
[AUTOEXTEND_SIZE [=] value]

InnoDB only:
[FILE_BLOCK_SIZE = value]
[ENCRYPTION [=] {'Y' | 'N'}]

NDB only:
USE LOGFILE GROUP logfile_group
[EXTENT_SIZE [=] extent_size]
[INITIAL_SIZE [=] initial_size]
[MAX_SIZE [=] max_size]
[NODEGROUP [=] nodegroup_id]
[WAIT]
[COMMENT [=] 'string']

InnoDB and NDB:
[ENGINE [=] engine_name]

Reserved for future use:
CREATE TABLESPACE Statement

This statement is used to create a tablespace. The precise syntax and semantics depend on the storage engine used. In standard MySQL releases, this is always an InnoDB tablespace. MySQL NDB Cluster also supports tablespaces using the NDB storage engine.

- Considerations for InnoDB
- Considerations for NDB Cluster
- Options
- Notes
- InnoDB Examples
- NDB Example

Considerations for InnoDB

CREATE TABLESPACE syntax is used to create general tablespaces or undo tablespaces. The UNDO keyword, introduced in MySQL 8.0.14, must be specified to create an undo tablespace.

A general tablespace is a shared tablespace. It can hold multiple tables, and supports all table row formats. General tablespaces can be created in a location relative to or independent of the data directory.

After creating an InnoDB general tablespace, use CREATE TABLE tbl_name ... TABLESPACE [=] tablespace_name or ALTER TABLE tbl_name TABLESPACE [=] tablespace_name to add tables to the tablespace. For more information, see Section 15.6.3.3, “General Tablespaces”.

Undo tablespaces contain undo logs. Undo tablespaces can be created in a chosen location by specifying a fully qualified data file path. For more information, see Section 15.6.3.4, “Undo Tablespaces”.

Considerations for NDB Cluster

This statement is used to create a tablespace, which can contain one or more data files, providing storage space for NDB Cluster Disk Data tables (see Section 23.5.10, “NDB Cluster Disk Data Tables”). One data file is created and added to the tablespace using this statement. Additional data files may be added to the tablespace by using the ALTER TABLESPACE statement (see Section 13.1.10, “ALTER TABLESPACE Statement”).

Note

All NDB Cluster Disk Data objects share the same namespace. This means that each Disk Data object must be uniquely named (and not merely each Disk Data object of a given type). For example, you cannot have a tablespace and a log file group with the same name, or a tablespace and a data file with the same name.

A log file group of one or more UNDO log files must be assigned to the tablespace to be created with the USE LOGFILE GROUP clause. logfile_group must be an existing log file group created with CREATE LOGFILE GROUP (see Section 13.1.16, “CREATE LOGFILE GROUP Statement”). Multiple tablespaces may use the same log file group for UNDO logging.

When setting EXTENT_SIZE or INITIAL_SIZE, you may optionally follow the number with a one-letter abbreviation for an order of magnitude, similar to those used in my.cnf. Generally, this is one of the letters M (for megabytes) or G (for gigabytes).
INITIAL_SIZE and EXTENT_SIZE are subject to rounding as follows:

- **EXTENT_SIZE** is rounded up to the nearest whole multiple of 32K.
- **INITIAL_SIZE** is rounded down to the nearest whole multiple of 32K; this result is rounded up to the nearest whole multiple of **EXTENT_SIZE** (after any rounding).

Note

NDB reserves 4% of a tablespace for data node restart operations. This reserved space cannot be used for data storage.

The rounding just described is done explicitly, and a warning is issued by the NDB kernel for calculating INFORMATION_SCHEMA.FILES column values and other purposes. However, to avoid an unexpected result, we suggest that you always use whole multiples of 32K in specifying these options.

When CREATE TABLESPACE is used with ENGINE [=] NDB, a tablespace and associated data file are created on each Cluster data node. You can verify that the data files were created and obtain information about them by querying the INFORMATION_SCHEMA.FILES table. (See the example later in this section.)

(See Section 26.3.15, “The INFORMATION_SCHEMA FILES Table”.)

Options

- **ADD DATAFILE**: Defines the name of a tablespace data file. This option is always required when creating an NDB tablespace; for InnoDB in MySQL 8.0.14 and later, it is required only when creating an undo tablespace. The file_name, including any specified path, must be quoted with single or double quotation marks. File names (not counting the file extension) and directory names must be at least one byte in length. Zero length file names and directory names are not supported.

Because there are considerable differences in how InnoDB and NDB treat data files, the two storage engines are covered separately in the discussion that follows.

**InnoDB data files.** An InnoDB tablespace supports only a single data file, whose name must include a .ibd extension.

To place an InnoDB general tablespace data file in a location outside of the data directory, include a fully qualified path or a path relative to the data directory. Only a fully qualified path is permitted for undo tablespaces. If you do not specify a path, a general tablespace is created in the data directory. An undo tablespace created without specifying a path is created in the directory defined by the innodb_undo_directory variable. If the innodb_undo_directory variable is undefined, undo tablespaces are created in the data directory.

To avoid conflicts with implicitly created file-per-table tablespaces, creating an InnoDB general tablespace in a subdirectory under the data directory is not supported. When creating a general tablespace or undo tablespace outside of the data directory, the directory must exist and must be known to InnoDB prior to creating the tablespace. To make a directory known to InnoDB, add it to the innodb_directories value or to one of the variables whose values are appended to the innodb_directories value. innodb_directories is a read-only variable. Configuring it requires restarting the server.

If the ADD DATAFILE clause is not specified when creating an InnoDB tablespace, a tablespace data file with a unique file name is created implicitly. The unique file name is a 128 bit UUID formatted into five groups of hexadecimal numbers separated by dashes (aaaaaaaa-bbbb-cccc-dddd-eeeeeeeeee). A file extension is added if required by the storage engine. An .ibd file extension is added for InnoDB general tablespace data files. In a replication environment, the data file name created on the replication source server is not the same as the data file name created on the replica.
As of MySQL 8.0.17, the `ADD DATAFILE` clause does not permit circular directory references when creating an InnoDB tablespace. For example, the circular directory reference (`/../../../`) in the following statement is not permitted:

```
CREATE TABLESPACE ts1 ADD DATAFILE ts1.ibd 'any_directory/../../../ts1.ibd';
```

An exception to this restriction exists on Linux, where a circular directory reference is permitted if the preceding directory is a symbolic link. For example, the data file path in the example above is permitted if `any_directory` is a symbolic link. (It is still permitted for data file paths to begin with `../../`).

**NDB data files.** An NDB tablespace supports multiple data files which can have any legal file names; more data files can be added to an NDB Cluster tablespace following its creation by using an `ALTER TABLESPACE` statement.

An NDB tablespace data file is created by default in the data node file system directory—that is, the directory named `ndb_nodeid_fs/TS` under the data node's data directory (`DataDir`), where `nodeid` is the data node's `NodeId`. To place the data file in a location other than the default, include an absolute directory path or a path relative to the default location. If the directory specified does not exist, NDB attempts to create it; the system user account under which the data node process is running must have the appropriate permissions to do so.

**Note**

When determining the path used for a data file, NDB does not expand the `~` (tilde) character.

When multiple data nodes are run on the same physical host, the following considerations apply:

- You cannot specify an absolute path when creating a data file.
- It is not possible to create tablespace data files outside the data node file system directory, unless each data node has a separate data directory.
- If each data node has its own data directory, data files can be created anywhere within this directory.
- If each data node has its own data directory, it may also be possible to create a data file outside the node’s data directory using a relative path, as long as this path resolves to a unique location on the host file system for each data node running on that host.

- **FILE_BLOCK_SIZE**: This option—which is specific to InnoDB general tablespaces, and is ignored by NDB—defines the block size for the tablespace data file. Values can be specified in bytes or kilobytes. For example, an 8 kilobyte file block size can be specified as 8192 or 8K. If you do not specify this option, `FILE_BLOCK_SIZE` defaults to the `innodb_page_size` value. `FILE_BLOCK_SIZE` is required when you intend to use the tablespace for storing compressed InnoDB tables (`ROW_FORMAT=COMPRESSED`). In this case, you must define the tablespace `FILE_BLOCK_SIZE` when creating the tablespace.

If `FILE_BLOCK_SIZE` is equal the `innodb_page_size` value, the tablespace can contain only tables having an uncompressed row format (`COMPACT`, `REDUNDANT`, and `DYNAMIC`). Tables with a `COMPRESSED` row format have a different physical page size than uncompressed tables. Therefore, compressed tables cannot coexist in the same tablespace as uncompressed tables.

For a general tablespace to contain compressed tables, `FILE_BLOCK_SIZE` must be specified, and the `FILE_BLOCK_SIZE` value must be a valid compressed page size in relation to the `innodb_page_size` value. Also, the physical page size of the compressed table (`KEY_BLOCK_SIZE`) must be equal to `FILE_BLOCK_SIZE/1024`. For example, if `innodb_page_size=16K`, and `FILE_BLOCK_SIZE=8K`, the `KEY_BLOCK_SIZE` of the table must be 8. For more information, see Section 15.6.3.3, “General Tablespaces”.
CREATE TABLESPACE Statement

- **USE LOGFILE GROUP**: Required for NDB, this is the name of a log file group previously created using `CREATE LOGFILE GROUP`. Not supported for InnoDB, where it fails with an error.

- **EXTENT_SIZE**: This option is specific to NDB, and is not supported by InnoDB, where it fails with an error. `EXTENT_SIZE` sets the size, in bytes, of the extents used by any files belonging to the tablespace. The default value is 1M. The minimum size is 32K, and theoretical maximum is 2G, although the practical maximum size depends on a number of factors. In most cases, changing the extent size does not have any measurable effect on performance, and the default value is recommended for all but the most unusual situations.

An **extent** is a unit of disk space allocation. One extent is filled with as much data as that extent can contain before another extent is used. In theory, up to 65,535 (64K) extents may used per data file; however, the recommended maximum is 32,768 (32K). The recommended maximum size for a single data file is 32G—that is, 32K extents × 1 MB per extent. In addition, once an extent is allocated to a given partition, it cannot be used to store data from a different partition; an extent cannot store data from more than one partition. This means, for example that a tablespace having a single datafile whose **INITIAL_SIZE** (described in the following item) is 256 MB and whose **EXTENT_SIZE** is 128M has just two extents, and so can be used to store data from at most two different disk data table partitions.

You can see how many extents remain free in a given data file by querying the `INFORMATION_SCHEMA.FILES` table, and so derive an estimate for how much space remains free in the file. For further discussion and examples, see Section 26.3.15, “The INFORMATION_SCHEMA FILES Table”.

- **INITIAL_SIZE**: This option is specific to NDB, and is not supported by InnoDB, where it fails with an error.

The **INITIAL_SIZE** parameter sets the total size in bytes of the data file that was specific using `ADD DATATFILE`. Once this file has been created, its size cannot be changed; however, you can add more data files to the tablespace using `ALTER TABLESPACE ... ADD DATATFILE`.

**INITIAL_SIZE** is optional; its default value is 134217728 (128 MB).

On 32-bit systems, the maximum supported value for **INITIAL_SIZE** is 4294967296 (4 GB).

- **AUTOEXTEND_SIZE**: Ignored by MySQL prior to MySQL 8.0.23; From MySQL 8.0.23, defines the amount by which InnoDB extends the size of the tablespace when it becomes full. The setting must be a multiple of 4MB. The default setting is 0, which causes the tablespace to be extended according to the implicit default behavior. For more information, see Section 15.6.3.9, “Tablespace AUTOEXTEND_SIZE Configuration”.

Has no effect in any release of MySQL NDB Cluster 8.0, regardless of the storage engine used.

- **MAX_SIZE**: Currently ignored by MySQL; reserved for possible future use. Has no effect in any release of MySQL 8.0 or MySQL NDB Cluster 8.0, regardless of the storage engine used.

- **NODEGROUP**: Currently ignored by MySQL; reserved for possible future use. Has no effect in any release of MySQL 8.0 or MySQL NDB Cluster 8.0, regardless of the storage engine used.

- **WAIT**: Currently ignored by MySQL; reserved for possible future use. Has no effect in any release of MySQL 8.0 or MySQL NDB Cluster 8.0, regardless of the storage engine used.

- **COMMENT**: Currently ignored by MySQL; reserved for possible future use. Has no effect in any release of MySQL 8.0 or MySQL NDB Cluster 8.0, regardless of the storage engine used.

- **The ENCRYPTION clause enables or disables page-level data encryption for an InnoDB general tablespace. Encryption support for general tablespaces was introduced in MySQL 8.0.13.**

As of MySQL 8.0.16, if the **ENCRYPTION clause is not specified, the default_table_encryption setting controls whether encryption is enabled. The ENCRYPTION clause overrides the
default_table_encryption setting. However, if the table_encryption_privilege_check variable is enabled, the TABLE_ENCRYPTION_ADMIN privilege is required to use an ENCRYPTION clause setting that differs from the default_table_encryption setting.

A keyring plugin must be installed and configured before an encryption-enabled tablespace can be created.

When a general tablespace is encrypted, all tables residing in the tablespace are encrypted. Likewise, a table created in an encrypted tablespace is encrypted.

For more information, see Section 15.13, “InnoDB Data-at-Rest Encryption”

- **ENGINE**: Defines the storage engine which uses the tablespace, where engine_name is the name of the storage engine. Currently, only the InnoDB storage engine is supported by standard MySQL 8.0 releases. MySQL NDB Cluster supports both NDB and InnoDB tablespaces. The value of the default_storage_engine system variable is used for ENGINE if the option is not specified.

- The **ENGINE_ATTRIBUTE** option (available as of MySQL 8.0.21) is used to specify tablespace attributes for primary storage engines. The option is reserved for future use.

Permitted values are a string literal containing a valid JSON document or an empty string (""). Invalid JSON is rejected.

```
CREATE TABLESPACE ts1 ENGINE_ATTRIBUTE='{"key":"value"}';
```

ENGINE_ATTRIBUTE values can be repeated without error. In this case, the last specified value is used.

ENGINE_ATTRIBUTE values are not checked by the server, nor are they cleared when the table's storage engine is changed.

**Notes**

- For the rules covering the naming of MySQL tablespaces, see Section 9.2, “Schema Object Names”. In addition to these rules, the slash character ("/") is not permitted, nor can you use names beginning with `innodb_`, as this prefix is reserved for system use.

- Creation of temporary general tablespaces is not supported.

- General tablespaces do not support temporary tables.

- The TABLESPACE option may be used with CREATE TABLE or ALTER TABLE to assign an InnoDB table partition or subpartition to a file-per-table tablespace. All partitions must belong to the same storage engine. Assigning table partitions to shared InnoDB tablespaces is not supported. Shared tablespaces include the InnoDB system tablespace and general tablespaces.

- General tablespaces support the addition of tables of any row format using CREATE TABLE ... TABLESPACE. innodb_file_per_table does not need to be enabled.

- innodb_strict_mode is not applicable to general tablespaces. Tablespace management rules are strictly enforced independently of innodb_strict_mode. If CREATE TABLESPACE parameters are incorrect or incompatible, the operation fails regardless of the innodb_strict_mode setting. When a table is added to a general tablespace using CREATE TABLE ... TABLESPACE or ALTER TABLE ... TABLESPACE, innodb_strict_mode is ignored but the statement is evaluated as if innodb_strict_mode is enabled.

- Use DROP TABLESPACE to remove a tablespace. All tables must be dropped from a tablespace using DROP TABLE prior to dropping the tablespace. Before dropping an NDB Cluster tablespace you must also remove all its data files using one or more ALTER TABLESPACE ... DROP DATATFILE statements. See Section 23.5.10.1, “NDB Cluster Disk Data Objects”.

2402
CREATE TABLESPACE Statement

- All parts of an InnoDB table added to an InnoDB general tablespace reside in the general tablespace, including indexes and BLOB pages.

For an NDB table assigned to a tablespace, only those columns which are not indexed are stored on disk, and actually use the tablespace data files. Indexes and indexed columns for all NDB tables are always kept in memory.

- Similar to the system tablespace, truncating or dropping tables stored in a general tablespace creates free space internally in the general tablespace .ibd data file which can only be used for new InnoDB data. Space is not released back to the operating system as it is for file-per-table tablespaces.

- A general tablespace is not associated with any database or schema.

- **ALTER TABLE ... DISCARD TABLESPACE** and **ALTER TABLE ...IMPORT TABLESPACE** are not supported for tables that belong to a general tablespace.

- The server uses tablespace-level metadata locking for DDL that references general tablespaces. By comparison, the server uses table-level metadata locking for DDL that references file-per-table tablespaces.

- A generated or existing tablespace cannot be changed to a general tablespace.

- There is no conflict between general tablespace names and file-per-table tablespace names. The “/” character, which is present in file-per-table tablespace names, is not permitted in general tablespace names.

- mysql_dump and mysqlpump do not dump InnoDB CREATE TABLESPACE statements.

### InnoDB Examples

This example demonstrates creating a general tablespace and adding three uncompressed tables of different row formats.

```sql
mysql> CREATE TABLESPACE `ts1` ADD DATAFILE 'ts1.ibd' ENGINE=INNODB;

mysql> CREATE TABLE t1 (c1 INT PRIMARY KEY) TABLESPACE ts1 ROW_FORMAT=REDUNDANT;

mysql> CREATE TABLE t2 (c1 INT PRIMARY KEY) TABLESPACE ts1 ROW_FORMAT=COMPACT;

mysql> CREATE TABLE t3 (c1 INT PRIMARY KEY) TABLESPACE ts1 ROW_FORMAT=DYNAMIC;
```

This example demonstrates creating a general tablespace and adding a compressed table. The example assumes a default innodb_page_size value of 16K. The FILE_BLOCK_SIZE of 8192 requires that the compressed table have a KEY_BLOCK_SIZE of 8.

```sql
mysql> CREATE TABLESPACE `ts2` ADD DATAFILE 'ts2.ibd' FILE_BLOCK_SIZE = 8192 Engine=InnoDB;

mysql> CREATE TABLE t4 (c1 INT PRIMARY KEY) TABLESPACE ts2 ROW_FORMAT=COMPRESSED KEY_BLOCK_SIZE=8;
```

This example demonstrates creating a general tablespace without specifying the **ADD DATAFILE** clause, which is optional as of MySQL 8.0.14.

```sql
mysql> CREATE TABLESPACE `ts3` ENGINE=INNODB;
```

This example demonstrates creating an undo tablespace.

```sql
mysql> CREATE UNDO TABLESPACE undo_003 ADD DATAFILE 'undo_003.ibu';
```

### NDB Example

Suppose that you wish to create an NDB Cluster Disk Data tablespace named myts using a datafile named mydata-1.dat. An NDB tablespace always requires the use of a log file group consisting of one or more undo log files. For this example, we first create a log file group named mylg that contains
one undo long file named `myundo-1.dat`, using the `CREATE LOGFILE GROUP` statement shown here:

```sql
mysql> CREATE LOGFILE GROUP myg1
    -> ADD UNDOFILE 'myundo-1.dat'
    -> ENGINE=NDB;
Query OK, 0 rows affected (3.29 sec)
```

Now you can create the tablespace previously described using the following statement:

```sql
mysql> CREATE TABLESPACE myts
    -> ADD DATAFILE 'mydata-1.dat'
    -> USE LOGFILE GROUP mylg
    -> ENGINE=NDB;
Query OK, 0 rows affected (2.98 sec)
```

You can now create a Disk Data table using a `CREATE TABLE` statement with the `TABLESPACE` and `STORAGE DISK` options, similar to what is shown here:

```sql
mysql> CREATE TABLE mytable (
    -> id INT UNSIGNED NOT NULL AUTO_INCREMENT PRIMARY KEY,
    -> lname VARCHAR(50) NOT NULL,
    -> fname VARCHAR(50) NOT NULL,
    -> dob DATE NOT NULL,
    -> joined DATE NOT NULL,
    -> INDEX(last_name, first_name)
    ->)
    -> TABLESPACE myts STORAGE DISK
    -> ENGINE=NDB;
Query OK, 0 rows affected (1.41 sec)
```

It is important to note that only the `dob` and `joined` columns from `mytable` are actually stored on disk, due to the fact that the `id`, `lname`, and `fname` columns are all indexed.

As mentioned previously, when `CREATE TABLESPACE` is used with `ENGINE = NDB`, a tablespace and associated data file are created on each NDB Cluster data node. You can verify that the data files were created and obtain information about them by querying the `INFORMATION_SCHEMA.FILES` table, as shown here:

```sql
mysql> SELECT FILE_NAME, FILE_TYPE, LOGFILE_GROUP_NAME, STATUS, EXTRA
    -> FROM INFORMATION_SCHEMA.FILES
    -> WHERE TABLESPACE_NAME = 'myts';
```

<table>
<thead>
<tr>
<th>file_name</th>
<th>file_type</th>
<th>logfile_group_name</th>
<th>status</th>
<th>extra</th>
</tr>
</thead>
<tbody>
<tr>
<td>mydata-1.dat</td>
<td>DATAFILE</td>
<td>mylg</td>
<td>NORMAL</td>
<td>CLUSTER_NODE=5</td>
</tr>
<tr>
<td>mydata-1.dat</td>
<td>DATAFILE</td>
<td>mylg</td>
<td>NORMAL</td>
<td>CLUSTER_NODE=6</td>
</tr>
<tr>
<td>NULL</td>
<td>TABLESPACE</td>
<td>mylg</td>
<td>NORMAL</td>
<td>NULL</td>
</tr>
</tbody>
</table>

3 rows in set (0.01 sec)

For additional information and examples, see Section 23.5.10.1, “NDB Cluster Disk Data Objects”.

### 13.1.22 CREATE TRIGGER Statement

```
CREATE
    [DEFINER = user]
    TRIGGER trigger_name
    trigger_time trigger_event
    ON tbl_name FOR EACH ROW
    [trigger_order]
    trigger_body

trigger_time: { BEFORE | AFTER }

trigger_event: { INSERT | UPDATE | DELETE }

trigger_order: { FOLLOW | PRECEDES } other_trigger_name
```
This statement creates a new trigger. A trigger is a named database object that is associated with a table, and that activates when a particular event occurs for the table. The trigger becomes associated with the table named `tbl_name`, which must refer to a permanent table. You cannot associate a trigger with a `TEMPORARY` table or a view.

Trigger names exist in the schema namespace, meaning that all triggers must have unique names within a schema. Triggers in different schemas can have the same name.

This section describes `CREATE TRIGGER` syntax. For additional discussion, see Section 25.3.1, “Trigger Syntax and Examples”.

`CREATE TRIGGER` requires the `TRIGGER` privilege for the table associated with the trigger. If the `DEFINER` clause is present, the privileges required depend on the `user` value, as discussed in Section 25.6, “Stored Object Access Control”. If binary logging is enabled, `CREATE TRIGGER` might require the `SUPER` privilege, as discussed in Section 25.7, “Stored Program Binary Logging”.

The `DEFINER` clause determines the security context to be used when checking access privileges at trigger activation time, as described later in this section.

`trigger_time` is the trigger action time. It can be `BEFORE` or `AFTER` to indicate that the trigger activates before or after each row to be modified.

Basic column value checks occur prior to trigger activation, so you cannot use `BEFORE` triggers to convert values inappropriate for the column type to valid values.

`trigger_event` indicates the kind of operation that activates the trigger. These `trigger_event` values are permitted:

- **INSERT**: The trigger activates whenever a new row is inserted into the table (for example, through `INSERT`, `LOAD DATA`, and `REPLACE` statements).
- **UPDATE**: The trigger activates whenever a row is modified (for example, through `UPDATE` statements).
- **DELETE**: The trigger activates whenever a row is deleted from the table (for example, through `DELETE` and `REPLACE` statements). `DROP TABLE` and `TRUNCATE TABLE` statements on the table do not activate this trigger, because they do not use `DELETE`. Dropping a partition does not activate `DELETE` triggers, either.

The `trigger_event` does not represent a literal type of SQL statement that activates the trigger so much as it represents a type of table operation. For example, an `INSERT` trigger activates not only for `INSERT` statements but also `LOAD DATA` statements because both statements insert rows into a table.

A potentially confusing example of this is the `INSERT INTO ... ON DUPLICATE KEY UPDATE ...` syntax: a `BEFORE INSERT` trigger activates for every row, followed by either an `AFTER INSERT` trigger or both the `BEFORE UPDATE` and `AFTER UPDATE` triggers, depending on whether there was a duplicate key for the row.

![Note](Image)

Cascaded foreign key actions do not activate triggers.

It is possible to define multiple triggers for a given table that have the same trigger event and action time. For example, you can have two `BEFORE UPDATE` triggers for a table. By default, triggers that have the same trigger event and action time activate in the order they were created. To affect trigger order, specify a `trigger_order` clause that indicates `FOLLOWS` or `PRECEDES` and the name of an existing trigger that also has the same trigger event and action time. With `FOLLOWS`, the new trigger activates after the existing trigger. With `PRECEDES`, the new trigger activates before the existing trigger.

`trigger_body` is the statement to execute when the trigger activates. To execute multiple statements, use the `BEGIN ... END` compound statement construct. This also enables you to use
CREATE VIEW Statement

the same statements that are permitted within stored routines. See Section 13.6.1, “BEGIN ... END Compound Statement”. Some statements are not permitted in triggers; see Section 25.8, “Restrictions on Stored Programs”.

Within the trigger body, you can refer to columns in the subject table (the table associated with the trigger) by using the aliases OLD and NEW. OLD.col_name refers to a column of an existing row before it is updated or deleted. NEW.col_name refers to the column of a new row to be inserted or an existing row after it is updated.

Triggers cannot use NEW.col_name or use OLD.col_name to refer to generated columns. For information about generated columns, see Section 13.1.20.8, “CREATE TABLE and Generated Columns”.

MySQL stores the sql_mode system variable setting in effect when a trigger is created, and always executes the trigger body with this setting in force, regardless of the current server SQL mode when the trigger begins executing.

The DEFINER clause specifies the MySQL account to be used when checking access privileges at trigger activation time. If the DEFINER clause is present, the user value should be a MySQL account specified as 'user_name'@'host_name', CURRENT_USER, or CURRENT_USER(). The permitted user values depend on the privileges you hold, as discussed in Section 25.6, “Stored Object Access Control”. Also see that section for additional information about trigger security.

If the DEFINER clause is omitted, the default definer is the user who executes the CREATE TRIGGER statement. This is the same as specifying DEFINER = CURRENT_USER explicitly.

MySQL takes the DEFINER user into account when checking trigger privileges as follows:

• At CREATE TRIGGER time, the user who issues the statement must have the TRIGGER privilege.

• At trigger activation time, privileges are checked against the DEFINER user. This user must have these privileges:

  • The TRIGGER privilege for the subject table.

  • The SELECT privilege for the subject table if references to table columns occur using OLD.col_name or NEW.col_name in the trigger body.

  • The UPDATE privilege for the subject table if table columns are targets of SET NEW.col_name = value assignments in the trigger body.

  • Whatever other privileges normally are required for the statements executed by the trigger.

Within a trigger body, the CURRENT_USER function returns the account used to check privileges at trigger activation time. This is the DEFINER user, not the user whose actions caused the trigger to be activated. For information about user auditing within triggers, see Section 6.2.22, “SQL-Based Account Activity Auditing”.

If you use LOCK TABLES to lock a table that has triggers, the tables used within the trigger are also locked, as described in LOCK TABLES and Triggers.

For additional discussion of trigger use, see Section 25.3.1, “Trigger Syntax and Examples”.

13.1.23 CREATE VIEW Statement

```sql
CREATE VIEW view_name [(column_list)] AS select_statement
```

2406
The `CREATE VIEW` statement creates a new view, or replaces an existing view if the `OR REPLACE` clause is given. If the view does not exist, `CREATE OR REPLACE VIEW` is the same as `CREATE VIEW`. If the view does exist, `CREATE OR REPLACE VIEW` replaces it.

For information about restrictions on view use, see Section 25.9, “Restrictions on Views”.

The `select_statement` is a `SELECT` statement that provides the definition of the view. (Selecting from the view selects, in effect, using the `SELECT` statement.) The `select_statement` can select from base tables, other views. Beginning with MySQL 8.0.19, the `SELECT` statement can use a `VALUES` statement as its source, or can be replaced with a `TABLE` statement, as with `CREATE TABLE ... SELECT`.

The view definition is “frozen” at creation time and is not affected by subsequent changes to the definitions of the underlying tables. For example, if a view is defined as `SELECT *` on a table, new columns added to the table later do not become part of the view, and columns dropped from the table result in an error when selecting from the view.

The `ALGORITHM` clause affects how MySQL processes the view. The `DEFINER` and `SQL_SECURITY` clauses specify the security context to be used when checking access privileges at view invocation time. The `WITH CHECK OPTION` clause can be given to constrain inserts or updates to rows in tables referenced by the view. These clauses are described later in this section.

When a view is referenced, privilege checking occurs as described later in this section.

A view belongs to a database. By default, a new view is created in the default database. To create the view explicitly in a given database, use `db_name.view_name` syntax to qualify the view name with the database name:

```sql
CREATE VIEW test.v AS SELECT * FROM t;
```

Unqualified table or view names in the `SELECT` statement are also interpreted with respect to the default database. A view can refer to tables or views in other databases by qualifying the table or view name with the appropriate database name.

Within a database, base tables and views share the same namespace, so a base table and a view cannot have the same name.

Columns retrieved by the `SELECT` statement can be simple references to table columns, or expressions that use functions, constant values, operators, and so forth.

A view must have unique column names with no duplicates, just like a base table. By default, the names of the columns retrieved by the `SELECT` statement are used for the view column names. To define explicit names for the view columns, specify the optional `column_list` clause as a list of comma-separated identifiers. The number of names in `column_list` must be the same as the number of columns retrieved by the `SELECT` statement.

A view can be created from many kinds of `SELECT` statements. It can refer to base tables or other views. It can use joins, `UNION`, and subqueries. The `SELECT` need not even refer to any tables:

```sql
CREATE VIEW v_today (today) AS SELECT CURRENT_DATE;
```

The following example defines a view that selects two columns from another table as well as an expression calculated from those columns:

```sql
CREATE VIEW v_today (today) AS SELECT CURRENT_DATE;
```
A view definition is subject to the following restrictions:

- The **SELECT** statement cannot refer to system variables or user-defined variables.
- Within a stored program, the **SELECT** statement cannot refer to program parameters or local variables.
- The **SELECT** statement cannot refer to prepared statement parameters.
- Any table or view referred to in the definition must exist. If, after the view has been created, a table or view that the definition refers to is dropped, use of the view results in an error. To check a view definition for problems of this kind, use the **CHECK TABLE** statement.
- The definition cannot refer to a **TEMPORARY** table, and you cannot create a **TEMPORARY** view.
- You cannot associate a trigger with a view.
- Aliases for column names in the **SELECT** statement are checked against the maximum column length of 64 characters (not the maximum alias length of 256 characters).

**ORDER BY** is permitted in a view definition, but it is ignored if you select from a view using a statement that has its own **ORDER BY**.

For other options or clauses in the definition, they are added to the options or clauses of the statement that references the view, but the effect is undefined. For example, if a view definition includes a **LIMIT** clause, and you select from the view using a statement that has its own **LIMIT** clause, it is undefined which limit applies. This same principle applies to options such as **ALL**, **DISTINCT**, or **SQL_SMALL_RESULT** that follow the **SELECT** keyword, and to clauses such as **INTO**, **FOR UPDATE**, **FOR SHARE**, **LOCK IN SHARE MODE**, and **PROCEDURE**.

The results obtained from a view may be affected if you change the query processing environment by changing system variables:

```sql
mysql> CREATE VIEW v (mycol) AS SELECT 'abc';
Query OK, 0 rows affected (0.01 sec)

mysql> SET sql_mode = '';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT "mycol" FROM v;
+-------+
| mycol |
+-------+
1 row in set (0.01 sec)

mysql> SET sql_mode = 'ANSI_QUOTES';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT "mycol" FROM v;
+-------+
|   abc  |
+-------+
1 row in set (0.00 sec)
```
The `DEFINER` and `SQL SECURITY` clauses determine which MySQL account to use when checking access privileges for the view when a statement is executed that references the view. The valid `SQL SECURITY` characteristic values are `DEFINER` (the default) and `INVOKER`. These indicate that the required privileges must be held by the user who defined or invoked the view, respectively.

If the `DEFINER` clause is present, the `user` value should be a MySQL account specified as `${user_name}@${host_name}`, `CURRENT_USER`, or `CURRENT_USER()`. The permitted `user` values depend on the privileges you hold, as discussed in Section 25.6, “Stored Object Access Control”. Also see that section for additional information about view security.

If the `DEFINER` clause is omitted, the default definer is the user who executes the `CREATE VIEW` statement. This is the same as specifying `DEFINER = CURRENT_USER` explicitly.

Within a view definition, the `CURRENT_USER` function returns the view’s `DEFINER` value by default. For views defined with the `SQL SECURITY INVOKER` characteristic, `CURRENT_USER` returns the account for the view’s invoker. For information about user auditing within views, see Section 6.2.22, “SQL-Based Account Activity Auditing”.

Within a stored routine that is defined with the `SQL SECURITY DEFINER` characteristic, `CURRENT_USER` returns the routine’s `DEFINER` value. This also affects a view defined within such a routine, if the view definition contains a `DEFINER` value of `CURRENT_USER`.

MySQL checks view privileges like this:

- At view definition time, the view creator must have the privileges needed to use the top-level objects accessed by the view. For example, if the view definition refers to table columns, the creator must have some privilege for each column in the select list of the definition, and the `SELECT` privilege for each column used elsewhere in the definition. If the definition refers to a stored function, only the privileges needed to invoke the function can be checked. The privileges required at function invocation time can be checked only as it executes: For different invocations, different execution paths within the function might be taken.

- The user who references a view must have appropriate privileges to access it (`SELECT` to select from it, `INSERT` to insert into it, and so forth.)

- When a view has been referenced, privileges for objects accessed by the view are checked against the privileges held by the view `DEFINER` account or invoker, depending on whether the `SQL SECURITY` characteristic is `DEFINER` or `INVOKER`, respectively.

- If reference to a view causes execution of a stored function, privilege checking for statements executed within the function depend on whether the function `SQL SECURITY` characteristic is `DEFINER` or `INVOKER`. If the security characteristic is `DEFINER`, the function runs with the privileges determined by the view’s `SQL SECURITY` characteristic.

Example: A view might depend on a stored function, and that function might invoke other stored routines. For example, the following view invokes a stored function `f()`:

```sql
CREATE VIEW v AS SELECT * FROM t WHERE t.id = f(t.name);
```

Suppose that `f()` contains a statement such as this:

```sql
IF name IS NULL then
  CALL p1();
ELSE
  CALL p2();
END IF;
```

The privileges required for executing statements within `f()` need to be checked when `f()` executes. This might mean that privileges are needed for `p1()` or `p2()`, depending on the execution path within `f()`. Those privileges must be checked at runtime, and the user who must possess the privileges is determined by the `SQL SECURITY` values of the view `v` and the function `f()`. 

---

2409
The `DEFINER` and `SQL SECURITY` clauses for views are extensions to standard SQL. In standard SQL, views are handled using the rules for `SQL SECURITY DEFINER`. The standard says that the definer of the view, which is the same as the owner of the view's schema, gets applicable privileges on the view (for example, `SELECT`) and may grant them. MySQL has no concept of a schema “owner”, so MySQL adds a clause to identify the definer. The `DEFINER` clause is an extension where the intent is to have what the standard has; that is, a permanent record of who defined the view. This is why the default `DEFINER` value is the account of the view creator.

The optional `ALGORITHM` clause is a MySQL extension to standard SQL. It affects how MySQL processes the view. `ALGORITHM` takes three values: `MERGE`, `TEMPTABLE`, or `UNDEFINED`. For more information, see Section 25.5.2, “View Processing Algorithms”, as well as Section 8.2.2.4, “Optimizing Derived Tables, View References, and Common Table Expressions with Merging or Materialization”.

Some views are updatable. That is, you can use them in statements such as `UPDATE`, `DELETE`, or `INSERT` to update the contents of the underlying table. For a view to be updatable, there must be a one-to-one relationship between the rows in the view and the rows in the underlying table. There are also certain other constructs that make a view nonupdatable.

A generated column in a view is considered updatable because it is possible to assign to it. However, if such a column is updated explicitly, the only permitted value is `DEFAULT`. For information about generated columns, see Section 13.1.20.8, “CREATE TABLE and Generated Columns”.

The `WITH CHECK OPTION` clause can be given for an updatable view to prevent inserts or updates to rows except those for which the `WHERE` clause in the `select_statement` is true.

In a `WITH CHECK OPTION` clause for an updatable view, the `LOCAL` and `CASCADED` keywords determine the scope of check testing when the view is defined in terms of another view. The `LOCAL` keyword restricts the `CHECK OPTION` only to the view being defined. `CASCADED` causes the checks for underlying views to be evaluated as well. When neither keyword is given, the default is `CASCADED`.

For more information about updatable views and the `WITH CHECK OPTION` clause, see Section 25.5.3, “Updatable and Insertable Views”, and Section 25.5.4, “The View WITH CHECK OPTION Clause”.

### 13.1.24 DROP DATABASE Statement

DROP `{DATABASE | SCHEMA} [IF EXISTS] db_name`

DROP DATABASE drops all tables in the database and deletes the database. Be very careful with this statement! To use DROP DATABASE, you need the DROP privilege on the database. DROP SCHEMA is a synonym for DROP DATABASE.

**Important**

When a database is dropped, privileges granted specifically for the database are not automatically dropped. They must be dropped manually. See Section 13.7.1.6, “GRANT Statement”.

`IF EXISTS` is used to prevent an error from occurring if the database does not exist.

If the default database is dropped, the default database is unset (the `DATABASE()` function returns `NULL`).

If you use DROP DATABASE on a symbolically linked database, both the link and the original database are deleted.

DROP DATABASE returns the number of tables that were removed.

The `DROP DATABASE` statement removes from the given database directory those files and directories that MySQL itself may create during normal operation. This includes all files with the extensions shown in the following list:
If other files or directories remain in the database directory after MySQL removes those just listed, the database directory cannot be removed. In this case, you must remove any remaining files or directories manually and issue the `DROP DATABASE` statement again.

Dropping a database does not remove any `TEMPORARY` tables that were created in that database. `TEMPORARY` tables are automatically removed when the session that created them ends. See Section 13.1.20.2, “CREATE TEMPORARY TABLE Statement”.

You can also drop databases with `mysqladmin`. See Section 4.5.2, “mysqladmin — A MySQL Server Administration Program”.

### 13.1.25 DROP EVENT Statement

```sql
DROP EVENT [IF EXISTS] event_name
```

This statement drops the event named `event_name`. The event immediately ceases being active, and is deleted completely from the server.

If the event does not exist, the error `ERROR 1517 (HY000): Unknown event 'event_name'` results. You can override this and cause the statement to generate a warning for nonexistent events instead using `IF EXISTS`.

This statement requires the `EVENT` privilege for the schema to which the event to be dropped belongs.

### 13.1.26 DROP FUNCTION Statement

The `DROP FUNCTION` statement is used to drop stored functions and user-defined functions (UDFs):

- For information about dropping stored functions, see Section 13.1.29, “DROP PROCEDURE and DROP FUNCTION Statements”.

- For information about dropping user-defined functions, see Section 13.7.4.2, “DROP FUNCTION Statement for User-Defined Functions”.

### 13.1.27 DROP INDEX Statement

```sql
DROP INDEX index_name ON tbl_name
   [algorithm_option | lock_option] ...
```

- **algorithm_option**: 
  - `ALGORITHM` (=) {DEFAULT | INPLACE | COPY}

- **lock_option**: 
  - `LOCK` (=) {DEFAULT | NONE | SHARED | EXCLUSIVE}

2411
DROP INDEX drops the index named \textit{index\_name} from the table \textit{tbl\_name}. This statement is mapped to an \textit{ALTER TABLE} statement to drop the index. See Section 13.1.9, "ALTER TABLE Statement".

To drop a primary key, the index name is always \textbf{PRIMARY}, which must be specified as a quoted identifier because \textbf{PRIMARY} is a reserved word:

\begin{verbatim}
DROP INDEX 'PRIMARY' ON t;
\end{verbatim}

Indexes on variable-width columns of NDB tables are dropped online; that is, without any table copying. The table is not locked against access from other NDB Cluster API nodes, although it is locked against other operations on the same API node for the duration of the operation. This is done automatically by the server whenever it determines that it is possible to do so; you do not have to use any special SQL syntax or server options to cause it to happen.

\textbf{ALGORITHM} and \textbf{LOCK} clauses may be given to influence the table copying method and level of concurrency for reading and writing the table while its indexes are being modified. They have the same meaning as for the \textit{ALTER TABLE} statement. For more information, see Section 13.1.9, "ALTER TABLE Statement".

MySQL NDB Cluster supports online operations using the same \texttt{ALGORITHM=INPLACE} syntax supported in the standard MySQL Server. See Section 23.5.11, "Online Operations with ALTER TABLE in NDB Cluster", for more information.

13.1.28 DROP LOGFILE GROUP Statement

\begin{verbatim}
DROP LOGFILE GROUP logfile\_group [ENGINE [=] engine\_name]
\end{verbatim}

This statement drops the log file group named \textit{logfile\_group}. The log file group must already exist or an error results. (For information on creating log file groups, see Section 13.1.16, "CREATE LOGFILE GROUP Statement".)

\textbf{Important}

Before dropping a log file group, you must drop all tablespaces that use that log file group for UNDO logging.

The required \texttt{ENGINE} clause provides the name of the storage engine used by the log file group to be dropped. Currently, the only permitted values for \texttt{engine\_name} are \textit{NDB} and \textit{NDBCLUSTER}.

\texttt{DROP LOGFILE GROUP} is useful only with Disk Data storage for NDB Cluster. See Section 23.5.10, "NDB Cluster Disk Data Tables".

13.1.29 DROP PROCEDURE and DROP FUNCTION Statements

\begin{verbatim}
DROP \{PROCEDURE \mid FUNCTION\} \[IF EXISTS\] sp\_name
\end{verbatim}

These statements are used to drop a stored routine (a stored procedure or function). That is, the specified routine is removed from the server. (\texttt{DROP FUNCTION} is also used to drop user-defined functions; see Section 13.7.4.2, "DROP FUNCTION Statement for User-Defined Functions".)

To drop a stored routine, you must have the \textit{ALTER ROUTINE} privilege for it. (If the \texttt{automatic_sp_privileges} system variable is enabled, that privilege and \texttt{EXECUTE} are granted automatically to the routine creator when the routine is created and dropped from the creator when the routine is dropped. See Section 25.2.2, "Stored Routines and MySQL Privileges".)

The \texttt{IF EXISTS} clause is a MySQL extension. It prevents an error from occurring if the procedure or function does not exist. A warning is produced that can be viewed with \texttt{SHOW WARNINGS}.

\texttt{DROP FUNCTION} is also used to drop user-defined functions (see Section 13.7.4.2, "DROP FUNCTION Statement for User-Defined Functions").
13.1.30 DROP SERVER Statement

```
DROP SERVER [ IF EXISTS ] server_name
```

Drops the server definition for the server named `server_name`. The corresponding row in the `mysql.servers` table is deleted. This statement requires the `SUPER` privilege.

Dropping a server for a table does not affect any `FEDERATED` tables that used this connection information when they were created. See Section 13.1.18, "CREATE SERVER Statement".

DROP SERVER causes an implicit commit. See Section 13.3.3, "Statements That Cause an Implicit Commit".

DROP SERVER is not written to the binary log, regardless of the logging format that is in use.

13.1.31 DROP SPATIAL REFERENCE SYSTEM Statement

```
DROP SPATIAL REFERENCE SYSTEM [IF EXISTS] srid
```

`srid`: 32-bit unsigned integer

This statement removes a spatial reference system (SRS) definition from the data dictionary. It requires the `SUPER` privilege.

Example:

```
DROP SPATIAL REFERENCE SYSTEM 4120;
```

If no SRS definition with the SRID value exists, an error occurs unless `IF EXISTS` is specified. In that case, a warning occurs rather than an error.

If the SRID value is used by some column in an existing table, an error occurs. For example:

```
mysql> DROP SPATIAL REFERENCE SYSTEM 4326;
ERROR 3716 (SR005): Can't modify SRID 4326. There is at least one column depending on it.
```

To identify which column or columns use the SRID, use this query:

```
SELECT * FROM INFORMATION_SCHEMA.ST_GEOMETRY_COLUMNS WHERE SRS_ID=4326;
```

SRID values must be in the range of 32-bit unsigned integers, with these restrictions:

- SRID 0 is a valid SRID but cannot be used with `DROP SPATIAL REFERENCE SYSTEM`.
- If the value is in a reserved SRID range, a warning occurs. Reserved ranges are [0, 32767] (reserved by EPSG), [60,000,000, 69,999,999] (reserved by EPSG), and [2,000,000,000, 2,147,483,647] (reserved by MySQL). EPSG stands for the European Petroleum Survey Group.
- Users should not drop SRSs with SRIDs in the reserved ranges. If system-installed SRSs are dropped, the SRS definitions may be recreated for MySQL upgrades.

13.1.32 DROP TABLE Statement

```
DROP [TEMPORARY] TABLE [IF EXISTS] tbl_name [, tbl_name] ...
[RESTRICT | CASCADE]
```

DROP TABLE removes one or more tables. You must have the `DROP` privilege for each table.

*Be careful* with this statement! For each table, it removes the table definition and all table data. If the table is partitioned, the statement removes the table definition, all its partitions, all data stored in those partitions, and all partition definitions associated with the dropped table.
Dropping a table also drops any triggers for the table.

DROP TABLE causes an implicit commit, except when used with the TEMPORARY keyword. See Section 13.3.3, “Statements That Cause an Implicit Commit”.

**Important**

When a table is dropped, privileges granted specifically for the table are not automatically dropped. They must be dropped manually. See Section 13.7.1.6, “GRANT Statement”.

If any tables named in the argument list do not exist, DROP TABLE behavior depends on whether the IF EXISTS clause is given:

- Without IF EXISTS, the statement fails with an error indicating which nonexisting tables it was unable to drop, and no changes are made.
- With IF EXISTS, no error occurs for nonexisting tables. The statement drops all named tables that do exist, and generates a NOTE diagnostic for each nonexistent table. These notes can be displayed with SHOW WARNINGS. See Section 13.7.7.42, “SHOW WARNINGS Statement”.

IF EXISTS can also be useful for dropping tables in unusual circumstances under which there is an entry in the data dictionary but no table managed by the storage engine. (For example, if an abnormal server exit occurs after removal of the table from the storage engine but before removal of the data dictionary entry.)

The TEMPORARY keyword has the following effects:

- The statement drops only TEMPORARY tables.
- The statement does not cause an implicit commit.
- No access rights are checked. A TEMPORARY table is visible only with the session that created it, so no check is necessary.

Including the TEMPORARY keyword is a good way to prevent accidentally dropping non-TEMPORARY tables.

The RESTRICT and CASCADE keywords do nothing. They are permitted to make porting easier from other database systems.

DROP TABLE is not supported with all innodb_force_recovery settings. See Section 15.21.2, “Forcing InnoDB Recovery”.

### 13.1.33 DROP TABLESPACE Statement

```
DROP [UNDO] TABLESPACE tablespace_name
    [ENGINE [=] engine_name]
```

This statement drops a tablespace that was previously created using CREATE TABLESPACE. It is supported by the NDB and InnoDB storage engines.

The UNDO keyword, introduced in MySQL 8.0.14, must be specified to drop an undo tablespace. Only undo tablespaces created using CREATE UNDO TABLESPACE syntax can be dropped. An undo tablespace must be in an empty state before it can be dropped. For more information, see Section 15.6.3.4, “Undo Tablespaces”.

ENGINE sets the storage engine that uses the tablespace, where engine_name is the name of the storage engine. Currently, the values InnoDB and NDB are supported. If not set, the value of default_storage_engine is used. If it is not the same as the storage engine used to create the tablespace, the DROP TABLESPACE statement fails.
**tablespace_name** is a case-sensitive identifier in MySQL.

For an InnoDB general tablespace, all tables must be dropped from the tablespace prior to a DROP TABLESPACE operation. If the tablespace is not empty, DROP TABLESPACE returns an error.

An NDB tablespace to be dropped must not contain any data files; in other words, before you can drop an NDB tablespace, you must first drop each of its data files using ALTER TABLESPACE ... DROP DATAFILE.

**Notes**

- A general InnoDB tablespace is not deleted automatically when the last table in the tablespace is dropped. The tablespace must be dropped explicitly using DROP TABLESPACE tablespace_name.

- A DROP DATABASE operation can drop tables that belong to a general tablespace but it cannot drop the tablespace, even if the operation drops all tables that belong to the tablespace. The tablespace must be dropped explicitly using DROP TABLESPACE tablespace_name.

- Similar to the system tablespace, truncating or dropping tables stored in a general tablespace creates free space internally in the general tablespace .ibd data file which can only be used for new InnoDB data. Space is not released back to the operating system as it is for file-per-table tablespaces.

**InnoDB Examples**

This example demonstrates how to drop an InnoDB general tablespace. The general tablespace ts1 is created with a single table. Before dropping the tablespace, the table must be dropped.

```
mysql> CREATE TABLESPACE `ts1` ADD DATAFILE 'ts1.ibd' Engine=InnoDB;
mysql> CREATE TABLE t1 (c1 INT PRIMARY KEY) TABLESPACE ts1 Engine=InnoDB;
mysql> DROP TABLE t1;
mysql> DROP TABLESPACE ts1;
```

This example demonstrates dropping an undo tablespace. An undo tablespace must be in an empty state before it can be dropped. For more information, see Section 15.6.3.4, “Undo Tablespaces”.

```
mysql> DROP UNDO TABLESPACE undo_003;
```

**NDB Example**

This example shows how to drop an NDB tablespace myts having a data file named mydata-1.dat after first creating the tablespace, and assumes the existence of a log file group named mylg (see Section 13.1.16, “CREATE LOGFILE GROUP Statement”).

```
mysql> CREATE TABLESPACE myts
    -> ADD DATAFILE 'mydata-1.dat'
    -> USE LOGFILE GROUP mylg
    -> ENGINE=NDB;
```

You must remove all data files from the tablespace using ALTER TABLESPACE, as shown here, before it can be dropped:

```
mysql> ALTER TABLESPACE myts
    -> DROP DATAFILE 'mydata-1.dat'
    -> ENGINE=NDB;
```

```
mysql> DROP TABLESPACE myts;
```

**13.1.34 DROP TRIGGER Statement**

DROP TRIGGER [IF EXISTS] [schema_name.]trigger_name
This statement drops a trigger. The schema (database) name is optional. If the schema is omitted, the trigger is dropped from the default schema. **DROP TRIGGER** requires the **TRIGGER** privilege for the table associated with the trigger.

Use **IF EXISTS** to prevent an error from occurring for a trigger that does not exist. A **NOTE** is generated for a nonexistent trigger when using **IF EXISTS**. See Section 13.7.7.42, “SHOW WARNINGS Statement”.

Triggers for a table are also dropped if you drop the table.

### 13.1.35 DROP VIEW Statement

```
DROP VIEW [IF EXISTS] view_name [, view_name] ...
[RESTRICT | CASCADE]
```

**DROP VIEW** removes one or more views. You must have the **DROP** privilege for each view.

If any views named in the argument list do not exist, the statement fails with an error indicating by name which nonexisting views it was unable to drop, and no changes are made.

**Note**

In MySQL 5.7 and earlier, **DROP VIEW** returns an error if any views named in the argument list do not exist, but also drops all views in the list that do exist. Due to the change in behavior in MySQL 8.0, a partially completed **DROP VIEW** operation on a MySQL 5.7 replication source server fails when replicated on a MySQL 8.0 replica. To avoid this failure scenario, use **IF EXISTS** syntax in **DROP VIEW** statements to prevent an error from occurring for views that do not exist. For more information, see Section 13.1.1, “Atomic Data Definition Statement Support”.

The **IF EXISTS** clause prevents an error from occurring for views that don't exist. When this clause is given, a **NOTE** is generated for each nonexistent view. See Section 13.7.7.42, “SHOW WARNINGS Statement”.

**RESTRICT** and **CASCADE**, if given, are parsed and ignored.

### 13.1.36 RENAME TABLE Statement

```
RENAME TABLE tbl_name TO new_tbl_name [, tbl_name2 TO new_tbl_name2] ...
```

**RENAME TABLE** renames one or more tables. You must have **ALTER** and **DROP** privileges for the original table, and **CREATE** and **INSERT** privileges for the new table.

For example, to rename a table named **old_table** to **new_table**, use this statement:

```
RENAME TABLE old_table TO new_table;
```

That statement is equivalent to the following **ALTER TABLE** statement:

```
ALTER TABLE old_table RENAME new_table;
```

**RENAME TABLE**, unlike **ALTER TABLE**, can rename multiple tables within a single statement:

```
RENAME TABLE old_table1 TO new_table1,
    old_table2 TO new_table2,
    old_table3 TO new_table3;
```

Renaming operations are performed left to right. Thus, to swap two table names, do this (assuming that a table with the intermediary name **tmp_table** does not already exist):

```
RENAME TABLE old_table1 TO new_table1,
    tmp_table TO old_table2;
RENAME TABLE old_table1 TO new_table1;
```
RENAME TABLE Statement

RENAME TABLE old_table TO tmp_table,
    new_table TO old_table,
    tmp_table TO new_table;

Metadata locks on tables are acquired in name order, which in some cases can make a difference in operation outcome when multiple transactions execute concurrently. See Section 8.11.4, “Metadata Locking”.

As of MySQL 8.0.13, you can rename tables locked with a LOCK TABLES statement, provided that they are locked with a WRITE lock or are the product of renaming WRITE-locked tables from earlier steps in a multiple-table rename operation. For example, this is permitted:

LOCK TABLE old_table1 WRITE;
RENAME TABLE old_table1 TO new_table1,
    new_table1 TO new_table2;

This is not permitted:

LOCK TABLE old_table1 READ;
RENAME TABLE old_table1 TO new_table1,
    new_table1 TO new_table2;

Prior to MySQL 8.0.13, to execute RENAME TABLE, there must be no tables locked with LOCK TABLES.

With the transaction table locking conditions satisfied, the rename operation is done atomically; no other session can access any of the tables while the rename is in progress.

If any errors occur during a RENAME TABLE, the statement fails and no changes are made.

You can use RENAME TABLE to move a table from one database to another:

RENAME TABLE current_db.tbl_name TO other_db.tbl_name;

Using this method to move all tables from one database to a different one in effect renames the database (an operation for which MySQL has no single statement), except that the original database continues to exist, albeit with no tables.

Like RENAME TABLE, ALTER TABLE ... RENAME can also be used to move a table to a different database. Regardless of the statement used, if the rename operation would move the table to a database located on a different file system, the success of the outcome is platform specific and depends on the underlying operating system calls used to move table files.

If a table has triggers, attempts to rename the table into a different database fail with a Trigger in wrong schema (ER_TRG_IN_WRONG_SCHEMA) error.

An unencrypted table can be moved to an encryption-enabled database and vice versa. However, if the table_encryption_privilege_check variable is enabled, the TABLE_ENCRYPTION_ADMIN privilege is required if the table encryption setting differs from the default database encryption.

To rename TEMPORARY tables, RENAME TABLE does not work. Use ALTER TABLE instead.

RENAME TABLE works for views, except that views cannot be renamed into a different database.

Any privileges granted specifically for a renamed table or view are not migrated to the new name. They must be changed manually.

RENAME TABLE tbl_name TO new_tbl_name changes internally generated foreign key constraint names and user-defined foreign key constraint names that begin with the string "tbl_name_ibfk_" to reflect the new table name. InnoDB interprets foreign key constraint names that begin with the string "tbl_name_ibfk_" as internally generated names.

Foreign key constraint names that point to the renamed table are automatically updated unless there is a conflict, in which case the statement fails with an error. A conflict occurs if the renamed constraint
name already exists. In such cases, you must drop and re-create the foreign keys for them to function properly.

RENAME TABLE tbl_name TO new_tbl_name changes internally generated and user-defined CHECK constraint names that begin with the string “tbl_name_chk_” to reflect the new table name. MySQL interprets CHECK constraint names that begin with the string “tbl_name_chk_” as internally generated names. Example:

```
mysql> SHOW CREATE TABLE t1
+-----------------------+------------------------------------------+
| Create Table: | CREATE TABLE `t1` ( |
| `i1` int(11) DEFAULT NULL, | `i2` int(11) DEFAULT NULL, |
| CONSTRAINT `t1_chk_1` CHECK (`i1` > 0), | CONSTRAINT `t1_chk_2` CHECK (`i2` < 0) |
| ) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_0900_ai_ci |
+-----------------------+------------------------------------------+
| 1 row in set (0.02 sec) |
```

mysql> RENAME TABLE t1 TO t3;
Query OK, 0 rows affected (0.03 sec)

mysql> SHOW CREATE TABLE t3
+-----------------------+------------------------------------------+
| Create Table: | CREATE TABLE `t3` ( |
| `i1` int(11) DEFAULT NULL, | `i2` int(11) DEFAULT NULL, |
| CONSTRAINT `t3_chk_1` CHECK (`i1` > 0), | CONSTRAINT `t3_chk_2` CHECK (`i2` < 0) |
| ) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_0900_ai_ci |
+-----------------------+------------------------------------------+
| 1 row in set (0.01 sec) |
```

13.1.37 TRUNCATE TABLE Statement

TRUNCATE [TABLE] tbl_name

TRUNCATE TABLE empties a table completely. It requires the DROP privilege. Logically, TRUNCATE TABLE is similar to a DELETE statement that deletes all rows, or a sequence of DROP TABLE and CREATE TABLE statements.

To achieve high performance, TRUNCATE TABLE bypasses the DML method of deleting data. Thus, it does not cause ON DELETE triggers to fire, it cannot be performed for InnoDB tables with parent-child foreign key relationships, and it cannot be rolled back like a DML operation. However, TRUNCATE TABLE operations on tables that use an atomic DDL-supported storage engine are either fully committed or rolled back if the server halts during their operation. For more information, see Section 13.1.1, “Atomic Data Definition Statement Support”.

Although TRUNCATE TABLE is similar to DELETE, it is classified as a DDL statement rather than a DML statement. It differs from DELETE in the following ways:

• Truncate operations drop and re-create the table, which is much faster than deleting rows one by one, particularly for large tables.

• Truncate operations cause an implicit commit, and so cannot be rolled back. See Section 13.3.3, “Statements That Cause an Implicit Commit”.

• Truncation operations cannot be performed if the session holds an active table lock.

• TRUNCATE TABLE fails for an InnoDB table or NDB table if there are any FOREIGN KEY constraints from other tables that reference the table. Foreign key constraints between columns of the same table are permitted.

• Truncation operations do not return a meaningful value for the number of deleted rows. The usual result is “0 rows affected,” which should be interpreted as “no information.”
• As long as the table definition is valid, the table can be re-created as an empty table with TRUNCATE TABLE, even if the data or index files have become corrupted.

• Any AUTO_INCREMENT value is reset to its start value. This is true even for MyISAM and InnoDB, which normally do not reuse sequence values.

• When used with partitioned tables, TRUNCATE TABLE preserves the partitioning; that is, the data and index files are dropped and re-created, while the partition definitions are unaffected.

• The TRUNCATE TABLE statement does not invoke ON DELETE triggers.

• Truncating a corrupted InnoDB table is supported.

TRUNCATE TABLE is treated for purposes of binary logging and replication as DDL rather than DML, and is always logged as a statement.

TRUNCATE TABLE for a table closes all handlers for the table that were opened with HANDLER OPEN.

In MySQL 5.7 and earlier, on a system with a large buffer pool and innodb_adaptive_hash_index enabled, a TRUNCATE TABLE operation could cause a temporary drop in system performance due to an LRU scan that occurred when removing the table's adaptive hash index entries (Bug #68184). The remapping of TRUNCATE TABLE to DROP TABLE and CREATE TABLE in MySQL 8.0 avoids the problematic LRU scan.

TRUNCATE TABLE can be used with Performance Schema summary tables, but the effect is to reset the summary columns to 0 or NULL, not to remove rows. See Section 27.12.20, “Performance Schema Summary Tables”.

Truncating an InnoDB table that resides in a file-per-table tablespace drops the existing tablespace and creates a new one. As of MySQL 8.0.21, if the tablespace was created with an earlier version and resides in an unknown directory, InnoDB creates the new tablespace in the default location and writes the following warning to the error log: The DATA DIRECTORY location must be in a known directory. The DATA DIRECTORY location will be ignored and the file will be put into the default datadir location. Known directories are those defined by the datadir, innodb_data_home_dir, and innodb_directories variables. To have TRUNCATE TABLE create the tablespace in its current location, add the directory to the innodb_directories setting before running TRUNCATE TABLE.

13.2 Data Manipulation Statements

13.2.1 CALL Statement

CALL sp_name([parameter[,...]])
CALL sp_name()   

The CALL statement invokes a stored procedure that was defined previously with CREATE PROCEDURE.

Stored procedures that take no arguments can be invoked without parentheses. That is, CALL p() and CALL p are equivalent.

CALL can pass back values to its caller using parameters that are declared as OUT or INOUT parameters. When the procedure returns, a client program can also obtain the number of rows affected for the final statement executed within the routine: At the SQL level, call the ROW_COUNT() function; from the C API, call the mysql_affected_rows() function.

For information about the effect of unhandled conditions on procedure parameters, see Section 13.6.7.8, “Condition Handling and OUT or INOUT Parameters”.

To get back a value from a procedure using an OUT or INOUT parameter, pass the parameter by means of a user variable, and then check the value of the variable after the procedure returns. (If you
are calling the procedure from within another stored procedure or function, you can also pass a routine parameter or local routine variable as an IN or INOUT parameter.) For an INOUT parameter, initialize its value before passing it to the procedure. The following procedure has an OUT parameter that the procedure sets to the current server version, and an INOUT value that the procedure increments by one from its current value:

```sql
CREATE PROCEDURE p (OUT ver_param VARCHAR(25), INOUT incr_param INT)
BEGIN
  # Set value of OUT parameter
  SELECT VERSION() INTO ver_param;
  # Increment value of INOUT parameter
  SET incr_param = incr_param + 1;
END;
```

Before calling the procedure, initialize the variable to be passed as the INOUT parameter. After calling the procedure, you can see that the values of the two variables are set or modified:

```sql
mysql> SET @increment = 10;
mysql> CALL p(@version, @increment);
mysql> SELECT @version, @increment;
+--------------------+------------+
| @version           | @increment |
| 8.0.3-rc-debug-log |         11 |
+--------------------+------------+
```

In prepared CALL statements used with PREPARE and EXECUTE, placeholders can be used for IN parameters, OUT, and INOUT parameters. These types of parameters can be used as follows:

```sql
mysql> SET @increment = 10;
mysql> PREPARE s FROM 'CALL p(?, ?)';
mysql> EXECUTE s USING @version, @increment;
mysql> SELECT @version, @increment;
+--------------------+------------+
| @version           | @increment |
| 8.0.3-rc-debug-log |         11 |
+--------------------+------------+
```

To write C programs that use the CALL SQL statement to execute stored procedures that produce result sets, the CLIENT_MULTI_RESULTS flag must be enabled. This is because each CALL returns a result to indicate the call status, in addition to any result sets that might be returned by statements executed within the procedure. CLIENT_MULTI_RESULTS must also be enabled if CALL is used to execute any stored procedure that contains prepared statements. It cannot be determined when such a procedure is loaded whether those statements produce result sets, so it is necessary to assume that they do so.

CLIENT_MULTI_RESULTS can be enabled when you call mysql_real_connect(), either explicitly by passing the CLIENT_MULTI_RESULTS flag itself, or implicitly by passing CLIENT_MULTI_STATEMENTS (which also enables CLIENT_MULTI_RESULTS). CLIENT_MULTI_RESULTS is enabled by default.

To process the result of a CALL statement executed using mysql_query() or mysql_real_query(), use a loop that calls mysql_next_result() to determine whether there are more results. For an example, see Multiple Statement Execution Support.

C programs can use the prepared-statement interface to execute CALL statements and access OUT and INOUT parameters. This is done by processing the result of a CALL statement using a loop that calls mysql_stmt_next_result() to determine whether there are more results. For an example, see Prepared CALL Statement Support. Languages that provide a MySQL interface can use prepared CALL statements to directly retrieve OUT and INOUT procedure parameters.

Metadata changes to objects referred to by stored programs are detected and cause automatic reparsing of the affected statements when the program is next executed. For more information, see Section 8.10.3, “Caching of Prepared Statements and Stored Programs”.

2420
13.2.2 DELETE Statement

DELETE is a DML statement that removes rows from a table.

A DELETE statement can start with a WITH clause to define common table expressions accessible within the DELETE. See Section 13.2.15, “WITH (Common Table Expressions)”.

Single-Table Syntax

DELETE [LOW_PRIORITY] [QUICK] [IGNORE] FROM tbl_name [AS tbl_alias] 
[PARTITION (partition_name [, partition_name] ...)]
[WHERE where_condition]
[ORDER BY ...]
[LIMIT row_count]

The DELETE statement deletes rows from tbl_name and returns the number of deleted rows. To check the number of deleted rows, call the ROW_COUNT() function described in Section 12.16, “Information Functions”.

Main Clauses

The conditions in the optional WHERE clause identify which rows to delete. With no WHERE clause, all rows are deleted.

where_condition is an expression that evaluates to true for each row to be deleted. It is specified as described in Section 13.2.10, “SELECT Statement”.

If the ORDER BY clause is specified, the rows are deleted in the order that is specified. The LIMIT clause places a limit on the number of rows that can be deleted. These clauses apply to single-table deletes, but not multi-table deletes.

Multiple-Table Syntax

DELETE [LOW_PRIORITY] [QUICK] [IGNORE] 
from tbl_name[.*] [AS tbl_alias] ] ...
FROM table_references 
[WHERE where_condition]

DELETE [LOW_PRIORITY] [QUICK] [IGNORE] 
from tbl_name[.*] [AS tbl_alias] ] ...
USING table_references 
[WHERE where_condition]

Privileges

You need the DELETE privilege on a table to delete rows from it. You need only the SELECT privilege for any columns that are only read, such as those named in the WHERE clause.

Performance

When you do not need to know the number of deleted rows, the TRUNCATE TABLE statement is a faster way to empty a table than a DELETE statement with no WHERE clause. Unlike DELETE, TRUNCATE TABLE cannot be used within a transaction or if you have a lock on the table. See Section 13.1.37, “TRUNCATE TABLE Statement” and Section 13.3.6, “LOCK TABLES and UNLOCK TABLES Statements”.

The speed of delete operations may also be affected by factors discussed in Section 8.2.5.3, “Optimizing DELETE Statements”.

To ensure that a given DELETE statement does not take too much time, the MySQL-specific LIMIT row_count clause for DELETE specifies the maximum number of rows to be deleted. If the number of rows to delete is larger than the limit, repeat the DELETE statement until the number of affected rows is less than the LIMIT value.
Subqueries

You cannot delete from a table and select from the same table in a subquery.

Partitioned Table Support

`DELETE` supports explicit partition selection using the `PARTITION` clause, which takes a list of the comma-separated names of one or more partitions or subpartitions (or both) from which to select rows to be dropped. Partitions not included in the list are ignored. Given a partitioned table `t` with a partition named `p0`, executing the statement `DELETE FROM t PARTITION (p0)` has the same effect on the table as executing `ALTER TABLE t TRUNCATE PARTITION (p0)`; in both cases, all rows in partition `p0` are dropped.

`PARTITION` can be used along with a `WHERE` condition, in which case the condition is tested only on rows in the listed partitions. For example, `DELETE FROM t PARTITION (p0) WHERE c < 5` deletes rows only from partition `p0` for which the condition `c < 5` is true; rows in any other partitions are not checked and thus not affected by the `DELETE`.

The `PARTITION` clause can also be used in multiple-table `DELETE` statements. You can use up to one such option per table named in the `FROM` option.

For more information and examples, see Section 24.5, “Partition Selection”.

Auto-Increment Columns

If you delete the row containing the maximum value for an `AUTO_INCREMENT` column, the value is not reused for a MyISAM or InnoDB table. If you delete all rows in the table with `DELETE FROM tbl_name` (without a `WHERE` clause) in autocommit mode, the sequence starts over for all storage engines except InnoDB and MyISAM. There are some exceptions to this behavior for InnoDB tables, as discussed in Section 15.6.1.6, “AUTO_INCREMENT Handling in InnoDB”.

For MyISAM tables, you can specify an `AUTO_INCREMENT` secondary column in a multiple-column key. In this case, reuse of values deleted from the top of the sequence occurs even for MyISAM tables. See Section 3.6.9, “Using AUTO_INCREMENT”.

Modifiers

The `DELETE` statement supports the following modifiers:

- If you specify the `LOW_PRIORITY` modifier, the server delays execution of the `DELETE` until no other clients are reading from the table. This affects only storage engines that use only table-level locking (such as MyISAM, MEMORY, and MERGE).

- For MyISAM tables, if you use the `QUICK` modifier, the storage engine does not merge index leaves during delete, which may speed up some kinds of delete operations.

- The `IGNORE` modifier causes MySQL to ignore ignorable errors during the process of deleting rows. (Errors encountered during the parsing stage are processed in the usual manner.) Errors that are ignored due to the use of `IGNORE` are returned as warnings. For more information, see The Effect of `IGNORE` on Statement Execution.

Order of Deletion

If the `DELETE` statement includes an `ORDER BY` clause, rows are deleted in the order specified by the clause. This is useful primarily in conjunction with `LIMIT`. For example, the following statement finds rows matching the `WHERE` clause, sorts them by `timestamp_column`, and deletes the first (oldest) one:

```
DELETE FROM somelog WHERE user = 'jcole'
ORDER BY timestamp_column LIMIT 1;
```
DELETE Statement

ORDER BY also helps to delete rows in an order required to avoid referential integrity violations.

InnoDB Tables

If you are deleting many rows from a large table, you may exceed the lock table size for an InnoDB table. To avoid this problem, or simply to minimize the time that the table remains locked, the following strategy (which does not use DELETE at all) might be helpful:

1. Select the rows not to be deleted into an empty table that has the same structure as the original table:

   ```sql
   INSERT INTO t_copy SELECT * FROM t WHERE ... ;
   ```

2. Use RENAME TABLE to atomically move the original table out of the way and rename the copy to the original name:

   ```sql
   RENAME TABLE t TO t_old, t_copy TO t;
   ```

3. Drop the original table:

   ```sql
   DROP TABLE t_old;
   ```

No other sessions can access the tables involved while RENAME TABLE executes, so the rename operation is not subject to concurrency problems. See Section 13.1.36, “RENAME TABLE Statement”.

MyISAM Tables

In MyISAM tables, deleted rows are maintained in a linked list and subsequent INSERT operations reuse old row positions. To reclaim unused space and reduce file sizes, use the OPTIMIZE TABLE statement or the myisamchk utility to reorganize tables. OPTIMIZE TABLE is easier to use, but myisamchk is faster. See Section 13.7.3.4, “OPTIMIZE TABLE Statement”, and Section 4.6.4, “myisamchk — MyISAM Table-Maintenance Utility”.

The QUICK modifier affects whether index leaves are merged for delete operations. DELETE QUICK is most useful for applications where index values for deleted rows are replaced by similar index values from rows inserted later. In this case, the holes left by deleted values are reused.

DELETE QUICK is not useful when deleted values lead to underfilled index blocks spanning a range of index values for which new inserts occur again. In this case, use of QUICK can lead to wasted space in the index that remains unreclaimed. Here is an example of such a scenario:

1. Create a table that contains an indexed AUTO_INCREMENT column.

2. Insert many rows into the table. Each insert results in an index value that is added to the high end of the index.

3. Delete a block of rows at the low end of the column range using DELETE QUICK.

In this scenario, the index blocks associated with the deleted index values become underfilled but are not merged with other index blocks due to the use of QUICK. They remain underfilled when new inserts occur, because new rows do not have index values in the deleted range. Furthermore, they remain underfilled even if you later use DELETE without QUICK, unless some of the deleted index values happen to lie in index blocks within or adjacent to the underfilled blocks. To reclaim unused index space under these circumstances, use OPTIMIZE TABLE.

If you are going to delete many rows from a table, it might be faster to use DELETE QUICK followed by OPTIMIZE TABLE. This rebuilds the index rather than performing many index block merge operations.

Multi-Table Deletes

You can specify multiple tables in a DELETE statement to delete rows from one or more tables depending on the condition in the WHERE clause. You cannot use ORDER BY or LIMIT in a multiple-
**DO Statement**

The *table_references* clause lists the tables involved in the join, as described in Section 13.2.10.2, "JOIN Clause".

For the first multiple-table syntax, only matching rows from the tables listed before the FROM clause are deleted. For the second multiple-table syntax, only matching rows from the tables listed in the FROM clause (before the USING clause) are deleted. The effect is that you can delete rows from many tables at the same time and have additional tables that are used only for searching:

```sql
DELETE t1, t2 FROM t1 INNER JOIN t2 INNER JOIN t3
WHERE t1.id=t2.id AND t2.id=t3.id;
```

Or:

```sql
DELETE FROM t1, t2 USING t1 INNER JOIN t2 INNER JOIN t3
WHERE t1.id=t2.id AND t2.id=t3.id;
```

These statements use all three tables when searching for rows to delete, but delete matching rows only from tables *t1* and *t2*.

The preceding examples use INNER JOIN, but multiple-table DELETE statements can use other types of join permitted in SELECT statements, such as LEFT JOIN. For example, to delete rows that exist in *t1* that have no match in *t2*, use a LEFT JOIN:

```sql
DELETE t1 FROM t1 LEFT JOIN t2 ON t1.id=t2.id WHERE t2.id IS NULL;
```

The syntax permits .* after each *tbl_name* for compatibility with Access.

If you use a multiple-table DELETE statement involving InnoDB tables for which there are foreign key constraints, the MySQL optimizer might process tables in an order that differs from that of their parent/child relationship. In this case, the statement fails and rolls back. Instead, you should delete from a single table and rely on the **ON DELETE** capabilities that InnoDB provides to cause the other tables to be modified accordingly.

---

**Note**

If you declare an alias for a table, you must use the alias when referring to the table:

```sql
DELETE t1 FROM test AS t1, test2 WHERE ...
```

Table aliases in a multiple-table DELETE should be declared only in the *table_references* part of the statement. Elsewhere, alias references are permitted but not alias declarations.

**Correct:**

```sql
DELETE a1, a2 FROM t1 AS a1 INNER JOIN t2 AS a2
WHERE a1.id=a2.id;
```

```sql
DELETE FROM a1, a2 USING t1 AS a1 INNER JOIN t2 AS a2
WHERE a1.id=a2.id;
```

**Incorrect:**

```sql
DELETE t1 AS a1, t2 AS a2 FROM t1 INNER JOIN t2
WHERE a1.id=a2.id;
```

```sql
DELETE FROM t1 AS a1, t2 AS a2 USING t1 INNER JOIN t2
WHERE a1.id=a2.id;
```

Table aliases are also supported for single-table DELETE statements beginning with MySQL 8.0.16.

(Bug #89410,Bug #27455809)

### 13.2.3 DO Statement

```sql
DO expr [, expr] ...
```
**HANDLER Statement**

**DO** executes the expressions but does not return any results. In most respects, **DO** is shorthand for **SELECT expr, ...**, but has the advantage that it is slightly faster when you do not care about the result.

**DO** is useful primarily with functions that have side effects, such as **RELEASE_LOCK()**.

Example: This **SELECT** statement pauses, but also produces a result set:

```sql
mysql> SELECT SLEEP(5);
+----------+
| SLEEP(5) |
+----------+
|        0 |
+----------+
1 row in set (5.02 sec)
```

**DO**, on the other hand, pauses without producing a result set:

```sql
mysql> DO SLEEP(5);
Query OK, 0 rows affected (4.99 sec)
```

This could be useful, for example in a stored function or trigger, which prohibit statements that produce result sets.

**DO** only executes expressions. It cannot be used in all cases where **SELECT** can be used. For example, **DO id FROM t1** is invalid because it references a table.

### 13.2.4 HANDLER Statement

```sql
HANDLER tbl_name OPEN [ [AS] alias ]
HANDLER tbl_name READ index_name { = | <= | >= | < | > } (value1, value2, ...)
[ WHERE where_condition ] [ LIMIT ... ]
HANDLER tbl_name READ index_name { FIRST | NEXT | PREV | LAST }
[ WHERE where_condition ] [ LIMIT ... ]
HANDLER tbl_name READ { FIRST | NEXT }
[ WHERE where_condition ] [ LIMIT ... ]
HANDLER tbl_name CLOSE
```

The **HANDLER** statement provides direct access to table storage engine interfaces. It is available for **InnoDB** and **MyISAM** tables.

The **HANDLER ... OPEN** statement opens a table, making it accessible using subsequent **HANDLER ... READ** statements. This table object is not shared by other sessions and is not closed until the session calls **HANDLER ... CLOSE** or the session terminates.

If you open the table using an alias, further references to the open table with other **HANDLER** statements must use the alias rather than the table name. If you do not use an alias, but open the table using a table name qualified by the database name, further references must use the unqualified table name. For example, for a table opened using `mydb.mytable`, further references must use `mytable`.

The first **HANDLER ... READ** syntax fetches a row where the index specified satisfies the given values and the **WHERE** condition is met. If you have a multiple-column index, specify the index column values as a comma-separated list. Either specify values for all the columns in the index, or specify values for a leftmost prefix of the index columns. Suppose that an index `my_idx` includes three columns named `col_a`, `col_b`, and `col_c`, in that order. The **HANDLER** statement can specify values for all three columns in the index, or for the columns in a leftmost prefix. For example:

```sql
HANDLER ... READ my_idx = (col_a_val, col_b_val, col_c_val) ...  
HANDLER ... READ my_idx = (col_a_val, col_b_val) ...  
HANDLER ... READ my_idx = (col_a_val) ...
```

To employ the **HANDLER** interface to refer to a table's **PRIMARY KEY**, use the quoted identifier `\`PRIMARY\`":
The second `HANDLER ... READ` syntax fetches a row from the table in index order that matches the `WHERE` condition.

The third `HANDLER ... READ` syntax fetches a row from the table in natural row order that matches the `WHERE` condition. It is faster than `HANDLER tbl_name READ index_name` when a full table scan is desired. Natural row order is the order in which rows are stored in a MyISAM table data file. This statement works for InnoDB tables as well, but there is no such concept because there is no separate data file.

Without a `LIMIT` clause, all forms of `HANDLER ... READ` fetch a single row if one is available. To return a specific number of rows, include a `LIMIT` clause. It has the same syntax as for the `SELECT` statement. See Section 13.2.10, “SELECT Statement”.

`HANDLER ... CLOSE` closes a table that was opened with `HANDLER ... OPEN`.

There are several reasons to use the `HANDLER` interface instead of normal `SELECT` statements:

- **HANDLER** is faster than `SELECT`:
  - A designated storage engine handler object is allocated for the `HANDLER ... OPEN`. The object is reused for subsequent `HANDLER` statements for that table; it need not be reinitialized for each one.
  - There is less parsing involved.
  - There is no optimizer or query-checking overhead.
  - The handler interface does not have to provide a consistent look of the data (for example, dirty reads are permitted), so the storage engine can use optimizations that `SELECT` does not normally permit.
  - `HANDLER` makes it easier to port to MySQL applications that use a low-level ISAM-like interface. (See Section 15.20, “InnoDB memcached Plugin” for an alternative way to adapt applications that use the key-value store paradigm.)
  - `HANDLER` enables you to traverse a database in a manner that is difficult (or even impossible) to accomplish with `SELECT`. The `HANDLER` interface is a more natural way to look at data when working with applications that provide an interactive user interface to the database.

`HANDLER` is a somewhat low-level statement. For example, it does not provide consistency. That is, `HANDLER ... OPEN` does not take a snapshot of the table, and does not lock the table. This means that after a `HANDLER ... OPEN` statement is issued, table data can be modified (by the current session or other sessions) and these modifications might be only partially visible to `HANDLER ... NEXT` or `HANDLER ... PREV` scans.

An open handler can be closed and marked for reopen, in which case the handler loses its position in the table. This occurs when both of the following circumstances are true:

- Any session executes `FLUSH TABLES` or DDL statements on the handler's table.
- The session in which the handler is open executes non-`HANDLER` statements that use tables.

`TRUNCATE TABLE` for a table closes all handlers for the table that were opened with `HANDLER OPEN`.

If a table is flushed with `FLUSH TABLES tbl_name WITH READ LOCK` was opened with `HANDLER`, the handler is implicitly flushed and loses its position.

### 13.2.5 IMPORT TABLE Statement

```
IMPORT TABLE FROM sdifile [, sdifile] ...
```
The IMPORT TABLE statement imports MyISAM tables based on information contained in .sdi (serialized dictionary information) metadata files. IMPORT TABLE requires the FILE privilege to read the .sdi and table content files, and the CREATE privilege for the table to be created.

Tables can be exported from one server using mysqldump to write a file of SQL statements and imported into another server using mysql to process the dump file. IMPORT TABLE provides a faster alternative using the “raw” table files.

Prior to import, the files that provide the table content must be placed in the appropriate schema directory for the import server, and the .sdi file must be located in a directory accessible to the server. For example, the .sdi file can be placed in the directory named by the secure_file_priv system variable, or (if secure_file_priv is empty) in a directory under the server data directory.

The following example describes how to export MyISAM tables named employees and managers from the hr schema of one server and import them into the hr schema of another server. The example uses these assumptions (to perform a similar operation on your own system, modify the path names as appropriate):

- For the export server, export_basedir represents its base directory, and its data directory is export_basedir/data.
- For the import server, import_basedir represents its base directory, and its data directory is import_basedir/data.
- Table files are exported from the export server into the /tmp/export directory and this directory is secure (not accessible to other users).
- The import server uses /tmp/mysql-files as the directory named by its secure_file_priv system variable.

To export tables from the export server, use this procedure:

1. Ensure a consistent snapshot by executing this statement to lock the tables so that they cannot be modified during export:

   ```
   mysql> FLUSH TABLES hr.employees, hr.managers WITH READ LOCK;
   ```

   While the lock is in effect, the tables can still be used, but only for read access.

2. At the file system level, copy the .sdi and table content files from the hr schema directory to the secure export directory:

   - The .sdi file is located in the hr schema directory, but might not have exactly the same basename as the table name. For example, the .sdi files for the employees and managers tables might be named employees_125.sdi and managers_238.sdi.
   - For a MyISAM table, the content files are its .MYD data file and .MYI index file.

   Given those file names, the copy commands look like this:

   ```
   shell> cd export_basedir/data/hr
   shell> cp employees_125.sdi /tmp/export
   shell> cp managers_238.sdi /tmp/export
   ```

3. Unlock the tables:

   ```
   mysql> UNLOCK TABLES;
   ```

To import tables into the import server, use this procedure:

1. The import schema must exist. If necessary, execute this statement to create it:
import table statement

mysql> create schema hr;

2. At the file system level, copy the .sdi files to the import server secure_file_priv directory, /tmp/mysql-files. Also, copy the table content files to the hr schema directory:

shell> cd /tmp/export
shell> cp employees_125.sdi /tmp/mysql-files
shell> cp managers_238.sdi /tmp/mysql-files
shell> cp employees.{MYD,MYI} import_basedir/data/hr
shell> cp managers.{MYD,MYI} import_basedir/data/hr

3. Import the tables by executing an IMPORT TABLE statement that names the .sdi files:

mysql> import table from '/tmp/mysql-files/employees.sdi',
    > '/tmp/mysql-files/managers.sdi';

The .sdi file need not be placed in the import server directory named by the secure_file_priv system variable if that variable is empty; it can be in any directory accessible to the server, including the schema directory for the imported table. If the .sdi file is placed in that directory, however, it may be rewritten; the import operation creates a new .sdi file for the table, which overwrites the old .sdi file if the operation uses the same file name for the new file.

Each sdi_file value must be a string literal that names the .sdi file for a table or is a pattern that matches .sdi files. If the string is a pattern, any leading directory path and the .sdi file name suffix must be given literally. Pattern characters are permitted only in the base name part of the file name:

- ? matches any single character
- * matches any sequence of characters, including no characters

Using a pattern, the previous IMPORT TABLE statement could have been written like this (assuming that the /tmp/mysql-files directory contains no other .sdi files matching the pattern):

import table from '/tmp/mysql-files/*.sdi';

To interpret the location of .sdi file path names, the server uses the same rules for IMPORT TABLE as the server-side rules for LOAD DATA (that is, the non-LOCAL rules). See Section 13.2.7, "LOAD DATA Statement", paying particular attention to the rules used to interpret relative path names.

IMPORT TABLE fails if the .sdi or table files cannot be located. After importing a table, the server attempts to open it and reports as warnings any problems detected. To attempt a repair to correct any reported issues, use REPAIR TABLE.

IMPORT TABLE is not written to the binary log.

restrictions and limitations

IMPORT TABLE applies only to non-temporary MyISAM tables. It does not apply to tables created with a transactional storage engine, tables created with CREATE TEMPORARY TABLE, or views.

An .sdi file used in an import operation must be generated on a server with the same data dictionary version and sdi version as the import server. The version information of the generating server is found in the .sdi file:

{  "myqld_version_id":80019,  "dd_version":80017,  "sdi_version":80016,  ...
}

To determine the data dictionary and sdi version of the import server, you can check the .sdi file of a recently created table on the import server.
The table data and index files must be placed in the schema directory for the import server prior to the import operation, unless the table as defined on the export server uses the DATA DIRECTORY or INDEX DIRECTORY table options. In that case, modify the import procedure using one of these alternatives before executing the IMPORT TABLE statement:

- Put the data and index files into the same directory on the import server host as on the export server host, and create symlinks in the import server schema directory to those files.
- Put the data and index files into an import server host directory different from that on the export server host, and create symlinks in the import server schema directory to those files. In addition, modify the .sdi file to reflect the different file locations.
- Put the data and index files into the schema directory on the import server host, and modify the .sdi file to remove the data and index directory table options.

Any collation IDs stored in the .sdi file must refer to the same collations on the export and import servers.

Trigger information for a table is not serialized into the table .sdi file, so triggers are not restored by the import operation.

Some edits to an .sdi file are permissible prior to executing the IMPORT TABLE statement, whereas others are problematic or may even cause the import operation to fail:

- Changing the data directory and index directory table options is required if the locations of the data and index files differ between the export and import servers.
- Changing the schema name is required to import the table into a different schema on the import server than on the export server.
- Changing schema and table names may be required to accommodate differences between file system case-sensitivity semantics on the export and import servers or differences in lower_case_table_names settings. Changing the table names in the .sdi file may require renaming the table files as well.
- In some cases, changes to column definitions are permitted. Changing data types is likely to cause problems.

### 13.2.6 INSERT Statement

```
INSERT [LOW_PRIORITY | DELAYED | HIGH_PRIORITY] [IGNORE]
    [INTO] tbl_name
    [PARTITION (partition_name [, partition_name] ...)]
    [(col_name [, col_name] ...)]
    { VALUES | VALUE} (value_list) [, (value_list)] ...
    | VALUES row_constructor_list
    )
    [AS row_alias[(col_alias [, col_alias] ...)]]
    [ON DUPLICATE KEY UPDATE assignment_list]
```

```
INSERT [LOW_PRIORITY | DELAYED | HIGH_PRIORITY] [IGNORE]
    [INTO] tbl_name
    [PARTITION (partition_name [, partition_name] ...)]
    [AS row_alias[(col_alias [, col_alias] ...)]]
    SET assignment_list
    [ON DUPLICATE KEY UPDATE assignment_list]
```

```
INSERT [LOW_PRIORITY | HIGH_PRIORITY] [IGNORE]
    [INTO] tbl_name
    [PARTITION (partition_name [, partition_name] ...)]
    [(col_name [, col_name] ...)]
    [AS row_alias[(col_alias [, col_alias] ...)]]
    [SELECT ... | TABLE table_name]
    [ON DUPLICATE KEY UPDATE assignment_list]
```
### INSERT Statement

**value:**

```
{expr | DEFAULT}
```

**value_list:**

```
value [, value] ...  
```

**row_constructor_list:**

```
ROW(value_list)[, ROW(value_list)][, ...]
```

**assignment:**

```
col_name = [row_alias.]value
```

**assignment_list:**

```
assignment [, assignment] ...
```

**INSERT** inserts new rows into an existing table. The **INSERT ... VALUES**, **INSERT ... VALUES ROW()**, and **INSERT ... SET** forms of the statement insert rows based on explicitly specified values. The **INSERT ... SELECT** form inserts rows selected from another table or tables. You can also use **INSERT ... TABLE** in MySQL 8.0.19 and later to insert rows from a single table. **INSERT** with an **ON DUPLICATE KEY UPDATE** clause enables existing rows to be updated if a row to be inserted would cause a duplicate value in a **UNIQUE** index or **PRIMARY KEY**. In MySQL 8.0.19 and later, a row alias with one or more optional column aliases can be used with **ON DUPLICATE KEY UPDATE** to refer to the row to be inserted.

For additional information about **INSERT ... SELECT** and **INSERT ... ON DUPLICATE KEY UPDATE**, see Section 13.2.6.1, “**INSERT ... SELECT Statement**”, and Section 13.2.6.2, “**INSERT ... ON DUPLICATE KEY UPDATE Statement**”.

In MySQL 8.0, the **DELAYED** keyword is accepted but ignored by the server. For the reasons for this, see Section 13.2.6.3, “**INSERT DELAYED Statement**”.

Inserting into a table requires the **INSERT** privilege for the table. If the **ON DUPLICATE KEY UPDATE** clause is used and a duplicate key causes an **UPDATE** to be performed instead, the statement requires the **UPDATE** privilege for the columns to be updated. For columns that are read but not modified you need only the **SELECT** privilege (such as for a column referenced only on the right hand side of an `col_name = expr` assignment in an **ON DUPLICATE KEY UPDATE** clause).

When inserting into a partitioned table, you can control which partitions and subpartitions accept new rows. The **PARTITION** clause takes a list of the comma-separated names of one or more partitions or subpartitions (or both) of the table. If any of the rows to be inserted by a given **INSERT** statement do not match one of the partitions listed, the **INSERT** statement fails with the error **Found a row not matching the given partition set**. For more information and examples, see Section 24.5, “**Partition Selection**”.

**tbl_name** is the table into which rows should be inserted. Specify the columns for which the statement provides values as follows:

- Provide a parenthesized list of comma-separated column names following the table name. In this case, a value for each named column must be provided by the **VALUES** list, **VALUES ROW()** list, or **SELECT** statement. For the **INSERT TABLE** form, the number of columns in the source table must match the number of columns to be inserted.

- If you do not specify a list of column names for **INSERT ... VALUES** or **INSERT ... SELECT**, values for every column in the table must be provided by the **VALUES** list, **SELECT** statement, or **TABLE** statement. If you do not know the order of the columns in the table, use **DESCRIBE tbl_name** to find out.

- A **SET** clause indicates columns explicitly by name, together with the value to assign each one.

Column values can be given in several ways:

- If strict SQL mode is not enabled, any column not explicitly given a value is set to its default (explicit or implicit) value. For example, if you specify a column list that does not name all the columns in the
table, unnamed columns are set to their default values. Default value assignment is described in Section 11.6, “Data Type Default Values”. See also Section 1.7.3.3, “Enforced Constraints on Invalid Data”.

If strict SQL mode is enabled, an INSERT statement generates an error if it does not specify an explicit value for every column that has no default value. See Section 5.1.11, “Server SQL Modes”.

- If both the column list and the VALUES list are empty, INSERT creates a row with each column set to its default value:

  ```sql
  INSERT INTO tbl_name () VALUES();
  ```

  If strict mode is not enabled, MySQL uses the implicit default value for any column that has no explicitly defined default. If strict mode is enabled, an error occurs if any column has no default value.

- Use the keyword DEFAULT to set a column explicitly to its default value. This makes it easier to write INSERT statements that assign values to all but a few columns, because it enables you to avoid writing an incomplete VALUES list that does not include a value for each column in the table. Otherwise, you must provide the list of column names corresponding to each value in the VALUES list.

- If a generated column is inserted into explicitly, the only permitted value is DEFAULT. For information about generated columns, see Section 13.1.20.8, “CREATE TABLE and Generated Columns”.

- In expressions, you can use `DEFAULT(col_name)` to produce the default value for column `col_name`.

- Type conversion of an expression `expr` that provides a column value might occur if the expression data type does not match the column data type. Conversion of a given value can result in different inserted values depending on the column type. For example, inserting the string `'1999.0e-2'` into an INT, FLOAT, DECIMAL(10, 6), or YEAR column inserts the value 1999, 19.9921, 19.992100, or 1999, respectively. The value stored in the INT and YEAR columns is 1999 because the string-to-number conversion looks only at as much of the initial part of the string as may be considered a valid integer or year. For the FLOAT and DECIMAL columns, the string-to-number conversion considers the entire string a valid numeric value.

- An expression `expr` can refer to any column that was set earlier in a value list. For example, you can do this because the value for `col2` refers to `col1`, which has previously been assigned:

  ```sql
  INSERT INTO tbl_name (col1,col2) VALUES(15,col1*2);
  ```

  But the following is not legal, because the value for `col1` refers to `col2`, which is assigned after `col1`:

  ```sql
  INSERT INTO tbl_name (col1,col2) VALUES(col2*2,15);
  ```

  An exception occurs for columns that contain AUTO_INCREMENT values. Because AUTO_INCREMENT values are generated after other value assignments, any reference to an AUTO_INCREMENT column in the assignment returns a 0.

- INSERT statements that use VALUES syntax can insert multiple rows. To do this, include multiple lists of comma-separated column values, with lists enclosed within parentheses and separated by commas. Example:

  ```sql
  INSERT INTO tbl_name (a,b,c) VALUES(1,2,3), (4,5,6), (7,8,9);
  ```

  Each values list must contain exactly as many values as are to be inserted per row. The following statement is invalid because it contains one list of nine values, rather than three lists of three values each:

  ```sql
  INSERT INTO tbl_name (a,b,c) VALUES(1,2,3,4,5,6,7,8,9);
  ```
**INSERT Statement**

**VALUE** is a synonym for **VALUES** in this context. Neither implies anything about the number of values lists, nor about the number of values per list. Either may be used whether there is a single values list or multiple lists, and regardless of the number of values per list.

**INSERT** statements using **VALUES ROW()** syntax can also insert multiple rows. In this case, each value list must be contained within a **ROW()** (row constructor), like this:

```
INSERT INTO tbl_name (a,b,c)
VALUES ROW(1,2,3), ROW(4,5,6), ROW(7,8,9);
```

The affected-rows value for an **INSERT** can be obtained using the **ROW_COUNT()** SQL function or the **mysql_affected_rows()** C API function. See Section 12.16, “Information Functions”, and **mysql_affected_rows()**.

If you use **INSERT ... VALUES** or **INSERT ... VALUES ROW()** with multiple value lists, or **INSERT ... SELECT** or **INSERT ... TABLE**, the statement returns an information string in this format:

Records: \( N_1 \) Duplicates: \( N_2 \) Warnings: \( N_3 \)

If you are using the C API, the information string can be obtained by invoking the **mysql_info()** function. See **mysql_info()**.

**Records** indicates the number of rows processed by the statement. (This is not necessarily the number of rows actually inserted because **Duplicates** can be nonzero.) **Duplicates** indicates the number of rows that could not be inserted because they would duplicate some existing unique index value. **Warnings** indicates the number of attempts to insert column values that were problematic in some way. Warnings can occur under any of the following conditions:

- Inserting **NULL** into a column that has been declared **NOT NULL**. For multiple-row **INSERT** statements or **INSERT INTO ... SELECT** statements, the column is set to the implicit default value for the column data type. This is 0 for numeric types, the empty string ('') for string types, and the “zero” value for date and time types. **INSERT INTO ... SELECT** statements are handled the same way as multiple-row inserts because the server does not examine the result set from the **SELECT** to see whether it returns a single row. (For a single-row **INSERT**, no warning occurs when **NULL** is inserted into a **NOT NULL** column. Instead, the statement fails with an error.)

- Setting a numeric column to a value that lies outside the column range. The value is clipped to the closest endpoint of the range.

- Assigning a value such as \'10.34 a\' to a numeric column. The trailing nonnumeric text is stripped off and the remaining numeric part is inserted. If the string value has no leading numeric part, the column is set to 0.

- Inserting a string into a string column (**CHAR**, **VARCHAR**, **TEXT**, or **BLOB**) that exceeds the column maximum length. The value is truncated to the column maximum length.

- Inserting a value into a date or time column that is illegal for the data type. The column is set to the appropriate zero value for the type.

- For **INSERT** examples involving **AUTO_INCREMENT** column values, see Section 3.6.9, “Using **AUTO_INCREMENT**”.

If **INSERT** inserts a row into a table that has an **AUTO_INCREMENT** column, you can find the value used for that column by using the **LAST_INSERT_ID()** SQL function or the **mysql_insert_id()** C API function.

**Note**

These two functions do not always behave identically. The behavior of **INSERT** statements with respect to **AUTO_INCREMENT** columns is discussed further in Section 12.16, “Information Functions”, and **mysql_insert_id()**.
The INSERT statement supports the following modifiers:

- If you use the LOW_PRIORITY modifier, execution of the INSERT is delayed until no other clients are reading from the table. This includes other clients that began reading while existing clients are reading, and while the INSERT LOW_PRIORITY statement is waiting. It is possible, therefore, for a client that issues an INSERT LOW_PRIORITY statement to wait for a very long time.

  LOW_PRIORITY affects only storage engines that use only table-level locking (such as MyISAM, MEMORY, and MERGE).

  Note
  LOW_PRIORITY should normally not be used with MyISAM tables because doing so disables concurrent inserts. See Section 8.11.3, “Concurrent Inserts”.

- If you specify HIGH_PRIORITY, it overrides the effect of the --low-priority-updates option if the server was started with that option. It also causes concurrent inserts not to be used. See Section 8.11.3, “Concurrent Inserts”.

  HIGH_PRIORITY affects only storage engines that use only table-level locking (such as MyISAM, MEMORY, and MERGE).

- If you use the IGNORE modifier, ignorable errors that occur while executing the INSERT statement are ignored. For example, without IGNORE, a row that duplicates an existing UNIQUE index or PRIMARY KEY value in the table causes a duplicate-key error and the statement is aborted. With IGNORE, the row is discarded and no error occurs. Ignored errors generate warnings instead.

  IGNORE has a similar effect on inserts into partitioned tables where no partition matching a given value is found. Without IGNORE, such INSERT statements are aborted with an error. When INSERT IGNORE is used, the insert operation fails silently for rows containing the unmatched value, but inserts rows that are matched. For an example, see Section 24.2.2, “LIST Partitioning”.

  Data conversions that would trigger errors abort the statement if IGNORE is not specified. With IGNORE, invalid values are adjusted to the closest values and inserted; warnings are produced but the statement does not abort. You can determine with the mysql_info() C API function how many rows were actually inserted into the table.

  For more information, see The Effect of IGNORE on Statement Execution.

  You can use REPLACE instead of INSERT to overwrite old rows. REPLACE is the counterpart to INSERT IGNORE in the treatment of new rows that contain unique key values that duplicate old rows: The new rows replace the old rows rather than being discarded. See Section 13.2.9, “REPLACE Statement”.

- If you specify ON DUPLICATE KEY UPDATE, and a row is inserted that would cause a duplicate value in a UNIQUE index or PRIMARY KEY, an UPDATE of the old row occurs. The affected-rows value per row is 1 if the row is inserted as a new row, 2 if an existing row is updated, and 0 if an existing row is set to its current values. If you specify the CLIENT_FOUND_ROWS flag to the mysql_real_connect() C API function when connecting to mysqld, the affected-rows value is 1 (not 0) if an existing row is set to its current values. See Section 13.2.6.2, “INSERT ... ON DUPLICATE KEY UPDATE Statement”.

- INSERT DELAYED was deprecated in MySQL 5.6, and is scheduled for eventual removal. In MySQL 8.0, the DELAYED modifier is accepted but ignored. Use INSERT (without DELAYED) instead. See Section 13.2.6.3, “INSERT DELAYED Statement”.

### 13.2.6.1 INSERT ... SELECT Statement

```sql
INSERT [LOW_PRIORITY | HIGH_PRIORITY] [IGNORE]
[INTO] tbl_name
```
With INSERT ... SELECT, you can quickly insert many rows into a table from the result of a SELECT statement, which can select from one or many tables. For example:

```
INSERT INTO tbl_temp2 (fld_id)
SELECT tbl_temp1.fld_order_id
FROM tbl_temp1 WHERE tbl_temp1.fld_order_id > 100;
```

Beginning with MySQL 8.0.19, you can use a TABLE statement in place of SELECT, as shown here:

```
INSERT INTO ta TABLE tb;
```

TABLE tb is equivalent to SELECT * FROM tb. It can be useful when inserting all columns from the source table into the target table, and no filtering with WHERE is required. In addition, the rows from TABLE can be ordered by one or more columns using ORDER BY, and the number of rows inserted can be limited using a LIMIT clause. For more information, see Section 13.2.12, “TABLE Statement”.

The following conditions hold for INSERT ... SELECT statements, and, except where noted, for INSERT ... TABLE as well:

- Specify IGNORE to ignore rows that would cause duplicate-key violations.
- The target table of the INSERT statement may appear in the FROM clause of the SELECT part of the query, or as the table named by TABLE. However, you cannot insert into a table and select from the same table in a subquery.

When selecting from and inserting into the same table, MySQL creates an internal temporary table to hold the rows from the SELECT and then inserts those rows into the target table. However, you cannot use INSERT INTO t ... SELECT ... FROM t when t is a TEMPORARY table, because TEMPORARY tables cannot be referred to twice in the same statement. For the same reason, you cannot use INSERT INTO t ... TABLE t when t is a temporary table. See Section 8.4.4, “Internal Temporary Table Use in MySQL”, and Section B.3.6.2, “TEMPORARY Table Problems”.

- AUTO_INCREMENT columns work as usual.
- To ensure that the binary log can be used to re-create the original tables, MySQL does not permit concurrent inserts for INSERT ... SELECT or INSERT ... TABLE statements (see Section 8.11.3, “Concurrent Inserts”).
- To avoid ambiguous column reference problems when the SELECT and the INSERT refer to the same table, provide a unique alias for each table used in the SELECT part, and qualify column names in that part with the appropriate alias.

The TABLE statement does not support aliases.

You can explicitly select which partitions or subpartitions (or both) of the source or target table (or both) are to be used with a PARTITION clause following the name of the table. When PARTITION is used with the name of the source table in the SELECT portion of the statement, rows are selected only from the partitions or subpartitions named in its partition list. When PARTITION is used with the name of the target table for the INSERT portion of the statement, it must be possible to insert all rows selected into the partitions or subpartitions named in the partition list following the option. Otherwise,
the `INSERT ... SELECT` statement fails. For more information and examples, see Section 24.5, “Partition Selection”.

**TABLE** does not support a `PARTITION` clause.

For `INSERT ... SELECT` statements, see Section 13.2.6.2, “INSERT ... ON DUPLICATE KEY UPDATE Statement” for conditions under which the `SELECT` columns can be referred to in an `ON DUPLICATE KEY UPDATE` clause. This also works for `INSERT ... TABLE`.

The order in which a `SELECT` or `TABLE` statement with no `ORDER BY` clause returns rows is nondeterministic. This means that, when using replication, there is no guarantee that such a `SELECT` returns rows in the same order on the source and the replica, which can lead to inconsistencies between them. To prevent this from occurring, always write `INSERT ... SELECT` or `INSERT ... TABLE` statements that are to be replicated using an `ORDER BY` clause that produces the same row order on the source and the replica. See also Section 17.1.18, “Replication and LIMIT”.

Due to this issue, `INSERT ... SELECT ON DUPLICATE KEY UPDATE` and `INSERT IGNORE ... SELECT` statements are flagged as unsafe for statement-based replication. Such statements produce a warning in the error log when using statement-based mode and are written to the binary log using the row-based format when using `MIXED` mode. (Bug #11758262, Bug #50439)

See also Section 17.2.1.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”.

### 13.2.6.2 INSERT ... ON DUPLICATE KEY UPDATE Statement

If you specify an `ON DUPLICATE KEY UPDATE` clause and a row to be inserted would cause a duplicate value in a `UNIQUE` index or `PRIMARY KEY`, an `UPDATE` of the old row occurs. For example, if column `a` is declared as `UNIQUE` and contains the value `1`, the following two statements have similar effect:

```
INSERT INTO t1 (a,b,c) VALUES (1,2,3)
  ON DUPLICATE KEY UPDATE c=c+1;
UPDATE t1 SET c=c+1 WHERE a=1;
```

The effects are not quite identical: For an `InnoDB` table where `a` is an auto-increment column, the `INSERT` statement increases the auto-increment value but the `UPDATE` does not.

If column `b` is also unique, the `INSERT` is equivalent to this `UPDATE` statement instead:

```
UPDATE t1 SET c=c+1 WHERE a=1 OR b=2 LIMIT 1;
```

If `a=1 OR b=2` matches several rows, only one row is updated. In general, you should try to avoid using an `ON DUPLICATE KEY UPDATE` clause on tables with multiple unique indexes.

With `ON DUPLICATE KEY UPDATE`, the affected-rows value per row is 1 if the row is inserted as a new row, 2 if an existing row is updated, and 0 if an existing row is set to its current values. If you specify the `CLIENT_FOUND_ROWS` flag to the `mysql_real_connect()` C API function when connecting to `mysqld`, the affected-rows value is 1 (not 0) if an existing row is set to its current values.

If a table contains an `AUTO_INCREMENT` column and `INSERT ... ON DUPLICATE KEY UPDATE` inserts or updates a row, the `LAST_INSERT_ID()` function returns the `AUTO_INCREMENT` value.

The `ON DUPLICATE KEY UPDATE` clause can contain multiple column assignments, separated by commas.

In assignment value expressions in the `ON DUPLICATE KEY UPDATE` clause, you can use the `VALUES(col_name)` function to refer to column values from the `INSERT` portion of the `INSERT ... ON DUPLICATE KEY UPDATE` statement. In other words, `VALUES(col_name)` in the `ON DUPLICATE KEY UPDATE` clause refers to the value of `col_name` that would be inserted, had no duplicate-key...
conflict occurred. This function is especially useful in multiple-row inserts. The `VALUES()` function is meaningful only in the `ON DUPLICATE KEY UPDATE` clause or `INSERT` statements and returns `NULL` otherwise. Example:

```
INSERT INTO t1 (a,b,c) VALUES (1,2,3),(4,5,6)
ON DUPLICATE KEY UPDATE c=VALUES(a)+VALUES(b);
```

That statement is identical to the following two statements:

```
INSERT INTO t1 (a,b,c) VALUES (1,2,3)
ON DUPLICATE KEY UPDATE c=3;
INSERT INTO t1 (a,b,c) VALUES (4,5,6)
ON DUPLICATE KEY UPDATE c=9;
```

---

**Note**

The use of `VALUES()` to refer to the new row and columns is deprecated beginning with MySQL 8.0.20, and is subject to removal in a future version of MySQL. Instead, use row and column aliases, as described in the next few paragraphs of this section.

Beginning with MySQL 8.0.19, it is possible to use an alias for the row, with, optionally, one or more of its columns to be inserted, following the `VALUES` or `SET` clause, and preceded by the `AS` keyword. Using the row alias `new`, the statement shown previously using `VALUES()` to access the new column values can be written in the form shown here:

```
INSERT INTO t1 (a,b,c) VALUES (1,2,3),(4,5,6) AS new
ON DUPLICATE KEY UPDATE c = new.a+new.b;
```

If, in addition, you use the column aliases `m`, `n`, and `p`, you can omit the row alias in the assignment clause and write the same statement like this:

```
INSERT INTO t1 (a,b,c) VALUES (1,2,3),(4,5,6) AS new(m,n,p)
ON DUPLICATE KEY UPDATE c = m+n;
```

When using column aliases in this fashion, you must still use a row alias following the `VALUES` clause, even if you do not make direct use of it in the assignment clause.

You can also use row and column aliases with a `SET` clause, as mentioned previously. Employing `SET` instead of `VALUES` in the two `INSERT ... ON DUPLICATE KEY UPDATE` statements just shown can be done as shown here:

```
INSERT INTO t1 SET a=1,b=2,c=3 AS new
ON DUPLICATE KEY UPDATE c = new.a+new.b;
```

```
INSERT INTO t1 SET a=1,b=2,c=3 AS new(m,n,p)
ON DUPLICATE KEY UPDATE c = m+n;
```

The row alias must not be the same as the name of the table. If column aliases are not used, or if they are the same as the column names, they must be distinguished using the row alias in the `ON DUPLICATE KEY UPDATE` clause. Column aliases must be unique with regard to the row alias to which they apply (that is, no column aliases referring to columns of the same row may be the same).

For `INSERT ... SELECT` statements, these rules apply regarding acceptable forms of `SELECT` query expressions that you can refer to in an `ON DUPLICATE KEY UPDATE` clause:

- References to columns from queries on a single table, which may be a derived table.
- References to columns from queries on a join over multiple tables.
- References to columns from `DISTINCT` queries.
- References to columns in other tables, as long as the `SELECT` does not use `GROUP BY`. One side effect is that you must qualify references to nonunique column names.
References to columns from a `UNION` are not supported. To work around this restriction, rewrite the `UNION` as a derived table so that its rows can be treated as a single-table result set. For example, this statement produces an error:

```sql
INSERT INTO t1 (a, b)
  SELECT c, d FROM t2
  UNION
  SELECT e, f FROM t3
  ON DUPLICATE KEY UPDATE b = b + c;
```

Instead, use an equivalent statement that rewrites the `UNION` as a derived table:

```sql
INSERT INTO t1 (a, b)
  SELECT * FROM
    (SELECT c, d FROM t2
     UNION
     SELECT e, f FROM t3) AS dt
  ON DUPLICATE KEY UPDATE b = b + c;
```

The technique of rewriting a query as a derived table also enables references to columns from `GROUP BY` queries.

Because the results of `INSERT ... SELECT` statements depend on the ordering of rows from the `SELECT` and this order cannot always be guaranteed, it is possible when logging `INSERT ... SELECT ON DUPLICATE KEY UPDATE` statements for the source and the replica to diverge. Thus, `INSERT ... SELECT ... ON DUPLICATE KEY UPDATE` statements are flagged as unsafe for statement-based replication. Such statements produce a warning in the error log when using statement-based mode and are written to the binary log using the row-based format when using `MIXED` mode. An `INSERT ... ON DUPLICATE KEY UPDATE` statement against a table having more than one unique or primary key is also marked as unsafe. (Bug #11765650, Bug #58637)

See also Section 17.2.1.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”.

**13.2.6.3 INSERT DELAYED Statement**

The `DELAYED` option for the `INSERT` statement is a MySQL extension to standard SQL. In previous versions of MySQL, it can be used for certain kinds of tables (such as `MyISAM`), such that when a client uses `INSERT DELAYED`, it gets an okay from the server at once, and the row is queued to be inserted when the table is not in use by any other thread.

`DELAYED` inserts and replaces were deprecated in MySQL 5.6. In MySQL 8.0, `DELAYED` is not supported. The server recognizes but ignores the `DELAYED` keyword, handles the insert as a nondelayed insert, and generates an `ER_WARN_LEGACY_SYNTAX_CONVERTED` warning: `INSERT DELAYED is no longer supported. The statement was converted to INSERT`. The `DELAYED` keyword is scheduled for removal in a future release.

**13.2.7 LOAD DATA Statement**

```sql
LOAD DATA
  [LOW_PRIORITY | CONCURRENT] [LOCAL]
  INFILE 'file_name'
  [REPLACE | IGNORE]
  INTO TABLE tbl_name
  [PARTITION (partition_name [, partition_name] ...)]
  [CHARACTER SET charset_name]
  [FIELDS | COLUMNS]
    [TERMINATED BY 'string']
    [[OPTIONALLY] ENCLOSED BY 'char']
    [ESCAPED BY 'char']
  ]
  [LINES
    [STARTING BY 'string']
```
The **LOAD DATA** statement reads rows from a text file into a table at a very high speed. The file can be read from the server host or the client host, depending on whether the **LOCAL** modifier is given. **LOCAL** also affects data interpretation and error handling.

**LOAD DATA** is the complement of **SELECT ... INTO OUTFILE**. (See Section 13.2.10.1, “**SELECT ... INTO Statement**”.) To write data from a table to a file, use **SELECT ... INTO OUTFILE**. To read the file back into a table, use **LOAD DATA**. The syntax of the **FIELDS** and **LINES** clauses is the same for both statements.

The **mysqlimport** utility provides another way to load data files; it operates by sending a **LOAD DATA** statement to the server. See Section 4.5.5, “**mysqlimport — A Data Import Program**”.

For information about the efficiency of **INSERT** versus **LOAD DATA** and speeding up **LOAD DATA**, see Section 8.2.5.1, “Optimizing **INSERT** Statements”.

- **Non-LOCAL Versus LOCAL Operation**
- **Input File Character Set**
- **Input File Location**
- **Security Requirements**
- **Duplicate-Key and Error Handling**
- **Index Handling**
- **Field and Line Handling**
- **Column List Specification**
- **Input Preprocessing**
- **Column Value Assignment**
- **Partitioned Table Support**
- **Concurrency Considerations**
- **Statement Result Information**
- **Replication Considerations**
- **Miscellaneous Topics**

**Non-LOCAL Versus LOCAL Operation**

The **LOCAL** modifier affects these aspects of **LOAD DATA**, compared to non-LOCAL operation:

- It changes the expected location of the input file; see **Input File Location**.
- It changes the statement security requirements; see **Security Requirements**.
- It has the same effect as the **IGNORE** modifier on the interpretation of input file contents and error handling; see **Duplicate-Key and Error Handling**, and **Column Value Assignment**.
**LOAD DATA Statement**

**LOCAL** works only if the server and your client both have been configured to permit it. For example, if `mysqld` was started with the `local_infile` system variable disabled, **LOCAL** produces an error. See Section 6.1.6, “Security Considerations for LOAD DATA LOCAL”.

**Input File Character Set**

The file name must be given as a literal string. On Windows, specify backslashes in path names as forward slashes or doubled backslashes. The server interprets the file name using the character set indicated by the `character_set_filesystem` system variable.

By default, the server interprets the file contents using the character set indicated by the `character_set_database` system variable. If the file contents use a character set different from this default, it is a good idea to specify that character set by using the `CHARACTER SET` clause. A character set of `binary` specifies “no conversion.”

**SET NAMES** and the setting of `character_set_client` do not affect interpretation of file contents.

**LOAD DATA** interprets all fields in the file as having the same character set, regardless of the data types of the columns into which field values are loaded. For proper interpretation of the file, you must ensure that it was written with the correct character set. For example, if you write a data file with `mysqldump -T` or by issuing a `SELECT ... INTO OUTFILE` statement in `mysql`, be sure to use a `--default-character-set` option to write output in the character set to be used when the file is loaded with **LOAD DATA**.

**Note**

It is not possible to load data files that use the `ucs2`, `utf16`, `utf16le`, or `utf32` character set.

**Input File Location**

These rules determine the **LOAD DATA** input file location:

- If **LOCAL** is not specified, the file must be located on the server host. The server reads the file directly, locating it as follows:
  - If the file name is an absolute path name, the server uses it as given.
  - If the file name is a relative path name with leading components, the server looks for the file relative to its data directory.
  - If the file name has no leading components, the server looks for the file in the database directory of the default database.

- If **LOCAL** is specified, the file must be located on the client host. The client program reads the file, locating it as follows:
  - If the file name is an absolute path name, the client program uses it as given.
  - If the file name is a relative path name, the client program looks for the file relative to its invocation directory.

When **LOCAL** is used, the client program reads the file and sends its contents to the server. The server creates a copy of the file in the directory where it stores temporary files. See Section 6.1.6, “Where MySQL Stores Temporary Files”. Lack of sufficient space for the copy in this directory can cause the **LOAD DATA LOCAL** statement to fail.

The non-**LOCAL** rules mean that the server reads a file named as `.myfile.txt` relative to its data directory, whereas it reads a file named as `myfile.txt` from the database directory of the default database. For example, if the following **LOAD DATA** statement is executed while `db1` is the default...
database, the server reads the file `data.txt` from the database directory for `db1`, even though the statement explicitly loads the file into a table in the `db2` database:

```sql
LOAD DATA INFILE 'data.txt' INTO TABLE db2.my_table;
```

### Note

The server also uses the non-`LOCAL` rules to locate `.sdi` files for the `IMPORT TABLE` statement.

### Security Requirements

For a non-`LOCAL` load operation, the server reads a text file located on the server host, so these security requirements must be satisfied:

- You must have the `FILE` privilege. See Section 6.2.2, “Privileges Provided by MySQL”.
- The operation is subject to the `secure_file_priv` system variable setting:
  - If the variable value is a nonempty directory name, the file must be located in that directory.
  - If the variable value is empty (which is insecure), the file need only be readable by the server.

For a `LOCAL` load operation, the client program reads a text file located on the client host. Because the file contents are sent over the connection by the client to the server, using `LOCAL` is a bit slower than when the server accesses the file directly. On the other hand, you do not need the `FILE` privilege, and the file can be located in any directory the client program can access.

### Duplicate-Key and Error Handling

The `REPLACE` and `IGNORE` modifiers control handling of new (input) rows that duplicate existing table rows on unique key values (`PRIMARY KEY` or `UNIQUE` index values):

- With `REPLACE`, new rows that have the same value as a unique key value in an existing row replace the existing row. See Section 13.2.9, “REPLACE Statement”.
- With `IGNORE`, new rows that duplicate an existing row on a unique key value are discarded. For more information, see The Effect of `IGNORE` on Statement Execution.

The `LOCAL` modifier has the same effect as `IGNORE`. This occurs because the server has no way to stop transmission of the file in the middle of the operation.

If none of `REPLACE`, `IGNORE`, or `LOCAL` is specified, an error occurs when a duplicate key value is found, and the rest of the text file is ignored.

In addition to affecting duplicate-key handling as just described, `IGNORE` and `LOCAL` also affect error handling:

- With neither `IGNORE` nor `LOCAL`, data-interpretation errors terminate the operation.
- With `IGNORE` or `LOCAL`, data-interpretation errors become warnings and the load operation continues, even if the SQL mode is restrictive. For examples, see Column Value Assignment.

### Index Handling

To ignore foreign key constraints during the load operation, execute a `SET foreign_key_checks = 0` statement before executing `LOAD DATA`.

If you use `LOAD DATA` on an empty `MyISAM` table, all nonunique indexes are created in a separate batch (as for `REPAIR TABLE`). Normally, this makes `LOAD DATA` much faster when you have many
indexes. In some extreme cases, you can create the indexes even faster by turning them off with
`ALTER TABLE ... DISABLE KEYS` before loading the file into the table and re-creating the indexes
with `ALTER TABLE ... ENABLE KEYS` after loading the file. See Section 8.2.5.1, “Optimizing
`INSERT Statements”.

Field and Line Handling

For both the `LOAD DATA` and `SELECT ... INTO OUTFILE` statements, the syntax of the `FIELDS`
and `LINES` clauses is the same. Both clauses are optional, but `FIELDS` must precede `LINES` if both
are specified.

If you specify a `FIELDS` clause, each of its subclauses (`TERMINATED BY`, `[OPTIONALLY] ENCLOSSED
BY`, and `ESCAPED BY`) is also optional, except that you must specify at least one of them. Arguments to
these clauses are permitted to contain only ASCII characters.

If you specify no `FIELDS` or `LINES` clause, the defaults are the same as if you had written this:

```
FIELDS TERMINATED BY '"' ENCLOSED BY '' ESCAPED BY '\'
LINES TERMINATED BY '
' STARTING BY ''
```

Backslash is the MySQL escape character within strings in SQL statements. Thus, to specify a literal
backslash, you must specify two backslashes for the value to be interpreted as a single backslash. The
escape sequences `\t` and `\n` specify tab and newline characters, respectively.

In other words, the defaults cause `LOAD DATA` to act as follows when reading input:

- Look for line boundaries at newlines.
- Do not skip any line prefix.
- Break lines into fields at tabs.
- Do not expect fields to be enclosed within any quoting characters.
- Interpret characters preceded by the escape character \ as escape sequences. For example,
  `\t`, `\n`, and `\\` signify tab, newline, and backslash, respectively. See the discussion of `FIELDS
  ESCAPED BY` later for the full list of escape sequences.

Conversely, the defaults cause `SELECT ... INTO OUTFILE` to act as follows when writing output:

- Write tabs between fields.
- Do not enclose fields within any quoting characters.
- Use `\` to escape instances of tab, newline, or `\` that occur within field values.
- Write newlines at the ends of lines.

**Note**

For a text file generated on a Windows system, proper file reading might require
`LINES TERMINATED BY '"\n'` because Windows programs typically use
two characters as a line terminator. Some programs, such as WordPad, might
use `\r` as a line terminator when writing files. To read such files, use `LINES
TERMINATED BY '"\r'`.

If all the input lines have a common prefix that you want to ignore, you can use `LINES STARTING BY
'prefix_string'` to skip the prefix and anything before it. If a line does not include the prefix, the
entire line is skipped. Suppose that you issue the following statement:

```
LOAD DATA INFILE '/tmp/test.txt' INTO TABLE test
FIELDS TERMINATED BY ',' LINES STARTING BY 'xxx';
```
If the data file looks like this:

```
xxx"abc",1
something xxx"def",2
"ghi",3
```

The resulting rows are ("abc",1) and ("def",2). The third row in the file is skipped because it does not contain the prefix.

The **IGNORE number LINES** clause can be used to ignore lines at the start of the file. For example, you can use **IGNORE 1 LINES** to skip an initial header line containing column names:

```
LOAD DATA INFILE '/tmp/test.txt' INTO TABLE test IGNORE 1 LINES;
```

When you use **SELECT ... INTO OUTFILE** in tandem with **LOAD DATA** to write data from a database into a file and then read the file back into the database later, the field- and line-handling options for both statements must match. Otherwise, **LOAD DATA** does not interpret the contents of the file properly. Suppose that you use **SELECT ... INTO OUTFILE** to write a file with fields delimited by commas:

```
SELECT * INTO OUTFILE 'data.txt'
    FIELDS TERMINATED BY ','
FROM table2;
```

To read the comma-delimited file, the correct statement is:

```
LOAD DATA INFILE 'data.txt' INTO TABLE table2
    FIELDS TERMINATED BY ',';
```

If instead you tried to read the file with the statement shown following, it would not work because it instructs **LOAD DATA** to look for tabs between fields:

```
LOAD DATA INFILE 'data.txt' INTO TABLE table2
    FIELDS TERMINATED BY '\t';
```

The likely result is that each input line would be interpreted as a single field.

**LOAD DATA** can be used to read files obtained from external sources. For example, many programs can export data in comma-separated values (CSV) format, such that lines have fields separated by commas and enclosed within double quotation marks, with an initial line of column names. If the lines in such a file are terminated by carriage return/newline pairs, the statement shown here illustrates the field- and line-handling options you would use to load the file:

```
LOAD DATA INFILE 'data.txt' INTO TABLE `tbl_name`
    FIELDS TERMINATED BY '\'',
    ENCLOSED BY '"',
    LINES TERMINATED BY '\r\n'
    IGNORE 1 LINES;
```

If the input values are not necessarily enclosed within quotation marks, use **OPTIONALLY** before the **ENCLOSED BY** option.

Any of the field- or line-handling options can specify an empty string ("''). If not empty, the **FIELDS [OPTIONALLY] ENCLOSED BY** and **FIELDS ESCAPED BY** values must be a single character. The **FIELDS TERMINATED BY**, **LINES STARTING BY**, and **LINES TERMINATED BY** values can be more than one character. For example, to write lines that are terminated by carriage return/linefeed pairs, or to read a file containing such lines, specify a **LINES TERMINATED BY '\r\n'** clause.

To read a file containing jokes that are separated by lines consisting of %%%, you can do this:

```
CREATE TABLE jokes
    (a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
     joke TEXT NOT NULL);
LOAD DATA INFILE '/tmp/jokes.txt' INTO TABLE jokes
    FIELDS TERMINATED BY ' ';
```
LOAD DATA Statement

LINES TERMINATED BY '\n%%\n' (joke);

FIELDS [OPTIONALLY] ENCLOSED BY controls quoting of fields. For output (SELECT ... INTO OUTFILE), if you omit the word OPTIONALLY, all fields are enclosed by the ENCLOSED BY character. An example of such output (using a comma as the field delimiter) is shown here:

1,"a string","100.20"
2,"a string containing a , comma","102.20"
3,"a string containing a " quote","102.20"
4,"a string containing a ", quote and comma","102.20"

If you specify OPTIONALLY, the ENCLOSED BY character is used only to enclose values from columns that have a string data type (such as CHAR, BINARY, TEXT, or ENUM):

1,"a string",100.20
2,"a string containing a , comma",102.20
3,"a string containing a " quote",102.20
4,"a string containing a ", quote and comma",102.20

Occurrences of the ENCLOSED BY character within a field value are escaped by prefixing them with the ESCAPED BY character. Also, if you specify an empty ESCAPED BY value, it is possible to inadvertently generate output that cannot be read properly by LOAD DATA. For example, the preceding output just shown would appear as follows if the escape character is empty. Observe that the second field in the fourth line contains a comma following the quote, which (erroneously) appears to terminate the field:

1,"a string",100.20
2,"a string containing a , comma",102.20
3,"a string containing a " quote",102.20
4,"a string containing a ", quote and comma",102.20

For input, the ENCLOSED BY character, if present, is stripped from the ends of field values. (This is true regardless of whether OPTIONALLY is specified; OPTIONALLY has no effect on input interpretation.) Occurrences of the ENCLOSED BY character preceded by the ESCAPED BY character are interpreted as part of the current field value.

If the field begins with the ENCLOSED BY character, instances of that character are recognized as terminating a field value only if followed by the field or line TERMINATED BY sequence. To avoid ambiguity, occurrences of the ENCLOSED BY character within a field value can be doubled and are interpreted as a single instance of the character. For example, if ENCLOSED BY ' " ' is specified, quotation marks are handled as shown here:

"The ""BIG"" boss"  ->  The "BIG" boss
The "BIG" boss    ->  The "BIG" boss
The ""BIG"" boss   ->  The ""BIG"" boss

FIELDS ESCAPED BY controls how to read or write special characters:

- For input, if the FIELDS ESCAPED BY character is not empty, occurrences of that character are stripped and the following character is taken literally as part of a field value. Some two-character sequences that are exceptions, where the first character is the escape character. These sequences are shown in the following table (using \ for the escape character). The rules for NULL handling are described later in this section.

<table>
<thead>
<tr>
<th>Character</th>
<th>Escape Sequence</th>
</tr>
</thead>
<tbody>
<tr>
<td>\0</td>
<td>An ASCII NUL (X'00') character</td>
</tr>
<tr>
<td>\b</td>
<td>A backspace character</td>
</tr>
<tr>
<td>\n</td>
<td>A newline (linefeed) character</td>
</tr>
<tr>
<td>\r</td>
<td>A carriage return character</td>
</tr>
<tr>
<td>\t</td>
<td>A tab character.</td>
</tr>
<tr>
<td>\z</td>
<td>ASCII 26 (Control+Z)</td>
</tr>

2443
LOAD DATA Statement

Character | Escape Sequence
---|---
\N | NULL

For more information about \\ escape syntax, see Section 9.1.1, “String Literals”.

If the FIELDS ESCAPED BY character is empty, escape-sequence interpretation does not occur.

• For output, if the FIELDS ESCAPED BY character is not empty, it is used to prefix the following characters on output:
  • The FIELDS ESCAPED BY character.
  • The FIELDS [OPTIONALLY] ENCLOSED BY character.
  • The first character of the FIELDS TERMINATED BY and LINES TERMINATED BY values, if the ENCLOSED BY character is empty or unspecified.
  • ASCII 0 (what is actually written following the escape character is ASCII 0, not a zero-valued byte).

If the FIELDS ESCAPED BY character is empty, no characters are escaped and NULL is output as NULL, not \N. It is probably not a good idea to specify an empty escape character, particularly if field values in your data contain any of the characters in the list just given.

In certain cases, field- and line-handling options interact:

• If LINES TERMINATED BY is an empty string and FIELDS TERMINATED BY is nonempty, lines are also terminated with FIELDS TERMINATED BY.

• If the FIELDS TERMINATED BY and FIELDS ENCLOSED BY values are both empty (‘ ’), a fixed-row (nondelimited) format is used. With fixed-row format, no delimiters are used between fields (but you can still have a line terminator). Instead, column values are read and written using a field width wide enough to hold all values in the field. For TINYINT, SMALLINT, MEDIUMINT, INT, and BIGINT, the field widths are 4, 6, 8, 11, and 20, respectively, no matter what the declared display width is.

LINES TERMINATED BY is still used to separate lines. If a line does not contain all fields, the rest of the columns are set to their default values. If you do not have a line terminator, you should set this to ‘ ’. In this case, the text file must contain all fields for each row.

Fixed-row format also affects handling of NULL values, as described later.

Note
Fixed-size format does not work if you are using a multibyte character set.

Handling of NULL values varies according to the FIELDS and LINES options in use:

• For the default FIELDS and LINES values, NULL is written as a field value of \N for output, and a field value of \N is read as NULL for input (assuming that the ESCAPED BY character is \\).

• If FIELDS ENCLOSED BY is not empty, a field containing the literal word NULL as its value is read as a NULL value. This differs from the word NULL enclosed within FIELDS ENCLOSED BY characters, which is read as the string ‘NULL’.

• If FIELDS ESCAPED BY is empty, NULL is written as the word NULL.

• With fixed-row format (which is used when FIELDS TERMINATED BY and FIELDS ENCLOSED BY are both empty), NULL is written as an empty string. This causes both NULL values and empty strings in the table to be indistinguishable when written to the file because both are written as empty strings. If you need to be able to tell the two apart when reading the file back in, you should not use fixed-row format.
An attempt to load NULL into a NOT NULL column produces either a warning or an error according to the rules described in Column Value Assignment.

Some cases are not supported by LOAD DATA:

- Fixed-size rows (FIELDS TERMINATED BY and FIELDS ENCLOSED BY both empty) and BLOB or TEXT columns.

- If you specify one separator that is the same as or a prefix of another, LOAD DATA cannot interpret the input properly. For example, the following FIELDS clause would cause problems:

  ```sql
  FIELDS TERMINATED BY '"' ENCLOSED BY '"'
  ```

- If FIELDS ESCAPED BY is empty, a field value that contains an occurrence of FIELDS ENCLOSED BY or LINES TERMINATED BY followed by the FIELDS TERMINATED BY value causes LOAD DATA to stop reading a field or line too early. This happens because LOAD DATA cannot properly determine where the field or line value ends.

**Column List Specification**

The following example loads all columns of the persondata table:

```sql
LOAD DATA INFILE 'persondata.txt' INTO TABLE persondata;
```

By default, when no column list is provided at the end of the LOAD DATA statement, input lines are expected to contain a field for each table column. If you want to load only some of a table's columns, specify a column list:

```sql
LOAD DATA INFILE 'persondata.txt' INTO TABLE persondata
(col_name_or_user_var [, col_name_or_user_var] ...);
```

You must also specify a column list if the order of the fields in the input file differs from the order of the columns in the table. Otherwise, MySQL cannot tell how to match input fields with table columns.

**Input Preprocessing**

Each instance of `col_name_or_user_var` in LOAD DATA syntax is either a column name or a user variable. With user variables, the SET clause enables you to perform preprocessing transformations on their values before assigning the result to columns.

User variables in the SET clause can be used in several ways. The following example uses the first input column directly for the value of `t1.column1`, and assigns the second input column to a user variable that is subjected to a division operation before being used for the value of `t1.column2`:

```sql
LOAD DATA INFILE 'file.txt' INTO TABLE t1
(column1, @var1)
SET column2 = @var1/100;
```

The SET clause can be used to supply values not derived from the input file. The following statement sets `column3` to the current date and time:

```sql
LOAD DATA INFILE 'file.txt' INTO TABLE t1
(column1, column2)
SET column3 = CURRENT_TIMESTAMP;
```

You can also discard an input value by assigning it to a user variable and not assigning the variable to any table column:

```sql
LOAD DATA INFILE 'file.txt' INTO TABLE t1
(column1, @dummy, column2, @dummy, column3);
```

Use of the column/variable list and SET clause is subject to the following restrictions:
LOAD DATA Statement

- Assignments in the `SET` clause should have only column names on the left hand side of assignment operators.

- You can use subqueries in the right hand side of `SET` assignments. A subquery that returns a value to be assigned to a column may be a scalar subquery only. Also, you cannot use a subquery to select from the table that is being loaded.

- Lines ignored by an `IGNORE number LINES` clause are not processed for the column/variable list or `SET` clause.

- User variables cannot be used when loading data with fixed-row format because user variables do not have a display width.

Column Value Assignment

To process an input line, `LOAD DATA` splits it into fields and uses the values according to the column/variable list and the `SET` clause, if they are present. Then the resulting row is inserted into the table. If there are `BEFORE INSERT` or `AFTER INSERT` triggers for the table, they are activated before or after inserting the row, respectively.

Interpretation of field values and assignment to table columns depends on these factors:

- The SQL mode (the value of the `sql_mode` system variable). The mode can be nonstrictive, or restrictive in various ways. For example, strict SQL mode can be enabled, or the mode can include values such as `NO_ZERO_DATE` or `NO_ZERO_IN_DATE`

- Presence or absence of the `IGNORE` and `LOCAL` modifiers.

Those factors combine to produce restrictive or nonrestrictive data interpretation by `LOAD DATA`:

- Data interpretation is restrictive if the SQL mode is restrictive and neither the `IGNORE` nor the `LOCAL` modifier is specified. Errors terminate the load operation.

- Data interpretation is nonrestrictive if the SQL mode is nonrestrictive or the `IGNORE` or `LOCAL` modifier is specified. (In particular, either modifier if specified overrides a restrictive SQL mode.) Errors become warnings and the load operation continues.

Restrictive data interpretation uses these rules:

- Too many or too few fields results an error.

- Assigning `NULL` (that is, `\N`) to a non-`NULL` column results in an error.

- A value that is out of range for the column data type results in an error.

- Invalid values produce errors. For example, a value such as `'x'` for a numeric column results in an error, not conversion to 0.

By contrast, nonrestrictive data interpretation uses these rules:

- If an input line has too many fields, the extra fields are ignored and the number of warnings is incremented.

- If an input line has too few fields, the columns for which input fields are missing are assigned their default values. Default value assignment is described in Section 11.6, "Data Type Default Values".

- Assigning `NULL` (that is, `\N`) to a non-`NULL` column results in assignment of the implicit default value for the column data type. Implicit default values are described in Section 11.6, "Data Type Default Values".

- Invalid values produce warnings rather than errors, and are converted to the "closest" valid value for the column data type. Examples:
LOAD DATA Statement

- A value such as 'x' for a numeric column results in conversion to 0.
- An out-of-range numeric or temporal value is clipped to the closest endpoint of the range for the column data type.
- An invalid value for a DATETIME, DATE, or TIME column is inserted as the implicit default value, regardless of the SQL mode NO_ZERO_DATE setting. The implicit default is the appropriate "zero" value for the type ('0000-00-00 00:00:00', '0000-00-00', or '00:00:00'). See Section 11.2, "Date and Time Data Types".

LOAD DATA interprets an empty field value differently from a missing field:

- For string types, the column is set to the empty string.
- For numeric types, the column is set to 0.
- For date and time types, the column is set to the appropriate “zero” value for the type. See Section 11.2, "Date and Time Data Types".

These are the same values that result if you assign an empty string explicitly to a string, numeric, or date or time type explicitly in an INSERT or UPDATE statement.

TIMESTAMP columns are set to the current date and time only if there is a NULL value for the column (that is, \N) and the column is not declared to permit NULL values, or if the TIMESTAMP column default value is the current timestamp and it is omitted from the field list when a field list is specified.

LOAD DATA regards all input as strings, so you cannot use numeric values for ENUM or SET columns the way you can with INSERT statements. All ENUM and SET values must be specified as strings.

BIT values cannot be loaded directly using binary notation (for example, b'011010'). To work around this, use the SET clause to strip off the leading b' and trailing ' and perform a base-2 to base-10 conversion so that MySQL loads the values into the BIT column properly:

```
shell> cat /tmp/bit_test.txt
b'10'
b'1111111'
shell> mysql test
mysql> LOAD DATA INFILE '/tmp/bit_test.txt'
    INTO TABLE bit_test (@var1)
    SET b = CAST(CONV(MID(@var1, 3, LENGTH(@var1)-3), 2, 10) AS UNSIGNED);
Query OK, 2 rows affected (0.00 sec)
Records: 2  Deleted: 0  Skipped: 0  Warnings: 0

mysql> SELECT BIN(b+0) FROM bit_test;
+----------+
<table>
<thead>
<tr>
<th>BIN(b+0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
</tr>
<tr>
<td>11111111</td>
</tr>
</tbody>
</table>
+----------+
2 rows in set (0.00 sec)
```

For BIT values in 0b binary notation (for example, 0b011010), use this SET clause instead to strip off the leading 0b:

```
SET b = CAST(CONV(MID(@var1, 3, LENGTH(@var1)-2), 2, 10) AS UNSIGNED)
```

Partitioned Table Support

LOAD DATA supports explicit partition selection using the PARTITION clause with a list of one or more comma-separated names of partitions, subpartitions, or both. When this clause is used, if any rows from the file cannot be inserted into any of the partitions or subpartitions named in the list, the statement fails with the error Found a row not matching the given partition set. For more information and examples, see Section 24.5, "Partition Selection".
Concurrency Considerations

With the `LOW_PRIORITY` modifier, execution of the `LOAD DATA` statement is delayed until no other clients are reading from the table. This affects only storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`).

With the `CONCURRENT` modifier and a `MyISAM` table that satisfies the condition for concurrent inserts (that is, it contains no free blocks in the middle), other threads can retrieve data from the table while `LOAD DATA` is executing. This modifier affects the performance of `LOAD DATA` a bit, even if no other thread is using the table at the same time.

Statement Result Information

When the `LOAD DATA` statement finishes, it returns an information string in the following format:

```
Records: 1  Deleted: 0  Skipped: 0  Warnings: 0
```

Warnings occur under the same circumstances as when values are inserted using the `INSERT` statement (see Section 13.2.6, “INSERT Statement”), except that `LOAD DATA` also generates warnings when there are too few or too many fields in the input row.

You can use `SHOW WARNINGS` to get a list of the first `max_error_count` warnings as information about what went wrong. See Section 13.7.7.42, "SHOW WARNINGS Statement".

If you are using the C API, you can get information about the statement by calling the `mysql_info()` function. See `mysql_info()`.

Replication Considerations

`LOAD DATA` is considered unsafe for statement-based replication. If you use `LOAD DATA` with `binlog_format=STATEMENT`, each replica on which the changes are to be applied creates a temporary file containing the data. This temporary file is not encrypted, even if binary log encryption is active on the source. If encryption is required, use row-based or mixed binary logging format instead, for which replicas do not create the temporary file. For more information on the interaction between `LOAD DATA` and replication, see Section 17.5.1.19, “Replication and LOAD DATA”.

Miscellaneous Topics

On Unix, if you need `LOAD DATA` to read from a pipe, you can use the following technique (the example loads a listing of the `/` directory into the table `tbl1.t1`):

```
mkfifo /mysql/data/db1/ls.dat
chmod 666 /mysql/data/db1/ls.dat
find / -ls > /mysql/data/db1/ls.dat &
mysql -e "LOAD DATA INFILE 'ls.dat' INTO TABLE t1" db1
```

Here you must run the command that generates the data to be loaded and the `mysql` commands either on separate terminals, or run the data generation process in the background (as shown in the preceding example). If you do not do this, the pipe blocks until data is read by the `mysql` process.

13.2.8 LOAD XML Statement

```sql
LOAD XML
[LOW_PRIORITY | CONCURRENT] [LOCAL]
INFILE 'file_name'
[REPLACE | IGNORE]
INTO TABLE [db_name.][tbl_name]
[CHARACTER SET charset_name]
[ROWS IDENTIFIED BY '<tagname>'
[IGNORE number (LINES | ROWS)]
[(field_name_or_user_var [,...])]
[SET col_name={expr | DEFAULT}]
```
The LOAD XML statement reads data from an XML file into a table. The file_name must be given as a literal string. The tagname in the optional ROWS IDENTIFIED BY clause must also be given as a literal string, and must be surrounded by angle brackets (< and >).

LOAD XML acts as the complement of running the mysql client in XML output mode (that is, starting the client with the --xml option). To write data from a table to an XML file, you can invoke the mysql client with the --xml and -e options from the system shell, as shown here:

```shell>
mysql --xml -e 'SELECT * FROM mydb.mytable' > file.xml
```

To read the file back into a table, use LOAD XML. By default, the <row> element is considered to be the equivalent of a database table row; this can be changed using the ROWS IDENTIFIED BY clause.

This statement supports three different XML formats:

1. **Column names as attributes and column values as attribute values**:

   ```xml
   <row column1="value1" column2="value2" .../>
   ```

2. **Column names as tags and column values as the content of these tags**:

   ```xml
   <row>
   <column1>value1</column1>
   <column2>value2</column2>
   </row>
   ```

3. **Column names are the name attributes of <field> tags, and values are the contents of these tags**:

   ```xml
   <row>
   <field name='column1'>value1</field>
   <field name='column2'>value2</field>
   </row>
   ```

   This is the format used by other MySQL tools, such as mysqldump.

All three formats can be used in the same XML file; the import routine automatically detects the format for each row and interprets it correctly. Tags are matched based on the tag or attribute name and the column name.

Prior to MySQL 8.0.21, LOAD XML did not support CDATA sections in the source XML. (Bug #30753708, Bug #98199)

The following clauses work essentially the same way for LOAD XML as they do for LOAD DATA:

- LOW_PRIORITY or CONCURRENT
- LOCAL
- REPLACE or IGNORE
- CHARACTER SET
- SET

See Section 13.2.7, “LOAD DATA Statement”, for more information about these clauses.

(field_name_or_user_var, ...) is a list of one or more comma-separated XML fields or user variables. The name of a user variable used for this purpose must match the name of a field from the XML file, prefixed with @. You can use field names to select only desired fields. User variables can be employed to store the corresponding field values for subsequent re-use.

The IGNORE number LINES or IGNORE number ROWS clause causes the first number rows in the XML file to be skipped. It is analogous to the LOAD DATA statement's IGNORE ... LINES clause.
Suppose that we have a table named `person`, created as shown here:

```sql
USE test;
CREATE TABLE person (
    person_id INT NOT NULL PRIMARY KEY,
    fname VARCHAR(40) NULL,
    lname VARCHAR(40) NULL,
    created TIMESTAMP
);
```

Suppose further that this table is initially empty.

Now suppose that we have a simple XML file `person.xml`, whose contents are as shown here:

```xml
<list>
    <person person_id="1" fname="Kapek" lname="Sainnouine"/>
    <person person_id="2" fname="Sajon" lname="Rondela"/>
    <person person_id="3"><fname>Likame</fname><lname>Örrtmons</lname></person>
    <person person_id="4"><fname>Slar</fname><lname>Manlanth</lname></person>
    <person person_id="5"><field name="person_id">5</field><field name="fname">Stoma</field>
        <field name="lname">Nilu</field></person>
    <person person_id="6"><field name="person_id">6</field><field name="fname">Nirtam</field>
        <field name="lname">Sklöd</field></person>
    <person person_id="7"><fname>Sungam</fname><lname>Dulbåd</lname></person>
    <person person_id="8" fname="Sraref" lname="Encmelt"/>
</list>
```

Each of the permissible XML formats discussed previously is represented in this example file.

To import the data in `person.xml` into the `person` table, you can use this statement:

```sql
mysql> LOAD XML LOCAL INFILE 'person.xml'
    -> INTO TABLE person
    -> ROWS IDENTIFIED BY '<person>';
```

Query OK, 8 rows affected (0.00 sec)
Records: 8 Deleted: 0 Skipped: 0 Warnings: 0

Here, we assume that `person.xml` is located in the MySQL data directory. If the file cannot be found, the following error results:

```sql
ERROR 2 (HY000): File '/person.xml' not found (Errcode: 2)
```

The `ROWS IDENTIFIED BY '<person>'` clause means that each `<person>` element in the XML file is considered equivalent to a row in the table into which the data is to be imported. In this case, this is the `person` table in the `test` database.

As can be seen by the response from the server, 8 rows were imported into the `test.person` table. This can be verified by a simple `SELECT` statement:

```sql
mysql> SELECT * FROM person;
+-----------+--------+------------+---------------------+
<table>
<thead>
<tr>
<th>person_id</th>
<th>fname</th>
<th>lname</th>
<th>created</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Kapek</td>
<td>Sainnouine</td>
<td>2007-07-13 16:18:47</td>
</tr>
<tr>
<td>2</td>
<td>Sajon</td>
<td>Rondela</td>
<td>2007-07-13 16:18:47</td>
</tr>
<tr>
<td>3</td>
<td>Likame</td>
<td>Örrtmons</td>
<td>2007-07-13 16:18:47</td>
</tr>
<tr>
<td>4</td>
<td>Slar</td>
<td>Manlanth</td>
<td>2007-07-13 16:18:47</td>
</tr>
<tr>
<td>5</td>
<td>Stoma</td>
<td>Nilu</td>
<td>2007-07-13 16:18:47</td>
</tr>
<tr>
<td>6</td>
<td>Nirtam</td>
<td>Sklöd</td>
<td>2007-07-13 16:18:47</td>
</tr>
<tr>
<td>7</td>
<td>Sungam</td>
<td>Dulbåd</td>
<td>2007-07-13 16:18:47</td>
</tr>
<tr>
<td>8</td>
<td>Sraref</td>
<td>Encmelt</td>
<td>2007-07-13 16:18:47</td>
</tr>
</tbody>
</table>
+-----------+--------+------------+---------------------+
8 rows in set (0.00 sec)
```

This shows, as stated earlier in this section, that any or all of the 3 permitted XML formats may appear in a single file and be read using `LOAD XML`.
The inverse of the import operation just shown—that is, dumping MySQL table data into an XML file—can be accomplished using the `mysql` client from the system shell, as shown here:

```
shell> mysql --xml -e "SELECT * FROM test.person" > person-dump.xml
shell> cat person-dump.xml
```

```
<?xml version="1.0"?>
<resultset statement="SELECT * FROM test.person" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
  <row>
    <field name="person_id">1</field>
    <field name="fname">Kapek</field>
    <field name="lname">Sainnouine</field>
  </row>
  <row>
    <field name="person_id">2</field>
    <field name="fname">Sajon</field>
    <field name="lname">Rondela</field>
  </row>
  <row>
    <field name="person_id">3</field>
    <field name="fname">Likema</field>
    <field name="lname">Örrtmons</field>
  </row>
  <row>
    <field name="person_id">4</field>
    <field name="fname">Slar</field>
    <field name="lname">Manlanth</field>
  </row>
  <row>
    <field name="person_id">5</field>
    <field name="fname">Stoma</field>
    <field name="lname">Nilu</field>
  </row>
  <row>
    <field name="person_id">6</field>
    <field name="fname">Nirtam</field>
    <field name="lname">Sklöd</field>
  </row>
  <row>
    <field name="person_id">7</field>
    <field name="fname">Sungam</field>
    <field name="lname">Dulbåd</field>
  </row>
  <row>
    <field name="person_id">8</field>
    <field name="fname">Sreraf</field>
    <field name="lname">Encmelt</field>
  </row>
</resultset>
```

**Note**
The `--xml` option causes the `mysql` client to use XML formatting for its output; the `-e` option causes the client to execute the SQL statement immediately following the option. See Section 4.5.1, “mysql — The MySQL Command-Line Client”.

You can verify that the dump is valid by creating a copy of the `person` table and importing the dump file into the new table, like this:

```
mysql> USE test;
mysql> CREATE TABLE person2 LIKE person;
Query OK, 0 rows affected (0.00 sec)
```
LOAD XML Statement

mysql> LOAD XML LOCAL INFILE 'person-dump.xml'
-> INTO TABLE person2;
Query OK, 8 rows affected (0.01 sec)
Records: 8 Deleted: 0 Skipped: 0 Warnings: 0

<table>
<thead>
<tr>
<th>person_id</th>
<th>fname</th>
<th>lname</th>
<th>created</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Kapek</td>
<td>Sainnouine</td>
<td>2007-07-13 16:18:47</td>
</tr>
<tr>
<td>2</td>
<td>Sajon</td>
<td>Rondela</td>
<td>2007-07-13 16:18:47</td>
</tr>
<tr>
<td>3</td>
<td>Likema</td>
<td>Örrtmons</td>
<td>2007-07-13 16:18:47</td>
</tr>
<tr>
<td>4</td>
<td>Slar</td>
<td>Manlanth</td>
<td>2007-07-13 16:18:47</td>
</tr>
<tr>
<td>5</td>
<td>Stoma</td>
<td>Nilu</td>
<td>2007-07-13 16:18:47</td>
</tr>
<tr>
<td>6</td>
<td>Nirtam</td>
<td>Sklöd</td>
<td>2007-07-13 16:18:47</td>
</tr>
<tr>
<td>7</td>
<td>Sungam</td>
<td>Dulbåd</td>
<td>2007-07-13 16:18:47</td>
</tr>
<tr>
<td>8</td>
<td>Sreraf</td>
<td>Encmelt</td>
<td>2007-07-13 16:18:47</td>
</tr>
</tbody>
</table>
8 rows in set (0.00 sec)

There is no requirement that every field in the XML file be matched with a column in the corresponding table. Fields which have no corresponding columns are skipped. You can see this by first emptying the person2 table and dropping the created column, then using the same LOAD XML statement we just employed previously, like this:

mysql> TRUNCATE person2;
Query OK, 8 rows affected (0.26 sec)

mysql> ALTER TABLE person2 DROP COLUMN created;
Query OK, 0 rows affected (0.52 sec)
Records: 0 Duplicates: 0 Warnings: 0

mysql> SHOW CREATE TABLE person2\G
*************************** 1. row ***************************
| Table: person2 |
Create Table: CREATE TABLE `person2` (
  `person_id` int(11) NOT NULL,
  `fname` varchar(40) DEFAULT NULL,
  `lname` varchar(40) DEFAULT NULL,
  PRIMARY KEY (`person_id`) ) ENGINE=InnoDB DEFAULT CHARSET=utf8

1 row in set (0.00 sec)

mysql> LOAD XML LOCAL INFILE 'person-dump.xml'
-> INTO TABLE person2;
Query OK, 8 rows affected (0.01 sec)
Records: 8 Deleted: 0 Skipped: 0 Warnings: 0

mysql> SELECT * FROM person2;
+-----------+--------+------------+
<table>
<thead>
<tr>
<th>person_id</th>
<th>fname</th>
<th>lname</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Kapek</td>
<td>Sainnouine</td>
</tr>
<tr>
<td>2</td>
<td>Sajon</td>
<td>Rondela</td>
</tr>
<tr>
<td>3</td>
<td>Likema</td>
<td>Örrtmons</td>
</tr>
<tr>
<td>4</td>
<td>Slar</td>
<td>Manlanth</td>
</tr>
<tr>
<td>5</td>
<td>Stoma</td>
<td>Nilu</td>
</tr>
<tr>
<td>6</td>
<td>Nirtam</td>
<td>Sklöd</td>
</tr>
<tr>
<td>7</td>
<td>Sungam</td>
<td>Dulbåd</td>
</tr>
<tr>

</table>
8 rows in set (0.00 sec)

The order in which the fields are given within each row of the XML file does not affect the operation of LOAD XML; the field order can vary from row to row, and is not required to be in the same order as the corresponding columns in the table.

As mentioned previously, you can use a (field_name_or_user_var, ... ) list of one or more XML fields (to select desired fields only) or user variables (to store the corresponding field values for
later use). User variables can be especially useful when you want to insert data from an XML file into table columns whose names do not match those of the XML fields. To see how this works, we first create a table named `individual` whose structure matches that of the `person` table, but whose columns are named differently:

```sql
mysql> CREATE TABLE individual (
    -> individual_id INT NOT NULL PRIMARY KEY,
    -> name1 VARCHAR(40) NULL,
    -> name2 VARCHAR(40) NULL,
    -> made TIMESTAMP
    ->);
Query OK, 0 rows affected (0.42 sec)
```

In this case, you cannot simply load the XML file directly into the table, because the field and column names do not match:

```sql
mysql> LOAD XML INFILE '../bin/person-dump.xml' INTO TABLE test.individual;
ERROR 1263 (22004): Column set to default value; NULL supplied to NOT NULL column 'individual_id' at row 1
```

This happens because the MySQL server looks for field names matching the column names of the target table. You can work around this problem by selecting the field values into user variables, then setting the target table's columns equal to the values of those variables using `SET`. You can perform both of these operations in a single statement, as shown here:

```sql
mysql> LOAD XML INFILE '../bin/person-dump.xml'
    -> INTO TABLE test.individual (@person_id, @fname, @lname, @created)
    -> SET individual_id=@person_id, name1=@fname, name2=@lname, made=@created;
Query OK, 8 rows affected (0.05 sec)
Records: 8  Deleted: 0  Skipped: 0  Warnings: 0
```

```sql
mysql> SELECT * FROM individual;
+---------------+--------+------------+---------------------+
<table>
<thead>
<tr>
<th>individual_id</th>
<th>name1</th>
<th>name2</th>
<th>made</th>
</tr>
</thead>
<tbody>

</tbody>
</table>
+---------------+--------+------------+---------------------+
8 rows in set (0.00 sec)
```

The names of the user variables must match those of the corresponding fields from the XML file, with the addition of the required @ prefix to indicate that they are variables. The user variables need not be listed or assigned in the same order as the corresponding fields.

Using a `ROWS IDENTIFIED BY '<tagname>'` clause, it is possible to import data from the same XML file into database tables with different definitions. For this example, suppose that you have a file named `address.xml` which contains the following XML:

```xml
<?xml version="1.0"?>
<list>
  <person person_id="1">
    <fname>Robert</fname>
    <lname>Jones</lname>
    <address address_id="1" street="Mill Creek Road" zip="45365" city="Sidney"/>
    <address address_id="2" street="Main Street" zip="28681" city="Taylorsville"/>
  </person>

  <person person_id="2">
    <fname>Mary</fname>
    <lname>Smith</lname>
    <address address_id="3" street="River Road" zip="80239" city="Denver"/>
</list>
```

```sql
mysql> SELECT * FROM address;
+-------------+----------------+-----------------+--------+
<table>
<thead>
<tr>
<th>address_id</th>
<th>street</th>
<th>zip</th>
<th>city</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Mill Creek Road</td>
<td>45365</td>
<td>Sidney</td>
</tr>
<tr>
<td>2</td>
<td>Main Street</td>
<td>28681</td>
<td>Taylorsville</td>
</tr>
<tr>
<td>3</td>
<td>River Road</td>
<td>80239</td>
<td>Denver</td>
</tr>
</tbody>
</table>
```

The `ROWS IDENTIFIED BY` clause identifies the rows from the XML file that are to be imported into the `address` table.
You can again use the `test.person` table as defined previously in this section, after clearing all the existing records from the table and then showing its structure as shown here:

```sql
mysql< TRUNCATE person;
Query OK, 0 rows affected (0.04 sec)

mysql< SHOW CREATE TABLE person\G
*************************** 1. row ***************************
Table: person
Create Table: CREATE TABLE `person` (  
`person_id` int(11) NOT NULL,  
`fname` varchar(40) DEFAULT NULL,  
`lname` varchar(40) DEFAULT NULL,  
`created` timestamp NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,  
PRIMARY KEY (`person_id`)  
) ENGINE=MyISAM DEFAULT CHARSET=utf8mb4
1 row in set (0.00 sec)
```

Now create an `address` table in the `test` database using the following `CREATE TABLE` statement:

```sql
CREATE TABLE address (  
  address_id INT NOT NULL PRIMARY KEY,  
  person_id INT NULL,  
  street VARCHAR(40) NULL,  
  zip INT NULL,  
  city VARCHAR(40) NULL,  
  created TIMESTAMP
);
```

To import the data from the XML file into the `person` table, execute the following `LOAD XML` statement, which specifies that rows are to be specified by the `<person>` element, as shown here;

```sql
mysql> LOAD XML LOCAL INFILE 'address.xml'  
  -> INTO TABLE person  
  -> ROWS IDENTIFIED BY '<person>';  
Query OK, 2 rows affected (0.00 sec)
Records: 2  Deleted: 0  Skipped: 0  Warnings: 0
```

You can verify that the records were imported using a `SELECT` statement:

```sql
mysql> SELECT * FROM person;
+-----------+--------+-------+---------------------+  
| person_id | fname  | lname | created             |  
|-----------+--------+-------+---------------------|  
|         1 | Robert | Jones | 2007-07-24 17:37:06 |  
|         2 | Mary   | Smith | 2007-07-24 17:37:06 |  
+-----------+--------+-------+---------------------+
2 rows in set (0.00 sec)
```

Since the `<address>` elements in the XML file have no corresponding columns in the `person` table, they are skipped.

To import the data from the `<address>` elements into the `address` table, use the `LOAD XML` statement shown here:

```sql
mysql> LOAD XML LOCAL INFILE 'address.xml'  
  -> INTO TABLE address  
  -> ROWS IDENTIFIED BY '<address>';  
Query OK, 3 rows affected (0.00 sec)
Records: 3  Deleted: 0  Skipped: 0  Warnings: 0
```

You can see that the data was imported using a `SELECT` statement such as this one:

```sql
mysql> SELECT * FROM address;
```
The data from the `<address>` element that is enclosed in XML comments is not imported. However, since there is a `person_id` column in the `address` table, the value of the `person_id` attribute from the parent `<person>` element for each `<address>` is imported into the `address` table.

**Security Considerations.** As with the `LOAD DATA` statement, the transfer of the XML file from the client host to the server host is initiated by the MySQL server. In theory, a patched server could be built that would tell the client program to transfer a file of the server’s choosing rather than the file named by the client in the `LOAD XML` statement. Such a server could access any file on the client host to which the client user has read access.

In a Web environment, clients usually connect to MySQL from a Web server. A user that can run any command against the MySQL server can use `LOAD XML LOCAL` to read any files to which the Web server process has read access. In this environment, the client with respect to the MySQL server is actually the Web server, not the remote program being run by the user who connects to the Web server.

You can disable loading of XML files from clients by starting the server with `--local-infile=0` or `--local-infile=OFF`. This option can also be used when starting the `mysql` client to disable `LOAD XML` for the duration of the client session.

To prevent a client from loading XML files from the server, do not grant the `FILE` privilege to the corresponding MySQL user account, or revoke this privilege if the client user account already has it.

---

### 13.2.9 REPLACE Statement

```
REPLACE [LOW_PRIORITY | DELAYED]
  [INTO] tbl_name
  [PARTITION (partition_name [, partition_name] ...)]
  [(col_name [, col_name] ...)]
  { VALUES | VALUE} (value_list) [, (value_list)] ... 
  | VALUES row_constructor_list

REPLACE [LOW_PRIORITY | DELAYED]
  [INTO] tbl_name
  [PARTITION (partition_name [, partition_name] ...)]
  SET assignment_list

REPLACE [LOW_PRIORITY | DELAYED]
  [INTO] tbl_name
  [PARTITION (partition_name [, partition_name] ...)]
  [(col_name [, col_name] ...)]
  {SELECT ... | TABLE table_name}
```
REPLACE works exactly like INSERT, except that if an old row in the table has the same value as a new row for a PRIMARY KEY or a UNIQUE index, the old row is deleted before the new row is inserted. See Section 13.2.6, “INSERT Statement”.

REPLACE is a MySQL extension to the SQL standard. It either inserts, or deletes and inserts. For another MySQL extension to standard SQL—that either inserts or updates—see Section 13.2.6.2, “INSERT ... ON DUPLICATE KEY UPDATE Statement”.

DELAYED inserts and replaces were deprecated in MySQL 5.6. In MySQL 8.0, DELAYED is not supported. The server recognizes but ignores the DELAYED keyword, handles the replace as a nondelayed replace, and generates an ER_WARN_LEGACY_SYNTAX_CONVERTED warning: REPLACE DELAYED is no longer supported. The statement was converted to REPLACE. The DELAYED keyword is scheduled for removal in a future release.

Note

REPLACE makes sense only if a table has a PRIMARY KEY or UNIQUE index. Otherwise, it becomes equivalent to INSERT, because there is no index to be used to determine whether a new row duplicates another.

Values for all columns are taken from the values specified in the REPLACE statement. Any missing columns are set to their default values, just as happens for INSERT. You cannot refer to values from the current row and use them in the new row. If you use an assignment such as SET col_name = col_name + 1, the reference to the column name on the right hand side is treated as DEFAULT(col_name), so the assignment is equivalent to SET col_name = DEFAULT(col_name) + 1.

In MySQL 8.0.19 and later, you can specify the column values that REPLACE attempts to insert using VALUES ROW().

To use REPLACE, you must have both the INSERT and DELETE privileges for the table.

If a generated column is replaced explicitly, the only permitted value is DEFAULT. For information about generated columns, see Section 13.1.20.8, “CREATE TABLE and Generated Columns”.

REPLACE supports explicit partition selection using the PARTITION clause with a list of comma-separated names of partitions, subpartitions, or both. As with INSERT, if it is not possible to insert the new row into any of these partitions or subpartitions, the REPLACE statement fails with the error Found a row not matching the given partition set. For more information and examples, see Section 24.5, “Partition Selection”.

The REPLACE statement returns a count to indicate the number of rows affected. This is the sum of the rows deleted and inserted. If the count is 1 for a single-row REPLACE, a row was inserted and no rows were deleted. If the count is greater than 1, one or more old rows were deleted before the new row was inserted. It is possible for a single row to replace more than one old row if the table contains multiple unique indexes and the new row duplicates values for different old rows in different unique indexes.
The affected-rows count makes it easy to determine whether `REPLACE` only added a row or whether it also replaced any rows: Check whether the count is 1 (added) or greater (replaced).

If you are using the C API, the affected-rows count can be obtained using the `mysql_affected_rows()` function.

You cannot replace into a table and select from the same table in a subquery.

MySQL uses the following algorithm for `REPLACE` (and `LOAD DATA ... REPLACE`):

1. Try to insert the new row into the table
2. While the insertion fails because a duplicate-key error occurs for a primary key or unique index:
   a. Delete from the table the conflicting row that has the duplicate key value
   b. Try again to insert the new row into the table

It is possible that in the case of a duplicate-key error, a storage engine may perform the `REPLACE` as an update rather than a delete plus insert, but the semantics are the same. There are no user-visible effects other than a possible difference in how the storage engine increments `Handler_`xxx` status variables.

Because the results of `REPLACE ... SELECT` statements depend on the ordering of rows from the `SELECT` and this order cannot always be guaranteed, it is possible when logging these statements for the source and the replica to diverge. For this reason, `REPLACE ... SELECT` statements are flagged as unsafe for statement-based replication. such statements produce a warning in the error log when using statement-based mode and are written to the binary log using the row-based format when using `MIXED` mode. See also Section 17.2.1.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”.

MySQL 8.0.19 and later supports `TABLE` as well as `SELECT` with `REPLACE`, just as it does with `INSERT`. See Section 13.2.6.1, “INSERT ... SELECT Statement”, for more information and examples.

When modifying an existing table that is not partitioned to accommodate partitioning, or, when modifying the partitioning of an already partitioned table, you may consider altering the table's primary key (see Section 24.6.1, “Partitioning Keys, Primary Keys, and Unique Keys”). You should be aware that, if you do this, the results of `REPLACE` statements may be affected, just as they would be if you modified the primary key of a nonpartitioned table. Consider the table created by the following `CREATE TABLE` statement:

```sql
CREATE TABLE test (
    id INT UNSIGNED NOT NULL AUTO_INCREMENT,
    data VARCHAR(64) DEFAULT NULL,
    ts TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
    PRIMARY KEY (id)
);
```

When we create this table and run the statements shown in the mysql client, the result is as follows:

```
mysql> REPLACE INTO test VALUES (1, 'Old', '2014-08-20 18:47:00');
Query OK, 1 row affected (0.04 sec)

mysql> REPLACE INTO test VALUES (1, 'New', '2014-08-20 18:47:42');
Query OK, 2 rows affected (0.04 sec)

mysql> SELECT * FROM test;
+----+------+---------------------+
| id | data | ts                  |
+----+------+---------------------+
|  1 | New  | 2014-08-20 18:47:42 |
+----+------+---------------------+
1 row in set (0.00 sec)
```

Now we create a second table almost identical to the first, except that the primary key now covers 2 columns, as shown here (emphasized text):
CREATE TABLE test2 {
    id INT UNSIGNED NOT NULL AUTO_INCREMENT,
    data VARCHAR(64) DEFAULT NULL,
    ts TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
    PRIMARY KEY (id, ts)
};

When we run on `test2` the same two REPLACE statements as we did on the original `test` table, we obtain a different result:

```sql
mysql> REPLACE INTO test2 VALUES (1, 'Old', '2014-08-20 18:47:00');
Query OK, 1 row affected (0.05 sec)

mysql> REPLACE INTO test2 VALUES (1, 'New', '2014-08-20 18:47:42');
Query OK, 1 row affected (0.06 sec)

mysql> SELECT * FROM test2;
+----+------+---------------------+
<table>
<thead>
<tr>
<th>id</th>
<th>data</th>
<th>ts</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Old</td>
<td>2014-08-20 18:47:00</td>
</tr>
<tr>
<td>1</td>
<td>New</td>
<td>2014-08-20 18:47:42</td>
</tr>
</tbody>
</table>
+----+------+---------------------+
2 rows in set (0.00 sec)
```

This is due to the fact that, when run on `test2`, both the `id` and `ts` column values must match those of an existing row for the row to be replaced; otherwise, a row is inserted.

### 13.2.10 SELECT Statement

**SELECT** is used to retrieve rows selected from one or more tables, and can include UNION statements and subqueries. See Section 13.2.10.3, “UNION Clause”, and Section 13.2.11, “Subqueries”. A SELECT statement can start with a WITH clause to define common table expressions accessible within the SELECT. See Section 13.2.15, “WITH (Common Table Expressions)”. The most commonly used clauses of SELECT statements are these:
• Each `select_expr` indicates a column that you want to retrieve. There must be at least one `select_expr`.

• `table_references` indicates the table or tables from which to retrieve rows. Its syntax is described in Section 13.2.10.2, “JOIN Clause”.

• `SELECT` supports explicit partition selection using the `PARTITION` clause with a list of partitions or subpartitions (or both) following the name of the table in a `table_reference` (see Section 13.2.10.2, “JOIN Clause”). In this case, rows are selected only from the partitions listed, and any other partitions of the table are ignored. For more information and examples, see Section 24.5, “Partition Selection”.

• The `WHERE` clause, if given, indicates the condition or conditions that rows must satisfy to be selected. `where_condition` is an expression that evaluates to true for each row to be selected. The statement selects all rows if there is no `WHERE` clause.

    In the `WHERE` expression, you can use any of the functions and operators that MySQL supports, except for aggregate (group) functions. See Section 9.5, “Expressions”, and Chapter 12, `Functions and Operators`.

`SELECT` can also be used to retrieve rows computed without reference to any table.

For example:

```sql
mysql> SELECT 1 + 1;
  -> 2
```

You are permitted to specify `DUAL` as a dummy table name in situations where no tables are referenced:

```sql
mysql> SELECT 1 + 1 FROM DUAL;
  -> 2
```

`DUAL` is purely for the convenience of people who require that all `SELECT` statements should have `FROM` and possibly other clauses. MySQL may ignore the clauses. MySQL does not require `FROM DUAL` if no tables are referenced.

In general, clauses used must be given in exactly the order shown in the syntax description. For example, a `HAVING` clause must come after any `GROUP BY` clause and before any `ORDER BY` clause. The `INTO` clause, if present, can appear in any position indicated by the syntax description, but within a given statement can appear only once, not in multiple positions. For more information about `INTO`, see Section 13.2.10.1, “SELECT ... INTO Statement”.

The list of `select_expr` terms comprises the select list that indicates which columns to retrieve. Terms specify a column or expression or can use `*`-shorthand:

• A select list consisting only of a single unqualified `*` can be used as shorthand to select all columns from all tables:

  ```sql
  SELECT * FROM t1 INNER JOIN t2 ... 
  ```

• `tbl_name.*` can be used as a qualified shorthand to select all columns from the named table:

  ```sql
  SELECT t1.*, t2.* FROM t1 INNER JOIN t2 ... 
  ```

• If a table has invisible columns, `*` and `tbl_name.*` do not include them. To be included, invisible columns must be referenced explicitly.

• Use of an unqualified `*` with other items in the select list may produce a parse error. To avoid this problem, use a qualified `tbl_name.*` reference:

  ```sql
  SELECT AVG(score), t1.* FROM t1 ... 
  ```

The following list provides additional information about other `SELECT` clauses:
SELECT Statement

- A select_expr can be given an alias using AS alias_name. The alias is used as the expression's column name and can be used in GROUP BY, ORDER BY, or HAVING clauses. For example:

```sql
SELECT CONCAT(last_name, ', ', first_name) AS full_name
FROM mytable ORDER BY full_name;
```

The AS keyword is optional when aliasing a select_expr with an identifier. The preceding example could have been written like this:

```sql
SELECT CONCAT(last_name, ', ', first_name) full_name
FROM mytable ORDER BY full_name;
```

However, because the AS is optional, a subtle problem can occur if you forget the comma between two select_expr expressions: MySQL interprets the second as an alias name. For example, in the following statement, columnb is treated as an alias name:

```sql
SELECT columna columnb FROM mytable;
```

For this reason, it is good practice to be in the habit of using AS explicitly when specifying column aliases.

It is not permissible to refer to a column alias in a WHERE clause, because the column value might not yet be determined when the WHERE clause is executed. See Section B.3.4.4, “Problems with Column Aliases”.

- The FROM table_references clause indicates the table or tables from which to retrieve rows. If you name more than one table, you are performing a join. For information on join syntax, see Section 13.2.10.2, “JOIN Clause”. For each table specified, you can optionally specify an alias.

```sql
tbl_name [[AS] alias] [index_hint]
```

The use of index hints provides the optimizer with information about how to choose indexes during query processing. For a description of the syntax for specifying these hints, see Section 8.9.4, “Index Hints”.

You can use SET max_seeks_for_key=value as an alternative way to force MySQL to prefer key scans instead of table scans. See Section 5.1.8, “Server System Variables”.

- You can refer to a table within the default database as tbl_name, or as db_name.tbl_name to specify a database explicitly. You can refer to a column as col_name, tbl_name.col_name, or db_name.tbl_name.col_name. You need not specify a tbl_name or db_name.tbl_name prefix for a column reference unless the reference would be ambiguous. See Section 9.2.2, “Identifier Qualifiers”, for examples of ambiguity that require the more explicit column reference forms.

- A table reference can be aliased using tbl_name AS alias_name or tbl_name alias_name. These statements are equivalent:

```sql
SELECT t1.name, t2.salary FROM employee AS t1, info AS t2
WHERE t1.name = t2.name;
SELECT t1.name, t2.salary FROM employee t1, info t2
WHERE t1.name = t2.name;
```

- Columns selected for output can be referred to in ORDER BY and GROUP BY clauses using column names, column aliases, or column positions. Column positions are integers and begin with 1:

```sql
SELECT college, region, seed FROM tournament
ORDER BY region, seed;
SELECT college, region AS r, seed AS s FROM tournament
ORDER BY r, s;
SELECT college, region, seed FROM tournament
```
SELECT Statement

ORDER BY 2, 3;

To sort in reverse order, add the **DESC** (descending) keyword to the name of the column in the **ORDER BY** clause that you are sorting by. The default is ascending order; this can be specified explicitly using the **ASC** keyword.

If **ORDER BY** occurs within a parenthesized query expression and also is applied in the outer query, the results are undefined and may change in a future version of MySQL.

Use of column positions is deprecated because the syntax has been removed from the SQL standard.

- Prior to MySQL 8.0.13, MySQL supported a nonstandard syntax extension that permitted explicit **ASC** or **DESC** designators for **GROUP BY** columns. MySQL 8.0.12 and later supports **ORDER BY** with grouping functions so that use of this extension is no longer necessary. (Bug #86312, Bug #26073525) This also means you can sort on an arbitrary column or columns when using **GROUP BY**, like this:

  ```sql
  SELECT a, b, COUNT(c) AS t FROM test_table GROUP BY a,b ORDER BY a,t DESC;
  ```

  As of MySQL 8.0.13, the **GROUP BY** extension is no longer supported: **ASC** or **DESC** designators for **GROUP BY** columns are not permitted.

- When you use **ORDER BY** or **GROUP BY** to sort a column in a **SELECT**, the server sorts values using only the initial number of bytes indicated by the **max_sort_length** system variable.

- MySQL extends the use of **GROUP BY** to permit selecting fields that are not mentioned in the **GROUP BY** clause. If you are not getting the results that you expect from your query, please read the description of **GROUP BY** found in Section 12.20, “Aggregate Functions”.

- **GROUP BY** permits a **WITH ROLLUP** modifier. See Section 12.20.2, “GROUP BY Modifiers”.

  Previously, it was not permitted to use **ORDER BY** in a query having a **WITH ROLLUP** modifier. This restriction is lifted as of MySQL 8.0.12. See Section 12.20.2, “GROUP BY Modifiers”.

- The **HAVING** clause, like the **WHERE** clause, specifies selection conditions. The **WHERE** clause specifies conditions on columns in the select list, but cannot refer to aggregate functions. The **HAVING** clause specifies conditions on groups, typically formed by the **GROUP BY** clause. The query result includes only groups satisfying the **HAVING** conditions. (If no **GROUP BY** is present, all rows implicitly form a single aggregate group.)

  The **HAVING** clause is applied nearly last, just before items are sent to the client, with no optimization. (**LIMIT** is applied after **HAVING**.)

  The SQL standard requires that **HAVING** must reference only columns in the **GROUP BY** clause or columns used in aggregate functions. However, MySQL supports an extension to this behavior, and permits **HAVING** to refer to columns in the **SELECT** list and columns in outer subqueries as well.

  If the **HAVING** clause refers to a column that is ambiguous, a warning occurs. In the following statement, **col12** is ambiguous because it is used as both an alias and a column name:

  ```sql
  SELECT COUNT(col1) AS col2 FROM t GROUP BY col12 HAVING col12 = 2;
  ```

  Preference is given to standard SQL behavior, so if a **HAVING** column name is used both in **GROUP BY** and as an aliased column in the select column list, preference is given to the column in the **GROUP BY** column.

  - Do not use **HAVING** for items that should be in the **WHERE** clause. For example, do not write the following:

    ```sql
    SELECT col_name FROM tbl_name HAVING col_name > 0;
    ```

    Write this instead:
SELECT \textit{col\_name} FROM \textit{tbl\_name} WHERE \textit{col\_name} > 0;

- The \texttt{HAVING} clause can refer to aggregate functions, which the \texttt{WHERE} clause cannot:

\begin{verbatim}
SELECT user, MAX(salary) FROM users
GROUP BY user HAVING MAX(salary) > 10;
\end{verbatim}

(This did not work in some older versions of MySQL.)

- MySQL permits duplicate column names. That is, there can be more than one \texttt{select\_expr} with the same name. This is an extension to standard SQL. Because MySQL also permits \texttt{GROUP \ BY} and \texttt{HAVING} to refer to \texttt{select\_expr} values, this can result in an ambiguity:

\begin{verbatim}
SELECT 12 AS a, a FROM t GROUP BY a;
\end{verbatim}

In that statement, both columns have the name \texttt{a}. To ensure that the correct column is used for grouping, use different names for each \texttt{select\_expr}.

- The \texttt{WINDOW} clause, if present, defines named windows that can be referred to by window functions. For details, see Section 12.21.4, “Named Windows”.

- MySQL resolves unqualified column or alias references in \texttt{ORDER \ BY} clauses by searching in the \texttt{select\_expr} values, then in the columns of the tables in the \texttt{FROM} clause. For \texttt{GROUP \ BY} or \texttt{HAVING} clauses, it searches the \texttt{FROM} clause before searching in the \texttt{select\_expr} values. (For \texttt{GROUP \ BY} and \texttt{HAVING}, this differs from the pre-MySQL 5.0 behavior that used the same rules as for \texttt{ORDER \ BY}.)

- The \texttt{LIMIT} clause can be used to constrain the number of rows returned by the \texttt{SELECT} statement. \texttt{LIMIT} takes one or two numeric arguments, which must both be nonnegative integer constants, with these exceptions:
  - Within prepared statements, \texttt{LIMIT} parameters can be specified using \texttt{?} placeholder markers.
  - Within stored programs, \texttt{LIMIT} parameters can be specified using integer-valued routine parameters or local variables.

With two arguments, the first argument specifies the offset of the first row to return, and the second specifies the maximum number of rows to return. The offset of the initial row is 0 (not 1):

\begin{verbatim}
SELECT * FROM tbl LIMIT 5,10;  # Retrieve rows 6-15
\end{verbatim}

To retrieve all rows from a certain offset up to the end of the result set, you can use some large number for the second parameter. This statement retrieves all rows from the 96th row to the last:

\begin{verbatim}
SELECT * FROM tbl LIMIT 95,18446744073709551615;
\end{verbatim}

With one argument, the value specifies the number of rows to return from the beginning of the result set:

\begin{verbatim}
SELECT * FROM tbl LIMIT 5;     # Retrieve first 5 rows
\end{verbatim}

In other words, \texttt{LIMIT row\_count} is equivalent to \texttt{LIMIT 0, row\_count}.

For prepared statements, you can use placeholders. The following statements return one row from the \texttt{tbl} table:

\begin{verbatim}
SET @a=1;
PREPARE STMT FROM 'SELECT * FROM tbl LIMIT ?';
EXECUTE STMT USING @a;
\end{verbatim}

The following statements return the second to sixth rows from the \texttt{tbl} table:

\begin{verbatim}
SET @skip=1; SET @numrows=5;
PREPARE STMT FROM 'SELECT * FROM tbl LIMIT ?, ?';
\end{verbatim}
EXECUTE STMT USING @skip, @numrows;

For compatibility with PostgreSQL, MySQL also supports the `LIMIT row_count OFFSET offset` syntax.

If `LIMIT` occurs within a parenthesized query expression and also is applied in the outer query, the results are undefined and may change in a future version of MySQL.

- The `SELECT ... INTO` form of `SELECT` enables the query result to be written to a file or stored in variables. For more information, see Section 13.2.10.1, "SELECT ... INTO Statement".

- If you use `FOR UPDATE` with a storage engine that uses page or row locks, rows examined by the query are write-locked until the end of the current transaction.

You cannot use `FOR UPDATE` as part of the `SELECT` in a statement such as `CREATE TABLE new_table SELECT ... FROM old_table ...`. (If you attempt to do so, the statement is rejected with the error `Can't update table 'old_table' while 'new_table' is being created`.)

`FOR SHARE` and `LOCK IN SHARE MODE` set shared locks that permit other transactions to read the examined rows but not to update or delete them. `FOR SHARE` and `LOCK IN SHARE MODE` are equivalent. However, `FOR SHARE`, like `FOR UPDATE`, supports `NOWAIT`, `SKIP LOCKED`, and `OF tbl_name` options. `FOR SHARE` is a replacement for `LOCK IN SHARE MODE`, but `LOCK IN SHARE MODE` remains available for backward compatibility.

`NOWAIT` causes a `FOR UPDATE` or `FOR SHARE` query to execute immediately, returning an error if a row lock cannot be obtained due to a lock held by another transaction.

`SKIP LOCKED` causes a `FOR UPDATE` or `FOR SHARE` query to execute immediately, excluding rows from the result set that are locked by another transaction.

`NOWAIT` and `SKIP LOCKED` options are unsafe for statement-based replication.

**Note**

Queries that skip locked rows return an inconsistent view of the data. `SKIP LOCKED` is therefore not suitable for general transactional work. However, it may be used to avoid lock contention when multiple sessions access the same queue-like table.

`OF tbl_name` applies `FOR UPDATE` and `FOR SHARE` queries to named tables. For example:

```
SELECT * FROM t1, t2 FOR SHARE OF t1 FOR UPDATE OF t2;
```

All tables referenced by the query block are locked when `OF tbl_name` is omitted. Consequently, using a locking clause without `OF tbl_name` in combination with another locking clause returns an error. Specifying the same table in multiple locking clauses returns an error. If an alias is specified as the table name in the `SELECT` statement, a locking clause may only use the alias. If the `SELECT` statement does not specify an alias explicitly, the locking clause may only specify the actual table name.

For more information about `FOR UPDATE` and `FOR SHARE`, see Section 15.7.2.4, "Locking Reads". For additional information about `NOWAIT` and `SKIP LOCKED` options, see Locking Read Concurrency with NOWAIT and SKIP LOCKED.

Following the `SELECT` keyword, you can use a number of modifiers that affect the operation of the statement. `HIGH_PRIORITY`, `STRAIGHT_JOIN`, and modifiers beginning with `SQL_` are MySQL extensions to standard SQL.

- The `ALL` and `DISTINCT` modifiers specify whether duplicate rows should be returned. `ALL` (the default) specifies that all matching rows should be returned, including duplicates. `DISTINCT`
SELECT Statement

specifies removal of duplicate rows from the result set. It is an error to specify both modifiers.

DISTINCTROW is a synonym for DISTINCT.

In MySQL 8.0.12 and later, DISTINCT can be used with a query that also uses WITH ROLLUP. (Bug #87450, Bug #26640100)

• HIGH_PRIORITY gives the SELECT higher priority than a statement that updates a table. You should use this only for queries that are very fast and must be done at once. A SELECT HIGH_PRIORITY query that is issued while the table is locked for reading runs even if there is an update statement waiting for the table to be free. This affects only storage engines that use only table-level locking (such as MyISAM, MEMORY, and MERGE).

HIGH_PRIORITY cannot be used with SELECT statements that are part of a UNION.

• STRAIGHT_JOIN forces the optimizer to join the tables in the order in which they are listed in the FROM clause. You can use this to speed up a query if the optimizer joins the tables in nonoptimal order. STRAIGHT_JOIN also can be used in the table_references list. See Section 13.2.10.2, “JOIN Clause”.

STRAIGHT_JOIN does not apply to any table that the optimizer treats as a const or system table. Such a table produces a single row, is read during the optimization phase of query execution, and references to its columns are replaced with the appropriate column values before query execution proceeds. These tables appear first in the query plan displayed by EXPLAIN. See Section 8.8.1, “Optimizing Queries with EXPLAIN”. This exception may not apply to const or system tables that are used on the NULL-complemented side of an outer join (that is, the right-side table of a LEFT JOIN or the left-side table of a RIGHT JOIN).

• SQL_BIG_RESULT or SQL_SMALL_RESULT can be used with GROUP BY or DISTINCT to tell the optimizer that the result set has many rows or is small, respectively. For SQL_BIG_RESULT, MySQL directly uses disk-based temporary tables if they are created, and prefers sorting to using a temporary table with a key on the GROUP BY elements. For SQL_SMALL_RESULT, MySQL uses in-memory temporary tables to store the resulting table instead of using sorting. This should not normally be needed.

• SQL_BUFFER_RESULT forces the result to be put into a temporary table. This helps MySQL free the table locks early and helps in cases where it takes a long time to send the result set to the client. This modifier can be used only for top-level SELECT statements, not for subqueries or following UNION.

• SQL_CALC_FOUND_ROWS tells MySQL to calculate how many rows there would be in the result set, disregarding any LIMIT clause. The number of rows can then be retrieved with SELECT FOUND_ROWS(). See Section 12.16, “Information Functions”.

Note

The SQL_CALC_FOUND_ROWS query modifier and accompanying FOUND_ROWS() function are deprecated as of MySQL 8.0.17; expect them to be removed in a future version of MySQL. See the FOUND_ROWS() description for information about an alternative strategy.

• The SQL_CACHE and SQL_NO_CACHE modifiers were used with the query cache prior to MySQL 8.0. The query cache was removed in MySQL 8.0. The SQL_CACHE modifier was removed as well. SQL_NO_CACHE is deprecated, and has no effect; expect it to be removed in a future MySQL release.

13.2.10.1 SELECT ... INTO Statement

The SELECT ... INTO form of SELECT enables a query result to be stored in variables or written to a file:
SELECT Statement

- **SELECT ... INTO var_list** selects column values and stores them into variables.

- **SELECT ... INTO OUTFILE** writes the selected rows to a file. Column and line terminators can be specified to produce a specific output format.

- **SELECT ... INTO DUMPFILE** writes a single row to a file without any formatting.

A given **SELECT** statement can contain at most one **INTO** clause, although as shown by the **SELECT** syntax description (see Section 13.2.10, “SELECT Statement”), the **INTO** can appear in different positions:

- **Before** FROM. Example:
  
  ```sql
  SELECT * INTO @myvar FROM t1;
  ```

- **Before a trailing locking clause.** Example:
  
  ```sql
  SELECT * FROM t1 INTO @myvar FOR UPDATE;
  ```

- **At the end of the SELECT.** Example:
  
  ```sql
  SELECT * FROM t1 FOR UPDATE INTO @myvar;
  ```

  The **INTO** position at the end of the statement is supported as of MySQL 8.0.20, and is the preferred position. The position before a locking clause is deprecated as of MySQL 8.0.20; expect support for it to be removed in a future version of MySQL. In other words, **INTO** after **FROM** but not at the end of the **SELECT** produces a warning.

  An **INTO** clause should not be used in a nested **SELECT** because such a **SELECT** must return its result to the outer context. There are also constraints on the use of **INTO** within **UNION** statements; see Section 13.2.10.3, “UNION Clause”.

  For the **INTO var_list** variant:

  - **var_list** names a list of one or more variables, each of which can be a user-defined variable, stored procedure or function parameter, or stored program local variable. (Within a prepared **SELECT ... INTO var_list** statement, only user-defined variables are permitted; see Section 13.6.4.2, “Local Variable Scope and Resolution”.)

  - The selected values are assigned to the variables. The number of variables must match the number of columns. The query should return a single row. If the query returns no rows, a warning with error code 1329 occurs (**No data**), and the variable values remain unchanged. If the query returns multiple rows, error 1172 occurs (**Result consisted of more than one row**). If it is possible that the statement may retrieve multiple rows, you can use **LIMIT 1** to limit the result set to a single row.

  ```sql
  SELECT id, data INTO @x, @y FROM test.t1 LIMIT 1;
  ```

  **INTO var_list** can also be used with a **TABLE** statement, subject to these restrictions:

  - The number of variables must match the number of columns in the table.

  - If the table contains more than one row, you must use **LIMIT 1** to limit the result set to a single row. **LIMIT 1** must precede the **INTO** keyword.

  An example of such a statement is shown here:

  ```sql
  TABLE employees ORDER BY lname DESC LIMIT 1
  INTO @id, @fname, @lname, @hired, @separated, @job_code, @store_id;
  ```

  You can also select values from a **VALUES** statement that generates a single row into a set of user variables. In this case, you must employ a table alias, and you must assign each value from the value list to a variable. Each of the two statements shown here is equivalent to **SET @x=2, @y=4, @z=8**:
SELECT * FROM (VALUES ROW(2,4,8)) AS t INTO @x,@y,@z;

SELECT * FROM (VALUES ROW(2,4,8)) AS t(a,b,c) INTO @x,@y,@z;

User variable names are not case-sensitive. See Section 9.4, “User-Defined Variables”.

The SELECT ... INTO OUTFILE 'file_name' form of SELECT writes the selected rows to a file. The file is created on the server host, so you must have the FILE privilege to use this syntax. file_name cannot be an existing file, which among other things prevents files such as /etc/passwd and database tables from being modified. The character_set_filesystem system variable controls the interpretation of the file name.

The SELECT ... INTO OUTFILE statement is intended to enable dumping a table to a text file on the server host. To create the resulting file on some other host, SELECT ... INTO OUTFILE normally is unsuitable because there is no way to write a path to the file relative to the server host file system, unless the location of the file on the remote host can be accessed using a network-mapped path on the server host file system.

Alternatively, if the MySQL client software is installed on the remote host, you can use a client command such as mysql -e "SELECT ..." > file_name to generate the file on that host.

SELECT ... INTO OUTFILE is the complement of LOAD DATA. Column values are written converted to the character set specified in the CHARACTER SET clause. If no such clause is present, values are dumped using the binary character set. In effect, there is no character set conversion. If a result set contains columns in several character sets, so is the output data file, and it may not be possible to reload the file correctly.

The syntax for the export_options part of the statement consists of the same FIELDS and LINES clauses that are used with the LOAD DATA statement. For information about the FIELDS and LINES clauses, including their default values and permissible values, see Section 13.2.7, “LOAD DATA Statement”.

FIELDS ESCAPED BY controls how to write special characters. If the FIELDS ESCAPED BY character is not empty, it is used when necessary to avoid ambiguity as a prefix that precedes following characters on output:

- The FIELDS ESCAPED BY character
- The FIELDS [OPTIONALLY] ENCLOSED BY character
- The first character of the FIELDS TERMINATED BY and LINES TERMINATED BY values
- ASCII NUL (the zero-valued byte; what is actually written following the escape character is ASCII 0, not a zero-valued byte)

The FIELDS TERMINATED BY, ENCLOSED BY, ESCAPED BY, or LINES TERMINATED BY characters must be escaped so that you can read the file back in reliably. ASCII NUL is escaped to make it easier to view with some pagers.

The resulting file need not conform to SQL syntax, so nothing else need be escaped.

If the FIELDS ESCAPED BY character is empty, no characters are escaped and NULL is output as NULL, not \N. It is probably not a good idea to specify an empty escape character, particularly if field values in your data contain any of the characters in the list just given.

INTO OUTFILE can also be used with a TABLE statement when you want to dump all columns of a table into a text file. In this case, the ordering and number of rows can be controlled using ORDER BY and LIMIT; these clauses must precede INTO OUTFILE.TABLE ... INTO OUTFILE supports the same export_options as does SELECT ... INTO OUTFILE, and it is subject to the same restrictions on writing to the file system. An example of such a statement is shown here:

TABLE employees ORDER BY lname LIMIT 1000
    INTO OUTFILE '/tmp/employee_data_1.txt'
    FIELDS TERMINATED BY ',', OPTIONALLY ENCLOSED BY '"', ESCAPED BY '\'
LINES TERMINATED BY '\n';

You can also use `SELECT ... INTO OUTFILE` with a `VALUES` statement to write values directly into a file. An example is shown here:

```sql
SELECT * FROM (VALUES ROW(1,2,3),ROW(4,5,6),ROW(7,8,9)) AS t
  INTO OUTFILE '/tmp/select-values.txt';
```

You must use a table alias; column aliases are also supported, and can optionally be used to write values only from desired columns. You can also use any or all of the export options supported by `SELECT ... INTO OUTFILE` to format the output to the file.

Here is an example that produces a file in the comma-separated values (CSV) format used by many programs:

```sql
SELECT a,b,a+b INTO OUTFILE '/tmp/result.txt'
  FIELDS TERMINATED BY ',' OPTIONALLY ENCLOSED BY '"'
  LINES TERMINATED BY '\n'
  FROM test_table;
```

If you use `INTO DUMPFILE` instead of `INTO OUTFILE`, MySQL writes only one row into the file, without any column or line termination and without performing any escape processing. This is useful for selecting a `BLOB` value and storing it in a file.

`TABLE` also supports `INTO DUMPFILE`. If the table contains more than one row, you must also use `LIMIT 1` to limit the output to a single row. `INTO DUMPFILE` can also be used with `SELECT * FROM (VALUES ROW() [, ...]) AS table_alias [LIMIT 1]`. See Section 13.2.14, "VALUES Statement".

**Note**

Any file created by `INTO OUTFILE` or `INTO DUMPFILE` is owned by the operating system user under whose account `mysqld` runs. (You should never run `mysqld` as `root` for this and other reasons.) As of MySQL 8.0.17, the umask for file creation is 0640; you must have sufficient access privileges to manipulate the file contents. Prior to MySQL 8.0.17, the umask is 0666 and the file is writable by all users on the server host.

If the `secure_file_priv` system variable is set to a nonempty directory name, the file to be written must be located in that directory.

In the context of `SELECT ... INTO` statements that occur as part of events executed by the Event Scheduler, diagnostics messages (not only errors, but also warnings) are written to the error log, and, on Windows, to the application event log. For additional information, see Section 25.4.5, "Event Scheduler Status".

As of MySQL 8.0.22, support is provided for periodic synchronization of output files written to by `SELECT INTO OUTFILE` and `SELECT INTO DUMPFILE`, enabled by setting the `select_into_disk_sync` server system variable introduced in that version. Output buffer size and optional delay can be set using, respectively, `select_into_buffer_size` and `select_into_disk_sync_delay`. For more information, see the descriptions of these system variables.

### 13.2.10.2 JOIN Clause

MySQL supports the following `JOIN` syntax for the `table_references` part of `SELECT` statements and multiple-table `DELETE` and `UPDATE` statements:

```sql
table_references:
  escaped_table_reference [, escaped_table_reference] ...  

escaped_table_reference:  
  table_reference  
  | { OJ table_reference }
```

2467
A table reference is also known as a join expression.

A table reference (when it refers to a partitioned table) may contain a `PARTITION` clause, including a list of comma-separated partitions, subpartitions, or both. This option follows the name of the table and precedes any alias declaration. The effect of this option is that rows are selected only from the listed partitions or subpartitions. Any partitions or subpartitions not named in the list are ignored. For more information and examples, see Section 24.5, “Partition Selection”.

The syntax of `table_factor` is extended in MySQL in comparison with standard SQL. The standard accepts only `table_reference`, not a list of them inside a pair of parentheses.

This is a conservative extension if each comma in a list of `table_reference` items is considered as equivalent to an inner join. For example:

```sql
SELECT * FROM t1 LEFT JOIN (t2, t3, t4) ON (t2.a = t1.a AND t3.b = t1.b AND t4.c = t1.c)
```

is equivalent to:

```sql
SELECT * FROM t1 LEFT JOIN (t2 CROSS JOIN t3 CROSS JOIN t4) ON (t2.a = t1.a AND t3.b = t1.b AND t4.c = t1.c)
```

In MySQL, `JOIN`, `CROSS JOIN`, and `INNER JOIN` are syntactic equivalents (they can replace each other). In standard SQL, they are not equivalent. `INNER JOIN` is used with an `ON` clause, `CROSS JOIN` is used otherwise.

In general, parentheses can be ignored in join expressions containing only inner join operations. MySQL also supports nested joins. See Section 8.2.1.8, “Nested Join Optimization”.

```sql
SELECT * FROM t1 LEFT JOIN (t2 CROSS JOIN t3 CROSS JOIN t4) ON (t2.a = t1.a AND t3.b = t1.b AND t4.c = t1.c)
```
Index hints can be specified to affect how the MySQL optimizer makes use of indexes. For more information, see Section 8.9.4, “Index Hints”. Optimizer hints and the optimizer_switch system variable are other ways to influence optimizer use of indexes. See Section 8.9.3, “Optimizer Hints”, and Section 8.9.2, “Switchable Optimizations”.

The following list describes general factors to take into account when writing joins:

- A table reference can be aliased using `tbl_name AS alias_name` or `tbl_name alias_name`:

  ```sql
  SELECT t1.name, t2.salary
  FROM employee AS t1 INNER JOIN info AS t2 ON t1.name = t2.name;
  ```

  ```sql
  SELECT t1.name, t2.salary
  FROM employee t1 INNER JOIN info t2 ON t1.name = t2.name;
  ```

- A `table_subquery` is also known as a derived table or subquery in the `FROM` clause. See Section 13.2.11.8, “Derived Tables”. Such subqueries must include an alias to give the subquery result a table name, and may optionally include a list of table column names in parentheses. A trivial example follows:

  ```sql
  SELECT * FROM (SELECT 1, 2, 3) AS t1;
  ```

- The maximum number of tables that can be referenced in a single join is 61. This includes a join handled by merging derived tables and views in the `FROM` clause into the outer query block (see Section 8.2.2.4, “Optimizing Derived Tables, View References, and Common Table Expressions with Merging or Materialization”).

- `INNER JOIN` and `,` (comma) are semantically equivalent in the absence of a join condition: both produce a Cartesian product between the specified tables (that is, each and every row in the first table is joined to each and every row in the second table).

  However, the precedence of the comma operator is less than that of `INNER JOIN`, `CROSS JOIN`, `LEFT JOIN`, and so on. If you mix comma joins with the other join types when there is a join condition, an error of the form `Unknown column 'col_name' in 'on clause'` may occur. Information about dealing with this problem is given later in this section.

- The `search_condition` used with `ON` is any conditional expression of the form that can be used in a `WHERE` clause. Generally, the `ON` clause serves for conditions that specify how to join tables, and the `WHERE` clause restricts which rows to include in the result set.

  If there is no matching row for the right table in the `ON` or `USING` part in a `LEFT JOIN`, a row with all columns set to `NULL` is used for the right table. You can use this fact to find rows in a table that have no counterpart in another table:

  ```sql
  SELECT left_tbl.*
  FROM left_tbl LEFT JOIN right_tbl ON left_tbl.id = right_tbl.id
  WHERE right_tbl.id IS NULL;
  ```

  This example finds all rows in `left_tbl` with an `id` value that is not present in `right_tbl` (that is, all rows in `left_tbl` with no corresponding row in `right_tbl`). See Section 8.2.1.9, “Outer Join Optimization”.

- The `USING(join_column_list)` clause names a list of columns that must exist in both tables. If tables `a` and `b` both contain columns `c1`, `c2`, and `c3`, the following join compares corresponding columns from the two tables:

  ```sql
  a LEFT JOIN b USING (c1, c2, c3)
  ```

- The `NATURAL [LEFT] JOIN` of two tables is defined to be semantically equivalent to an `INNER JOIN` or a `LEFT JOIN` with a `USING` clause that names all columns that exist in both tables.

- `RIGHT JOIN` works analogously to `LEFT JOIN`. To keep code portable across databases, it is recommended that you use `LEFT JOIN` instead of `RIGHT JOIN`. 
• The { OJ ... } syntax shown in the join syntax description exists only for compatibility with ODBC. The curly braces in the syntax should be written literally; they are not metasyntax as used elsewhere in syntax descriptions.

```sql
SELECT left_tbl.*
FROM { OJ left_tbl LEFT OUTER JOIN right_tbl
ON left_tbl.id = right_tbl.id }
WHERE right_tbl.id IS NULL;
```

You can use other types of joins within { OJ ... }, such as INNER JOIN or RIGHT OUTER JOIN. This helps with compatibility with some third-party applications, but is not official ODBC syntax.

• STRAIGHT_JOIN is similar to JOIN, except that the left table is always read before the right table. This can be used for those (few) cases for which the join optimizer processes the tables in a suboptimal order.

Some join examples:

```sql
SELECT * FROM table1, table2;
SELECT * FROM table1 INNER JOIN table2 ON table1.id = table2.id;
SELECT * FROM table1 LEFT JOIN table2 ON table1.id = table2.id;
SELECT * FROM table1 LEFT JOIN table2 USING (id);
SELECT * FROM table1 LEFT JOIN table2 ON table1.id = table2.id
  LEFT JOIN table3 ON table2.id = table3.id;
```

Natural joins and joins with USING, including outer join variants, are processed according to the SQL:2003 standard:

• Redundant columns of a NATURAL join do not appear. Consider this set of statements:

```sql
CREATE TABLE t1 (i INT, j INT);
CREATE TABLE t2 (k INT, j INT);
INSERT INTO t1 VALUES(1, 1);
INSERT INTO t2 VALUES(1, 1);
SELECT * FROM t1 NATURAL JOIN t2;
SELECT * FROM t1 JOIN t2 USING (j);
```

In the first SELECT statement, column j appears in both tables and thus becomes a join column, so, according to standard SQL, it should appear only once in the output, not twice. Similarly, in the second SELECT statement, column j is named in the USING clause and should appear only once in the output, not twice.

Thus, the statements produce this output:

```
+------+------+------+
<table>
<thead>
<tr>
<th>j</th>
<th>i</th>
<th>k</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>
+------+------+------+
```

Redundant column elimination and column ordering occurs according to standard SQL, producing this display order:

• First, coalesced common columns of the two joined tables, in the order in which they occur in the first table

• Second, columns unique to the first table, in order in which they occur in that table
• Third, columns unique to the second table, in order in which they occur in that table

The single result column that replaces two common columns is defined using the coalesce operation. That is, for two \texttt{t1.a} and \texttt{t2.a} the resulting single join column \texttt{a} is defined as \texttt{a = COALESCE(t1.a, t2.a)}, where:

\[
\text{COALESCE}(x, y) = (\text{CASE WHEN } x \text{ IS NOT NULL THEN } x \text{ ELSE } y \text{ END})
\]

If the join operation is any other join, the result columns of the join consist of the concatenation of all columns of the joined tables.

A consequence of the definition of coalesced columns is that, for outer joins, the coalesced column contains the value of the non-	exttt{NULL} column if one of the two columns is always 	exttt{NULL}. If neither or both columns are 	exttt{NULL}, both common columns have the same value, so it doesn't matter which one is chosen as the value of the coalesced column. A simple way to interpret this is to consider that a coalesced column of an outer join is represented by the common column of the inner table of a \texttt{JOIN}. Suppose that the tables \texttt{t1(a, b)} and \texttt{t2(a, c)} have the following contents:

<table>
<thead>
<tr>
<th>t1</th>
<th>t2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>x</td>
<td>z</td>
</tr>
<tr>
<td>2</td>
<td>3</td>
</tr>
<tr>
<td>y</td>
<td>w</td>
</tr>
</tbody>
</table>

Then, for this join, column \texttt{a} contains the values of \texttt{t1.a}:

```
mysql> SELECT * FROM t1 NATURAL LEFT JOIN t2;
+------+------+------+
| a    | b    | c    |
+------+------+------+
| 1    | x    | NULL |
| 2    | y    | z    |
+------+------+------+
```

By contrast, for this join, column \texttt{a} contains the values of \texttt{t2.a}.

```
mysql> SELECT * FROM t1 NATURAL RIGHT JOIN t2;
+------+------+------+
| a    | c    | b    |
+------+------+------+
| 2    | z    | y    |
| 3    | w    | NULL |
+------+------+------+
```

Compare those results to the otherwise equivalent queries with \texttt{JOIN ... ON}:

```
mysql> SELECT * FROM t1 LEFT JOIN t2 ON (t1.a = t2.a);
+------+------+------+
| a    | b    | a    | c    |
+------+------+------+
| 1    | x    | NULL | NULL |
| 2    | y    | 2    | z    |
+------+------+------+
```

```
mysql> SELECT * FROM t1 RIGHT JOIN t2 ON (t1.a = t2.a);
+------+------+------+
| a    | b    | a    | c    |
+------+------+------+
| 2    | y    | 2    | z    |
| NULL | NULL | 3    | w    |
+------+------+------+
```

• A \texttt{USING} clause can be rewritten as an \texttt{ON} clause that compares corresponding columns. However, although \texttt{USING} and \texttt{ON} are similar, they are not quite the same. Consider the following two queries:

```
a LEFT JOIN b USING (c1, c2, c3)
```
a LEFT JOIN b ON a.c1 = b.c1 AND a.c2 = b.c2 AND a.c3 = b.c3  

With respect to determining which rows satisfy the join condition, both joins are semantically identical.

With respect to determining which columns to display for `SELECT *` expansion, the two joins are not semantically identical. The `USING` join selects the coalesced value of corresponding columns, whereas the `ON` join selects all columns from all tables. For the `USING` join, `SELECT *` selects these values:

```
COALESCE(a.c1, b.c1), COALESCE(a.c2, b.c2), COALESCE(a.c3, b.c3)
```

For the `ON` join, `SELECT *` selects these values:

```
a.c1, a.c2, a.c3, b.c1, b.c2, b.c3
```

With an inner join, `COALESCE(a.c1, b.c1)` is the same as either `a.c1` or `b.c1` because both columns have the same value. With an outer join (such as `LEFT JOIN`), one of the two columns can be `NULL`. That column is omitted from the result.

- An `ON` clause can refer only to its operands.

Example:

```
CREATE TABLE t1 (i1 INT);
CREATE TABLE t2 (i2 INT);
CREATE TABLE t3 (i3 INT);
SELECT * FROM t1 JOIN t2 ON (i1 = i3) JOIN t3;
```

The statement fails with an `Unknown column 'i3' in 'on clause'` error because `i3` is a column in `t3`, which is not an operand of the `ON` clause. To enable the join to be processed, rewrite the statement as follows:

```
SELECT * FROM t1 JOIN t2 JOIN t3 ON (i1 = i3);
```

- `JOIN` has higher precedence than the comma operator (,), so the join expression `t1, t2 JOIN t3` is interpreted as `(t1, (t2 JOIN t3))`, not as `((t1, t2) JOIN t3)`. This affects statements that use an `ON` clause because that clause can refer only to columns in the operands of the join, and the precedence affects interpretation of what those operands are.

Example:

```
CREATE TABLE t1 (i1 INT, j1 INT);
CREATE TABLE t2 (i2 INT, j2 INT);
CREATE TABLE t3 (i3 INT, j3 INT);
INSERT INTO t1 VALUES(1, 1);
INSERT INTO t2 VALUES(1, 1);
INSERT INTO t3 VALUES(1, 1);
SELECT * FROM t1, t2 JOIN t3 ON (t1.i1 = t3.i3);
```

The `JOIN` takes precedence over the comma operator, so the operands for the `ON` clause are `t2` and `t3`. Because `t1.i1` is not a column in either of the operands, the result is an `Unknown column 't1.i1' in 'on clause'` error.

To enable the join to be processed, use either of these strategies:

- Group the first two tables explicitly with parentheses so that the operands for the `ON` clause are `t1` and `t3`:

```
SELECT * FROM (t1, t2) JOIN t3 ON (t1.i1 = t3.i3);
```
SELECT Statement

- Avoid the use of the comma operator and use JOIN instead:

  ```sql
  SELECT * FROM t1 JOIN t2 JOIN t3 ON (t1.i1 = t3.i3);
  ```

  The same precedence interpretation also applies to statements that mix the comma operator with INNER JOIN, CROSS JOIN, LEFT JOIN, and RIGHT JOIN, all of which have higher precedence than the comma operator.

- A MySQL extension compared to the SQL:2003 standard is that MySQL permits you to qualify the common (coalesced) columns of NATURAL or USING joins, whereas the standard disallows that.

### 13.2.10.3 UNION Clause

```sql
SELECT ... 
UNION [ALL | DISTINCT] SELECT ... 
[UNION [ALL | DISTINCT] SELECT ...]
```

The `UNION` combines the result from multiple SELECT statements into a single result set. Example:

```sql
mysql> SELECT 1, 2;
+---+---+
| 1 | 2 |
| 1 | 2 |
+---+---+
mysql> SELECT 'a', 'b';
+---+---+
| a | b |
| a | b |
+---+---+
mysql> SELECT 1, 2 UNION SELECT 'a', 'b';
+---+---+
| 1 | 2 |
| 1 | 2 |
| a | b |
+---+---+
```

- Result Set Column Names and Data Types
- TABLE in Unions
- UNION DISTINCT and UNION ALL
- ORDER BY and LIMIT in Unions
- UNION Restrictions
- UNION Handling in MySQL 8.0 Compared to MySQL 5.7

**Result Set Column Names and Data Types**

The column names for a UNION result set are taken from the column names of the first SELECT statement.

Selected columns listed in corresponding positions of each SELECT statement should have the same data type. For example, the first column selected by the first statement should have the same type as the first column selected by the other statements. If the data types of corresponding SELECT columns do not match, the types and lengths of the columns in the UNION result take into account the values retrieved by all the SELECT statements. For example, consider the following, where the column length is not constrained to the length of the value from the first SELECT:

```sql
mysql> SELECT REPEAT('a',1) UNION SELECT REPEAT('b',20);
```

Result set column names and data types

---

2473
TABLE in Unions

Beginning with MySQL 8.0.19, you can also use a TABLE statement or VALUES statement in a UNION wherever you can employ the equivalent SELECT statement. Assume that tables \( t_1 \) and \( t_2 \) are created and populated as shown here:

```sql
CREATE TABLE t1 (x INT, y INT);
INSERT INTO t1 VALUES ROW(4,-2),ROW(5,9);
CREATE TABLE t2 (a INT, b INT);
INSERT INTO t2 VALUES ROW(1,2),ROW(3,4);
```

The preceding being the case, and disregarding the column names in the output of the queries beginning with VALUES, all of the following UNION queries yield the same result:

```sql
SELECT * FROM t1 UNION SELECT * FROM t2;
TABLE t1 UNION SELECT * FROM t2;
VALUES ROW(4,-2), ROW(5,9) UNION SELECT * FROM t2;
SELECT * FROM t1 UNION TABLE t2;
TABLE t1 UNION TABLE t2;
VALUES ROW(4,-2), ROW(5,9) UNION TABLE t2;
SELECT * FROM t1 UNION VALUES ROW(4,-2),ROW(5,9);
TABLE t1 UNION VALUES ROW(4,-2),ROW(5,9);
VALUES ROW(4,-2), ROW(5,9) UNION VALUES ROW(4,-2),ROW(5,9);
```

To force the column names to be the same, wrap the VALUES on the left hand side in a SELECT and use aliases, like this:

```sql
SELECT * FROM (VALUES ROW(4,-2), ROW(5,9)) AS t(x,y) UNION VALUES ROW(4,-2),ROW(5,9);
```

UNION DISTINCT and UNION ALL

By default, duplicate rows are removed from UNION results. The optional DISTINCT keyword has the same effect but makes it explicit. With the optional ALL keyword, duplicate-row removal does not occur and the result includes all matching rows from all the SELECT statements.

You can mix UNION ALL and UNION DISTINCT in the same query. Mixed UNION types are treated such that a DISTINCT union overrides any ALL union to its left. A DISTINCT union can be produced explicitly by using UNION DISTINCT or implicitly by using UNION with no following DISTINCT or ALL keyword.

In MySQL 8.0.19 and later, UNION ALL and UNION DISTINCT work the same way when one or more TABLE statements are used in the union.

ORDER BY and LIMIT in Unions

To apply an ORDER BY or LIMIT clause to an individual SELECT, parenthesize the SELECT and place the clause inside the parentheses:

```sql
(SELECT a FROM t1 WHERE a=10 AND b=1 ORDER BY a LIMIT 10)
UNION
(SELECT a FROM t2 WHERE a=11 AND b=2 ORDER BY a LIMIT 10);
```

Use of ORDER BY for individual SELECT statements implies nothing about the order in which the rows appear in the final result because UNION by default produces an unordered set of rows. Therefore, ORDER BY in this context typically is used in conjunction with LIMIT, to determine the subset of the selected rows to retrieve for the SELECT, even though it does not necessarily affect the order of those
rows in the final \texttt{UNION} result. If \texttt{ORDER BY} appears without \texttt{LIMIT} in a \texttt{SELECT}, it is optimized away because it has no effect in any case.

To use an \texttt{ORDER BY} or \texttt{LIMIT} clause to sort or limit the entire \texttt{UNION} result, parenthesize the individual \texttt{SELECT} statements and place the \texttt{ORDER BY} or \texttt{LIMIT} after the last one:

```
(SELECT a FROM t1 WHERE a=10 AND b=1)
UNION
(SELECT a FROM t2 WHERE a=11 AND b=2)
ORDER BY a LIMIT 10;
```

A statement without parentheses is equivalent to one parenthesized as just shown.

Beginning with MySQL 8.0.19, you can use \texttt{ORDER BY} and \texttt{LIMIT} with \texttt{TABLE} in unions in the same way as just shown, bearing in mind that \texttt{TABLE} does not support a \texttt{WHERE} clause.

This kind of \texttt{ORDER BY} cannot use column references that include a table name (that is, names in \texttt{tbl_name.col_name} format). Instead, provide a column alias in the first \texttt{SELECT} statement and refer to the alias in the \texttt{ORDER BY}. (Alternatively, refer to the column in the \texttt{ORDER BY} using its column position. However, use of column positions is deprecated.)

Also, if a column to be sorted is aliased, the \texttt{ORDER BY} clause \texttt{must} refer to the alias, not the column name. The first of the following statements is permitted, but the second fails with an \texttt{Unknown column 'a' in 'order clause' error}:

```
(SELECT a AS b FROM t) UNION (SELECT ...) ORDER BY b;
(SELECT a AS b FROM t) UNION (SELECT ...) ORDER BY a;
```

To cause rows in a \texttt{UNION} result to consist of the sets of rows retrieved by each \texttt{SELECT} one after the other, select an additional column in each \texttt{SELECT} to use as a sort column and add an \texttt{ORDER BY} that sorts on that column following the last \texttt{SELECT}:

```
(SELECT 1 AS sort_col, colla, collb, ... FROM t1)
UNION
(SELECT 2, col2a, col2b, ... FROM t2) ORDER BY sort_col;
```

To additionally maintain sort order within individual \texttt{SELECT} results, add a secondary column to the \texttt{ORDER BY} clause:

```
(SELECT 1 AS sort_col, colla, collb, ... FROM t1)
UNION
(SELECT 2, col2a, col2b, ... FROM t2) ORDER BY sort_col, colla;
```

Use of an additional column also enables you to determine which \texttt{SELECT} each row comes from. Extra columns can provide other identifying information as well, such as a string that indicates a table name.

**UNION Restrictions**

In a \texttt{UNION}, the \texttt{SELECT} statements are normal select statements, but with the following restrictions:

- \texttt{HIGH_PRIORITY} in the first \texttt{SELECT} has no effect. \texttt{HIGH_PRIORITY} in any subsequent \texttt{SELECT} produces a syntax error.
- Only the last \texttt{SELECT} statement can use an \texttt{INTO} clause. However, the entire \texttt{UNION} result is written to the \texttt{INTO} output destination.

As of MySQL 8.0.20, these two \texttt{UNION} variants containing \texttt{INTO} are deprecated and you should expect support for them to be removed in a future version of MySQL:

- In the trailing query block of a query expression, use of \texttt{INTO} before \texttt{FROM} produces a warning. Example:
  ```
  ... UNION SELECT * INTO 'file_name' FROM table_name;
  ```

- In a parenthesized trailing block of a query expression, use of \texttt{INTO} (regardless of its position relative to \texttt{FROM}) produces a warning. Example:
Those variants are deprecated because they are confusing, as if they collect information from the named table rather than the entire query expression (the \texttt{UNION}).

UNION queries with an aggregate function in an \texttt{ORDER BY} clause are rejected with an \texttt{ER_AGGREGATE_ORDER_FOR_UNION} error. Example:

\begin{verbatim}
SELECT 1 AS foo UNION SELECT 2 ORDER BY MAX(1);
\end{verbatim}

\textbf{UNION Handing in MySQL 8.0 Compared to MySQL 5.7}

In MySQL 8.0, the parser rules for \texttt{SELECT} and \texttt{UNION} were refactored to be more consistent (the same \texttt{SELECT} syntax applies uniformly in each such context) and reduce duplication. Compared to MySQL 5.7, several user-visible effects resulted from this work, which may require rewriting of certain statements:

- \textbf{NATURAL JOIN} permits an optional \texttt{INNER} keyword (\texttt{NATURAL INNER JOIN}), in compliance with standard SQL.
- Right-deep joins without parentheses are permitted (for example, \texttt{... JOIN ... JOIN ... ON ... ON}), in compliance with standard SQL.
- \textbf{STRAIGHT_JOIN} now permits a \texttt{USING} clause, similar to other inner joins.
- The parser accepts parentheses around query expressions. For example, \texttt{(SELECT ... UNION SELECT ...)} is permitted. See also Section 13.2.10.4, "Parenthesized Query Expressions".
- The parser better conforms to the documented permitted placement of the \texttt{SQL_CACHE} and \texttt{SQL_NO_CACHE} query modifiers.
- Left-hand nesting of unions, previously permitted only in subqueries, is now permitted in top-level statements. For example, this statement is now accepted as valid:

\begin{verbatim}
(SELECT 1 UNION SELECT 1) UNION SELECT 1;
\end{verbatim}

- Locking clauses (\texttt{FOR UPDATE}, \texttt{LOCK IN SHARE MODE}) are allowed only in non-UNION queries. This means that parentheses must be used for \texttt{SELECT} statements containing locking clauses. This statement is no longer accepted as valid:

\begin{verbatim}
SELECT 1 FOR UPDATE UNION SELECT 1 FOR UPDATE;
\end{verbatim}

Instead, write the statement like this:

\begin{verbatim}
(SELECT 1 FOR UPDATE) UNION (SELECT 1 FOR UPDATE);
\end{verbatim}

\textbf{13.2.10.4 Parenthesized Query Expressions}

\begin{verbatim}
parenthesized_query_expression:
  ( query_expression [order_by_clause] [limit_clause] )
  [order_by_clause]
  [limit_clause]
  [into_clause]
query_expression:
  query_block [UNION query_block [UNION query_block ...]]
  [order_by_clause]
  [limit_clause]
  [into_clause]
query_block:
  SELECT ...
  (see Section 13.2.10, "SELECT Statement")
order_by_clause:
  ORDER BY as for SELECT (see Section 13.2.10, "SELECT Statement")
\end{verbatim}
MySQL 8.0.22 and higher supports parenthesized query expressions according to the preceding syntax. At its simplest, a parenthesized query expression contains a single `SELECT` and no following optional clauses:

```sql
(SELECT 1);
(SELECT * FROM INFORMATION_SCHEMA.SCHEMATA WHERE SCHEMA_NAME = 'mysql');
```

A parenthesized query expression can also contain a `UNION` comprising multiple `SELECT` statements, and end with any or all of the optional clauses:

```sql
mysql> (SELECT 1 AS result UNION SELECT 2);
+--------+
| result |
+--------+
|      1 |
|      2 |
mysql>

mysql> (SELECT 1 AS result UNION SELECT 2) LIMIT 1;
+--------+
| result |
+--------+
|      1 |

mysql> (SELECT 1 AS result UNION SELECT 2) LIMIT 1 OFFSET 1;
+--------+
| result |
+--------+
|      2 |

mysql> (SELECT 1 AS result UNION SELECT 2)
       ORDER BY result DESC LIMIT 1;
+--------+
| result |
+--------+
|      2 |

mysql> (SELECT 1 AS result UNION SELECT 2)
       ORDER BY result DESC LIMIT 1 OFFSET 1;
+--------+
| result |
+--------+
|      1 |

mysql> (SELECT 1 AS result UNION SELECT 3 UNION SELECT 2)
       ORDER BY result LIMIT 1 OFFSET 1 INTO @var;

mysql> SELECT @var;
+------+
| @var |
+------+
|    2 |
```

Parenthesized query expressions are also used as query expressions, so a query expression, usually composed of query blocks, may also consist of parenthesized query expressions:

```sql
(SELECT * FROM t1 ORDER BY a) UNION (SELECT * FROM t2 ORDER BY b) ORDER BY z;
```

Query blocks may have trailing `ORDER BY` and `LIMIT` clauses, which are applied before the outer `UNION` and `ORDER BY` and `LIMIT`.

You cannot have a query block with a trailing `ORDER BY` or `LIMIT`, without wrapping it in parentheses, but parentheses may be used for enforcement in various ways:
• To enforce `LIMIT` on each query block:

```sql
(SELECT 1 LIMIT 1) UNION (SELECT 2 LIMIT 1);
```

• To enforce `LIMIT` on both query blocks and the entire query expression:

```sql
(SELECT 1 LIMIT 1) UNION (SELECT 2 LIMIT 1) LIMIT 1;
```

• To enforce `LIMIT` on the entire query expression (with no parentheses):

```sql
SELECT 1 UNION SELECT 2 LIMIT 1;
```

• Hybrid enforcement: `LIMIT` on the first query block and on the entire query expression:

```sql
(SELECT 1 LIMIT 1) UNION SELECT 2 LIMIT 1;
```

The syntax described in this section is subject to certain restrictions:

• If `ORDER BY` occurs within a parenthesized query expression and also is applied in the outer query, the results are undefined and may change in a future version of MySQL. The same is true if `LIMIT` occurs within a parenthesized query expression and also is applied in the outer query.

• A trailing `INTO` clause for a query expression is not permitted if there is another `INTO` clause inside parentheses.

• Parenthesized query expressions do not permit multiple levels of `ORDER BY` or `LIMIT` operations. For example:

```sql
mysql> (SELECT 'a' UNION SELECT 'b' LIMIT 1) LIMIT 2;
ERROR 1235 (42000): This version of MySQL doesn't yet support 'parenthesized query expression with more than one external level of ORDER/LIMIT operations'
```

### 13.2.11 Subqueries

A subquery is a `SELECT` statement within another statement.

All subquery forms and operations that the SQL standard requires are supported, as well as a few features that are MySQL-specific.

Here is an example of a subquery:

```sql
SELECT * FROM t1 WHERE column1 = (SELECT column1 FROM t2);
```

In this example, `SELECT * FROM t1 ...` is the outer query (or outer statement), and `(SELECT column1 FROM t2)` is the subquery. We say that the subquery is nested within the outer query, and in fact it is possible to nest subqueries within other subqueries, to a considerable depth. A subquery must always appear within parentheses.

The main advantages of subqueries are:

• They allow queries that are structured so that it is possible to isolate each part of a statement.

• They provide alternative ways to perform operations that would otherwise require complex joins and unions.

• Many people find subqueries more readable than complex joins or unions. Indeed, it was the innovation of subqueries that gave people the original idea of calling the early SQL “Structured Query Language.”

Here is an example statement that shows the major points about subquery syntax as specified by the SQL standard and supported in MySQL:

```sql
DELETE FROM t1
```
WHERE s11 > ANY
(SELECT COUNT(*) /* no hint */ FROM t2
WHERE NOT EXISTS
(SELECT * FROM t3
WHERE ROW(5*t2.s1,77)=
(SELECT 50,11*s1 FROM t4 UNION SELECT 50,77 FROM
(SELECT * FROM t5) AS t5)));
When you see examples in the following sections that contain the rather spartan construct `(SELECT column1 FROM t1)`, imagine that your own code contains much more diverse and complex constructions.

Suppose that we make two tables:

```sql
CREATE TABLE t1 (s1 INT);
INSERT INTO t1 VALUES (1);
CREATE TABLE t2 (s1 INT);
INSERT INTO t2 VALUES (2);
```

Then perform a `SELECT`:

```sql
SELECT (SELECT s1 FROM t2) FROM t1;
```

The result is 2 because there is a row in `t2` containing a column `s1` that has a value of 2.

In MySQL 8.0.19 and later, the preceding query can also be written like this, using `TABLE`:

```sql
SELECT (TABLE t2) FROM t1;
```

A scalar subquery can be part of an expression, but remember the parentheses, even if the subquery is an operand that provides an argument for a function. For example:

```sql
SELECT UPPER((SELECT s1 FROM t1)) FROM t2;
```

The same result can be obtained in MySQL 8.0.19 and later using `SELECT UPPER((TABLE t1))` FROM t2.

### 13.2.11.2 Comparisons Using Subqueries

The most common use of a subquery is in the form:

```
non_subquery_operand comparison_operator (subquery)
```

Where `comparison_operator` is one of these operators:

```
=  >  >=  <=  <>  !=  <=>
```

For example:

```sql
... WHERE 'a' = (SELECT column1 FROM t1)
```

MySQL also permits this construct:

```
non_subquery_operand LIKE (subquery)
```

At one time the only legal place for a subquery was on the right side of a comparison, and you might still find some old DBMSs that insist on this.

Here is an example of a common-form subquery comparison that you cannot do with a join. It finds all the rows in table `t1` for which the `column1` value is equal to a maximum value in table `t2`:

```sql
SELECT * FROM t1
WHERE column1 = (SELECT MAX(column2) FROM t2);
```

Here is another example, which again is impossible with a join because it involves aggregating for one of the tables. It finds all rows in table `t1` containing a value that occurs twice in a given column:

```sql
SELECT * FROM t1 AS t
WHERE 2 = (SELECT COUNT(*) FROM t1 WHERE t.id = t.id);
```

For a comparison of the subquery to a scalar, the subquery must return a scalar. For a comparison of the subquery to a row constructor, the subquery must be a row subquery that returns a row with the same number of values as the row constructor. See Section 13.2.11.5, “Row Subqueries”.
13.2.11.3 Subqueries with ANY, IN, or SOME

Syntax:

- `operand comparison_operator ANY (subquery)`
- `operand IN (subquery)`
- `operand comparison_operator SOME (subquery)`

Where `comparison_operator` is one of these operators:

- `=`, `<`, `>`, `>=`, `<=`, `<>`, `!=`

The `ANY` keyword, which must follow a comparison operator, means “return `TRUE` if the comparison is `TRUE` for `ANY` of the values in the column that the subquery returns.” For example:

```
SELECT s1 FROM t1 WHERE s1 > ANY (SELECT s1 FROM t2);
```

Suppose that there is a row in table `t1` containing `(10)`. The expression is `TRUE` if table `t2` contains `(21,14,7)` because there is a value `7` in `t2` that is less than `10`. The expression is `FALSE` if table `t2` contains `(20,10)`, or if table `t2` is empty. The expression is `unknown` (that is, `NULL`) if table `t2` contains `(NULL,NULL,NULL)`.

When used with a subquery, the word `IN` is an alias for `ANY`. Thus, these two statements are the same:

```
SELECT s1 FROM t1 WHERE s1 = ANY (SELECT s1 FROM t2);
SELECT s1 FROM t1 WHERE s1 IN (SELECT s1 FROM t2);
```

`IN` and `= ANY` are not synonyms when used with an expression list. `IN` can take an expression list, but `= ANY` cannot. See Section 12.4.2, “Comparison Functions and Operators”.

`NOT IN` is not an alias for `<> ANY`, but for `<> ALL`. See Section 13.2.11.4, “Subqueries with ALL”.

The word `SOME` is an alias for `ANY`. Thus, these two statements are the same:

```
SELECT s1 FROM t1 WHERE s1 <> ANY  (SELECT s1 FROM t2);
SELECT s1 FROM t1 WHERE s1 <> SOME (SELECT s1 FROM t2);
```

Use of the word `SOME` is rare, but this example shows why it might be useful. To most people, the English phrase “a is not equal to any b” means “there is no b which is equal to a,” but that is not what is meant by the SQL syntax. The syntax means “there is some b to which a is not equal.” Using `<> SOME` instead helps ensure that everyone understands the true meaning of the query.

Beginning with MySQL 8.0.19, you can use `TABLE` in a scalar `IN`, `ANY`, or `SOME` subquery provided the table contains only a single column. If `t2` has only one column, the statements shown previously in this section can be written as shown here, in each case substituting `TABLE t2` for `SELECT s1 FROM t2`:

```
SELECT s1 FROM t1 WHERE s1 > ANY (TABLE t2);
SELECT s1 FROM t1 WHERE s1 = ANY (TABLE t2);
SELECT s1 FROM t1 WHERE s1 IN (TABLE t2);
SELECT s1 FROM t1 WHERE s1 <> ANY (TABLE t2);
SELECT s1 FROM t1 WHERE s1 <> SOME (TABLE t2);
```

13.2.11.4 Subqueries with ALL

Syntax:

```
operand comparison_operator ALL (subquery)
```

The word `ALL`, which must follow a comparison operator, means “return `TRUE` if the comparison is `TRUE` for `ALL` of the values in the column that the subquery returns.” For example:
Suppose that there is a row in table \( t_1 \) containing \((10)\). The expression is TRUE if table \( t_2 \) contains \((-5,0,+5)\) because 10 is greater than all three values in \( t_2 \). The expression is FALSE if table \( t_2 \) contains \((12,6,NULL,-100)\) because there is a single value 12 in table \( t_2 \) that is greater than 10. The expression is unknown (that is, NULL) if table \( t_2 \) contains \((0,NULL,1)\).

Finally, the expression is TRUE if table \( t_2 \) is empty. So, the following expression is TRUE when table \( t_2 \) is empty:

\[
\text{SELECT * FROM } t_1 \text{ WHERE } 1 > \text{ ALL (SELECT s1 FROM } t_2);\]

But this expression is NULL when table \( t_2 \) is empty:

\[
\text{SELECT * FROM } t_1 \text{ WHERE } 1 > (\text{SELECT s1 FROM } t_2);\]

In addition, the following expression is NULL when table \( t_2 \) is empty:

\[
\text{SELECT * FROM } t_1 \text{ WHERE } 1 > \text{ ALL (SELECT MAX(s1) FROM } t_2);\]

In general, tables containing NULL values and empty tables are “edge cases.” When writing subqueries, always consider whether you have taken those two possibilities into account.

**NOT IN** is an alias for \(<> \text{ ALL} \). Thus, these two statements are the same:

\[
\text{SELECT s1 FROM } t_1 \text{ WHERE } s1 <> \text{ ALL (SELECT s1 FROM } t_2);\]

\[
\text{SELECT s1 FROM } t_1 \text{ WHERE } s1 \not\in \text{ (SELECT s1 FROM } t_2);\]

MySQL 8.0.19 supports the **TABLE** statement. As with **IN**, **ANY**, and **SOME**, you can use **TABLE** with **ALL** and **NOT IN** provided that the following two conditions are met:

- The table in the subquery contains only one column
- The subquery does not depend on a column expression

For example, assuming that table \( t_2 \) consists of a single column, the last two statements shown previously can be written using **TABLE t2** like this:

\[
\text{SELECT s1 FROM } t_1 \text{ WHERE } s1 <> \text{ ALL (TABLE t2);}\]

\[
\text{SELECT s1 FROM } t_1 \text{ WHERE } s1 \not\in \text{ (TABLE t2);}\]

A query such as \(\text{SELECT * FROM } t_1 \text{ WHERE } 1 > \text{ ALL (SELECT MAX(s1) FROM } t_2);\) cannot be written using **TABLE t2** because the subquery depends on a column expression.

### 13.2.11.5 Row Subqueries

Scalar or column subqueries return a single value or a column of values. A row subquery is a subquery variant that returns a single row and can thus return more than one column value. Legal operators for row subquery comparisons are:

\[
= \text{ } > \text{ } <= \text{ } = \text{ } <= \text{ } <> \text{ } != \text{ } <=<>\]

Here are two examples:

```sql
SELECT * FROM t1
WHERE (col1,col2) = (SELECT col3, col4 FROM t2 WHERE id = 10);
```

```sql
SELECT * FROM t1
WHERE ROW(col1,col2) = (SELECT col3, col4 FROM t2 WHERE id = 10);
```

For both queries, if the table \( t_2 \) contains a single row with \( id = 10 \), the subquery returns a single row. If this row has \( \text{col3} \) and \( \text{col4} \) values equal to the \( \text{col1} \) and \( \text{col2} \) values of any rows in \( t_1 \), the \( \text{WHERE} \) expression is TRUE and each query returns those \( t_1 \) rows. If the \( t_2 \) row \( \text{col3} \) and \( \text{col4} \) values are not equal the \( \text{col1} \) and \( \text{col2} \) values of any \( t_1 \) row, the expression is FALSE and the query returns an empty result set. The expression is unknown (that is, NULL) if the subquery produces no rows. An
error occurs if the subquery produces multiple rows because a row subquery can return at most one row.

For information about how each operator works for row comparisons, see Section 12.4.2, “Comparison Functions and Operators”.

The expressions \((1,2)\) and \(\text{ROW}(1,2)\) are sometimes called row constructors. The two are equivalent. The row constructor and the row returned by the subquery must contain the same number of values.

A row constructor is used for comparisons with subqueries that return two or more columns. When a subquery returns a single column, this is regarded as a scalar value and not as a row, so a row constructor cannot be used with a subquery that does not return at least two columns. Thus, the following query fails with a syntax error:

```sql
SELECT * FROM t1 WHERE \text{ROW}(1) = (SELECT column1 FROM t2)
```

Row constructors are legal in other contexts. For example, the following two statements are semantically equivalent (and are handled in the same way by the optimizer):

```sql
SELECT * FROM t1 WHERE (column1,column2) = (1,1);
SELECT * FROM t1 WHERE column1 = 1 AND column2 = 1;
```

The following query answers the request, “find all rows in table \(t1\) that also exist in table \(t2\)”: 

```sql
SELECT column1,column2,column3
FROM t1
WHERE (column1,column2,column3) IN
  (SELECT column1,column2,column3 FROM t2);
```

For more information about the optimizer and row constructors, see Section 8.2.1.22, “Row Constructor Expression Optimization”.

### 13.2.11.6 Subqueries with EXISTS or NOT EXISTS

If a subquery returns any rows at all, \text{EXISTS} subquery is TRUE, and \text{NOT EXISTS} subquery is FALSE. For example:

```sql
SELECT column1 FROM t1 WHERE EXISTS (SELECT * FROM t2);
```

Traditionally, an \text{EXISTS} subquery starts with SELECT *, but it could begin with SELECT 5 or SELECT column1 or anything at all. MySQL ignores the SELECT list in such a subquery, so it makes no difference.

For the preceding example, if \(t2\) contains any rows, even rows with nothing but NULL values, the \text{EXISTS} condition is TRUE. This is actually an unlikely example because a \text{NOT EXISTS} subquery almost always contains correlations. Here are some more realistic examples:

- What kind of store is present in one or more cities?

```sql
SELECT DISTINCT store_type FROM stores
WHERE EXISTS (SELECT * FROM cities_stores
  WHERE cities_stores.store_type = stores.store_type);
```

- What kind of store is present in no cities?

```sql
SELECT DISTINCT store_type FROM stores
WHERE NOT EXISTS (SELECT * FROM cities_stores
  WHERE cities_stores.store_type = stores.store_type);
```

- What kind of store is present in all cities?

```sql
SELECT DISTINCT store_type FROM stores s1
WHERE NOT EXISTS (SELECT * FROM cities WHERE NOT EXISTS (Select * FROM cities_stores
  WHERE cities_stores.store_type = s1.store_type))
```

```sql
SELECT * FROM t1 WHERE NOT EXISTS (SELECT * FROM t2)
```
The last example is a double-nested NOT EXISTS query. That is, it has a NOT EXISTS clause within a NOT EXISTS clause. Formally, it answers the question "does a city exist with a store that is not in Stores?" But it is easier to say that a nested NOT EXISTS answers the question "is $x$ TRUE for all $y$?"

In MySQL 8.0.19 and later, you can also use NOT EXISTS or NOT EXISTS with TABLE in the subquery, like this:

```sql
SELECT column1 FROM t1 WHERE EXISTS (TABLE t2);
```

The results are the same as when using SELECT * with no WHERE clause in the subquery.

### 13.2.11.7 Correlated Subqueries

A **correlated subquery** is a subquery that contains a reference to a table that also appears in the outer query. For example:

```sql
SELECT * FROM t1
  WHERE column1 = ANY (SELECT column1 FROM t2
                        WHERE t2.column2 = t1.column2);
```

Notice that the subquery contains a reference to a column of t1, even though the subquery's FROM clause does not mention a table t1. So, MySQL looks outside the subquery, and finds t1 in the outer query.

Suppose that table t1 contains a row where column1 = 5 and column2 = 6; meanwhile, table t2 contains a row where column1 = 5 and column2 = 7. The simple expression ...

WHERE column1 = ANY (SELECT column1 FROM t2)

would be TRUE, but in this example, the WHERE clause within the subquery is FALSE (because (5,6) is not equal to (5,7)), so the expression as a whole is FALSE.

**Scoping rule:** MySQL evaluates from inside to outside. For example:

```sql
SELECT column1 FROM t1 AS x
  WHERE x.column1 = (SELECT column1 FROM t2 AS x
                   WHERE x.column1 = (SELECT column1 FROM t3
                                    WHERE x.column2 = t3.column1));
```

In this statement, x.column2 must be a column in table t2 because SELECT column1 FROM t2 AS x ... renames t2. It is not a column in table t1 because SELECT column1 FROM t1 ... is an outer query that is farther out.

Beginning with MySQL 8.0.24, the optimizer can transform a correlated scalar subquery to a derived table. Consider the query shown here:

```sql
SELECT * FROM t1
  WHERE ( SELECT a FROM t2
           WHERE t2.a = t1.a ) > 0;
```

To avoid materializing several times for a given derived table, we can instead materialize—once—a derived table which adds a grouping on the join column from the table referenced in the inner query (t2.a) and then an outer join on the lifted predicate (t1.a = derived.a) in order to select the correct group to match up with the outer row. (If the subquery already has an explicit grouping, the extra grouping is added to the end of the grouping list.) The query previously shown can thus be rewritten like this:

```sql
SELECT t1.* FROM t1
  LEFT OUTER JOIN
    (SELECT a, COUNT(*) AS ct FROM t2 GROUP BY a) AS derived
  ON t1.a = derived.a
  AND REJECT_IF(
```
In the rewritten query, `REJECT_IF()` represents an internal function which tests a given condition (here, the comparison `ct > 1`) and raises a given error (in this case, `ER_SUBQUERY_NO_1_ROW`) if the condition is true. This reflects the cardinality check that the optimizer performs as part of evaluating the **JOIN** or **WHERE** clause, prior to evaluating any lifted predicate, which is done only if the subquery does not return more than one row.

This type of transformation can be performed, provided the following conditions are met:

- The subquery can be part of a **SELECT** list, **WHERE** condition, or **HAVING** condition, but cannot be part of a **JOIN** condition, and cannot contain a **LIMIT** or **OFFSET** clause. In addition, the subquery cannot contain any set operations such as **UNION**.
- The **WHERE** clause may contain one or more predicates, combined with **AND**. If the **WHERE** clause contains an **OR** clause, it cannot be transformed. At least one of the **WHERE** clause predicates must be eligible for transformation, and none of them may reject transformation.
- To be eligible for transformation, a **WHERE** clause predicate must be an equality predicate in which each operand should be a simple column reference. No other predicates—including other comparison predicates—are eligible for transformation. The predicate must employ the equality operator `=` for making the comparison; the null-safe `<>` operator is not supported in this context.
- A **WHERE** clause predicate that contains only inner references is not eligible for transformation, since it can be evaluated before the grouping. A **WHERE** clause predicate that contains only outer references is eligible for transformation, even though it can be lifted up to the outer query block. This is made possible by adding a cardinality check without grouping in the derived table.
- To be eligible, a **WHERE** clause predicate must have one operand that contains only inner references and one operand that contains only outer references. If the predicate is not eligible due to this rule, transformation of the query is rejected.
- A correlated column can be present only in the subquery’s **WHERE** clause (and not in the **SELECT** list, a **JOIN** or **ORDER BY** clause, a **GROUP BY** list, or a **HAVING** clause). Nor can there be any correlated column inside a derived table in the subquery’s **FROM** list.
- A correlated column can not be contained in an aggregate function’s list of arguments.
- A correlated column must be resolved in the query block directly containing the subquery being considered for transformation.
- A correlated column cannot be present in a nested scalar subquery in the **WHERE** clause.
- The subquery cannot contain any window functions, and must not contain any aggregate function which aggregates in a query block outer to the subquery. A **COUNT()** aggregate function, if contained in the **SELECT** list element of the subquery, must be at the topmost level, and cannot be part of an expression.

See also Section 13.2.11.8, “Derived Tables”.

### 13.2.11.8 Derived Tables

This section discusses general characteristics of derived tables. For information about lateral derived tables preceded by the **LATERAL** keyword, see Section 13.2.11.9, “Lateral Derived Tables”.

A derived table is an expression that generates a table within the scope of a query **FROM** clause. For example, a subquery in a **SELECT** statement **FROM** clause is a derived table:

```sql
SELECT ... FROM (subquery) [AS] tbl_name ...```
Subqueries

The `JSON_TABLE()` function generates a table and provides another way to create a derived table:

```sql
SELECT * FROM JSON_TABLE(arg_list) [AS] tbl_name ...
```

The `[AS] tbl_name` clause is mandatory because every table in a `FROM` clause must have a name. Any columns in the derived table must have unique names. Alternatively, `tbl_name` may be followed by a parenthesized list of names for the derived table columns:

```sql
SELECT ... FROM (subquery) [AS] tbl_name (col_list) ...
```

The number of column names must be the same as the number of table columns.

For the sake of illustration, assume that you have this table:

```sql
CREATE TABLE t1 (s1 INT, s2 CHAR(5), s3 FLOAT);
```

Here is how to use a subquery in the `FROM` clause, using the example table:

```sql
INSERT INTO t1 VALUES (1,'1',1.0);
INSERT INTO t1 VALUES (2,'2',2.0);
SELECT sb1,sb2,sb3
FROM (SELECT s1 AS sb1, s2 AS sb2, s3*2 AS sb3 FROM t1) AS sb
WHERE sb1 > 1;
```

Result:

```
+---+---+---+
| 2 | 2 | 4 |
+---+---+---+
```

Here is another example: Suppose that you want to know the average of a set of sums for a grouped table. This does not work:

```sql
SELECT AVG(SUM(column1)) FROM t1 GROUP BY column1;
```

However, this query provides the desired information:

```sql
SELECT AVG(sum_column1)
FROM (SELECT SUM(column1) AS sum_column1
FROM t1 GROUP BY column1) AS t1;
```

Notice that the column name used within the subquery (`sum_column1`) is recognized in the outer query.

The column names for a derived table come from its select list:

```sql
mysql> SELECT * FROM (SELECT 1, 2, 3, 4) AS dt;
+---+---+---+---+
| 1 | 2 | 3 | 4 |
+---+---+---+---+
| 1 | 2 | 3 | 4 |
+---+---+---+---+
```

To provide column names explicitly, follow the derived table name with a parenthesized list of column names:

```sql
mysql> SELECT * FROM (SELECT 1, 2, 3, 4) AS dt (a, b, c, d);
+---+---+---+---+
| a | b | c | d |
+---+---+---+---+
| 1 | 2 | 3 | 4 |
+---+---+---+---+
```

A derived table can return a scalar, column, row, or table.

Derived tables are subject to these restrictions:
• A derived table cannot contain references to other tables of the same SELECT (use a LATERAL derived table for that; see Section 13.2.11.9, “Lateral Derived Tables”).

• Prior to MySQL 8.0.14, a derived table cannot contain outer references. This is a MySQL restriction that is lifted in MySQL 8.0.14, not a restriction of the SQL standard. For example, the derived table `dt` in the following query contains a reference `t1.b` to the table `t1` in the outer query:

```sql
SELECT * FROM t1 WHERE t1.d > (SELECT AVG(dt.a)
    FROM (SELECT SUM(t2.a) AS a
        FROM t2
        WHERE t2.b = t1.b GROUP BY t2.c) dt
    WHERE dt.a > 10);
```

The query is valid in MySQL 8.0.14 and higher. Before 8.0.14, it produces an error: Unknown column 't1.b' in 'where clause'

The optimizer determines information about derived tables in such a way that EXPLAIN does not need to materialize them. See Section 8.2.2.4, “Optimizing Derived Tables, View References, and Common Table Expressions with Merging or Materialization”.

It is possible under certain circumstances that using EXPLAIN SELECT modifies table data. This can occur if the outer query accesses any tables and an inner query invokes a stored function that changes one or more rows of a table. Suppose that there are two tables `t1` and `t2` in database `d1`, and a stored function `f1` that modifies `t2`, created as shown here:

```sql
CREATE DATABASE d1;
USE d1;
CREATE TABLE t1 (c1 INT);
CREATE TABLE t2 (c1 INT);
CREATE FUNCTION f1(p1 INT) RETURNS INT BEGIN
    INSERT INTO t2 VALUES (p1);
    RETURN p1;
END;
```

Referencing the function directly in an EXPLAIN SELECT has no effect on `t2`, as shown here:

```sql
mysql> SELECT * FROM t2;
Empty set (0.02 sec)

mysql> EXPLAIN SELECT f1(5)\G
*************************** 1. row ***************************
id: 1
select_type: SIMPLE
table: NULL
partitions: NULL
type: NULL
possible_keys: NULL
key: NULL
key_len: NULL
ref: NULL
rows: NULL
filtered: NULL
Extra: No tables used
1 row in set (0.01 sec)

mysql> SELECT * FROM t2;
Empty set (0.01 sec)
```

This is because the SELECT statement did not reference any tables, as can be seen in the table and Extra columns of the output. This is also true of the following nested SELECT:

```sql
mysql> EXPLAIN SELECT NOW() AS a1, (SELECT f1(5)) AS a2\G
*************************** 1. row ***************************
id: 1
select_type: PRIMARY
table: NULL
```
However, if the outer `SELECT` references any tables, the optimizer executes the statement in the subquery as well, with the result that `t2` is modified:

```sql
mysql> EXPLAIN SELECT * FROM t1 AS a1, (SELECT f1(5)) AS a2
G
*************************** 1. row ***************************
  id: 1
  select_type: PRIMARY
  table: <derived2>
  partitions: NULL
  type: system
  possible_keys: NULL
  key: NULL
  key_len: NULL
  ref: NULL
  rows: 1
  filtered: 100.00
  Extra: NULL

*************************** 2. row ***************************
  id: 1
  select_type: PRIMARY
  table: a1
  partitions: NULL
  type: ALL
  possible_keys: NULL
  key: NULL
  key_len: NULL
  ref: NULL
  rows: 1
  filtered: 100.00
  Extra: NULL

*************************** 3. row ***************************
  id: 2
  select_type: DERIVED
  table: NULL
  partitions: NULL
  type: NULL
  possible_keys: NULL
  key: NULL
  key_len: NULL
  ref: NULL
  rows: NULL
  filtered: NULL
  Extra: No tables used
3 rows in set (0.00 sec)
```

```sql
mysql> SELECT * FROM t2;
+------+
<table>
<thead>
<tr>
<th>c1</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
</tr>
</tbody>
</table>
+------+
```
This also means that an `EXPLAIN SELECT` statement such as the one shown here may take a long time to execute because the `BENCHMARK()` function is executed once for each row in `t1`:

```sql
EXPLAIN SELECT * FROM t1 AS a1, (SELECT BENCHMARK(1000000, MD5(NOW())));
```

The derived table optimization can also be employed with many correlated (scalar) subqueries (MySQL 8.0.24 and later). For more information and examples, see Section 13.2.11.7, “Correlated Subqueries”.

### 13.2.11.9 Lateral Derived Tables

A derived table cannot normally refer to (depend on) columns of preceding tables in the same `FROM` clause. As of MySQL 8.0.14, a derived table may be defined as a lateral derived table to specify that such references are permitted.

Nonlateral derived tables are specified using the syntax discussed in Section 13.2.11.8, “Derived Tables”. The syntax for a lateral derived table is the same as for a nonlateral derived table except that the keyword `LATERAL` is specified before the derived table specification. The `LATERAL` keyword must precede each table to be used as a lateral derived table.

Lateral derived tables are subject to these restrictions:

- A lateral derived table can occur only in a `FROM` clause, either in a list of tables separated with commas or in a join specification (`JOIN`, `INNER JOIN`, `CROSS JOIN`, `LEFT [OUTER] JOIN`, or `RIGHT [OUTER] JOIN`).

- If a lateral derived table is in the right operand of a join clause and contains a reference to the left operand, the join operation must be an `INNER JOIN`, `CROSS JOIN`, or `LEFT [OUTER] JOIN`.

  If the table is in the left operand and contains a reference to the right operand, the join operation must be an `INNER JOIN`, `CROSS JOIN`, or `RIGHT [OUTER] JOIN`.

- If a lateral derived table references an aggregate function, the function's aggregation query cannot be the one that owns the `FROM` clause in which the lateral derived table occurs.

- Per the SQL standard, a table function has an implicit `LATERAL`, so it behaves as in MySQL 8.0 versions prior to 8.0.14. However, per the standard, the `LATERAL` word is not allowed before `JSON_TABLE()`, even though it is implicit.

The following discussion shows how lateral derived tables make possible certain SQL operations that cannot be done with nonlateral derived tables or that require less-efficient workarounds.

Suppose that we want to solve this problem: Given a table of people in a sales force (where each row describes a member of the sales force), and a table of all sales (where each row describes a sale: salesperson, customer, amount, date), determine the size and customer of the largest sale for each salesperson. This problem can be approached two ways.

First approach to solving the problem: For each salesperson, calculate the maximum sale size, and also find the customer who provided this maximum. In MySQL, that can be done like this:

```sql
SELECT
  salesperson.name,
  -- find maximum size for this salesperson
  (SELECT MAX(amount) AS amount
   FROM all_sales
   WHERE all_sales.salesperson_id = salesperson.id)
  AS amount,
  -- find customer for this maximum size
  (SELECT customer_name
   FROM all_sales
   WHERE all_sales.salesperson_id = salesperson.id
   AND all_sales.amount =
   -- find maximum size, again
```

```sql
  (SELECT MAX(amount) AS amount
   FROM all_sales
   WHERE all_sales.salesperson_id = salesperson.id)
  )
FROM salesperson
INNER JOIN all_sales
ON salesperson.id = all_sales.salesperson_id
GROUP BY salesperson.id,
```
Subqueries

(SELECT MAX(amount) AS amount
    FROM all_sales
    WHERE all_sales.salesperson_id = salesperson.id)
AS customer_name
FROM salesperson;

That query is inefficient because it calculates the maximum size twice per salesperson (once in the first subquery and once in the second).

We can try to achieve an efficiency gain by calculating the maximum once per salesperson and “caching” it in a derived table, as shown by this modified query:

SELECT salesperson.name,
    max_sale.amount,
    max_sale_customer.customer_name
FROM salesperson,
    -- calculate maximum size, cache it in transient derived table max_sale
    (SELECT MAX(amount) AS amount
        FROM all_sales
        WHERE all_sales.salesperson_id = salesperson.id)
    AS max_sale,
    -- find customer, reusing cached maximum size
    (SELECT customer_name
        FROM all_sales
        WHERE all_sales.salesperson_id = salesperson.id
        AND all_sales.amount =
            -- the cached maximum size
            max_sale.amount)
    AS max_sale_customer;

However, the query is illegal in SQL-92 because derived tables cannot depend on other tables in the same FROM clause. Derived tables must be constant over the query's duration, not contain references to columns of other FROM clause tables. As written, the query produces this error:

ERROR 1054 (42S22): Unknown column 'salesperson.id' in 'where clause'

In SQL:1999, the query becomes legal if the derived tables are preceded by the LATERAL keyword (which means “this derived table depends on previous tables on its left side”):

SELECT salesperson.name,
    max_sale.amount,
    max_sale_customer.customer_name
FROM salesperson,
    -- calculate maximum size, cache it in transient derived table max_sale
    LATERAL (SELECT MAX(amount) AS amount
            FROM all_sales
            WHERE all_sales.salesperson_id = salesperson.id)
    AS max_sale,
    -- find customer, reusing cached maximum size
    LATERAL (SELECT customer_name
            FROM all_sales
            WHERE all_sales.salesperson_id = salesperson.id
            AND all_sales.amount =
                -- the cached maximum size
                max_sale.amount)
    AS max_sale_customer;

A lateral derived table need not be constant and is brought up to date each time a new row from a preceding table on which it depends is processed by the top query.

Second approach to solving the problem: A different solution could be used if a subquery in the SELECT list could return multiple columns:
Subqueries

SELECT
  salesperson.name,
  -- find maximum size and customer at same time
  (SELECT amount, customer_name
    FROM all_sales
    WHERE all_sales.salesperson_id = salesperson.id
    ORDER BY amount DESC LIMIT 1)
FROM
  salesperson;

That is efficient but illegal. It does not work because such subqueries can return only a single column:

ERROR 1241 (21000): Operand should contain 1 column(s)

One attempt at rewriting the query is to select multiple columns from a derived table:

SELECT
  salesperson.name,
  max_sale.amount,
  max_sale.customer_name
FROM
  salesperson,
  -- find maximum size and customer at same time
  (SELECT amount, customer_name
    FROM all_sales
    WHERE all_sales.salesperson_id = salesperson.id
    ORDER BY amount DESC LIMIT 1)
AS max_sale;

However, that also does not work. The derived table is dependent on the salesperson table and thus fails without LATERAL:

ERROR 1054 (42S22): Unknown column 'salesperson.id' in 'where clause'

Adding the LATERAL keyword makes the query legal:

SELECT
  salesperson.name,
  max_sale.amount,
  max_sale.customer_name
FROM
  salesperson,
  -- find maximum size and customer at same time
  LATERAL
  (SELECT amount, customer_name
    FROM all_sales
    WHERE all_sales.salesperson_id = salesperson.id
    ORDER BY amount DESC LIMIT 1)
AS max_sale;

In short, LATERAL is the efficient solution to all drawbacks in the two approaches just discussed.

13.2.11.10 Subquery Errors

There are some errors that apply only to subqueries. This section describes them.

- Unsupported subquery syntax:

  ERROR 1235 (ER_NOT_SUPPORTED_YET)
  SQLSTATE = 42000
  Message = "This version of MySQL doesn't yet support 'LIMIT & IN/ALL/ANY/SOME subquery'"

  This means that MySQL does not support statements like the following:

  SELECT * FROM t1 WHERE s1 IN (SELECT s2 FROM t2 ORDER BY s1 LIMIT 1)

- Incorrect number of columns from subquery:

  ERROR 1241 (ER_OPERAND_COL)
Subqueries

This error occurs in cases like this:

```
SELECT (SELECT column1, column2 FROM t2) FROM t1;
```

You may use a subquery that returns multiple columns, if the purpose is row comparison. In other contexts, the subquery must be a scalar operand. See Section 13.2.11.5, “Row Subqueries”.

- Incorrect number of rows from subquery:

```
ERROR 1242 (ER_SUBSELECT_NO_1_ROW)
SQLSTATE = 21000
Message = "Subquery returns more than 1 row"
```

This error occurs for statements where the subquery must return at most one row but returns multiple rows. Consider the following example:

```
SELECT * FROM t1 WHERE column1 = (SELECT column1 FROM t2);
```

If `SELECT column1 FROM t2` returns just one row, the previous query works. If the subquery returns more than one row, error 1242 occurs. In that case, the query should be rewritten as:

```
SELECT * FROM t1 WHERE column1 = ANY (SELECT column1 FROM t2);
```

- Incorrectly used table in subquery:

```
Error 1093 (ER_UPDATE_TABLE_USED)
SQLSTATE = HY000
Message = "You can't specify target table 'x' for update in FROM clause"
```

This error occurs in cases such as the following, which attempts to modify a table and select from the same table in the subquery:

```
UPDATE t1 SET column2 = (SELECT MAX(column1) FROM t1);
```

You can use a common table expression or derived table to work around this. See Section 13.2.11.12, “Restrictions on Subqueries”.

In MySQL 8.0.19 and later, all of the errors described in this section also apply when using `TABLE` in subqueries.

For transactional storage engines, the failure of a subquery causes the entire statement to fail. For nontransactional storage engines, data modifications made before the error was encountered are preserved.

### 13.2.11.11 Optimizing Subqueries

Development is ongoing, so no optimization tip is reliable for the long term. The following list provides some interesting tricks that you might want to play with. See also Section 8.2.2, “Optimizing Subqueries, Derived Tables, View References, and Common Table Expressions”.

- Move clauses from outside to inside the subquery. For example, use this query:

```
SELECT * FROM t1
  WHERE s1 IN (SELECT s1 FROM t1 UNION ALL SELECT s1 FROM t2);
```

Instead of this query:

```
SELECT * FROM t1
  WHERE s1 IN (SELECT s1 FROM t1) OR s1 IN (SELECT s1 FROM t2);
```

For another example, use this query:

### 13.2.11.12 Restrictions on Subqueries

- In general, you cannot modify a table and select from the same table in a subquery. For example, this limitation applies to statements of the following forms:

```
DELETE FROM t WHERE ... (SELECT ... FROM t ...);
UPDATE t ... WHERE col = (SELECT ... FROM t ...);
{INSERT|REPLACE} INTO t (SELECT ... FROM t ...);
```

Exception: The preceding prohibition does not apply if for the modified table you are using a derived table and that derived table is materialized rather than merged into the outer query. (See Section 8.2.2.4, “Optimizing Derived Tables, View References, and Common Table Expressions with Merging or Materialization”.) Example:

```
UPDATE t ... WHERE col = (SELECT * FROM (SELECT ... FROM t...) AS dt ...);
```

Here the result from the derived table is materialized as a temporary table, so the relevant rows in `t` have already been selected by the time the update to `t` takes place.

In general, you may be able to influence the optimizer to materialize a derived table by adding a NO_MERGE optimizer hint. See Section 8.9.3, “Optimizer Hints”.

- Row comparison operations are only partially supported:

  - For `expr [NOT] IN subquery, expr` can be an n-tuple (specified using row constructor syntax) and the subquery can return rows of n-tuples. The permitted syntax is therefore more specifically expressed as `row_constructor [NOT] IN table_subquery`

  - For `expr op {ALL|ANY|SOME} subquery`, `expr` must be a scalar value and the subquery must be a column subquery; it cannot return multiple-column rows.

In other words, for a subquery that returns rows of n-tuples, this is supported:

```
(expr_1, ..., expr_n) [NOT] IN table_subquery
```

But this is not supported:

```
(expr_1, ..., expr_n) op {ALL|ANY|SOME} subquery
```

The reason for supporting row comparisons for **IN** but not for the others is that **IN** is implemented by rewriting it as a sequence of **=** comparisons and **AND** operations. This approach cannot be used for **ALL**, **ANY**, or **SOME**.

- Prior to MySQL 8.0.14, subqueries in the **FROM** clause cannot be correlated subqueries. They are materialized in whole (evaluated to produce a result set) during query execution, so they cannot be evaluated per row of the outer query. The optimizer delays materialization until the result is needed, which may permit materialization to be avoided. See Section 8.2.2.4, “Optimizing Derived Tables, View References, and Common Table Expressions with Merging or Materialization”.

- MySQL does not support **LIMIT** in subqueries for certain subquery operators:

```
mysql> SELECT * FROM t1
         WHERE s1 IN (SELECT s2 FROM t2 ORDER BY s1 LIMIT 1);
ERROR 1235 (42000): This version of MySQL doesn't yet support 'LIMIT & IN/ALL/ANY/SOME subquery'
```

See Section 13.2.11.10, “Subquery Errors”.

---

**SELECT (SELECT column1 + 5 FROM t1) FROM t2;**

Instead of this query:

**SELECT (SELECT column1 FROM t1) + 5 FROM t2;**
MySQL permits a subquery to refer to a stored function that has data-modifying side effects such as inserting rows into a table. For example, if \( f() \) inserts rows, the following query can modify data:

\[
\text{SELECT ... WHERE x IN (SELECT f() ...);}
\]

This behavior is an extension to the SQL standard. In MySQL, it can produce nondeterministic results because \( f() \) might be executed a different number of times for different executions of a given query depending on how the optimizer chooses to handle it.

For statement-based or mixed-format replication, one implication of this indeterminism is that such a query can produce different results on the source and its replicas.

### 13.2.12 TABLE Statement

**TABLE** is a DML statement introduced in MySQL 8.0.19 which returns rows and columns of the named table.

\[
\text{TABLE \ table_name [ORDER BY column_name] [LIMIT number [OFFSET number]]}
\]

The **TABLE** statement in some ways acts like **SELECT**. Given the existence of a table named \( t \), the following two statements produce identical output:

```sql
TABLE t;
SELECT * FROM t;
```

You can order and limit the number of rows produced by **TABLE** using **ORDER BY** and **LIMIT** clauses, respectively. These function identically to the same clauses when used with **SELECT** (including an optional **OFFSET** clause with **LIMIT**), as you can see here:

```sql
mysql> TABLE t;
+----+----+
| a  | b  |
+----+----+
|  1 |  2 |
|  6 |  7 |
|  9 |  5 |
| 10 | -4 |
| 11 | -1 |
| 13 |  3 |
| 14 |  6 |
+----+----+
7 rows in set (0.00 sec)

mysql> TABLE t ORDER BY b;
+----+----+
| a  | b  |
+----+----+
| 10 | -4 |
| 11 | -1 |
|  1 |  2 |
| 13 |  3 |
|  9 |  5 |
| 14 |  6 |
|  6 |  7 |
+----+----+
7 rows in set (0.00 sec)

mysql> TABLE t LIMIT 3;
+----+----+
| a  | b  |
+----+----+
|  1 |  2 |
|  6 |  7 |
|  9 |  5 |
+----+----+
3 rows in set (0.00 sec)

mysql> TABLE t ORDER BY b LIMIT 3;
```
### TABLE Statement

<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>-4</td>
</tr>
<tr>
<td>11</td>
<td>-1</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
</tr>
</tbody>
</table>

3 rows in set (0.00 sec)

mysql> TABLE t ORDER BY b LIMIT 3 OFFSET 2;

<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>13</td>
<td>3</td>
</tr>
<tr>
<td>9</td>
<td>5</td>
</tr>
</tbody>
</table>

3 rows in set (0.00 sec)

**TABLE** differs from **SELECT** in two key respects:

- **TABLE** always displays all columns of the table.
- **TABLE** does not allow for any arbitrary filtering of rows; that is, **TABLE** does not support any `WHERE` clause.

For limiting which table columns are returned, filtering rows beyond what can be accomplished using `ORDER BY` and `LIMIT`, or both, use `SELECT`.

**TABLE** can be used with temporary tables.

**TABLE** can also be used in place of `SELECT` in a number of other constructs, including those listed here:

- With `UNION`, as shown here:

```sql
mysql> TABLE t1;

+----+----+
<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>10</td>
</tr>
<tr>
<td>5</td>
<td>3</td>
</tr>
<tr>
<td>7</td>
<td>8</td>
</tr>
</tbody>
</table>

3 rows in set (0.00 sec)

mysql> TABLE t2;

+----+----+
<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>3</td>
<td>4</td>
</tr>
<tr>
<td>6</td>
<td>7</td>
</tr>
</tbody>
</table>

3 rows in set (0.00 sec)

mysql> TABLE t1 UNION TABLE t2;

+----+----+
<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>10</td>
</tr>
<tr>
<td>5</td>
<td>3</td>
</tr>
<tr>
<td>7</td>
<td>8</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>3</td>
<td>4</td>
</tr>
<tr>
<td>6</td>
<td>7</td>
</tr>
</tbody>
</table>

6 rows in set (0.00 sec)
```

The `UNION` just shown is equivalent to the following statement:
### UPDATE Statement

An **UPDATE** statement can start with a **WITH** clause to define common table expressions accessible within the **UPDATE**. See [Section 13.2.15, “WITH (Common Table Expressions)”](#).

#### Single-table syntax:

```sql
UPDATE [LOW_PRIORITY] [IGNORE] table_reference
    SET assignment_list
    [WHERE where_condition]
    [ORDER BY ...]
    [LIMIT row_count]
```

value:

- `{expr | DEFAULT}`

assignment:

- `col_name = value`

assignment_list:

- `assignment [, assignment] ...`

Multiple-table syntax:
UPDATE [LOW_PRIORITY] [IGNORE] table_references
  SET assignment_list
  [WHERE where_condition]

For the single-table syntax, the **UPDATE** statement updates columns of existing rows in the named table with new values. The **SET** clause indicates which columns to modify and the values they should be given. Each value can be given as an expression, or the keyword **DEFAULT** to set a column explicitly to its default value. The **WHERE** clause, if given, specifies the conditions that identify which rows to update. With no **WHERE** clause, all rows are updated. If the **ORDER BY** clause is specified, the rows are updated in the order that is specified. The **LIMIT** clause places a limit on the number of rows that can be updated.

For the multiple-table syntax, **UPDATE** updates rows in each table named in `table_references` that satisfy the conditions. Each matching row is updated once, even if it matches the conditions multiple times. For multiple-table syntax, **ORDER BY** and **LIMIT** cannot be used.

For partitioned tables, both the single-single and multiple-table forms of this statement support the use of a **PARTITION** clause as part of a table reference. This option takes a list of one or more partitions or subpartitions (or both). Only the partitions (or subpartitions) listed are checked for matches, and a row that is not in any of these partitions or subpartitions is not updated, whether it satisfies the **where_condition** or not.

**Note**

Unlike the case when using **PARTITION** with an **INSERT** or **REPLACE** statement, an otherwise valid **UPDATE ... PARTITION** statement is considered successful even if no rows in the listed partitions (or subpartitions) match the **where_condition**.

For more information and examples, see Section 24.5, “Partition Selection”.

**where_condition** is an expression that evaluates to true for each row to be updated. For expression syntax, see Section 9.5, “Expressions”.

**table_references** and **where_condition** are specified as described in Section 13.2.10, “SELECT Statement”.

You need the **UPDATE** privilege only for columns referenced in an **UPDATE** that are actually updated. You need only the **SELECT** privilege for any columns that are read but not modified.

The **UPDATE** statement supports the following modifiers:

- With the **LOW_PRIORITY** modifier, execution of the **UPDATE** is delayed until no other clients are reading from the table. This affects only storage engines that use only table-level locking (such as **MyISAM**, **MEMORY**, and **MERGE**).

- With the **IGNORE** modifier, the update statement does not abort even if errors occur during the update. Rows for which duplicate-key conflicts occur on a unique key value are not updated. Rows updated to values that would cause data conversion errors are updated to the closest valid values instead. For more information, see The Effect of **IGNORE** on Statement Execution.

**UPDATE IGNORE** statements, including those having an **ORDER BY** clause, are flagged as unsafe for statement-based replication. (This is because the order in which the rows are updated determines which rows are ignored.) Such statements produce a warning in the error log when using statement-based mode and are written to the binary log using the row-based format when using **MIXED** mode. (Bug #11758262, Bug #50439) See Section 17.2.1.3, “Determination of Safe and Unsafe Statements in Binary Logging”, for more information.

If you access a column from the table to be updated in an expression, **UPDATE** uses the current value of the column. For example, the following statement sets `col1` to one more than its current value:

```
UPDATE t1 SET col1 = col1 + 1;
```
The second assignment in the following statement sets `col2` to the current (updated) `col1` value, not the original `col1` value. The result is that `col1` and `col2` have the same value. This behavior differs from standard SQL.

```sql
UPDATE t1 SET col1 = col1 + 1, col2 = col1;
```

Single-table `UPDATE` assignments are generally evaluated from left to right. For multiple-table updates, there is no guarantee that assignments are carried out in any particular order.

If you set a column to the value it currently has, MySQL notices this and does not update it.

If you update a column that has been declared `NOT NULL` by setting to `NULL`, an error occurs if strict SQL mode is enabled; otherwise, the column is set to the implicit default value for the column data type and the warning count is incremented. The implicit default value is 0 for numeric types, the empty string ('') for string types, and the “zero” value for date and time types. See Section 11.6, “Data Type Default Values”.

If a generated column is updated explicitly, the only permitted value is `DEFAULT`. For information about generated columns, see Section 13.1.20.8, “CREATE TABLE and Generated Columns”.

`UPDATE` returns the number of rows that were actually changed. The `mysql_info()` C API function returns the number of rows that were matched and updated and the number of warnings that occurred during the `UPDATE`.

You can use `LIMIT row_count` to restrict the scope of the `UPDATE`. A `LIMIT` clause is a rows-matched restriction. The statement stops as soon as it has found `row_count` rows that satisfy the `WHERE` clause, whether or not they actually were changed.

If an `UPDATE` statement includes an `ORDER BY` clause, the rows are updated in the order specified by the clause. This can be useful in certain situations that might otherwise result in an error. Suppose that a table `t` contains a column `id` that has a unique index. The following statement could fail with a duplicate-key error, depending on the order in which rows are updated:

```sql
UPDATE t SET id = id + 1;
```

For example, if the table contains 1 and 2 in the `id` column and 1 is updated to 2 before 2 is updated to 3, an error occurs. To avoid this problem, add an `ORDER BY` clause to cause the rows with larger `id` values to be updated before those with smaller values:

```sql
UPDATE t SET id = id + 1 ORDER BY id DESC;
```

You can also perform `UPDATE` operations covering multiple tables. However, you cannot use `ORDER BY` or `LIMIT` with a multiple-table `UPDATE`. The `table_references` clause lists the tables involved in the join. Its syntax is described in Section 13.2.10.2, “JOIN Clause”. Here is an example:

```sql
UPDATE items,month SET items.price=month.price
WHERE items.id=month.id;
```

The preceding example shows an inner join that uses the comma operator, but multiple-table `UPDATE` statements can use any type of join permitted in `SELECT` statements, such as `LEFT JOIN`.

If you use a multiple-table `UPDATE` statement involving InnoDB tables for which there are foreign key constraints, the MySQL optimizer might process tables in an order that differs from that of their parent/child relationship. In this case, the statement fails and rolls back. Instead, update a single table and rely on the `ON UPDATE` capabilities that InnoDB provides to cause the other tables to be modified accordingly. See Section 13.1.20.5, “FOREIGN KEY Constraints”.

You cannot update a table and select directly from the same table in a subquery. You can work around this by using a multi-table update in which one of the tables is derived from the table that you actually wish to update, and referring to the derived table using an alias. Suppose you wish to update a table named `items` which is defined using the statement shown here:

```sql
CREATE TABLE items {
```
VALUES Statement

VALUES is a DML statement introduced in MySQL 8.0.19 which returns a set of one or more rows as a table. In other words, it is a table value constructor which also functions as a standalone SQL statement.

VALUES row_constructor_list [ORDER BY column_designator] [LIMIT BY number]

row_constructor_list:
VALUES Statement

\[ \text{ROW(value_list), ROW(value_list)}, \ldots \]  

\text{value_list:} \[ \text{value, value}, \ldots \]  

\text{column_designator:} \[ \text{column_index} \]

The VALUES statement consists of the VALUES keyword followed by a list of one or more row constructors, separated by commas. A row constructor consists of the ROW() row constructor clause with a value list of one or more scalar values enclosed in the parentheses. A value can be a literal of any MySQL data type or an expression that resolves to a scalar value.

ROW() cannot be empty (but each of the supplied scalar values can be NULL). Each ROW() in the same VALUES statement must have the same number of values in its value list.

The DEFAULT keyword is not supported by VALUES and causes a syntax error, except when it is used to supply values in an INSERT statement.

The output of VALUES is a table:

```
mysql> VALUES ROW(1,-2,3), ROW(5,7,9), ROW(4,6,8);
+----------+----------+----------+
| column_0 | column_1 | column_2 |
+----------+----------+----------+
|        1 |       -2 |        3 |
|        5 |        7 |        9 |
|        4 |        6 |        8 |
+----------+----------+----------+
3 rows in set (0.00 sec)
```

The columns of the table output from VALUES have the implicitly named columns column_0, column_1, column_2, and so on, always beginning with 0. This fact can be used to order the rows by column using an optional ORDER BY clause in the same way that this clause works with a SELECT statement, as shown here:

```
mysql> VALUES ROW(1,-2,3), ROW(5,7,9), ROW(4,6,8) ORDER BY column_1;
+----------+----------+----------+
| column_0 | column_1 | column_2 |
+----------+----------+----------+
|        1 |       -2 |        3 |
|        4 |        6 |        8 |
|        5 |        7 |        9 |
+----------+----------+----------+
3 rows in set (0.00 sec)
```

The VALUES statement also supports a LIMIT clause for limiting the number of rows in the output.

The VALUES statement is permissive regarding data types of column values; you can mix types within the same column, as shown here:

```
mysql> VALUES ROW("q", 42, '2019-12-18'),
        -> ROW(23, "abc", 98.6),
        -> ROW(27.0002, "Mary Smith", '{"a": 10, "b": 25}');
+----------+------------+--------------------+
| column_0 | column_1   | column_2           |
+----------+------------+--------------------+
| q        | 42         | 2019-12-18         |
| 23       | abc        | 98.6               |
| 27.0002  | Mary Smith |{"a": 10, "b": 25}|
+----------+------------+--------------------+
3 rows in set (0.00 sec)
```

**Important**

VALUES with one or more instances of ROW() acts as a table value constructor; although it can be used to supply values in an INSERT or REPLACE statement, do not confuse it with the VALUES keyword that is also used for this purpose.
VALUES Statement

You should also not confuse it with the VALUES() function that refers to column values in INSERT ... ON DUPLICATE KEY UPDATE.

You should also bear in mind that ROW() is a row value constructor (see Section 13.2.11.5, “Row Subqueries”, whereas VALUES ROW() is a table value constructor; the two cannot be used interchangeably.

VALUES can be used in many cases where you could employ SELECT, including those listed here:

- With UNION, as shown here:

```
mysql> SELECT 1,2 UNION SELECT 10,15;
+----+----+
| 1  | 2  |
| 10 | 15 |
+----+----+
2 rows in set (0.00 sec)
```

```
mysql> VALUES ROW(1,2) UNION VALUES ROW(10,15);
+----------+----------+
| column_0 | column_1 |
| 1        | 2        |
| 10       | 15       |
+----------+----------+
2 rows in set (0.00 sec)
```

It is also possible in this fashion to union together constructed tables having more than one row, like this:

```
mysql> VALUES ROW(1,2), ROW(3,4), ROW(5,6)
    > UNION VALUES ROW(10,15),ROW(20,25);
+----------+----------+
| column_0 | column_1 |
| 1        | 2        |
| 3        | 4        |
| 5        | 6        |
| 10       | 15       |
| 20       | 25       |
+----------+----------+
5 rows in set (0.00 sec)
```

You can also (and it is usually preferable to) omit UNION altogether in such cases and use a single VALUES statement, like this:

```
mysql> VALUES ROW(1,2), ROW(3,4), ROW(5,6), ROW(10,15), ROW(20,25);
+----------+----------+
| column_0 | column_1 |
| 1        | 2        |
| 3        | 4        |
| 5        | 6        |
| 10       | 15       |
| 20       | 25       |
+----------+----------+
```

VALUES can also be used in unions with SELECT statements, TABLE statements, or both.

The constructed tables in the UNION must contain the same number of columns, just as if you were using SELECT. See Section 13.2.10.3, “UNION Clause”, for further examples.

- In joins. See Section 13.2.10.2, “JOIN Clause”, for more information and examples.

- In place of VALUES() in an INSERT or REPLACE statement, in which case its semantics differ slightly from what is described here. See Section 13.2.6, “INSERT Statement”, for details.
• In place of the source table in `CREATE TABLE ... SELECT` and `CREATE VIEW ... SELECT`. See the descriptions of these statements for more information and examples.

### 13.2.15 WITH (Common Table Expressions)

A common table expression (CTE) is a named temporary result set that exists within the scope of a single statement and that can be referred to later within that statement, possibly multiple times. The following discussion describes how to write statements that use CTEs.

- **Common Table Expressions**
- **Recursive Common Table Expressions**
- **Limiting Common Table Expression Recursion**
- **Recursive Common Table Expression Examples**
- **Common Table Expressions Compared to Similar Constructs**

For information about CTE optimization, see Section 8.2.2.4, “Optimizing Derived Tables, View References, and Common Table Expressions with Merging or Materialization”.

### Additional Resources

These articles contain additional information about using CTEs in MySQL, including many examples:

- MySQL 8.0 Labs: [Recursive] Common Table Expressions in MySQL (CTEs)
- MySQL 8.0 Labs: [Recursive] Common Table Expressions in MySQL (CTEs), Part Two – how to generate series
- MySQL 8.0 Labs: [Recursive] Common Table Expressions in MySQL (CTEs), Part Three – hierarchies
- MySQL 8.0.1: [Recursive] Common Table Expressions in MySQL (CTEs), Part Four – depth-first or breadth-first traversal, transitive closure, cycle avoidance

### Common Table Expressions

To specify common table expressions, use a `WITH` clause that has one or more comma-separated subclauses. Each subclause provides a subquery that produces a result set, and associates a name with the subquery. The following example defines CTEs named `cte1` and `cte2` in the `WITH` clause, and refers to them in the top-level `SELECT` that follows the `WITH` clause:

```sql
WITH
  cte1 AS (SELECT a, b FROM table1),
  cte2 AS (SELECT c, d FROM table2)
SELECT b, d FROM cte1 JOIN cte2
WHERE cte1.a = cte2.c;
```

In the statement containing the `WITH` clause, each CTE name can be referenced to access the corresponding CTE result set.

A CTE name can be referenced in other CTEs, enabling CTEs to be defined based on other CTEs.

A CTE can refer to itself to define a recursive CTE. Common applications of recursive CTEs include series generation and traversal of hierarchical or tree-structured data.

Common table expressions are an optional part of the syntax for DML statements. They are defined using a `WITH` clause:

```sql
WITH [RECURSIVE]
  cte_name [(col_name [, col_name] ...)] AS (subquery)
[, cte_name [(col_name [, col_name] ...)] AS (subquery)] ...
```
**cte_name** names a single common table expression and can be used as a table reference in the statement containing the **WITH** clause.

The **subquery** part of **AS (subquery)** is called the “subquery of the CTE” and is what produces the CTE result set. The parentheses following **AS** are required.

A common table expression is recursive if its subquery refers to its own name. The **RECURSIVE** keyword must be included if any CTE in the **WITH** clause is recursive. For more information, see [Recursive Common Table Expressions](#).

Determination of column names for a given CTE occurs as follows:

- If a parenthesized list of names follows the CTE name, those names are the column names:

  ```sql
  WITH cte (col1, col2) AS
  (SELECT 1, 2
   UNION ALL
   SELECT 3, 4)
  SELECT col1, col2 FROM cte;
  ```

  The number of names in the list must be the same as the number of columns in the result set.

- Otherwise, the column names come from the select list of the first **SELECT** within the **AS (subquery)** part:

  ```sql
  WITH cte AS
  (SELECT 1 AS col1, 2 AS col2
   UNION ALL
   SELECT 3, 4)
  SELECT col1, col2 FROM cte;
  ```

A **WITH** clause is permitted in these contexts:

- At the beginning of **SELECT**, **UPDATE**, and **DELETE** statements.

  ```sql
  WITH ... SELECT ...
  WITH ... UPDATE ...
  WITH ... DELETE ...
  ```

- At the beginning of subqueries (including derived table subqueries):

  ```sql
  SELECT ... WHERE id IN (WITH ... SELECT ...) ...
  SELECT * FROM (WITH ... SELECT ...) AS dt ...
  ```

- Immediately preceding **SELECT** for statements that include a **SELECT** statement:

  ```sql
  INSERT ... WITH ... SELECT ...
  REPLACE ... WITH ... SELECT ...
  CREATE TABLE ... WITH ... SELECT ...
  CREATE VIEW ... WITH ... SELECT ...
  DECLARE CURSOR ... WITH ... SELECT ...
  EXPLAIN ... WITH ... SELECT ...
  ```

Only one **WITH** clause is permitted at the same level. **WITH** followed by **WITH** at the same level is not permitted, so this is illegal:

```sql
WITH cte1 AS (...) WITH cte2 AS (...) SELECT ...
```

To make the statement legal, use a single **WITH** clause that separates the subclauses by a comma:

```sql
WITH cte1 AS (...), cte2 AS (...) SELECT ...
```

However, a statement can contain multiple **WITH** clauses if they occur at different levels:

```sql
WITH cte1 AS {SELECT 1}
```
WITH (Common Table Expressions)

WITH cte AS (...), cte AS (...) SELECT ...

A CTE can refer to itself or to other CTEs:
• A self-referencing CTE is recursive.
• A CTE can refer to CTEs defined earlier in the same WITH clause, but not those defined later.

This constraint rules out mutually-recursive CTEs, where cte1 references cte2 and cte2 references cte1. One of those references must be to a CTE defined later, which is not permitted.
• A CTE in a given query block can refer to CTEs defined in query blocks at a more outer level, but not CTEs defined in query blocks at a more inner level.

For resolving references to objects with the same names, derived tables hide CTEs; and CTEs hide base tables, TEMPORARY tables, and views. Name resolution occurs by searching for objects in the same query block, then proceeding to outer blocks in turn while no object with the name is found.

Like derived tables, a CTE cannot contain outer references prior to MySQL 8.0.14. This is a MySQL restriction that is lifted in MySQL 8.0.14, not a restriction of the SQL standard. For additional syntax considerations specific to recursive CTEs, see Recursive Common Table Expressions.

Recursive Common Table Expressions

A recursive common table expression is one having a subquery that refers to its own name. For example:

WITH RECURSIVE cte (n) AS

(  SELECT 1
  UNION ALL
  SELECT n + 1 FROM cte WHERE n < 5
)

SELECT * FROM cte;

When executed, the statement produces this result, a single column containing a simple linear sequence:

<table>
<thead>
<tr>
<th>n</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
</tr>
<tr>
<td>2</td>
</tr>
<tr>
<td>3</td>
</tr>
<tr>
<td>4</td>
</tr>
<tr>
<td>5</td>
</tr>
</tbody>
</table>

A recursive CTE has this structure:
• The WITH clause must begin with WITH RECURSIVE if any CTE in the WITH clause refers to itself. (If no CTE refers to itself, RECURSIVE is permitted but not required.)

If you forget RECURSIVE for a recursive CTE, this error is a likely result:

ERROR 1146 (42S02): Table 'cte_name' doesn't exist

• The recursive CTE subquery has two parts, separated by UNION (ALL) or UNION DISTINCT:
WITH (Common Table Expressions)

```
SELECT ...  -- return initial row set
UNION ALL
SELECT ...  -- return additional row sets
```

The first `SELECT` produces the initial row or rows for the CTE and does not refer to the CTE name. The second `SELECT` produces additional rows and recurses by referring to the CTE name in its `FROM` clause. Recursion ends when this part produces no new rows. Thus, a recursive CTE consists of a nonrecursive `SELECT` part followed by a recursive `SELECT` part.

Each `SELECT` part can itself be a union of multiple `SELECT` statements.

- The types of the CTE result columns are inferred from the column types of the nonrecursive `SELECT` part only, and the columns are all nullable. For type determination, the recursive `SELECT` part is ignored.

- If the nonrecursive and recursive parts are separated by `UNION DISTINCT`, duplicate rows are eliminated. This is useful for queries that perform transitive closures, to avoid infinite loops.

- Each iteration of the recursive part operates only on the rows produced by the previous iteration. If the recursive part has multiple query blocks, iterations of each query block are scheduled in unspecified order, and each query block operates on rows that have been produced either by its previous iteration or by other query blocks since that previous iteration’s end.

The recursive CTE subquery shown earlier has this nonrecursive part that retrieves a single row to produce the initial row set:

```
SELECT 1
```

The CTE subquery also has this recursive part:

```
SELECT n + 1 FROM cte WHERE n < 5
```

At each iteration, that `SELECT` produces a row with a new value one greater than the value of `n` from the previous row set. The first iteration operates on the initial row set (1) and produces 1+1=2; the second iteration operates on the first iteration’s row set (2) and produces 2+1=3; and so forth. This continues until recursion ends, which occurs when `n` is no longer less than 5.

If the recursive part of a CTE produces wider values for a column than the nonrecursive part, it may be necessary to widen the column in the nonrecursive part to avoid data truncation. Consider this statement:

```
WITH RECURSIVE cte AS
  (  
      SELECT 1 AS n, 'abc' AS str
      UNION ALL
      SELECT n + 1, CONCAT(str, str) FROM cte WHERE n < 3
  )
SELECT * FROM cte;
```

In nonstrict SQL mode, the statement produces this output:

```
+-----+------+
| n   | str  |
+-----+------+
|    1 | abc  |
|    2 | abc  |
|    3 | abc  |
```

The `str` column values are all 'abc' because the nonrecursive `SELECT` determines the column widths. Consequently, the wider `str` values produced by the recursive `SELECT` are truncated.

In strict SQL mode, the statement produces an error:

```
ERROR 1406 (22001): Data too long for column 'str' at row 1
```
To address this issue, so that the statement does not produce truncation or errors, use \texttt{CAST()} in the nonrecursive \texttt{SELECT} to make the \texttt{str} column wider:

\begin{verbatim}
WITH RECURSIVE cte AS
  (
    SELECT 1 AS n, CAST('abc' AS CHAR(20)) AS str
    UNION ALL
    SELECT n + 1, CONCAT(str, str) FROM cte WHERE n < 3
  )
SELECT * FROM cte;
\end{verbatim}

Now the statement produces this result, without truncation:

\begin{verbatim}
+-----+--------------+
| n   | str          |
|-----+--------------|
| 1   | abc          |
| 2   | abcabc       |
| 3   | abcabcabcabc |
+-----+--------------+
\end{verbatim}

Columns are accessed by name, not position, which means that columns in the recursive part can access columns in the nonrecursive part that have a different position, as this CTE illustrates:

\begin{verbatim}
WITH RECURSIVE cte AS
  (
    SELECT 1 AS n, 1 AS p, -1 AS q
    UNION ALL
    SELECT n + 1, q * 2, p * 2 FROM cte WHERE n < 5
  )
SELECT * FROM cte;
\end{verbatim}

Because \texttt{p} in one row is derived from \texttt{q} in the previous row, and vice versa, the positive and negative values swap positions in each successive row of the output:

\begin{verbatim}
+----+--------+------+
| n  | p      | q    |
|----+--------+------|
| 1  | 1      | -1   |
| 2  | -2     |  2   |
| 3  |  4     | -4   |
| 4  | -8     |  8   |
| 5  | 16     | -16  |
+----+--------+------+
\end{verbatim}

Some syntax constraints apply within recursive CTE subqueries:

- The recursive \texttt{SELECT} part must not contain these constructs:
  - Aggregate functions such as \texttt{SUM()}
  - Window functions
  - \texttt{GROUP BY}
  - \texttt{ORDER BY}
  - \texttt{DISTINCT}

Prior to MySQL 8.0.19, the recursive \texttt{SELECT} part of a recursive CTE also could not use a \texttt{LIMIT} clause. This restriction is lifted in MySQL 8.0.19, and \texttt{LIMIT} is now supported in such cases, along with an optional \texttt{OFFSET} clause. The effect on the result set is the same as when using \texttt{LIMIT} in the outermost \texttt{SELECT}, but is also more efficient, since using it with the recursive \texttt{SELECT} stops the generation of rows as soon as the requested number of them has been produced.

These constraints do not apply to the nonrecursive \texttt{SELECT} part of a recursive CTE. The prohibition on \texttt{DISTINCT} applies only to \texttt{UNION} members; \texttt{UNION DISTINCT} is permitted.
• The recursive `SELECT` part must reference the CTE only once and only in its `FROM` clause, not in any subquery. It can reference tables other than the CTE and join them with the CTE. If used in a join like this, the CTE must not be on the right side of a `LEFT JOIN`.

These constraints come from the SQL standard, other than the MySQL-specific exclusions of `ORDER BY, LIMIT` (MySQL 8.0.18 and earlier), and `DISTINCT`.

For recursive CTEs, `EXPLAIN` output rows for recursive `SELECT` parts display `Recursive` in the `Extra` column.

Cost estimates displayed by `EXPLAIN` represent cost per iteration, which might differ considerably from total cost. The optimizer cannot predict the number of iterations because it cannot predict at what point the `WHERE` clause becomes false.

CTE actual cost may also be affected by result set size. A CTE that produces many rows may require an internal temporary table large enough to be converted from in-memory to on-disk format and may suffer a performance penalty. If so, increasing the permitted in-memory temporary table size may improve performance; see Section 8.4.4, “Internal Temporary Table Use in MySQL”.

**Limiting Common Table Expression Recursion**

It is important for recursive CTEs that the recursive `SELECT` part include a condition to terminate recursion. As a development technique to guard against a runaway recursive CTE, you can force termination by placing a limit on execution time:

• The `cte_max_recursion_depth` system variable enforces a limit on the number of recursion levels for CTEs. The server terminates execution of any CTE that recurses more levels than the value of this variable.

• The `max_execution_time` system variable enforces an execution timeout for `SELECT` statements executed within the current session.

• The `MAX_EXECUTION_TIME` optimizer hint enforces a per-query execution timeout for the `SELECT` statement in which it appears.

Suppose that a recursive CTE is mistakenly written with no recursion execution termination condition:

```sql
WITH RECURSIVE cte (n) AS
  (
    SELECT 1
    UNION ALL
    SELECT n + 1 FROM cte
  )
SELECT * FROM cte;
```

By default, `cte_max_recursion_depth` has a value of 1000, causing the CTE to terminate when it recurses past 1000 levels. Applications can change the session value to adjust for their requirements:

```sql
SET SESSION cte_max_recursion_depth = 10; -- permit only shallow recursion
SET SESSION cte_max_recursion_depth = 1000000; -- permit deeper recursion
```

You can also set the global `cte_max_recursion_depth` value to affect all sessions that begin subsequently.

For queries that execute and thus recurse slowly or in contexts for which there is reason to set the `cte_max_recursion_depth` value very high, another way to guard against deep recursion is to set a per-session timeout. To do so, execute a statement like this prior to executing the CTE statement:

```sql
SET max_execution_time = 1000; -- impose one second timeout
```

Alternatively, include an optimizer hint within the CTE statement itself:

```sql
WITH RECURSIVE cte (n) AS
  (
    SELECT 1
  )
SELECT * FROM cte;
```
WITH (Common Table Expressions)

```sql
WITH RECURSIVE cte (n) AS
  (SELECT 1
   UNION ALL
   SELECT n + 1 FROM cte
  )
SELECT /*+ MAX_EXECUTION_TIME(1000) */ * FROM cte;
```

Beginning with MySQL 8.0.19, you can also use `LIMIT` within the recursive query to impose a maximum number of rows to be returned to the outermost `SELECT`, for example:

```sql
WITH RECURSIVE cte (n) AS
  (SELECT 1
   UNION ALL
   SELECT n + 1 FROM cte LIMIT 10000
  )
SELECT * FROM cte;
```

You can do this in addition to or instead of setting a time limit. Thus, the following CTE terminates after returning ten thousand rows or running for one thousand seconds, whichever occurs first:

```sql
WITH RECURSIVE cte (n) AS
  (SELECT 1
   UNION ALL
   SELECT n + 1 FROM cte LIMIT 10000
  )
SELECT /*+ MAX_EXECUTION_TIME(1000) */ * FROM cte;
```

If a recursive query without an execution time limit enters an infinite loop, you can terminate it from another session using `KILL QUERY`. Within the session itself, the client program used to run the query might provide a way to kill the query. For example, in `mysql`, typing `Control+C` interrupts the current statement.

### Recursive Common Table Expression Examples

As mentioned previously, recursive common table expressions (CTEs) are frequently used for series generation and traversing hierarchical or tree-structured data. This section shows some simple examples of these techniques.

- **Fibonacci Series Generation**
- **Date Series Generation**
- **Hierarchical Data Traversal**

#### Fibonacci Series Generation

A Fibonacci series begins with the two numbers 0 and 1 (or 1 and 1) and each number after that is the sum of the previous two numbers. A recursive common table expression can generate a Fibonacci series if each row produced by the recursive `SELECT` has access to the two previous numbers from the series. The following CTE generates a 10-number series using 0 and 1 as the first two numbers:

```sql
WITH RECURSIVE fibonacci (n, fib_n, next_fib_n) AS
  (SELECT 1, 0, 1
   UNION ALL
   SELECT n + 1, next_fib_n, fib_n + next_fib_n
   FROM fibonacci WHERE n < 10
  )
SELECT * FROM fibonacci;
```
WITH (Common Table Expressions)

The CTE produces this result:

<table>
<thead>
<tr>
<th>n</th>
<th>fib_n</th>
<th>next_fib_n</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>3</td>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>4</td>
<td>2</td>
<td>3</td>
</tr>
<tr>
<td>5</td>
<td>3</td>
<td>5</td>
</tr>
<tr>
<td>6</td>
<td>5</td>
<td>8</td>
</tr>
<tr>
<td>7</td>
<td>8</td>
<td>13</td>
</tr>
<tr>
<td>8</td>
<td>13</td>
<td>21</td>
</tr>
<tr>
<td>9</td>
<td>21</td>
<td>34</td>
</tr>
<tr>
<td>10</td>
<td>34</td>
<td>55</td>
</tr>
</tbody>
</table>

How the CTE works:

• \( n \) is a display column to indicate that the row contains the \( n \)-th Fibonacci number. For example, the 8th Fibonacci number is 13.

• The \( \text{fib}_n \) column displays Fibonacci number \( n \).

• The \( \text{next}_\text{fib}_n \) column displays the next Fibonacci number after number \( n \). This column provides the next series value to the next row, so that row can produce the sum of the two previous series values in its \( \text{fib}_n \) column.

• Recursion ends when \( n \) reaches 10. This is an arbitrary choice, to limit the output to a small set of rows.

The preceding output shows the entire CTE result. To select just part of it, add an appropriate \textit{WHERE} clause to the top-level \textit{SELECT}. For example, to select the 8th Fibonacci number, do this:

```sql
mysql> WITH RECURSIVE fibonacci ... 
... 
    SELECT fib_n FROM fibonacci WHERE n = 8;
```

<table>
<thead>
<tr>
<th>fib_n</th>
</tr>
</thead>
<tbody>
<tr>
<td>13</td>
</tr>
</tbody>
</table>

Date Series Generation

A common table expression can generate a series of successive dates, which is useful for generating summaries that include a row for all dates in the series, including dates not represented in the summarized data.

Suppose that a table of sales numbers contains these rows:

```sql
mysql> SELECT * FROM sales ORDER BY date, price;
```

<table>
<thead>
<tr>
<th>date</th>
<th>price</th>
</tr>
</thead>
<tbody>
<tr>
<td>2017-01-03</td>
<td>100.00</td>
</tr>
<tr>
<td>2017-01-03</td>
<td>200.00</td>
</tr>
<tr>
<td>2017-01-06</td>
<td>50.00</td>
</tr>
<tr>
<td>2017-01-08</td>
<td>10.00</td>
</tr>
<tr>
<td>2017-01-08</td>
<td>20.00</td>
</tr>
<tr>
<td>2017-01-08</td>
<td>150.00</td>
</tr>
<tr>
<td>2017-01-10</td>
<td>5.00</td>
</tr>
</tbody>
</table>

This query summarizes the sales per day:

```sql
mysql> SELECT date, SUM(price) AS sum_price FROM sales GROUP BY date;
```
ORDER BY date;

+------------+-----------+
| date       | sum_price |
+------------+-----------+
| 2017-01-03 |    300.00 |
| 2017-01-06 |     50.00 |
| 2017-01-08 |    180.00 |
| 2017-01-10 |      5.00 |
+------------+-----------+

However, that result contains “holes” for dates not represented in the range of dates spanned by the table. A result that represents all dates in the range can be produced using a recursive CTE to generate that set of dates, joined with a \texttt{LEFT JOIN} to the sales data.

Here is the CTE to generate the date range series:

\begin{verbatim}
WITH RECURSIVE dates (date) AS
  (SELECT MIN(date) FROM sales
   UNION ALL
   SELECT date + INTERVAL 1 DAY FROM dates
   WHERE date + INTERVAL 1 DAY <= (SELECT MAX(date) FROM sales)
  )
SELECT * FROM dates;
\end{verbatim}

The CTE produces this result:

+------------+
| date       |
+------------+
| 2017-01-03 |
| 2017-01-04 |
| 2017-01-05 |
| 2017-01-06 |
| 2017-01-07 |
| 2017-01-08 |
| 2017-01-09 |
| 2017-01-10 |
+------------+

How the CTE works:

- The nonrecursive \texttt{SELECT} produces the lowest date in the date range spanned by the \texttt{sales} table.
- Each row produced by the recursive \texttt{SELECT} adds one day to the date produced by the previous row.
- Recursion ends after the dates reach the highest date in the date range spanned by the \texttt{sales} table.

Joining the CTE with a \texttt{LEFT JOIN} against the \texttt{sales} table produces the sales summary with a row for each date in the range:

\begin{verbatim}
WITH RECURSIVE dates (date) AS
  (SELECT MIN(date) FROM sales
   UNION ALL
   SELECT date + INTERVAL 1 DAY FROM dates
   WHERE date + INTERVAL 1 DAY <= (SELECT MAX(date) FROM sales)
  )
SELECT dates.date, COALESCE(SUM(price), 0) AS sum_price
FROM dates LEFT JOIN sales ON dates.date = sales.date
GROUP BY dates.date
ORDER BY dates.date;
\end{verbatim}

The output looks like this:

+------------+-----------+
| date       | sum_price |
+------------+-----------+
| 2017-01-03 |    300.00 |
+------------+-----------+
WITH (Common Table Expressions)

Some points to note:

- Are the queries inefficient, particularly the one with the MAX() subquery executed for each row in the recursive SELECT? EXPLAIN shows that the subquery containing MAX() is evaluated only once and the result is cached.

- The use of COALESCE() avoids displaying NULL in the sum_price column on days for which no sales data occur in the sales table.

Hierarchical Data Traversal

Recursive common table expressions are useful for traversing data that forms a hierarchy. Consider these statements that create a small data set that shows, for each employee in a company, the employee name and ID number, and the ID of the employee's manager. The top-level employee (the CEO), has a manager ID of NULL (no manager).

CREATE TABLE employees (
  id         INT PRIMARY KEY NOT NULL,
  name       VARCHAR(100) NOT NULL,
  manager_id INT NULL,
  INDEX (manager_id),
  FOREIGN KEY (manager_id) REFERENCES employees (id)
);

INSERT INTO employees VALUES
  (333, "Yasmina", NULL),  # Yasmina is the CEO (manager_id is NULL)
  (198, "John", 333),      # John has ID 198 and reports to 333 (Yasmina)
  (692, "Tarek", 333),
  (29, "Pedro", 198),
  (4610, "Sarah", 29),
  (72, "Pierre", 29),
  (123, "Adil", 692);

The resulting data set looks like this:

mysql> SELECT * FROM employees ORDER BY id;
+------+---------+------------+
| id   | name    | manager_id |
+------+---------+------------+
| 29   | Pedro   |          198|
| 72   | Pierre  |           29|
| 123  | Adil    |          692|
| 198  | John    |          333|
| 333  | Yasmina |          NULL|
| 692  | Tarek   |          333|
| 4610 | Sarah   |           29|
+------+---------+------------+

To produce the organizational chart with the management chain for each employee (that is, the path from CEO to employee), use a recursive CTE:

WITH RECURSIVE employee_paths (id, name, path) AS
  (SELECT id, name, CAST(id AS CHAR(200))
  FROM employees
  WHERE manager_id IS NULL
  UNION ALL
  SELECT e.id, e.name, CONCAT(ep.path, ',', e.id)
  FROM employee_paths AS ep JOIN employees AS e
  ON ep.id = e.manager_id)

2511
WITH (Common Table Expressions)

SELECT * FROM employee_paths ORDER BY path;

The CTE produces this output:

<table>
<thead>
<tr>
<th>id</th>
<th>name</th>
<th>path</th>
</tr>
</thead>
<tbody>
<tr>
<td>333</td>
<td>Yasmina</td>
<td>333</td>
</tr>
<tr>
<td>198</td>
<td>John</td>
<td>333,198</td>
</tr>
<tr>
<td>29</td>
<td>Pedro</td>
<td>333,198,29</td>
</tr>
<tr>
<td>4610</td>
<td>Sarah</td>
<td>333,198,29,4610</td>
</tr>
<tr>
<td>72</td>
<td>Pierre</td>
<td>333,198,29,72</td>
</tr>
<tr>
<td>692</td>
<td>Tarek</td>
<td>333,692</td>
</tr>
<tr>
<td>123</td>
<td>Adil</td>
<td>333,692,123</td>
</tr>
</tbody>
</table>

How the CTE works:

• The nonrecursive SELECT produces the row for the CEO (the row with a NULL manager ID).

  The path column is widened to CHAR(200) to ensure that there is room for the longer path values produced by the recursive SELECT.

• Each row produced by the recursive SELECT finds all employees who report directly to an employee produced by a previous row. For each such employee, the row includes the employee ID and name, and the employee management chain. The chain is the manager's chain, with the employee ID added to the end.

• Recursion ends when employees have no others who report to them.

To find the path for a specific employee or employees, add a WHERE clause to the top-level SELECT. For example, to display the results for Tarek and Sarah, modify that SELECT like this:

```sql
.mysql> WITH RECURSIVE ...
... 
SELECT * FROM employees_extended
WHERE id IN (692, 4610)
ORDER BY path;
```

+-------+-------+-----------------+
<table>
<thead>
<tr>
<th>id</th>
<th>name</th>
<th>path</th>
</tr>
</thead>
<tbody>
<tr>
<td>4610</td>
<td>Sarah</td>
<td>333,198,29,4610</td>
</tr>
<tr>
<td>692</td>
<td>Tarek</td>
<td>333,692</td>
</tr>
</tbody>
</table>
+-------+-------+-----------------+

Common Table Expressions Compared to Similar Constructs

Common table expressions (CTEs) are similar to derived tables in some ways:

• Both constructs are named.

• Both constructs exist for the scope of a single statement.

Because of these similarities, CTEs and derived tables often can be used interchangeably. As a trivial example, these statements are equivalent:

```sql
WITH cte AS (SELECT 1) SELECT * FROM cte;
SELECT * FROM (SELECT 1) AS dt;
```

However, CTEs have some advantages over derived tables:

• A derived table can be referenced only a single time within a query. A CTE can be referenced multiple times. To use multiple instances of a derived table result, you must derive the result multiple times.

• A CTE can be self-referencing (recursive).

• One CTE can refer to another.
• A CTE may be easier to read when its definition appears at the beginning of the statement rather than embedded within it.

CTEs are similar to tables created with `CREATE [TEMPORARY] TABLE` but need not be defined or dropped explicitly. For a CTE, you need no privileges to create tables.

### 13.3 Transactional and Locking Statements

MySQL supports local transactions (within a given client session) through statements such as `SET autocommit`, `START TRANSACTION`, `COMMIT`, and `ROLLBACK`. See Section 13.3.1, "START TRANSACTION, COMMIT, and ROLLBACK Statements". XA transaction support enables MySQL to participate in distributed transactions as well. See Section 13.3.8, “XA Transactions”.

#### 13.3.1 START TRANSACTION, COMMIT, and ROLLBACK Statements

```
START TRANSACTION [transaction_characteristic [, transaction_characteristic] ...]

transaction_characteristic: {
  WITH CONSISTENT SNAPSHOT
  | READ WRITE
  | READ ONLY
}

BEGIN [WORK]
COMMIT [WORK] [AND [NO] CHAIN] [([NO] RELEASE]
ROLLBACK [WORK] [AND [NO] CHAIN] [([NO] RELEASE]

SET autocommit = {0 | 1}
```

These statements provide control over use of transactions:

- **START TRANSACTION** or **BEGIN** start a new transaction.
- **COMMIT** commits the current transaction, making its changes permanent.
- **ROLLBACK** rolls back the current transaction, canceling its changes.
- **SET autocommit** disables or enables the default autocommit mode for the current session.

By default, MySQL runs with **autocommit** mode enabled. This means that, when not otherwise inside a transaction, each statement is atomic, as if it were surrounded by **START TRANSACTION** and **COMMIT**. You cannot use **ROLLBACK** to undo the effect; however, if an error occurs during statement execution, the statement is rolled back.

To disable autocommit mode implicitly for a single series of statements, use the **START TRANSACTION** statement:

```
START TRANSACTION;
SELECT @A:=SUM(salary) FROM table1 WHERE type=1;
UPDATE table2 SET summary=@A WHERE type=1;
COMMIT;
```

With **START TRANSACTION**, autocommit remains disabled until you end the transaction with **COMMIT** or **ROLLBACK**. The autocommit mode then reverts to its previous state.

**START TRANSACTION** permits several modifiers that control transaction characteristics. To specify multiple modifiers, separate them by commas.

- The **WITH CONSISTENT SNAPSHOT** modifier starts a **consistent read** for storage engines that are capable of it. This applies only to **InnoDB**. The effect is the same as issuing a **START TRANSACTION** followed by a **SELECT** from any **InnoDB** table. See Section 15.7.2.3, “Consistent Nonlocking Reads”. The **WITH CONSISTENT SNAPSHOT** modifier does not change the current transaction **isolation level**, so it provides a consistent snapshot only if the current isolation level is one that permits a consistent read. The only isolation level that permits a consistent read is
REPEATABLE READ. For all other isolation levels, the WITH CONSISTENT SNAPSHOT clause is ignored. A warning is generated when the WITH CONSISTENT SNAPSHOT clause is ignored.

- The READ WRITE and READ ONLY modifiers set the transaction access mode. They permit or prohibit changes to tables used in the transaction. The READ ONLY restriction prevents the transaction from modifying or locking both transactional and nontransactional tables that are visible to other transactions; the transaction can still modify or lock temporary tables.

MySQL enables extra optimizations for queries on InnoDB tables when the transaction is known to be read-only. Specifying READ ONLY ensures these optimizations are applied in cases where the read-only status cannot be determined automatically. See Section 8.5.3, “Optimizing InnoDB Read-Only Transactions” for more information.

If no access mode is specified, the default mode applies. Unless the default has been changed, it is read/write. It is not permitted to specify both READ WRITE and READ ONLY in the same statement.

In read-only mode, it remains possible to change tables created with the TEMPORARY keyword using DML statements. Changes made with DDL statements are not permitted, just as with permanent tables.

For additional information about transaction access mode, including ways to change the default mode, see Section 13.3.7, “SET TRANSACTION Statement”.

If the read_only system variable is enabled, explicitly starting a transaction with START TRANSACTION READ WRITE requires the CONNECTION_ADMIN privilege (or the deprecated SUPER privilege).

Important

Many APIs used for writing MySQL client applications (such as JDBC) provide their own methods for starting transactions that can (and sometimes should) be used instead of sending a START TRANSACTION statement from the client. See Chapter 29, Connectors and APIs, or the documentation for your API, for more information.

To disable autocommit mode explicitly, use the following statement:

```
SET autocommit=0;
```

After disabling autocommit mode by setting the autocommit variable to zero, changes to transaction-safe tables (such as those for InnoDB or NDB) are not made permanent immediately. You must use COMMIT to store your changes to disk or ROLLBACK to ignore the changes.

autocommit is a session variable and must be set for each session. To disable autocommit mode for each new connection, see the description of the autocommit system variable at Section 5.1.8, “Server System Variables”.

BEGIN and BEGIN WORK are supported as aliases of START TRANSACTION for initiating a transaction. START TRANSACTION is standard SQL syntax, is the recommended way to start an ad-hoc transaction, and permits modifiers that BEGIN does not.

The BEGIN statement differs from the use of the BEGIN keyword that starts a BEGIN ... END compound statement. The latter does not begin a transaction. See Section 13.6.1, “BEGIN ... END Compound Statement”.

Note

Within all stored programs (stored procedures and functions, triggers, and events), the parser treats BEGIN [WORK] as the beginning of a BEGIN ... END block. Begin a transaction in this context with START TRANSACTION instead.
The optional \texttt{WORK} keyword is supported for \texttt{COMMIT} and \texttt{ROLLBACK}, as are the \texttt{CHAIN} and \texttt{RELEASE} clauses. \texttt{CHAIN} and \texttt{RELEASE} can be used for additional control over transaction completion. The value of the \texttt{completion_type} system variable determines the default completion behavior. See Section 5.1.8, “Server System Variables”.

The \texttt{AND CHAIN} clause causes a new transaction to begin as soon as the current one ends, and the new transaction has the same isolation level as the just-terminated transaction. The new transaction also uses the same access mode (\texttt{READ WRITE} or \texttt{READ ONLY}) as the just-terminated transaction. The \texttt{RELEASE} clause causes the server to disconnect the current client session after terminating the current transaction. Including the \texttt{NO} keyword suppresses \texttt{CHAIN} or \texttt{RELEASE} completion, which can be useful if the \texttt{completion_type} system variable is set to cause chaining or release completion by default.

Beginning a transaction causes any pending transaction to be committed. See Section 13.3.3, “Statements That Cause an Implicit Commit”, for more information.

Beginning a transaction also causes table locks acquired with \texttt{LOCK TABLES} to be released, as though you had executed \texttt{UNLOCK TABLES}. Beginning a transaction does not release a global read lock acquired with \texttt{FLUSH TABLES WITH READ LOCK}.

For best results, transactions should be performed using only tables managed by a single transaction-safe storage engine. Otherwise, the following problems can occur:

- If you use tables from more than one transaction-safe storage engine (such as \texttt{InnoDB}), and the transaction isolation level is not \texttt{SERIALIZABLE}, it is possible that when one transaction commits, another ongoing transaction that uses the same tables sees only some of the changes made by the first transaction. That is, the atomicity of transactions is not guaranteed with mixed engines and inconsistencies can result. (If mixed-engine transactions are infrequent, you can use \texttt{SET TRANSACTION ISOLATION LEVEL} to set the isolation level to \texttt{SERIALIZABLE} on a per-transaction basis as necessary.)

- If you use tables that are not transaction-safe within a transaction, changes to those tables are stored at once, regardless of the status of autocommit mode.

- If you issue a \texttt{ROLLBACK} statement after updating a nontransactional table within a transaction, an \texttt{ER_WARNING_NOT_COMPLETE_ROLLBACK} warning occurs. Changes to transaction-safe tables are rolled back, but not changes to nontransactional-tables.

Each transaction is stored in the binary log in one chunk, upon \texttt{COMMIT}. Transactions that are rolled back are not logged. (Exception: Modifications to nontransactional tables cannot be rolled back. If a transaction that is rolled back includes modifications to nontransactional tables, the entire transaction is logged with a \texttt{ROLLBACK} statement at the end to ensure that modifications to the nontransactional tables are replicated.) See Section 5.4.4, “The Binary Log”.

You can change the isolation level or access mode for transactions with the \texttt{SET TRANSACTION} statement. See Section 13.3.7, “SET TRANSACTION Statement”.

Rolling back can be a slow operation that may occur implicitly without the user having explicitly asked for it (for example, when an error occurs). Because of this, \texttt{SHOW PROCESSLIST} displays \texttt{Rolling back} in the \texttt{State} column for the session, not only for explicit rollbacks performed with the \texttt{ROLLBACK} statement but also for implicit rollbacks.

\textbf{Note}

In MySQL 8.0, \texttt{BEGIN}, \texttt{COMMIT}, and \texttt{ROLLBACK} are not affected by \texttt{--replicate-do-db} or \texttt{--replicate-ignore-db} rules.

When \texttt{InnoDB} performs a complete rollback of a transaction, all locks set by the transaction are released. If a single SQL statement within a transaction rolls back as a result of an error, such as a duplicate key error, locks set by the statement are preserved while the transaction remains active. This
happens because InnoDB stores row locks in a format such that it cannot know afterward which lock was set by which statement.

If a SELECT statement within a transaction calls a stored function, and a statement within the stored function fails, that statement rolls back. If ROLLBACK is executed for the transaction subsequently, the entire transaction rolls back.

13.3.2 Statements That Cannot Be Rolled Back

Some statements cannot be rolled back. In general, these include data definition language (DDL) statements, such as those that create or drop databases, those that create, drop, or alter tables or stored routines.

You should design your transactions not to include such statements. If you issue a statement early in a transaction that cannot be rolled back, and then another statement later fails, the full effect of the transaction cannot be rolled back in such cases by issuing a ROLLBACK statement.

13.3.3 Statements That Cause an Implicit Commit

The statements listed in this section (and any synonyms for them) implicitly end any transaction active in the current session, as if you had done a COMMIT before executing the statement.

Most of these statements also cause an implicit commit after executing. The intent is to handle each such statement in its own special transaction. Transaction-control and locking statements are exceptions: If an implicit commit occurs before execution, another does not occur after.

- **Data definition language (DDL) statements that define or modify database objects.** ALTER EVENT, ALTER FUNCTION, ALTER PROCEDURE, ALTER SERVER, ALTER TABLE, ALTER VIEW, CREATE DATABASE, CREATE EVENT, CREATE FUNCTION, CREATE INDEX, CREATE PROCEDURE, CREATE ROLE, CREATE SERVER, CREATE SPATIAL REFERENCE SYSTEM, CREATE TABLE, CREATE TRIGGER, CREATE VIEW, DROP DATABASE, DROP EVENT, DROP FUNCTION, DROP INDEX, DROP PROCEDURE, DROP ROLE, DROP SERVER, DROP SPATIAL REFERENCE SYSTEM, DROP TABLE, DROP TRIGGER, DROP VIEW, INSTALL PLUGIN, RENAME TABLE, TRUNCATE TABLE, UNINSTALL PLUGIN.

CREATE TABLE and DROP TABLE statements do not commit a transaction if the TEMPORARY keyword is used. (This does not apply to other operations on temporary tables such as ALTER TABLE and CREATE INDEX, which do cause a commit.) However, although no implicit commit occurs, neither can the statement be rolled back, which means that the use of such statements causes transactional atomicity to be violated. For example, if you use CREATE TEMPORARY TABLE and then roll back the transaction, the table remains in existence.

The CREATE TABLE statement in InnoDB is processed as a single transaction. This means that a ROLLBACK from the user does not undo CREATE TABLE statements the user made during that transaction.

CREATE TABLE ... SELECT causes an implicit commit before and after the statement is executed when you are creating nontemporary tables. (No commit occurs for CREATE TEMPORARY TABLE ... SELECT.)

- **Statements that implicitly use or modify tables in the mysql database.** ALTER USER, CREATE USER, DROP USER, GRANT, RENAME USER, REVOKE, SET PASSWORD.

- **Transaction-control and locking statements.** BEGIN, LOCK TABLES, SET autocommit = 1 (if the value is not already 1), START TRANSACTION, UNLOCK TABLES.

UNLOCK TABLES commits a transaction only if any tables currently have been locked with LOCK TABLES to acquire nontransactional table locks. A commit does not occur for UNLOCK TABLES following FLUSH TABLES WITH READ LOCK because the latter statement does not acquire table-level locks.
Transactions cannot be nested. This is a consequence of the implicit commit performed for any current transaction when you issue a `START TRANSACTION` statement or one of its synonyms.

Statements that cause an implicit commit cannot be used in an XA transaction while the transaction is in an `ACTIVE` state.

The `BEGIN` statement differs from the use of the `BEGIN` keyword that starts a `BEGIN ... END` compound statement. The latter does not cause an implicit commit. See Section 13.6.1, “BEGIN ... END Compound Statement”.

- **Data loading statements.** `LOAD DATA` causes an implicit commit only for tables using the NDB storage engine.
- **Administrative statements.** `ANALYZE TABLE`, `CACHE INDEX`, `CHECK TABLE`, `FLUSH`, `LOAD INDEX INTO CACHE`, `OPTIMIZE TABLE`, `REPAIR TABLE`, `RESET` (but not `RESET PERSIST`).
- **Replication control statements.** `START REPLICA | SLAVE`, `STOP REPLICA | SLAVE`, `RESET REPLICA | SLAVE`, `CHANGE REPLICATION SOURCE TO`, `CHANGE MASTER TO`.

### 13.3.4 SAVEPOINT, ROLLBACK TO SAVEPOINT, and RELEASE SAVEPOINT Statements

```
SAVEPOINT identifier
ROLLBACK [WORK] TO [SAVEPOINT] identifier
RELEASE SAVEPOINT identifier
```

InnoDB supports the SQL statements `SAVEPOINT`, `ROLLBACK TO SAVEPOINT`, `RELEASE SAVEPOINT` and the optional `WORK` keyword for `ROLLBACK`.

The `SAVEPOINT` statement sets a named transaction savepoint with a name of `identifier`. If the current transaction has a savepoint with the same name, the old savepoint is deleted and a new one is set.

The `ROLLBACK TO SAVEPOINT` statement rolls back a transaction to the named savepoint without terminating the transaction. Modifications that the current transaction made to rows after the savepoint was set are undone in the rollback, but InnoDB does not release the row locks that were stored in memory after the savepoint. (For a new inserted row, the lock information is carried by the transaction ID stored in the row; the lock is not separately stored in memory. In this case, the row lock is released in the undo.) Savepoints that were set at a later time than the named savepoint are deleted.

If the `ROLLBACK TO SAVEPOINT` statement returns the following error, it means that no savepoint with the specified name exists:

```
ERROR 1305 (42000): SAVEPOINT identifier does not exist
```

The `RELEASE SAVEPOINT` statement removes the named savepoint from the set of savepoints of the current transaction. No commit or rollback occurs. It is an error if the savepoint does not exist.

All savepoints of the current transaction are deleted if you execute a `COMMIT`, or a `ROLLBACK` that does not name a savepoint.

A new savepoint level is created when a stored function is invoked or a trigger is activated. The savepoints on previous levels become unavailable and thus do not conflict with savepoints on the new level. When the function or trigger terminates, any savepoints it created are released and the previous savepoint level is restored.

### 13.3.5 LOCK INSTANCE FOR BACKUP and UNLOCK INSTANCE Statements

```
LOCK INSTANCE FOR BACKUP
UNLOCK INSTANCE
```
LOCK TABLES and UNLOCK TABLES Statements

UNLOCK INSTANCE

LOCK INSTANCE FOR BACKUP acquires an instance-level backup lock that permits DML during an online backup while preventing operations that could result in an inconsistent snapshot.

Executing the LOCK INSTANCE FOR BACKUP statement requires the BACKUP_ADMIN privilege. The BACKUP_ADMIN privilege is automatically granted to users with the RELOAD privilege when performing an in-place upgrade to MySQL 8.0 from an earlier version.

Multiple sessions can hold a backup lock simultaneously.

UNLOCK INSTANCE releases a backup lock held by the current session. A backup lock held by a session is also released if the session is terminated.

LOCK INSTANCE FOR BACKUP prevents files from being created, renamed, or removed. REPAIR TABLE TRUNCATE TABLE, OPTIMIZE TABLE, and account management statements are blocked. See Section 13.7.1, “Account Management Statements”. Operations that modify InnoDB files that are not recorded in the InnoDB redo log are also blocked.

LOCK INSTANCE FOR BACKUP permits DDL operations that only affect user-created temporary tables. In effect, files that belong to user-created temporary tables can be created, renamed, or removed while a backup lock is held. Creation of binary log files is also permitted.

A backup lock acquired by LOCK INSTANCE FOR BACKUP is independent of transactional locks and locks taken by FLUSH TABLES tbl_name [, tbl_name] ... WITH READ LOCK, and the following sequences of statements are permitted:

LOCK INSTANCE FOR BACKUP;
FLUSH TABLES tbl_name [, tbl_name] ... WITH READ LOCK;
UNLOCK TABLES;
UNLOCK INSTANCE;

The lock_wait_timeout setting defines the amount of time that a LOCK INSTANCE FOR BACKUP statement waits to acquire a lock before giving up.

13.3.6 LOCK TABLES and UNLOCK TABLES Statements

LOCK TABLES
    tbl_name [[AS] alias] lock_type
    [, tbl_name [[AS] alias] lock_type] ...

lock_type: {
    READ [LOCAL]
    | [LOW_PRIORITY] WRITE
}

UNLOCK TABLES

MySQL enables client sessions to acquire table locks explicitly for the purpose of cooperating with other sessions for access to tables, or to prevent other sessions from modifying tables during periods when a session requires exclusive access to them. A session can acquire or release locks only for itself. One session cannot acquire locks for another session or release locks held by another session.

Locks may be used to emulate transactions or to get more speed when updating tables. This is explained in more detail in Table-Locking Restrictions and Conditions.

LOCK TABLES explicitly acquires table locks for the current client session. Table locks can be acquired for base tables or views. You must have the LOCK TABLES privilege, and the SELECT privilege for each object to be locked.
For view locking, `LOCK TABLES` adds all base tables used in the view to the set of tables to be locked and locks them automatically. For tables underlying any view being locked, `LOCK TABLES` checks that the view definer (for `SQL SECURITY DEFINER` views) or invoker (for all views) has the proper privileges on the tables.

If you lock a table explicitly with `LOCK TABLES`, any tables used in triggers are also locked implicitly, as described in `LOCK TABLES` and Triggers.

If you lock a table explicitly with `LOCK TABLES`, any tables related by a foreign key constraint are opened and locked implicitly. For foreign key checks, a shared read-only lock (`LOCK TABLES READ`) is taken on related tables. For cascading updates, a shared-nothing write lock (`LOCK TABLES WRITE`) is taken on related tables that are involved in the operation.

`UNLOCK TABLES` explicitly releases any table locks held by the current session. `LOCK TABLES` implicitly releases any table locks held by the current session before acquiring new locks.

Another use for `UNLOCK TABLES` is to release the global read lock acquired with the `FLUSH TABLES WITH READ LOCK` statement, which enables you to lock all tables in all databases. See Section 13.7.8.3, “FLUSH Statement”. (This is a very convenient way to get backups if you have a file system such as Veritas that can take snapshots in time.)

A table lock protects only against inappropriate reads or writes by other sessions. A session holding a `WRITE` lock can perform table-level operations such as `DROP TABLE` or `TRUNCATE TABLE`. For sessions holding a `READ` lock, `DROP TABLE` and `TRUNCATE TABLE` operations are not permitted.

The following discussion applies only to non-`TEMPORARY` tables. `LOCK TABLES` is permitted (but ignored) for a `TEMPORARY` table. The table can be accessed freely by the session within which it was created, regardless of what other locking may be in effect. No lock is necessary because no other session can see the table.

- Table Lock Acquisition
- Table Lock Release
- Interaction of Table Locking and Transactions
- `LOCK TABLES` and Triggers
- Table-Locking Restrictions and Conditions

### Table Lock Acquisition

To acquire table locks within the current session, use the `LOCK TABLES` statement, which acquires metadata locks (see Section 8.11.4, “Metadata Locking”).

The following lock types are available:

- **READ [LOCAL]** lock:
  - The session that holds the lock can read the table (but not write it).
  - Multiple sessions can acquire a `READ` lock for the table at the same time.
  - Other sessions can read the table without explicitly acquiring a `READ` lock.
  - The `LOCAL` modifier enables nonconflicting `INSERT` statements (concurrent inserts) by other sessions to execute while the lock is held. (See Section 8.11.3, “Concurrent Inserts”.) However, `READ LOCAL` cannot be used if you are going to manipulate the database using processes external to the server while you hold the lock. For InnoDB tables, `READ LOCAL` is the same as `READ`.

- **[LOW_PRIORITY] WRITE** lock:
  - The session that holds the lock can read and write the table.
LOCK TABLES and UNLOCK TABLES Statements

- Only the session that holds the lock can access the table. No other session can access it until the lock is released.

- Lock requests for the table by other sessions block while the WRITE lock is held.

- The LOW_PRIORITY modifier has no effect. In previous versions of MySQL, it affected locking behavior, but this is no longer true. It is now deprecated and its use produces a warning. Use WRITE without LOW_PRIORITY instead.

WRITE locks normally have higher priority than READ locks to ensure that updates are processed as soon as possible. This means that if one session obtains a READ lock and then another session requests a WRITE lock, subsequent READ lock requests wait until the session that requested the WRITE lock has obtained the lock and released it. (An exception to this policy can occur for small values of the max_write_lock_count system variable; see Section 8.11.4, “Metadata Locking”.)

If the LOCK TABLES statement must wait due to locks held by other sessions on any of the tables, it blocks until all locks can be acquired.

A session that requires locks must acquire all the locks that it needs in a single LOCK TABLES statement. While the locks thus obtained are held, the session can access only the locked tables. For example, in the following sequence of statements, an error occurs for the attempt to access t2 because it was not locked in the LOCK TABLES statement:

```sql
mysql> LOCK TABLES t1 READ;
mysql> SELECT COUNT(*) FROM t1;
+----------+
| COUNT(*) |
+----------+
|        3 |
+----------+
mysql> SELECT COUNT(*) FROM t2;
ERROR 1100 (HY000): Table 't2' was not locked with LOCK TABLES
```

Tables in the INFORMATION_SCHEMA database are an exception. They can be accessed without being locked explicitly even while a session holds table locks obtained with LOCK TABLES.

You cannot refer to a locked table multiple times in a single query using the same name. Use aliases instead, and obtain a separate lock for the table and each alias:

```sql
mysql> LOCK TABLE t WRITE, t AS t1 READ;
mysql> INSERT INTO t SELECT * FROM t;
ERROR 1100: Table 't' was not locked with LOCK TABLES
mysql> INSERT INTO t SELECT * FROM t AS t1;
```

The error occurs for the first INSERT because there are two references to the same name for a locked table. The second INSERT succeeds because the references to the table use different names.

If your statements refer to a table by means of an alias, you must lock the table using that same alias. It does not work to lock the table without specifying the alias:

```sql
mysql> LOCK TABLE t READ;
mysql> SELECT * FROM t AS myalias;
ERROR 1100: Table 'myalias' was not locked with LOCK TABLES
```

Conversely, if you lock a table using an alias, you must refer to it in your statements using that alias:

```sql
mysql> LOCK TABLE t AS myalias READ;
mysql> SELECT * FROM t;
ERROR 1100: Table 't' was not locked with LOCK TABLES
mysql> SELECT * FROM t AS myalias;
```

Table Lock Release

When the table locks held by a session are released, they are all released at the same time. A session can release its locks explicitly, or locks may be released implicitly under certain conditions.
• A session can release its locks explicitly with `UNLOCK TABLES`.

• If a session issues a `LOCK TABLES` statement to acquire a lock while already holding locks, its existing locks are released implicitly before the new locks are granted.

• If a session begins a transaction (for example, with `START TRANSACTION`), an implicit `UNLOCK TABLES` is performed, which causes existing locks to be released. (For additional information about the interaction between table locking and transactions, see `Interaction of Table Locking and Transactions`.)

If the connection for a client session terminates, whether normally or abnormally, the server implicitly releases all table locks held by the session (transactional and nontransactional). If the client reconnects, the locks are no longer in effect. In addition, if the client had an active transaction, the server rolls back the transaction upon disconnect, and if reconnect occurs, the new session begins with autocommit enabled. For this reason, clients may wish to disable auto-reconnect. With auto-reconnect in effect, the client is not notified if reconnect occurs but any table locks or current transaction are lost. With auto-reconnect disabled, if the connection drops, an error occurs for the next statement issued. The client can detect the error and take appropriate action such as reacquiring the locks or redoing the transaction. See `Automatic Reconnection Control`.

If you use `ALTER TABLE` on a locked table, it may become unlocked. For example, if you attempt a second `ALTER TABLE` operation, the result may be an error `Table 'tbl_name' was not locked with LOCK TABLES`. To handle this, lock the table again prior to the second alteration. See also Section B.3.6.1, “Problems with ALTER TABLE”.

Interaction of Table Locking and Transactions

`LOCK TABLES` and `UNLOCK TABLES` interact with the use of transactions as follows:

• `LOCK TABLES` is not transaction-safe and implicitly commits any active transaction before attempting to lock the tables.

• `UNLOCK TABLES` implicitly commits any active transaction, but only if `LOCK TABLES` has been used to acquire table locks. For example, in the following set of statements, `UNLOCK TABLES` releases the global read lock but does not commit the transaction because no table locks are in effect:

```
FLUSH TABLES WITH READ LOCK;
START TRANSACTION;
SELECT ...;
UNLOCK TABLES;
```

• Beginning a transaction (for example, with `START TRANSACTION`) implicitly commits any current transaction and releases existing table locks.

• `FLUSH TABLES WITH READ LOCK` acquires a global read lock and not table locks, so it is not subject to the same behavior as `LOCK TABLES` and `UNLOCK TABLES` with respect to table locking and implicit commits. For example, `START TRANSACTION` does not release the global read lock. See Section 13.7.8.3, “FLUSH Statement”.

• Other statements that implicitly cause transactions to be committed do not release existing table locks. For a list of such statements, see Section 13.3.3, “Statements That Cause an Implicit Commit”.

• The correct way to use `LOCK TABLES` and `UNLOCK TABLES` with transactional tables, such as InnoDB tables, is to begin a transaction with `SET autocommit = 0` (not `START TRANSACTION`) followed by `LOCK TABLES`, and to not call `UNLOCK TABLES` until you commit the transaction explicitly. For example, if you need to write to table `t1` and read from table `t2`, you can do this:

```
SET autocommit=0;
LOCK TABLES t1 WRITE, t2 READ, ...;
... do something with tables t1 and t2 here ...
```
When you call `LOCK TABLES`, InnoDB internally takes its own table lock, and MySQL takes its own table lock. InnoDB releases its internal table lock at the next commit, but for MySQL to release its table lock, you have to call `UNLOCK TABLES`. You should not have `autocommit = 1`, because then InnoDB releases its internal table lock immediately after the call of `LOCK TABLES`, and deadlocks can very easily happen. InnoDB does not acquire the internal table lock at all if `autocommit = 1`, to help old applications avoid unnecessary deadlocks.

- `ROLLBACK` does not release table locks.

### LOCK TABLES and Triggers

If you lock a table explicitly with `LOCK TABLES`, any tables used in triggers are also locked implicitly:

- The locks are taken as the same time as those acquired explicitly with the `LOCK TABLES` statement.
- The lock on a table used in a trigger depends on whether the table is used only for reading. If so, a read lock suffices. Otherwise, a write lock is used.
- If a table is locked explicitly for reading with `LOCK TABLES`, but needs to be locked for writing because it might be modified within a trigger, a write lock is taken rather than a read lock. (That is, an implicit write lock needed due to the table’s appearance within a trigger causes an explicit read lock request for the table to be converted to a write lock request.)

Suppose that you lock two tables, `t1` and `t2`, using this statement:

```
LOCK TABLES t1 WRITE, t2 READ;
```

If `t1` or `t2` have any triggers, tables used within the triggers are also locked. Suppose that `t1` has a trigger defined like this:

```
CREATE TRIGGER t1_a_ins AFTER INSERT ON t1 FOR EACH ROW
BEGIN
    UPDATE t4 SET count = count+1
    WHERE id = NEW.id AND EXISTS (SELECT a FROM t3);
    INSERT INTO t2 VALUES(1, 2);
END;
```

The result of the `LOCK TABLES` statement is that `t1` and `t2` are locked because they appear in the statement, and `t3` and `t4` are locked because they are used within the trigger:

- `t1` is locked for writing per the `WRITE` lock request.
- `t2` is locked for writing, even though the request is for a `READ` lock. This occurs because `t2` is inserted into within the trigger, so the `READ` request is converted to a `WRITE` request.
- `t3` is locked for reading because it is only read from within the trigger.
- `t4` is locked for reading because it might be updated within the trigger.

### Table-Locking Restrictions and Conditions

You can safely use `KILL` to terminate a session that is waiting for a table lock. See Section 13.7.8.4, "KILL Statement".

`LOCK TABLES` and `UNLOCK TABLES` cannot be used within stored programs.

Tables in the `performance_schema` database cannot be locked with `LOCK TABLES`, except the `setup_xxx` tables.

The following statements are prohibited while a `LOCK TABLES` statement is in effect: `CREATE TABLE`, `CREATE TABLE ... LIKE`, `CREATE VIEW`, `DROP VIEW`, and DDL statements on stored functions and procedures and events.
For some operations, system tables in the mysql database must be accessed. For example, the HELP statement requires the contents of the server-side help tables, and CONVERT_TZ() might need to read the time zone tables. The server implicitly locks the system tables for reading as necessary so that you need not lock them explicitly. These tables are treated as just described:

mysql.help_category
mysql.help_keyword
mysql.help_relation
mysql.help_topic
mysql.time_zone
mysql.time_zone_leap_second
mysql.time_zone_name
mysql.time_zone_transition
mysql.time_zone_transition_type

If you want to explicitly place a WRITE lock on any of those tables with a LOCK TABLES statement, the table must be the only one locked; no other table can be locked with the same statement.

Normally, you do not need to lock tables, because all single UPDATE statements are atomic; no other session can interfere with any other currently executing SQL statement. However, there are a few cases when locking tables may provide an advantage:

- If you are going to run many operations on a set of MyISAM tables, it is much faster to lock the tables you are going to use. Locking MyISAM tables speeds up inserting, updating, or deleting on them because MySQL does not flush the key cache for the locked tables until UNLOCK TABLES is called. Normally, the key cache is flushed after each SQL statement.

The downside to locking the tables is that no session can update a READ-locked table (including the one holding the lock) and no session can access a WRITE-locked table other than the one holding the lock.

- If you are using tables for a nontransactional storage engine, you must use LOCK TABLES if you want to ensure that no other session modifies the tables between a SELECT and an UPDATE. The example shown here requires LOCK TABLES to execute safely:

```
LOCK TABLES trans READ, customer WRITE;
SELECT SUM(value) FROM trans WHERE customer_id=some_id;
UPDATE customer
  SET total_value=sum_from_previous_statement
  WHERE customer_id=some_id;
UNLOCK TABLES;
```

Without LOCK TABLES, it is possible that another session might insert a new row in the trans table between execution of the SELECT and UPDATE statements.

You can avoid using LOCK TABLES in many cases by using relative updates (UPDATE customer SET value=value+new_value) or the LAST_INSERT_ID() function.

You can also avoid locking tables in some cases by using the user-level advisory lock functions GET_LOCK() and RELEASE_LOCK(). These locks are saved in a hash table in the server and implemented with pthread_mutex_lock() and pthread_mutex_unlock() for high speed. See Section 12.15, “Locking Functions”.

See Section 8.11.1, “Internal Locking Methods”, for more information on locking policy.

### 13.3.7 SET TRANSACTION Statement

```
SET [GLOBAL | SESSION] TRANSACTION
  transaction_characteristic [, transaction_characteristic] ...

transaction_characteristic: {
  ISOLATION LEVEL level
  | access_mode
}
```
SET TRANSACTION Statement

This statement specifies transaction characteristics. It takes a list of one or more characteristic values separated by commas. Each characteristic value sets the transaction isolation level or access mode. The isolation level is used for operations on InnoDB tables. The access mode specifies whether transactions operate in read/write or read-only mode.

In addition, SET TRANSACTION can include an optional GLOBAL or SESSION keyword to indicate the scope of the statement:

- Transaction Isolation Levels
- Transaction Access Mode
- Transaction Characteristic Scope

Transaction Isolation Levels

To set the transaction isolation level, use an ISOLATION LEVEL level clause. It is not permitted to specify multiple ISOLATION LEVEL clauses in the same SET TRANSACTION statement.

The default isolation level is REPEATABLE READ. Other permitted values are READ COMMITTED, READ UNCOMMITTED, and SERIALizable. For information about these isolation levels, see Section 15.7.2.1, “Transaction Isolation Levels”.

Transaction Access Mode

To set the transaction access mode, use a READ WRITE or READ ONLY clause. It is not permitted to specify multiple access-mode clauses in the same SET TRANSACTION statement.

By default, a transaction takes place in read/write mode, with both reads and writes permitted to tables used in the transaction. This mode may be specified explicitly using SET TRANSACTION with an access mode of READ WRITE.

If the transaction access mode is set to READ ONLY, changes to tables are prohibited. This may enable storage engines to make performance improvements that are possible when writes are not permitted.

In read-only mode, it remains possible to change tables created with the TEMPORARY keyword using DML statements. Changes made with DDL statements are not permitted, just as with permanent tables.

The READ WRITE and READ ONLY access modes also may be specified for an individual transaction using the START TRANSACTION statement.

Transaction Characteristic Scope

You can set transaction characteristics globally, for the current session, or for the next transaction only:

- With the GLOBAL keyword:
  - The statement applies globally for all subsequent sessions.
  - Existing sessions are unaffected.

- With the SESSION keyword:
SET TRANSACTION Statement

- The statement applies to all subsequent transactions performed within the current session.
- The statement is permitted within transactions, but does not affect the current ongoing transaction.
- If executed between transactions, the statement overrides any preceding statement that sets the next-transaction value of the named characteristics.

Without any `SESSION` or `GLOBAL` keyword:

- The statement applies only to the next single transaction performed within the session.
- Subsequent transactions revert to using the session value of the named characteristics.
- The statement is not permitted within transactions:

```sql
mysql> START TRANSACTION;
Query OK, 0 rows affected (0.02 sec)

mysql> SET TRANSACTION ISOLATION LEVEL SERIALIZABLE;
ERROR 1568 (25001): Transaction characteristics can't be changed while a transaction is in progress
```

A change to global transaction characteristics requires the `CONNECTION_ADMIN` privilege (or the deprecated `SUPER` privilege). Any session is free to change its session characteristics (even in the middle of a transaction), or the characteristics for its next transaction (prior to the start of that transaction).

To set the global isolation level at server startup, use the `--transaction-isolation=level` option on the command line or in an option file. Values of `level` for this option use dashes rather than spaces, so the permissible values are `READ-UNCOMMITTED`, `READ-COMMITTED`, `REPEATABLE-READ`, or `SERIALIZABLE`.

Similarly, to set the global transaction access mode at server startup, use the `--transaction-read-only` option. The default is `OFF` (read/write mode) but the value can be set to `ON` for a mode of read only.

For example, to set the isolation level to `REPEATABLE READ` and the access mode to `READ WRITE`, use these lines in the `[mysqld]` section of an option file:

```ini
[mysqld]
transaction-isolation = REPEATABLE-READ
transaction-read-only = OFF
```

At runtime, characteristics at the global, session, and next-transaction scope levels can be set indirectly using the `SET TRANSACTION` statement, as described previously. They can also be set directly using the `SET` statement to assign values to the `transaction_isolation` and `transaction_read_only` system variables:

- `SET TRANSACTION` permits optional `GLOBAL` and `SESSION` keywords for setting transaction characteristics at different scope levels.
- The `SET` statement for assigning values to the `transaction_isolation` and `transaction_read_only` system variables has syntaxes for setting these variables at different scope levels.

The following tables show the characteristic scope level set by each `SET TRANSACTION` and variable-assignment syntax.

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Affected Characteristic Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>SET GLOBAL TRANSACTION transaction_characteristic</code></td>
<td>Global</td>
</tr>
</tbody>
</table>
### 13.3.8 XA Transactions

On the client side, there are no special requirements. The XA interface to a MySQL server consists of SQL statements that begin with the `XA` keyword. MySQL client programs must be able to send SQL statements and to understand the semantics of the XA statement interface. They do not need to be linked against a recent client library. Older client libraries also work.

Among the MySQL Connectors, MySQL Connector/J 5.0.0 and higher supports XA directly, by means of a class interface that handles the XA SQL statement interface for you.

XA supports distributed transactions, that is, the ability to permit multiple separate transactional resources to participate in a global transaction. Transactional resources often are RDBMSs but may be other kinds of resources.

A global transaction involves several actions that are transactional in themselves, but that all must either complete successfully as a group, or all be rolled back as a group. In essence, this extends ACID properties “up a level” so that multiple ACID transactions can be executed in concert as components of a global operation that also has ACID properties. (As with nondistributed transactions, `SERIALIZABLE` may be preferred if your applications are sensitive to read phenomena. `REPEATABLE READ` may not be sufficient for distributed transactions.)

Some examples of distributed transactions:

- An application may act as an integration tool that combines a messaging service with an RDBMS. The application makes sure that transactions dealing with message sending, retrieval, and
processing that also involve a transactional database all happen in a global transaction. You can think of this as “transactional email.”

- An application performs actions that involve different database servers, such as a MySQL server and an Oracle server (or multiple MySQL servers), where actions that involve multiple servers must happen as part of a global transaction, rather than as separate transactions local to each server.

- A bank keeps account information in an RDBMS and distributes and receives money through automated teller machines (ATMs). It is necessary to ensure that ATM actions are correctly reflected in the accounts, but this cannot be done with the RDBMS alone. A global transaction manager integrates the ATM and database resources to ensure overall consistency of financial transactions.

Applications that use global transactions involve one or more Resource Managers and a Transaction Manager:

- A Resource Manager (RM) provides access to transactional resources. A database server is one kind of resource manager. It must be possible to either commit or roll back transactions managed by the RM.

- A Transaction Manager (TM) coordinates the transactions that are part of a global transaction. It communicates with the RMs that handle each of these transactions. The individual transactions within a global transaction are “branches” of the global transaction. Global transactions and their branches are identified by a naming scheme described later.

The MySQL implementation of XA enables a MySQL server to act as a Resource Manager that handles XA transactions within a global transaction. A client program that connects to the MySQL server acts as the Transaction Manager.

To carry out a global transaction, it is necessary to know which components are involved, and bring each component to a point when it can be committed or rolled back. Depending on what each component reports about its ability to succeed, they must all commit or roll back as an atomic group. That is, either all components must commit, or all components must roll back. To manage a global transaction, it is necessary to take into account that any component or the connecting network might fail.

The process for executing a global transaction uses two-phase commit (2PC). This takes place after the actions performed by the branches of the global transaction have been executed.

1. In the first phase, all branches are prepared. That is, they are told by the TM to get ready to commit. Typically, this means each RM that manages a branch records the actions for the branch in stable storage. The branches indicate whether they are able to do this, and these results are used for the second phase.

2. In the second phase, the TM tells the RMs whether to commit or roll back. If all branches indicated when they were prepared that they were able to commit, all branches are told to commit. If any branch indicated when it was prepared that it was not able to commit, all branches are told to roll back.

In some cases, a global transaction might use one-phase commit (1PC). For example, when a Transaction Manager finds that a global transaction consists of only one transactional resource (that is, a single branch), that resource can be told to prepare and commit at the same time.

### 13.3.8.1 XA Transaction SQL Statements

To perform XA transactions in MySQL, use the following statements:

- `XA START xid [JOIN | RESUME]`
- `XA END xid [SUSPEND [FOR MIGRATE]]`
- `XA PREPARE xid`
- `XA COMMIT xid [ONE PHASE]`
XA Transactions

XA ROLLBACK xid
XA RECOVER [CONVERT XID]

For XA START, the JOIN and RESUME clauses are recognized but have no effect.

For XA END the SUSPEND [FOR MIGRATE] clause is recognized but has no effect.

Each XA statement begins with the XA keyword, and most of them require an xid value. An xid is an XA transaction identifier. It indicates which transaction the statement applies to. xid values are supplied by the client, or generated by the MySQL server. An xid value has from one to three parts:

xid: gtrid [, bqual [, formatID ]]

gtrid is a global transaction identifier, bqual is a branch qualifier, and formatID is a number that identifies the format used by the gtrid and bqual values. As indicated by the syntax, bqual and formatID are optional. The default bqual value is '' if not given. The default formatID value is 1 if not given.

gtrid and bqual must be string literals, each up to 64 bytes (not characters) long. gtrid and bqual can be specified in several ways. You can use a quoted string ('ab'), hex string (X'6162', 0x6162), or bit value (b'n1n2n3n4').

formatID is an unsigned integer.

The gtrid and bqual values are interpreted in bytes by the MySQL server’s underlying XA support routines. However, while an SQL statement containing an XA statement is being parsed, the server works with some specific character set. To be safe, write gtrid and bqual as hex strings.

xid values typically are generated by the Transaction Manager. Values generated by one TM must be different from values generated by other TMs. A given TM must be able to recognize its own xid values in a list of values returned by the XA RECOVER statement.

XA START xid starts an XA transaction with the given xid value. Each XA transaction must have a unique xid value, so the value must not currently be used by another XA transaction. Uniqueness is assessed using the gtrid and bqual values. All following XA statements for the XA transaction must be specified using the same xid value as that given in the XA START statement. If you use any of those statements but specify an xid value that does not correspond to some existing XA transaction, an error occurs.

One or more XA transactions can be part of the same global transaction. All XA transactions within a given global transaction must use the same gtrid value in the xid value. For this reason, gtrid values must be globally unique so that there is no ambiguity about which global transaction a given XA transaction is part of. The bqual part of the xid value must be different for each XA transaction within a global transaction. (The requirement that bqual values be different is a limitation of the current MySQL XA implementation. It is not part of the XA specification.)

The XA RECOVER statement returns information for those XA transactions on the MySQL server that are in the PREPARED state. (See Section 13.3.8.2, “XA Transaction States”.) The output includes a row for each such XA transaction on the server, regardless of which client started it.

XA RECOVER requires the XA_RECOVER_ADMIN privilege. This privilege requirement prevents users from discovering the XID values for outstanding prepared XA transactions other than their own. It does not affect normal commit or rollback of an XA transaction because the user who started it knows its XID.

XA RECOVER output rows look like this (for an example xid value consisting of the parts 'abc', 'def', and 7):

mysql> XA RECOVER;
+
<table>
<thead>
<tr>
<th>formatID</th>
<th>gtrid_length</th>
<th>bqual_length</th>
<th>data</th>
</tr>
</thead>
</table>
The output columns have the following meanings:

- **formatID** is the formatID part of the transaction xid
- **gtrid_length** is the length in bytes of the gtrid part of the xid
- **bqual_length** is the length in bytes of the bqual part of the xid
- **data** is the concatenation of the gtrid and bqual parts of the xid

XID values may contain nonprintable characters. **XA RECOVER** permits an optional **CONVERT XID** clause so that clients can request XID values in hexadecimal.

### 13.3.8.2 XA Transaction States

An XA transaction progresses through the following states:

1. Use **XA START** to start an XA transaction and put it in the **ACTIVE** state.

2. For an **ACTIVE** XA transaction, issue the SQL statements that make up the transaction, and then issue an **XA END** statement. **XA END** puts the transaction in the **IDLE** state.

3. For an **IDLE** XA transaction, you can issue either an **XA PREPARE** statement or an **XA COMMIT ... ONE PHASE** statement:
   - **XA PREPARE** puts the transaction in the **PREPARED** state. An **XA RECOVER** statement at this point includes the transaction's xid value in its output, because **XA RECOVER** lists all XA transactions that are in the **PREPARED** state.
   - **XA COMMIT ... ONE PHASE** prepares and commits the transaction. The xid value is not listed by **XA RECOVER** because the transaction terminates.

4. For a **PREPARED** XA transaction, you can issue an **XA COMMIT** statement to commit and terminate the transaction, or **XA ROLLBACK** to roll back and terminate the transaction.

Here is a simple XA transaction that inserts a row into a table as part of a global transaction:

```sql
mysql> XA START 'xatest';
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO mytable (i) VALUES(10); Query OK, 1 row affected (0.04 sec)

mysql> XA END 'xatest';
Query OK, 0 rows affected (0.00 sec)

mysql> XA PREPARE 'xatest';
Query OK, 0 rows affected (0.00 sec)

mysql> XA COMMIT 'xatest';
Query OK, 0 rows affected (0.00 sec)
```

Within the context of a given client connection, XA transactions and local (non-XA) transactions are mutually exclusive. For example, if **XA START** has been issued to begin an XA transaction, a local transaction cannot be started until the XA transaction has been committed or rolled back. Conversely, if a local transaction has been started with **START TRANSACTION**, no XA statements can be used until the transaction has been committed or rolled back.

If an XA transaction is in the **ACTIVE** state, you cannot issue any statements that cause an implicit commit. That would violate the XA contract because you could not roll back the XA transaction. Trying to execute such a statement raises the following error:
Statements to which the preceding remark applies are listed at Section 13.3.3, “Statements That Cause an Implicit Commit”.

### 13.3.8.3 Restrictions on XA Transactions

XA transaction support is limited to the InnoDB storage engine.

For “external XA,” a MySQL server acts as a Resource Manager and client programs act as Transaction Managers. For “Internal XA”, storage engines within a MySQL server act as RMs, and the server itself acts as a TM. Internal XA support is limited by the capabilities of individual storage engines. Internal XA is required for handling XA transactions that involve more than one storage engine. The implementation of internal XA requires that a storage engine support two-phase commit at the table handler level, and currently this is true only for InnoDB.

For **XA START**, the **JOIN** and **RESUME** clauses are recognized but have no effect.

For **XA END** the **SUSPEND [FOR MIGRATE]** clause is recognized but has no effect.

The requirement that the `bqual` part of the `xid` value be different for each XA transaction within a global transaction is a limitation of the current MySQL XA implementation. It is not part of the XA specification.

An XA transaction is written to the binary log in two parts. When **XA PREPARE** is issued, the first part of the transaction up to **XA PREPARE** is written using an initial GTID. A **XA_prepare_log_event** is used to identify such transactions in the binary log. When **XA COMMIT** or **XA ROLLBACK** is issued, a second part of the transaction containing only the **XA COMMIT** or **XA ROLLBACK** statement is written using a second GTID. Note that the initial part of the transaction, identified by **XA_prepare_log_event**, is not necessarily followed by its **XA COMMIT** or **XA ROLLBACK**, which can cause interleaved binary logging of any two XA transactions. The two parts of the XA transaction can even appear in different binary log files. This means that an XA transaction in **PREPARED** state is now persistent until an explicit **XA COMMIT** or **XA ROLLBACK** statement is issued, ensuring that XA transactions are compatible with replication.

On a replica, immediately after the XA transaction is prepared, it is detached from the replication applier thread, and can be committed or rolled back by any thread on the replica. This means that the same XA transaction can appear in the **events_transactions_current** table with different states on different threads. The **events_transactions_current** table displays the current status of the most recent monitored transaction event on the thread, and does not update this status when the thread is idle. So the XA transaction can still be displayed in the **PREPARED** state for the original applier thread, after it has been processed by another thread. To positively identify XA transactions that are still in the **PREPARED** state and need to be recovered, use the **XA RECOVER** statement rather than the Performance Schema transaction tables.

The following restrictions exist for using XA transactions:

- XA transactions are not fully resilient to an unexpected halt with respect to the binary log. If there is an unexpected halt while the server is in the middle of executing an **XA PREPARE, XA COMMIT, XA ROLLBACK**, or **XA COMMIT ... ONE PHASE** statement, the server might not be able to recover to a correct state, leaving the server and the binary log in an inconsistent state. In this situation, the binary log might either contain extra XA transactions that are not applied, or miss XA transactions that are applied. Also, if GTIDs are enabled, after recovery `@@GLOBAL.GTID_EXECUTED` might not correctly describe the transactions that have been applied. Note that if an unexpected halt occurs before **XA PREPARE**, between **XA PREPARE** and **XA COMMIT** (or **XA ROLLBACK**), or after **XA COMMIT** (or **XA ROLLBACK**), the server and binary log are correctly recovered and taken to a consistent state.

- The use of replication filters or binary log filters in combination with XA transactions is not supported. Filtering of tables could cause an XA transaction to be empty on a replica, and empty XA
transactions are not supported. Also, with the replica’s connection metadata repository and applier metadata repository stored in InnoDB tables, which became the default in MySQL 8.0, the internal state of the data engine transaction is changed following a filtered XA transaction, and can become inconsistent with the replication transaction context state.

The error ER_XA_REPLICATION_FILTERS is logged whenever an XA transaction is impacted by a replication filter, whether or not the transaction was empty as a result. If the transaction is not empty, the replica is able to continue running, but you should take steps to discontinue the use of replication filters with XA transactions in order to avoid potential issues. If the transaction is empty, the replica stops. In that event, the replica might be in an undetermined state in which the consistency of the replication process might be compromised. In particular, the gtid_executed set on a replica of the replica might be inconsistent with that on the source. To resolve this situation, isolate the source and stop all replication, then check GTID consistency across the replication topology. Undo the XA transaction that generated the error message, then restart replication.

• XA transactions are considered unsafe for statement-based replication. If two XA transactions committed in parallel on the source are being prepared on the replica in the inverse order, locking dependencies can occur that cannot be safely resolved, and it is possible for replication to fail with deadlock on the replica. This situation can occur for a single-threaded or multithreaded replica. When `binlog_format=STATEMENT` is set, a warning is issued for DML statements inside XA transactions. When `binlog_format=MIXED` or `binlog_format=ROW` is set, DML statements inside XA transactions are logged using row-based replication, and the potential issue is not present.

Note
Prior to MySQL 5.7.7, XA transactions were not compatible with replication at all. This was because an XA transaction that was in PREPARED state would be rolled back on clean server shutdown or client disconnect. Similarly, an XA transaction that was in PREPARED state would still exist in PREPARED state in case the server was shutdown abnormally and then started again, but the contents of the transaction could not be written to the binary log. In both of these situations the XA transaction could not be replicated correctly.

13.4 Replication Statements
Replication can be controlled through the SQL interface using the statements described in this section. Statements are split into a group which controls source servers, a group which controls replica servers, and a group which can be applied to any replication servers.

13.4.1 SQL Statements for Controlling Source Servers
This section discusses statements for managing replication source servers. Section 13.4.2, “SQL Statements for Controlling Replica Servers”, discusses statements for managing replica servers.

In addition to the statements described here, the following SHOW statements are used with source servers in replication. For information about these statements, see Section 13.7.7, “SHOW Statements”.

• SHOW BINARY LOGS
• SHOW BINLOG EVENTS
• SHOW MASTER STATUS
• SHOW REPLICA | SHOW SLAVE HOSTS

13.4.1.1 PURGE BINARY LOGS Statement

```
PURGE { BINARY | MASTER } LOGS { TO 'log_name' }
```
The binary log is a set of files that contain information about data modifications made by the MySQL server. The log consists of a set of binary log files, plus an index file (see Section 5.4.4, “The Binary Log”).

The PURGE BINARY LOGS statement deletes all the binary log files listed in the log index file prior to the specified log file name or date. BINARY and MASTER are synonyms. Deleted log files also are removed from the list recorded in the index file, so that the given log file becomes the first in the list.

PURGE BINARY LOGS requires the BINLOG_ADMIN privilege. This statement has no effect if the server was not started with the --log-bin option to enable binary logging.

Examples:

```
PURGE BINARY LOGS TO 'mysql-bin.010';
PURGE BINARY LOGS BEFORE '2019-04-02 22:46:26';
```

The BEFORE variant’s datetime_expr argument should evaluate to a DATETIME value (a value in ‘YYYY-MM-DD hh:mm:ss’ format).

This statement is safe to run while replicas are replicating. You need not stop them. If you have an active replica that currently is reading one of the log files you are trying to delete, this statement does not delete the log file that is in use or any log files later than that one, but it deletes any earlier log files. A warning message is issued in this situation. However, if a replica is not connected and you happen to purge one of the log files it has yet to read, the replica cannot replicate after it reconnects.

To safely purge binary log files, follow this procedure:

1. On each replica, use SHOW REPLICA | SLAVE STATUS to check which log file it is reading.
2. Obtain a listing of the binary log files on the source with SHOW BINARY LOGS.
3. Determine the earliest log file among all the replicas. This is the target file. If all the replicas are up to date, this is the last log file on the list.
4. Make a backup of all the log files you are about to delete. (This step is optional, but always advisable.)
5. Purge all log files up to but not including the target file.

```
PURGE BINARY LOGS TO and PURGE BINARY LOGS BEFORE both fail with an error when binary log files listed in the .index file had been removed from the system by some other means (such as using rm on Linux). (Bug #18199, Bug #18453) To handle such errors, edit the .index file (which is a simple text file) manually to ensure that it lists only the binary log files that are actually present, then run again the PURGE BINARY LOGS statement that failed.
```

Binary log files are automatically removed after the server’s binary log expiration period. Removal of the files can take place at startup and when the binary log is flushed. The default binary log expiration period is 30 days. You can specify an alternative expiration period using the binlog_expire_logs_seconds system variable. If you are using replication, you should specify an expiration period that is no lower than the maximum amount of time your replicas might lag behind the source.

### 13.4.1.2 RESET MASTER Statement

```
RESET MASTER [TO binary_log_file_index_number]
```

**Warning**

Use this statement with caution to ensure you do not lose any wanted binary log file data and GTID execution history.
RESET MASTER requires the RELOAD privilege.

For a server where binary logging is enabled (log_bin is ON), RESET MASTER deletes all existing binary log files and resets the binary log index file, resetting the server to its state before binary logging was started. A new empty binary log file is created so that binary logging can be restarted.

For a server where GTIDs are in use (gtid_mode is ON), issuing RESET MASTER resets the GTID execution history. The value of the gtid_purged system variable is set to an empty string ("'"), the global value (but not the session value) of the gtid_executed system variable is set to an empty string, and the mysql.gtid_executed table is cleared (see mysql.gtid_executed Table). If the GTID-enabled server has binary logging enabled, RESET MASTER also resets the binary log as described above. Note that RESET MASTER is the method to reset the GTID execution history even if the GTID-enabled server is a replica where binary logging is disabled; RESET REPLICA | SLAVE has no effect on the GTID execution history. For more information on resetting the GTID execution history, see Resetting the GTID Execution History.

Issuing RESET MASTER without the optional TO clause deletes all binary log files listed in the index file, resets the binary log index file to be empty, and creates a new binary log file starting at 1. Use the optional TO clause to start the binary log file index from a number other than 1 after the reset.

Using RESET MASTER with the TO clause to specify a binary log file index number to start from simplifies failover by providing a single statement alternative to the FLUSH BINARY LOGS and PURGE BINARY LOGS TO statements. Check that you are using a reasonable value for the index number. If you enter an incorrect value, you can correct this by issuing another RESET MASTER statement with or without the TO clause. If you do not correct a value that is out of range, the server cannot be restarted.

The following example demonstrates TO clause usage:

```
RESET MASTER TO 1234;
SHOW BINARY LOGS;
```

<table>
<thead>
<tr>
<th>Log_name</th>
<th>File_size</th>
<th>Encrypted</th>
</tr>
</thead>
<tbody>
<tr>
<td>source-bin.001234</td>
<td>154</td>
<td>No</td>
</tr>
</tbody>
</table>

Important

The effects of RESET MASTER without the TO clause differ from those of PURGE BINARY LOGS in 2 key ways:

1. RESET MASTER removes all binary log files that are listed in the index file, leaving only a single, empty binary log file with a numeric suffix of .000001, whereas the numbering is not reset by PURGE BINARY LOGS.

2. RESET MASTER is not intended to be used while any replicas are running. The behavior of RESET MASTER when used while replicas are running is undefined (and thus unsupported), whereas PURGE BINARY LOGS may be safely used while replicas are running.

See also Section 13.4.1.1, “PURGE BINARY LOGS Statement”.

RESET MASTER without the TO clause can prove useful when you first set up a source and replica, so that you can verify the setup as follows:

1. Start the source and replica, and start replication (see Section 17.1.2, “Setting Up Binary Log File Position Based Replication”).

2. Execute a few test queries on the source.

3. Check that the queries were replicated to the replica.
4. When replication is running correctly, issue `STOP REPLICA | SLAVE` followed by `RESET REPLICA | SLAVE` on the replica, then verify that no unwanted data from the test queries exists on the replica.

5. Issue `RESET MASTER` on the source to clean up the test queries.

After verifying the setup, resetting the source and replica and ensuring that no unwanted data or binary log files generated by testing remain on the source or replica, you can start the replica and begin replicating.

### 13.4.1.3 SET sql_log_bin Statement

```
SET sql_log_bin = {OFF|ON}
```

The `sql_log_bin` variable controls whether logging to the binary log is enabled for the current session (assuming that the binary log itself is enabled). The default value is `ON`. To disable or enable binary logging for the current session, set the session `sql_log_bin` variable to `OFF` or `ON`.

Set this variable to `OFF` for a session to temporarily disable binary logging while making changes to the source that you do not want replicated to the replica.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See Section 5.1.9.1, "System Variable Privileges".

It is not possible to set the session value of `sql_log_bin` within a transaction or subquery.

*Setting this variable to `OFF` prevents new GTIDs from being assigned to transactions in the binary log.*

If you are using GTIDs for replication, this means that even when binary logging is later enabled again, the GTIDs written into the log from this point do not account for any transactions that occurred in the meantime, so in effect those transactions are lost.

`mysqldump` adds a `SET @SESSION.sql_log_bin=0` statement to a dump file from a server where GTIDs are in use, which disables binary logging while the dump file is being reloaded. The statement prevents new GTIDs from being generated and assigned to the transactions in the dump file as they are executed, so that the original GTIDs for the transactions are used.

### 13.4.2 SQL Statements for Controlling Replica Servers

This section discusses statements for managing replica servers. Section 13.4.1, "SQL Statements for Controlling Source Servers", discusses statements for managing source servers.

In addition to the statements described here, `SHOW REPLICA | SLAVE STATUS` and `SHOW RELAYLOG EVENTS` are also used with replicas. For information about these statements, see Section 13.7.7.35, “SHOW REPLICA | SLAVE STATUS Statement”, and Section 13.7.7.32, “SHOW RELAYLOG EVENTS Statement”.

### 13.4.2.1 CHANGE MASTER TO Statement

```
CHANGE MASTER TO option [, option] ... [ channel_option ]
```

`option`: {
- `MASTER_BIND` = `interface_name`
- `MASTER_HOST` = `host_name`
- `MASTER_USER` = `user_name`
- `MASTER_PASSWORD` = `password`
- `MASTER_PORT` = `port_num`
- `PRIVILEGE_CHECKS_USER` = `{account` | `NULL}`
- `REQUIRE_ROW_FORMAT` = `{0 | 1}`
- `REQUIRE_TABLE_PRIMARY_KEY_CHECK` = `{STREAM | ON | OFF}`
- `ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS` = `{OFF | LOCAL | `uuid`}`
- `MASTER_LOG_FILE` = `source_log_name`
- `MASTER_LOG_POS` = `source_log_pos`
}
| MASTER_AUTO_POSITION = {0|1} |
| RELAY_LOG_FILE = 'relay_log_name' |
| RELAY_LOG_POS = relay_log_pos |
| MASTER_HEARTBEAT_PERIOD = interval |
| MASTER_CONNECT_RETRY = interval |
| MASTER_RETRY_COUNT = count |
| SOURCE_CONNECTION_AUTO_FAILOVER = {0|1} |
| MASTER_DELAY = interval |
| MASTER_COMPRESSION_ALGORITHMS = 'value' |
| MASTER_ZSTD_COMPRESSION_LEVEL = level |
| MASTER_SSL = {0|1} |
| MASTER_SSL_CA = 'ca_file_name' |
| MASTER_SSL_CAPATH = 'ca_directory_name' |
| MASTER_SSL_CERT = 'cert_file_name' |
| MASTER_SSL_CRL = 'crl_file_name' |
| MASTER_SSL_CRLPATH = 'crl_directory_name' |
| MASTER_SSL_KEY = 'key_file_name' |
| MASTER_SSL_CIPHER = 'cipher_list' |
| MASTER_SSL_VERIFY_SERVER_CERT = {0|1} |
| TLS_VERSION = 'protocol_list' |
| MASTER_TLS_CIPHERSUITE = 'ciphersuite_list' |
| MASTER_PUBLIC_KEY_PATH = 'key_file_name' |
| GET_MASTER_PUBLIC_KEY = {0|1} |
| NETWORK_NAMESPACE = 'namespace' |
| IGNORE_SERVER_IDS = (server_id_list) |

channel_option:
   FOR CHANNEL channel

server_id_list:
   [server_id [, server_id] ... ]

CHANGE MASTER TO changes the parameters that the replica server uses for connecting to the source and for reading data from the source. It also updates the contents of the replication metadata repositories (see Section 17.2.4, “Relay Log and Replication Metadata Repositories”). From MySQL 8.0.23, use CHANGE REPLICATION SOURCE TO in place of CHANGE MASTER TO, which is deprecated from that release. In releases before MySQL 8.0.23, use CHANGE MASTER TO.

You can issue CHANGE MASTER TO statements on a running replica without first stopping it, depending on the states of the replication SQL thread and replication I/O thread. The rules governing such use are provided later in this section. CHANGE MASTER TO requires the REPLICATION_SLAVE_ADMIN privilege (or the deprecated SUPER privilege).

When using a multithreaded replica (in other words slave_parallel_workers is greater than 0), stopping the replica can cause “gaps” in the sequence of transactions that have been executed from the relay log, regardless of whether the replica was stopped intentionally or otherwise. When such gaps exist, issuing CHANGE MASTER TO fails. The solution in this situation is to issue START REPLICA | SLAVE UNTIL SQL_AFTER_MTS_GAPS which ensures that the gaps are closed.

The optional FOR CHANNEL channel clause enables you to name which replication channel the statement applies to. Providing a FOR CHANNEL channel clause applies the CHANGE MASTER TO statement to a specific replication channel, and is used to add a new channel or modify an existing channel. For example, to add a new channel called channel12:

CHANGE MASTER TO MASTER_HOST=host1, MASTER_PORT=3002 FOR CHANNEL 'channel12'

If no clause is named and no extra channels exist, the statement applies to the default channel.

When using multiple replication channels, if a CHANGE MASTER TO statement does not name a channel using a FOR CHANNEL channel clause, an error occurs. See Section 17.2.2, “Replication Channels” for more information.

Values used for MASTER_HOST and other CHANGE MASTER TO options are checked for linefeed (\n or 0x0A) characters. The presence of such characters in these values causes the statement to fail with ER_MASTER_INFO.
Invoking `CHANGE MASTER TO` causes the previous values for `MASTER_HOST`, `MASTER_PORT`, `MASTER_LOG_FILE`, and `MASTER_LOG_POS` to be written to the error log, along with other information about the replica’s state prior to execution.

`CHANGE MASTER TO` causes an implicit commit of an ongoing transaction. See Section 13.3.3, “Statements That Cause an Implicit Commit”.

For some of the options of the `CHANGE MASTER TO` statement, you must issue a `STOP REPLICA` | `SLAVE` statement prior to issuing a `CHANGE MASTER TO` statement (and a `START REPLICA` | `SLAVE` statement afterwards). Sometimes, you only need to stop the replication SQL thread or the replication I/O thread, not both:

- When the SQL thread is stopped, you can execute `CHANGE MASTER TO` using any combination that is otherwise allowed of `RELAY_LOG_FILE`, `RELAY_LOG_POS`, and `MASTER_DELAY` options, even if the replication I/O thread is running. No other options may be used with this statement when the I/O thread is running.

- When the I/O thread is stopped, you can execute `CHANGE MASTER TO` using any of the options for this statement (in any allowed combination) except `RELAY_LOG_FILE`, `RELAY_LOG_POS`, `MASTER_DELAY`, or `MASTER_AUTO_POSITION = 1` even when the SQL thread is running.

- Both the SQL thread and the I/O thread must be stopped before issuing a `CHANGE MASTER TO` statement that employs `MASTER_AUTO_POSITION = 1` or `ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS`.

You can check the current state of the replication SQL thread and replication I/O thread using `SHOW REPLICA | SLAVE STATUS`. Note that the Group Replication applier channel (`group_replication_applier`) has no I/O thread, only an SQL thread.

For more information, see Section 17.4.8, “Switching Sources During Failover”.

If you are using statement-based replication and temporary tables, it is possible for a `CHANGE MASTER TO` statement following a `STOP REPLICA` | `SLAVE` statement to leave behind temporary tables on the replica. A warning (`ER_WARN_OPEN_TEMP_TABLES_MUST_BE_ZERO`) is now issued whenever this occurs. You can avoid this in such cases by making sure that the value of the `Slave_open_temp_tables` system status variable is equal to 0 prior to executing such a `CHANGE MASTER TO` statement.

`CHANGE MASTER TO` is useful for setting up a replica when you have the snapshot of the source and have recorded the source’s binary log coordinates corresponding to the time of the snapshot. After loading the snapshot into the replica to synchronize it with the source, you can run `CHANGE MASTER TO MASTER_LOG_FILE='log_name', MASTER_LOG_POS=log_pos` on the replica to specify the coordinates at which the replica should begin reading the source’s binary log.

The following example changes the source server the replica uses and establishes the source’s binary log coordinates from which the replica begins reading:

```sql
CHANGE MASTER TO
  MASTER_HOST='source2.example.com',
  MASTER_USER='replication',
  MASTER_PASSWORD='password',
  MASTER_PORT=3306,
  MASTER_LOG_FILE='source2-bin.001',
  MASTER_LOG_POS=4,
  MASTER_CONNECT_RETRY=10;
```

The next example shows an operation that is less frequently employed. It is used when the replica has relay log files that you want it to execute again for some reason. To do this, the source need not be reachable. You need only use `CHANGE MASTER TO` and start the SQL thread (`START REPLICA` | `SLAVE SQL_THREAD`):

```sql
CHANGE MASTER TO
  RELAY_LOG_FILE='replica-relay-bin.006',
```
Options that you do not specify on a `CHANGE MASTER TO` statement retain their value, except as indicated in the following discussion. Thus, in most cases, there is no need to specify options that do not change.

**ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS**

Makes the replication channel assign a GTID to replicated transactions that do not have one, enabling replication from a source that does not use GTID-based replication, to a replica that does. For a multi-source replica, you can have a mix of channels that use `ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS`, and channels that do not. The default is `OFF`, meaning that the feature is not used.

- **LOCAL** assigns a GTID including the replica's own UUID (the `server_uuid` setting).
- **uuid** assigns a GTID including the specified UUID, such as the `server_uuid` setting for the replication source server. Using a nonlocal UUID lets you differentiate between transactions that originated on the replica and transactions that originated on the source, and for a multi-source replica, between transactions that originated on different sources. The UUID you choose only has significance for the replica's own use. If any of the transactions sent by the source do have a GTID already, that GTID is retained.

Channels specific to Group Replication cannot use `ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS`, but an asynchronous replication channel for another source on a server instance that is a Group Replication group member can do so. In that case, do not specify the Group Replication group name as the UUID for creating the GTIDs.

To set `ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS` to `LOCAL` or `uuid`, the replica must have `gtid_mode=ON` set, and this cannot be changed afterwards. This option is for use with a source that has binary log file position based replication, so `MASTER_AUTO_POSITION=1` cannot be set for the channel. Both the replication SQL thread and the replication I/O thread must be stopped before setting this option.

### Important

A replica set up with `ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS` on any channel cannot be promoted to replace the replication source server in the event that a failover is required, and a backup taken from the replica cannot be used to restore the replication source server. The same restriction applies to replacing or restoring other replicas that use `ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS` on any channel.

For further restrictions and information, see Section 17.1.3.6, “Replication From a Source Without GTIDs to a Replica With GTIDs”.

**GET_MASTER_PUBLIC_KEY**

Enables RSA key pair-based password exchange by requesting the public key from the source. This option applies to replicas that
authenticate with the `caching_sha2_password` authentication plugin. For connections by accounts that authenticate using this plugin, the source does not send the public key unless requested, so it must be requested or specified in the client. If `MASTER_PUBLIC_KEY_PATH` is given and specifies a valid public key file, it takes precedence over `GET_MASTER_PUBLIC_KEY`. If you are using a replication user account that authenticates with the `caching_sha2_password` plugin (which is the default from MySQL 8.0), and you are not using a secure connection, you must specify either this option or the `MASTER_PUBLIC_KEY_PATH` option to provide the RSA public key to the replica.

**IGNORE_SERVER_IDS**

 Makes the replica ignore events originating from the specified servers. The option takes a comma-separated list of 0 or more server IDs. Log rotation and deletion events from the servers are not ignored, and are recorded in the relay log.

In circular replication, the originating server normally acts as the terminator of its own events, so that they are not applied more than once. Thus, this option is useful in circular replication when one of the servers in the circle is removed. Suppose that you have a circular replication setup with 4 servers, having server IDs 1, 2, 3, and 4, and server 3 fails. When bridging the gap by starting replication from server 2 to server 4, you can include `IGNORE_SERVER_IDS = (3)` in the `CHANGE MASTER TO` statement that you issue on server 4 to tell it to use server 2 as its source instead of server 3. Doing so causes it to ignore and not to propagate any statements that originated with the server that is no longer in use.

If `IGNORE_SERVER_IDS` contains the server's own ID and the server was started with the `--replicate-same-server-id` option enabled, an error results.

**Note**

When global transaction identifiers (GTIDs) are used for replication, transactions that have already been applied are automatically ignored, so the `IGNORE_SERVER_IDS` function is not required and is deprecated. If `gtid_mode=ON` is set for the server, a deprecation warning is issued if you include the `IGNORE_SERVER_IDS` option in a `CHANGE MASTER TO` statement.

The source metadata repository and the output of `SHOW REPLICA | SLAVE STATUS` provide the list of servers that are currently ignored. For more information, see Section 17.2.4.2, “Replication Metadata Repositories”, and Section 13.7.7.35, “SHOW REPLICA | SLAVE STATUS Statement”.

If a `CHANGE MASTER TO` statement is issued without any `IGNORE_SERVER_IDS` option, any existing list is preserved. To clear the list of ignored servers, it is necessary to use the option with an empty list:

```
CHANGE MASTER TO IGNORE_SERVER_IDS = ();
```

`RESET REPLICA | SLAVE ALL` clears `IGNORE_SERVER_IDS`.
SQL Statements for Controlling Replica Servers

Note

A deprecation warning is issued if SET GTID_MODE=ON is issued when any channel has existing server IDs set with IGNORE_SERVER_IDS. Before starting GTID-based replication, check for and clear all ignored server ID lists on the servers involved. The SHOW REPLICA | SLAVE STATUS statement displays the list of ignored IDs, if there is one. If you do receive the deprecation warning, you can still clear a list after gtid_mode=ON is set by issuing a CHANGE MASTER TO statement containing the IGNORE_SERVER_IDS option with an empty list.

MASTER_AUTO_POSITION

Makes the replica attempt to connect to the source using the auto-positioning feature of GTID-based replication, rather than a binary log file based position. This option can be used with CHANGE MASTER TO only if both the replication SQL thread and replication I/O thread are stopped.

Both the replica and the source must have GTIDs enabled (GTID_MODE=ON, ON_PERMISSIVE, or OFF_PERMISSIVE on the replica, and GTID_MODE=ON on the source). MASTER_LOG_FILE, MASTER_LOG_POS, RELAY_LOG_FILE, and RELAY_LOG_POS cannot be specified together with MASTER_AUTO_POSITION = 1. If multi-source replication is enabled on the replica, you need to set the MASTER_AUTO_POSITION = 1 option for each applicable replication channel.

With MASTER_AUTO_POSITION = 1 set, in the initial connection handshake, the replica sends a GTID set containing the transactions that it has already received, committed, or both. The source responds by sending all transactions recorded in its binary log whose GTID is not included in the GTID set sent by the replica. This exchange ensures that the source only sends the transactions with a GTID that the replica has not already recorded or committed. If the replica receives transactions from more than one source, as in the case of a diamond topology, the auto-skip function ensures that the transactions are not applied twice. For details of how the GTID set sent by the replica is computed, see Section 17.1.3.3, “GTID Auto-Positioning”.

If any of the transactions that should be sent by the source have been purged from the source's binary log, or added to the set of GTIDs in the gtid_purged system variable by another method, the source sends the error ER_MASTER_HAS_PURGED_REQUIRED_GTIDS to the replica, and replication does not start. The GTIDs of the missing purged transactions are identified and listed in the source's error log in the warning message ER_FOUND_MISSING_GTIDS. Also, if during the exchange of transactions it is found that the replica has recorded or committed transactions with the source's UUID in the GTID, but the source itself has not committed them, the source sends the error ER_SLAVE_HAS_MORE_GTIDS_THAN_MASTER to the replica and
replication does not start. For information on how to handle these situations, see Section 17.1.3.3, “GTID Auto-Positioning”.

You can see whether replication is running with GTID auto-positioning enabled by checking the Performance Schema replication_connection_status table or the output of SHOW REPLICA STATUS. Disabling the MASTER_AUTO_POSITION option again makes the replica revert to file-based replication.

**MASTER_BIND**

Determines which of the replica’s network interfaces is chosen for connecting to the source, for use on replicas that have multiple network interfaces. The address configured with this option, if any, can be seen in the Master_Bind column of the output from SHOW REPLICA | SLAVE STATUS. In the source metadata repository table mysql.slave_master_info, the value can be seen as the Master_bind column. The ability to bind a replica to a specific network interface is also supported by NDB Cluster.

**MASTER_COMPRESSION_ALGORITHMS**

Specifies the permitted compression algorithms for connections to the replication source server. The available algorithms are the same as for the protocol_compression_algorithms system variable. The default value is uncompressed. MASTER_COMPRESSION_ALGORITHMS is available as of MySQL 8.0.18.

The value of MASTER_COMPRESSION_ALGORITHMS applies only if the slave_compressed_protocol system variable is disabled. If slave_compressed_protocol is enabled, it takes precedence over MASTER_COMPRESSION_ALGORITHMS and connections to the source use zlib compression if both source and replica support that algorithm. For more information, see Section 4.2.8, “Connection Compression Control”.

Binary log transaction compression (available as of MySQL 8.0.20), which is activated by the binlog_transaction_compression system variable, can also be used to save bandwidth. If you do this in combination with connection compression, connection compression has less opportunity to act on the data, but can still compress headers and those events and transaction payloads that are uncompressed. For more information on binary log transaction compression, see Section 5.4.4.5, “Binary Log Transaction Compression”.

**MASTER_CONNECT_RETRY**

Specifies the interval between the reconnection attempts that the replica makes after the connection to the source times out. The attempts are limited by the MASTER_RETRY_COUNT option. If both the default settings are used, the replica waits 60 seconds between reconnection attempts (MASTER_CONNECT_RETRY=60), and keeps attempting to reconnect at this rate for 60 days (MASTER_RETRY_COUNT=86400). These values are recorded in the source metadata repository and shown in the replication_connection_configuration Performance Schema table.

**MASTER_DELAY**

Specifies how many seconds behind the source the replica must lag. An event received from the source is not executed until at least interval seconds later than its execution on the source. The default is 0. An error occurs if interval is not a nonnegative integer in the range from 0 to $2^{31}-1$. For more information, see
Section 17.4.11, “Delayed Replication”. A `CHANGE MASTER TO` statement employing the `MASTER_DELAY` option can be executed on a running replica when the replication SQL thread is stopped.

**MASTER_HEARTBEAT_PERIOD**

Controls the heartbeat interval, which stops the connection timeout occurring in the absence of data if the connection is still good. A heartbeat signal is sent to the replica after that number of seconds, and the waiting period is reset whenever the source's binary log is updated with an event. Heartbeats are therefore sent by the source only if there are no unsent events in the binary log file for a period longer than this.

The heartbeat interval `interval` is a decimal value having the range 0 to 4294967 seconds and a resolution in milliseconds; the smallest nonzero value is 0.001. Setting `interval` to 0 disables heartbeats altogether. The heartbeat interval defaults to half the value of the `slave_net_timeout` system variable. It is recorded in the source metadata repository and shown in the `replication_connection_configuration` Performance Schema table. Issuing `RESET REPLICA | SLAVE` resets the heartbeat interval to the default value.

The `slave_net_timeout` system variable specifies the number of seconds that the replica waits for either more data or a heartbeat signal from the source, before the replica considers the connection broken, aborts the read, and tries to reconnect. The default value is 60 seconds (one minute). Note that a change to the value or default setting of `slave_net_timeout` does not automatically change the heartbeat interval, whether that has been set explicitly or is using a previously calculated default. A warning is issued if you set `@@GLOBAL.slave_net_timeout` to a value less than that of the current heartbeat interval. If `slave_net_timeout` is changed, you must also issue `CHANGE MASTER TO` to adjust the heartbeat interval to an appropriate value so that the heartbeat signal occurs before the connection timeout. If you do not do this, the heartbeat signal has no effect, and if no data is received from the source, the replica can make repeated reconnection attempts, creating zombie dump threads.

**MASTER_HOST**

The host name or IP address of the replication source server. The replica uses this to connect to the source.

If you specify `MASTER_HOST` or `MASTER_PORT`, the replica assumes that the source server is different from before (even if the option value is the same as its current value.) In this case, the old values for the source's binary log file name and position are considered no longer applicable, so if you do not specify `MASTER_LOG_FILE` and `MASTER_LOG_POS` in the statement, `MASTER_LOG_FILE=''` and `MASTER_LOG_POS=4` are silently appended to it.

Setting `MASTER_HOST=''` (that is, setting its value explicitly to an empty string) is not the same as not setting `MASTER_HOST` at all. Trying to set `MASTER_HOST` to an empty string fails with an error.

**MASTER_LOG_FILE, MASTER_LOG_POS**

The binary log file name, and the location in that file, at which the replication I/O thread begins reading from the source's binary log the next time the thread starts. Specify these options if you are using binary log file position based replication. `MASTER_LOG_FILE` must include the numeric suffix of a specific
binary log file that is available on the source server, for example, 
`MASTER_LOG_FILE='binlog.000145'`. `MASTER_LOG_POS` is the numeric position for the replica to start reading in that file. 
`MASTER_LOG_POS=4` represents the start of the events in a binary log file.

If you specify either of `MASTER_LOG_FILE` or `MASTER_LOG_POS`, you cannot specify `MASTER_AUTO_POSITION = 1`, which is for GTID-based replication.

If neither of `MASTER_LOG_FILE` or `MASTER_LOG_POS` is specified, the replica uses the last coordinates of the replication SQL thread before `CHANGE MASTER TO` was issued. This ensures that there is no discontinuity in replication, even if the replication SQL thread was late compared to the replication I/O thread.

**MASTER_PASSWORD**

The password for the replication user account to use for connecting to the replication source server. If you specify `MASTER_PASSWORD`, `MASTER_USER` is also required.

The password used for a replication user account in a `CHANGE MASTER TO` statement is limited to 32 characters in length. Trying to use a password of more than 32 characters causes `CHANGE MASTER TO` to fail.

**MASTER_PORT**

The TCP/IP port number that the replica uses to connect to the replication source server.

<table>
<thead>
<tr>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>Replication cannot use Unix socket files. You must be able to connect to the replication source server using TCP/IP.</td>
</tr>
</tbody>
</table>

If you specify `MASTER_HOST` or `MASTER_PORT`, the replica assumes that the source server is different from before (even if the option value is the same as its current value.) In this case, the old values for the source's binary log file name and position are considered no longer applicable, so if you do not specify `MASTER_LOG_FILE` and `MASTER_LOG_POS` in the statement, `MASTER_LOG_FILE=''` and `MASTER_LOG_POS=4` are silently appended to it.

**MASTER_PUBLIC_KEY_PATH**

Enables RSA key pair-based password exchange by providing the path name to a file containing a replica-side copy of the public key required by the source. The file must be in PEM format. This option applies to replicas that authenticate with the `sha256_password` or `caching_sha2_password` authentication plugin. (For `sha256_password`, `MASTER_PUBLIC_KEY_PATH` can be used only if MySQL was built using OpenSSL.) If you are using a replication user account that authenticates with the `caching_sha2_password` plugin (which is the default from MySQL 8.0), and you are not using a secure connection, you must specify either this option or the `GET_MASTER_PUBLIC_KEY=1` option to provide the RSA public key to the replica.

**MASTER_RETRY_COUNT**

Sets the maximum number of reconnection attempts that the replica makes after the connection to the source times out, as determined by the `slave_net_timeout` system variable. If the replica does need to reconnect, the first retry occurs immediately after the
timeout. The interval between the attempts is specified by the `MASTER_CONNECT_RETRY` option.

If both the default settings are used, the replica waits 60 seconds between reconnection attempts (`MASTER_CONNECT_RETRY=60`), and keeps attempting to reconnect at this rate for 60 days (`MASTER_RETRY_COUNT=86400`). A setting of 0 for `MASTER_RETRY_COUNT` means that there is no limit on the number of reconnection attempts, so the replica keeps trying to reconnect indefinitely.

The values for `MASTER_CONNECT_RETRY` and `MASTER_RETRY_COUNT` are recorded in the source metadata repository and shown in the `replication_connection_configuration` Performance Schema table. `MASTER_RETRY_COUNT` supersedes the `--master-retry-count` server startup option.

**MASTER_SSL_**, **MASTER_TLS_**

Specify how the replica uses encryption and ciphers to secure the replication connection. These options can be changed even on replicas that are compiled without SSL support. They are saved to the source metadata repository, but are ignored if the replica does not have SSL support enabled. The `MASTER_SSL_` and `MASTER_TLS_` options perform the same functions as the `--ssl-` and `--tls-` client options described in Command Options for Encrypted Connections. The correspondence between the two sets of options, and the use of the `MASTER_SSL_` and `MASTER_TLS_` options to set up a secure connection, is explained in Section 17.3.1, “Setting Up Replication to Use Encrypted Connections”.

**MASTER_USER**

The user name for the replication user account to use for connecting to the replication source server.

---

**Important**

To connect to the source using a replication user account that authenticates with the `caching_sha2_password` plugin, you must either set up a secure connection as described in Section 17.3.1, “Setting Up Replication to Use Encrypted Connections”, or enable the unencrypted connection to support password exchange using an RSA key pair. The `caching_sha2_password` authentication plugin is the default for new users created from MySQL 8.0 (for details, see Section 6.4.1.2, “Caching SHA-2 Pluggable Authentication”). If the user account that you create or use for replication uses this authentication plugin, and you are not using a secure connection, you must enable RSA key pair-based password exchange for a successful connection. You can do this using either the `MASTER_PUBLIC_KEY_PATH` option or the
It is possible to set an empty user name by specifying `MASTER_USER=''
but the replication channel cannot be started with an empty user name. In releases before MySQL 8.0.21,
only set an empty `MASTER_USER` user name if you need to
clear previously used credentials from the replication metadata
repositories for security purposes. Do not use the channel
afterwards, due to a bug in these releases that can substitute
a default user name if an empty user name is read from the
repositories (for example, during an automatic restart of a Group
Replication channel). From MySQL 8.0.21, it is valid to set an empty
`MASTER_USER` user name and use the channel afterwards if you
always provide user credentials using the `START REPLICA | SLAVE`
statement or `START GROUP_REPLICATION` statement
that starts the replication channel. This approach means that the
replication channel always needs operator intervention to restart,
but the user credentials are not recorded in the replication metadata
repositories.

The text of a running `CHANGE MASTER TO` statement, including
values for `MASTER_USER` and `MASTER_PASSWORD`, can be seen in
the output of a concurrent `SHOW PROCESSLIST` statement. (The
complete text of a `START REPLICA | SLAVE` statement is also
visible to `SHOW PROCESSLIST`.)

The compression level to use for connections to the replication
source server that use the `zstd` compression algorithm.
The permitted levels are from 1 to 22, with larger values
indicating increasing levels of compression. The default `zstd
compression level is 3. The compression level setting has
no effect on connections that do not use `zstd` compression.
`MASTER_ZSTD_COMPRESSION_LEVEL` is available as of MySQL
8.0.18. For more information, see Section 4.2.8, "Connection
Compression Control".

The network namespace to use for TCP/IP connections to the
replication source server. If this option is omitted, connections from
the replica use the default (global) namespace. On platforms that
do not implement network namespace support, failure occurs when
the replica attempts to connect to the source. For information about
network namespaces, see Section 5.1.14, "Network Namespace
Support". `NETWORK_NAMESPACE` is available as of MySQL 8.0.22.

Names a user account that supplies a security context for the
specified channel. `NULL`, which is the default, means no security
context is used. `PRIVILEGE_CHECKS_USER` is available as of
MySQL 8.0.18.

The user name and host name for the user account must follow the
syntax described in Section 6.2.4, "Specifying Account Names",
and the user must not be an anonymous user (with a blank
user name) or the `CURRENT_USER`. The account must have the
`REPLICATION_APPLIER` privilege, plus the required privileges to
execute the transactions replicated on the channel. For details of the
privileges required by the account, see Section 17.3.3, "Replication
Privilege Checks". When you restart the replication channel, the
privilege checks are applied from that point on. If you do not specify
a channel and no other channels exist, the statement is applied to
the default channel.

The use of row-based binary logging is strongly recommended
when PRIVILEGE_CHECKS_USER is set, and you can set
REQUIRE_ROW_FORMAT to enforce this. For example, to start
privilege checks on the channel channel_1 on a running replica,
issue the following statements:

```
mysql> STOP REPLICA | SLAVE FOR CHANNEL 'channel_1';
mysql> CHANGE MASTER TO
    PRIVILEGE_CHECKS_USER = 'priv_repl'@'%.example.com',
    REQUIRE_ROW_FORMAT = 1,
    FOR CHANNEL 'channel_1';
mysql> START REPLICA | SLAVE FOR CHANNEL 'channel_1';
```

The relay log file name, and the location in that file, at which the
replication SQL thread begins reading from the replica's relay log
the next time the thread starts. RELAY_LOG_FILE can use either
an absolute or relative path, and uses the same base name as
MASTER_LOG_FILE.

A CHANGE MASTER TO statement using RELAY_LOG_FILE,
RELAY_LOG_POS, or both options can be executed on a running
replica when the replication SQL thread is stopped. Relay logs
are preserved if at least one of the replication SQL thread and the
replication I/O thread is running. If both threads are stopped, all
relay log files are deleted unless at least one of RELAY_LOG_FILE
or RELAY_LOG_POS is specified. For the Group Replication
applier channel (group_replication_applier), which only
has an SQL thread and no I/O thread, this is the case if the SQL
thread is stopped, but with that channel you cannot use the
RELAY_LOG_FILE and RELAY_LOG_POS options.

REQUIRE_ROW_FORMAT

Permits only row-based replication events to be processed by the
replication channel. This option prevents the replication applier from
taking actions such as creating temporary tables and executing
LOAD DATA INFILE requests, which increases the security of the
channel. Group Replication channels are automatically created with
REQUIRE_ROW_FORMAT set, and you cannot change the option
for those channels. For more information, see Section 17.3.3,
“Replication Privilege Checks”. REQUIRE_ROW_FORMAT is available
as of MySQL 8.0.19.

REQUIRE_TABLE_PRIMARY_KEY

Enables a replica to select its own policy for primary key checks.
When the option is set to ON for a replication channel, the replica
always uses the value ON for the sql_require_primary_key
system variable in replication operations, requiring a primary
key. When the option is set to OFF, the replica always uses
the value OFF for the sql_require_primary_key system
variable in replication operations, so that a primary key is
never required, even if the source required one. When the
REQUIRE_TABLE_PRIMARY_KEY option is set to
STREAM, which is the default, the replica uses whatever
value is replicated from the source for each transaction.
REQUIRE_TABLE_PRIMARY_KEY is available as of MySQL
8.0.20.

For multisource replication, setting
REQUIRE_TABLE_PRIMARY_KEY to ON or OFF enables
a replica to normalize behavior across the replication channels
for different sources, and keep a consistent setting for the
`sql_require_primary_key` system variable. Using **ON** safeguards against the accidental loss of primary keys when multiple sources update the same set of tables. Using **OFF** allows sources that can manipulate primary keys to work alongside sources that cannot.

When `PRIVILEGE_CHECKS_USER` is set, setting
`REQUIRE_TABLE_PRIMARY_KEY_CHECK` to **ON** or **OFF** means that the user account does not need session administration level privileges to set restricted session variables, which are required to change the value of `sql_require_primary_key` to match the source’s setting for each transaction. For more information, see Section 17.3.3, “Replication Privilege Checks”.

**SOURCE_CONNECTION_AUTO_FAILOVER** activates the asynchronous connection failover mechanism for a replication channel if one or more alternative replication source servers are available (so when there are multiple MySQL servers or groups of servers that share the replicated data). **SOURCE_CONNECTION_AUTO_FAILOVER** is available as of MySQL 8.0.22. The asynchronous connection failover mechanism takes over after the reconnection attempts controlled by `MASTER_CONNECT_RETRY` and `MASTER_RETRY_COUNT` are exhausted. It reconnects the replica to an alternative source chose from a specified source list, which you manage using the asynchronous_connection_failover_add_source and asynchronous_connection_failover_delete_source UDFs. To add and remove managed groups of servers, use the asynchronous_connection_failover_add_managed and asynchronous_connection_failover_delete_managed UDFs instead. For more information, see Section 17.4.9, “Switching Sources with Asynchronous Connection Failover”.

**Important**

1. You can only set
   ```
   SOURCE_CONNECTION_AUTO_FAILOVER = 1
   ```
   when GTID auto-positioning is in use (```MASTER_AUTO_POSITION = 1```).

2. When you set
   ```
   SOURCE_CONNECTION_AUTO_FAILOVER = 1, set MASTER_RETRY_COUNT and
   MASTER_CONNECT_RETRY to minimal numbers that just allow a few retry
   attempts with the same source in a short time, in case the connection
   failure is caused by a transient network outage. Otherwise the asynchronous
   connection failover mechanism cannot be activated promptly. Suitable values
   are ```MASTER_RETRY_COUNT=3``` and ```MASTER_CONNECT_RETRY=10``` which
   make the replica retry the connection 3 times with 10-second intervals between.

3. When you set
   ```
   SOURCE_CONNECTION_AUTO_FAILOVER = 1
   ```
   the replication metadata repositories
SQL Statements for Controlling Replica Servers

must contain the credentials for a replication user account that can be used to connect to all the servers on the source list for the replication channel. These credentials can be set using the CHANGE REPLICATION SOURCE TO statement with the MASTER_USER and MASTER_PASSWORD options. For more information, see Section 17.4.9, “Switching Sources with Asynchronous Connection Failover”.

The following table shows the maximum permissible length for the string-valued options.

### 13.4.2.2 CHANGE REPLICATION FILTER Statement

```
CHANGE REPLICATION FILTER filter[, filter] [, ...] [FOR CHANNEL channel]

filter: {
  | REPPLICATE_DO_DB = (db_list)
  | REPPLICATE_IGNORE_DB = (db_list)
  | REPPLICATE_DO_TABLE = (tbl_list)
  | REPPLICATE_IGNORE_TABLE = (tbl_list)
  | REPPLICATE_WILDO_DB_TABLE = (wild_tbl_list)
  | REPPLICATE_WILDO_IGNORE_TABLE = (wild_tbl_list)
  | REPPLICATE_REWRITE_DB = (db_pair_list)
}

db_list:
  | db_name[, db_name][, ...]

tbl_list:
  | db_name.table_name[, db_name.table_name][, ...]

wild_tbl_list:
  | 'db_pattern.table_pattern'[, 'db_pattern.table_pattern'][, ...]

db_pair_list:
```

2547
SQL Statements for Controlling Replica Servers

CHANGE REPLICATION FILTER sets one or more replication filtering rules on the replica in the same way as starting the replica `mysqld` with replication filtering options such as `--replicate-do-db` or `--replicate-wild-ignore-table`. Unlike the case with the server options, this statement does not require restarting the server to take effect, only that the replication SQL thread be stopped using `STOP REPLICA | SLAVE SQL_THREAD` first (and restarted with `START REPLICA | SLAVE SQL_THREAD` afterwards). CHANGE REPLICATION FILTER requires the `REPLICATION_SLAVE_ADMIN` privilege (or the deprecated `SUPER` privilege). Use the `FOR CHANNEL` clause to make a replication filter specific to a replication channel, for example on a multi-source replica. Filters applied without a specific `FOR CHANNEL` clause are considered global filters, meaning that they are applied to all replication channels.

Note
Global replication filters cannot be set on a MySQL server instance that is configured for Group Replication, because filtering transactions on some servers would make the group unable to reach agreement on a consistent state. Channel specific replication filters can be set on replication channels that are not directly involved with Group Replication, such as where a group member also acts as a replica to a source that is outside the group. They cannot be set on the `group_replication_applier` or `group_replication_recovery` channels.

The following list shows the CHANGE REPLICATION FILTER options and how they relate to `--replicate-*` server options:

- **REPLICATE_DO_DB**: Include updates based on database name. Equivalent to `--replicate-do-db`.
- **REPLICATE_IGNORE_DB**: Exclude updates based on database name. Equivalent to `--replicate-ignore-db`.
- **REPLICATE_DO_TABLE**: Include updates based on table name. Equivalent to `--replicate-do-table`.
- **REPLICATE_IGNORE_TABLE**: Exclude updates based on table name. Equivalent to `--replicate-ignore-table`.
- **REPLICATE_WILD_DO_TABLE**: Include updates based on wildcard pattern matching table name. Equivalent to `--replicate-wild-do-table`.
- **REPLICATE_WILD_IGNORE_TABLE**: Exclude updates based on wildcard pattern matching table name. Equivalent to `--replicate-wild-ignore-table`.
- **REPLICATE_REWRITE_DB**: Perform updates on replica after substituting new name on replica for specified database on source. Equivalent to `--replicate-rewrite-db`.

The precise effects of REPLICATE_DO_DB and REPLICATE_IGNORE_DB filters are dependent on whether statement-based or row-based replication is in effect. See Section 17.2.5, "How Servers Evaluate Replication Filtering Rules", for more information.

Multiple replication filtering rules can be created in a single CHANGE REPLICATION FILTER statement by separating the rules with commas, as shown here:

```
CHANGE REPLICATION FILTER
  REPLICATE_DO_DB = (d1), REPLICATE_IGNORE_DB = (d2);
```

Issuing the statement just shown is equivalent to starting the replica `mysqld` with the options `--replicate-do-db=d1 --replicate-ignore-db=d2`. 

---

(db_pair), (db_pair), ...

```
db_pair: (from_db, to_db)
```
On a multi-source replica, which uses multiple replication channels to process transaction from different sources, use the `FOR CHANNEL channel` clause to set a replication filter on a replication channel:

```sql
CHANGE REPLICATION FILTER REPLICATE_DO_DB = (d1) FOR CHANNEL channel_1;
```

This enables you to create a channel specific replication filter to filter out selected data from a source. When a `FOR CHANNEL` clause is provided, the replication filter statement acts on that replication channel, removing any existing replication filter which has the same filter type as the specified replication filters, and replacing them with the specified filter. Filter types not explicitly listed in the statement are not modified. If issued against a replication channel which is not configured, the statement fails with an `ER_SLAVEConfigurationException` error. If issued against Group Replication channels, the statement fails with an `ER_SLAVE_CHANNEL_OPERATION_NOT_ALLOWED` error.

On a replica with multiple replication channels configured, issuing `CHANGE REPLICATION FILTER` with no `FOR CHANNEL` clause configures the replication filter for every configured replication channel, and for the global replication filters. For every filter type, if the filter type is listed in the statement, then any existing filter rules of that type are replaced by the filter rules specified in the most recently issued statement, otherwise the old value of the filter type is retained. For more information see Section 17.2.5.4, “Replication Channel Based Filters”.

If the same filtering rule is specified multiple times, only the last such rule is actually used. For example, the two statements shown here have exactly the same effect, because the first `REPLICATE_DO_DB` rule in the first statement is ignored:

```sql
CHANGE REPLICATION FILTER
  REPLICATE_DO_DB = (db1, db2), REPLICATE_DO_DB = (db3, db4);

CHANGE REPLICATION FILTER
  REPLICATE_DO_DB = (db3, db4);
```

**Caution**

This behavior differs from that of the `--replicate-*` filter options where specifying the same option multiple times causes the creation of multiple filter rules.

Names of tables and database not containing any special characters need not be quoted. Values used with `REPLICATE_WILD_TABLE` and `REPLICATION_WILD_IGNORE_TABLE` are string expressions, possibly containing (special) wildcard characters, and so must be quoted. This is shown in the following example statements:

```sql
CHANGE REPLICATION FILTER
  REPLICATE_WILD_DO_TABLE = ('db1.old%');

CHANGE REPLICATION FILTER
  REPLICATE_WILD_IGNORE_TABLE = ('db1.new%', 'db2.new%');
```

Values used with `REPLICATE_REWRITE_DB` represent pairs of database names; each such value must be enclosed in parentheses. The following statement rewrites statements occurring on database `db1` on the source to database `db2` on the replica:

```sql
CHANGE REPLICATION FILTER REPLICATE_REWRITE_DB = ((db1, db2));
```

The statement just shown contains two sets of parentheses, one enclosing the pair of database names, and the other enclosing the entire list. This is perhaps more easily seen in the following example, which creates two `rewrite-db` rules, one rewriting database `dbA` to `dbB`, and one rewriting database `dbC` to `dbD`:

```sql
CHANGE REPLICATION FILTER
  REPLICATE_REWRITE_DB = ((dbA, dbB), (dbC, dbD));
```

The `CHANGE REPLICATION FILTER` statement replaces replication filtering rules only for the filter types and replication channels affected by the statement, and leaves other rules and channels unchanged. If you want to unset all filters of a given type, set the filter's value to an
explicitly empty list, as shown in this example, which removes all existing \texttt{REPLICATE\_DO\_DB} and \texttt{REPLICATE\_IGNORE\_DB} rules:

\begin{verbatim}
CHANGE REPLICATION FILTER
  REPLICATE\_DO\_DB = (), REPLICATE\_IGNORE\_DB = ();
\end{verbatim}

Setting a filter to empty in this way removes all existing rules, does not create any new ones, and does not restore any rules set at mysqld startup using \texttt{--replicate-\*} options on the command line or in the configuration file.

The \texttt{RESET REPLICA | SLAVE ALL} statement removes channel specific replication filters that were set on channels deleted by the statement. When the deleted channel or channels are recreated, any global replication filters specified for the replica are copied to them, and no channel specific replication filters are applied.

For more information, see Section 17.2.5, “How Servers Evaluate Replication Filtering Rules”.

### 13.4.2.3 CHANGE REPLICATION SOURCE TO Statement

\texttt{CHANGE REPLICATION SOURCE TO} changes the parameters that the replica server uses for connecting to the source and for reading data from the source. It also updates the contents of the replication metadata repositories (see Section 17.2.4, “Relay Log and Replication Metadata”.

\begin{verbatim}
CHANGE REPLICATION SOURCE TO option [, option] ... [ channel_option ]
option: {
  SOURCE\_BIND = 'interface_name'
  SOURCE\_HOST = 'host_name'
  SOURCE\_USER = 'user_name'
  SOURCE\_PASSWORD = 'password'
  SOURCE\_PORT = port_num
  PRIVILEGE\_CHECKS\_USER = '{'account' | NULL}
  REQUIRE\_ROW\_FORMAT = {0\|1}
  REQUIRE\_TABLE\_PRIMARY\_KEY\_CHECK = {STREAM | ON | OFF}
  ASSIGN\_GTIDS\_TO\_ANONYMOUS\_TRANSACTIONS = {OFF | LOCAL | uid}
  SOURCE\_LOG\_FILE = 'source_log_name'
  SOURCE\_LOG\_POS = source_log_pos
  SOURCE\_AUTO\_POSITION = {0\|1}
  RELAY\_LOG\_FILE = 'relay_log_name'
  RELAY\_LOG\_POS = relay_log_pos
  SOURCE\_HEARTBEAT\_PERIOD = interval
  SOURCE\_CONNECT\_RETRY = interval
  SOURCE\_RETRY\_COUNT = count
  SOURCE\_CONNECTION\_AUTO\_FAILOVER = {0\|1}
  SOURCE\_DELAY = interval
  SOURCE\_COMPRESS\_ALGORITHMS = '{value}'
  SOURCE\_STD\_COMPRESS\_LEVEL = level
  SOURCE\_SSL = {0\|1}
  SOURCE\_SSL\_CA = 'ca_file_name'
  SOURCE\_SSL\_CAPATH = 'ca_directory_name'
  SOURCE\_SSL\_CERT = 'cert_file_name'
  SOURCE\_SSL\_CRL = 'crl_file_name'
  SOURCE\_SSL\_CRLPATH = 'crl_directory_name'
  SOURCE\_SSL\_KEY = 'key_file_name'
  SOURCE\_SSL\_CIPHER = '{cipher_list}'
  SOURCE\_SSL\_VERIFY\_SERVER\_CERT = {0\|1}
  SOURCE\_TLS\_VERSION = '{protocol_list}'
  SOURCE\_TLS\_CIPHERSUITES = '{ciphersuite_list}'
  SOURCE\_PUBLIC\_KEY\_PATH = 'key_file_name'
  GET\_SOURCE\_PUBLIC\_KEY = {0\|1}
  NETWORK\_NAMESPACE = 'namespace'
  IGNORE\_SERVER\_IDS = (server_id_list)
}
channel_option:
  FOR CHANNEL channel
server_id_list:
  [server_id [, server_id] ... ]
\end{verbatim}
SQL Statements for Controlling Replica Servers

Repositories). From MySQL 8.0.23, use `CHANGE REPLICATION SOURCE TO` in place of `CHANGE MASTER TO`, which is deprecated from that release. In releases before MySQL 8.0.23, use `CHANGE MASTER TO`.

You can issue `CHANGE REPLICATION SOURCE TO` statements on a running replica without first stopping it, depending on the states of the replication SQL thread and replication I/O thread. The rules governing such use are provided later in this section. `CHANGE REPLICATION SOURCE TO` requires the `REPLICATION_SLAVE_ADMIN` privilege (or the deprecated `SUPER` privilege).

When using a multithreaded replica (in other words `slave_parallel_workers` is greater than 0), stopping the replica can cause “gaps” in the sequence of transactions that have been executed from the relay log, regardless of whether the replica was stopped intentionally or otherwise. When such gaps exist, issuing `CHANGE REPLICATION SOURCE TO` fails. The solution in this situation is to issue `START REPLICA UNTIL SQL_AFTER_MTS_GAPS` which ensures that the gaps are closed.

The optional `FOR CHANNEL channel` clause enables you to name which replication channel the statement applies to. Providing a `FOR CHANNEL channel` clause applies the `CHANGE REPLICATION SOURCE TO` statement to a specific replication channel, and is used to add a new channel or modify an existing channel. For example, to add a new channel called `channel2`:

```
CHANGE REPLICATION SOURCE TO SOURCE_HOST=host1, SOURCE_PORT=3002 FOR CHANNEL 'channel2'
```

If no clause is named and no extra channels exist, the statement applies to the default channel.

When using multiple replication channels, if a `CHANGE REPLICATION SOURCE TO` statement does not name a channel using a `FOR CHANNEL channel` clause, an error occurs. See Section 17.2.2, “Replication Channels” for more information.

Values used for `SOURCE_HOST` and other `CHANGE REPLICATION SOURCE TO` options are checked for linefeed (`\n` or `0x0A`) characters. The presence of such characters in these values causes the statement to fail with `ER_MASTER_INFO`.

Invoking `CHANGE REPLICATION SOURCE TO` causes the previous values for `SOURCE_HOST`, `SOURCE_PORT`, `SOURCE_LOG_FILE`, and `SOURCE_LOG_POS` to be written to the error log, along with other information about the replica's state prior to execution.

`CHANGE REPLICATION SOURCE TO` causes an implicit commit of an ongoing transaction. See Section 13.3.3, “Statements That Cause an Implicit Commit”.

For some of the options of the `CHANGE REPLICATION SOURCE TO` statement, you must issue a `STOP REPLICA` statement prior to issuing a `CHANGE REPLICATION SOURCE TO` statement (and a `START REPLICA` statement afterwards). Sometimes, you only need to stop the replication SQL thread or the replication I/O thread, not both:

- When the SQL thread is stopped, you can execute `CHANGE REPLICATION SOURCE TO` using any combination that is otherwise allowed of `RELAY_LOG_FILE`, `RELAY_LOG_POS`, and `SOURCE_DELAY` options, even if the replication I/O thread is running. No other options may be used with this statement when the I/O thread is running.

- When the I/O thread is stopped, you can execute `CHANGE REPLICATION SOURCE TO` using any of the options for this statement (in any allowed combination) except `RELAY_LOG_FILE`, `RELAY_LOG_POS`, `SOURCE_DELAY`, or `SOURCE_AUTO_POSITION = 1` even when the SQL thread is running.

- Both the SQL thread and the I/O thread must be stopped before issuing a `CHANGE REPLICATION SOURCE TO` statement that employs `SOURCE_AUTO_POSITION = 1` or `ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS`.

You can check the current state of the replication SQL thread and replication I/O thread using `SHOW REPLICA STATUS`. Note that the Group Replication applier channel (`group_replication_applier`) has no I/O thread, only an SQL thread.

For more information, see Section 17.4.8, “Switching Sources During Failover”.
If you are using statement-based replication and temporary tables, it is possible for a `CHANGE REPLICATION SOURCE TO` statement following a `STOP REPLICA` statement to leave behind temporary tables on the replica. A warning (ER_WARN_OPEN_TEMP_TABLES_MUST_BE_ZERO) is now issued whenever this occurs. You can avoid this in such cases by making sure that the value of the Slave_open_temp_tables system status variable is equal to 0 prior to executing such a `CHANGE REPLICATION SOURCE TO` statement.

`CHANGE REPLICATION SOURCE TO` is useful for setting up a replica when you have the snapshot of the source and have recorded the source's binary log coordinates corresponding to the time of the snapshot. After loading the snapshot into the replica to synchronize it with the source, you can run `CHANGE REPLICATION SOURCE TO` `SOURCE_LOG_FILE='log_name'`, `SOURCE_LOG_POS=log_pos` on the replica to specify the coordinates at which the replica should begin reading the source's binary log.

The following example changes the source server the replica uses and establishes the source's binary log coordinates from which the replica begins reading:

```
CHANGE REPLICATION SOURCE TO
  SOURCE_HOST='source2.example.com',
  SOURCE_USER='replication',
  SOURCE_PASSWORD='password',
  SOURCE_PORT=3306,
  SOURCE_LOG_FILE='source2-bin.001',
  SOURCE_LOG_POS=4,
  SOURCE_CONNECT_RETRY=10;
```

The next example shows an operation that is less frequently employed. It is used when the replica has relay log files that you want it to execute again for some reason. To do this, the source need not be reachable. You need only use `CHANGE REPLICATION SOURCE TO` and start the SQL thread (`START REPLICA SQL_THREAD`):

```
CHANGE REPLICATION SOURCE TO
  RELAY_LOG_FILE='replica-relay-bin.006',
  RELAY_LOG_POS=4025;
```

Options that you do not specify on a `CHANGE REPLICATION SOURCE TO` statement retain their value, except as indicated in the following discussion. Thus, in most cases, there is no need to specify options that do not change.

`ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS` makes the replication channel assign a GTID to replicated transactions that do not have one, enabling replication from a source that does not use GTID-based replication, to a replica that does. For a multi-source replica, you can have a mix of channels that use `ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS`, and channels that do not. The default is `OFF`, meaning that the feature is not used.

`LOCAL` assigns a GTID including the replica’s own UUID (the `server_uuid` setting). `uuid` assigns a GTID including the specified UUID, such as the `server_uuid` setting for the replication source server. Using a nonlocal UUID lets you differentiate between transactions that originated on the replica and transactions that originated on the source, and for a multi-source replica, between transactions that originated on different sources. The UUID you choose only has significance for the replica’s own use. If any of the transactions sent by the source do have a GTID already, that GTID is retained.

Channels specific to Group Replication cannot use `ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS`, but an asynchronous replication channel for another source on a server instance that is a Group Replication group member can do so.
that case, do not specify the Group Replication group name as the UUID for creating the GTIDs.

To set `ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS` to `LOCAL` or `uuid`, the replica must have `gtid_mode=ON` set, and this cannot be changed afterwards. This option is for use with a source that has binary log file position based replication, so `MASTER_AUTO_POSITION=1` cannot be set for the channel. Both the replication SQL thread and the replication I/O thread must be stopped before setting this option.

**Important**

A replica set up with `ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS` on any channel cannot be promoted to replace the replication source server in the event that a failover is required, and a backup taken from the replica cannot be used to restore the replication source server. The same restriction applies to replacing or restoring other replicas that use `ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS` on any channel.

For further restrictions and information, see Section 17.1.3.6, “Replication From a Source Without GTIDs to a Replica With GTIDs”.

**GET_SOURCE_PUBLIC_KEY**

Enables RSA key pair-based password exchange by requesting the public key from the source. This option applies to replicas that authenticate with the `caching_sha2_password` authentication plugin. For connections by accounts that authenticate using this plugin, the source does not send the public key unless requested, so it must be requested or specified in the client. If `SOURCE_PUBLIC_KEY_PATH` is given and specifies a valid public key file, it takes precedence over `GET_SOURCE_PUBLIC_KEY`. If you are using a replication user account that authenticates with the `caching_sha2_password` plugin (which is the default from MySQL 8.0), and you are not using a secure connection, you must specify either this option or the `SOURCE_PUBLIC_KEY_PATH` option to provide the RSA public key to the replica.

**IGNORE_SERVER_IDS**

Makes the replica ignore events originating from the specified servers. The option takes a comma-separated list of 0 or more server IDs. Log rotation and deletion events from the servers are not ignored, and are recorded in the relay log.

In circular replication, the originating server normally acts as the terminator of its own events, so that they are not applied more than once. Thus, this option is useful in circular replication when one of the servers in the circle is removed. Suppose that you have a circular replication setup with 4 servers, having server IDs 1, 2, 3, and 4, and server 3 fails. When bridging the gap by starting replication from server 2 to server 4, you can include `_IGNORE_SERVER_IDS = (3)` in the `CHANGE REPLICATION SOURCE TO` statement that you issue on server 4 to tell it to use server 2 as its source instead of server 3. Doing so causes it to
ignore and not to propagate any statements that originated with the server that is no longer in use.

If `IGNORE_SERVER_IDS` contains the server's own ID and the server was started with the `--replicate-same-server-id` option enabled, an error results.

**Note**
When global transaction identifiers (GTIDs) are used for replication, transactions that have already been applied are automatically ignored, so the `IGNORE_SERVER_IDS` function is not required and is deprecated. If `gtid_mode=ON` is set for the server, a deprecation warning is issued if you include the `IGNORE_SERVER_IDS` option in a `CHANGE REPLICATION SOURCE TO` statement.

The source metadata repository and the output of `SHOW REPLICA STATUS` provide the list of servers that are currently ignored. For more information, see Section 17.2.4.2, “Replication Metadata Repositories”, and Section 13.7.7.35, “SHOW REPLICA | SLAVE STATUS Statement”.

If a `CHANGE REPLICATION SOURCE TO` statement is issued without any `IGNORE_SERVER_IDS` option, any existing list is preserved. To clear the list of ignored servers, it is necessary to use the option with an empty list:

```sql
CHANGE REPLICATION SOURCE TO IGNORE_SERVER_IDS = ();
```

`RESET REPLICA ALL` clears `IGNORE_SERVER_IDS`.

**Note**
A deprecation warning is issued if `SET GTID_MODE=ON` is issued when any channel has existing server IDs set with `IGNORE_SERVER_IDS`. Before starting GTID-based replication, check for and clear all ignored server ID lists on the servers involved. The `SHOW REPLICA STATUS` statement displays the list of ignored IDs, if there is one. If you do receive the deprecation warning, you can still clear a list after `gtid_mode=ON` is set by issuing a `CHANGE REPLICATION SOURCE TO` statement containing the `IGNORE_SERVER_IDS` option with an empty list.

**NETWORK_NAMESPACE**

The network namespace to use for TCP/IP connections to the replication source server. If this option is omitted, connections from the replica use the default (global) namespace. On platforms that do not implement network namespace support, failure occurs when the replica attempts to connect to the source. For information about network namespaces, see Section 5.1.14, “Network Namespace Support”. `NETWORK_NAMESPACE` is available as of MySQL 8.0.22.
PRIVILEGE_CHECKS_USER

Names a user account that supplies a security context for the specified channel. NULL, which is the default, means no security context is used. PRIVILEGE_CHECKS_USER is available as of MySQL 8.0.18.

The user name and host name for the user account must follow the syntax described in Section 6.2.4, “Specifying Account Names”, and the user must not be an anonymous user (with a blank user name) or the CURRENT_USER. The account must have the REPLICATION_APPLIER privilege, plus the required privileges to execute the transactions replicated on the channel. For details of the privileges required by the account, see Section 17.3.3, “Replication Privilege Checks”. When you restart the replication channel, the privilege checks are applied from that point on. If you do not specify a channel and no other channels exist, the statement is applied to the default channel.

The use of row-based binary logging is strongly recommended when PRIVILEGE_CHECKS_USER is set, and you can set REQUIRE_ROW_FORMAT to enforce this. For example, to start privilege checks on the channel channel_1 on a running replica, issue the following statements:

```
mysql> STOP REPLICA FOR CHANNEL 'channel_1';
mysql> CHANGE REPLICATION SOURCE TO
PRIVILEGE_CHECKS_USER = 'priv_repl'@'%.example.com',
REQUIRE_ROW_FORMAT = 1,
FOR CHANNEL 'channel_1';
mysql> START REPLICA FOR CHANNEL 'channel_1';
```

RELAY_LOG_FILE, RELAY_LOG_POS

The relay log file name, and the location in that file, at which the replication SQL thread begins reading from the replica’s relay log the next time the thread starts. RELAY_LOG_FILE can use either an absolute or relative path, and uses the same base name as SOURCE_LOG_FILE.

A CHANGE REPLICATION SOURCE TO statement using RELAY_LOG_FILE, RELAY_LOG_POS, or both options can be executed on a running replica when the replication SQL thread is stopped. Relay logs are preserved if at least one of the replication SQL thread and the replication I/O thread is running. If both threads are stopped, all relay log files are deleted unless at least one of RELAY_LOG_FILE or RELAY_LOG_POS is specified. For the Group Replication applier channel (group_replication_applier), which only has an SQL thread and no I/O thread, this is the case if the SQL thread is stopped, but with that channel you cannot use the RELAY_LOG_FILE and RELAY_LOG_POS options.

REQUIRE_ROW_FORMAT

Permits only row-based replication events to be processed by the replication channel. This option prevents the replication applier from taking actions such as creating temporary tables and executing LOAD DATA INFILE requests, which increases the security of the channel. Group Replication channels are automatically created with REQUIRE_ROW_FORMAT set, and you cannot change the option for those channels. For more information, see Section 17.3.3, “Replication Privilege Checks”. REQUIRE_ROW_FORMAT is available as of MySQL 8.0.19.

REQUIRE_TABLE_PRIMARY_KEY

Enables a replica to select its own policy for primary key checks. When the option is set to ON for a replication channel, the replica always uses the value ON for the sql_require_primary_key
system variable in replication operations, requiring a primary key. When the option is set to `OFF`, the replica always uses the value `OFF` for the `sql_require_primary_key` system variable in replication operations, so that a primary key is never required, even if the source required one. When the `REQUIRE_TABLE_PRIMARY_KEY_CHECK` option is set to `STREAM`, which is the default, the replica uses whatever value is replicated from the source for each transaction. `REQUIRE_TABLE_PRIMARY_KEY_CHECK` is available as of MySQL 8.0.20.

For multisource replication, setting `REQUIRE_TABLE_PRIMARY_KEY_CHECK` to `ON` or `OFF` enables a replica to normalize behavior across the replication channels for different sources, and keep a consistent setting for the `sql_require_primary_key` system variable. Using `ON` safeguards against the accidental loss of primary keys when multiple sources update the same set of tables. Using `OFF` allows sources that can manipulate primary keys to work alongside sources that cannot.

When `PRIVILEGE_CHECKS_USER` is set, setting `REQUIRE_TABLE_PRIMARY_KEY_CHECK` to `ON` or `OFF` means that the user account does not need session administration level privileges to set restricted session variables, which are required to change the value of `sql_require_primary_key` to match the source's setting for each transaction. For more information, see Section 17.3.3, “Replication Privilege Checks”.

`SOURCE_AUTO_POSITION` makes the replica attempt to connect to the source using the auto-positioning feature of GTID-based replication, rather than a binary log file based position. This option can be used with `CHANGE REPLICATION SOURCE TO` only if both the replication SQL thread and replication I/O thread are stopped.

Both the replica and the source must have GTIDs enabled (`GTID_MODE=ON`, `ON_PERMISSIVE`, or `OFF_PERMISSIVE` on the replica, and `GTID_MODE=ON` on the source). `SOURCE_LOG_FILE`, `SOURCE_LOG_POS`, `RELAY_LOG_FILE`, and `RELAY_LOG_POS` cannot be specified together with `SOURCE_AUTO_POSITION = 1`. If multi-source replication is enabled on the replica, you need to set the `SOURCE_AUTO_POSITION = 1` option for each applicable replication channel.

With `SOURCE_AUTO_POSITION = 1` set, in the initial connection handshake, the replica sends a GTID set containing the transactions that it has already received, committed, or both. The source responds by sending all transactions recorded in its binary log whose GTID is not included in the GTID set sent by the replica. This exchange ensures that the source only sends the transactions with a GTID that the replica has not already recorded or committed. If the replica receives transactions from more than one source, as in the case of a diamond topology, the auto-skip function ensures that the transactions are not applied twice. For details of how the GTID set sent by the replica is computed, see Section 17.1.3.3, “GTID Auto-Positioning”.

If any of the transactions that should be sent by the source have been purged from the source's binary log, or
added to the set of GTIDs in the `gtid_purged` system variable by another method, the source sends the error `ER_MASTER_HAS_PURGED_REQUIRED_GTIDS` to the replica, and replication does not start. The GTIDs of the missing purged transactions are identified and listed in the source's error log in the warning message `ER_FOUND_MISSING_GTIDS`. Also, if during the exchange of transactions it is found that the replica has recorded or committed transactions with the source's UUID in the GTID, but the source itself has not committed them, the source sends the error `ER_SLAVE_HAS_MORE_GTIDS_THAN_MASTER` to the replica and replication does not start. For information on how to handle these situations, see Section 17.1.3.3, "GTID Auto-Positioning".

You can see whether replication is running with GTID auto-positioning enabled by checking the Performance Schema `replication_connection_status` table or the output of `SHOW REPLICA STATUS`. Disabling the `SOURCE_AUTO_POSITION` option again makes the replica revert to file-based replication.

**SOURCE_BIND**

Determines which of the replica's network interfaces is chosen for connecting to the source, for use on replicas that have multiple network interfaces. The address configured with this option, if any, can be seen in the `Source_Bind` column of the output from `SHOW REPLICA STATUS`. In the source metadata repository table `mysql.slave_master_info`, the value can be seen as the `Source_bind` column. The ability to bind a replica to a specific network interface is also supported by NDB Cluster.

**SOURCE_COMPRESSION_ALGORITHMS**

Specifies the permitted compression algorithms for connections to the replication source server. The available algorithms are the same as for the `protocol_compression_algorithms` system variable. The default value is uncompressed. `SOURCE_COMPRESSION_ALGORITHMS` is available as of MySQL 8.0.18.

The value of `SOURCE_COMPRESSION_ALGORITHMS` applies only if the `slave_compressed_protocol` system variable is disabled. If `slave_compressed_protocol` is enabled, it takes precedence over `SOURCE_COMPRESSION_ALGORITHMS` and connections to the source use zlib compression if both source and replica support that algorithm. For more information, see Section 4.2.8, "Connection Compression Control".

Binary log transaction compression (available as of MySQL 8.0.20), which is activated by the `binlog_transaction_compression` system variable, can also be used to save bandwidth. If you do this in combination with connection compression, connection compression has less opportunity to act on the data, but can still compress headers and those events and transaction payloads that are uncompressed. For more information on binary log transaction compression, see Section 5.4.4.5, "Binary Log Transaction Compression".

**SOURCE_CONNECT_RETRY**

Specifies the interval between the reconnection attempts that the replica makes after the connection to the source times out. The attempts are limited by the `SOURCE_RETRY_COUNT` option. If both the default settings are used, the replica waits 60 seconds between reconnection attempts (`SOURCE_CONNECT_RETRY=60`), and keeps attempting to reconnect at this rate for 60 days.
SQL Statements for Controlling Replica Servers

`SOURCE_RETRY_COUNT=86400`. These values are recorded in the source metadata repository and shown in the `replication_connection_configuration` Performance Schema table.

**SOURCE_CONNECTION_AUTO_FAILOVER** activates the asynchronous connection failover mechanism for a replication channel if one or more alternative replication source servers are available (so when there are multiple MySQL servers or groups of servers that share the replicated data). `SOURCE_CONNECTION_AUTO_FAILOVER` is available as of MySQL 8.0.22. The asynchronous connection failover mechanism takes over after the reconnection attempts controlled by `SOURCE_CONNECT_RETRY` and `SOURCE_RETRY_COUNT` are exhausted. It reconnects the replica to an alternative source chosen from a specified source list, which you manage using the `asynchronous_connection_failover_add_source` and `asynchronous_connection_failover_delete_source` UDFs. To add and remove managed groups of servers, use the `asynchronous_connection_failover_add_managed` and `asynchronous_connection_failover_delete_managed` UDFs instead. For more information, see Section 17.4.9, “Switching Sources with Asynchronous Connection Failover”.

**Important**

1. You can only set `SOURCE_CONNECTION_AUTO_FAILOVER = 1` when GTID auto-positioning is in use (`SOURCE_AUTO_POSITION = 1`).

2. When you set `SOURCE_CONNECTION_AUTO_FAILOVER = 1`, set `SOURCE_RETRY_COUNT` and `SOURCE_CONNECT_RETRY` to minimal numbers that just allow a few retry attempts with the same source, in case the connection failure is caused by a transient network outage. Otherwise the asynchronous connection failover mechanism cannot be activated promptly. Suitable values are `SOURCE_RETRY_COUNT=3` and `SOURCE_CONNECT_RETRY=10`, which make the replica retry the connection 3 times with 10-second intervals between.

3. When you set `SOURCE_CONNECTION_AUTO_FAILOVER = 1`, the replication metadata repositories must contain the credentials for a replication user account that can be used to connect to all the servers on the source list for the replication channel. The account must also have **SELECT** permissions on the Performance Schema tables. These credentials can be set using the `CHANGE REPLICATION SOURCE TO` statement with the `SOURCE_USER` and `SOURCE_PASSWORD`
SQL Statements for Controlling Replica Servers

- **SOURCE_DELAY**: Specifies how many seconds behind the source the replica must lag. An event received from the source is not executed until at least \( \text{interval} \) seconds later than its execution on the source. The default is 0. An error occurs if \( \text{interval} \) is not a nonnegative integer in the range from 0 to \( 2^{31} - 1 \). For more information, see Section 17.4.11, "Delayed Replication". A `CHANGE REPLICATION SOURCE TO` statement using the `SOURCE_DELAY` option can be executed on a running replica when the replication SQL thread is stopped.

- **SOURCE_HEARTBEAT_PERIOD**: Controls the heartbeat interval, which stops the connection timeout occurring in the absence of data if the connection is still good. A heartbeat signal is sent to the replica after that number of seconds, and the waiting period is reset whenever the source's binary log is updated with an event. Heartbeats are therefore sent by the source only if there are no unsent events in the binary log file for a period longer than this.

  The heartbeat interval \( \text{interval} \) is a decimal value having the range 0 to 4924967 seconds and a resolution in milliseconds; the smallest nonzero value is 0.001. Setting \( \text{interval} \) to 0 disables heartbeats altogether. The heartbeat interval defaults to half the value of the `slave_net_timeout` system variable. It is recorded in the source metadata repository and shown in the `replication_connection_configuration` Performance Schema table. Issuing `RESET REPLICA` resets the heartbeat interval to the default value.

  The `slave_net_timeout` system variable specifies the number of seconds that the replica waits for either more data or a heartbeat signal from the source, before the replica considers the connection broken, aborts the read, and tries to reconnect. The default value is 60 seconds (one minute). Note that a change to the value or default setting of `slave_net_timeout` does not automatically change the heartbeat interval, whether that has been set explicitly or is using a previously calculated default. A warning is issued if you set `@GLOBAL slave_net_timeout` to a value less than that of the current heartbeat interval. If `slave_net_timeout` is changed, you must also issue `CHANGE REPLICATION SOURCE TO` to adjust the heartbeat interval to an appropriate value so that the heartbeat signal occurs before the connection timeout. If you do not do this, the heartbeat signal has no effect, and if no data is received from the source, the replica can make repeated reconnection attempts, creating zombie dump threads.

- **SOURCE_HOST**: The host name or IP address of the replication source server. The replica uses this to connect to the source.

  If you specify `SOURCE_HOST` or `SOURCE_PORT`, the replica assumes that the source server is different from before (even if the option value is the same as its current value.) In this case, the old values for the source's binary log file name and position are considered no longer applicable, so if you do not specify `SOURCE_LOG_FILE` and...
SOURCE_LOG_POS in the statement, SOURCE_LOG_FILE='' and SOURCE_LOG_POS=4 are silently appended to it.

Setting SOURCE_HOST='' (that is, setting its value explicitly to an empty string) is not the same as not setting SOURCE_HOST at all. Trying to set SOURCE_HOST to an empty string fails with an error.

The binary log file name, and the location in that file, at which the replication I/O thread begins reading from the source's binary log the next time the thread starts. Specify these options if you are using binary log file position based replication. SOURCE_LOG_FILE must include the numeric suffix of a specific binary log file that is available on the source server, for example, SOURCE_LOG_FILE='binlog.000145'. SOURCE_LOG_POS is the numeric position for the replica to start reading in that file. SOURCE_LOG_POS=4 represents the start of the events in a binary log file.

If you specify either of SOURCE_LOG_FILE or SOURCE_LOG_POS, you cannot specify SOURCE_AUTO_POSITION = 1, which is for GTID-based replication.

If neither of SOURCE_LOG_FILE or SOURCE_LOG_POS is specified, the replica uses the last coordinates of the replication SQL thread before CHANGE REPLICATION SOURCE TO was issued. This ensures that there is no discontinuity in replication, even if the replication SQL thread was late compared to the replication I/O thread.

The password for the replication user account to use for connecting to the replication source server. If you specify SOURCE_PASSWORD, SOURCE_USER is also required.

The password used for a replication user account in a CHANGE REPLICATION SOURCE TO statement is limited to 32 characters in length. Trying to use a password of more than 32 characters causes CHANGE REPLICATION SOURCE TO to fail.

The TCP/IP port number that the replica uses to connect to the replication source server.

**Note**

Replication cannot use Unix socket files. You must be able to connect to the replication source server using TCP/IP.

If you specify SOURCE_HOST or SOURCE_PORT, the replica assumes that the source server is different from before (even if the option value is the same as its current value.) In this case, the old values for the source's binary log file name and position are considered no longer applicable, so if you do not specify SOURCE_LOG_FILE and SOURCE_LOG_POS in the statement, SOURCE_LOG_FILE='' and SOURCE_LOG_POS=4 are silently appended to it.

Enables RSA key pair-based password exchange by providing the path name to a file containing a replica-side copy of the public key required by the source. The file must be in PEM format. This option applies to replicas that authenticate with the sha256_password or caching_sha2_password authentication methods.
SQL Statements for Controlling Replica Servers

**SOURCE_RETY_COUNT**

Sets the maximum number of reconnection attempts that the replica makes after the connection to the source times out, as determined by the `slave_net_timeout` system variable. If the replica does need to reconnect, the first retry occurs immediately after the timeout.

The interval between the attempts is specified by the `SOURCE_CONNECT_RETRY` option. If both the default settings are used, the replica waits 60 seconds between reconnection attempts (`SOURCE_CONNECT_RETRY=60`), and keeps attempting to reconnect at this rate for 60 days (`SOURCE_RETRY_COUNT=86400`). A setting of 0 for `SOURCE_RETRY_COUNT` means that there is no limit on the number of reconnection attempts, so the replica keeps trying to reconnect indefinitely.

The values for `SOURCE_CONNECT_RETRY` and `SOURCE_RETRY_COUNT` are recorded in the source metadata repository and shown in the `replication_connection_configuration` Performance Schema table. `SOURCE_RETRY_COUNT` supersedes the `--master-retry-count` server startup option.

**SOURCE_SSL_***, **SOURCE_TLS_***

Specify how the replica uses encryption and ciphers to secure the replication connection. These options can be changed even on replicas that are compiled without SSL support. They are saved to the source metadata repository, but are ignored if the replica does not have SSL support enabled. The `SOURCE_SSL_***` and `SOURCE_TLS_***` options perform the same functions as the `--ssl-***` and `--tls-***` client options described in Command Options for Encrypted Connections. The correspondence between the two sets of options, and the use of the `SOURCE_SSL_***` and `SOURCE_TLS_***` options to set up a secure connection, is explained in Section 17.3.1, “Setting Up Replication to Use Encrypted Connections”.

**SOURCE_USER**

The user name for the replication user account to use for connecting to the replication source server.

---

Important

To connect to the source using a replication user account that authenticates with the `caching_sha2_password` plugin, you must either set up a secure connection as described in Section 17.3.1, “Setting Up Replication to Use Encrypted Connections”, or enable the unencrypted connection to support password exchange using an RSA key pair. The `caching_sha2_password` authentication plugin is the default for new users created from MySQL 8.0 (for
SQL Statements for Controlling Replica Servers

It is possible to set an empty user name by specifying `SOURCE_USER=NULL`, but the replication channel cannot be started with an empty user name. In releases before MySQL 8.0.21, only set an empty `SOURCE_USER` user name if you need to clear previously used credentials from the replication metadata repositories for security purposes. Do not use the channel afterwards, due to a bug in these releases that can substitute a default user name if an empty user name is read from the repositories (for example, during an automatic restart of a Group Replication channel). From MySQL 8.0.21, it is valid to set an empty `SOURCE_USER` user name and use the channel afterwards if you always provide user credentials using the `START REPLICA` statement or `START GROUP_REPLICATION` statement that starts the replication channel. This approach means that the replication channel always needs operator intervention to restart, but the user credentials are not recorded in the replication metadata repositories.

The text of a running `CHANGE REPLICATION SOURCE TO` statement, including values for `SOURCE_USER` and `SOURCE_PASSWORD`, can be seen in the output of a concurrent `SHOW PROCESSLIST` statement. (The complete text of a `START REPLICA` statement is also visible to `SHOW PROCESSLIST`.)

The compression level to use for connections to the replication source server that use the `zstd` compression algorithm. The permitted levels are from 1 to 22, with larger values indicating increasing levels of compression. The default `zstd` compression level is 3. The compression level setting has no effect on connections that do not use `zstd` compression. `SOURCE_ZSTD_COMPRESSION_LEVEL` is available as of MySQL 8.0.18. For more information, see Section 4.2.8, “Connection Compression Control”.

The following table shows the maximum permissible length for the string-valued options.

<table>
<thead>
<tr>
<th>Option</th>

### 13.4.2.4 MASTER_POS_WAIT() Statement

```sql
SELECT MASTER_POS_WAIT('source_log_file', source_log_pos [, timeout] [, channel])
```

This is actually a function, not a statement. It is used to ensure that the replica has read and executed events up to a given position in the source's binary log. See Section 12.24, “Miscellaneous Functions”, for a full description.

### 13.4.2.5 RESET REPLICA | SLAVE Statement

```
RESET {REPLICA | SLAVE} [ALL] [channel_option]
```

- `channel_option`:
  ```
  FOR CHANNEL channel
  ```

**RESET REPLICA | SLAVE** makes the replica forget its position in the source's binary log. From MySQL 8.0.22, use `RESET REPLICA` in place of `RESET SLAVE`, which is deprecated from that release. In releases before MySQL 8.0.22, use `RESET SLAVE`.

This statement is meant to be used for a clean start; it clears the replication metadata repositories, deletes all the relay log files, and starts a new relay log file. It also resets to 0 the replication delay specified with the `SOURCE_DELAY` | `MASTER_DELAY` option of the `CHANGE REPLICATION SOURCE TO` statement (from MySQL 8.0.23) or `CHANGE MASTER TO` statement (before MySQL 8.0.23).

**Note**

All relay log files are deleted, even if they have not been completely executed by the replication SQL thread. (This is a condition likely to exist on a replica if you have issued a `STOP REPLICA | SLAVE` statement or if the replica is highly loaded.)

For a server where GTIDs are in use (`gtid_mode` is `ON`), issuing `RESET REPLICA | SLAVE` has no effect on the GTID execution history. The statement does not change the values of `gtid_executed` or `gtid_purged`, or the `mysql.gtid_executed` table. If you need to reset the GTID execution history, use `RESET MASTER`, even if the GTID-enabled server is a replica where binary logging is disabled.

**RESET REPLICA | SLAVE** requires the `RELOAD` privilege.

To use `RESET REPLICA | SLAVE`, the replication SQL thread and replication I/O thread must be stopped, so on a running replica use `STOP REPLICA | SLAVE` before issuing `RESET REPLICA | SLAVE`. To use `RESET REPLICA | SLAVE` on a Group Replication group member, the member status must be `OFFLINE`, meaning that the plugin is loaded but the member does not currently belong to any group. A group member can be taken offline by using a `STOP GROUP REPLICATION` statement.

The optional `FOR CHANNEL channel` clause enables you to name which replication channel the statement applies to. Providing a `FOR CHANNEL channel` clause applies the `RESET REPLICA | SLAVE`
SLAVE statement to a specific replication channel. Combining a FOR CHANNEL channel clause with the ALL option deletes the specified channel. If no channel is named and no extra channels exist, the statement applies to the default channel. Issuing a RESET REPLICA | SLAVE ALL statement without a FOR CHANNEL channel clause when multiple replication channels exist deletes all replication channels and recreates only the default channel. See Section 17.2.2, “Replication Channels” for more information.

RESET REPLICA | SLAVE does not change any replication connection parameters, which include the source’s host name and port, the replication user account and its password, the PRIVILEGE_CHECKS_USER account, the REQUIRE_ROW_FORMAT option, the REQUIRE_TABLE_PRIMARY_KEY_CHECK option, and the ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS option. If you want to change any of the replication connection parameters, you can do this using a CHANGE REPLICA SOURCE TO statement (from MySQL 8.0.23) or CHANGE MASTER TO statement (before MySQL 8.0.23) after the server start. If you want to remove all of the replication connection parameters, use RESET REPLICA | SLAVE ALL. RESET REPLICA | SLAVE ALL also clears the IGNORE_SERVER_IDS list set by CHANGE REPLICA SOURCE TO | CHANGE MASTER TO. When you have used RESET REPLICA | SLAVE ALL, if you want to use the instance as a replica again, you need to issue a CHANGE REPLICA SOURCE TO | CHANGE MASTER TO statement after the server start to specify new connection parameters.

In the event of an unexpected server exit or deliberate restart after issuing RESET REPLICA | SLAVE but before issuing START REPLICA | SLAVE, retention of the replication connection parameters depends on the repository used for the replication metadata:

• When master_info_repository=TABLE and relay_log_info_repository=TABLE are set on the server (which are the default settings from MySQL 8.0), replication connection parameters are preserved in the crash-safe InnoDB tables mysql.slave_master_info and mysql.slave_relay_log_info as part of the RESET REPLICA | SLAVE operation. They are also retained in memory. In the event of an unexpected server exit or deliberate restart after issuing RESET REPLICA | SLAVE but before issuing START REPLICA | SLAVE, the replication connection parameters are retrieved from the tables and reapplied to the channel. This situation applies from MySQL 8.0.13 for the connection metadata repository, and from MySQL 8.0.19 for the applier metadata repository.

• If master_info_repository=FILE and relay_log_info_repository=FILE are set on the server, which is deprecated from MySQL 8.0, or the MySQL Server release is earlier than those specified above, replication connection parameters are only retained in memory. If the replica mysql is restarted immediately after issuing RESET REPLICA | SLAVE due to an unexpected server exit or deliberate restart, the connection parameters are lost. In that case, you must issue a CHANGE REPLICA SOURCE TO statement (from MySQL 8.0.23) or CHANGE MASTER TO statement (before MySQL 8.0.23) after the server start to respecify the connection parameters before issuing START REPLICA | SLAVE.

RESET REPLICA | SLAVE does not change any replication filter settings (such as --replicate-ignore-table) for channels affected by the statement. However, RESET REPLICA | SLAVE ALL removes the replication filters that were set on the channels deleted by the statement. When the deleted channel or channels are recreated, any global replication filters specified for the replica are copied to them, and no channel specific replication filters are applied. For more information see Section 17.2.5.4, “Replication Channel Based Filters”.

RESET REPLICA | SLAVE causes an implicit commit of an ongoing transaction. See Section 13.3.3, “Statements That Cause an Implicit Commit”.

If the replication SQL thread was in the middle of replicating temporary tables when it was stopped, and RESET REPLICA | SLAVE is issued, these replicated temporary tables are deleted on the replica.

RESET REPLICA | SLAVE does not reset the heartbeat period or SSL_VERIFY_SERVER_CERT.
### Note

When used on an NDB Cluster replica SQL node, `RESET REPLICA | SLAVE` clears the `mysql.ndb_apply_status` table. You should keep in mind when using this statement that `ndb_apply_status` uses the NDB storage engine and so is shared by all SQL nodes attached to the cluster.

You can override this behavior by issuing `SET GLOBAL @@ndb_clear_apply_status=OFF` prior to executing `RESET REPLICA | SLAVE`, which keeps the replica from purging the `ndb_apply_status` table in such cases.

#### 13.4.2.6 RESET SLAVE | REPLICA Statement

```
RESET (SLAVE | REPLICA) [ALL] [channel_option]
```

**channel_option:**
- `FOR CHANNEL` `channel`

Makes the replica forget its position in the source's binary log. From MySQL 8.0.22, `RESET SLAVE` is deprecated and the alias `RESET REPLICA` should be used instead. In releases before MySQL 8.0.22, use `RESET SLAVE`. The statement works in the same way as before, only the terminology used for the statement and its output has changed. Both versions of the statement update the same status variables when used. Please see the documentation for `RESET REPLICA` for a description of the statement.

#### 13.4.2.7 START REPLICA | SLAVE Statement

```
START (REPLICA | SLAVE) [thread_types] [until_option] [connection_options] [channel_option]
```

**thread_types:**
- `[thread_type [, thread_type] ... ]`

**thread_type:**
- `IO_THREAD`
- `SQL_THREAD`

**until_option:**
- `UNTIL { SQL_BEFORE_GTIDS | SQL_AFTER_GTIDS } = gtid_set`
- `MASTER_LOG_FILE = 'log_name', MASTER_LOG_POS = log_pos`
- `SOURCE_LOG_FILE = 'log_name', SOURCE_LOG_POS = log_pos`
- `RELAY_LOG_FILE = 'log_name', RELAY_LOG_POS = log_pos`
- `SQL_AFTER_MTS_GAPS`

**connection_options:**
- `[USER='user_name']`
- `[PASSWORD='user_pass']`
- `[DEFAULT_AUTH='plugin_name']`
- `[PLUGIN_DIR='plugin_dir']`

**channel_option:**
- `FOR CHANNEL` `channel`

**gtid_set:**
- `uuid_set [, uuid_set] ...`
- `''`

**uuid_set:**
- `uuid:interval[::interval]...`

**uuid:**
- `hhhhhhhh-hhhh-hhhh-hhhh-hhhhhhhhhhh`

**h:**
- `[0-9,a-f]`

**interval:**
- `n[-n]`
- `(n >= 1)`
START REPLICA | SLAVE starts one or both of the replication threads. From MySQL 8.0.22, use START REPLICA in place of START SLAVE, which is deprecated from that release. In releases before MySQL 8.0.22, use START SLAVE.

START REPLICA | SLAVE with no thread_type options starts both of the replication threads. The replication I/O thread reads events from the source server and stores them in the relay log. The replication SQL thread reads events from the relay log and executes them. START REPLICA | SLAVE requires the REPLICATION_SLAVE_ADMIN privilege (or the deprecated SUPER privilege).

If START REPLICA | SLAVE succeeds in starting the replication threads, it returns without any error. However, even in that case, it might be that the replication threads start and then later stop (for example, because they do not manage to connect to the source or read its binary log, or some other problem). START REPLICA | SLAVE does not warn you about this. You must check the replica’s error log for error messages generated by the replication threads, or check that they are running satisfactorily with SHOW REPLICA | SLAVE STATUS.

START REPLICA | SLAVE causes an implicit commit of an ongoing transaction. See Section 13.3.3, “Statements That Cause an Implicit Commit”.

gtid_next must be set to AUTOMATIC before issuing this statement.

The optional FOR CHANNEL channel clause enables you to name which replication channel the statement applies to. Providing a FOR CHANNEL channel clause applies the START REPLICA | SLAVE statement to a specific replication channel. If no clause is named and no extra channels exist, the statement applies to the default channel. If a START REPLICA | SLAVE statement does not have a channel defined when using multiple channels, this statement starts the specified threads for all channels. This statement is disallowed for the group_replication_recovery channel. See Section 17.2.2, “Replication Channels” for more information.

You can add IO_THREAD and SQL_THREAD options to the statement to name which of the threads to start. Note that the Group Replication applier channel (group_replication_applier) has no I/O thread, only an SQL thread. Specifying the IO_THREAD or SQL_THREAD options when you start this channel has no benefit.

START REPLICA | SLAVE supports pluggable user-password authentication with the USER, PASSWORD, DEFAULT_AUTH and PLUGIN_DIR options, as described in the following list:

- **USER**: User name. Cannot be set to an empty or null string, or left unset if PASSWORD is used.
- **PASSWORD**: Password.
- **DEFAULT_AUTH**: Name of plugin; default is MySQL native authentication.
- **PLUGIN_DIR**: Location of plugin.

You cannot use the SQL_THREAD option when specifying any of USER, PASSWORD, DEFAULT_AUTH, or PLUGIN_DIR, unless the IO_THREAD option is also provided.

For more information, see Section 6.2.17, “Pluggable Authentication”.

If an insecure connection is used with any these options, the server issues the warning Sending passwords in plain text without SSL/TLS is extremely insecure.

START REPLICA | SLAVE ... UNTIL supports two additional options for use with global transaction identifiers (GTIDs) (see Section 17.1.3, “Replication with Global Transaction Identifiers”). Each of these takes a set of one or more global transaction identifiers gtid_set as an argument (see GTID Sets, for more information).

When no thread_type is specified, START REPLICA | SLAVE UNTIL SQL_BEFORE_GTIDS causes the replication SQL thread to process transactions until it has reached the first transaction whose GTID is listed in the gtid_set. START REPLICA | SLAVE UNTIL SQL_AFTER_GTIDS causes the replication threads to process all transactions until the last transaction in the gtid_set
has been processed by both threads. In other words, **START REPLICA | SLAVE UNTIL SQL_BEFORE_GTIDS** causes the replication SQL thread to process all transactions occurring before the first GTID in the `gtid_set` is reached, and **START REPLICA | SLAVE UNTIL SQL_AFTER_GTIDS** causes the replication threads to handle all transactions, including those whose GTIDs are found in `gtid_set`, until each has encountered a transaction whose GTID is not part of the set. **SQL_BEFORE_GTIDS** and **SQL_AFTER_GTIDS** each support the **SQL_THREAD** and **IO_THREAD** options, although using **IO_THREAD** with them currently has no effect.

For example, **START REPLICA | SLAVE SQL_THREAD UNTIL SQL_BEFORE_GTIDS = 3E11FA47-71CA-11E1-9E33-C80AA9429562:11-56** causes the replication SQL thread to process all transactions originating from the source whose `server_uuid` is `3E11FA47-71CA-11E1-9E33-C80AA9429562` until it encounters the transaction having sequence number 11; it then stops without processing this transaction. In other words, all transactions up to and including the transaction with sequence number 10 are processed. Executing **START REPLICA | SLAVE SQL_THREAD UNTIL SQL_AFTER_GTIDS = 3E11FA47-71CA-11E1-9E33-C80AA9429562:11-56**, on the other hand, would cause the replication SQL thread to obtain all transactions just mentioned from the source, including all of the transactions having the sequence numbers 11 through 56, and then to stop without processing any additional transactions; that is, the transaction having sequence number 56 would be the last transaction fetched by the replication SQL thread.

When using a multithreaded replica with `slave_preserve_commit_order=0` set, there is a chance of gaps in the sequence of transactions that have been executed from the relay log in the following cases:

- killing the coordinator thread
- after an error occurs in the applier threads
- `mysqld` shuts down unexpectedly

Use the **START REPLICA | SLAVE UNTIL SQL_AFTER_MTS_GAPS** statement to cause a multithreaded replica’s worker threads to only run until no more gaps are found in the relay log, and then to stop. This statement can take an **SQL_THREAD** option, but the effects of the statement remain unchanged. It has no effect on the replication I/O thread (and cannot be used with the **IO_THREAD** option).

Issuing **START REPLICA | SLAVE** on a multithreaded replica with gaps in the sequence of transactions executed from the relay log generates a warning. In such a situation, the solution is to use **START REPLICA | SLAVE UNTIL SQL_AFTER_MTS_GAPS**, then issue **RESET REPLICA | SLAVE** to remove any remaining relay logs. See Section 17.5.1.34, “Replication and Transaction Inconsistencies” for more information.

To change a failed multithreaded replica to single-threaded mode, you can issue the following series of statements, in the order shown:

```
START {REPLICA | SLAVE} UNTIL SQL_AFTER_MTS_GAPS;
SET @@GLOBAL.slave_parallel_workers = 0;
START {REPLICA | SLAVE} SQL_THREAD;
```

**Note**

It is possible to view the entire text of a running **START REPLICA | SLAVE** statement, including any **USER** or **PASSWORD** values used, in the output of **SHOW PROCESSLIST**. This is also true for the text of a running **CHANGE REPLICATION SOURCE TO | CHANGE MASTER TO** statement, including any values it employs for **SOURCE_USER | MASTER_USER** or **SOURCE_PASSWORD | MASTER_PASSWORD**.

**START REPLICA | SLAVE** sends an acknowledgment to the user after both the replication I/O thread and the replication SQL thread have started. However, the replication I/O thread may
not yet have connected. For this reason, a successful `START REPLICA | SLAVE` causes `SHOW REPLICA | SLAVE STATUS` to show `Replica_SQL_Running=Yes`, but this does not guarantee that `Replica_IO_Running=Yes` (because `Replica_IO_Running=Yes` only if the I/O thread is running and connected). For more information, see Section 13.7.7.35, “SHOW REPLICA | SLAVE STATUS Statement”, and Section 17.1.7.1, “Checking Replication Status”.

An `UNTIL` clause (`until_option`, in the preceding grammar) may be added to specify that the replica should start and run until the replication SQL thread reaches a given point in the source's binary log or in the replica's relay log. Use one of the following pairs of options to specify the position:

- `MASTER_LOG_POS` and `MASTER_LOG_FILE` for the binary log (to MySQL 8.0.22).
- `SOURCE_LOG_POS` and `SOURCE_LOG_FILE` for the binary log (from MySQL 8.0.23).
- `RELAY_LOG_POS` and `RELAY_LOG_FILE` for the relay log.

For compressed transaction payloads, the position must be based on the compressed `Transaction_payload_event`. When the SQL thread reaches the point specified, it stops. If the `SQL_THREAD` option is specified in the statement, it starts only the SQL thread. Otherwise, it starts both replication threads. If the SQL thread is running, the `UNTIL` clause is ignored and a warning is issued. You cannot use an `UNTIL` clause with the `IO_THREAD` option.

It is also possible with `START REPLICA | SLAVE UNTIL` to specify a stop point relative to a given GTID or set of GTIDs using one of the options `SQL_BEFORE_GTIDS` or `SQL_AFTER_GTIDS`, as explained previously in this section. When using one of these options, you can specify `SQL_THREAD`, `IO_THREAD`, both of these, or neither of them. If you specify only `SQL_THREAD`, then only the replication SQL thread is affected by the statement; if only `IO_THREAD` is used, then only the replication I/O thread is affected. If both `SQL_THREAD` and `IO_THREAD` are used, or if neither of them is used, then both the SQL and I/O threads are affected by the statement.

For an `UNTIL` clause, you must specify any one of the following:

- `Both` a log file name and a position in that file
- `Either of` `SQL_BEFORE_GTIDS` or `SQL_AFTER_GTIDS`
- `SQL_AFTER_MTS_GAPS`

Do not mix source and relay log options. Do not mix log file options with GTID options.

The `UNTIL` clause is not supported for multithreaded replicas except when also using `SQL_AFTER_MTS_GAPS`. If `UNTIL` is used on a multithreaded replica without `SQL_AFTER_MTS_GAPS`, the replica operates in single-threaded (sequential) mode for replication until the point specified by the `UNTIL` clause is reached.

Any `UNTIL` condition is reset by a subsequent `STOP REPLICA | SLAVE` statement, a `START REPLICA | SLAVE` statement that includes no `UNTIL` clause, or a server restart.

When specifying a log file and position, you can use the `IO_THREAD` option with `START REPLICA | SLAVE ... UNTIL` even though only the SQL thread is affected by this statement. The `IO_THREAD` option is ignored in such cases. The preceding restriction does not apply when using one of the GTID options (`SQL_BEFORE_GTIDS` and `SQL_AFTER_GTIDS`); the GTID options support both `SQL_THREAD` and `IO_THREAD`, as explained previously in this section.

The `UNTIL` clause can be useful for debugging replication, or to cause replication to proceed until just before the point where you want to avoid having the replica replicate an event. For example, if an unwise `DROP TABLE` statement was executed on the source, you can use `UNTIL` to tell the replica to execute up to that point but no farther. To find what the event is, use `mysqlbinlog` with the source's binary log or the replica's relay log, or by using a `SHOW BINLOG EVENTS` statement.

If you are using `UNTIL` to have the replica process replicated queries in sections, it is recommended that you start the replica with the `--skip-slave-start` option, or from MySQL 8.0.24, the `skip_slave_start` system variable, to prevent the SQL thread from running when the replica server
starts. Remove the option or system variable setting after the procedure is complete, so that it is not forgotten in the event of an unexpected server restart.

The `SHOW REPLICA | SLAVE STATUS` statement includes output fields that display the current values of the `UNTIL` condition.

### 13.4.2.8 START SLAVE | REPLICA Statement

```
START {SLAVE | REPLICA} [thread_types] [until_option] [connection_options] [channel_option]
```

- **thread_types**: `[thread_type [, thread_type] ...]`
  - `thread_type`: `IO_THREAD` | `SQL_THREAD`
- **until_option**: `UNTIL { SQL_BEFORE_GTIDS | SQL_AFTER_GTIDS } = gtid_set`
  - `MASTER_LOG_FILE = 'log_name', MASTER_LOG_POS = log_pos`
  - `SOURCE_LOG_FILE = 'log_name', SOURCE_LOG_POS = log_pos`
  - `RELAY_LOG_FILE = 'log_name', RELAY_LOG_POS = log_pos`
  - `SQL_AFTER_MTS_GAPS`
- **connection_options**: `[USER='user_name'] [PASSWORD='user_pass'] [DEFAULT_AUTH='plugin_name'] [PLUGIN_DIR='plugin_dir']`
- **channel_option**: `FOR CHANNEL channel`

```
gtid_set:
  uuid_set [, uuid_set] ...
  | ''
uuid_set:
  uuid:interval[:interval]...
uuid:
  hhhhhhh-hhhh-hhhh-hhhhh-hhhhhhhhhhh
h:
  [0-9,A-F]
interval:
  n[-n]
(n >= 1)
```

Starts the replication threads. From MySQL 8.0.22, `START SLAVE` is deprecated and the alias `START REPLICA` should be used instead. The statement works in the same way as before, only the terminology used for the statement and its output has changed. Both versions of the statement update the same status variables when used. Please see the documentation for `START REPLICA` for a description of the statement.

### 13.4.2.9 STOP REPLICA | SLAVE Statement

```
STOP {REPLICA | SLAVE} [thread_types] [channel_option]
```

- **thread_types**: `[thread_type [, thread_type] ...]`
  - `thread_type`: `IO_THREAD` | `SQL_THREAD`
- **channel_option**: `FOR CHANNEL channel`

```
channel_option:
  FOR CHANNEL channel
```

```
```

 Stops the replication threads. From MySQL 8.0.22, use `STOP REPLICA` in place of `STOP SLAVE`, which is now deprecated. In releases before MySQL 8.0.22, use `STOP SLAVE`.  

STOP REPLICA | SLAVE requires the REPLICATION_SLAVE_ADMIN privilege (or the deprecated SUPER privilege). Recommended best practice is to execute STOP REPLICA | SLAVE on the replica before stopping the replica server (see Section 5.1.19, “The Server Shutdown Process”, for more information).

Like START REPLICA | SLAVE, this statement may be used with the IO_THREAD and SQL_THREAD options to name the replication thread or threads to be stopped. Note that the Group Replication applier channel (group_replication_applier) has no replication I/O thread, only a replication SQL thread. Using the SQL_THREAD option therefore stops this channel completely.

STOP REPLICA | SLAVE causes an implicit commit of an ongoing transaction. See Section 13.3.3, “Statements That Cause an Implicit Commit”.

gtid_next must be set to AUTOMATIC before issuing this statement.

You can control how long STOP REPLICA | SLAVE waits before timing out by setting the rpl_stop_slave_timeout system variable. This can be used to avoid deadlocks between STOP REPLICA | SLAVE and other SQL statements using different client connections to the replica. When the timeout value is reached, the issuing client returns an error message and stops waiting, but the STOP REPLICA | SLAVE instruction remains in effect. Once the replication threads are no longer busy, the STOP REPLICA | SLAVE statement is executed and the replica stops.

Some CHANGE REPLICATION SOURCE TO | CHANGE MASTER TO statements are allowed while the replica is running, depending on the states of the replication threads. However, using STOP REPLICA | SLAVE prior to executing a CHANGE REPLICATION SOURCE TO | CHANGE MASTER TO statement in such cases is still supported. See Section 13.4.2.3, “CHANGE REPLICATION SOURCE TO Statement”, Section 13.4.2.1, “CHANGE MASTER TO Statement”, and Section 17.4.8, “Switching Sources During Failover”, for more information.

The optional FOR CHANNEL channel clause enables you to name which replication channel the statement applies to. Providing a FOR CHANNEL channel clause applies the STOP REPLICA | SLAVE statement to a specific replication channel. If no channel is named and no extra channels exist, the statement applies to the default channel. If a STOP REPLICA | SLAVE statement does not name a channel when using multiple channels, this statement stops the specified threads for all channels. This statement cannot be used with the group_replication_recovery channel. See Section 17.2.2, “Replication Channels” for more information.

When the replica is multithreaded (slave_parallel_workers is a nonzero value), any gaps in the sequence of transactions executed from the relay log are closed as part of stopping the worker threads. If the replica is stopped unexpectedly (for example due to an error in a worker thread, or another thread issuing KILL while a STOP REPLICA | SLAVE statement is executing, the sequence of executed transactions from the relay log may become inconsistent. See Section 17.5.1.34, “Replication and Transaction Inconsistencies”, for more information.

When the source is using the row-based binary logging format, you should execute STOP REPLICA | SLAVE or STOP REPLICA | SLAVE SQL_THREAD on the replica prior to shutting down the replica server if you are replicating any tables that use a nontransactional storage engine. If the current replication event group has modified one or more nontransactional tables, STOP REPLICA | SLAVE waits for up to 60 seconds for the event group to complete, unless you issue a KILL QUERY or KILL CONNECTION statement for the replication SQL thread. If the event group remains incomplete after the timeout, an error message is logged.

When the source is using the statement-based binary logging format, changing the source while it has open temporary tables is potentially unsafe. This is one of the reasons why statement-based replication of temporary tables is not recommended. You can find out whether there are any temporary tables on the replica by checking the value of Slave_open_temp_tables; when using statement-based replication, this value should be 0 before executing CHANGE REPLICATION SOURCE TO | CHANGE MASTER TO. If there are any temporary tables open on the replica, issuing a CHANGE REPLICATION SOURCE TO | CHANGE MASTER TO statement after issuing a STOP REPLICA | SLAVE causes an ER_WARN_OPEN_TEMP_TABLES_MUST_BE_ZERO warning.
13.4.2.10 STOP SLAVE | REPLICA Statement

```sql
STOP {SLAVE | REPLICA} [thread_types] [channel_option]
```

**thread_types:**
- `[thread_type [, thread_type] ... ]`

**thread_type:** IO_THREAD | SQL_THREAD

**channel_option:**
- FOR CHANNEL channel

Stops the replication threads. From MySQL 8.0.22, `STOP SLAVE` is deprecated and the alias `STOP REPLICA` should be used instead. The statement works in the same way as before, only the terminology used for the statement and its output has changed. Both versions of the statement update the same status variables when used. Please see the documentation for `STOP REPLICA` for a description of the statement.

13.4.2.11 Functions which Configure the Source List

The following functions, which are available from MySQL 8.0.22 for standard source to replica replication and from MySQL 8.0.23 for Group Replication, enable you to add and remove replication source servers from the source list for a replication channel. The asynchronous connection failover mechanism automatically establishes an asynchronous (source to replica) replication connection to a new source from the appropriate list after the existing connection from the replica to its source fails. From MySQL 8.0.23, the connection is also changed if the currently connected source does not have the highest weighted priority in the group. For Group Replication source servers that are defined as part of a managed group, the connection is also failed over to another group member if the currently connected source leaves the group or is no longer in the majority. For more information on the mechanism, see Section 17.4.9, “Switching Sources with Asynchronous Connection Failover”.

The source lists are stored in the `mysql.replication_asynchronous_connection_failover` and `mysql.replication_asynchronous_connection_failoverManaged` tables, and can be viewed in the Performance Schema table `replication_asynchronous_connection_failover`.

- `asynchronous_connection_failover_add_source()`

  Add configuration information for a replication source server to the source list for a replication channel.

  **Syntax:**
  ```sql
  asynchronous_connection_failover_add_source(channel, host, port, network_namespace, weight)
  ```

  **Arguments:**
  - `channel`: The replication channel for which this replication source server is part of the source list.
  - `host`: The host name for this replication source server.
  - `port`: The port number for this replication source server.
  - `network_namespace`: The network namespace for this replication source server. Specify an empty string, as this parameter is reserved for future use.
  - `weight`: The priority of this replication source server in the replication channel's source list. The priority is from 1 to 100, with 100 being the highest, and 50 being the default. When the asynchronous connection failover mechanism activates, the source with the highest priority setting among the alternative sources listed in the source list for the channel is chosen for the first connection attempt. If this attempt does not work, the replica tries with all the listed sources in descending order of priority, then starts again from the highest priority source. If multiple sources have the same priority, the replica orders them randomly. From MySQL 8.0.23, the asynchronous
connection failover mechanism activates if the currently connected source is not the highest weighted in the group.

Return value:

A string containing the result of the operation, for example whether it was successful or not.

Example:

```sql
SELECT asynchronous_connection_failover_add_source('channel2', '127.0.0.1', 3310, '', 80);
| asynchronous_connection_failover_add_source('channel2', '127.0.0.1', 3310, '', 80) |
| Source configuration details successfully inserted. |
```

For more information, see Section 17.4.9, “Switching Sources with Asynchronous Connection Failover”.

- `asynchronous_connection_failover_delete_source()`

Remove configuration information for a replication source server from the source list for a replication channel.

Syntax:

```sql
asynchronous_connection_failover_delete_source(channel, host, port, network_namespace)
```

Arguments:

- `channel`: The replication channel for which this replication source server was part of the source list.
- `host`: The host name for this replication source server.
- `port`: The port number for this replication source server.
- `network_namespace`: The network namespace for this replication source server. Specify an empty string, as this parameter is reserved for future use.

Return value:

A string containing the result of the operation, for example whether it was successful or not.

Example:

```sql
SELECT asynchronous_connection_failover_delete_source('channel2', '127.0.0.1', 3310, '');
| asynchronous_connection_failover_delete_source('channel2', '127.0.0.1', 3310, '') |
| Source configuration details successfully deleted. |
```

For more information, see Section 17.4.9, “Switching Sources with Asynchronous Connection Failover”.

- `asynchronous_connection_failover_add_managed()`

Add configuration information for a replication source server that is part of a managed group (a Group Replication group member) to the source list for a replication channel. You only need to add
one group member. The replica automatically adds the rest from the current group membership, then keeps the source list updated in line with membership change.

Syntax:

```sql
asynchronous_connection_failover_add_managed(channel, managed_type, managed_name, host, port, network_namespace, primary_weight, secondary_weight)
```

Arguments:

- **channel**: The replication channel for which this replication source server is part of the source list.
- **managed_type**: The type of managed service that the asynchronous connection failover mechanism must provide for this server. The only value currently accepted is `GroupReplication`.
- **managed_name**: The identifier for the managed group that the server is a part of. For the `GroupReplication` managed service, the identifier is the value of the `group_replication_group_name` system variable.
- **host**: The host name for this replication source server.
- **port**: The port number for this replication source server.
- **network_namespace**: The network namespace for this replication source server. Specify an empty string, as this parameter is reserved for future use.
- **primary_weight**: The priority of this replication source server in the replication channel's source list when it is acting as the primary for the managed group. The weight is from 1 to 100, with 100 being the highest. For the primary, 80 is a suitable weight. The asynchronous connection failover mechanism activates if the currently connected source is not the highest weighted in the group. Assuming that you set up the managed group to give a higher weight to a primary and a lower weight to a secondary, when the primary changes, its weight increases, and the replica changes over the connection to it.
- **secondary_weight**: The priority of this replication source server in the replication channel's source list when it is acting as a secondary in the managed group. The weight is from 1 to 100, with 100 being the highest. For a secondary, 60 is a suitable weight.

Return value:

A string containing the result of the operation, for example whether it was successful or not.

Example:

```sql
SELECT asynchronous_connection_failover_add_managed('channel2', 'GroupReplication', 'aaaaaaaa-aaaa-aaaa-aaaa-aaaaaaaaaaaa', '127.0.0.1', 3310, '', 80, 60);
```

```
+----------------------------------------------------------------------------------------------------------------------------------------------------+
| asynchronous_connection_failover_add_source('channel2', 'GroupReplication', 'aaaaaaaa-aaaa-aaaa-aaaa-aaaaaaaaaaaa', '127.0.0.1', 3310, '', 80, 60) |
+----------------------------------------------------------------------------------------------------------------------------------------------------+
| Source managed configuration details successfully inserted.                                                                                  |
+----------------------------------------------------------------------------------------------------------------------------------------------------+
```

For more information, see Section 17.4.9, “Switching Sources with Asynchronous Connection Failover”. 

2573
• synchronous_connection_failover_delete_managed()

Remove an entire managed group from the source list for a replication channel. When you use this UDF, all the replication source servers defined in the managed group are removed from the channel's source list.

Syntax:

```
asynchronous_connection_failover_delete_managed(channel, managed_name)```

Arguments:

• **channel**: The replication channel for which this replication source server was part of the source list.

• **managed_name**: The identifier for the managed group that the server is a part of.

For the GroupReplication managed service, the identifier is the value of the `group_replication_group_name` system variable.

Return value:

A string containing the result of the operation, for example whether it was successful or not.

Example:

```
SELECT asynchronous_connection_failover_delete_managed('channel2', 'aaaaaaaa-aaaa-aaaa-aaaa-aaaaaaaaaaaa')
```

A string containing the result of the operation, for example whether it was successful or not.

```
+-----------------------------------------------------------------------------------------------------+
| asynchronous_connection_failover_delete_managed('channel2', 'aaaaaaaa-aaaa-aaaa-aaaa-aaaaaaaaaaaa') |
+-----------------------------------------------------------------------------------------------------+
| Source managed configuration details successfully deleted.                                          |
+-----------------------------------------------------------------------------------------------------+
```

For more information, see Section 17.4.9, “Switching Sources with Asynchronous Connection Failover”.

### 13.4.3 SQL Statements for Controlling Group Replication

This section provides information about the statements used for controlling group replication.

#### 13.4.3.1 START GROUP_REPLICATION Statement

```
START GROUP_REPLICATION
[USER='user_name']
[, PASSWORD='user_pass']
[, DEFAULT_AUTH='plugin_name']
```

Starts group replication. This statement requires the GROUP_REPLICATION_ADMIN privilege (or the deprecated SUPER privilege). If `super_read_only=ON` is set and the member should join as a primary, `super_read_only` is set to OFF once Group Replication successfully starts.

From MySQL 8.0.21, you can specify user credentials for distributed recovery on the START GROUP_REPLICATION statement using the USER, PASSWORD, and DEFAULT_AUTH options, as follows:

• **USER**: The replication user for distributed recovery. For instructions to set up this account, see Section 18.2.1.3, “User Credentials For Distributed Recovery”. You cannot specify an empty or null string, or omit the USER option if PASSWORD is specified.

• **PASSWORD**: The password for the replication user account. The password cannot be encrypted, but it is masked in the query log.

• **DEFAULT_AUTH**: The name of the authentication plugin used for the replication user account. If you do not specify this option, MySQL native authentication (the mysql_native_password plugin) is assumed. This option acts as a hint to the server, and the donor for distributed recovery overrides it
if a different plugin is associated with the user account on that server. The authentication plugin used by default when you create user accounts in MySQL 8 is the caching SHA-2 authentication plugin (caching_sha2_password). See Section 6.2.17, "Pluggable Authentication" for more information on authentication plugins.

These credentials are used for distributed recovery on the group_replication_recovery channel. When you specify user credentials on START GROUP_REPLICATION, the credentials are saved in memory only, and are removed by a STOP_GROUP_REPLICATION statement or server shutdown. You must issue a START_GROUP_REPLICATION statement to provide the credentials again. This method is therefore not compatible with starting Group Replication automatically on server start, as specified by the group_replication_start_on_boot system variable.

User credentials specified on START_GROUP_REPLICATION take precedence over any user credentials set for the group_replication_recovery channel using a CHANGE_REPLICATION_SOURCE_TO statement (from MySQL 8.0.23) or CHANGE_MASTER_TO statement (before MySQL 8.0.23). Note that user credentials set using these statements are stored in the replication metadata repositories, and are used when START_GROUP_REPLICATION is specified without user credentials, including automatic starts if the group_replication_start_on_boot system variable is set to ON. To gain the security benefits of specifying user credentials on START_GROUP_REPLICATION, ensure that group_replication_start_on_boot is set to OFF (the default is ON), and clear any user credentials previously set for the group_replication_recovery channel, following the instructions in Section 18.6.3, "Securing Distributed Recovery Connections".

13.4.3.2 STOP_GROUP_REPLICATION Statement

STOP_GROUP_REPLICATION

Stops Group Replication. This statement requires the GROUP_REPLICATION_ADMIN privilege (or the deprecated SUPER privilege). As soon as you issue STOP_GROUP_REPLICATION the member is set to super_read_only=ON, which ensures that no writes can be made to the member while Group Replication stops. Any other replication channels running on the member are also stopped. Any user credentials that you specified on the START_GROUP_REPLICATION statement when starting Group Replication on this member are removed from memory, and must be supplied when you start Group Replication again.

Warning

Use this statement with extreme caution because it removes the server instance from the group, meaning it is no longer protected by Group Replication's consistency guarantee mechanisms. To be completely safe, ensure that your applications can no longer connect to the instance before issuing this statement to avoid any chance of stale reads.

13.4.3.3 Function which Configures Group Replication Primary

The following function enables you to configure which member of a single-primary replication group is the primary.

• group_replication_set_as_primary()

Appoints a specific member of the group as the new primary, overriding any election process. Pass in member_uuid which is the server_uuid of the member that you want to become the new primary. Must be issued on a member of a replication group running in single-primary mode.

Syntax:

STRING group_replication_set_as_primary(member_uuid)

Return value:

A string containing the result of the operation, for example whether it was successful or not.
Example:

```
SELECT group_replication_set_as_primary(member_uuid)
```

For more information, see Section 18.5.1.1, “Changing a Group’s Primary Member”

### 13.4.3.4 Functions which Configure the Group Replication Mode

The following functions enable you to control the mode which a replication group is running in, either single-primary or multi-primary mode.

- **`group_replication_switch_to_single_primary_mode()`**

  Changes a group running in multi-primary mode to single-primary mode, without the need to stop Group Replication. Must be issued on a member of a replication group running in multi-primary mode. When you change to single-primary mode, strict consistency checks are also disabled on all group members, as required in single-primary mode (`group_replication_enforce_update_everywhere_checks=OFF`).

  Syntax:

  ```
  STRING group_replication_switch_to_single_primary_mode([str])
  ```

  Arguments:

  - **str**: A string containing the UUID of a member of the group which should become the new single primary. Other members of the group become secondaries.

  Return value:

  A string containing the result of the operation, for example whether it was successful or not.

  Example:

  ```
  SELECT group_replication_switch_to_single_primary_mode(member_uuid);
  ```

  For more information, see Section 18.5.1.2, “Changing a Group’s Mode”

- **`group_replication_switch_to_multi_primary_mode()`**

  Changes a group running in single-primary mode to multi-primary mode. Must be issued on a member of a replication group running in single-primary mode.

  Syntax:

  ```
  STRING group_replication_switch_to_multi_primary_mode()
  ```

  This function has no parameters.

  Return value:

  A string containing the result of the operation, for example whether it was successful or not.

  Example:

  ```
  SELECT group_replication_switch_to_multi_primary_mode();
  ```

  For more information, see Section 18.5.1.2, “Changing a Group’s Mode”
13.4.3.5 Functions to Inspect and Configure the Maximum Consensus Instances of a Group

The following functions enable you to inspect and configure the maximum number of consensus instances that a group can execute in parallel.

- **group_replication_get_write_concurrency()**
  
  Check the maximum number of consensus instances that a group can execute in parallel.
  
  **Syntax:**
  
  ```
  INT group_replication_get_write_concurrency()
  ```
  
  This function has no parameters.
  
  **Return value:**
  
  The maximum number of consensus instances currently set for the group.
  
  **Example:**
  
  ```
  SELECT group_replication_get_write_concurrency()
  ```
  
  For more information, see Section 18.5.1.3, “Using Group Replication Group Write Consensus”.

- **group_replication_set_write_concurrency()**
  
  Configures the maximum number of consensus instances that a group can execute in parallel. The GROUP_REPLICATION_ADMIN privilege is required to use this UDF.
  
  **Syntax:**
  
  ```
  STRING group_replication_set_write_concurrency(instances)
  ```
  
  **Arguments:**
  
  - `members`: Sets the maximum number of consensus instances that a group can execute in parallel. Default value is 10, valid values are integers in the range of 10 to 200.
  
  **Return value:**
  
  Any resulting error as a string.
  
  **Example:**
  
  ```
  SELECT group_replication_set_write_concurrency(instances);
  ```
  
  For more information, see Section 18.5.1.3, “Using Group Replication Group Write Consensus”.

13.4.3.6 Functions to Inspect and Set the Group Replication Communication Protocol Version

The following functions enable you to inspect and configure the Group Replication communication protocol version that is used by a replication group.

- **group_replication_get_communication_protocol()**
  
  Inspect the Group Replication communication protocol version that is currently in use for a group.
  
  **Syntax:**
  
  ```
  STRING group_replication_get_communication_protocol()
  ```
This function has no parameters.

Return value:

The oldest MySQL Server version that can join this group and use the group's communication protocol. Versions from MySQL 5.7.14 allow compression of messages, and versions from MySQL 8.0.16 also allow fragmentation of messages. Note that the `group_replication_get_communication_protocol()` UDF returns the minimum MySQL version that the group supports, which might differ from the version number that was passed to the `group_replication_set_communication_protocol()` UDF, and from the MySQL Server version that is installed on the member where you use the UDF.

If the protocol cannot be inspected because this server instance does not belong to a replication group, an error is returned as a string.

Example:

```
SELECT group_replication_get_communication_protocol();
+------------------------------------------------+
| group_replication_get_communication_protocol() |
+------------------------------------------------+
| 8.0.16                                         |
+------------------------------------------------+
```

For more information, see Section 18.5.1.4, “Setting a Group's Communication Protocol Version”.

• `group_replication_set_communication_protocol()`

Downgrade the Group Replication communication protocol version of a group so that members at earlier releases can join, or upgrade the Group Replication communication protocol version of a group after upgrading MySQL Server on all members. The `GROUP_REPLICATION_ADMIN` privilege is required to use this UDF, and all existing group members must be online when you issue the statement, with no loss of majority.

Note

For MySQL InnoDB cluster, the communication protocol version is managed automatically whenever the cluster topology is changed using AdminAPI operations. You do not have to use these UDFs yourself for an InnoDB cluster.

Syntax:

```
STRING group_replication_set_communication_protocol(version)
```

Arguments:

• `version`: For a downgrade, specify the MySQL Server version of the prospective group member that has the oldest installed server version. In this case, the command makes the group fall back to a communication protocol compatible with that server version if possible. The minimum server version that you can specify is MySQL 5.7.14. For an upgrade, specify the new MySQL Server version to which the existing group members have been upgraded.

Return value:

A string containing the result of the operation, for example whether it was successful or not.

Example:

```
SELECT group_replication_set_communication_protocol("5.7.25");
```

For more information, see Section 18.5.1.4, “Setting a Group's Communication Protocol Version”.

2578
13.5 Prepared Statements

MySQL 8.0 provides support for server-side prepared statements. This support takes advantage of the efficient client/server binary protocol. Using prepared statements with placeholders for parameter values has the following benefits:

- Less overhead for parsing the statement each time it is executed. Typically, database applications process large volumes of almost-identical statements, with only changes to literal or variable values in clauses such as `WHERE` for queries and deletes, `SET` for updates, and `VALUES` for inserts.

- Protection against SQL injection attacks. The parameter values can contain unescaped SQL quote and delimiter characters.

The following sections provide an overview of the characteristics of prepared statements:

- Prepared Statements in Application Programs
- Prepared Statements in SQL Scripts
- PREPARE, EXECUTE, and DEALLOCATE PREPARE Statements
- SQL Syntax Permitted in Prepared Statements

Prepared Statements in Application Programs

You can use server-side prepared statements through client programming interfaces, including the MySQL C API client library for C programs, MySQL Connector/J for Java programs, and MySQL Connector/.NET for programs using .NET technologies. For example, the C API provides a set of function calls that make up its prepared statement API. See C API Prepared Statement Interface. Other language interfaces can provide support for prepared statements that use the binary protocol by linking in the C client library, one example being the `mysqli` extension, available in PHP 5.0 and higher.

Prepared Statements in SQL Scripts

An alternative SQL interface to prepared statements is available. This interface is not as efficient as using the binary protocol through a prepared statement API, but requires no programming because it is available directly at the SQL level:

- You can use it when no programming interface is available to you.
- You can use it from any program that can send SQL statements to the server to be executed, such as the `mysql` client program.
- You can use it even if the client is using an old version of the client library.

SQL syntax for prepared statements is intended to be used for situations such as these:

- To test how prepared statements work in your application before coding it.
- To use prepared statements when you do not have access to a programming API that supports them.
- To interactively troubleshoot application issues with prepared statements.
- To create a test case that reproduces a problem with prepared statements, so that you can file a bug report.

PREPARE, EXECUTE, and DEALLOCATE PREPARE Statements

SQL syntax for prepared statements is based on three SQL statements:
PREPARE, EXECUTE, and DEALLOCATE PREPARE Statements

- **PREPARE** prepares a statement for execution (see Section 13.5.1, “PREPARE Statement”).
- **EXECUTE** executes a prepared statement (see Section 13.5.2, “EXECUTE Statement”).
- **DEALLOCATE PREPARE** releases a prepared statement (see Section 13.5.3, “DEALLOCATE PREPARE Statement”).

The following examples show two equivalent ways of preparing a statement that computes the hypotenuse of a triangle given the lengths of the two sides.

The first example shows how to create a prepared statement by using a string literal to supply the text of the statement:

```sql
mysql> PREPARE stmt1 FROM 'SELECT SQRT(POW(?,2) + POW(?,2)) AS hypotenuse';
```

```sql
mysql> SET @a = 3;
```

```sql
mysql> SET @b = 4;
```

```sql
mysql> EXECUTE stmt1 USING @a, @b;
```

```sql
+------------+
| hypotenuse |
| 5          |
+------------+
```

```sql
mysql> DEALLOCATE PREPARE stmt1;
```

The second example is similar, but supplies the text of the statement as a user variable:

```sql
mysql> SET @s = 'SELECT SQRT(POW(?,2) + POW(?,2)) AS hypotenuse';
```

```sql
mysql> PREPARE stmt2 FROM @s;
```

```sql
mysql> SET @a = 6;
```

```sql
mysql> SET @b = 8;
```

```sql
mysql> EXECUTE stmt2 USING @a, @b;
```

```sql
+------------+
| hypotenuse |
| 10         |
+------------+
```

```sql
mysql> DEALLOCATE PREPARE stmt2;
```

Here is an additional example that demonstrates how to choose the table on which to perform a query at runtime, by storing the name of the table as a user variable:

```sql
mysql> USE test;
```

```sql
mysql> CREATE TABLE t1 (a INT NOT NULL);
```

```sql
mysql> INSERT INTO t1 VALUES (4), (8), (11), (32), (80);
```

```sql
mysql> SET @table = 't1';
```

```sql
mysql> SET @s = CONCAT('SELECT * FROM ', @table);
```

```sql
mysql> PREPARE stmt3 FROM @s;
```

```sql
mysql> EXECUTE stmt3;
```

```sql
+----+
| a  |
+----+
|  4 |
|  8 |
| 11 |
| 32 |
| 80 |
+----+
```

```sql
mysql> DEALLOCATE PREPARE stmt3;
```

A prepared statement is specific to the session in which it was created. If you terminate a session without deallocating a previously prepared statement, the server deallocates it automatically.

A prepared statement is also global to the session. If you create a prepared statement within a stored routine, it is not deallocated when the stored routine ends.
To guard against too many prepared statements being created simultaneously, set the `max_prepared_stmt_count` system variable. To prevent the use of prepared statements, set the value to 0.

**SQL Syntax Permitted in Prepared Statements**

The following SQL statements can be used as prepared statements:

```
ALTER TABLE
ALTER USER
ANALYZE TABLE
CACHE INDEX
CALL
CHANGE MASTER
CHECKSUM {TABLE | TABLES}
COMMIT
{CREATE | DROP} INDEX
{CREATE | RENAME | DROP} DATABASE
{CREATE | DROP} TABLE
{CREATE | RENAME | DROP} USER
{CREATE | DROP} VIEW
DELETE
DO
FLUSH {TABLE | TABLES | TABLES WITH READ LOCK | HOSTS | PRIVILEGES
    | LOGS | STATUS | MASTER | SLAVE | USER_RESOURCES}
GRANT
INSERT
INSTALL PLUGIN
KILL
LOAD INDEX INTO CACHE
OPTIMIZE TABLE
RENAME TABLE
REPAIR TABLE
REPLACE
RESET {MASTER | SLAVE}
REVOKE
SELECT
SET
SHOW BINLOG EVENTS
SHOW CREATE {PROCEDURE | FUNCTION | EVENT | TABLE | VIEW}
SHOW {MASTER | BINARY} LOGS
SHOW {MASTER | SLAVE} STATUS
SLAVE {START | STOP}
TRUNCATE TABLE
UNINSTALL PLUGIN
UPDATE
```

Other statements are not supported.

For compliance with the SQL standard, which states that diagnostics statements are not preparable, MySQL does not support the following as prepared statements:

- `SHOW WARNINGS, SHOW COUNT(*) WARNINGS`
- `SHOW ERRORS, SHOW COUNT(*) ERRORS`
- Statements containing any reference to the `warning_count` or `error_count` system variable.

Generally, statements not permitted in SQL prepared statements are also not permitted in stored programs. Exceptions are noted in Section 25.8, “Restrictions on Stored Programs”.

Metadata changes to tables or views referred to by prepared statements are detected and cause automatic repreparation of the statement when it is next executed. For more information, see Section 8.10.3, “Caching of Prepared Statements and Stored Programs”.

Placeholders can be used for the arguments of the `LIMIT` clause when using prepared statements. See Section 13.2.10, “SELECT Statement”.

---

*2581*
In prepared `CALL` statements used with `PREPARE` and `EXECUTE`, placeholder support for `OUT` and `INOUT` parameters is available beginning with MySQL 8.0. See Section 13.2.1, “CALL Statement”, for an example and a workaround for earlier versions. Placeholders can be used for `IN` parameters regardless of version.

SQL syntax for prepared statements cannot be used in nested fashion. That is, a statement passed to `PREPARE` cannot itself be a `PREPARE`, `EXECUTE`, or `DEALLOCATE PREPARE` statement.

SQL syntax for prepared statements is distinct from using prepared statement API calls. For example, you cannot use the `mysql_stmt_prepare()` C API function to prepare a `PREPARE`, `EXECUTE`, or `DEALLOCATE PREPARE` statement.

SQL syntax for prepared statements can be used within stored procedures, but not in stored functions or triggers. However, a cursor cannot be used for a dynamic statement that is prepared and executed with `PREPARE` and `EXECUTE`. The statement for a cursor is checked at cursor creation time, so the statement cannot be dynamic.

SQL syntax for prepared statements does not support multi-statements (that is, multiple statements within a single string separated by `;` characters).

To write C programs that use the `CALL` SQL statement to execute stored procedures that contain prepared statements, the `CLIENT_MULTI_RESULTS` flag must be enabled. This is because each `CALL` returns a result to indicate the call status, in addition to any result sets that might be returned by statements executed within the procedure.

`CLIENT_MULTI_RESULTS` can be enabled when you call `mysql_real_connect()`, either explicitly by passing the `CLIENT_MULTI_RESULTS` flag itself, or implicitly by passing `CLIENT_MULTI_STATEMENTS` (which also enables `CLIENT_MULTI_RESULTS`). For additional information, see Section 13.2.1, “CALL Statement”.

### 13.5.1 PREPARE Statement

```
PREPARE stmt_name FROM preparable_stmt
```

The `PREPARE` statement prepares a SQL statement and assigns it a name, `stmt_name`, by which to refer to the statement later. The prepared statement is executed with `EXECUTE` and released with `DEALLOCATE PREPARE`. For examples, see Section 13.5, “Prepared Statements”.

Statement names are not case-sensitive. `preparable_stmt` is either a string literal or a user variable that contains the text of the SQL statement. The text must represent a single statement, not multiple statements. Within the statement, `?` characters can be used as parameter markers to indicate where data values are to be bound to the query later when you execute it. The `?` characters should not be enclosed within quotation marks, even if you intend to bind them to string values. Parameter markers can be used only where data values should appear, not for SQL keywords, identifiers, and so forth.

If a prepared statement with the given name already exists, it is deallocated implicitly before the new statement is prepared. This means that if the new statement contains an error and cannot be prepared, an error is returned and no statement with the given name exists.

The scope of a prepared statement is the session within which it is created, which as several implications:

- A prepared statement created in one session is not available to other sessions.
- When a session ends, whether normally or abnormally, its prepared statements no longer exist. If auto-reconnect is enabled, the client is not notified that the connection was lost. For this reason, clients may wish to disable auto-reconnect. See Automatic Reconnection Control.
- A prepared statement created within a stored program continues to exist after the program finishes executing and can be executed outside the program later.
PREPARE Statement

- A statement prepared in stored program context cannot refer to stored procedure or function parameters or local variables because they go out of scope when the program ends and would be unavailable were the statement to be executed later outside the program. As a workaround, refer instead to user-defined variables, which also have session scope; see Section 9.4, “User-Defined Variables”.

Beginning with MySQL 8.0.22, a parameter used in a prepared statement has its type determined when the statement is first prepared, and retains this type whenever EXECUTE is invoked for this prepared statement (unless the statement is reprepared, as explained later in this section). Rules for determining a parameter's type are listed here:

- A parameter which is an operand of a binary arithmetic operator has the same data type as the other operand.

- If both operands of a binary arithmetic operator are parameters, the type of the parameters is decided by the context of the operator.

- If a parameter is the operand of a unary arithmetic operator, the parameter's type is decided by the context of the operator.

- If an arithmetic operator has no type-determining context, the derived type for any parameters involved is DOUBLE PRECISION. This can happen, for example, when the parameter is a top-level node in a SELECT list, or when it is part of a comparison operator.

- A parameter which is an operand of a character string operator has the same derived type as the aggregated type of the other operands. If all operands of the operator are parameters, the derived type is VARCHAR; its collation is determined by the value of collation_connection.

- A parameter which is an operand of a temporal operator has type DATETIME if the operator returns a DATETIME, TIME if the operator returns a TIME, and DATE if the operator returns a DATE.

- A parameter which is an operand of a binary comparison operator has the same derived type as the other operand of the comparison.

- A parameter that is an operand of a ternary comparison operator such as BETWEEN has the same derived type as the aggregated type of the other operands.

- If all operands of a comparison operator are parameters, the derived type for each of them is VARCHAR, with collation determined by the value of collation_connection.

- A parameter that is an output operand of any of CASE, COALESCE, IF, IFNULL, or NULLIF has the same derived type as the aggregated type of the operator's other output operands.

- If all output operands of any of CASE, COALESCE, IF, IFNULL, or NULLIF are parameters, or they are all NULL, the type of the parameter is decided by the context of the operator.

- If the parameter is an operand of any of of CASE, COALESCE(), IF, or IFNULL, and has no type-determining context, the derived type for each of the parameters involved is VARCHAR, and its collation is determined by the value of collation_connection.

- A parameter which is the operand of a CAST() has the same type as specified by the CAST().

- If a parameter is an immediate member of a SELECT list that is not part of an INSERT statement, the derived type of the parameter is VARCHAR, and its collation is determined by the value of collation_connection.

- If a parameter is an immediate member of a SELECT list that is part of an INSERT statement, the derived type of the parameter is the type of the corresponding column into which the parameter is inserted.

- If a parameter is used as source for an assignment in a SET clause of an UPDATE statement or in the ON DUPLICATE KEY UPDATE clause of an INSERT statement, the derived type of the parameter is
the type of the corresponding column which is updated by the \texttt{SET} or \texttt{ON DUPLICATE KEY UPDATE} clause.

- If a parameter is an argument of a function, the derived type depends on the function's return type.

For some combinations of actual type and derived type, an automatic repreparation of the statement is triggered, to ensure closer compatibility with previous versions of MySQL. Repreparation does not occur if any of the following conditions are true:

- \texttt{NULL} is used as the actual parameter value.
- A parameter is an operand of a \texttt{CAST}(). (Instead, a cast to the derived type is attempted, and an exception raised if the cast fails.)
- A parameter is a string. (In this case, an implicit \texttt{CAST(? AS derived_type)} is performed.)
- The derived type and actual type of the parameter are both \texttt{INTEGER} and have the same sign.
- The parameter's derived type is \texttt{DECIMAL} and its actual type is either \texttt{DECIMAL} or \texttt{INTEGER}.
- The derived type is \texttt{DOUBLE} and the actual type is any numeric type.
- Both the derived type and the actual type are string types.
- If the derived type is temporal and the actual type is temporal. \textit{Exceptions:} The derived type is \texttt{TIME} and the actual type is not \texttt{TIME}; the derived type is \texttt{DATE} and the actual type is not \texttt{DATE}.
- The derived type is temporal and the actual type is numeric.

For cases other than those just listed, the statement is reprepared and the actual parameter types are used instead of the derived parameter types.

These rules also apply to a user variable referenced in a prepared statement.

Using a different data type for a given parameter or user variable within a prepared statement for executions of the statement subsequent to the first execution causes the statement to be reprepared. This is less efficient; it may also lead to the parameter's (or variable's) actual type to vary, and thus for results to be inconsistent, with subsequent executions of the prepared statement. For these reasons, it is advisable to use the same data type for a given parameter when re-executing a prepared statement.

### 13.5.2 EXECUTE Statement

**EXECUTE** \texttt{stmt\_name}

[\texttt{USING @var\_name [, @var\_name] ...}]

After preparing a statement with \texttt{PREPARE}, you execute it with an \texttt{EXECUTE} statement that refers to the prepared statement name. If the prepared statement contains any parameter markers, you must supply a \texttt{USING} clause that lists user variables containing the values to be bound to the parameters. Parameter values can be supplied only by user variables, and the \texttt{USING} clause must name exactly as many variables as the number of parameter markers in the statement.

You can execute a given prepared statement multiple times, passing different variables to it or setting the variables to different values before each execution.

For examples, see Section 13.5, “Prepared Statements”.

### 13.5.3 DEALLOCATE PREPARE Statement

**(DEALLOCATE | DROP) PREPARE** \texttt{stmt\_name}

To deallocate a prepared statement produced with \texttt{PREPARE}, use a \texttt{DEALLOCATE PREPARE} statement that refers to the prepared statement name. Attempting to execute a prepared statement after
deallocating it results in an error. If too many prepared statements are created and not deallocated by either the DEALLOCATE PREPARE statement or the end of the session, you might encounter the upper limit enforced by the max_prepared_stmt_count system variable.

For examples, see Section 13.5, “Prepared Statements”.

13.6 Compound Statement Syntax

This section describes the syntax for the BEGIN ... END compound statement and other statements that can be used in the body of stored programs: Stored procedures and functions, triggers, and events. These objects are defined in terms of SQL code that is stored on the server for later invocation (see Chapter 25, Stored Objects).

A compound statement is a block that can contain other blocks; declarations for variables, condition handlers, and cursors; and flow control constructs such as loops and conditional tests.

13.6.1 BEGIN ... END Compound Statement

BEGIN ... END syntax is used for writing compound statements, which can appear within stored programs (stored procedures and functions, triggers, and events). A compound statement can contain multiple statements, enclosed by the BEGIN and END keywords. statement_list represents a list of one or more statements, each terminated by a semicolon (;) statement delimiter. The statement_list itself is optional, so the empty compound statement (BEGIN END) is legal.

BEGIN ... END blocks can be nested.

Use of multiple statements requires that a client is able to send statement strings containing the ; statement delimiter. In the mysql command-line client, this is handled with the delimiter command. Changing the ; end-of-statement delimiter (for example, to //) permit ; to be used in a program body. For an example, see Section 25.1, “Defining Stored Programs”.

A BEGIN ... END block can be labeled. See Section 13.6.2, “Statement Labels”.

The optional [NOT] ATOMIC clause is not supported. This means that no transactional savepoint is set at the start of the instruction block and the BEGIN clause used in this context has no effect on the current transaction.

Note

Within all stored programs, the parser treats BEGIN [WORK] as the beginning of a BEGIN ... END block. To begin a transaction in this context, use START TRANSACTION instead.

13.6.2 Statement Labels
Labels are permitted for BEGIN ... END blocks and for the LOOP, REPEAT, and WHILE statements. Label use for those statements follows these rules:

- `begin_label` must be followed by a colon.
- `begin_label` can be given without `end_label`. If `end_label` is present, it must be the same as `begin_label`.
- `end_label` cannot be given without `begin_label`.
- Labels at the same nesting level must be distinct.
- Labels can be up to 16 characters long.

To refer to a label within the labeled construct, use an ITERATE or LEAVE statement. The following example uses those statements to continue iterating or terminate the loop:

```sql
CREATE PROCEDURE doiterate(p1 INT)
BEGIN
    label1: LOOP
        SET p1 = p1 + 1;
        IF p1 < 10 THEN ITERATE label1; END IF;
        LEAVE label1;
    END LOOP label1;
END;
```

The scope of a block label does not include the code for handlers declared within the block. For details, see Section 13.6.7.2, "DECLARE ... HANDLER Statement".

### 13.6.3 DECLARE Statement

The DECLARE statement is used to define various items local to a program:

- Local variables. See Section 13.6.4, "Variables in Stored Programs".
- Conditions and handlers. See Section 13.6.7, "Condition Handling".
- Cursors. See Section 13.6.6, "Cursors".

DECLARE is permitted only inside a BEGIN ... END compound statement and must be at its start, before any other statements.

Declarations must follow a certain order. Cursor declarations must appear before handler declarations. Variable and condition declarations must appear before cursor or handler declarations.

### 13.6.4 Variables in Stored Programs

System variables and user-defined variables can be used in stored programs, just as they can be used outside stored-program context. In addition, stored programs can use DECLARE to define local variables, and stored routines (procedures and functions) can be declared to take parameters that communicate values between the routine and its caller.

- To declare local variables, use the DECLARE statement, as described in Section 13.6.4.1, "Local Variable DECLARE Statement”.
- Variables can be set directly with the SET statement. See Section 13.7.6.1, “SET Syntax for Variable Assignment”.

```sql
DECLARE [begin_label:] WHILE search_condition DO
    statement_list
END WHILE [end_label]
```
• Results from queries can be retrieved into local variables using `SELECT ... INTO var_list` or by opening a cursor and using `FETCH ... INTO var_list`. See Section 13.2.10.1, “SELECT ... INTO Statement”, and Section 13.6.6, “Cursors”.

For information about the scope of local variables and how MySQL resolves ambiguous names, see Section 13.6.4.2, “Local Variable Scope and Resolution”.

It is not permitted to assign the value `DEFAULT` to stored procedure or function parameters or stored program local variables (for example with a `SET var_name = DEFAULT` statement). In MySQL 8.0, this results in a syntax error.

### 13.6.4.1 Local Variable DECLARE Statement

```sql
DECLARE var_name [, var_name] ... type [DEFAULT value]
```

This statement declares local variables within stored programs. To provide a default value for a variable, include a `DEFAULT` clause. The value can be specified as an expression; it need not be a constant. If the `DEFAULT` clause is missing, the initial value is `NULL`.

Local variables are treated like stored routine parameters with respect to data type and overflow checking. See Section 13.1.17, “CREATE PROCEDURE and CREATE FUNCTION Statements”.

Variable declarations must appear before cursor or handler declarations.

Local variable names are not case-sensitive. Permissible characters and quoting rules are the same as for other identifiers, as described in Section 9.2, “Schema Object Names”.

The scope of a local variable is the `BEGIN ... END` block within which it is declared. The variable can be referred to in blocks nested within the declaring block, except those blocks that declare a variable with the same name.

For examples of variable declarations, see Section 13.6.4.2, “Local Variable Scope and Resolution”.

### 13.6.4.2 Local Variable Scope and Resolution

The scope of a local variable is the `BEGIN ... END` block within which it is declared. The variable can be referred to in blocks nested within the declaring block, except those blocks that declare a variable with the same name.

Because local variables are in scope only during stored program execution, references to them are not permitted in prepared statements created within a stored program. Prepared statement scope is the current session, not the stored program, so the statement could be executed after the program ends, at which point the variables would no longer be in scope. For example, `SELECT ... INTO local_var` cannot be used as a prepared statement. This restriction also applies to stored procedure and function parameters. See Section 13.5.1, “PREPARE Statement”.

A local variable should not have the same name as a table column. If an SQL statement, such as a `SELECT ... INTO` statement, contains a reference to a column and a declared local variable with the same name, MySQL currently interprets the reference as the name of a variable. Consider the following procedure definition:

```sql
CREATE PROCEDURE sp1 (x VARCHAR(5))
BEGIN
  DECLARE xname VARCHAR(5) DEFAULT 'bob';
  DECLARE newname VARCHAR(5);
  DECLARE xid INT;
  SELECT xname, id INTO newname, xid
  FROM table1 WHERE xname = xname;
  SELECT newname;
END;
```
MySQL interprets `xname` in the `SELECT` statement as a reference to the `xname` variable rather than the `xname` column. Consequently, when the procedure `sp1()` is called, the `newname` variable returns the value 'bob' regardless of the value of the `table1.xname` column.

Similarly, the cursor definition in the following procedure contains a `SELECT` statement that refers to `xname`. MySQL interprets this as a reference to the variable of that name rather than a column reference.

```sql
CREATE PROCEDURE sp2 (x VARCHAR(5))
BEGIN
    DECLARE xname VARCHAR(5) DEFAULT 'bob';
    DECLARE newname VARCHAR(5);
    DECLARE xid INT;
    DECLARE done TINYINT DEFAULT 0;
    DECLARE cur1 CURSOR FOR SELECT xname, id FROM table1;
    DECLARE CONTINUE HANDLER FOR NOT FOUND SET done = 1;
    OPEN cur1;
    read_loop: LOOP
        FETCH FROM cur1 INTO newname, xid;
        IF done THEN LEAVE read_loop; END IF;
        SELECT newname;
    END LOOP;
    CLOSE cur1;
END;
```

See also Section 25.8, “Restrictions on Stored Programs”.

### 13.6.5 Flow Control Statements

MySQL supports the `IF`, `CASE`, `ITERATE`, `LEAVE LOOP`, `WHILE`, and `REPEAT` constructs for flow control within stored programs. It also supports `RETURN` within stored functions.

Many of these constructs contain other statements, as indicated by the grammar specifications in the following sections. Such constructs may be nested. For example, an `IF` statement might contain a `WHILE` loop, which itself contains a `CASE` statement.

MySQL does not support `FOR` loops.

#### 13.6.5.1 CASE Statement

```sql
CASE case_value
    WHEN when_value THEN statement_list
    [WHEN when_value THEN statement_list] ...
    [ELSE statement_list]
END CASE
```

Or:

```sql
CASE
    WHEN search_condition THEN statement_list
    [WHEN search_condition THEN statement_list] ...
    [ELSE statement_list]
END CASE
```

The `CASE` statement for stored programs implements a complex conditional construct.

### Note

There is also a `CASE` operator, which differs from the `CASE` statement described here. See Section 12.5, “Flow Control Functions”. The `CASE` statement cannot have an `ELSE NULL` clause, and it is terminated with `END CASE` instead of `END`.

For the first syntax, `case_value` is an expression. This value is compared to the `when_value` expression in each `WHEN` clause until one of them is equal. When an equal `when_value` is found, the
corresponding THEN clause \textit{statement_list} executes. If no \textit{when_value} is equal, the ELSE clause \textit{statement_list} executes, if there is one.

This syntax cannot be used to test for equality with \texttt{NULL} because \texttt{NULL = NULL} is false. See Section 3.3.4.6, “Working with NULL Values”.

For the second syntax, each WHEN clause \textit{search_condition} expression is evaluated until one is true, at which point its corresponding THEN clause \textit{statement_list} executes. If no \textit{search_condition} is equal, the ELSE clause \textit{statement_list} executes, if there is one.

If no \textit{when_value} or \textit{search_condition} matches the value tested and the CASE statement contains no ELSE clause, a Case not found for CASE statement error results.

Each \textit{statement_list} consists of one or more SQL statements; an empty \textit{statement_list} is not permitted.

To handle situations where no value is matched by any WHEN clause, use an ELSE containing an empty BEGIN ... END block, as shown in this example. (The indentation used here in the ELSE clause is for purposes of clarity only, and is not otherwise significant.)

```sql
DELIMITER |
CREATE PROCEDURE p()
BEGIN
  DECLARE v INT DEFAULT 1;
  CASE v
    WHEN 2 THEN SELECT v;
    WHEN 3 THEN SELECT 0;
    ELSE
      BEGIN
        END;
    END CASE;
END;
|
```

### 13.6.5.2 IF Statement

IF \textit{search_condition} THEN \textit{statement_list}
  [ELSEIF \textit{search_condition} THEN \textit{statement_list}] ...
  [ELSE \textit{statement_list}]
END IF

The IF statement for stored programs implements a basic conditional construct.

\begin{quote}
\textbf{Note}

There is also an \texttt{IF()} function, which differs from the IF statement described here. See Section 12.5, “Flow Control Functions”. The IF statement can have THEN, ELSE, and ELSEIF clauses, and it is terminated with END IF.
\end{quote}

If a given \textit{search_condition} evaluates to true, the corresponding THEN or ELSEIF clause \textit{statement_list} executes. If no \textit{search_condition} matches, the ELSE clause \textit{statement_list} executes.

Each \textit{statement_list} consists of one or more SQL statements; an empty \textit{statement_list} is not permitted.

An IF ... END IF block, like all other flow-control blocks used within stored programs, must be terminated with a semicolon, as shown in this example:

```sql
DELIMITER //
CREATE FUNCTION SimpleCompare(n INT, m INT)
```
Flow Control Statements

RETURNS VARCHAR(20)
BEGIN
DECLARE s VARCHAR(20);
IF n > m THEN SET s = '>'; ELSEIF n = m THEN SET s = '='; ELSE SET s = '<'; END IF;
SET s = CONCAT(n, ' ', s, ' ', m);
RETURN s;
END //
DELIMITER ;

As with other flow-control constructs, IF ... END IF blocks may be nested within other flow-control constructs, including other IF statements. Each IF must be terminated by its own END IF followed by a semicolon. You can use indentation to make nested flow-control blocks more easily readable by humans (although this is not required by MySQL), as shown here:

DELIMITER //
CREATE FUNCTION VerboseCompare (n INT, m INT)
RETURNS VARCHAR(50)
BEGIN
DECLARE s VARCHAR(50);
IF n = m THEN SET s = 'equals'; ELSE IF n > m THEN SET s = 'greater'; ELSE SET s = 'less'; END IF;
SET s = CONCAT('is ', s, ' than');
END IF;
SET s = CONCAT(n, ' ', s, ' ', m, '.');
RETURN s;
END //
DELIMITER ;

In this example, the inner IF is evaluated only if n is not equal to m.

13.6.5.3 ITERATE Statement

ITERATE label

ITERATE can appear only within LOOP, REPEAT, and WHILE statements. ITERATE means “start the loop again.”

For an example, see Section 13.6.5.5, “LOOP Statement”.

13.6.5.4 LEAVE Statement

LEAVE label

This statement is used to exit the flow control construct that has the given label. If the label is for the outermost stored program block, LEAVE exits the program.

LEAVE can be used within BEGIN ... END or loop constructs (LOOP, REPEAT, WHILE).

For an example, see Section 13.6.5.5, “LOOP Statement”.
13.6.5.5 LOOP Statement

Loop Statement

```sql
[begin_label:] LOOP
    statement_list
END LOOP [end_label]
```

**LOOP** implements a simple loop construct, enabling repeated execution of the statement list, which consists of one or more statements, each terminated by a semicolon (;) statement delimiter. The statements within the loop are repeated until the loop is terminated. Usually, this is accomplished with a **LEAVE** statement. Within a stored function, **RETURN** can also be used, which exits the function entirely.

Neglecting to include a loop-termination statement results in an infinite loop.

A **LOOP** statement can be labeled. For the rules regarding label use, see Section 13.6.2, “Statement Labels”.

Example:

```
CREATE PROCEDURE doiterate(p1 INT)
BEGIN
    label1: LOOP
        SET p1 = p1 + 1;
        IF p1 < 10 THEN
            ITERATE label1;
        END IF;
        LEAVE label1;
    END LOOP label1;
    SET @x = p1;
END;
```

13.6.5.6 REPEAT Statement

Repeat Statement

```sql
[begin_label:] REPEAT
    statement_list
UNTIL search_condition
END REPEAT [end_label]
```

The statement list within a **REPEAT** statement is repeated until the **search_condition** expression is true. Thus, a **REPEAT** always enters the loop at least once. **statement_list** consists of one or more statements, each terminated by a semicolon (;) statement delimiter.

A **REPEAT** statement can be labeled. For the rules regarding label use, see Section 13.6.2, “Statement Labels”.

Example:

```
mysql> delimiter //
mysql> CREATE PROCEDURE dorepeat(p1 INT)
BEGIN
    SET @x = 0;
    REPEAT
        SET @x = @x + 1;
        UNTIL @x > p1 END REPEAT;
    END //
Query OK, 0 rows affected (0.00 sec)
mysql> CALL dorepeat(1000)\
Query OK, 0 rows affected (0.00 sec)
mysql> SELECT @x//
+------+
<table>
<thead>
<tr>
<th>@x</th>
</tr>
</thead>
<tbody>
<tr>
<td>1001</td>
</tr>
</tbody>
</table>
```

---

2591
13.6.5.7 RETURN Statement

```
RETURN expr
```

The RETURN statement terminates execution of a stored function and returns the value expr to the function caller. There must be at least one RETURN statement in a stored function. There may be more than one if the function has multiple exit points.

This statement is not used in stored procedures, triggers, or events. The LEAVE statement can be used to exit a stored program of those types.

13.6.5.8 WHILE Statement

```
[begin_label:] WHILE search_condition DO
    statement_list
END WHILE [end_label]
```

The statement list within a WHILE statement is repeated as long as the search_condition expression is true. statement_list consists of one or more SQL statements, each terminated by a semicolon (;) statement delimiter.

A WHILE statement can be labeled. For the rules regarding label use, see Section 13.6.2, “Statement Labels”.

Example:

```
CREATE PROCEDURE dowhile()
BEGIN
    DECLARE v1 INT DEFAULT 5;
    WHILE v1 > 0 DO
        ...
        SET v1 = v1 - 1;
    END WHILE;
END;
```

13.6.6 Cursors

MySQL supports cursors inside stored programs. The syntax is as in embedded SQL. Cursors have these properties:

- Asensitive: The server may or may not make a copy of its result table
- Read only: Not updatable
- Nonscrollable: Can be traversed only in one direction and cannot skip rows

Cursor declarations must appear before handler declarations and after variable and condition declarations.

Example:

```
CREATE PROCEDURE curdemo()
BEGIN
    DECLARE done INT DEFAULT FALSE;
    DECLARE a CHAR(16);
    DECLARE b, c INT;
    DECLARE cur1 CURSOR FOR SELECT id, data FROM test.t1;
    DECLARE cur2 CURSOR FOR SELECT i FROM test.t2;
    DECLARE CONTINUE HANDLER FOR NOT FOUND SET done = TRUE;
    OPEN cur1;
    OPEN cur2;
```

read_loop: LOOP  
  FETCH cur1 INTO a, b;  
  FETCH cur2 INTO c;  
  IF done THEN  
    LEAVE read_loop;  
  END IF;  
  IF b < c THEN  
    INSERT INTO test.t3 VALUES (a,b);  
  ELSE  
    INSERT INTO test.t3 VALUES (a,c);  
  END IF;  
END LOOP;  
CLOSE cur1;  
CLOSE cur2;  
END;

13.6.6.1 Cursor CLOSE Statement

CLOSE cursor_name

This statement closes a previously opened cursor. For an example, see Section 13.6.6, “Cursors”.

An error occurs if the cursor is not open.

If not closed explicitly, a cursor is closed at the end of the BEGIN ... END block in which it was declared.

13.6.6.2 Cursor DECLARE Statement

DECLARE cursor_name CURSOR FOR select_statement

This statement declares a cursor and associates it with a SELECT statement that retrieves the rows to be traversed by the cursor. To fetch the rows later, use a FETCH statement. The number of columns retrieved by the SELECT statement must match the number of output variables specified in the FETCH statement.

The SELECT statement cannot have an INTO clause.

Cursor declarations must appear before handler declarations and after variable and condition declarations.

A stored program may contain multiple cursor declarations, but each cursor declared in a given block must have a unique name. For an example, see Section 13.6.6, “Cursors”.

For information available through SHOW statements, it is possible in many cases to obtain equivalent information by using a cursor with an INFORMATION_SCHEMA table.

13.6.6.3 Cursor FETCH Statement

FETCH [[NEXT] FROM] cursor_name INTO var_name [, var_name] ...

This statement fetches the next row for the SELECT statement associated with the specified cursor (which must be open), and advances the cursor pointer. If a row exists, the fetched columns are stored in the named variables. The number of columns retrieved by the SELECT statement must match the number of output variables specified in the FETCH statement.

If no more rows are available, a No Data condition occurs with SQLSTATE value '02000'. To detect this condition, you can set up a handler for it (or for a NOT FOUND condition). For an example, see Section 13.6.6, “Cursors”.

Be aware that another operation, such as a SELECT or another FETCH, may also cause the handler to execute by raising the same condition. If it is necessary to distinguish which operation raised the
condition, place the operation within its own `BEGIN ... END` block so that it can be associated with its own handler.

### 13.6.6.4 Cursor OPEN Statement

```
OPEN cursor_name
```

This statement opens a previously declared cursor. For an example, see Section 13.6.6, “Cursors”.

### 13.6.6.5 Restrictions on Server-Side Cursors

Server-side cursors are implemented in the C API using the `mysql_stmt_attr_set()` function. The same implementation is used for cursors in stored routines. A server-side cursor enables a result set to be generated on the server side, but not transferred to the client except for those rows that the client requests. For example, if a client executes a query but is only interested in the first row, the remaining rows are not transferred.

In MySQL, a server-side cursor is materialized into an internal temporary table. Initially, this is a `MEMORY` table, but is converted to a `MyISAM` table when its size exceeds the minimum value of the `max_heap_table_size` and `tmp_table_size` system variables. The same restrictions apply to internal temporary tables created to hold the result set for a cursor as for other uses of internal temporary tables. See Section 8.4.4, “Internal Temporary Table Use in MySQL”. One limitation of the implementation is that for a large result set, retrieving its rows through a cursor might be slow.

Cursors are read only; you cannot use a cursor to update rows.

**UPDATE WHERE CURRENT OF** and **DELETE WHERE CURRENT OF** are not implemented, because updatable cursors are not supported.

Cursors are nonholdable (not held open after a commit).

Cursors are asensitive.

Cursors are nonscrollable.

Cursors are not named. The statement handler acts as the cursor ID.

You can have open only a single cursor per prepared statement. If you need several cursors, you must prepare several statements.

You cannot use a cursor for a statement that generates a result set if the statement is not supported in prepared mode. This includes statements such as `CHECK TABLE`, `HANDLER READ`, and `SHOW BINLOG EVENTS`.

### 13.6.7 Condition Handling

Conditions may arise during stored program execution that require special handling, such as exiting the current program block or continuing execution. Handlers can be defined for general conditions such as warnings or exceptions, or for specific conditions such as a particular error code. Specific conditions can be assigned names and referred to that way in handlers.

To name a condition, use the `DECLARE ... CONDITION` statement. To declare a handler, use the `DECLARE ... HANDLER` statement. See Section 13.6.7.1, “DECLARE ... CONDITION Statement”, and Section 13.6.7.2, “DECLARE ... HANDLER Statement”. For information about how the server chooses handlers when a condition occurs, see Section 13.6.7.6, “Scope Rules for Handlers”.

To raise a condition, use the `SIGNAL` statement. To modify condition information within a condition handler, use `RESIGNAL`. See Section 13.6.7.1, “DECLARE ... CONDITION Statement”, and Section 13.6.7.2, “DECLARE ... HANDLER Statement”.

2594
To retrieve information from the diagnostics area, use the **GET DIAGNOSTICS** statement (see **Section 13.6.7.3, “GET DIAGNOSTICS Statement”**). For information about the diagnostics area, see **Section 13.6.7.7, “The MySQL Diagnostics Area”**.

### 13.6.7.1 DECLARE ... CONDITION Statement

```sql
DECLARE condition_name CONDITION FOR condition_value

condition_value: {
  mysql_error_code
  | SQLSTATE [VALUE] sqlstate_value
}
```

The **DECLARE ... CONDITION** statement declares a named error condition, associating a name with a condition that needs specific handling. The name can be referred to in a subsequent **DECLARE ... HANDLER** statement (see **Section 13.6.7.2, “DECLARE ... HANDLER Statement”**).

Condition declarations must appear before cursor or handler declarations.

The **condition_value** for **DECLARE ... CONDITION** indicates the specific condition or class of conditions to associate with the condition name. It can take the following forms:

- **mysql_error_code**: An integer literal indicating a MySQL error code.
  
  Do not use MySQL error code 0 because that indicates success rather than an error condition. For a list of MySQL error codes, see [Server Error Message Reference](#).

- **SQLSTATE [VALUE] sqlstate_value**: A 5-character string literal indicating an SQLSTATE value.
  
  Do not use SQLSTATE values that begin with '00' because those indicate success rather than an error condition. For a list of SQLSTATE values, see [Server Error Message Reference](#).

Condition names referred to in **SIGNAL** or use **RESIGNAL** statements must be associated with SQLSTATE values, not MySQL error codes.

Using names for conditions can help make stored program code clearer. For example, this handler applies to attempts to drop a nonexistent table, but that is apparent only if you know that 1051 is the MySQL error code for “unknown table”:

```sql
DECLARE CONTINUE HANDLER FOR 1051
BEGIN
  -- body of handler
END;
```

By declaring a name for the condition, the purpose of the handler is more readily seen:

```sql
DECLARE no_such_table CONDITION FOR 1051;
DECLARE CONTINUE HANDLER FOR no_such_table
BEGIN
  -- body of handler
END;
```

Here is a named condition for the same condition, but based on the corresponding SQLSTATE value rather than the MySQL error code:

```sql
DECLARE no_such_table CONDITION FOR SQLSTATE '42S02';
DECLARE CONTINUE HANDLER FOR no_such_table
BEGIN
  -- body of handler
END;
```

### 13.6.7.2 DECLARE ... HANDLER Statement

```sql
DECLARE handler_action HANDLER
  FOR condition_value [, condition_value] ...
  statement
```

---

13.6.7.1 DECLARE ... CONDITION Statement

13.6.7.2 DECLARE ... HANDLER Statement
The `DECLARE ... HANDLER` statement specifies a handler that deals with one or more conditions. If one of these conditions occurs, the specified `statement` executes. `statement` can be a simple statement such as `SET var_name = value`, or a compound statement written using `BEGIN` and `END` (see Section 13.6.1, “BEGIN ... END Compound Statement”).

Handler declarations must appear after variable or condition declarations.

The `handler_action` value indicates what action the handler takes after execution of the handler statement:

- **CONTINUE**: Execution of the current program continues.
- **EXIT**: Execution terminates for the `BEGIN ... END` compound statement in which the handler is declared. This is true even if the condition occurs in an inner block.
- **UNDO**: Not supported.

The `condition_value` for `DECLARE ... HANDLER` indicates the specific condition or class of conditions that activates the handler. It can take the following forms:

- **mysql_error_code**: An integer literal indicating a MySQL error code, such as 1051 to specify “unknown table”:

```
DECLARE CONTINUE HANDLER FOR 1051
BEGIN
   -- body of handler
END;
```

Do not use MySQL error code 0 because that indicates success rather than an error condition. For a list of MySQL error codes, see Server Error Message Reference.

- **SQLSTATE [VALUE] sqlstate_value**: A 5-character string literal indicating an SQLSTATE value, such as '42S01' to specify “unknown table”:

```
DECLARE CONTINUE HANDLER FOR SQLSTATE '42S02'
BEGIN
   -- body of handler
END;
```

Do not use SQLSTATE values that begin with '00' because those indicate success rather than an error condition. For a list of SQLSTATE values, see Server Error Message Reference.

- **condition_name**: A condition name previously specified with `DECLARE ... CONDITION`. A condition name can be associated with a MySQL error code or SQLSTATE value. See Section 13.6.7.1, “DECLARE ... CONDITION Statement”.

- **SQLWARNING**: Shorthand for the class of SQLSTATE values that begin with '01'.

```
DECLARE CONTINUE HANDLER FOR SQLWARNING
BEGIN
```

2596
**Condition Handling**

- **body of handler**

**NOT FOUND**: Shorthand for the class of SQLSTATE values that begin with '02'. This is relevant within the context of cursors and is used to control what happens when a cursor reaches the end of a data set. If no more rows are available, a No Data condition occurs with SQLSTATE value '02000'. To detect this condition, you can set up a handler for it or for a **NOT FOUND** condition.

```sql
DECLARE CONTINUE HANDLER FOR NOT FOUND
BEGIN
-- body of handler
END;
```

For another example, see Section 13.6.6, “Cursors”. The **NOT FOUND** condition also occurs for `SELECT ... INTO var_list` statements that retrieve no rows.

- **SQLEXCEPTION**: Shorthand for the class of SQLSTATE values that do not begin with '00', '01', or '02'.

```sql
DECLARE CONTINUE HANDLER FOR SQLEXCEPTION
BEGIN
-- body of handler
END;
```

For information about how the server chooses handlers when a condition occurs, see Section 13.6.7.6, “Scope Rules for Handlers”.

If a condition occurs for which no handler has been declared, the action taken depends on the condition class:

- For **SQLEXCEPTION** conditions, the stored program terminates at the statement that raised the condition, as if there were an **EXIT** handler. If the program was called by another stored program, the calling program handles the condition using the handler selection rules applied to its own handlers.

- For **SQLWARNING** conditions, the program continues executing, as if there were a **CONTINUE** handler.

- For **NOT FOUND** conditions, if the condition was raised normally, the action is **CONTINUE**. If it was raised by **SIGNAL** or **RESIGNAL**, the action is **EXIT**.

The following example uses a handler for SQLSTATE '23000', which occurs for a duplicate-key error:

```sql
mysql> CREATE TABLE test.t (s1 INT, PRIMARY KEY (s1));
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE PROCEDURE handlerdemo ()
BEGIN
    DECLARE CONTINUE HANDLER FOR SQLSTATE '23000' SET @x2 = 1;
    SET @x = 1;
    INSERT INTO test.t VALUES (1);
    SET @x = 2;
    INSERT INTO test.t VALUES (1);
    SET @x = 3;
END;
//
Query OK, 0 rows affected (0.00 sec)

mysql> CALL handlerdemo();
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @x;
+-----+
| @x  |
+-----+
```

2597
Notice that `@x` is 3 after the procedure executes, which shows that execution continued to the end of the procedure after the error occurred. If the `DECLARE ... HANDLER` statement had not been present, MySQL would have taken the default action (`EXIT`) after the second `INSERT` failed due to the `PRIMARY KEY` constraint, and `SELECT @x` would have returned 2.

To ignore a condition, declare a `CONTINUE` handler for it and associate it with an empty block. For example:

```
DECLARE CONTINUE HANDLER FOR SQLWARNING BEGIN END;
```

The scope of a block label does not include the code for handlers declared within the block. Therefore, the statement associated with a handler cannot use `ITERATE` or `LEAVE` to refer to labels for blocks that enclose the handler declaration. Consider the following example, where the `REPEAT` block has a label of `retry`:

```
CREATE PROCEDURE p ()
BEGIN
  DECLARE i INT DEFAULT 3;
  retry:
  REPEAT
    BEGIN
      DECLARE CONTINUE HANDLER FOR SQLWARNING
      BEGIN
        ITERATE retry;    # illegal
      END;
      IF i < 0 THEN
        LEAVE retry;        # legal
      END IF;
    END;
  UNTIL FALSE END REPEAT;
END;
```

The `retry` label is in scope for the `IF` statement within the block. It is not in scope for the `CONTINUE` handler, so the reference there is invalid and results in an error:

```
ERROR 1308 (42000): LEAVE with no matching label: retry
```

To avoid references to outer labels in handlers, use one of these strategies:

- To leave the block, use an `EXIT` handler. If no block cleanup is required, the `BEGIN ... END` handler body can be empty:

```
DECLARE EXIT HANDLER FOR SQLWARNING BEGIN END;
```

Otherwise, put the cleanup statements in the handler body:

```
DECLARE EXIT HANDLER FOR SQLWARNING
BEGIN
  block cleanup statements
END;
```

- To continue execution, set a status variable in a `CONTINUE` handler that can be checked in the enclosing block to determine whether the handler was invoked. The following example uses the variable `done` for this purpose:

```
CREATE PROCEDURE p ()
BEGIN
  DECLARE i INT DEFAULT 3;
  DECLARE done INT DEFAULT FALSE;
  retry:
  REPEAT
    BEGIN
      DECLARE CONTINUE HANDLER FOR SQLWARNING
```

13.6.7.3 GET DIAGNOSTICS Statement

```
BEGIN
    SET done = TRUE;
    END;
    IF done OR i < 0 THEN
        LEAVE retry;
    END IF;
    SET i = i - 1;
    END;
UNTIL FALSE END REPEAT;
END;
```

SQL statements produce diagnostic information that populates the diagnostics area. The `GET DIAGNOSTICS` statement enables applications to inspect this information. (You can also use `SHOW WARNINGS` or `SHOW ERRORS` to see conditions or errors.)

No special privileges are required to execute `GET DIAGNOSTICS`.

The keyword `CURRENT` means to retrieve information from the current diagnostics area. The keyword `STACKED` means to retrieve information from the second diagnostics area, which is available only if the current context is a condition handler. If neither keyword is given, the default is to use the current diagnostics area.

The `GET DIAGNOSTICS` statement is typically used in a handler within a stored program. It is a MySQL extension that `GET [CURRENT] DIAGNOSTICS` is permitted outside handler context to check the execution of any SQL statement. For example, if you invoke the `mysql` client program, you can enter these statements at the prompt:

```
mysql> DROP TABLE test.no_such_table;
ERROR 1051 (42S02): Unknown table 'test.no_such_table'
```
### Condition Handling

This extension applies only to the current diagnostics area. It does not apply to the second diagnostics area because `GET STACKED DIAGNOSTICS` is permitted only if the current context is a condition handler. If that is not the case, a `GET STACKED DIAGNOSTICS when handler not active` error occurs.

For a description of the diagnostics area, see Section 13.6.7.7, “The MySQL Diagnostics Area”. Briefly, it contains two kinds of information:

- **Statement information**, such as the number of conditions that occurred or the affected-rows count.

- **Condition information**, such as the error code and message. If a statement raises multiple conditions, this part of the diagnostics area has a condition area for each one. If a statement raises no conditions, this part of the diagnostics area is empty.

For a statement that produces three conditions, the diagnostics area contains statement and condition information like this:

```
<table>
<thead>
<tr>
<th>Error code for condition 1</th>
<th>Error message for condition 1</th>
</tr>
</thead>
<tbody>
<tr>
<td>Error code for condition 2</td>
<td>Error message for condition 2</td>
</tr>
<tr>
<td>Error code for condition 3</td>
<td>Error message for condition 3</td>
</tr>
</tbody>
</table>
```

`GET DIAGNOSTICS` can obtain either statement or condition information, but not both in the same statement:

- **To obtain statement information**, retrieve the desired statement items into target variables. This instance of `GET DIAGNOSTICS` assigns the number of available conditions and the rows-affected count to the user variables `@p1` and `@p2`:

  ```sql
  GET DIAGNOSTICS @p1 = NUMBER, @p2 = ROW_COUNT;
  ```

- **To obtain condition information**, specify the condition number and retrieve the desired condition items into target variables. This instance of `GET DIAGNOSTICS` assigns the SQLSTATE value and error message to the user variables `@p3` and `@p4`:

  ```sql
  GET DIAGNOSTICS CONDITION 1
  @p3 = RETURNED_SQLSTATE, @p4 = MESSAGE_TEXT;
  ```

The retrieval list specifies one or more `target = item_name` assignments, separated by commas. Each assignment names a target variable and either a `statement_information_item_name` or `condition_information_item_name` designator, depending on whether the statement retrieves statement or condition information.

Valid `target` designators for storing item information can be stored procedure or function parameters, stored program local variables declared with `DECLARE`, or user-defined variables.
Valid condition_number designators can be stored procedure or function parameters, stored program local variables declared with DECLARE, user-defined variables, system variables, or literals. A character literal may include a _charset introducer. A warning occurs if the condition number is not in the range from 1 to the number of condition areas that have information. In this case, the warning is added to the diagnostics area without clearing it.

When a condition occurs, MySQL does not populate all condition items recognized by GET DIAGNOSTICS. For example:

```
mysql> GET DIAGNOSTICS CONDITION 1
@p5 = SCHEMA_NAME, @p6 = TABLE_NAME;
mysql> SELECT @p5, @p6;
+-------+-------+
| @p5   | @p6   |
|       |       |
+-------+-------+
```

In standard SQL, if there are multiple conditions, the first condition relates to the SQLSTATE value returned for the previous SQL statement. In MySQL, this is not guaranteed. To get the main error, you cannot do this:

```
GET DIAGNOSTICS CONDITION 1 @errno = MYSQL_ERRNO;
```

Instead, retrieve the condition count first, then use it to specify which condition number to inspect:

```
GET DIAGNOSTICS @cno = NUMBER;
GET DIAGNOSTICS CONDITION @cno @errno = MYSQL_ERRNO;
```

For information about permissible statement and condition information items, and which ones are populated when a condition occurs, see Diagnostics Area Information Items.

Here is an example that uses GET DIAGNOSTICS and an exception handler in stored procedure context to assess the outcome of an insert operation. If the insert was successful, the procedure uses GET DIAGNOSTICS multiple times to retrieve information about a statement as long as the current diagnostics area has not been cleared.

```
CREATE PROCEDURE do_insert(value INT)
BEGIN
  -- Declare variables to hold diagnostics area information
  DECLARE code CHAR(5) DEFAULT '00000';
  DECLARE msg TEXT;
  DECLARE nrows INT;
  DECLARE result TEXT;
  -- Declare exception handler for failed insert
  DECLARE CONTINUE HANDLER FOR SQLEXCEPTION
  BEGIN
    GET DIAGNOSTICS CONDITION 1
    code = RETURNED_SQLSTATE, msg = MESSAGE_TEXT;
  END;
  -- Perform the insert
  INSERT INTO t1 (int_col) VALUES(value);
  -- Check whether the insert was successful
  IF code = '00000' THEN
    GET DIAGNOSTICS nrows = ROW_COUNT;
    SET result = CONCAT('insert succeeded, row count = ',nrows);
    ELSE
    SET result = CONCAT('insert failed, error = ',code,', message = ',msg);
  END IF;
  -- Say what happened
  SELECT result;
END;
```

Suppose that t1.int_col is an integer column that is declared as NOT NULL. The procedure produces these results when invoked to insert non-NULL and NULL values, respectively:
When a condition handler activates, a push to the diagnostics area stack occurs:

- The first (current) diagnostics area becomes the second (stacked) diagnostics area and a new current diagnostics area is created as a copy of it.

- `GET [CURRENT] DIAGNOSTICS` and `GET STACKED DIAGNOSTICS` can be used within the handler to access the contents of the current and stacked diagnostics areas.

- Initially, both diagnostics areas return the same result, so it is possible to get information from the current diagnostics area about the condition that activated the handler, as long as you execute no statements within the handler that change its current diagnostics area.

- However, statements executing within the handler can modify the current diagnostics area, clearing and setting its contents according to the normal rules (see How the Diagnostics Area is Cleared and Populated).

A more reliable way to obtain information about the handler-activating condition is to use the stacked diagnostics area, which cannot be modified by statements executing within the handler except `RESIGNAL`. For information about when the current diagnostics area is set and cleared, see Section 13.6.7.7, “The MySQL Diagnostics Area”.

The next example shows how `GET STACKED DIAGNOSTICS` can be used within a handler to obtain information about the handled exception, even after the current diagnostics area has been modified by handler statements.

Within a stored procedure `p()`, we attempt to insert two values into a table that contains a TEXT NOT NULL column. The first value is a non-NULL string and the second is NULL. The column prohibits NULL values, so the first insert succeeds but the second causes an exception. The procedure includes an exception handler that maps attempts to insert NULL into inserts of the empty string:

```sql
DROP TABLE IF EXISTS t1;
CREATE TABLE t1 (c1 TEXT NOT NULL);
DROP PROCEDURE IF EXISTS p;
delimiter //
CREATE PROCEDURE p ()
BEGIN
  -- Declare variables to hold diagnostics area information
  DECLARE errcount INT;
  DECLARE errno INT;
  DECLARE msg TEXT;
  DECLARE EXIT HANDLER FOR SQLEXCEPTION
  BEGIN
    -- Here the current DA is nonempty because no prior statements
    -- executing within the handler have cleared it
    GET CURRENT DIAGNOSTICS CONDITION 1
    errno = MYSQL_ERRNO, msg = MESSAGE_TEXT;
    SELECT 'current DA before mapped insert' AS op, errno, msg;
    GET STACKED DIAGNOSTICS CONDITION 1
    errno = MYSQL_ERRNO, msg = MESSAGE_TEXT;
    SELECT 'stacked DA before mapped insert' AS op, errno, msg;
    -- Map attempted NULL insert to empty string insert
    INSERT INTO t1 (c1) VALUES('');
```
When the handler activates, a copy of the current diagnostics area is pushed to the diagnostics area stack. The handler first displays the contents of the current and stacked diagnostics areas, which are both the same initially:

<table>
<thead>
<tr>
<th>op</th>
<th>errno</th>
<th>msg</th>
</tr>
</thead>
<tbody>
<tr>
<td>current DA before mapped insert</td>
<td>1048</td>
<td>Column 'c1' cannot be null</td>
</tr>
<tr>
<td>stacked DA before mapped insert</td>
<td>1048</td>
<td>Column 'c1' cannot be null</td>
</tr>
</tbody>
</table>

Statements executing after the `GET DIAGNOSTICS` statements may reset the current diagnostics area. statements may reset the current diagnostics area. For example, the handler maps the `NULL` insert to an empty-string insert and displays the result. The new insert succeeds and clears the current diagnostics area, but the stacked diagnostics area remains unchanged and still contains information about the condition that activated the handler:

<table>
<thead>
<tr>
<th>op</th>
</tr>
</thead>
<tbody>
<tr>
<td>mapped insert succeeded, current DA is empty</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>op</th>
<th>errno</th>
<th>msg</th>
</tr>
</thead>
<tbody>
<tr>
<td>stacked DA after mapped insert</td>
<td>1048</td>
<td>Column 'c1' cannot be null</td>
</tr>
</tbody>
</table>

When the condition handler ends, its current diagnostics area is popped from the stack and the stacked diagnostics area becomes the current diagnostics area in the stored procedure.

After the procedure returns, the table contains two rows. The empty row results from the attempt to insert `NULL` that was mapped to an empty-string insert:

<table>
<thead>
<tr>
<th>c1</th>
</tr>
</thead>
<tbody>
<tr>
<td>string l</td>
</tr>
</tbody>
</table>
In the preceding example, the first two `GET DIAGNOSTICS` statements within the condition handler that retrieve information from the current and stacked diagnostics areas return the same values. This is not the case if statements that reset the current diagnostics area execute earlier within the handler. Suppose that `p()` is rewritten to place the `DECLARE` statements within the handler definition rather than preceding it:

```sql
CREATE PROCEDURE p ()
BEGIN
  DECLARE EXIT HANDLER FOR SQLEXCEPTION
  BEGIN
    -- Declare variables to hold diagnostics area information
    DECLARE errcount INT;
    DECLARE errno INT;
    DECLARE msg TEXT;
    GET CURRENT DIAGNOSTICS CONDITION 1
      errno = MYSQL_ERRNO, msg = MESSAGE_TEXT;
    SELECT 'current DA before mapped insert' AS op, errno, msg;
    GET STACKED DIAGNOSTICS CONDITION 1
      errno = MYSQL_ERRNO, msg = MESSAGE_TEXT;
    SELECT 'stacked DA before mapped insert' AS op, errno, msg;
    ...  
  END;
END;
```

In this case, the result is version-dependent:

- Before MySQL 5.7.2, `DECLARE` does not change the current diagnostics area, so the first two `GET DIAGNOSTICS` statements return the same result, just as in the original version of `p()`.

In MySQL 5.7.2, work was done to ensure that all nondiagnostic statements populate the diagnostics area, per the SQL standard. `DECLARE` is one of them, so in 5.7.2 and higher, `DECLARE` statements executing at the beginning of the handler clear the current diagnostics area and the `GET DIAGNOSTICS` statements produce different results:

```
| op                              | errno | msg  |
+---------------------------------+-------+------+
| current DA before mapped insert |  NULL | NULL |
+---------------------------------+-------+------+
```

```
| op                              | errno | msg                        |
+---------------------------------+-------+----------------------------+
| stacked DA before mapped insert |  1048 | Column 'c1' cannot be null |
+---------------------------------+-------+----------------------------+
```

To avoid this issue within a condition handler when seeking to obtain information about the condition that activated the handler, be sure to access the stacked diagnostics area, not the current diagnostics area.

### 13.6.7.4 RESIGNAL Statement

```
RESIGNAL [ condition_value ]
  [SET signal_information_item
    [, signal_information_item] ...]
```

`condition_value`: 
- `SQLSTATE [VALUE] sqlstate_value`
- `condition_name`

`signal_information_item`: 
- `condition_information_item_name = simple_value_specification`

`condition_information_item_name`: 
- `CLASS_ORIGIN`
- `SUBCLASS_ORIGIN`
Condition Handling

| MESSAGE_TEXT |
| MYSQL_ERRNO |
| CONSTRAINT_CATALOG |
| CONSTRAINT_SCHEMA |
| CONSTRAINT_NAME |
| CATALOG_NAME |
| TABLE_NAME |
| COLUMN_NAME |
| CURSOR_NAME |

\}

\)

condition_name, simple_value_specification:
(see following discussion)

**RESIGNAL** passes on the error condition information that is available during execution of a condition handler within a compound statement inside a stored procedure or function, trigger, or event. **RESIGNAL** may change some or all information before passing it on. **RESIGNAL** is related to **SIGNAL**, but instead of originating a condition as **SIGNAL** does, **RESIGNAL** relays existing condition information, possibly after modifying it.

**RESIGNAL** makes it possible to both handle an error and return the error information. Otherwise, by executing an SQL statement within the handler, information that caused the handler's activation is destroyed. **RESIGNAL** also can make some procedures shorter if a given handler can handle part of a situation, then pass the condition “up the line” to another handler.

No privileges are required to execute the **RESIGNAL** statement.

All forms of **RESIGNAL** require that the current context be a condition handler. Otherwise, **RESIGNAL** is illegal and a **RESIGNAL when handler not active** error occurs.

To retrieve information from the diagnostics area, use the **GET DIAGNOSTICS** statement (see Section 13.6.7.3, “GET DIAGNOSTICS Statement”). For information about the diagnostics area, see Section 13.6.7.7, “The MySQL Diagnostics Area”.

- **RESIGNAL Overview**
- **RESIGNAL Alone**
- **RESIGNAL with New Signal Information**
- **RESIGNAL with a Condition Value and Optional New Signal Information**
- **RESIGNAL Requires Condition Handler Context**

**RESIGNAL Overview**

For `condition_value` and `signal_information_item`, the definitions and rules are the same for **RESIGNAL** as for **SIGNAL**. For example, the `condition_value` can be an **SQLSTATE** value, and the value can indicate errors, warnings, or “not found.” For additional information, see Section 13.6.7.5, “**SIGNAL Statement**”.

The **RESIGNAL** statement takes `condition_value` and **SET** clauses, both of which are optional. This leads to several possible uses:

- **RESIGNAL** alone:

  ```
  RESIGNAL;
  ```

- **RESIGNAL** with new signal information:

  ```
  RESIGNAL SET signal_information_item [, signal_information_item] ...;
  ```

- **RESIGNAL** with a condition value and possibly new signal information:
RESIGNAL condition_value
[SET signal_information_item [, signal_information_item] ...];

These use cases all cause changes to the diagnostics and condition areas:

- A diagnostics area contains one or more condition areas.
- A condition area contains condition information items, such as the SQLSTATE value, MYSQL_ERRNO, or MESSAGE_TEXT.

There is a stack of diagnostics areas. When a handler takes control, it pushes a diagnostics area to the top of the stack, so there are two diagnostics areas during handler execution:

- The first (current) diagnostics area, which starts as a copy of the last diagnostics area, but is overwritten by the first statement in the handler that changes the current diagnostics area.
- The last (stacked) diagnostics area, which has the condition areas that were set up before the handler took control.

The maximum number of condition areas in a diagnostics area is determined by the value of the max_error_count system variable. See Diagnostics Area-Related System Variables.

RESIGNAL Alone

A simple RESIGNAL alone means “pass on the error with no change.” It restores the last diagnostics area and makes it the current diagnostics area. That is, it “pops” the diagnostics area stack.

Within a condition handler that catches a condition, one use for RESIGNAL alone is to perform some other actions, and then pass on without change the original condition information (the information that existed before entry into the handler).

Example:

```
DROP TABLE IF EXISTS xx;
delimiter //
CREATE PROCEDURE p ()
BEGIN
    DECLARE EXIT HANDLER FOR SQLEXCEPTION
    BEGIN
        SET @error_count = @error_count + 1;
        IF @a = 0 THEN RESIGNAL; END IF;
    END;
    DROP TABLE xx;
END;//
delimiter ;
SET @error_count = 0;
SET @a = 0;
CALL p();
```

Suppose that the DROP TABLE xx statement fails. The diagnostics area stack looks like this:

```
DA 1. ERROR 1051 (42S02): Unknown table 'xx'
```

Then execution enters the EXIT handler. It starts by pushing a diagnostics area to the top of the stack, which now looks like this:

```
DA 1. ERROR 1051 (42S02): Unknown table 'xx'
DA 2. ERROR 1051 (42S02): Unknown table 'xx'
```

At this point, the contents of the first (current) and second (stacked) diagnostics areas are the same. The first diagnostics area may be modified by statements executing subsequently within the handler.

Usually a procedure statement clears the first diagnostics area. BEGIN is an exception, it does not clear, it does nothing. SET is not an exception, it clears, performs the operation, and produces a result of “success.” The diagnostics area stack now looks like this:
Condition Handling

DA 1. ERROR 0000 (00000): Successful operation
DA 2. ERROR 1051 (42S02): Unknown table 'xx'

At this point, if \@a = 0, \texttt{RESIGNAL} pops the diagnostics area stack, which now looks like this:

DA 1. ERROR 1051 (42S02): Unknown table 'xx'

And that is what the caller sees.

If \@a is not 0, the handler simply ends, which means that there is no more use for the current diagnostics area (it has been “handled”), so it can be thrown away, causing the stacked diagnostics area to become the current diagnostics area again. The diagnostics area stack looks like this:

DA 1. ERROR 0000 (00000): Successful operation

The details make it look complex, but the end result is quite useful: Handlers can execute without destroying information about the condition that caused activation of the handler.

\textbf{RESIGNAL with New Signal Information}

\texttt{RESIGNAL} with \texttt{SET} clause provides new signal information, so the statement means “pass on the error with changes”:

\texttt{RESIGNAL SET signal\_information\_item [, signal\_information\_item] ...;}

As with \texttt{RESIGNAL} alone, the idea is to pop the diagnostics area stack so that the original information goes out. Unlike \texttt{RESIGNAL} alone, anything specified in the \texttt{SET} clause changes.

Example:

\begin{verbatim}
DROP TABLE IF EXISTS xx;
delimiter //
CREATE PROCEDURE p ()
BEGIN
    DECLARE EXIT HANDLER FOR SQLEXCEPTION
    BEGIN
        SET @error_count = @error_count + 1;
        IF @a = 0 THEN RESIGNAL SET MYSQL_ERRNO = 5; END IF;
    END;
    DROP TABLE xx;
END;//
delimiter ;
SET @error_count = 0;
SET @a = 0;
CALL p();
\end{verbatim}

Remember from the previous discussion that \texttt{RESIGNAL} alone results in a diagnostics area stack like this:

DA 1. ERROR 1051 (42S02): Unknown table 'xx'

The \texttt{RESIGNAL SET MYSQL_ERRNO = 5} statement results in this stack instead, which is what the caller sees:

DA 1. ERROR 5 (42S02): Unknown table 'xx'

In other words, it changes the error number, and nothing else.

The \texttt{RESIGNAL} statement can change any or all of the signal information items, making the first condition area of the diagnostics area look quite different.

\textbf{RESIGNAL with a Condition Value and Optional New Signal Information}

\texttt{RESIGNAL} with a condition value means “push a condition into the current diagnostics area.” If the \texttt{SET} clause is present, it also changes the error information.
\textbf{RESIGNAL} \texttt{condition\_value}
\[[\text{SET} \ \texttt{signal\_information\_item} [\ , \ \texttt{signal\_information\_item}] \ ...]];

This form of \texttt{RESIGNAL} restores the last diagnostics area and makes it the current diagnostics area. That is, it "pops" the diagnostics area stack, which is the same as what a simple \texttt{RESIGNAL} alone would do. However, it also changes the diagnostics area depending on the condition value or signal information.

\textbf{Example:}

\begin{verbatim}
DROP TABLE IF EXISTS xx;
delimiter //
CREATE PROCEDURE p ()
BEGIN
  DECLARE EXIT HANDLER FOR SQLEXCEPTION
  BEGIN
    SET @error_count = @error_count + 1;
    IF @a = 0 THEN RESIGNAL SQLSTATE '45000' SET MYSQL_ERRNO=5; END IF;
  END;
  DROP TABLE xx;
END/
delimiter ;
SET @error_count = 0;
SET @a = 0;
SET @@max_error_count = 2;
CALL p();
SHOW ERRORS;
\end{verbatim}

This is similar to the previous example, and the effects are the same, except that if \texttt{RESIGNAL} happens, the current condition area looks different at the end. (The reason the condition adds to rather than replaces the existing condition is the use of a condition value.)

The \texttt{RESIGNAL} statement includes a condition value (\texttt{SQLSTATE '45000'}), so it adds a new condition area, resulting in a diagnostics area stack that looks like this:

\begin{verbatim}
DA 1. (condition 2) ERROR 1051 (42S02): Unknown table 'xx'
   (condition 1) ERROR 5 (45000) Unknown table 'xx'
\end{verbatim}

The result of \texttt{CALL p()} and \texttt{SHOW ERRORS} for this example is:

\begin{verbatim}
mysql> CALL p();
ERROR 5 (45000): Unknown table 'xx'
mysql> SHOW ERRORS;
+-------+------+----------------------------------+
| Level | Code | Message                          |
+-------+------+----------------------------------+
| Error | 1051 | Unknown table 'xx'               |
| Error |    5 | Unknown table 'xx'               |
+-------+------+----------------------------------+
\end{verbatim}

\textbf{RESIGNAL Requires Condition Handler Context}

All forms of \texttt{RESIGNAL} require that the current context be a condition handler. Otherwise, \texttt{RESIGNAL} is illegal and a \texttt{RESIGNAL when handler not active} error occurs. For example:

\begin{verbatim}
mysql> CREATE PROCEDURE p () RESIGNAL;
Query OK, 0 rows affected (0.00 sec)
mysql> CALL p();
ERROR 1645 (0K000): RESIGNAL when handler not active
\end{verbatim}

Here is a more difficult example:

\begin{verbatim}
delimiter //
CREATE FUNCTION f () RETURNS INT
BEGIN
  RESIGNAL;
\end{verbatim}

2608
RETURN 5;
END;

CREATE PROCEDURE p()
BEGIN
    DECLARE EXIT HANDLER FOR SQLEXCEPTION SET @a=f();
    SIGNAL SQLSTATE '55555';
END;
delimiter ;
CALL p();

RESIGNAL occurs within the stored function f(). Although f() itself is invoked within the context of the EXIT handler, execution within f() has its own context, which is not handler context. Thus, RESIGNAL within f() results in a "handler not active" error.

13.6.7.5 SIGNAL Statement

SIGNAL condition_value
    [SET signal_information_item
     [, signal_information_item] ...]
condition_value: {
    SQLSTATE [VALUE] sqlstate_value
    | condition_name
}
signal_information_item: condition_information_item_name = simple_value_specification
condition_information_item_name: {
    CLASS_ORIGIN
    | SUBCLASS_ORIGIN
    | MESSAGE_TEXT
    | MYSQL_ERRNO
    | CONSTRAINT_CATALOG
    | CONSTRAINT_SCHEMA
    | CONSTRAINT_NAME
    | CATALOG_NAME
    | SCHEMA_NAME
    | TABLE_NAME
    | COLUMN_NAME
    | CURSOR_NAME
}
condition_name, simple_value_specification:
    (see following discussion)

SIGNAL is the way to "return" an error. SIGNAL provides error information to a handler, to an outer portion of the application, or to the client. Also, it provides control over the error's characteristics (error number, SQLSTATE value, message). Without SIGNAL, it is necessary to resort to workarounds such as deliberately referring to a nonexistent table to cause a routine to return an error.

No privileges are required to execute the SIGNAL statement.

To retrieve information from the diagnostics area, use the GET DIAGNOSTICS statement (see Section 13.6.7.3, "GET DIAGNOSTICS Statement"). For information about the diagnostics area, see Section 13.6.7.7, "The MySQL Diagnostics Area".

- SIGNAL Overview
- Signal Condition Information Items
- Effect of Signals on Handlers, Cursors, and Statements

SIGNAL Overview

The condition_value in a SIGNAL statement indicates the error value to be returned. It can be an SQLSTATE value (a 5-character string literal) or a condition_name that refers to a named condition
Condition Handling

previously defined with DECLARE ... CONDITION (see Section 13.6.7.1, “DECLARE ... CONDITION Statement”).

An SQLSTATE value can indicate errors, warnings, or “not found.” The first two characters of the value indicate its error class, as discussed in Signal Condition Information Items. Some signal values cause statement termination; see Effect of Signals on Handlers, Cursors, and Statements.

The SQLSTATE value for a SIGNAL statement should not start with '00' because such values indicate success and are not valid for signaling an error. This is true whether the SQLSTATE value is specified directly in the SIGNAL statement or in a named condition referred to in the statement. If the value is invalid, a Bad SQLSTATE error occurs.

To signal a generic SQLSTATE value, use '45000', which means “unhandled user-defined exception.”

The SIGNAL statement optionally includes a SET clause that contains multiple signal items, in a list of condition_information_item_name = simple_value_specification assignments, separated by commas.

Each condition_information_item_name may be specified only once in the SET clause. Otherwise, a Duplicate condition information item error occurs.

Valid simple_value_specification designators can be specified using stored procedure or function parameters, stored program local variables declared with DECLARE, user-defined variables, system variables, or literals. A character literal may include a _charset introducer.

For information about permissible condition_information_item_name values, see Signal Condition Information Items.

The following procedure signals an error or warning depending on the value of pval, its input parameter:

```
CREATE PROCEDURE p (pval INT)
BEGIN
    DECLARE specialty CONDITION FOR SQLSTATE '45000';
    IF pval = 0 THEN
        SIGNAL SQLSTATE '01000';
    ELSEIF pval = 1 THEN
        SIGNAL SQLSTATE '45000'
        SET MESSAGE_TEXT = 'An error occurred';
    ELSEIF pval = 2 THEN
        SIGNAL specialty
        SET MESSAGE_TEXT = 'An error occurred';
    ELSE
        SIGNAL SQLSTATE '01000'
        SET MESSAGE_TEXT = 'A warning occurred', MYSQL_ERRNO = 1000;
        SIGNAL SQLSTATE '45000'
        SET MESSAGE_TEXT = 'An error occurred', MYSQL_ERRNO = 1001;
    END IF;
END;
```

If pval is 0, p() signals a warning because SQLSTATE values that begin with '01' are signals in the warning class. The warning does not terminate the procedure, and can be seen with SHOW WARNINGS after the procedure returns.

If pval is 1, p() signals an error and sets the MESSAGE_TEXT condition information item. The error terminates the procedure, and the text is returned with the error information.

If pval is 2, the same error is signaled, although the SQLSTATE value is specified using a named condition in this case.

If pval is anything else, p() first signals a warning and sets the message text and error number condition information items. This warning does not terminate the procedure, so execution continues and p() then signals an error. The error does terminate the procedure. The message text and error
number set by the warning are replaced by the values set by the error, which are returned with the
error information.

**SIGNAL** is typically used within stored programs, but it is a MySQL extension that it is permitted outside
handler context. For example, if you invoke the *mysql* client program, you can enter any of these
statements at the prompt:

```sql
SIGNAL SQLSTATE '77777';
CREATE TRIGGER t_bi BEFORE INSERT ON t
  FOR EACH ROW SIGNAL SQLSTATE '77777';
CREATE EVENT e ON SCHEDULE EVERY 1 SECOND
  DO SIGNAL SQLSTATE '77777';
```

**SIGNAL** executes according to the following rules:

If the **SIGNAL** statement indicates a particular **SQLSTATE** value, that value is used to signal the
condition specified. Example:

```sql
CREATE PROCEDURE p (divisor INT)
BEGIN
  IF divisor = 0 THEN
    SIGNAL SQLSTATE '22012';
  END IF;
END;
```

If the **SIGNAL** statement uses a named condition, the condition must be declared in some scope that
applies to the **SIGNAL** statement, and must be defined using an **SQLSTATE** value, not a MySQL error
number. Example:

```sql
CREATE PROCEDURE p (divisor INT)
BEGIN
  DECLARE divide_by_zero CONDITION FOR SQLSTATE '22012';
  IF divisor = 0 THEN
    SIGNAL divide_by_zero;
  END IF;
END;
```

If the named condition does not exist in the scope of the **SIGNAL** statement, an **Undefined
CONDITION** error occurs.

If **SIGNAL** refers to a named condition that is defined with a MySQL error number rather than
an **SQLSTATE** value, a **SIGNAL/RESIGNAL** can only use a **CONDITION** defined with
**SQLSTATE** error occurs. The following statements cause that error because the named condition is
associated with a MySQL error number:

```sql
DECLARE no_such_table CONDITION FOR 1051;
SIGNAL no_such_table;
```

If a condition with a given name is declared multiple times in different scopes, the declaration with the
most local scope applies. Consider the following procedure:

```sql
CREATE PROCEDURE p (divisor INT)
BEGIN
  DECLARE my_error CONDITION FOR SQLSTATE '45000';
  IF divisor = 0 THEN
    BEGIN
      DECLARE my_error CONDITION FOR SQLSTATE '22012';
      SIGNAL my_error;
    END;
  END IF;
  SIGNAL my_error;
END;
```

If **divisor** is 0, the first **SIGNAL** statement executes. The innermost **my_error** condition declaration
applies, raising **SQLSTATE '22012'**.
If `divisor` is not 0, the second `SIGNAL` statement executes. The outermost `my_error` condition declaration applies, raising `SQLSTATE '45000'`.

For information about how the server chooses handlers when a condition occurs, see Section 13.6.7.6, “Scope Rules for Handlers”.

Signals can be raised within exception handlers:

```sql
CREATE PROCEDURE p ()
BEGIN
    DECLARE EXIT HANDLER FOR SQLEXCEPTION
    BEGIN
        SIGNAL SQLSTATE VALUE '99999'
        SET MESSAGE_TEXT = 'An error occurred';
    END;
    DROP TABLE no_such_table;
END;
CALL p();
```

`CALL p()` reaches the `DROP TABLE` statement. There is no table named `no_such_table`, so the error handler is activated. The error handler destroys the original error ("no such table") and makes a new error with `SQLSTATE '99999'` and message "An error occurred.”

### Signal Condition Information Items

The following table lists the names of diagnostics area condition information items that can be set in a `SIGNAL` (or `RESIGNAL`) statement. All items are standard SQL except `MYSQL_ERRNO`, which is a MySQL extension. For more information about these items see Section 13.6.7.7, “The MySQL Diagnostics Area”.

<table>
<thead>
<tr>
<th>Item Name</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLASS_ORIGIN</td>
<td>VARCHAR(64)</td>
</tr>
<tr>
<td>SUBCLASS_ORIGIN</td>
<td>VARCHAR(64)</td>
</tr>
<tr>
<td>CONSTRAINT_CATALOG</td>
<td>VARCHAR(64)</td>
</tr>
<tr>
<td>CONSTRAINT_SCHEMA</td>
<td>VARCHAR(64)</td>
</tr>
<tr>
<td>CONSTRAINT_NAME</td>
<td>VARCHAR(64)</td>
</tr>
<tr>
<td>CATALOG_NAME</td>
<td>VARCHAR(64)</td>
</tr>
<tr>
<td>SCHEMA_NAME</td>
<td>VARCHAR(64)</td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td>VARCHAR(64)</td>
</tr>
<tr>
<td>COLUMN_NAME</td>
<td>VARCHAR(64)</td>
</tr>
<tr>
<td>CURSOR_NAME</td>
<td>VARCHAR(64)</td>
</tr>
<tr>
<td>MESSAGE_TEXT</td>
<td>VARCHAR(128)</td>
</tr>
<tr>
<td>MYSQL_ERRNO</td>
<td>SMALLINT UNSIGNED</td>
</tr>
</tbody>
</table>

The character set for character items is UTF-8.

It is illegal to assign `NULL` to a condition information item in a `SIGNAL` statement.

A `SIGNAL` statement always specifies an `SQLSTATE` value, either directly, or indirectly by referring to a named condition defined with an `SQLSTATE` value. The first two characters of an `SQLSTATE` value are its class, and the class determines the default value for the condition information items:

- **Class = '00'** (success)
  
  Illegal. `SQLSTATE` values that begin with '00' indicate success and are not valid for `SIGNAL`.

- **Class = '01'** (warning)
  
  ```sql
  MESSAGE_TEXT = 'Unhandled user-defined warning condition';
  MYSQL_ERRNO = ER_SIGNAL_WARN
  ```

- **Class = '02'** (not found)
  
  ```sql
  MESSAGE_TEXT = 'Unhandled user-defined not found condition';
  MYSQL_ERRNO = ER_SIGNAL_NOT_FOUND
  ```

- **Class > '02'** (exception)
MESSAGE_TEXT = 'Unhandled user-defined exception condition';
MYSQL_ERRNO = ER_SIGNAL_EXCEPTION

For legal classes, the other condition information items are set as follows:

CLASS_ORIGIN = SUBCLASS_ORIGIN = '';
CONSTRAINT_CATALOG = CONSTRAINT_SCHEMA = CONSTRAINT_NAME = '';
CATALOG_NAME = SCHEMA_NAME = TABLE_NAME = COLUMN_NAME = '';
CURSOR_NAME = '';

The error values that are accessible after SIGNAL executes are the SQLSTATE value raised by the SIGNAL statement and the MESSAGE_TEXT and MYSQL_ERRNO items. These values are available from the C API:

• mysql_sqlstate() returns the SQLSTATE value.
• mysql_errno() returns the MYSQL_ERRNO value.
• mysql_error() returns the MESSAGE_TEXT value.

At the SQL level, the output from SHOW WARNINGS and SHOW ERRORS indicates the MYSQL_ERRNO and MESSAGE_TEXT values in the Code and Message columns.

To retrieve information from the diagnostics area, use the GET DIAGNOSTICS statement (see Section 13.6.7.3, "GET DIAGNOSTICS Statement"). For information about the diagnostics area, see Section 13.6.7.7, "The MySQL Diagnostics Area".

Effect of Signals on Handlers, Cursors, and Statements

Signals have different effects on statement execution depending on the signal class. The class determines how severe an error is. MySQL ignores the value of the sql_mode system variable; in particular, strict SQL mode does not matter. MySQL also ignores IGNORE: The intent of SIGNAL is to raise a user-generated error explicitly, so a signal is never ignored.

In the following descriptions, “unhandled” means that no handler for the signaled SQLSTATE value has been defined with DECLARE ... HANDLER.

• Class = '00' (success)
  Illegal. SQLSTATE values that begin with '00' indicate success and are not valid for SIGNAL.

• Class = '01' (warning)
  The value of the warning_count system variable goes up. SHOW WARNINGS shows the signal.
  SQLWARNING handlers catch the signal.
  Warnings cannot be returned from stored functions because the RETURN statement that causes the function to return clears the diagnostic area. The statement thus clears any warnings that may have been present there (and resets warning_count to 0).

• Class = '02' (not found)
  NOT_FOUND handlers catch the signal. There is no effect on cursors. If the signal is unhandled in a stored function, statements end.

• Class > '02' (exception)
  SQLEXCEPTION handlers catch the signal. If the signal is unhandled in a stored function, statements end.

• Class = '40'
  Treated as an ordinary exception.
13.6.7.6 Scope Rules for Handlers

A stored program may include handlers to be invoked when certain conditions occur within the program. The applicability of each handler depends on its location within the program definition and on the condition or conditions that it handles:

- A handler declared in a `BEGIN ... END` block is in scope only for the SQL statements following the handler declarations in the block. If the handler itself raises a condition, it cannot handle that condition, nor can any other handlers declared in the block. In the following example, handlers `H1` and `H2` are in scope for conditions raised by statements `stmt1` and `stmt2`. But neither `H1` nor `H2` are in scope for conditions raised in the body of `H1` or `H2`.

```
BEGIN -- outer block
  DECLARE EXIT HANDLER FOR ...; -- handler H1
  DECLARE EXIT HANDLER FOR ...; -- handler H2
  stmt1;
  stmt2;
END;
```

- A handler is in scope only for the block in which it is declared, and cannot be activated for conditions occurring outside that block. In the following example, handler `H1` is in scope for `stmt1` in the inner block, but not for `stmt2` in the outer block:

```
BEGIN -- outer block
  BEGIN -- inner block
    DECLARE EXIT HANDLER FOR ...; -- handler H1
    stmt1;
  END;
  stmt2;
END;
```

- A handler can be specific or general. A specific handler is for a MySQL error code, `SQLSTATE` value, or condition name. A general handler is for a condition in the `SQLWARNING`, `SQLEXCEPTION`, or `NOT FOUND` class. Condition specificity is related to condition precedence, as described later.

Multiple handlers can be declared in different scopes and with different specificities. For example, there might be a specific MySQL error code handler in an outer block, and a general `SQLWARNING` handler in an inner block. Or there might be handlers for a specific MySQL error code and the general `SQLWARNING` class in the same block.

Whether a handler is activated depends not only on its own scope and condition value, but on what other handlers are present. When a condition occurs in a stored program, the server searches for applicable handlers in the current scope (current `BEGIN ... END` block). If there are no applicable handlers, the search continues outward with the handlers in each successive containing scope (block). When the server finds one or more applicable handlers at a given scope, it chooses among them based on condition precedence:

- A MySQL error code handler takes precedence over an `SQLSTATE` value handler.

- An `SQLSTATE` value handler takes precedence over general `SQLWARNING`, `SQLEXCEPTION`, or `NOT FOUND` handlers.

- An `SQLEXCEPTION` handler takes precedence over an `SQLWARNING` handler.

- It is possible to have several applicable handlers with the same precedence. For example, a statement could generate multiple warnings with different error codes, for each of which an error-specific handler exists. In this case, the choice of which handler the server activates is nondeterministic, and may change depending on the circumstances under which the condition occurs.

One implication of the handler selection rules is that if multiple applicable handlers occur in different scopes, handlers with the most local scope take precedence over handlers in outer scopes, even over those for more specific conditions.
If there is no appropriate handler when a condition occurs, the action taken depends on the class of the condition:

- For **SQLEXCEPTION** conditions, the stored program terminates at the statement that raised the condition, as if there were an **EXIT** handler. If the program was called by another stored program, the calling program handles the condition using the handler selection rules applied to its own handlers.

- For **SQLWARNING** conditions, the program continues executing, as if there were a **CONTINUE** handler.

- For **NOT FOUND** conditions, if the condition was raised normally, the action is **CONTINUE**. If it was raised by **SIGNAL** or **RESIGNAL**, the action is **EXIT**.

The following examples demonstrate how MySQL applies the handler selection rules.

This procedure contains two handlers, one for the specific **SQLSTATE** value ('42S02') that occurs for attempts to drop a nonexistent table, and one for the general **SQLEXCEPTION** class:

```sql
CREATE PROCEDURE p1()
BEGIN
  DECLARE CONTINUE HANDLER FOR SQLSTATE '42S02'
  SELECT 'SQLSTATE handler was activated' AS msg;
  DECLARE CONTINUE HANDLER FOR SQLEXCEPTION
  SELECT 'SQLEXCEPTION handler was activated' AS msg;
  DROP TABLE test.t;
END;
```

Both handlers are declared in the same block and have the same scope. However, **SQLSTATE** handlers take precedence over **SQLEXCEPTION** handlers, so if the table `t` is nonexistent, the **DROP TABLE** statement raises a condition that activates the **SQLSTATE** handler:

```
mysql> CALL p1();
+---------------------------------+
| msg                            |
| SQLSTATE handler was activated |
+---------------------------------+
```

This procedure contains the same two handlers. But this time, the **DROP TABLE** statement and **SQLEXCEPTION** handler are in an inner block relative to the **SQLSTATE** handler:

```sql
CREATE PROCEDURE p2()
BEGIN -- outer block
  DECLARE CONTINUE HANDLER FOR SQLSTATE '42S02'
  SELECT 'SQLSTATE handler was activated' AS msg;
BEGIN -- inner block
  DECLARE CONTINUE HANDLER FOR SQLEXCEPTION
  SELECT 'SQLEXCEPTION handler was activated' AS msg;
  DROP TABLE test.t; -- occurs within inner block
END;
END;
```

In this case, the handler that is more local to where the condition occurs takes precedence. The **SQLEXCEPTION** handler activates, even though it is more general than the **SQLSTATE** handler:

```
mysql> CALL p2();
+---------------------------------+
| msg                            |
| SQLEXCEPTION handler was activated |
+---------------------------------+
```

In this procedure, one of the handlers is declared in a block inner to the scope of the **DROP TABLE** statement:
CREATE PROCEDURE p3()
BEGIN -- outer block
    DECLARE CONTINUE HANDLER FOR SQLEXCEPTION
    SELECT 'SQLEXCEPTION handler was activated' AS msg;
BEGIN -- inner block
    DECLARE CONTINUE HANDLER FOR SQLSTATE '42S02'
    SELECT 'SQLSTATE handler was activated' AS msg;
END;
DROP TABLE test.t; -- occurs within outer block
END;

Only the SQLEXCEPTION handler applies because the other one is not in scope for the condition raised by the DROP TABLE:

mysql> CALL p3();
+------------------------------------+
<table>
<thead>
<tr>
<th>msg</th>
</tr>
</thead>
<tbody>
<tr>
<td>SQLEXCEPTION handler was activated</td>
</tr>
</tbody>
</table>
+------------------------------------+

In this procedure, both handlers are declared in a block inner to the scope of the DROP TABLE statement:

CREATE PROCEDURE p4()
BEGIN -- outer block
BEGIN -- inner block
    DECLARE CONTINUE HANDLER FOR SQLEXCEPTION
    SELECT 'SQLEXCEPTION handler was activated' AS msg;
    DECLARE CONTINUE HANDLER FOR SQLSTATE '42S02'
    SELECT 'SQLSTATE handler was activated' AS msg;
END;
DROP TABLE test.t; -- occurs within outer block
END;

Neither handler applies because they are not in scope for the DROP TABLE. The condition raised by the statement goes unhandled and terminates the procedure with an error:

mysql> CALL p4();
ERROR 1051 (42S02): Unknown table 'test.t'

13.6.7.7 The MySQL Diagnostics Area

SQL statements produce diagnostic information that populates the diagnostics area. Standard SQL has a diagnostics area stack, containing a diagnostics area for each nested execution context. Standard SQL also supports GET STACKED DIAGNOSTICS syntax for referring to the second diagnostics area during condition handler execution.

The following discussion describes the structure of the diagnostics area in MySQL, the information items recognized by MySQL, how statements clear and set the diagnostics area, and how diagnostics areas are pushed to and popped from the stack.

- Diagnostics Area Structure
- Diagnostics Area Information Items
- How the Diagnostics Area is Cleared and Populated
- How the Diagnostics Area Stack Works
- Diagnostics Area-Related System Variables

Diagnostics Area Structure

The diagnostics area contains two kinds of information:
• Statement information, such as the number of conditions that occurred or the affected-rows count.

• Condition information, such as the error code and message. If a statement raises multiple conditions, this part of the diagnostics area has a condition area for each one. If a statement raises no conditions, this part of the diagnostics area is empty.

For a statement that produces three conditions, the diagnostics area contains statement and condition information like this:

```
Statement information:
  row count
  ... other statement information items ...
Condition area list:
  Condition area 1:
    error code for condition 1
    error message for condition 1
    ... other condition information items ...
  Condition area 2:
    error code for condition 2:
    error message for condition 2
    ... other condition information items ...
  Condition area 3:
    error code for condition 3
    error message for condition 3
    ... other condition information items ...
```

Diagnostics Area Information Items

The diagnostics area contains statement and condition information items. Numeric items are integers. The character set for character items is UTF-8. No item can be NULL. If a statement or condition item is not set by a statement that populates the diagnostics area, its value is 0 or the empty string, depending on the item data type.

The statement information part of the diagnostics area contains these items:

• **NUMBER**: An integer indicating the number of condition areas that have information.

• **ROW_COUNT**: An integer indicating the number of rows affected by the statement. **ROW_COUNT** has the same value as the **ROW_COUNT()** function (see Section 12.16, "Information Functions").

The condition information part of the diagnostics area contains a condition area for each condition. Condition areas are numbered from 1 to the value of the **NUMBER** statement condition item. If **NUMBER** is 0, there are no condition areas.

Each condition area contains the items in the following list. All items are standard SQL except **MYSQL_ERRNO**, which is a MySQL extension. The definitions apply for conditions generated other than by a signal (that is, by a **SIGNAL** or **RESIGNAL** statement). For nonsignal conditions, MySQL populates only those condition items not described as always empty. The effects of signals on the condition area are described later.

• **CLASS_ORIGIN**: A string containing the class of the **RETURNED_SQLSTATE** value. If the **RETURNED_SQLSTATE** value begins with a class value defined in SQL standards document ISO 9075-2 (section 24.1, **SQLSTATE**), **CLASS_ORIGIN** is 'ISO 9075'. Otherwise, **CLASS_ORIGIN** is 'MySQL'.

• **SUBCLASS_ORIGIN**: A string containing the subclass of the **RETURNED_SQLSTATE** value. If **CLASS_ORIGIN** is 'ISO 9075' or **RETURNED_SQLSTATE** ends with '000', **SUBCLASS_ORIGIN** is 'ISO 9075'. Otherwise, **SUBCLASS_ORIGIN** is 'MySQL'.

• **RETURNED_SQLSTATE**: A string that indicates the **SQLSTATE** value for the condition.

• **MESSAGE_TEXT**: A string that indicates the error message for the condition.

• **MYSQL_ERRNO**: An integer that indicates the MySQL error code for the condition.
**Condition Handling**

- **CONSTRAINT_CATALOG, CONSTRAINT_SCHEMA, CONSTRAINT_NAME**: Strings that indicate the catalog, schema, and name for a violated constraint. They are always empty.

- **CATALOG_NAME, SCHEMA_NAME, TABLE_NAME, COLUMN_NAME**: Strings that indicate the catalog, schema, table, and column related to the condition. They are always empty.

- **CURSOR_NAME**: A string that indicates the cursor name. This is always empty.

For the **RETURNED_SQLSTATE**, **MESSAGE_TEXT**, and **MYSQL_ERRNO** values for particular errors, see Server Error Message Reference.

If a **SIGNAL** (or **RESIGNAL**) statement populates the diagnostics area, its **SET** clause can assign to any condition information item except **RETURNED_SQLSTATE** any value that is legal for the item data type. **SIGNAL** also sets the **RETURNED_SQLSTATE** value, but not directly in its **SET** clause. That value comes from the **SIGNAL** statement **SQLSTATE** argument.

**SIGNAL** also sets statement information items. It sets **NUMBER** to 1. It sets **ROW_COUNT** to −1 for errors and 0 otherwise.

### How the Diagnostics Area is Cleared and Populated

Nondiagnostic SQL statements populate the diagnostics area automatically, and its contents can be set explicitly with the **SIGNAL** and **RESIGNAL** statements. The diagnostics area can be examined with **GET DIAGNOSTICS** to extract specific items, or with **SHOW WARNINGS** or **SHOW ERRORS** to see conditions or errors.

SQL statements clear and set the diagnostics area as follows:

- When the server starts executing a statement after parsing it, it clears the diagnostics area for nondiagnostic statements. Diagnostic statements do not clear the diagnostics area. These statements are diagnostic:
  - **GET DIAGNOSTICS**
  - **SHOW ERRORS**
  - **SHOW WARNINGS**

- If a statement raises a condition, the diagnostics area is cleared of conditions that belong to earlier statements. The exception is that conditions raised by **GET DIAGNOSTICS** and **RESIGNAL** are added to the diagnostics area without clearing it.

Thus, even a statement that does not normally clear the diagnostics area when it begins executing clears it if the statement raises a condition.

The following example shows the effect of various statements on the diagnostics area, using **SHOW WARNINGS** to display information about conditions stored there.

This **DROP TABLE** statement clears the diagnostics area and populates it when the condition occurs:

```sql
mysql> DROP TABLE IF EXISTS test.no_such_table;
Query OK, 0 rows affected, 1 warning (0.01 sec)

mysql> SHOW WARNINGS;
+-------+------+------------------------------------+
| Level | Code | Message                            |
+-------+------+------------------------------------+
| Note  | 1051 | Unknown table 'test.no_such_table' |
+-------+------+------------------------------------+
1 row in set (0.00 sec)
```

This **SET** statement generates an error, so it clears and populates the diagnostics area:

```sql
mysql> SET @x = @@x;
ERROR 1193 (HY000): Unknown system variable 'x'
```
Condition Handling

mysql> SHOW WARNINGS;
+-------+------+-----------------------------+
| Level | Code | Message                     |
+-------+------+-----------------------------+
| Error | 1193 | Unknown system variable 'x' |
+-------+------+-----------------------------+
1 row in set (0.00 sec)

The previous SET statement produced a single condition, so 1 is the only valid condition number for GET DIAGNOSTICS at this point. The following statement uses a condition number of 2, which produces a warning that is added to the diagnostics area without clearing it:

mysql> GET DIAGNOSTICS CONDITION 2 @p = MESSAGE_TEXT;
Query OK, 0 rows affected, 1 warning (0.00 sec)

mysql> SHOW WARNINGS;
+-------+------+------------------------------+
| Level | Code | Message                      |
+-------+------+------------------------------+
| Error | 1193 | Unknown system variable 'xx' |
| Error | 1753 | Invalid condition number     |
+-------+------+------------------------------+
2 rows in set (0.00 sec)

Now there are two conditions in the diagnostics area, so the same GET DIAGNOSTICS statement succeeds:

mysql> GET DIAGNOSTICS CONDITION 2 @p = MESSAGE_TEXT;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @p;
+--------------------------+
| @p                       |
+--------------------------+
| Invalid condition number |
+--------------------------+
1 row in set (0.01 sec)

How the Diagnostics Area Stack Works

When a push to the diagnostics area stack occurs, the first (current) diagnostics area becomes the second (stacked) diagnostics area and a new current diagnostics area is created as a copy of it. Diagnostics areas are pushed to and popped from the stack under the following circumstances:

• Execution of a stored program

A push occurs before the program executes and a pop occurs afterward. If the stored program ends while handlers are executing, there can be more than one diagnostics area to pop; this occurs due to an exception for which there are no appropriate handlers or due to RETURN in the handler.

Any warning or error conditions in the popped diagnostics areas then are added to the current diagnostics area, except that, for triggers, only errors are added. When the stored program ends, the caller sees these conditions in its current diagnostics area.

• Execution of a condition handler within a stored program

When a push occurs as a result of condition handler activation, the stacked diagnostics area is the area that was current within the stored program prior to the push. The new now-current diagnostics area is the handler's current diagnostics area. GET [CURRENT] DIAGNOSTICS and GET STACKED DIAGNOSTICS can be used within the handler to access the contents of the current (handler) and stacked (stored program) diagnostics areas. Initially, they return the same result, but statements executing within the handler modify the current diagnostics area, clearing and setting its contents according to the normal rules (see How the Diagnostics Area is Cleared and Populated). The stacked diagnostics area cannot be modified by statements executing within the handler except RESIGNAL.
Restrictions on Condition Handling

If the handler executes successfully, the current (handler) diagnostics area is popped and the stacked (stored program) diagnostics area again becomes the current diagnostics area. Conditions added to the handler diagnostics area during handler execution are added to the current diagnostics area.

- Execution of RESIGNAL

The RESIGNAL statement passes on the error condition information that is available during execution of a condition handler within a compound statement inside a stored program. RESIGNAL may change some or all information before passing it on, modifying the diagnostics stack as described in Section 13.6.7.4, “RESIGNAL Statement”.

Diagnostics Area-Related System Variables

Certain system variables control or are related to some aspects of the diagnostics area:

- max_error_count controls the number of condition areas in the diagnostics area. If more conditions than this occur, MySQL silently discards information for the excess conditions. (Conditions added by RESIGNAL are always added, with older conditions being discarded as necessary to make room.)

- warning_count indicates the number of conditions that occurred. This includes errors, warnings, and notes. Normally, NUMBER and warning_count are the same. However, as the number of conditions generated exceeds max_error_count, the value of warning_count continues to rise whereas NUMBER remains capped at max_error_count because no additional conditions are stored in the diagnostics area.

- error_count indicates the number of errors that occurred. This value includes “not found” and exception conditions, but excludes warnings and notes. Like warning_count, its value can exceed max_error_count.

- If the sql_notes system variable is set to 0, notes are not stored and do not increment warning_count.

Example: If max_error_count is 10, the diagnostics area can contain a maximum of 10 condition areas. Suppose that a statement raises 20 conditions, 12 of which are errors. In that case, the diagnostics area contains the first 10 conditions, NUMBER is 10, warning_count is 20, and error_count is 12.

Changes to the value of max_error_count have no effect until the next attempt to modify the diagnostics area. If the diagnostics area contains 10 condition areas and max_error_count is set to 5, that has no immediate effect on the size or content of the diagnostics area.

13.6.7.8 Condition Handling and OUT or INOUT Parameters

If a stored procedure exits with an unhandled exception, modified values of OUT and INOUT parameters are not propagated back to the caller.

If an exception is handled by a CONTINUE or EXIT handler that contains a RESIGNAL statement, execution of RESIGNAL pops the Diagnostics Area stack, thus signalling the exception (that is, the information that existed before entry into the handler). If the exception is an error, the values of OUT and INOUT parameters are not propagated back to the caller.

13.6.8 Restrictions on Condition Handling

SIGNAL, RESIGNAL, and GET DIAGNOSTICS are not permissible as prepared statements. For example, this statement is invalid:

PREPARE stmt1 FROM "SIGNAL SQLSTATE "02000";"
**13.7 Database Administration Statements**

**13.7.1 Account Management Statements**

MySQL account information is stored in the tables of the `mysql` system schema. This database and the access control system are discussed extensively in Chapter 5, *MySQL Server Administration*, which you should consult for additional details.

---

**Important**

Some MySQL releases introduce changes to the grant tables to add new privileges or features. To make sure that you can take advantage of any new capabilities, update your grant tables to the current structure whenever you upgrade MySQL. See Section 2.11, “Upgrading MySQL”.

When the `read_only` system variable is enabled, account-management statements require the `CONNECTION_ADMIN` privilege (or the deprecated `SUPER` privilege), in addition to any other required privileges. This is because they modify tables in the `mysql` system schema.

Account management statements are atomic and crash safe. For more information, see Section 13.1.1, “Atomic Data Definition Statement Support”.

---

**13.7.1.1 ALTER USER Statement**

```
ALTER USER [IF EXISTS] [IF EXISTS] USER() user_func_auth_option

ALTER USER [IF EXISTS] [IF EXISTS] user [auth_option] [, user [auth_option]] ...
[REQUIRE {NONE | tls_option [[AND] tls_option] ...}]
[WITH resource_option [resource_option] ...]
[COMMENT 'comment_string' | ATTRIBUTE 'json_object']

ALTER USER DEFAULT ROLE
{NONE | ALL | role [, role] ...}
```

user:

(see Section 6.2.4, “Specifying Account Names”)

auth_option:

- IDENTIFIED BY "auth_string"
  [REPLACE 'current_auth_string']
  [RETAIN CURRENT PASSWORD]
- IDENTIFIED BY RANDOM PASSWORD
  [REPLACE 'current_auth_string']
  [RETAIN CURRENT PASSWORD]
- IDENTIFIED WITH auth_plugin
- IDENTIFIED WITH auth_plugin BY "auth_string"
  [REPLACE 'current_auth_string']
  [RETAIN CURRENT PASSWORD]
The `ALTER USER` statement modifies MySQL accounts. It enables authentication, role, SSL/TLS, resource-limit, and password-management properties to be modified for existing accounts. It can also be used to lock and unlock accounts.

In most cases, `ALTER USER` requires the global `CREATE USER` privilege, or the `UPDATE` privilege for the `mysql` system schema. The exceptions are:

- Any client who connects to the server using a nonanonymous account can change the password for that account. (In particular, you can change your own password.) To see which account the server authenticated you as, invoke the `CURRENT_USER()` function:

```sql
SELECT CURRENT_USER();
```

- For `DEFAULT ROLE` syntax, `ALTER USER` requires these privileges:
  - Setting the default roles for another user requires the global `CREATE USER` privilege, or the `UPDATE` privilege for the `mysql.default_roles` system table.
  - Setting the default roles for yourself requires no special privileges, as long as the roles you want as the default have been granted to you.

- Statements that modify secondary passwords require these privileges:
  - The `APPLICATION_PASSWORD_ADMIN` privilege is required to use the `RETAIN CURRENT PASSWORD` or `DISCARD OLD PASSWORD` clause for `ALTER USER` statements that apply to your own account. The privilege is required to manipulate your own secondary password because most users require only one password.
If an account is to be permitted to manipulate secondary passwords for all accounts, it requires the `CREATE USER` privilege rather than `APPLICATION_PASSWORD_ADMIN`.

When the `read_only` system variable is enabled, `ALTER USER` additionally requires the `CONNECTION_ADMIN` privilege (or the deprecated `SUPER` privilege).

By default, an error occurs if you try to modify a user that does not exist. If the `IF EXISTS` clause is given, the statement produces a warning for each named user that does not exist, rather than an error.

Important

Under some circumstances, `ALTER USER` may be recorded in server logs or on the client side in a history file such as `~/.mysql_history`, which means that cleartext passwords may be read by anyone having read access to that information. For information about the conditions under which this occurs for the server logs and how to control it, see Section 6.1.2.3, “Passwords and Logging”. For similar information about client-side logging, see Section 4.5.1.3, “mysql Client Logging”.

There are several aspects to the `ALTER USER` statement, described under the following topics:

- **ALTER USER Overview**
- **ALTER USER Authentication Options**
- **ALTER USER Role Options**
- **ALTER USER SSL/TLS Options**
- **ALTER USER Resource-Limit Options**
- **ALTER USER Password-Management Options**
- **ALTER USER Account-Locking Options**
- **ALTER USER Binary Logging**

**ALTER USER Overview**

For each affected account, `ALTER USER` modifies the corresponding row in the `mysql.user` system table to reflect the properties specified in the statement. Unspecified properties retain their current values.

Each account name uses the format described in Section 6.2.4, “Specifying Account Names”. The host name part of the account name, if omitted, defaults to ‘%’. It is also possible to specify `CURRENT_USER` or `CURRENT_USER()` to refer to the account associated with the current session.

For one syntax only, the account may be specified with the `USER()` function:

```
ALTER USER USER() IDENTIFIED BY 'auth_string';
```

This syntax enables changing your own password without naming your account literally. (The syntax also supports the `REPLACE`, `RETAIN CURRENT PASSWORD`, and `DISCARD OLD PASSWORD` clauses described at `ALTER USER Authentication Options`.)

MySQL 8.0.21 and later supports user comments and user attributes, as described in Section 13.7.1.3, “CREATE USER Statement”. These can be modified employing `ALTER USER` by means of the `COMMENT` and `ATTRIBUTE` options, respectively. You cannot specify both options in the same `ALTER USER` statement; attempting to do so results in a syntax error.

The user comment and user attribute are stored in the `INFORMATION_SCHEMA.USER_ATTRIBUTES` table as a JSON object; the user comment is stored as the value for a `comment` key in the `ATTRIBUTE`
column of this table, as shown later in this discussion. The COMMENT text can be any arbitrary quoted text, and replaces any existing user comment. The ATTRIBUTE value must be the valid string representation of a JSON object. This is merged with any existing user attribute as if the JSON_MERGE_PATCH() function had been used on the existing user attribute and the new one; for any keys that are re-used, the new value overwrites the old one, as shown here:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.USER_ATTRIBUTES
   -> WHERE USER='bill' AND HOST='localhost';
+-----+----------+----------------------------------------------+
| USER | HOST     | ATTRIBUTE                                   |
+-----+----------+----------------------------------------------+
| bill | localhost| "foo": "bar"                                |
+-----+----------+----------------------------------------------+
1 row in set (0.11 sec)
```

mysql> ALTER USER 'bill'@'localhost' ATTRIBUTE '{"baz": "faz", "foo": "moo"}';
Query OK, 0 rows affected (0.22 sec)

```
mysql> SELECT * FROM INFORMATION_SCHEMA.USER_ATTRIBUTES
   -> WHERE USER='bill' AND HOST='localhost';
+-----+----------+----------------------------------------------+
| USER | HOST     | ATTRIBUTE                                   |
+-----+----------+----------------------------------------------+
| bill | localhost| "baz": "faz", "foo": "moo"                  |
+-----+----------+----------------------------------------------+
1 row in set (0.00 sec)
```

To remove a key and its value from the user attribute, set the key to JSON null (must be lowercase and unquoted), like this:

```
mysql> ALTER USER 'bill'@'localhost' ATTRIBUTE '{"foo": null}';
Query OK, 0 rows affected (0.08 sec)
```

```
mysql> SELECT * FROM INFORMATION_SCHEMA.USER_ATTRIBUTES
   -> WHERE USER='bill' AND HOST='localhost';
+-----+----------+----------------------------------------------+
| USER | HOST     | ATTRIBUTE                                   |
+-----+----------+----------------------------------------------+
| bill | localhost| "baz": "faz", "comment": "Something about Bill" |
+-----+----------+----------------------------------------------+
1 row in set (0.00 sec)
```

To set an existing user comment to an empty string, use ALTER USER ... COMMENT ''. This leaves an empty comment value in the USER_ATTRIBUTES table; to remove the user comment completely, use ALTER USER ... ATTRIBUTE ... with the value for the column key set to JSON null (unquoted, in lower case). This is illustrated by the following sequence of SQL statements:

```
mysql> ALTER USER 'bill'@'localhost' COMMENT 'Something about Bill';
Query OK, 0 rows affected (0.06 sec)
```

```
mysql> SELECT * FROM INFORMATION_SCHEMA.USER_ATTRIBUTES
   -> WHERE USER='bill' AND HOST='localhost';
+-----+----------+----------------------------------------------+
| USER | HOST     | ATTRIBUTE                                   |
+-----+----------+----------------------------------------------+
| bill | localhost| "baz": "faz", "comment": "Something about Bill" |
+-----+----------+----------------------------------------------+
1 row in set (0.00 sec)
```

```
mysql> ALTER USER 'bill'@'localhost' COMMENT '';
Query OK, 0 rows affected (0.09 sec)
```

```
mysql> SELECT * FROM INFORMATION_SCHEMA.USER_ATTRIBUTES
   -> WHERE USER='bill' AND HOST='localhost';
+-----+----------+----------------------------------------------+
| USER | HOST     | ATTRIBUTE                                   |
+-----+----------+----------------------------------------------+
| bill | localhost| "baz": "faz", "comment": ""                  |
+-----+----------+----------------------------------------------+
1 row in set (0.00 sec)
```
For `ALTER USER` syntax that permits an `auth_option` value to follow a `user` value, `auth_option` indicates how the account authenticates by specifying an account authentication plugin, credentials (for example, a password), or both. Each `auth_option` value applies only to the account named immediately preceding it.

Following the `user` specifications, the statement may include options for SSL/TLS, resource-limit, password-management, and locking properties. All such options are `global` to the statement and apply to all accounts named in the statement.

Example: Change an account's password and expire it. As a result, the user must connect with the named password and choose a new one at the next connection:

```
ALTER USER 'jeffrey'@'localhost'
IDENTIFIED BY 'new_password' PASSWORD EXPIRE;
```

Example: Modify an account to use the `caching_sha2_password` authentication plugin and the given password. Require that a new password be chosen every 180 days, and enable failed-login tracking, such that three consecutive incorrect passwords cause temporary account locking for two days:

```
ALTER USER 'jeffrey'@'localhost'
IDENTIFIED WITH caching_sha2_password BY 'new_password'
PASSWORD EXPIRE INTERVAL 180 DAY
FAILED_LOGIN_ATTEMPTS 3 PASSWORD_LOCK_TIME 2;
```

Example: Lock or unlock an account:

```
ALTER USER 'jeffrey'@'localhost' ACCOUNT LOCK;
ALTER USER 'jeffrey'@'localhost' ACCOUNT UNLOCK;
```

Example: Require an account to connect using SSL and establish a limit of 20 connections per hour:

```
ALTER USER 'jeffrey'@'localhost'
REQUIRE SSL WITH MAX_USER_CONNECTIONS 20;
```

Example: Alter multiple accounts, specifying some per-account properties and some global properties:

```
ALTER USER
'jeffrey'@'localhost'
IDENTIFIED BY 'jeffrey_new_password',
'jeanne'@'localhost',
'josh'@'localhost'
IDENTIFIED BY 'josh_new_password'
REPLACE 'josh_current_password'
REQUIRE SSL WITH MAX_USER_CONNECTIONS 2
PASSWORD_HISTORY 5;
```

The `IDENTIFIED BY` value following `jeffrey` applies only to its immediately preceding account, so it changes the password to `'jeffrey_new_password'` only for `jeffrey`. For `jeanne`, there is no per-account value (thus leaving the password unchanged). For `josh`, `IDENTIFIED BY` establishes a new password (`'josh_new_password'`), `REPLACE` is specified to verify that the user issuing the `ALTER USER` statement knows the current password (`'josh_current_password'`), and that current
password is also retained as the account secondary password. (As a result, josh can connect with either the primary or secondary password.)

The remaining properties apply globally to all accounts named in the statement, so for both accounts:

- Connections are required to use SSL.
- The account can be used for a maximum of two simultaneous connections.
- Password changes cannot reuse any of the five most recent passwords.

Example: Discard the secondary password for josh, leaving the account with only its primary password:

```sql
ALTER USER 'josh'@'localhost' DISCARD OLD PASSWORD;
```

In the absence of a particular type of option, the account remains unchanged in that respect. For example, with no locking option, the locking state of the account is not changed.

**ALTER USER Authentication Options**

An account name may be followed by an `auth_option` authentication option that specifies the account authentication plugin, credentials, or both. It may also include a password-verification clause that specifies the account current password to be replaced, and clauses that manage whether an account has a secondary password.

**Note**

Clauses for random password generation, password verification, and secondary passwords apply only to accounts that use an authentication plugin that stores credentials internally to MySQL. For accounts that use a plugin that performs authentication against a credentials system that is external to MySQL, password management must be handled externally against that system as well. For more information about internal credentials storage, see Section 6.2.15, “Password Management”.

- `auth_plugin` names an authentication plugin. The plugin name can be a quoted string literal or an unquoted name. Plugin names are stored in the `plugin` column of the `mysql.user` system table.

  For `auth_option` syntax that does not specify an authentication plugin, the default plugin is indicated by the value of the `default_authentication_plugin` system variable. For descriptions of each plugin, see Section 6.4.1, “Authentication Plugins”.

- Credentials that are stored internally are stored in the `mysql.user` system table. An `auth_string` value or `RANDOM PASSWORD` specifies account credentials, either as a cleartext (unencrypted) string or hashed in the format expected by the authentication plugin associated with the account, respectively:

  - For syntax that uses `BY 'auth_string'`, the string is cleartext and is passed to the authentication plugin for possible hashing. The result returned by the plugin is stored in the `mysql.user` table. A plugin may use the value as specified, in which case no hashing occurs.
  
  - For syntax that uses `BY RANDOM PASSWORD`, MySQL generates a random password and as cleartext and passes it to the authentication plugin for possible hashing. The result returned by the plugin is stored in the `mysql.user` table. A plugin may use the value as specified, in which case no hashing occurs.

  Randomly generated passwords are available as of MySQL 8.0.18 and have the characteristics described in Random Password Generation.

  - For syntax that uses `AS 'auth_string'`, the string is assumed to be already in the format the authentication plugin requires, and is stored as is in the `mysql.user` table. If a plugin requires a
hashed value, the value must be already hashed in a format appropriate for the plugin; otherwise, the value cannot be used by the plugin and correct authentication of client connections does not occur.

As of MySQL 8.0.17, a hashed string can be either a string literal or a hexadecimal value. The latter corresponds to the type of value displayed by \texttt{SHOW CREATE USER} for password hashes containing unprintable characters when the \texttt{print_identified_with_as_hex} system variable is enabled.

- If an authentication plugin performs no hashing of the authentication string, the \texttt{BY 'auth_string'} and \texttt{AS 'auth_string'} clauses have the same effect: The authentication string is stored as is in the \texttt{mysql.user} system table.

- The \texttt{REPLACE 'current_auth_string'} clause performs password verification and is available as of MySQL 8.0.13. If given:
  - \texttt{REPLACE} specifies the account current password to be replaced, as a cleartext (unencrypted) string.
  - The clause must be given if password changes for the account are required to specify the current password, as verification that the user attempting to make the change actually knows the current password.
  - The clause is optional if password changes for the account may but need not specify the current password.
  - The statement fails if the clause is given but does not match the current password, even if the clause is optional.
  - \texttt{REPLACE} can be specified only when changing the account password for the current user.

For more information about password verification by specifying the current password, see Section 6.2.15, “Password Management”.

- The \texttt{RETAIN CURRENT PASSWORD} and \texttt{DISCARD OLD PASSWORD} clauses implement dual-password capability and are available as of MySQL 8.0.14. Both are optional, but if given, have the following effects:
  - \texttt{RETAIN CURRENT PASSWORD} retains an account current password as its secondary password, replacing any existing secondary password. The new password becomes the primary password, but clients can use the account to connect to the server using either the primary or secondary password. (Exception: If the new password specified by the \texttt{ALTER USER} statement is empty, the secondary password becomes empty as well, even if \texttt{RETAIN CURRENT PASSWORD} is given.)
  - \texttt{DISCARD OLD PASSWORD} discards the secondary password, if one exists. The account retains only its primary password, and clients can use the account to connect to the server only with the primary password.

For more information about use of dual passwords, see Section 6.2.15, “Password Management”.

\texttt{ALTER USER} permits these \texttt{auth_option} syntaxes:
• IDENTIFIED BY 'auth_string' [REPLACE 'current_auth_string'] [RETAIN CURRENT PASSWORD]

Sets the account authentication plugin to the default plugin, passes the cleartext 'auth_string' value to the plugin for possible hashing, and stores the result in the account row in the `mysql.user` system table.

The REPLACE clause, if given, specifies the account current password, as described previously in this section.

The RETAIN CURRENT PASSWORD clause, if given, causes the account current password to be retained as its secondary password, as described previously in this section.

• IDENTIFIED BY RANDOM PASSWORD [REPLACE 'current_auth_string'] [RETAIN CURRENT PASSWORD]

Sets the account authentication plugin to the default plugin, generates a random password, passes the cleartext password value to the plugin for possible hashing, and stores the result in the account row in the `mysql.user` system table. The statement also returns the cleartext password in a result set to make it available to the user or application executing the statement. For details about the result set and characteristics of randomly generated passwords, see Random Password Generation.

The REPLACE clause, if given, specifies the account current password, as described previously in this section.

The RETAIN CURRENT PASSWORD clause, if given, causes the account current password to be retained as its secondary password, as described previously in this section.

• IDENTIFIED WITH auth_plugin

Sets the account authentication plugin to auth_plugin, clears the credentials to the empty string (the credentials are associated with the old authentication plugin, not the new one), and stores the result in the account row in the `mysql.user` system table.

In addition, the password is marked expired. The user must choose a new one when next connecting.

• IDENTIFIED WITH auth_plugin BY 'auth_string' [REPLACE 'current_auth_string'] [RETAIN CURRENT PASSWORD]

Sets the account authentication plugin to auth_plugin, passes the cleartext 'auth_string' value to the plugin for possible hashing, and stores the result in the account row in the `mysql.user` system table.

The REPLACE clause, if given, specifies the account current password, as described previously in this section.

The RETAIN CURRENT PASSWORD clause, if given, causes the account current password to be retained as its secondary password, as described previously in this section.

• IDENTIFIED WITH auth_plugin BY RANDOM PASSWORD [REPLACE 'current_auth_string'] [RETAIN CURRENT PASSWORD]

Sets the account authentication plugin to auth_plugin, generates a random password, passes the cleartext password value to the plugin for possible hashing, and stores the result in the account row in the `mysql.user` system table. The statement also returns the cleartext password in a result set to make it available to the user or application executing the statement. For details about the result set and characteristics of randomly generated passwords, see Random Password Generation.

The REPLACE clause, if given, specifies the account current password, as described previously in this section.
The `RETAIN CURRENT PASSWORD` clause, if given, causes the account current password to be retained as its secondary password, as described previously in this section.

- **IDENTIFIED WITH auth_plugin AS 'auth_string'**

Sets the account authentication plugin to `auth_plugin` and stores the `auth_string` value as is in the `mysql.user` account row. If the plugin requires a hashed string, the string is assumed to be already hashed in the format the plugin requires.

- **DISCARD OLD PASSWORD**

Discards the account secondary password, if there is one, as described previously in this section.

Example: Specify the password as cleartext; the default plugin is used:

```sql
ALTER USER 'jeffrey'@'localhost'
  IDENTIFIED BY 'password';
```

Example: Specify the authentication plugin, along with a cleartext password value:

```sql
ALTER USER 'jeffrey'@'localhost'
  IDENTIFIED WITH mysql_native_password
  BY 'password';
```

Example: Like the preceding example, but in addition, specify the current password as a cleartext value to satisfy any account requirement that the user making the change knows that password:

```sql
ALTER USER 'jeffrey'@'localhost'
  IDENTIFIED WITH mysql_native_password
  BY 'password'
  REPLACE 'current_password';
```

The preceding statement fails unless the current user is `jeffrey` because `REPLACE` is permitted only for changes to the current user's password.

Example: Establish a new primary password and retain the existing password as the secondary password:

```sql
ALTER USER 'jeffrey'@'localhost'
  IDENTIFIED BY 'new_password'
  RETAIN CURRENT PASSWORD;
```

Example: Discard the secondary password, leaving the account with only its primary password:

```sql
ALTER USER 'jeffrey'@'localhost' DISCARD OLD PASSWORD;
```

Example: Specify the authentication plugin, along with a hashed password value:

```sql
ALTER USER 'jeffrey'@'localhost'
  IDENTIFIED WITH mysql_native_password
  AS '*6C8989366EAF75BB670AD8EA7A7FC1176A95CEF4';
```

For additional information about setting passwords and authentication plugins, see Section 6.2.14, “Assigning Account Passwords”, and Section 6.2.17, “Pluggable Authentication”.

**ALTER USER Role Options**

`ALTER USER ... DEFAULT ROLE` defines which roles become active when the user connects to the server and authenticates, or when the user executes the `SET ROLE DEFAULT` statement during a session.

`ALTER USER ... DEFAULT ROLE` is alternative syntax for `SET DEFAULT ROLE` (see Section 13.7.1.9, “SET DEFAULT ROLE Statement”). However, `ALTER USER` can set the default for only a single user, whereas `SET DEFAULT ROLE` can set the default for multiple users. On the other hand, you can specify `CURRENT_USER` as the user name for the `ALTER USER` statement, whereas you cannot for `SET DEFAULT ROLE`. 
Each user account name uses the format described previously.

Each role name uses the format described in Section 6.2.5, “Specifying Role Names”. For example:

```
ALTER USER 'joe'@'10.0.0.1' DEFAULT ROLE administrator, developer;
```

The host name part of the role name, if omitted, defaults to '%'.

The clause following the DEFAULT ROLE keywords permits these values:

- **NONE**: Set the default to NONE (no roles).
- **ALL**: Set the default to all roles granted to the account.
- **role [, role ] ...**: Set the default to the named roles, which must exist and be granted to the account at the time ALTER USER ... DEFAULT ROLE is executed.

### ALTER USER SSL/TLS Options

MySQL can check X.509 certificate attributes in addition to the usual authentication that is based on the user name and credentials. For background information on the use of SSL/TLS with MySQL, see Section 6.3, “Using Encrypted Connections”.

To specify SSL/TLS-related options for a MySQL account, use a REQUIRE clause that specifies one or more tls_option values.

Order of REQUIRE options does not matter, but no option can be specified twice. The AND keyword is optional between REQUIRE options.

**ALTER USER** permits these tls_option values:

- **NONE**
  
  Indicates that all accounts named by the statement have no SSL or X.509 requirements. Unencrypted connections are permitted if the user name and password are valid. Encrypted connections can be used, at the client's option, if the client has the proper certificate and key files.

  ```
  ALTER USER 'jeffrey'@'localhost' REQUIRE NONE;
  ```

  Clients attempt to establish a secure connection by default. For clients that have REQUIRE NONE, the connection attempt falls back to an unencrypted connection if a secure connection cannot be established. To require an encrypted connection, a client need specify only the `--ssl-mode=REQUIRED` option; the connection attempt fails if a secure connection cannot be established.

- **SSL**
  
  Tells the server to permit only encrypted connections for all accounts named by the statement.

  ```
  ALTER USER 'jeffrey'@'localhost' REQUIRE SSL;
  ```

  Clients attempt to establish a secure connection by default. For accounts that have REQUIRE SSL, the connection attempt fails if a secure connection cannot be established.

- **X509**
  
  For all accounts named by the statement, requires that clients present a valid certificate, but the exact certificate, issuer, and subject do not matter. The only requirement is that it should be possible to verify its signature with one of the CA certificates. Use of X.509 certificates always implies encryption, so the SSL option is unnecessary in this case.

  ```
  ALTER USER 'jeffrey'@'localhost' REQUIRE X509;
  ```

  For accounts with REQUIRE X509, clients must specify the `--ssl-key` and `--ssl-cert` options to connect. (It is recommended but not required that `--ssl-ca` also be specified so that the public
Account Management Statements

certificate provided by the server can be verified.) This is true for ISSUER and SUBJECT as well because those REQUIRE options imply the requirements of X509.

- **ISSUER 'issuer'**

For all accounts named by the statement, requires that clients present a valid X.509 certificate issued by CA 'issuer'. If a client presents a certificate that is valid but has a different issuer, the server rejects the connection. Use of X.509 certificates always implies encryption, so the SSL option is unnecessary in this case.

```
ALTER USER 'jeffrey'@'localhost'
  REQUIRE ISSUER '/C=SE/ST=Stockholm/L=Stockholm/
  O=MySQL/CN=CA/emailAddress=ca@example.com';
```

Because ISSUER implies the requirements of X509, clients must specify the --ssl-key and --ssl-cert options to connect. (It is recommended but not required that --ssl-ca also be specified so that the public certificate provided by the server can be verified.)

- **SUBJECT 'subject'**

For all accounts named by the statement, requires that clients present a valid X.509 certificate containing the subject subject. If a client presents a certificate that is valid but has a different subject, the server rejects the connection. Use of X.509 certificates always implies encryption, so the SSL option is unnecessary in this case.

```
ALTER USER 'jeffrey'@'localhost'
  REQUIRE SUBJECT '/C=SE/ST=Stockholm/L=Stockholm/
  O=MySQL demo client certificate/
  CN=client/emailAddress=client@example.com';
```

MySQL does a simple string comparison of the 'subject' value to the value in the certificate, so lettercase and component ordering must be given exactly as present in the certificate.

Because SUBJECT implies the requirements of X509, clients must specify the --ssl-key and --ssl-cert options to connect. (It is recommended but not required that --ssl-ca also be specified so that the public certificate provided by the server can be verified.)

- **CIPHER 'cipher'**

For all accounts named by the statement, requires a specific cipher method for encrypting connections. This option is needed to ensure that ciphers and key lengths of sufficient strength are used. Encryption can be weak if old algorithms using short encryption keys are used.

```
ALTER USER 'jeffrey'@'localhost'
  REQUIRE CIPHER 'EDH-RSA-DES-CBC3-SHA';
```

The SUBJECT, ISSUER, and CIPHER options can be combined in the REQUIRE clause:

```
ALTER USER 'jeffrey'@'localhost'
  REQUIRE SUBJECT '/C=SE/ST=Stockholm/L=Stockholm/
  O=MySQL demo client certificate/
  CN=client/emailAddress=client@example.com'
  AND ISSUER '/C=SE/ST=Stockholm/L=Stockholm/
  O=MySQL/CN=CA/emailAddress=ca@example.com'
  AND CIPHER 'EDH-RSA-DES-CBC3-SHA';
```

**ALTER USER Resource-Limit Options**

It is possible to place limits on use of server resources by an account, as discussed in Section 6.2.20, “Setting Account Resource Limits”. To do so, use a WITH clause that specifies one or more resource_option values.

Order of WITH options does not matter, except that if a given resource limit is specified multiple times, the last instance takes precedence.
ALTER USER permits these resource_option values:

• MAX QUERIES PER HOUR count, MAX UPDATES PER HOUR count, MAX CONNECTIONS PER HOUR count

For all accounts named by the statement, these options restrict how many queries, updates, and connections to the server are permitted to each account during any given one-hour period. If count is 0 (the default), this means that there is no limitation for the account.

• MAX USER CONNECTIONS count

For all accounts named by the statement, restricts the maximum number of simultaneous connections to the server by each account. A nonzero count specifies the limit for the account explicitly. If count is 0 (the default), the server determines the number of simultaneous connections for the account from the global value of the max_user_connections system variable. If max_user_connections is also zero, there is no limit for the account.

Example:

ALTER USER 'jeffrey'@'localhost'
WITH MAX QUERIES PER HOUR 500 MAX UPDATES PER HOUR 100;

ALTER USER Password-Management Options

ALTER USER supports several password_option values for password management:

• Password expiration options: You can expire an account password manually and establish its password expiration policy. Policy options do not expire the password. Instead, they determine how the server applies automatic expiration to the account based on password age, which is assessed from the date and time of the most recent account password change.

• Password reuse options: You can restrict password reuse based on number of password changes, time elapsed, or both.

• Password verification-required options: You can indicate whether attempts to change an account password must specify the current password, as verification that the user attempting to make the change actually knows the current password.

• Incorrect-password failed-login tracking options: You can cause the server to track failed login attempts and temporarily lock accounts for which too many consecutive incorrect passwords are given. The required number of failures and the lock time are configurable.

This section describes the syntax for password-management options. For information about establishing policy for password management, see Section 6.2.15, “Password Management”.

If multiple password-management options of a given type are specified, the last one takes precedence. For example, PASSWORD EXPIRE DEFAULT PASSWORD EXPIRE NEVER is the same as PASSWORD EXPIRE NEVER.

Note

Except for the options that pertain to failed-login tracking, password-management options apply only to accounts that use an authentication plugin that stores credentials internally to MySQL. For accounts that use a plugin that performs authentication against a credentials system that is external to MySQL, password management must be handled externally against that system as well. For more information about internal credentials storage, see Section 6.2.15, “Password Management”.

A client has an expired password if the account password was expired manually or the password age is considered greater than its permitted lifetime per the automatic expiration policy. In this case, the server either disconnects the client or restricts the operations permitted to it (see Section 6.2.16,
“Server Handling of Expired Passwords”). Operations performed by a restricted client result in an error until the user establishes a new account password.

**Note**

Although it is possible to “reset” an expired password by setting it to its current value, it is preferable, as a matter of good policy, to choose a different password. DBAs can enforce non-reuse by establishing an appropriate password-reuse policy. See Password Reuse Policy.

**ALTER USER** permits these **password_option** values for controlling password expiration:

- **PASSWORD EXPIRE**
  
  Immediately marks the password expired for all accounts named by the statement.
  
  ```sql
  ALTER USER 'jeffrey'@'localhost' PASSWORD EXPIRE;
  ```

- **PASSWORD EXPIRE DEFAULT**
  
  Sets all accounts named by the statement so that the global expiration policy applies, as specified by the **default_password_lifetime** system variable.
  
  ```sql
  ALTER USER 'jeffrey'@'localhost' PASSWORD EXPIRE DEFAULT;
  ```

- **PASSWORD EXPIRE NEVER**
  
  This expiration option overrides the global policy for all accounts named by the statement. For each, it disables password expiration so that the password never expires.
  
  ```sql
  ALTER USER 'jeffrey'@'localhost' PASSWORD EXPIRE NEVER;
  ```

- **PASSWORD EXPIRE INTERVAL N DAY**
  
  This expiration option overrides the global policy for all accounts named by the statement. For each, it sets the password lifetime to \( N \) days. The following statement requires the password to be changed every 180 days:
  
  ```sql
  ALTER USER 'jeffrey'@'localhost' PASSWORD EXPIRE INTERVAL 180 DAY;
  ```

**ALTER USER** permits these **password_option** values for controlling reuse of previous passwords based on required minimum number of password changes:

- **PASSWORD HISTORY DEFAULT**
  
  Sets all accounts named by the statement so that the global policy about password history length applies, to prohibit reuse of passwords before the number of changes specified by the **password_history** system variable.
  
  ```sql
  ALTER USER 'jeffrey'@'localhost' PASSWORD HISTORY DEFAULT;
  ```

- **PASSWORD HISTORY N**
  
  This history-length option overrides the global policy for all accounts named by the statement. For each, it sets the password history length to \( N \) passwords, to prohibit reusing any of the \( N \) most recently chosen passwords. The following statement prohibits reuse of any of the previous 6 passwords:
  
  ```sql
  ALTER USER 'jeffrey'@'localhost' PASSWORD HISTORY 6;
  ```

**ALTER USER** permits these **password_option** values for controlling reuse of previous passwords based on time elapsed:

- **PASSWORD REUSE INTERVAL DEFAULT**
Sets all statements named by the account so that the global policy about time elapsed applies, to prohibit reuse of passwords newer than the number of days specified by the `password_reuse_interval` system variable.

```sql
ALTER USER 'jeffrey'@'localhost' PASSWORD REUSE INTERVAL DEFAULT;
```

- **PASSWORD REUSE INTERVAL N DAY**

  This time-elapsed option overrides the global policy for all accounts named by the statement. For each, it sets the password reuse interval to $N$ days, to prohibit reuse of passwords newer than that many days. The following statement prohibits password reuse for 360 days:

  ```sql
  ALTER USER 'jeffrey'@'localhost' PASSWORD REUSE INTERVAL 360 DAY;
  ```

`ALTER USER` permits these `password_option` values for controlling whether attempts to change an account password must specify the current password, as verification that the user attempting to make the change actually knows the current password:

- **PASSWORD REQUIRE CURRENT**

  This verification option overrides the global policy for all accounts named by the statement. For each, it requires that password changes specify the current password.

  ```sql
  ALTER USER 'jeffrey'@'localhost' PASSWORD REQUIRE CURRENT;
  ```

- **PASSWORD REQUIRE CURRENT OPTIONAL**

  This verification option overrides the global policy for all accounts named by the statement. For each, it does not require that password changes specify the current password. (The current password may but need not be given.)

  ```sql
  ALTER USER 'jeffrey'@'localhost' PASSWORD REQUIRE CURRENT OPTIONAL;
  ```

- **PASSWORD REQUIRE CURRENT DEFAULT**

  Sets all statements named by the account so that the global policy about password verification applies, as specified by the `password_require_current` system variable.

  ```sql
  ALTER USER 'jeffrey'@'localhost' PASSWORD REQUIRE CURRENT DEFAULT;
  ```

As of MySQL 8.0.19, `ALTER USER` permits these `password_option` values for controlling failed-login tracking:

- **FAILED_LOGIN_ATTEMPTS N**

  Whether to track account login attempts that specify an incorrect password. $N$ must be a number from 0 to 32767. A value of 0 disables failed-login tracking. Values greater than 0 indicate how many consecutive password failures cause temporary account locking (if `PASSWORD_LOCK_TIME` is also nonzero).

- **PASSWORD_LOCK_TIME (N | UNBOUNDED)**

  How long to lock the account after too many consecutive login attempts provide an incorrect password. $N$ must be a number from 0 to 32767, or `UNBOUNDED`. A value of 0 disables temporary account locking. Values greater than 0 indicate how long to lock the account in days. A value of `UNBOUNDED` causes the account locking duration to be unbounded; once locked, the account remains in a locked state until unlocked. For information about the conditions under which unlocking occurs, see Failed-Login Tracking and Temporary Account Locking.

For failed-login tracking and temporary locking to occur, an account's `FAILED_LOGIN_ATTEMPTS` and `PASSWORD_LOCK_TIME` options both must be nonzero. The following statement modifies an account such that it remains locked for two days after four consecutive password failures:

```sql
2634
```
ALTER USER 'jeffrey'@'localhost'
    FAILED_LOGIN_ATTEMPTS 4 PASSWORD_LOCK_TIME 2;

ALTER USER Account-Locking Options

MySQL supports account locking and unlocking using the ACCOUNT LOCK and ACCOUNT UNLOCK options, which specify the locking state for an account. For additional discussion, see Section 6.2.19, “Account Locking”.

If multiple account-locking options are specified, the last one takes precedence.

As of MySQL 8.0.19, ALTER USER ... UNLOCK unlocks any account named by the statement that is temporarily locked due to too many failed logins. See Section 6.2.15, “Password Management”.

ALTER USER Binary Logging

ALTER USER is written to the binary log if it succeeds, but not if it fails; in that case, rollback occurs and no changes are made. A statement written to the binary log includes all named users. If the IF EXISTS clause is given, this includes even users that do not exist and were not altered.

If the original statement changes the credentials for a user, the statement written to the binary log specifies the applicable authentication plugin for that user, determined as follows:

- The plugin named in the original statement, if one was specified.
- Otherwise, the plugin associated with the user account if the user exists, or the default authentication plugin if the user does not exist. (If the statement written to the binary log must specify a particular authentication plugin for a user, include it in the original statement.)

If the server adds the default authentication plugin for any users in the statement written to the binary log, it writes a warning to the error log naming those users.

If the original statement specifies the FAILED_LOGIN_ATTEMPTS or PASSWORD_LOCK_TIME option, the statement written to the binary log includes the option.

13.7.1.2 CREATE ROLE Statement

CREATE ROLE [IF NOT EXISTS] role [, role ] ...

CREATE ROLE creates one or more roles, which are named collections of privileges. To use this statement, you must have the global CREATE ROLE or CREATE USER privilege. When the read_only system variable is enabled, CREATE ROLE additionally requires the CONNECTION_ADMIN privilege (or the deprecated SUPER privilege).

A role when created is locked, has no password, and is assigned the default authentication plugin. (These role attributes can be changed later with the ALTER USER statement, by users who have the global CREATE USER privilege.)

CREATE ROLE either succeeds for all named roles or rolls back and has no effect if any error occurs. By default, an error occurs if you try to create a role that already exists. If the IF NOT EXISTS clause is given, the statement produces a warning for each named role that already exists, rather than an error.

The statement is written to the binary log if it succeeds, but not if it fails; in that case, rollback occurs and no changes are made. A statement written to the binary log includes all named roles. If the IF NOT EXISTS clause is given, this includes even roles that already exist and were not created.

Each role name uses the format described in Section 6.2.5, “Specifying Role Names”. For example:

CREATE ROLE 'admin', 'developer';
CREATE ROLE 'webapp'@'localhost';

The host name part of the role name, if omitted, defaults to '%'.

For role usage examples, see Section 6.2.10, “Using Roles”.

13.7.1.3 CREATE USER Statement

```
CREATE USER [IF NOT EXISTS]
    user [auth_option] [, user [auth_option]] ...
    DEFAULT ROLE role [, role ] ...
    [WITH resource_option [resource_option] ...]
    [require {NONE | tls_option} ...]
    [COMMENT 'comment_string' | ATTRIBUTE 'json_object']

user:
    (see Section 6.2.4, “Specifying Account Names”)

auth_option:
    { IDENTIFIED BY 'auth_string'
     | IDENTIFIED BY RANDOM PASSWORD
     | IDENTIFIED WITH auth_plugin
     | IDENTIFIED WITH auth_plugin AS 'auth_string'
     | IDENTIFIED WITH auth_plugin BY 'auth_string'
     }

tls_option:
    { SSL
      | X509
      | CIPHER 'cipher'
      | ISSUER 'issuer'
      | SUBJECT 'subject'
      }

resource_option:
    { MAX_QUERIES_PER_HOUR count
    | MAX_UPDATES_PER_HOUR count
    | MAX_CONNECTIONS_PER_HOUR count
    | MAX_USER_CONNECTIONS count
    }

password_option:
    { PASSWORD EXPIRE [DEFAULT | NEVER | INTERVAL N DAY]
    | PASSWORD HISTORY {DEFAULT | N]
    | PASSWORD REUSE INTERVAL {DEFAULT | N DAY}
    | PASSWORD REQUIRE CURRENT {DEFAULT | OPTIONAL}
    | FAILED_LOGIN_ATTEMPTS N
    | PASSWORD_LOCK_TIME {N | UNBOUNDED}
    }

lock_option:
    { ACCOUNT LOCK
    | ACCOUNT UNLOCK
    }
```

The CREATE USER statement creates new MySQL accounts. It enables authentication, role, SSL/TLS, resource-limit, and password-management properties to be established for new accounts. It also controls whether accounts are initially locked or unlocked.

To use CREATE USER, you must have the global CREATE USER privilege, or the INSERT privilege for the mysql system schema. When the read_only system variable is enabled, CREATE USER additionally requires the CONNECTION_ADMIN privilege (or the deprecated SUPER privilege).

As of MySQL 8.0.22, CREATE USER fails with an error if any account to be created is named as the DEFINER attribute for any stored object. (That is, the statement fails if creating an account would cause the account to adopt a currently orphaned stored object.) To perform the operation anyway, you must have the SET_USER_ID privilege; in this case, the statement succeeds with a warning rather
than failing with an error. Without \texttt{SET\_USER\_ID}, to perform the user-creation operation, drop the orphan objects, create the account and grant its privileges, and then re-create the dropped objects. For additional information, including how to identify which objects name a given account as the \texttt{DEFINER} attribute, see \texttt{Orphan\_Stored\_Objects}.

\textbf{Important}

Under some circumstances, \texttt{CREATE\_USER} may be recorded in server logs or on the client side in a history file such as ~/.mysql\_history, which means that cleartext passwords may be read by anyone having read access to that information. For information about the conditions under which this occurs for the server logs and how to control it, see Section 6.1.2.3, “Passwords and Logging”. For similar information about client-side logging, see Section 4.5.1.3, “mysql Client Logging”.

There are several aspects to the \texttt{CREATE\_USER} statement, described under the following topics:

- \texttt{CREATE\_USER Overview}
- \texttt{CREATE\_USER Authentication Options}
- \texttt{CREATE\_USER Role Options}
- \texttt{CREATE\_USER SSL/TLS Options}
- \texttt{CREATE\_USER Resource-Limit Options}
- \texttt{CREATE\_USER Password-Management Options}
- \texttt{CREATE\_USER Account-Locking Options}
- \texttt{CREATE\_USER Binary Logging}

\textbf{CREATE\_USER Overview}

For each account, \texttt{CREATE\_USER} creates a new row in the \texttt{mysql.user} system table. The account row reflects the properties specified in the statement. Unspecified properties are set to their default values:

- Authentication: The authentication plugin defined by the \texttt{default\_authentication\_plugin} system variable, and empty credentials
- Default role: \texttt{NONE}
- SSL/TLS: \texttt{NONE}
- Resource limits: Unlimited
- Password management:\texttt{PASSWORD\_EXP\_DEFAULT\_PASSWORD\_HISTORY\_DEFAULT\_PASSWORD\_RE\_INTERV\_DEFAULT\_PASSWORD\_RE\_CURRENT\_DEFAULT}; failed-login tracking and temporary account locking are disabled
- Account locking: \texttt{ACCOUNT\_UNLOCK}

An account when first created has no privileges and a default role of \texttt{NONE}. To assign privileges or roles, use the \texttt{GRANT} statement.
Each account name uses the format described in Section 6.2.4, “Specifying Account Names”. For example:

```
CREATE USER 'jeffrey'@'localhost' IDENTIFIED BY 'password';
```

The host name part of the account name, if omitted, defaults to '%'.

Each `user` value naming an account may be followed by an optional `auth_option` value that indicates how the account authenticates. These values enable account authentication plugins and credentials (for example, a password) to be specified. Each `auth_option` value applies only to the account named immediately preceding it.

Following the `user` specifications, the statement may include options for SSL/TLS, resource-limit, password-management, and locking properties. All such options are global to the statement and apply to all accounts named in the statement.

Example: Create an account that uses the default authentication plugin and the given password. Mark the password expired so that the user must choose a new one at the first connection to the server:

```
CREATE USER 'jeffrey'@'localhost'
IDENTIFIED BY 'new_password' PASSWORD EXPIRE;
```

Example: Create an account that uses the `caching_sha2_password` authentication plugin and the given password. Require that a new password be chosen every 180 days, and enable failed-login tracking, such that three consecutive incorrect passwords cause temporary account locking for two days:

```
CREATE USER 'jeffrey'@'localhost'
IDENTIFIED WITH caching_sha2_password BY 'new_password'
PASSWORD EXPIRE INTERVAL 180 DAY
FAILED_LOGIN_ATTEMPTS 3 PASSWORD_LOCK_TIME 2;
```

Example: Create multiple accounts, specifying some per-account properties and some global properties:

```
CREATE USER
  'jeffrey'@'localhost' IDENTIFIED WITH mysql_native_password
  BY 'new_password1',
  'jeanne'@'localhost' IDENTIFIED WITH caching_sha2_password
  BY 'new_password2'
REQUIRE X509 WITH MAX_QUERIES_PER_HOUR 60
  PASSWORD HISTORY 5
  ACCOUNT LOCK;
```

Each `auth_option` value (`IDENTIFIED WITH ... BY` in this case) applies only to the account named immediately preceding it, so each account uses the immediately following authentication plugin and password.

The remaining properties apply globally to all accounts named in the statement, so for both accounts:

- Connections must be made using a valid X.509 certificate.
- Up to 60 queries per hour are permitted.
- Password changes cannot reuse any of the five most recent passwords.
- The account is locked initially, so effectively it is a placeholder and cannot be used until an administrator unlocks it.

Beginning with MySQL 8.0.21, you can optionally create a user with a user comment or a user attribute, as described here:

- User comment
Account Management Statements

To set a user comment, add COMMENT 'user_comment' to the CREATE USER statement, where
user_comment is the text of the user comment.
Example (omitting any other options):
CREATE USER 'jon'@'localhost' COMMENT 'Some information about Jon';

• User attribute
A user attribute is a JSON object made up of one or more key-value pairs, and is set by including
ATTRIBUTE 'json_object' as part of of CREATE USER. json_object must be a valid JSON
object.
Example (omitting any other options):
CREATE USER 'jim'@'localhost'
ATTRIBUTE '{"fname": "James", "lname": "Scott", "phone": "123-456-7890"}';

User comments and user attributes are stored together in the ATTRIBUTE column of the
INFORMATION_SCHEMA.USER_ATTRIBUTES table. This query displays the row in this table inserted
by the statement just shown for creating the user jin@localhost:
mysql> SELECT * FROM INFORMATION_SCHEMA.USER_ATTRIBUTES
->
WHERE USER = 'jim' AND HOST = 'localhost'\G
*************************** 1. row ***************************
USER: jim
HOST: localhost
ATTRIBUTE: {"fname": "James", "lname": "Scott", "phone": "123-456-7890"}
1 row in set (0.00 sec)

The COMMENT option in actuality provides a shortcut for setting a user attribute whose only element
has comment as its key and whose value is the argument supplied for the option. You can see this by
executing the statement CREATE USER 'jon'@'localhost' COMMENT 'Some information
about Jon', and observing the row which it inserts into the USER_ATTRIBUTES table:
mysql> CREATE USER 'jon'@'localhost' COMMENT 'Some information about Jon';
Query OK, 0 rows affected (0.06 sec)
mysql> SELECT * FROM INFORMATION_SCHEMA.USER_ATTRIBUTES
->
WHERE USER = 'jon' AND HOST = 'localhost';
+------+-----------+-------------------------------------------+
| USER | HOST
| ATTRIBUTE
|
+------+-----------+-------------------------------------------+
| jon | localhost | {"comment": "Some information about Jon"} |
+------+-----------+-------------------------------------------+
1 row in set (0.00 sec)

You cannot use COMMENT and ATTRIBUTE together in the same CREATE USER statement; attempting
to do so causes a syntax error. To set a user comment concurrently with setting a user attribute, use
ATTRIBUTE and include in its argument a value with a comment key, like this:
mysql> CREATE USER 'bill'@'localhost'
->
ATTRIBUTE '{"fname":"William", "lname":"Schmidt",
->
"comment":"Website developer"}';
Query OK, 0 rows affected (0.16 sec)

Since the content of the ATTRIBUTE row is a JSON object, you can employ any appropriate MySQL
JSON functions or operators to manipulate it, as shown here:
mysql> SELECT
->
USER AS User,
->
HOST AS Host,
->
CONCAT(ATTRIBUTE->>"$.fname"," ",ATTRIBUTE->>"$.lname") AS 'Full Name',
->
ATTRIBUTE->>"$.comment" AS Comment
-> FROM INFORMATION_SCHEMA.USER_ATTRIBUTES
-> WHERE USER='bill' AND HOST='localhost';
+------+-----------+-----------------+-------------------+

2639


Account Management Statements

<table>
<thead>
<tr>
<th>User</th>
<th>Host</th>
<th>Full Name</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>bill</td>
<td>localhost</td>
<td>William Schmidt</td>
<td>Website developer</td>
</tr>
</tbody>
</table>

1 row in set (0.00 sec)

To set or to make changes in the user comment or user attribute for an existing user, you can use a `COMMENT` or `ATTRIBUTE` option with an `ALTER USER` statement.

Because the user comment and user attribute are stored together internally in a single JSON column, this sets an upper limit on their maximum combined size; see JSON Storage Requirements, for more information.

See also the description of the Information Schema `USER_ATTRIBUTES` table for more information and examples.

CREATE USER Authentication Options

An account name may be followed by an `auth_option` authentication option that specifies the account authentication plugin, credentials, or both.

**Note**

Clauses for random password generation apply only to accounts that use an authentication plugin that stores credentials internally to MySQL. For accounts that use a plugin that performs authentication against a credentials system that is external to MySQL, password management must be handled externally against that system as well. For more information about internal credentials storage, see Section 6.2.15, “Password Management”.

- `auth_plugin` names an authentication plugin. The plugin name can be a quoted string literal or an unquoted name. Plugin names are stored in the `plugin` column of the `mysql.user` system table.

  For `auth_option` syntax that does not specify an authentication plugin, the default plugin is indicated by the value of the `default_authentication_plugin` system variable. For descriptions of each plugin, see Section 6.4.1, “Authentication Plugins”.

- Credentials that are stored internally are stored in the `mysql.user` system table. An `auth_string` value or RANDOM PASSWORD specifies account credentials, either as a cleartext (unencrypted) string or hashed in the format expected by the authentication plugin associated with the account, respectively:

  - For syntax that uses `BY 'auth_string'`, the string is cleartext and is passed to the authentication plugin for possible hashing. The result returned by the plugin is stored in the `mysql.user` table. A plugin may use the value as specified, in which case no hashing occurs.

  - For syntax that uses `BY RANDOM PASSWORD`, MySQL generates a random password and as cleartext and passes it to the authentication plugin for possible hashing. The result returned by the plugin is stored in the `mysql.user` table. A plugin may use the value as specified, in which case no hashing occurs.

Randomly generated passwords are available as of MySQL 8.0.18 and have the characteristics described in Random Password Generation.

- For syntax that uses `AS 'auth_string'`, the string is assumed to be already in the format the authentication plugin requires, and is stored as is in the `mysql.user` table. If a plugin requires a hashed value, the value must be already hashed in a format appropriate for the plugin; otherwise, the value cannot be used by the plugin and correct authentication of client connections does not occur.

  As of MySQL 8.0.17, a hashed string can be either a string literal or a hexadecimal value. The latter corresponds to the type of value displayed by `SHOW CREATE USER` for password hashes.
containing unprintable characters when the `print_identified_with_as_hex` system variable is enabled.

- If an authentication plugin performs no hashing of the authentication string, the BY 'auth_string' and AS 'auth_string' clauses have the same effect: The authentication string is stored as is in the `mysql.user` system table.

`CREATE USER` permits these `auth_option` syntaxes:

- IDENTIFIED BY 'auth_string'

  Sets the account authentication plugin to the default plugin, passes the cleartext 'auth_string' value to the plugin for possible hashing, and stores the result in the account row in the `mysql.user` system table.

- IDENTIFIED BY RANDOM PASSWORD

  Sets the account authentication plugin to the default plugin, generates a random password, passes the cleartext password value to the plugin for possible hashing, and stores the result in the account row in the `mysql.user` system table. The statement also returns the cleartext password in a result set to make it available to the user or application executing the statement. For details about the result set and characteristics of randomly generated passwords, see Random Password Generation.

- IDENTIFIED WITH auth_plugin

  Sets the account authentication plugin to `auth_plugin`, clears the credentials to the empty string, and stores the result in the account row in the `mysql.user` system table.

- IDENTIFIED WITH auth_plugin BY 'auth_string'

  Sets the account authentication plugin to `auth_plugin`, passes the cleartext 'auth_string' value to the plugin for possible hashing, and stores the result in the account row in the `mysql.user` system table.

- IDENTIFIED WITH auth_plugin BY RANDOM PASSWORD

  Sets the account authentication plugin to `auth_plugin`, generates a random password, passes the cleartext password value to the plugin for possible hashing, and stores the result in the account row in the `mysql.user` system table. The statement also returns the cleartext password in a result set to make it available to the user or application executing the statement. For details about the result set and characteristics of randomly generated passwords, see Random Password Generation.

- IDENTIFIED WITH auth_plugin AS 'auth_string'

  Sets the account authentication plugin to `auth_plugin` and stores the 'auth_string' value as is in the `mysql.user` account row. If the plugin requires a hashed string, the string is assumed to be already hashed in the format the plugin requires.

Example: Specify the password as cleartext; the default plugin is used:

```
CREATE USER 'jeffrey'@'localhost'
  IDENTIFIED BY 'password';
```

Example: Specify the authentication plugin, along with a cleartext password value:

```
CREATE USER 'jeffrey'@'localhost'
  IDENTIFIED WITH mysql_native_password BY 'password';
```

In each case, the password value stored in the account row is the cleartext value 'password' after it has been hashed by the authentication plugin associated with the account.

For additional information about setting passwords and authentication plugins, see Section 6.2.14, “Assigning Account Passwords”, and Section 6.2.17, “Pluggable Authentication”. 

2641
CREATE USER Role Options

The `DEFAULT ROLE` clause defines which roles become active when the user connects to the server and authenticates, or when the user executes the `SET ROLE DEFAULT` statement during a session.

Each role name uses the format described in Section 6.2.5, “Specifying Role Names”. For example:

```sql
CREATE USER 'joe'@'10.0.0.1' DEFAULT ROLE administrator, developer;
```

The host name part of the role name, if omitted, defaults to `'%'.`

The `DEFAULT ROLE` clause permits a list of one or more comma-separated role names. These roles need not exist at the time `CREATE USER` is executed.

CREATE USER SSL/TLS Options

MySQL can check X.509 certificate attributes in addition to the usual authentication that is based on the user name and credentials. For background information on the use of SSL/TLS with MySQL, see Section 6.3, “Using Encrypted Connections”.

To specify SSL/TLS-related options for a MySQL account, use a `REQUIRE` clause that specifies one or more `tls_option` values.

Order of `REQUIRE` options does not matter, but no option can be specified twice. The `AND` keyword is optional between `REQUIRE` options.

`CREATE USER` permits these `tls_option` values:

- **NONE**
  
  Indicates that all accounts named by the statement have no SSL or X.509 requirements. Unencrypted connections are permitted if the user name and password are valid. Encrypted connections can be used, at the client's option, if the client has the proper certificate and key files.

```sql
CREATE USER 'jeffrey'@'localhost' REQUIRE NONE;
```

Clients attempt to establish a secure connection by default. For clients that have `REQUIRE NONE`, the connection attempt falls back to an unencrypted connection if a secure connection cannot be established. To require an encrypted connection, a client need specify only the `--ssl-mode=REQUIRED` option; the connection attempt fails if a secure connection cannot be established.

`NONE` is the default if no SSL-related `REQUIRE` options are specified.

- **SSL**
  
  Tells the server to permit only encrypted connections for all accounts named by the statement.

```sql
CREATE USER 'jeffrey'@'localhost' REQUIRE SSL;
```

Clients attempt to establish a secure connection by default. For accounts that have `REQUIRE SSL`, the connection attempt fails if a secure connection cannot be established.

- **X509**
  
  For all accounts named by the statement, requires that clients present a valid certificate, but the exact certificate, issuer, and subject do not matter. The only requirement is that it should be possible to verify its signature with one of the CA certificates. Use of X.509 certificates always implies encryption, so the `SSL` option is unnecessary in this case.

```sql
CREATE USER 'jeffrey'@'localhost' REQUIRE X509;
```

For accounts with `REQUIRE X509`, clients must specify the `--ssl-key` and `--ssl-cert` options to connect. (It is recommended but not required that `--ssl-ca` also be specified so that the public
certificate provided by the server can be verified.) This is true for **ISSUER** and **SUBJECT** as well because those **REQUIRE** options imply the requirements of **X509**.

- **ISSUER 'issuer'**

For all accounts named by the statement, requires that clients present a valid X.509 certificate issued by CA 'issuer'. If a client presents a certificate that is valid but has a different issuer, the server rejects the connection. Use of X.509 certificates always implies encryption, so the **SSL** option is unnecessary in this case.

```sql
CREATE USER 'jeffrey'@'localhost'
    REQUIRE ISSUER '/C=SE/ST=Stockholm/L=Stockholm/
        O=MySQL/CN=CA/emailAddress=ca@example.com';
```

Because **ISSUER** implies the requirements of **X509**, clients must specify the **--ssl-key** and **--ssl-cert** options to connect. (It is recommended but not required that **--ssl-ca** also be specified so that the public certificate provided by the server can be verified.)

- **SUBJECT 'subject'**

For all accounts named by the statement, requires that clients present a valid X.509 certificate containing the subject **subject**. If a client presents a certificate that is valid but has a different subject, the server rejects the connection. Use of X.509 certificates always implies encryption, so the **SSL** option is unnecessary in this case.

```sql
CREATE USER 'jeffrey'@'localhost'
    REQUIRE SUBJECT '/C=SE/ST=Stockholm/L=Stockholm/
        O=MySQL demo client certificate/
        CN=client/emailAddress=client@example.com';
```

MySQL does a simple string comparison of the **'subject'** value to the value in the certificate, so lettercase and component ordering must be given exactly as present in the certificate.

Because **SUBJECT** implies the requirements of **X509**, clients must specify the **--ssl-key** and **--ssl-cert** options to connect. (It is recommended but not required that **--ssl-ca** also be specified so that the public certificate provided by the server can be verified.)

- **CIPHER 'cipher'**

For all accounts named by the statement, requires a specific cipher method for encrypting connections. This option is needed to ensure that ciphers and key lengths of sufficient strength are used. Encryption can be weak if old algorithms using short encryption keys are used.

```sql
CREATE USER 'jeffrey'@'localhost'
    REQUIRE CIPHER 'EDH-RSA-DES-CBC3-SHA';
```

The **SUBJECT**, **ISSUER**, and **CIPHER** options can be combined in the **REQUIRE** clause:

```sql
CREATE USER 'jeffrey'@'localhost'
    REQUIRE SUBJECT '/C=SE/ST=Stockholm/L=Stockholm/
        O=MySQL demo client certificate/
        CN=client/emailAddress=client@example.com'
    AND ISSUER '/C=SE/ST=Stockholm/L=Stockholm/
        O=MySQL/CN=CA/emailAddress=ca@example.com'
    AND CIPHER 'EDH-RSA-DES-CBC3-SHA';
```

**CREATE USER Resource-Limit Options**

It is possible to place limits on use of server resources by an account, as discussed in Section 6.2.20, “Setting Account Resource Limits”. To do so, use a **WITH** clause that specifies one or more **resource_option** values.

Order of **WITH** options does not matter, except that if a given resource limit is specified multiple times, the last instance takes precedence.

2643
CREATE USER permits these resource_option values:

- MAX_QUERIES_PER_HOUR count, MAX_UPDATES_PER_HOUR count,
  MAX_CONNECTIONS_PER_HOUR count

For all accounts named by the statement, these options restrict how many queries, updates, and connections to the server are permitted to each account during any given one-hour period. If count is 0 (the default), this means that there is no limitation for the account.

- MAX_USER_CONNECTIONS count

For all accounts named by the statement, restricts the maximum number of simultaneous connections to the server by each account. A nonzero count specifies the limit for the account explicitly. If count is 0 (the default), the server determines the number of simultaneous connections for the account from the global value of the max_user_connections system variable. If max_user_connections is also zero, there is no limit for the account.

Example:

```
CREATE USER 'jeffrey'@'localhost'
  WITH MAX_QUERIES_PER_HOUR 500 MAX_UPDATES_PER_HOUR 100;
```

CREATE USER Password-Management Options

CREATE USER supports several password_option values for password management:

- Password expiration options: You can expire an account password manually and establish its password expiration policy. Policy options do not expire the password. Instead, they determine how the server applies automatic expiration to the account based on password age, which is assessed from the date and time of the most recent account password change.

- Password reuse options: You can restrict password reuse based on number of password changes, time elapsed, or both.

- Password verification-required options: You can indicate whether attempts to change an account password must specify the current password, as verification that the user attempting to make the change actually knows the current password.

- Incorrect-password failed-login tracking options: You can cause the server to track failed login attempts and temporarily lock accounts for which too many consecutive incorrect passwords are given. The required number of failures and the lock time are configurable.

This section describes the syntax for password-management options. For information about establishing policy for password management, see Section 6.2.15, “Password Management”.

If multiple password-management options of a given type are specified, the last one takes precedence. For example, PASSWORD EXPIRE DEFAULT PASSWORD EXPIRE NEVER is the same as PASSWORD EXPIRE NEVER.

**Note**

Except for the options that pertain to failed-login tracking, password-management options apply only to accounts that use an authentication plugin that stores credentials internally to MySQL. For accounts that use a plugin that performs authentication against a credentials system that is external to MySQL, password management must be handled externally against that system as well.

For more information about internal credentials storage, see Section 6.2.15, “Password Management”.

A client has an expired password if the account password was expired manually or the password age is considered greater than its permitted lifetime per the automatic expiration policy. In this case, the server either disconnects the client or restricts the operations permitted to it.
Account Management Statements

“Server Handling of Expired Passwords”). Operations performed by a restricted client result in an error until the user establishes a new account password.

CREATE USER permits these password_option values for controlling password expiration:

- **PASSWORD EXPIRE**
  
  Immediately marks the password expired for all accounts named by the statement.

  ```sql
  CREATE USER 'jeffrey'@'localhost' PASSWORD EXPIRE;
  ```

- **PASSWORD EXPIRE DEFAULT**
  
  Sets all accounts named by the statement so that the global expiration policy applies, as specified by the default_password_lifetime system variable.

  ```sql
  CREATE USER 'jeffrey'@'localhost' PASSWORD EXPIRE DEFAULT;
  ```

- **PASSWORD EXPIRE NEVER**
  
  This expiration option overrides the global policy for all accounts named by the statement. For each, it disables password expiration so that the password never expires.

  ```sql
  CREATE USER 'jeffrey'@'localhost' PASSWORD EXPIRE NEVER;
  ```

- **PASSWORD EXPIRE INTERVAL N DAY**
  
  This expiration option overrides the global policy for all accounts named by the statement. For each, it sets the password lifetime to \( N \) days. The following statement requires the password to be changed every 180 days:

  ```sql
  CREATE USER 'jeffrey'@'localhost' PASSWORD EXPIRE INTERVAL 180 DAY;
  ```

CREATE USER permits these password_option values for controlling reuse of previous passwords based on required minimum number of password changes:

- **PASSWORD HISTORY DEFAULT**
  
  Sets all accounts named by the statement so that the global policy about password history length applies, to prohibit reuse of passwords before the number of changes specified by the password_history system variable.

  ```sql
  CREATE USER 'jeffrey'@'localhost' PASSWORD HISTORY DEFAULT;
  ```

- **PASSWORD HISTORY N**
  
  This history-length option overrides the global policy for all accounts named by the statement. For each, it sets the password history length to \( N \) passwords, to prohibit reusing any of the \( N \) most recently chosen passwords. The following statement prohibits reuse of any of the previous 6 passwords:

  ```sql
  CREATE USER 'jeffrey'@'localhost' PASSWORD HISTORY 6;
  ```

CREATE USER permits these password_option values for controlling reuse of previous passwords based on time elapsed:

- **PASSWORD REUSE INTERVAL DEFAULT**
  
  Sets all statements named by the account so that the global policy about time elapsed applies, to prohibit reuse of passwords newer than the number of days specified by the password_reuse_interval system variable.

  ```sql
  CREATE USER 'jeffrey'@'localhost' PASSWORD REUSE INTERVAL DEFAULT;
  ```

- **PASSWORD REUSE INTERVAL N DAY**
This time-elapsed option overrides the global policy for all accounts named by the statement. For each, it sets the password reuse interval to $N$ days, to prohibit reuse of passwords newer than that many days. The following statement prohibits password reuse for 360 days:

```
CREATE USER 'jeffrey'@'localhost' PASSWORD REUSE INTERVAL 360 DAY;
```

`CREATE USER` permits these `password_option` values for controlling whether attempts to change an account password must specify the current password, as verification that the user attempting to make the change actually knows the current password:

- **PASSWORD REQUIRE CURRENT**

  This verification option overrides the global policy for all accounts named by the statement. For each, it requires that password changes specify the current password.

  ```
  CREATE USER 'jeffrey'@'localhost' PASSWORD REQUIRE CURRENT;
  ```

- **PASSWORD REQUIRE CURRENT OPTIONAL**

  This verification option overrides the global policy for all accounts named by the statement. For each, it does not require that password changes specify the current password. (The current password may but need not be given.)

  ```
  CREATE USER 'jeffrey'@'localhost' PASSWORD REQUIRE CURRENT OPTIONAL;
  ```

- **PASSWORD REQUIRE CURRENT DEFAULT**

  Sets all statements named by the account so that the global policy about password verification applies, as specified by the `password_require_current` system variable.

  ```
  CREATE USER 'jeffrey'@'localhost' PASSWORD REQUIRE CURRENT DEFAULT;
  ```

As of MySQL 8.0.19, `CREATE USER` permits these `password_option` values for controlling failed-login tracking:

- **FAILED_LOGIN_ATTEMPTS $N$**

  Whether to track account login attempts that specify an incorrect password. $N$ must be a number from 0 to 32767. A value of 0 disables failed-login tracking. Values greater than 0 indicate how many consecutive password failures cause temporary account locking (if `PASSWORD_LOCK_TIME` is also nonzero).

- **PASSWORD_LOCK_TIME { $N$ | UNBOUNDED }**

  How long to lock the account after too many consecutive login attempts provide an incorrect password. $N$ must be a number from 0 to 32767, or `UNBOUNDED`. A value of 0 disables temporary account locking. Values greater than 0 indicate how long to lock the account in days. A value of `UNBOUNDED` causes the account locking duration to be unbounded; once locked, the account remains in a locked state until unlocked. For information about the conditions under which unlocking occurs, see Failed-Login Tracking and Temporary Account Locking.

  For failed-login tracking and temporary locking to occur, an account's `FAILED_LOGIN_ATTEMPTS` and `PASSWORD_LOCK_TIME` options both must be nonzero. The following statement creates an account that remains locked for two days after four consecutive password failures:

  ```
  CREATE USER 'jeffrey'@'localhost' FAILED_LOGIN_ATTEMPTS 4 PASSWORD_LOCK_TIME 2;
  ```

### CREATE USER Account-Locking Options

MySQL supports account locking and unlocking using the `ACCOUNT_LOCK` and `ACCOUNT_UNLOCK` options, which specify the locking state for an account. For additional discussion, see Section 6.2.19, “Account Locking.”
If multiple account-locking options are specified, the last one takes precedence.

**CREATE USER Binary Logging**

*CREATE USER* is written to the binary log if it succeeds, but not if it fails; in that case, rollback occurs and no changes are made. A statement written to the binary log includes all named users. If the *IF NOT EXISTS* clause is given, this includes even users that already exist and were not created.

The statement written to the binary log specifies an authentication plugin for each user, determined as follows:

- The plugin named in the original statement, if one was specified.
- Otherwise, the default authentication plugin. In particular, if a user *u1* already exists and uses a nondefault authentication plugin, the statement written to the binary log for *CREATE USER IF NOT EXISTS u1* names the default authentication plugin. (If the statement written to the binary log must specify a nondefault authentication plugin for a user, include it in the original statement.)

If the server adds the default authentication plugin for any nonexisting users in the statement written to the binary log, it writes a warning to the error log naming those users.

If the original statement specifies the *FAILED_LOGIN_ATTEMPTS* or *PASSWORD_LOCK_TIME* option, the statement written to the binary log includes the option.

### 13.7.1.4 DROP ROLE Statement

*DROP ROLE* 

*DROP ROLE* removes one or more roles (named collections of privileges). To use this statement, you must have the global *DROP ROLE* or *CREATE USER* privilege. When the *read_only* system variable is enabled, *DROP ROLE* additionally requires the *CONNECTION_ADMIN* privilege (or the deprecated *SUPER* privilege).

As of MySQL 8.0.16, users who have the *CREATE USER* privilege can use this statement to drop accounts that are locked or unlocked. Users who have the *DROP ROLE* privilege can use this statement only to drop accounts that are locked (unlocked accounts are presumably user accounts used to log in to the server and not just as roles).

Roles named in the *mandatory_roles* system variable value cannot be dropped.

*DROP ROLE* either succeeds for all named roles or rolls back and has no effect if any error occurs. By default, an error occurs if you try to drop a role that does not exist. If the *IF EXISTS* clause is given, the statement produces a warning for each named role that does not exist, rather than an error.

The statement is written to the binary log if it succeeds, but not if it fails; in that case, rollback occurs and no changes are made. A statement written to the binary log includes all named roles. If the *IF EXISTS* clause is given, this includes even roles that do not exist and were not dropped.

Each role name uses the format described in Section 6.2.5, “Specifying Role Names”. For example:

```
DROP ROLE 'admin', 'developer';
DROP ROLE 'webapp'@'localhost';
```

The host name part of the role name, if omitted, defaults to '*%*'.

A dropped role is automatically revoked from any user account (or role) to which the role was granted. Within any current session for such an account, its adjusted privileges apply beginning with the next statement executed.

For role usage examples, see Section 6.2.10, “Using Roles”. 
13.7.1.5 DROP USER Statement

The **DROP USER** statement removes one or more MySQL accounts and their privileges. It removes privilege rows for the account from all grant tables.

Roles named in the `mandatory_roles` system variable value cannot be dropped.

To use **DROP USER**, you must have the global **CREATE USER** privilege, or the **DELETE** privilege for the `mysql` system schema. When the `read_only` system variable is enabled, **DROP USER** additionally requires the `CONNECTION_ADMIN` privilege (or the deprecated **SUPER** privilege).

As of MySQL 8.0.22, **DROP USER** fails with an error if any account to be dropped is named as the `DEFINER` attribute for any stored object. (That is, the statement fails if dropping an account would cause a stored object to become orphaned.) To perform the operation anyway, you must have the `SET_USER_ID` privilege; in this case, the statement succeeds with a warning rather than failing with an error. For additional information, including how to identify which objects name a given account as the `DEFINER` attribute, see Orphan Stored Objects.

**DROP USER** either succeeds for all named users or rolls back and has no effect if any error occurs. By default, an error occurs if you try to drop a user that does not exist. If the **IF EXISTS** clause is given, the statement produces a warning for each named user that does not exist, rather than an error.

The statement is written to the binary log if it succeeds, but not if it fails; in that case, rollback occurs and no changes are made. A statement written to the binary log includes all named users. If the **IF EXISTS** clause is given, this includes even users that do not exist and were not dropped.

Each account name uses the format described in Section 6.2.4, “Specifying Account Names”. For example:

```
DROP USER 'jeffrey'@'localhost';
```

The host name part of the account name, if omitted, defaults to `'%`.

**Important**

**DROP USER** does not automatically close any open user sessions. Rather, in the event that a user with an open session is dropped, the statement does not take effect until that user’s session is closed. Once the session is closed, the user is dropped, and that user’s next attempt to log in fails. **This is by design.**

**DROP USER** does not automatically drop or invalidate databases or objects within them that the old user created. This includes stored programs or views for which the `DEFINER` attribute names the dropped user. Attempts to access such objects may produce an error if they execute in definer security context. (For information about security context, see Section 25.6, “Stored Object Access Control”.)

13.7.1.6 GRANT Statement

```
GRANT priv_type [{(column_list)}] [, priv_type {(column_list)}] ... ON [object_type] priv_level
TO user_or_role [, user_or_role] ...
[WITH GRANT OPTION]
[AS user
 [WITH ROLE
 DEFAULT
 NONE
 ALL
 ALL EXCEPT role [, role ] ...
 role [, role ] ...]
```
The **GRANT** statement assigns privileges and roles to MySQL user accounts and roles. There are several aspects to the **GRANT** statement, described under the following topics:

- **GRANT General Overview**
- **Object Quoting Guidelines**
- **Account Names**
- **Privileges Supported by MySQL**
- **Global Privileges**
- **Database Privileges**
- **Table Privileges**
- **Column Privileges**
- **Stored Routine Privileges**
- **Proxy User Privileges**
- **Granting Roles**
- **The **AS** Clause and Privilege Restrictions**
- **Other Account Characteristics**
- **MySQL and Standard SQL Versions of GRANT**

**GRANT General Overview**

The **GRANT** statement enables system administrators to grant privileges and roles, which can be granted to user accounts and roles. These syntax restrictions apply:
Account Management Statements

- **GRANT** cannot mix granting both privileges and roles in the same statement. A given **GRANT** statement must grant either privileges or roles.

- The **ON** clause distinguishes whether the statement grants privileges or roles:
  - With **ON**, the statement grants privileges.
  - Without **ON**, the statement grants roles.

- It is permitted to assign both privileges and roles to an account, but you must use separate **GRANT** statements, each with syntax appropriate to what is to be granted.

For more information about roles, see Section 6.2.10, “Using Roles”.

To grant a privilege with **GRANT**, you must have the **GRANT OPTION** privilege, and you must have the privileges that you are granting. (Alternatively, if you have the **UPDATE** privilege for the grant tables in the **mysql** system schema, you can grant any account any privilege.) When the **read_only** system variable is enabled, **GRANT** additionally requires the **CONNECTION_ADMIN** privilege (or the deprecated **SUPER** privilege).

**GRANT** either succeeds for all named users and roles or rolls back and has no effect if any error occurs. The statement is written to the binary log only if it succeeds for all named users and roles.

The **REVOKE** statement is related to **GRANT** and enables administrators to remove account privileges. See Section 13.7.1.8, “REVOKE Statement”.

Each account name uses the format described in Section 6.2.4, “Specifying Account Names”. Each role name uses the format described in Section 6.2.5, “Specifying Role Names”. For example:

```sql
GRANT ALL ON db1.* TO 'jeffrey'@'localhost';
GRANT 'role1', 'role2' TO 'user1'@'localhost', 'user2'@'localhost';
GRANT SELECT ON world.* TO 'role3';
```

The host name part of the account or role name, if omitted, defaults to '%'.

Normally, a database administrator first uses **CREATE USER** to create an account and define its nonprivilege characteristics such as its password, whether it uses secure connections, and limits on access to server resources, then uses **GRANT** to define its privileges. **ALTER USER** may be used to change the nonprivilege characteristics of existing accounts. For example:

```sql
CREATE USER 'jeffrey'@'localhost' IDENTIFIED BY 'password';
GRANT ALL ON db1.* TO 'jeffrey'@'localhost';
GRANT SELECT ON db2.Invoice TO 'jeffrey'@'localhost';
ALTER USER 'jeffrey'@'localhost' WITH MAX_QUERIES_PER_HOUR 90;
```

From the **mysql** program, **GRANT** responds with **Query OK, 0 rows affected** when executed successfully. To determine what privileges result from the operation, use **SHOW GRANTS**. See Section 13.7.7.21, “SHOW GRANTS Statement”.

**Important**

Under some circumstances, **GRANT** may be recorded in server logs or on the client side in a history file such as `~/.mysql_history`, which means that cleartext passwords may be read by anyone having read access to that information. For information about the conditions under which this occurs for the server logs and how to control it, see Section 6.1.2.3, “Passwords and Logging”. For similar information about client-side logging, see Section 4.5.1.3, “mysql Client Logging”.

**GRANT** supports host names up to 255 characters long (60 characters prior to MySQL 8.0.17). User names can be up to 32 characters. Database, table, column, and routine names can be up to 64 characters.
Warning

Do not attempt to change the permissible length for user names by altering the `mysql.user` system table. Doing so results in unpredictable behavior which may even make it impossible for users to log in to the MySQL server. Never alter the structure of tables in the `mysql` system schema in any manner except by means of the procedure described in Section 2.11, “Upgrading MySQL”.

Object Quoting Guidelines

Several objects within `GRANT` statements are subject to quoting, although quoting is optional in many cases: Account, role, database, table, column, and routine names. For example, if a `user_name` or `host_name` value in an account name is legal as an unquoted identifier, you need not quote it. However, quotation marks are necessary to specify a `user_name` string containing special characters (such as `-`), or a `host_name` string containing special characters or wildcard characters such as `%` (for example, `'test-user'@'%.com'`). Quote the user name and host name separately.

To specify quoted values:

- Quote database, table, column, and routine names as identifiers.
- Quote user names and host names as identifiers or as strings.
- Quote passwords as strings.

The `_` and `%` wildcards are permitted when specifying database names in `GRANT` statements that grant privileges at the database level (`GRANT ... ON db_name.*`). This means, for example, that to use a `_` character as part of a database name, specify it as `\_` in the `GRANT` statement, to prevent the user from being able to access additional databases matching the wildcard pattern (for example, `GRANT ... ON `foo_bar`.* TO ...`).

When a database name not is used to grant privileges at the database level, but as a qualifier for granting privileges to some other object such as a table or routine (for example, `GRANT ... ON db_name.tbl_name`), wildcard characters are treated as normal characters.

Account Names

A `user` value in a `GRANT` statement indicates a MySQL account to which the statement applies. To accommodate granting rights to users from arbitrary hosts, MySQL supports specifying the `user` value in the form `'user_name'@'host_name'`.

You can specify wildcards in the host name. For example, `'user_name'@'%.example.com'` applies to `user_name` for any host in the `example.com` domain, and `'user_name'@'198.51.100.1'` applies to `user_name` for any host in the `198.51.100` class C subnet.

The simple form `'user_name'` is a synonym for `'user_name'@'%'`.

MySQL does not support wildcards in user names. To refer to an anonymous user, specify an account with an empty user name with the `GRANT` statement:

```
grant all on test.* to ''@'localhost' ...;```

In this case, any user who connects from the local host with the correct password for the anonymous user is permitted access, with the privileges associated with the anonymous-user account.

For additional information about user name and host name values in account names, see Section 6.2.4, “Specifying Account Names”.
Warning

If you permit local anonymous users to connect to the MySQL server, you should also grant privileges to all local users as 'user_name'@'localhost'. Otherwise, the anonymous user account for localhost in the mysql.user system table is used when named users try to log in to the MySQL server from the local machine. For details, see Section 6.2.6, “Access Control, Stage 1: Connection Verification”.

To determine whether this issue applies to you, execute the following query, which lists any anonymous users:

```
SELECT Host, User FROM mysql.user WHERE User='';
```

To avoid the problem just described, delete the local anonymous user account using this statement:

```
DROP USER ''@'localhost';
```

Privileges Supported by MySQL

The following tables summarize the permissible static and dynamic priv_type privilege types that can be specified for the GRANT and REVOKE statements, and the levels at which each privilege can be granted. For additional information about each privilege, see Section 6.2.2, “Privileges Provided by MySQL”. For information about the differences between static and dynamic privileges, see Static Versus Dynamic Privileges.

Table 13.11 Permissible Static Privileges for GRANT and REVOKE

<table>
<thead>
<tr>
<th>Privilege</th>
<th>Meaning and Grantable Levels</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALL [PRIVILEGES]</td>
<td>Grant all privileges at specified access level except GRANT OPTION and PROXY.</td>
</tr>
<tr>
<td>ALTER</td>
<td>Enable use of ALTER TABLE. Levels: Global, database, table.</td>
</tr>
<tr>
<td>ALTER ROUTINE</td>
<td>Enable stored routines to be altered or dropped. Levels: Global, database, routine.</td>
</tr>
<tr>
<td>CREATE</td>
<td>Enable database and table creation. Levels: Global, database, table.</td>
</tr>
<tr>
<td>CREATE ROLE</td>
<td>Enable role creation. Level: Global.</td>
</tr>
<tr>
<td>CREATE ROUTINE</td>
<td>Enable stored routine creation. Levels: Global, database.</td>
</tr>
<tr>
<td>CREATE TABLESPACE</td>
<td>Enable tablespaces and log file groups to be created, altered, or dropped. Level: Global.</td>
</tr>
<tr>
<td>CREATE TEMPORARY TABLES</td>
<td>Enable use of CREATE TEMPORARY TABLE. Levels: Global, database.</td>
</tr>
<tr>
<td>CREATE USER</td>
<td>Enable use of CREATE USER, DROP USER, RENAME USER, and REVOKE ALL PRIVILEGES. Level: Global.</td>
</tr>
<tr>
<td>CREATE VIEW</td>
<td>Enable views to be created or altered. Levels: Global, database, table.</td>
</tr>
<tr>
<td>DELETE</td>
<td>Enable use of DELETE. Level: Global, database, table.</td>
</tr>
<tr>
<td>DROP</td>
<td>Enable databases, tables, and views to be dropped. Levels: Global, database, table.</td>
</tr>
<tr>
<td>DROP ROLE</td>
<td>Enable roles to be dropped. Level: Global.</td>
</tr>
<tr>
<td>EVENT</td>
<td>Enable use of events for the Event Scheduler. Levels: Global, database.</td>
</tr>
<tr>
<td>EXECUTE</td>
<td>Enable the user to execute stored routines. Levels: Global, database, routine.</td>
</tr>
<tr>
<td>FILE</td>
<td>Enable the user to cause the server to read or write files. Level: Global.</td>
</tr>
</tbody>
</table>
### Account Management Statements

<table>
<thead>
<tr>
<th>Privilege</th>
<th>Meaning and Grantable Levels</th>
</tr>
</thead>
<tbody>
<tr>
<td>GRANT OPTION</td>
<td>Enable privileges to be granted to or removed from other accounts. Levels: Global, database, table, routine, proxy.</td>
</tr>
<tr>
<td>INDEX</td>
<td>Enable indexes to be created or dropped. Levels: Global, database, table.</td>
</tr>
<tr>
<td>INSERT</td>
<td>Enable use of INSERT. Levels: Global, database, table, column.</td>
</tr>
<tr>
<td>LOCK TABLES</td>
<td>Enable use of LOCK TABLES on tables for which you have the SELECT privilege. Levels: Global, database.</td>
</tr>
<tr>
<td>PROCESS</td>
<td>Enable the user to see all processes with SHOW PROCESSLIST. Level: Global.</td>
</tr>
<tr>
<td>PROXY</td>
<td>Enable user proxying. Level: From user to user.</td>
</tr>
<tr>
<td>REFERENCES</td>
<td>Enable foreign key creation. Levels: Global, database, table, column.</td>
</tr>
<tr>
<td>RELOAD</td>
<td>Enable use of FLUSH operations. Level: Global.</td>
</tr>
<tr>
<td>REPLICATION CLIENT</td>
<td>Enable the user to ask where source or replica servers are. Level: Global.</td>
</tr>
<tr>
<td>REPLICATION SLAVE</td>
<td>Enable replicas to read binary log events from the source. Level: Global.</td>
</tr>
<tr>
<td>SELECT</td>
<td>Enable use of SELECT. Levels: Global, database, table, column.</td>
</tr>
<tr>
<td>SHOW DATABASES</td>
<td>Enable SHOW DATABASES to show all databases. Level: Global.</td>
</tr>
<tr>
<td>SHOW VIEW</td>
<td>Enable use of SHOW CREATE VIEW. Levels: Global, database, table.</td>
</tr>
<tr>
<td>SHUTDOWN</td>
<td>Enable use of mysqladmin shutdown. Level: Global.</td>
</tr>
<tr>
<td>SUPER</td>
<td>Enable use of other administrative operations such as CHANGE REPLICATION SOURCE TO, CHANGE MASTER TO, KILL, PURGE BINARY LOGS, SET GLOBAL, and mysqladmin debug command. Level: Global.</td>
</tr>
<tr>
<td>TRIGGER</td>
<td>Enable trigger operations. Levels: Global, database, table.</td>
</tr>
<tr>
<td>UPDATE</td>
<td>Enable use of UPDATE. Levels: Global, database, table, column.</td>
</tr>
<tr>
<td>USAGE</td>
<td>Synonym for “no privileges”</td>
</tr>
</tbody>
</table>

### Table 13.12 Permissible Dynamic Privileges for GRANT and REVOKE

<table>
<thead>
<tr>
<th>Privilege</th>
<th>Meaning and Grantable Levels</th>
</tr>
</thead>
<tbody>
<tr>
<td>APPLICATION_PASSWORD_ADMIN</td>
<td>Enable dual password administration. Level: Global.</td>
</tr>
<tr>
<td>AUDIT_ADMIN</td>
<td>Enable audit log configuration. Level: Global.</td>
</tr>
<tr>
<td>BACKUP_ADMIN</td>
<td>Enable backup administration. Level: Global.</td>
</tr>
<tr>
<td>BINLOG_ADMIN</td>
<td>Enable binary log control. Level: Global.</td>
</tr>
<tr>
<td>BINLOG_ENCRYPTION_ADMIN</td>
<td>Enable activation and deactivation of binary log encryption. Level: Global.</td>
</tr>
<tr>
<td>CLONE_ADMIN</td>
<td>Enable clone administration. Level: Global.</td>
</tr>
<tr>
<td>CONNECTION_ADMIN</td>
<td>Enable connection limit/restriction control. Level: Global.</td>
</tr>
<tr>
<td>ENCRYPTION_KEY_ADMIN</td>
<td>Enable InnoDB key rotation. Level: Global.</td>
</tr>
<tr>
<td>FIREWALL_ADMIN</td>
<td>Enable firewall rule administration, any user. Level: Global.</td>
</tr>
<tr>
<td>FIREWALL_USER</td>
<td>Enable firewall rule administration, self. Level: Global.</td>
</tr>
<tr>
<td>FLUSH_OPTIMIZER_COSTS</td>
<td>Enable optimizer cost reloading. Level: Global.</td>
</tr>
<tr>
<td>FLUSH_STATUS</td>
<td>Enable status indicator flushing. Level: Global.</td>
</tr>
<tr>
<td>FLUSH_TABLES</td>
<td>Enable table flushing. Level: Global.</td>
</tr>
</tbody>
</table>
### Privilege Management and Grantable Levels

<table>
<thead>
<tr>
<th>Privilege</th>
<th>Meaning and Grantable Levels</th>
</tr>
</thead>
<tbody>
<tr>
<td>FLUSH_USER_RESOURCES</td>
<td>Enable user-resource flushing. Level: Global.</td>
</tr>
<tr>
<td>GROUP_REPLICATION_ADMIN</td>
<td>Enable Group Replication control. Level: Global.</td>
</tr>
<tr>
<td>INNODB_REDO_LOG_ENABLE</td>
<td>Enable or disable redo logging. Level: Global.</td>
</tr>
<tr>
<td>INNODB_REDO_LOG_ARCHIVE</td>
<td>Enable redo log archiving administration. Level: Global.</td>
</tr>
<tr>
<td>NDB_STORED_USER</td>
<td>Enable sharing of user or role between SQL nodes (NDB Cluster). Level: Global.</td>
</tr>
<tr>
<td>PERSIST_RO_VARIABLES_ADMIN</td>
<td>Enable persisting read-only system variables. Level: Global.</td>
</tr>
<tr>
<td>REPLICATION_APPLIER</td>
<td>Act as the PRIVILEGE_CHECKS_USER for a replication channel. Level: Global.</td>
</tr>
<tr>
<td>REPLICATION_SLAVE_ADMIN</td>
<td>Enable regular replication control. Level: Global.</td>
</tr>
<tr>
<td>RESOURCE_GROUP_ADMIN</td>
<td>Enable resource group administration. Level: Global.</td>
</tr>
<tr>
<td>ROLE_ADMIN</td>
<td>Enable roles to be granted or revoked, use of WITH ADMIN OPTION. Level: Global.</td>
</tr>
<tr>
<td>SESSION_VARIABLES_ADMIN</td>
<td>Enable setting restricted session system variables. Level: Global.</td>
</tr>
<tr>
<td>SET_USER_ID</td>
<td>Enable setting non-self DEFINER values. Level: Global.</td>
</tr>
<tr>
<td>SHOW_ROUTINE</td>
<td>Enable access to stored routine definitions. Level: Global.</td>
</tr>
<tr>
<td>SYSTEM_USER</td>
<td>Designate account as system account. Level: Global.</td>
</tr>
<tr>
<td>SYSTEM_VARIABLES_ADMIN</td>
<td>Enable modifying or persisting global system variables. Level: Global.</td>
</tr>
<tr>
<td>TABLE_ENCRYPTION_ADMIN</td>
<td>Enable overriding default encryption settings. Level: Global.</td>
</tr>
<tr>
<td>VERSION_TOKEN_ADMIN</td>
<td>Enable use of Version Tokens UDFs. Level: Global.</td>
</tr>
<tr>
<td>XA_RECOVER_ADMIN</td>
<td>Enable XA RECOVER execution. Level: Global.</td>
</tr>
</tbody>
</table>

A trigger is associated with a table. To create or drop a trigger, you must have the TRIGGER privilege for the table, not the trigger.

In GRANT statements, the ALL [PRIVILEGES] or PROXY privilege must be named by itself and cannot be specified along with other privileges. ALL [PRIVILEGES] stands for all privileges available for the level at which privileges are to be granted except for the GRANT OPTION and PROXY privileges.

MySQL account information is stored in the tables of the mysql system schema. For additional details, consult Section 6.2, “Access Control and Account Management”, which discusses the mysql system schema and the access control system extensively.

If the grant tables hold privilege rows that contain mixed-case database or table names and the lower_case_table_names system variable is set to a nonzero value, REVOKE cannot be used to revoke these privileges. It is necessary in such cases to manipulate the grant tables directly. (GRANT does not create such rows when lower_case_table_names is set, but such rows might have been created prior to setting that variable. The lower_case_table_names setting can only be configured at server startup.)

Privileges can be granted at several levels, depending on the syntax used for the ON clause. For REVOKE, the same ON syntax specifies which privileges to remove.

For the global, database, table, and routine levels, GRANT ALL assigns only the privileges that exist at the level you are granting. For example, GRANT ALL ON db_name.* is a database-level statement, so it does not grant any global-only privileges such as FILE. Granting ALL does not assign the GRANT OPTION or PROXY privilege.

The object_type clause, if present, should be specified as TABLE, FUNCTION, or PROCEDURE when the following object is a table, a stored function, or a stored procedure.
The privileges that a user holds for a database, table, column, or routine are formed additively as the logical OR of the account privileges at each of the privilege levels, including the global level. It is not possible to deny a privilege granted at a higher level by absence of that privilege at a lower level. For example, this statement grants the SELECT and INSERT privileges globally:

```sql
GRANT SELECT, INSERT ON *.* TO u1;
```

The globally granted privileges apply to all databases, tables, and columns, even though not granted at any of those lower levels.

As of MySQL 8.0.16, it is possible to explicitly deny a privilege granted at the global level by revoking it for particular databases, if the `partial_revokes` system variable is enabled:

```sql
GRANT SELECT, INSERT, UPDATE ON *.* TO u1;
REVOKE INSERT, UPDATE ON db1.* FROM u1;
```

The result of the preceding statements is that SELECT applies globally to all tables, whereas INSERT and UPDATE apply globally except to tables in db1. Account access to db1 is read only.

Details of the privilege-checking procedure are presented in Section 6.2.7, “Access Control, Stage 2: Request Verification”.

If you are using table, column, or routine privileges for even one user, the server examines table, column, and routine privileges for all users and this slows down MySQL a bit. Similarly, if you limit the number of queries, updates, or connections for any users, the server must monitor these values.

MySQL enables you to grant privileges on databases or tables that do not exist. For tables, the privileges to be granted must include the CREATE privilege. This behavior is by design, and is intended to enable the database administrator to prepare user accounts and privileges for databases or tables that are to be created at a later time.

---

**Important**

MySQL does not automatically revoke any privileges when you drop a database or table. However, if you drop a routine, any routine-level privileges granted for that routine are revoked.

---

**Global Privileges**

Global privileges are administrative or apply to all databases on a given server. To assign global privileges, use `ON *.*` syntax:

```sql
GRANT ALL ON *.* TO 'someuser'@'somehost';
GRANT SELECT, INSERT ON *.* TO 'someuser'@'somehost';
```

The `CREATE TABLESPACE`, `CREATE USER`, `FILE`, `PROCESS`, `RELOAD`, `REPLICATION CLIENT`, `REPLICATION SLAVE`, `SHOW DATABASES`, `SHUTDOWN`, and `SUPER` static privileges are administrative and can only be granted globally.

Dynamic privileges are all global and can only be granted globally.

Other privileges can be granted globally or at more specific levels.

The effect of `GRANT OPTION` granted at the global level differs for static and dynamic privileges:

- **GRANT OPTION** granted for any static global privilege applies to all static global privileges.
- **GRANT OPTION** granted for any dynamic privilege applies only to that dynamic privilege.

**GRANT ALL** at the global level grants all static global privileges and all currently registered dynamic privileges. A dynamic privilege registered subsequent to execution of the `GRANT` statement is not granted retroactively to any account.
MySQL stores global privileges in the `mysql.user` system table.

### Database Privileges

Database privileges apply to all objects in a given database. To assign database-level privileges, use `ON db_name.*` syntax:

```sql
GRANT ALL ON mydb.* TO 'someuser'@'somehost';
GRANT SELECT, INSERT ON mydb.* TO 'someuser'@'somehost';
```

If you use `ON *` syntax (rather than `ON *.`), privileges are assigned at the database level for the default database. An error occurs if there is no default database.

The `CREATE`, `DROP`, `EVENT`, `GRANT OPTION`, `LOCK TABLES`, and `REFERENCES` privileges can be specified at the database level. Table or routine privileges also can be specified at the database level, in which case they apply to all tables or routines in the database.

MySQL stores database privileges in the `mysql.db` system table.

### Table Privileges

Table privileges apply to all columns in a given table. To assign table-level privileges, use `ON db_name.tbl_name` syntax:

```sql
GRANT ALL ON mydb.mytbl TO 'someuser'@'somehost';
GRANT SELECT, INSERT ON mydb.mytbl TO 'someuser'@'somehost';
```

If you specify `tbl_name` rather than `db_name.tbl_name`, the statement applies to `tbl_name` in the default database. An error occurs if there is no default database.

The permissible `priv_type` values at the table level are `ALTER`, `CREATE VIEW`, `CREATE`, `DELETE`, `DROP`, `GRANT OPTION`, `INDEX`, `INSERT`, `REFERENCES`, `SELECT`, `SHOW VIEW`, `TRIGGER`, and `UPDATE`.

Table-level privileges apply to base tables and views. They do not apply to tables created with `CREATE TEMPORARY TABLE`, even if the table names match. For information about `TEMPORARY` table privileges, see Section 13.1.20.2, "CREATE TEMPORARY TABLE Statement".

MySQL stores table privileges in the `mysql.tables_priv` system table.

### Column Privileges

Column privileges apply to single columns in a given table. Each privilege to be granted at the column level must be followed by the column or columns, enclosed within parentheses.

```sql
GRANT SELECT (col1), INSERT (col1, col2) ON mydb.mytbl TO 'someuser'@'somehost';
```

The permissible `priv_type` values for a column (that is, when you use a `column_list` clause) are `INSERT`, `REFERENCES`, `SELECT`, and `UPDATE`.

MySQL stores column privileges in the `mysql.columns_priv` system table.

### Stored Routine Privileges

The `ALTER ROUTINE`, `CREATE ROUTINE`, `EXECUTE`, and `GRANT OPTION` privileges apply to stored routines (procedures and functions). They can be granted at the global and database levels. Except for `CREATE ROUTINE`, these privileges can be granted at the routine level for individual routines.

```sql
GRANT CREATE ROUTINE ON mydb.* TO 'someuser'@'somehost';
GRANT EXECUTE ON PROCEDURE mydb.myproc TO 'someuser'@'somehost';
```

The permissible `priv_type` values at the routine level are `ALTER ROUTINE`, `EXECUTE`, and `GRANT OPTION`. `CREATE ROUTINE` is not a routine-level privilege because you must have the privilege at the global or database level to create a routine in the first place.
MySQL stores routine-level privileges in the `mysql.procs_priv` system table.

**Proxy User Privileges**

The **PROXY** privilege enables one user to be a proxy for another. The proxy user impersonates or takes the identity of the proxied user; that is, it assumes the privileges of the proxied user.

```sql
GRANT PROXY ON 'localuser'@'localhost' TO 'externaluser'@'somehost';
```

When **PROXY** is granted, it must be the only privilege named in the `GRANT` statement, and the only permitted `WITH` option is `WITH GRANT OPTION`.

Proxying requires that the proxy user authenticate through a plugin that returns the name of the proxied user to the server when the proxy user connects, and that the proxy user have the **PROXY** privilege for the proxied user. For details and examples, see Section 6.2.18, “Proxy Users”.

MySQL stores proxy privileges in the `mysql.proxies_priv` system table.

**Granting Roles**

`GRANT` syntax without an `ON` clause grants roles rather than individual privileges. A role is a named collection of privileges; see Section 6.2.10, “Using Roles”. For example:

```sql
GRANT 'role1', 'role2' TO 'user1'@'localhost', 'user2'@'localhost';
```

Each role to be granted must exist, as well as each user account or role to which it is to be granted. As of MySQL 8.0.16, roles cannot be granted to anonymous users.

Granting a role does not automatically cause the role to be active. For information about role activation and inactivation, see Activating Roles.

These privileges are required to grant roles:

- If you have the **ROLE_ADMIN** privilege (or the deprecated **SUPER** privilege), you can grant or revoke any role to users or roles.
- If you were granted a role with a `GRANT` statement that includes the `WITH ADMIN OPTION` clause, you become able to grant that role to other users or roles, or revoke it from other users or roles, as long as the role is active at such time as you subsequently grant or revoke it. This includes the ability to use `WITH ADMIN OPTION` itself.
- To grant a role that has the **SYSTEM_USER** privilege, you must have the **SYSTEM_USER** privilege.

It is possible to create circular references with `GRANT`. For example:

```sql
CREATE USER 'u1', 'u2';
CREATE ROLE 'r1', 'r2';
GRANT 'u1' TO 'u1';  -- simple loop: u1 => u1
GRANT 'r1' TO 'r1';  -- simple loop: r1 => r1
GRANT 'r2' TO 'u2';
GRANT 'u2' TO 'r2';  -- mixed user/role loop: u2 => r2 => u2
```

Circular grant references are permitted but add no new privileges or roles to the grantee because a user or role already has its privileges and roles.

**The AS Clause and Privilege Restrictions**

As of MySQL 8.0.16, `GRANT` has an `AS user` (with `ROLE`) clause that specifies additional information about the privilege context to use for statement execution. This syntax is visible at the SQL level, although its primary purpose is to enable uniform replication across all nodes of grantor privilege...
restrictions imposed by partial revokes, by causing those restrictions to appear in the binary log. For information about partial revokes, see Section 6.2.12, “Privilege Restriction Using Partial Revokes”.

When the AS user clause is specified, statement execution takes into account any privilege restrictions associated with the named user, including all roles specified by WITH ROLE, if present. The result is that the privileges actually granted by the statement may be reduced relative to those specified.

These conditions apply to the AS user clause:

- **AS** has an effect only when the named user has privilege restrictions (which implies that the partial_revokes system variable is enabled).
- If WITH ROLE is given, all roles named must be granted to the named user.
- The named user should be a MySQL account specified as 'user_name'@'host_name', CURRENT_USER, or CURRENT_USER(). The current user may be named together with WITH ROLE for the case that the executing user wants GRANT to execute with a set of roles applied that may differ from the roles active within the current session.
- **AS** cannot be used to gain privileges not possessed by the user who executes the GRANT statement. The executing user must have at least the privileges to be granted, but the AS clause can only restrict the privileges granted, not escalate them.
- With respect to the privileges to be granted, **AS** cannot specify a user/role combination that has more privileges (fewer restrictions) than the user who executes the GRANT statement. The **AS** user/role combination is permitted to have more privileges than the executing user, but only if the statement does not grant those additional privileges.
- **AS** is supported only for granting global privileges (ON *.*).
- **AS** is not supported for PROXY grants.

The following example illustrates the effect of the AS clause. Create a user u1 that has some global privileges, as well as restrictions on those privileges:

```
CREATE USER u1;
GRANT SELECT, INSERT, UPDATE, DELETE ON *.* TO u1;
REVOKE INSERT, UPDATE ON schema1.* FROM u1;
REVOKE SELECT ON schema2.* FROM u1;
```

Also create a role r1 that lifts some of the privilege restrictions and grant the role to u1:

```
CREATE ROLE r1;
GRANT INSERT ON schema1.* TO r1;
GRANT SELECT ON schema2.* TO r1;
GRANT r1 TO u1;
```

Now, using an account that has no privilege restrictions of its own, grant to multiple users the same set of global privileges, but each with different restrictions imposed by the AS clause, and check which privileges are actually granted.

- The GRANT statement here has no AS clause, so the privileges granted are exactly those specified:

```
mysql> CREATE USER u2;
mysql> GRANT SELECT, INSERT, UPDATE ON *.* TO u2;
mysql> SHOW GRANTS FOR u2;
```

- The GRANT statement here has an AS clause, so the privileges granted are those specified but with the restrictions from u1 applied:
As mentioned previously, the `AS` clause can only add privilege restrictions; it cannot escalate privileges. Thus, although `u1` has the `DELETE` privilege, that is not included in the privileges granted because the statement does not specify granting `DELETE`.

- The `AS` clause for the `GRANT` statement here makes the role `r1` active for `u1`. That role lifts some of the restrictions on `u1`. Consequently, the privileges granted have some restrictions, but not so many as for the previous `GRANT` statement:

```sql
mysql> CREATE USER u4;
mysql> GRANT SELECT, INSERT, UPDATE ON *.* TO u4 AS u1 WITH ROLE r1;
mysql> SHOW GRANTS FOR u4;
```

If a `GRANT` statement includes an `AS user` clause, privilege restrictions on the user who executes the statement are ignored (rather than applied as they would be in the absence of an `AS` clause).

### Other Account Characteristics

The optional `WITH` clause is used to enable a user to grant privileges to other users. The `WITH GRANT OPTION` clause gives the user the ability to give to other users any privileges the user has at the specified privilege level.

To grant the `GRANT OPTION` privilege to an account without otherwise changing its privileges, do this:

```sql
GRANT USAGE ON *.* TO 'someuser'@'somehost' WITH GRANT OPTION;
```

Be careful to whom you give the `GRANT OPTION` privilege because two users with different privileges may be able to combine privileges!

You cannot grant another user a privilege which you yourself do not have; the `GRANT OPTION` privilege enables you to assign only those privileges which you yourself possess.

Be aware that when you grant a user the `GRANT OPTION` privilege at a particular privilege level, any privileges the user possesses (or may be given in the future) at that level can also be granted by that user to other users. Suppose that you grant a user the `INSERT` privilege on a database. If you then grant the `SELECT` privilege on the database and specify `WITH GRANT OPTION`, that user can give to other users not only the `SELECT` privilege, but also `INSERT`. If you then grant the `UPDATE` privilege to the user on the database, the user can grant `INSERT`, `SELECT`, and `UPDATE`.

For a nonadministrative user, you should not grant the `ALTER` privilege globally or for the `mysql` system schema. If you do that, the user can try to subvert the privilege system by renaming tables!

For additional information about security risks associated with particular privileges, see Section 6.2.2, “Privileges Provided by MySQL”.

### MySQL and Standard SQL Versions of GRANT

The biggest differences between the MySQL and standard SQL versions of `GRANT` are:
• MySQL associates privileges with the combination of a host name and user name and not with only a
user name.

• Standard SQL does not have global or database-level privileges, nor does it support all the privilege
types that MySQL supports.

• MySQL does not support the standard SQL \textit{UN}DER privilege.

• Standard SQL privileges are structured in a hierarchical manner. If you remove a user, all privileges
the user has been granted are revoked. This is also true in MySQL if you use \texttt{DROP USER}. See
Section 13.7.1.5, “DROP USER Statement”.

• In standard SQL, when you drop a table, all privileges for the table are revoked. In standard SQL,
when you revoke a privilege, all privileges that were granted based on that privilege are also
revoked. In MySQL, privileges can be dropped with \texttt{DROP USER} or \texttt{REVOKE} statements.

• In MySQL, it is possible to have the \texttt{INSERT} privilege for only some of the columns in a table. In this
case, you can still execute \texttt{INSERT} statements on the table, provided that you insert values only for
those columns for which you have the \texttt{INSERT} privilege. The omitted columns are set to their implicit
default values if strict SQL mode is not enabled. In strict mode, the statement is rejected if any of the
omitted columns have no default value. (Standard SQL requires you to have the \texttt{INSERT} privilege on
all columns.) For information about strict SQL mode and implicit default values, see Section 5.1.11,
“Server SQL Modes”, and Section 11.6, “Data Type Default Values”.

13.7.1.7 \texttt{RENAME USER} Statement

\begin{verbatim}
RENAME USER old_user TO new_user 
[, old_user TO new_user] ...
\end{verbatim}

The \texttt{RENAME USER} statement renames existing MySQL accounts. An error occurs for old accounts that
do not exist or new accounts that already exist.

To use \texttt{RENAME USER}, you must have the global \texttt{CREATE USER} privilege, or the \texttt{UPDATE}
privilege for the \texttt{mysql} system schema. When the \texttt{read_only} system variable is enabled, \texttt{RENAME USER}
additionally requires the \texttt{CONNECTION_ADMIN} privilege (or the deprecated \texttt{SUPER} privilege).

As of MySQL 8.0.22, \texttt{RENAME USER} fails with an error if any account to be renamed is named as the
\texttt{DEFINER} attribute for any stored object. (That is, the statement fails if renaming an account would
cause a stored object to become orphaned.) To perform the operation anyway, you must have the
\texttt{SET_USER_ID} privilege; in this case, the statement succeeds with a warning rather than failing with an
error. For additional information, including how to identify which objects name a given account as the
\texttt{DEFINER} attribute, see Orphan Stored Objects.

Each account name uses the format described in Section 6.2.4, “Specifying Account Names”. For
example:

\begin{verbatim}
RENAME USER 'jeffrey'@'localhost' TO 'jeff'@'127.0.0.1';
\end{verbatim}

The host name part of the account name, if omitted, defaults to \texttt{'}%\texttt{'}\texttt{.}

\texttt{RENAME USER} causes the privileges held by the old user to be those held by the new user. However,
\texttt{RENAME USER} does not automatically drop or invalidate databases or objects within them that the old
user created. This includes stored programs or views for which the \texttt{DEFINER} attribute names the old
user. Attempts to access such objects may produce an error if they execute in definer security context.
(For information about security context, see Section 25.6, “Stored Object Access Control”.)

The privilege changes take effect as indicated in Section 6.2.13, “When Privilege Changes Take
Effect”.

13.7.1.8 \texttt{REVOKE} Statement

\begin{verbatim}
REVOKE
\end{verbatim}
The `REVOKE` statement enables system administrators to revoke privileges and roles, which can be revoked from user accounts and roles.

For details on the levels at which privileges exist, the permissible `priv_type`, `priv_level`, and `object_type` values, and the syntax for specifying users and passwords, see Section 13.7.1.6, “GRANT Statement”.

For information about roles, see Section 6.2.10, “Using Roles”.

When the `read_only` system variable is enabled, `REVOKE` requires the `CONNECTION_ADMIN` or privilege (or the deprecated `SUPER` privilege), in addition to any other required privileges described in the following discussion.

`REVOKE` either succeeds for all named users and roles or rolls back and has no effect if any error occurs. The statement is written to the binary log only if it succeeds for all named users and roles.

Each account name uses the format described in Section 6.2.4, “Specifying Account Names”. Each role name uses the format described in Section 6.2.5, “Specifying Role Names”. For example:

```
REVOKE INSERT ON *.* FROM 'jeffrey'@'localhost';
REVOKE 'role1', 'role2' FROM 'user1'@'localhost', 'user2'@'localhost';
REVOKE SELECT ON world.* FROM 'role3';
```

The host name part of the account or role name, if omitted, defaults to ‘%’.

To use the first `REVOKE` syntax, you must have the `GRANT OPTION` privilege, and you must have the privileges that you are revoking.

To revoke all privileges, use the second syntax, which drops all global, database, table, column, and routine privileges for the named users or roles:

```
REVOKE ALL PRIVILEGES, GRANT OPTION
FROM user_or_role [, user_or_role] ... 
```

`REVOKE ALL PRIVILEGES, GRANT OPTION` does not revoke any roles.

To use this `REVOKE` syntax, you must have the global `CREATE USER` privilege, or the `UPDATE` privilege for the `mysql` system schema.

The syntax for which the `REVOKE` keyword is followed by one or more role names takes a `FROM` clause indicating one or more users or roles from which to revoke the roles.

Roles named in the `mandatory_roles` system variable value cannot be revoked.

A revoked role immediately affects any user account from which it was revoked, such that within any current session for the account, its privileges are adjusted for the next statement executed.
Revoking a role revokes the role itself, not the privileges that it represents. Suppose that an account is granted a role that includes a given privilege, and is also granted the privilege explicitly or another role that includes the privilege. In this case, the account still possesses that privilege if the first role is revoked. For example, if an account is granted two roles that each include `SELECT`, the account still can select after either role is revoked.

`REVOKE ALL ON *.*` (at the global level) revokes all granted static global privileges and all granted dynamic privileges.

User accounts and roles from which privileges and roles are to be revoked must exist, but the privileges and roles to be revoked need not be currently granted to them.

A revoked privilege that is granted but not known to the server is revoked with a warning. This situation can occur for dynamic privileges. For example, a dynamic privilege can be granted while the component that registers it is installed, but if that component is subsequently uninstalled, the privilege becomes unregistered, although accounts that possess the privilege still possess it and it can be revoked from them.

`REVOKE` removes privileges, but does not remove rows from the `mysql.user` system table. To remove a user account entirely, use `DROP USER`. See Section 13.7.1.5, “DROP USER Statement”.

If the grant tables hold privilege rows that contain mixed-case database or table names and the `lower_case_table_names` system variable is set to a nonzero value, `REVOKE` cannot be used to revoke these privileges. It is necessary in such cases to manipulate the grant tables directly. (`GRANT` does not create such rows when `lower_case_table_names` is set, but such rows might have been created prior to setting the variable. The `lower_case_table_names` setting can only be configured when initializing the server.)

When successfully executed from the `mysql` program, `REVOKE` responds with `Query OK, 0 rows affected`. To determine what privileges remain after the operation, use `SHOW GRANTS`. See Section 13.7.7.21, “SHOW GRANTS Statement”.

### 13.7.1.9 SET DEFAULT ROLE Statement

```sql
SET DEFAULT ROLE
   {NONE | ALL | role [, role] ...}
TO user [, user] ...
```

For each `user` named immediately after the `TO` keyword, this statement defines which roles become active when the user connects to the server and authenticates, or when the user executes the `SET ROLE DEFAULT` statement during a session.

`SET DEFAULT ROLE` is alternative syntax for `ALTER USER ... DEFAULT ROLE` (see Section 13.7.1.1, “ALTER USER Statement”). However, `ALTER USER` can set the default for only a single user, whereas `SET DEFAULT ROLE` can set the default for multiple users. On the other hand, you can specify `CURRENT_USER` as the user name for the `ALTER USER` statement, whereas you cannot for `SET DEFAULT ROLE`.

`SET DEFAULT ROLE` requires these privileges:

- Setting the default roles for another user requires the global `CREATE USER` privilege, or the `UPDATE` privilege for the `mysql.default_roles` system table.

- Setting the default roles for yourself requires no special privileges, as long as the roles you want as the default have been granted to you.

Each role name uses the format described in Section 6.2.5, “Specifying Role Names”. For example:

```sql
SET DEFAULT ROLE 'admin', 'developer' TO 'joe'@'10.0.0.1';
```

The host name part of the role name, if omitted, defaults to `'%'`. 

2662
The clause following the `DEFAULT ROLE` keywords permits these values:

- **NONE**: Set the default to `NONE` (no roles).
- **ALL**: Set the default to all roles granted to the account.
- `role [, role ] ...`: Set the default to the named roles, which must exist and be granted to the account at the time `SET DEFAULT ROLE` is executed.

**Note**

`SET DEFAULT ROLE` and `SET ROLE DEFAULT` are different statements:

- **SET DEFAULT ROLE** defines which account roles to activate by default within account sessions.
- **SET ROLE DEFAULT** sets the active roles within the current session to the current account default roles.

For role usage examples, see Section 6.2.10, “Using Roles”.

### 13.7.1.10 SET PASSWORD Statement

The `SET PASSWORD` statement assigns a password to a MySQL user account. The password may be either explicitly specified in the statement or randomly generated by MySQL. The statement may also include a password-verification clause that specifies the account current password to be replaced, and a clause that manages whether an account has a secondary password. `auth_string` and `current_auth_string` each represent a cleartext (unencrypted) password.

**Note**

Rather than using `SET PASSWORD` to assign passwords, `ALTER USER` is the preferred statement for account alterations, including assigning passwords. For example:

```
ALTER USER user IDENTIFIED BY 'auth_string';
```

**Note**

Clauses for random password generation, password verification, and secondary passwords apply only to accounts that use an authentication plugin that stores credentials internally to MySQL. For accounts that use a plugin that performs authentication against a credentials system that is external to MySQL, password management must be handled externally against that system as well. For more information about internal credentials storage, see Section 6.2.15, “Password Management”.

The `REPLACE 'current_auth_string'` clause performs password verification and is available as of MySQL 8.0.13. If given:

- **REPLACE** specifies the account current password to be replaced, as a cleartext (unencrypted) string.
- The clause must be given if password changes for the account are required to specify the current password, as verification that the user attempting to make the change actually knows the current password.
• The clause is optional if password changes for the account may but need not specify the current password.

• The statement fails if the clause is given but does not match the current password, even if the clause is optional.

• `REPLACE` can be specified only when changing the account password for the current user.

For more information about password verification by specifying the current password, see Section 6.2.15, “Password Management”.

The `RETAIN CURRENT PASSWORD` clause implements dual-password capability and is available as of MySQL 8.0.14. If given:

• `RETAIN CURRENT PASSWORD` retains an account current password as its secondary password, replacing any existing secondary password. The new password becomes the primary password, but clients can use the account to connect to the server using either the primary or secondary password. (Exception: If the new password specified by the `SET PASSWORD` statement is empty, the secondary password becomes empty as well, even if `RETAIN CURRENT PASSWORD` is given.)

• If you specify `RETAIN CURRENT PASSWORD` for an account that has an empty primary password, the statement fails.

• If an account has a secondary password and you change its primary password without specifying `RETAIN CURRENT PASSWORD`, the secondary password remains unchanged.

For more information about use of dual passwords, see Section 6.2.15, “Password Management”.

`SET PASSWORD` permits these `auth_option` sytaxes:

• `= 'auth_string'`
  Assigns the account the given literal password.

• `TO RANDOM`
  Assigns the account a password randomly generated by MySQL. The statement also returns the cleartext password in a result set to make it available to the user or application executing the statement.

  For details about the result set and characteristics of randomly generated passwords, see Random Password Generation.

  Random password generation is available as of MySQL 8.0.18.

**Important**

Under some circumstances, `SET PASSWORD` may be recorded in server logs or on the client side in a history file such as `~/.mysql_history`, which means that cleartext passwords may be read by anyone having read access to that information. For information about the conditions under which this occurs for the server logs and how to control it, see Section 6.1.2.3, “Passwords and Logging”.

For similar information about client-side logging, see Section 4.5.1.3, “mysql Client Logging”.

`SET PASSWORD` can be used with or without a `FOR` clause that explicitly names a user account:

• With a `FOR user` clause, the statement sets the password for the named account, which must exist:

  ```
  SET PASSWORD FOR 'jeffrey'@'localhost' = 'auth_string';
  ```

• With no `FOR user` clause, the statement sets the password for the current user:
Any client who connects to the server using a nonanonymous account can change the password for that account. (In particular, you can change your own password.) To see which account the server authenticated you as, invoke the `CURRENT_USER()` function:

```
SELECT CURRENT_USER();
```

If a `FOR user` clause is given, the account name uses the format described in Section 6.2.4, “Specifying Account Names”. For example:

```
SET PASSWORD FOR 'bob'@'%.example.org' = 'auth_string';
```

The host name part of the account name, if omitted, defaults to '%'.

`SET PASSWORD` interprets the string as a cleartext string, passes it to the authentication plugin associated with the account, and stores the result returned by the plugin in the account row in the `mysql.user` system table. (The plugin is given the opportunity to hash the value into the encryption format it expects. The plugin may use the value as specified, in which case no hashing occurs.)

Setting the password for a named account (with a `FOR` clause) requires the `UPDATE` privilege for the `mysql` system schema. Setting the password for yourself (for a nonanonymous account with no `FOR` clause) requires no special privileges.

Statements that modify secondary passwords require these privileges:

- The `APPLICATION_PASSWORD_ADMIN` privilege is required to use the `RETAIN CURRENT PASSWORD` clause for `SET PASSWORD` statements that apply to your own account. The privilege is required to manipulate your own secondary password because most users require only one password.

- If an account is to be permitted to manipulate secondary passwords for all accounts, it should be granted the `CREATE USER` privilege rather than `APPLICATION_PASSWORD_ADMIN`.

When the `read_only` system variable is enabled, `SET PASSWORD` requires the `CONNECTION_ADMIN` privilege (or the deprecated `SUPER` privilege), in addition to any other required privileges.

For additional information about setting passwords and authentication plugins, see Section 6.2.14, “Assigning Account Passwords”, and Section 6.2.17, “Pluggable Authentication”.

### 13.7.11 SET ROLE Statement

```
SET ROLE { DEFAULT | NONE | ALL | ALL EXCEPT role [, role ] ... | role [, role ] ... }
```

`SET ROLE` modifies the current user's effective privileges within the current session by specifying which of its granted roles are active. Granted roles include those granted explicitly to the user and those named in the `mandatory_roles` system variable value.

Examples:

```
SET ROLE DEFAULT;
SET ROLE 'role1', 'role2';
SET ROLE ALL;
SET ROLE ALL EXCEPT 'role1', 'role2';
```

Each role name uses the format described in Section 6.2.5, “Specifying Role Names”. The host name part of the role name, if omitted, defaults to '%'.

---

2665
Privileges that the user has been granted directly (rather than through roles) remain unaffected by changes to the active roles.

The statement permits these role specifiers:

• **DEFAULT**: Activate the account default roles. Default roles are those specified with `SET DEFAULT ROLE`.

When a user connects to the server and authenticates successfully, the server determines which roles to activate as the default roles. If the `activate_all_roles_on_login` system variable is enabled, the server activates all granted roles. Otherwise, the server executes `SET ROLE DEFAULT` implicitly. The server activates only default roles that can be activated. The server writes warnings to its error log for default roles that cannot be activated, but the client receives no warnings.

If a user executes `SET ROLE DEFAULT` during a session, an error occurs if any default role cannot be activated (for example, if it does not exist or is not granted to the user). In this case, the current active roles are not changed.

• **NONE**: Set the active roles to `NONE` (no active roles).

• **ALL**: Activate all roles granted to the account.

• **ALL EXCEPT role [ , role ] ...**: Activate all roles granted to the account except those named. The named roles need not exist or be granted to the account.

• **role [ , role ] ...**: Activate the named roles, which must be granted to the account.

---

Note

**SET DEFAULT ROLE** and **SET ROLE DEFAULT** are different statements:

• **SET DEFAULT ROLE** defines which account roles to activate by default within account sessions.

• **SET ROLE DEFAULT** sets the active roles within the current session to the current account default roles.

For role usage examples, see Section 6.2.10, “Using Roles”.

### 13.7.2 Resource Group Management Statements

MySQL supports creation and management of resource groups, and permits assigning threads running within the server to particular groups so that threads execute according to the resources available to the group. This section describes the SQL statements available for resource group management. For general discussion of the resource group capability, see Section 5.1.16, “Resource Groups”.

#### 13.7.2.1 ALTER RESOURCE GROUP Statement

```
ALTER RESOURCE GROUP group_name
    [VCPU [=] vcpu_spec [ , vcpu_spec ] ...]
    [THREAD_PRIORITY [=] N]
    [ENABLE|DISABLE [FORCE]]
```

**vcpu_spec**: `{N | M - N}`

**ALTER RESOURCE GROUP** is used for resource group management (see Section 5.1.16, “Resource Groups”). This statement alters modifiable attributes of an existing resource group. It requires the `RESOURCE_GROUP_ADMIN` privilege.

**group_name** identifies which resource group to alter. If the group does not exist, an error occurs.

The attributes for CPU affinity, priority, and whether the group is enabled can be modified with **ALTER RESOURCE GROUP**. These attributes are specified the same way as described for **CREATE RESOURCE...**
GROUP (see Section 13.7.2.2, “CREATE RESOURCE GROUP Statement”). Only the attributes specified are altered. Unspecified attributes retain their current values.

The FORCE modifier is used with DISABLE. It determines statement behavior if the resource group has any threads assigned to it:

- If FORCE is not given, existing threads in the group continue to run until they terminate, but new threads cannot be assigned to the group.
- If FORCE is given, existing threads in the group are moved to their respective default group (system threads to SYS_default, user threads to USR_default).

The name and type attributes are set at group creation time and cannot be modified thereafter with ALTER RESOURCE GROUP.

Examples:

- Alter a group CPU affinity:
  
  ALTER RESOURCE GROUP rg1 VCPU = 0-63;

- Alter a group thread priority:
  
  ALTER RESOURCE GROUP rg2 THREAD_PRIORITY = 5;

- Disable a group, moving any threads assigned to it to the default groups:
  
  ALTER RESOURCE GROUP rg3 DISABLE FORCE;

Resource group management is local to the server on which it occurs. ALTER RESOURCE GROUP statements are not written to the binary log and are not replicated.

### 13.7.2.2 CREATE RESOURCE GROUP Statement

```
CREATE RESOURCE GROUP group_name
  TYPE = {SYSTEM|USER}
  [VCPU = vcpu_spec [, vcpu_spec] ...]
  [THREAD_PRIORITY = N]
  [ENABLE|DISABLE]

vcpu_spec: {N | M - N}
```

CREATE RESOURCE GROUP is used for resource group management (see Section 5.1.16, “Resource Groups”). This statement creates a new resource group and assigns its initial attribute values. It requires the RESOURCE_GROUP_ADMIN privilege.

`group_name` identifies which resource group to create. If the group already exists, an error occurs.

The TYPE attribute is required. It should be SYSTEM for a system resource group, USER for a user resource group. The group type affects permitted THREAD_PRIORITY values, as described later.

The VCPU attribute indicates the CPU affinity; that is, the set of virtual CPUs the group can use:

- If VCPU is not given, the resource group has no CPU affinity and can use all available CPUs.
- If VCPU is given, the attribute value is a list of comma-separated CPU numbers or ranges:
  
  - Each number must be an integer in the range from 0 to the number of CPUs − 1. For example, on a system with 64 CPUs, the number can range from 0 to 63.
  - A range is given in the form \( M - N \), where \( M \) is less than or equal to \( N \) and both numbers are in the CPU range.
  - If a CPU number is an integer outside the permitted range or is not an integer, an error occurs.
Example **VCPU** specifiers (these are all equivalent):

<table>
<thead>
<tr>
<th>Specifier</th>
</tr>
</thead>
<tbody>
<tr>
<td>VCPU = 0,1,2,3,9,10</td>
</tr>
<tr>
<td>VCPU = 0-3,9-10</td>
</tr>
<tr>
<td>VCPU = 9,10,0-3</td>
</tr>
<tr>
<td>VCPU = 0,10,1,9,3,2</td>
</tr>
</tbody>
</table>

The **THREAD_PRIORITY** attribute indicates the priority for threads assigned to the group:

- If **THREAD_PRIORITY** is not given, the default priority is 0.
- If **THREAD_PRIORITY** is given, the attribute value must be in the range from -20 (highest priority) to 19 (lowest priority). The priority for system resource groups must be in the range from -20 to 0. The priority for user resource groups must be in the range from 0 to 19. Use of different ranges for system and user groups ensures that user threads never have a higher priority than system threads.

**ENABLE** and **DISABLE** specify that the resource group is initially enabled or disabled. If neither is specified, the group is enabled by default. A disabled group cannot have threads assigned to it.

Examples:

- Create an enabled user group that has a single CPU and the lowest priority:

  ```sql
  CREATE RESOURCE GROUP rg1
  TYPE = USER
  VCPU = 0
  THREAD_PRIORITY = 19;
  ```

- Create a disabled system group that has no CPU affinity (can use all CPUs) and the highest priority:

  ```sql
  CREATE RESOURCE GROUP rg2
  TYPE = SYSTEM
  THREAD_PRIORITY = -20
  DISABLE;
  ```

Resource group management is local to the server on which it occurs. **CREATE RESOURCE GROUP** statements are not written to the binary log and are not replicated.

### 13.7.2.3 DROP RESOURCE GROUP Statement

**DROP RESOURCE GROUP** group_name [FORCE]

**DROP RESOURCE GROUP** is used for resource group management (see Section 5.1.16, "Resource Groups"). This statement drops a resource group. It requires the **RESOURCE_GROUP_ADMIN** privilege.

**group_name** identifies which resource group to drop. If the group does not exist, an error occurs.

The **FORCE** modifier determines statement behavior if the resource group has any threads assigned to it:

- If **FORCE** is not given and any threads are assigned to the group, an error occurs.
- If **FORCE** is given, existing threads in the group are moved to their respective default group (system threads to **SYS_default**, user threads to **USR_default**).

Examples:

- Drop a group, failing if the group contains any threads:

  ```sql
  DROP RESOURCE GROUP rg1;
  ```

- Drop a group and move existing threads to the default groups:

  ```sql
  DROP RESOURCE GROUP rg2 FORCE;
  ```
Resource group management is local to the server on which it occurs. DROP RESOURCE GROUP statements are not written to the binary log and are not replicated.

### 13.7.2.4 SET RESOURCE GROUP Statement

```
SET RESOURCE GROUP group_name
   [FOR thread_id [, thread_id] ...]
```

**SET RESOURCE GROUP** is used for resource group management (see Section 5.1.16, “Resource Groups”). This statement assigns threads to a resource group. It requires the RESOURCE_GROUP_ADMIN or RESOURCE_GROUP_USER privilege.

*group_name* identifies which resource group to be assigned. Any *thread_id* values indicate threads to assign to the group. Thread IDs can be determined from the Performance Schema **threads** table. If the resource group or any named thread ID does not exist, an error occurs.

With no **FOR** clause, the statement assigns the current thread for the session to the resource group.

With a **FOR** clause that names thread IDs, the statement assigns those threads to the resource group.

For attempts to assign a system thread to a user resource group or a user thread to a system resource group, a warning occurs.

**Examples:**

- Assign the current session thread to a group:

  ```
  SET RESOURCE GROUP rg1;
  ```

- Assign the named threads to a group:

  ```
  SET RESOURCE GROUP rg2 FOR 14, 78, 4;
  ```

Resource group management is local to the server on which it occurs. SET RESOURCE GROUP statements are not written to the binary log and are not replicated.

An alternative to **SET RESOURCE GROUP** is the **RESOURCE_GROUP** optimizer hint, which assigns individual statements to a resource group. See Section 8.9.3, “Optimizer Hints”.

### 13.7.3 Table Maintenance Statements

#### 13.7.3.1 ANALYZE TABLE Statement

```
ANALYZE [NO_WRITE_TO_BINLOG | LOCAL]
   TABLE tbl_name [, tbl_name] ...
```

```
ANALYZE [NO_WRITE_TO_BINLOG | LOCAL]
   TABLE tbl_name
       UPDATE HISTOGRAM ON col_name [, col_name] ...
   [WITH N BUCKETS]
```

```
ANALYZE [NO_WRITE_TO_BINLOG | LOCAL]
   TABLE tbl_name
       DROP HISTOGRAM ON col_name [, col_name] ...
```

**ANALYZE TABLE** generates table statistics:

- **ANALYZE TABLE** without either **HISTOGRAM** clause performs a key distribution analysis and stores the distribution for the named table or tables. For **MyISAM** tables, **ANALYZE TABLE** for key distribution analysis is equivalent to using `myisamchk --analyze`.

- **ANALYZE TABLE** with the **UPDATE HISTOGRAM** clause generates histogram statistics for the named table columns and stores them in the data dictionary. Only one table name is permitted for this syntax.
**Table Maintenance Statements**

- **ANALYZE TABLE** with the `DROP HISTOGRAM` clause removes histogram statistics for the named table columns from the data dictionary. Only one table name is permitted for this syntax.

  This statement requires `SELECT` and `INSERT` privileges for the table.

  **ANALYZE TABLE** works with InnoDB, NDB, and MyISAM tables. It does not work with views.

  If the `innodb_read_only` system variable is enabled, **ANALYZE TABLE** may fail because it cannot update statistics tables in the data dictionary, which use InnoDB. For **ANALYZE TABLE** operations that update the key distribution, failure may occur even if the operation updates the table itself (for example, if it is a MyISAM table). To obtain the updated distribution statistics, set `information_schema_stats_expiry=0`.

  **ANALYZE TABLE** is supported for partitioned tables, and you can use `ALTER TABLE ... ANALYZE PARTITION` to analyze one or more partitions; for more information, see Section 13.1.9, "ALTER TABLE Statement" , and Section 24.3.4, "Maintenance of Partitions".

  During the analysis, the table is locked with a read lock for InnoDB and MyISAM.

  **ANALYZE TABLE** removes the table from the table definition cache, which requires a flush lock. If there are long running statements or transactions still using the table, subsequent statements and transactions must wait for those operations to finish before the flush lock is released. Because **ANALYZE TABLE** itself typically finishes quickly, it may not be apparent that delayed transactions or statements involving the same table are due to the remaining flush lock.

  By default, the server writes **ANALYZE TABLE** statements to the binary log so that they replicate to replicas. To suppress logging, specify the optional `NO_WRITE_TO_BINLOG` keyword or its alias `LOCAL`.

  - **ANALYZE TABLE Output**
  - **Key Distribution Analysis**
  - **Histogram Statistics Analysis**
  - **Other Considerations**

**ANALYZE TABLE Output**

**ANALYZE TABLE** returns a result set with the columns shown in the following table.

<table>
<thead>
<tr>
<th>Column</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table</td>
<td>The table name</td>
</tr>
<tr>
<td>Op</td>
<td><code>analyze</code> or <code>histogram</code></td>
</tr>
<tr>
<td>Msg_type</td>
<td><code>status</code>, <code>error</code>, <code>info</code>, <code>note</code>, or <code>warning</code></td>
</tr>
<tr>
<td>Msg_text</td>
<td>An informational message</td>
</tr>
</tbody>
</table>

**Key Distribution Analysis**

**ANALYZE TABLE** without either `HISTOGRAM` clause performs a key distribution analysis and stores the distribution for the table or tables. Any existing histogram statistics remain unaffected.

If the table has not changed since the last key distribution analysis, the table is not analyzed again.

MySQL uses the stored key distribution to decide the order in which tables should be joined for joins on something other than a constant. In addition, key distributions can be used when deciding which indexes to use for a specific table within a query.

To check the stored key distribution cardinality, use the `SHOW INDEX` statement or the `INFORMATION_SCHEMA STATISTICS` table. See Section 13.7.7.22, "SHOW INDEX Statement", and Section 26.3.34, "The INFORMATION_SCHEMA STATISTICS Table".
For InnoDB tables, `ANALYZE TABLE` determines index cardinality by performing random dives on each of the index trees and updating index cardinality estimates accordingly. Because these are only estimates, repeated runs of `ANALYZE TABLE` could produce different numbers. This makes `ANALYZE TABLE` fast on InnoDB tables but not 100% accurate because it does not take all rows into account.

You can make the statistics collected by `ANALYZE TABLE` more precise and more stable by enabling `innodb_stats_persistent`, as explained in Section 15.8.10.1, “Configuring Persistent Optimizer Statistics Parameters”. When `innodb_stats_persistent` is enabled, it is important to run `ANALYZE TABLE` after major changes to index column data, as statistics are not recalculated periodically (such as after a server restart).

If `innodb_stats_persistent` is enabled, you can change the number of random dives by modifying the `innodb_stats_persistent_sample_pages` system variable. If `innodb_stats_persistent` is disabled, modify `innodb_stats_transient_sample_pages` instead.

For more information about key distribution analysis in InnoDB, see Section 15.8.10.1, “Configuring Persistent Optimizer Statistics Parameters”, and Section 15.8.10.3, “Estimating ANALYZE TABLE Complexity for InnoDB Tables”.

MySQL uses index cardinality estimates in join optimization. If a join is not optimized in the right way, try running `ANALYZE TABLE`. In the few cases that `ANALYZE TABLE` does not produce values good enough for your particular tables, you can use `FORCE INDEX` with your queries to force the use of a particular index, or set the `max_seeks_for_key` system variable to ensure that MySQL prefers index lookups over table scans. See Section B.3.5, “Optimizer-Related Issues”.

**Histogram Statistics Analysis**

`ANALYZE TABLE` with the `HISTOGRAM` clauses enables management of histogram statistics for table column values. For information about histogram statistics, see Section 8.9.6, “Optimizer Statistics”.

These histogram operations are available:

- `ANALYZE TABLE` with an `UPDATE HISTOGRAM` clause generates histogram statistics for the named table columns and stores them in the data dictionary. Only one table name is permitted for this syntax.

  The optional `WITH N BUCKETS` clauses specifies the number of buckets for the histogram. The value of `N` must be an integer in the range from 1 to 1024. If this clause is omitted, the number of buckets is 100.

- `ANALYZE TABLE` with a `DROP HISTOGRAM` clause removes histogram statistics for the named table columns from the data dictionary. Only one table name is permitted for this syntax.

Stored histogram management statements affect only the named columns. Consider these statements:

```
ANALYZE TABLE t UPDATE HISTOGRAM ON c1, c2, c3 WITH 10 BUCKETS;
ANALYZE TABLE t UPDATE HISTOGRAM ON c1, c3 WITH 10 BUCKETS;
ANALYZE TABLE t DROP HISTOGRAM ON c2;
```

The first statement updates the histograms for columns `c1`, `c2`, and `c3`, replacing any existing histograms for those columns. The second statement updates the histograms for `c1` and `c3`, leaving the `c2` histogram unaffected. The third statement removes the histogram for `c2`, leaving those for `c1` and `c3` unaffected.

Histogram generation is not supported for encrypted tables (to avoid exposing data in the statistics) or `TEMPORARY` tables.

Histogram generation applies to columns of all data types except geometry types (spatial data) and `JSON`.

Histograms can be generated for stored and virtual generated columns.
Table Maintenance Statements

Histograms cannot be generated for columns that are covered by single-column unique indexes.

Histogram management statements attempt to perform as much of the requested operation as possible, and report diagnostic messages for the remainder. For example, if an UPDATE HISTOGRAM statement names multiple columns, but some of them do not exist or have an unsupported data type, histograms are generated for the other columns, and messages are produced for the invalid columns.

Histograms are affected by these DDL statements:

- **DROP TABLE** removes histograms for columns in the dropped table.

- **DROP DATABASE** removes histograms for any table in the dropped database because the statement drops all tables in the database.

- **RENAME TABLE** does not remove histograms. Instead, it renames histograms for the renamed table to be associated with the new table name.

- **ALTER TABLE** statements that remove or modify a column remove histograms for that column.

- **ALTER TABLE ... CONVERT TO CHARACTER SET** removes histograms for character columns because they are affected by the change of character set. Histograms for noncharacter columns remain unaffected.

The `histogram_generation_max_mem_size` system variable controls the maximum amount of memory available for histogram generation. The global and session values may be set at runtime.

Changing the global `histogram_generation_max_mem_size` value requires privileges sufficient to set global system variables. Changing the session `histogram_generation_max_mem_size` value requires privileges sufficient to set restricted session system variables. See Section 5.1.9.1, "System Variable Privileges".

If the estimated amount of data to be read into memory for histogram generation exceeds the limit defined by `histogram_generation_max_mem_size`, MySQL samples the data rather than reading all of it into memory. Sampling is evenly distributed over the entire table. MySQL uses **SYSTEM** sampling, which is a page-level sampling method.

The `sampling-rate` value in the HISTOGRAM column of `INFORMATION_SCHEMA.COLUMN_STATISTICS` table can be queried to determine the fraction of data that was sampled to create the histogram. The `sampling-rate` is a number between 0.0 and 1.0. A value of 1 means that all of the data was read (no sampling).

The following example demonstrates sampling. To ensure that the amount of data exceeds the `histogram_generation_max_mem_size` limit for the purpose of the example, the limit is set to a low value (2000000 bytes) prior to generating histogram statistics for the `birth_date` column of the `employees` table.

```
mysql> SET histogram_generation_max_mem_size = 2000000;
mysql> USE employees;
mysql> ANALYZE TABLE employees UPDATE HISTOGRAM ON birth_date WITH 16 BUCKETS\G
*************************** 1. row ***************************
Table: employees.employees
Op: histogram
Msg_type: status
Msg_text: Histogram statistics created for column 'birth_date'.
mysql> SELECT HISTOGRAM->>'$."sampling-rate"'
FROM INFORMATION_SCHEMA.COLUMN_STATISTICS
WHERE TABLE_NAME = "employees"
AND COLUMN_NAME = "birth_date";
+-------------------+
| HISTOGRAM->>'$."sampling-rate"'| 1.0
+-------------------+
```
A sampling-rate value of 0.0491431208869665 means that approximately 4.9% of the data from the birth_date column was read into memory for generating histogram statistics.

As of MySQL 8.0.19, the InnoDB storage engine provides its own sampling implementation for data stored in InnoDB tables. The default sampling implementation used by MySQL when storage engines do not provide their own requires a full table scan, which is costly for large tables. The InnoDB sampling implementation improves sampling performance by avoiding full table scans.

The sampled_pages_read and sampled_pages_skipped INNODB_METRICS counters can be used to monitor sampling of InnoDB data pages. (For general INNODB_METRICS counter usage information, see Section 26.4.23, “The INFORMATION_SCHEMA INNODB_METRICS Table”.)

The following example demonstrates sampling counter usage, which requires enabling the counters prior to generating histogram statistics.

```
mysql> SET GLOBAL innodb_monitor_enable = 'sampled%';

mysql> USE employees;

mysql> ANALYZE TABLE employees UPDATE HISTOGRAM ON birth_date WITH 16 BUCKETS
*************************** 1. row ***************************
Table: employees.employees
Op: histogram
Msg_type: status
Msg_text: Histogram statistics created for column 'birth_date'.

mysql> USE INFORMATION_SCHEMA;

mysql> SELECT NAME, COUNT FROM INNODB_METRICS WHERE NAME LIKE 'sampled%'
*************************** 1. row ***************************
NAME: sampled_pages_read
COUNT: 43
*************************** 2. row ***************************
NAME: sampled_pages_skipped
COUNT: 843
```

This formula approximates a sampling rate based on the sampling counter data:

```
sampling rate = sampled_page_read/(sampled_pages_read + sampled_pages_skipped)
```

A sampling rate based on sampling counter data is roughly the same as the sampling-rate value in the HISTOGRAM column of INFORMATION_SCHEMA.COLUMN_STATISTICS table.

For information about memory allocations performed for histogram generation, monitor the Performance Schema memory/sql/histograms instrument. See Section 27.12.20.10, “Memory Summary Tables”.

**Other Considerations**

ANALYZE TABLE clears table statistics from the INFORMATION_SCHEMA.INNODB_TABLESTATS table and sets the STATS_INITIALIZED column to Uninitialized. Statistics are collected again the next time the table is accessed.

**13.7.3.2 CHECK TABLE Statement**

```
CHECK TABLE tbl_name [, tbl_name] ... [option] ...
```

**option:**
- FOR UPGRADE
- QUICK
- FAST
- MEDIUM
### Table Maintenance Statements

**CHECK TABLE** checks a table or tables for errors. **CHECK TABLE** can also check views for problems, such as tables that are referenced in the view definition that no longer exist.

To check a table, you must have some privilege for it.

**CHECK TABLE** works for InnoDB, MyISAM, ARCHIVE, and CSV tables.

Before running **CHECK TABLE** on InnoDB tables, see **CHECK TABLE Usage Notes for InnoDB Tables**.

**CHECK TABLE** is supported for partitioned tables, and you can use **ALTER TABLE ... CHECK PARTITION** to check one or more partitions; for more information, see Section 13.1.9, “ALTER TABLE Statement”, and Section 24.3.4, “Maintenance of Partitions”.

**CHECK TABLE** ignores virtual generated columns that are not indexed.

- **CHECK TABLE Output**
- **Checking Version Compatibility**
- **Checking Data Consistency**
- **CHECK TABLE Usage Notes for InnoDB Tables**
- **CHECK TABLE Usage Notes for MyISAM Tables**

### CHECK TABLE Output

**CHECK TABLE** returns a result set with the columns shown in the following table.

<table>
<thead>
<tr>
<th>Column</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table</td>
<td>The table name</td>
</tr>
<tr>
<td>Op</td>
<td>Always check</td>
</tr>
<tr>
<td>Msg_type</td>
<td>status, error, info, note, or warning</td>
</tr>
<tr>
<td>Msg_text</td>
<td>An informational message</td>
</tr>
</tbody>
</table>

The statement might produce many rows of information for each checked table. The last row has a `Msg_type` value of `status` and the `Msg_text` normally should be `OK. Table is already up to date` means that the storage engine for the table indicated that there was no need to check the table.

### Checking Version Compatibility

The **FOR UPGRADE** option checks whether the named tables are compatible with the current version of MySQL. With **FOR UPGRADE**, the server checks each table to determine whether there have been any incompatible changes in any of the table’s data types or indexes since the table was created. If not, the check succeeds. Otherwise, if there is a possible incompatibility, the server runs a full check on the table (which might take some time).

Incompatibilities might occur because the storage format for a data type has changed or because its sort order has changed. Our aim is to avoid these changes, but occasionally they are necessary to correct problems that would be worse than an incompatibility between releases.

**FOR UPGRADE** discovers these incompatibilities:

- The indexing order for end-space in **TEXT** columns for **InnoDB** and **MyISAM** tables changed between MySQL 4.1 and 5.0.
Table Maintenance Statements

- The storage method of the new DECIMAL data type changed between MySQL 5.0.3 and 5.0.5.

- Changes are sometimes made to character sets or collations that require table indexes to be rebuilt. For details about such changes, see Section 2.11.4, “Changes in MySQL 8.0”. For information about rebuilding tables, see Section 2.11.13, “Rebuilding or Repairing Tables or Indexes”.

- MySQL 8.0 does not support the 2-digit YEAR(2) data type permitted in older versions of MySQL. For tables containing YEAR(2) columns, CHECK TABLE recommends REPAIR TABLE, which converts 2-digit YEAR(2) columns to 4-digit YEAR columns.

- Trigger creation time is maintained.

- A table is reported as needing a rebuild if it contains old temporal columns in pre-5.6.4 format (TIME, DATETIME, and TIMESTAMP columns without support for fractional seconds precision) and the avoid_temporal_upgrade system variable is disabled. This helps the MySQL upgrade procedure detect and upgrade tables containing old temporal columns. If avoid_temporal_upgrade is enabled, FOR UPGRADE ignores the old temporal columns present in the table; consequently, the upgrade procedure does not upgrade them.

  To check for tables that contain such temporal columns and need a rebuild, disable avoid_temporal_upgrade before executing CHECK TABLE ... FOR UPGRADE.

- Warnings are issued for tables that use nonnative partitioning because nonnative partitioning is removed in MySQL 8.0. See Chapter 24, Partitioning.

Checking Data Consistency

The following table shows the other check options that can be given. These options are passed to the storage engine, which may use or ignore them.

<table>
<thead>
<tr>
<th>Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>QUICK</td>
<td>Do not scan the rows to check for incorrect links. Applies to InnoDB and MyISAM tables and views.</td>
</tr>
<tr>
<td>FAST</td>
<td>Check only tables that have not been closed properly. Ignored for InnoDB; applies only to MyISAM tables and views.</td>
</tr>
<tr>
<td>CHANGED</td>
<td>Check only tables that have been changed since the last check or that have not been closed properly. Ignored for InnoDB; applies only to MyISAM tables and views.</td>
</tr>
<tr>
<td>MEDIUM</td>
<td>Scan rows to verify that deleted links are valid. This also calculates a key checksum for the rows and verifies this with a calculated checksum for the keys. Ignored for InnoDB; applies only to MyISAM tables and views.</td>
</tr>
<tr>
<td>EXTENDED</td>
<td>Do a full key lookup for all keys for each row. This ensures that the table is 100% consistent, but takes a long time. Ignored for InnoDB; applies only to MyISAM tables and views.</td>
</tr>
</tbody>
</table>

You can combine check options, as in the following example that does a quick check on the table to determine whether it was closed properly:

CHECK TABLE test_table FAST QUICK;

Note

If CHECK TABLE finds no problems with a table that is marked as “corrupted” or “not closed properly”, CHECK TABLE may remove the mark.

If a table is corrupted, the problem is most likely in the indexes and not in the data part. All of the preceding check types check the indexes thoroughly and should thus find most errors.

To check a table that you assume is okay, use no check options or the QUICK option. The latter should be used when you are in a hurry and can take the very small risk that QUICK does not find an error in
the data file. (In most cases, under normal usage, MySQL should find any error in the data file. If this happens, the table is marked as “corrupted” and cannot be used until it is repaired.)

**FAST** and **CHANGED** are mostly intended to be used from a script (for example, to be executed from **cron**) to check tables periodically. In most cases, **FAST** is to be preferred over **CHANGED**. (The only case when it is not preferred is when you suspect that you have found a bug in the **MyISAM** code.)

**EXTENDED** is to be used only after you have run a normal check but still get errors from a table when MySQL tries to update a row or find a row by key. This is very unlikely if a normal check has succeeded.

Use of **CHECK TABLE ... EXTENDED** might influence execution plans generated by the query optimizer.

Some problems reported by **CHECK TABLE** cannot be corrected automatically:

• **Found row where the auto_increment column has the value 0.**

  This means that you have a row in the table where the **AUTO_INCREMENT** index column contains the value 0. (It is possible to create a row where the **AUTO_INCREMENT** column is 0 by explicitly setting the column to 0 with an **UPDATE** statement.)

  This is not an error in itself, but could cause trouble if you decide to dump the table and restore it or do an **ALTER TABLE** on the table. In this case, the **AUTO_INCREMENT** column changes value according to the rules of **AUTO_INCREMENT** columns, which could cause problems such as a duplicate-key error.

  To get rid of the warning, execute an **UPDATE** statement to set the column to some value other than 0.

### CHECK TABLE Usage Notes for InnoDB Tables

The following notes apply to **InnoDB** tables:

• If **CHECK TABLE** encounters a corrupt page, the server exits to prevent error propagation (Bug #10132). If the corruption occurs in a secondary index but table data is readable, running **CHECK TABLE** can still cause a server exit.

• If **CHECK TABLE** encounters a corrupted **DB_TRX_ID** or **DB_ROLL_PTR** field in a clustered index, **CHECK TABLE** can cause **InnoDB** to access an invalid undo log record, resulting in an **MVCC**-related server exit.

• If **CHECK TABLE** encounters errors in **InnoDB** tables or indexes, it reports an error, and usually marks the index and sometimes marks the table as corrupted, preventing further use of the index or table. Such errors include an incorrect number of entries in a secondary index or incorrect links.

• If **CHECK TABLE** finds an incorrect number of entries in a secondary index, it reports an error but does not cause a server exit or prevent access to the file.

• **CHECK TABLE** surveys the index page structure, then surveys each key entry. It does not validate the key pointer to a clustered record or follow the path for **BLOB** pointers.

• When an **InnoDB** table is stored in its own **.ibd** file, the first 3 pages of the **.ibd** file contain header information rather than table or index data. The **CHECK TABLE** statement does not detect inconsistencies that affect only the header data. To verify the entire contents of an **InnoDB** **.ibd** file, use the **innochecksum** command.

• When running **CHECK TABLE** on large **InnoDB** tables, other threads may be blocked during **CHECK TABLE** execution. To avoid timeouts, the semaphore wait threshold (600 seconds) is extended by 2 hours (7200 seconds) for **CHECK TABLE** operations. If **InnoDB** detects semaphore waits of 240 seconds or more, it starts printing **InnoDB** monitor output to the error log. If a lock request extends
beyond the semaphore wait threshold, InnoDB aborts the process. To avoid the possibility of a semaphore wait timeout entirely, run `CHECK TABLE QUICK` instead of `CHECK TABLE`.

- `CHECK TABLE` functionality for InnoDB SPATIAL indexes includes an R-tree validity check and a check to ensure that the R-tree row count matches the clustered index.

- `CHECK TABLE` supports secondary indexes on virtual generated columns, which are supported by InnoDB.

- As of MySQL 8.0.14, InnoDB supports parallel clustered index reads, which can improve `CHECK TABLE` performance. InnoDB reads the clustered index twice during a `CHECK TABLE` operation. The second read can be performed in parallel. The `innodb_parallel_read_threads` session variable must be set to a value greater than 1 for parallel clustered index reads to occur. The default value is 4. The actual number of threads used to perform a parallel clustered index read is determined by the `innodb_parallel_read_threads` setting or the number of index subtrees to scan, whichever is smaller.

**CHECK TABLE Usage Notes for MyISAM Tables**

The following notes apply to MyISAM tables:

- `CHECK TABLE` updates key statistics for MyISAM tables.

- If `CHECK TABLE` output does not return OK or Table is already up to date, you should normally run a repair of the table. See Section 7.6, “MyISAM Table Maintenance and Crash Recovery”.

- If none of the `CHECK TABLE` options QUICK, MEDIUM, or EXTENDED are specified, the default check type for dynamic-format MyISAM tables is MEDIUM. This has the same result as running `myisamchk --medium-check tbl_name` on the table. The default check type also is MEDIUM for static-format MyISAM tables, unless CHANGED or FAST is specified. In that case, the default is QUICK. The row scan is skipped for CHANGED and FAST because the rows are very seldom corrupted.

### 13.7.3.3 CHECKSUM TABLE Statement

```sql
CHECKSUM TABLE tbl_name [, tbl_name] ... [QUICK | EXTENDED]
```

`CHECKSUM TABLE` reports a checksum for the contents of a table. You can use this statement to verify that the contents are the same before and after a backup, rollback, or other operation that is intended to put the data back to a known state.

This statement requires the `SELECT` privilege for the table.

This statement is not supported for views. If you run `CHECKSUM TABLE` against a view, the Checksum value is always NULL, and a warning is returned.

For a nonexistent table, `CHECKSUM TABLE` returns NULL and generates a warning.

During the checksum operation, the table is locked with a read lock for InnoDB and MyISAM.

**Performance Considerations**

By default, the entire table is read row by row and the checksum is calculated. For large tables, this could take a long time, thus you would only perform this operation occasionally. This row-by-row calculation is what you get with the `EXTENDED` clause, with InnoDB and all other storage engines other than MyISAM, and with MyISAM tables not created with the `CHECKSUM=1` clause.

For MyISAM tables created with the `CHECKSUM=1` clause, `CHECKSUM TABLE` or `CHECKSUM TABLE ... QUICK` returns the “live” table checksum that can be returned very fast. If the table does not meet all these conditions, the QUICK method returns NULL. The QUICK method is not
Table Maintenance Statements

supported with InnoDB tables. See Section 13.1.20, "CREATE TABLE Statement" for the syntax of the CHECKSUM clause.

The checksum value depends on the table row format. If the row format changes, the checksum also changes. For example, the storage format for temporal types such as TIME, DATETIME, and TIMESTAMP changed in MySQL 5.6 prior to MySQL 5.6.5, so if a 5.5 table is upgraded to MySQL 5.6, the checksum value may change.

Important

If the checksums for two tables are different, then it is almost certain that the tables are different in some way. However, because the hashing function used by CHECKSUM TABLE is not guaranteed to be collision-free, there is a slight chance that two tables which are not identical can produce the same checksum.

13.7.3.4 OPTIMIZE TABLE Statement

OPTIMIZE [NO_WRITE_TO_BINLOG | LOCAL]
TABLE tbl_name [, tbl_name] ...

OPTIMIZE TABLE reorganizes the physical storage of table data and associated index data, to reduce storage space and improve I/O efficiency when accessing the table. The exact changes made to each table depend on the storage engine used by that table.

Use OPTIMIZE TABLE in these cases, depending on the type of table:

• After doing substantial insert, update, or delete operations on an InnoDB table that has its own .ibd file because it was created with the innodb_file_per_table option enabled. The table and indexes are reorganized, and disk space can be reclaimed for use by the operating system.

• After doing substantial insert, update, or delete operations on columns that are part of a FULLTEXT index in an InnoDB table. Set the configuration option innodb_optimize_fulltext_only=1 first. To keep the index maintenance period to a reasonable time, set the innodb_ft_num_word_optimize option to specify how many words to update in the search index, and run a sequence of OPTIMIZE TABLE statements until the search index is fully updated.

• After deleting a large part of a MyISAM or ARCHIVE table, or making many changes to a MyISAM or ARCHIVE table with variable-length rows (tables that have VARCHAR, VARBINARY, BLOB, or TEXT columns). Deleted rows are maintained in a linked list and subsequent INSERT operations reuse old row positions. You can use OPTIMIZE TABLE to reclaim the unused space and to defragment the data file. After extensive changes to a table, this statement may also improve performance of statements that use the table, sometimes significantly.

This statement requires SELECT and INSERT privileges for the table.

OPTIMIZE TABLE works for InnoDB, MyISAM, and ARCHIVE tables. OPTIMIZE TABLE is also supported for dynamic columns of in-memory NDB tables. It does not work for fixed-width columns of in-memory tables, nor does it work for Disk Data tables. The performance of OPTIMIZE on NDB Cluster tables can be tuned using --ndb-optimization-delay, which controls the length of time to wait between processing batches of rows by OPTIMIZE TABLE. For more information, see Section 23.1.7.11, "Previous NDB Cluster Issues Resolved in NDB Cluster 8.0”.

For NDB Cluster tables, OPTIMIZE TABLE can be interrupted by (for example) killing the SQL thread performing the OPTIMIZE operation.

By default, OPTIMIZE TABLE does not work for tables created using any other storage engine and returns a result indicating this lack of support. You can make OPTIMIZE TABLE work for other storage engines by starting mysqld with the --skip-new option. In this case, OPTIMIZE TABLE is just mapped to ALTER TABLE.
This statement does not work with views.

OPTIMIZE TABLE is supported for partitioned tables. For information about using this statement with partitioned tables and table partitions, see Section 24.3.4, "Maintenance of Partitions".

By default, the server writes OPTIMIZE TABLE statements to the binary log so that they replicate to replicas. To suppress logging, specify the optional NO_WRITE_TO_BINLOG keyword or its alias LOCAL.

- OPTIMIZE TABLE Output
- InnoDB Details
- MyISAM Details
- Other Considerations

**OPTIMIZE TABLE Output**

OPTIMIZE TABLE returns a result set with the columns shown in the following table.

<table>
<thead>
<tr>
<th>Column</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table</td>
<td>The table name</td>
</tr>
<tr>
<td>Op</td>
<td>Always optimize</td>
</tr>
<tr>
<td>Msg_type</td>
<td>status, error, info, note, or warning</td>
</tr>
<tr>
<td>Msg_text</td>
<td>An informational message</td>
</tr>
</tbody>
</table>

OPTIMIZE TABLE catches and throws any errors that occur while copying table statistics from the old file to the newly created file. For example, if the user ID of the owner of the .MYD or .MYI file is different from the user ID of the mysqld process, OPTIMIZE TABLE generates a "cannot change ownership of the file" error unless mysqld is started by the root user.

**InnoDB Details**

For InnoDB tables, OPTIMIZE TABLE is mapped to ALTER TABLE ... FORCE, which rebuilds the table to update index statistics and free unused space in the clustered index. This is displayed in the output of OPTIMIZE TABLE when you run it on an InnoDB table, as shown here:

```
mysql> OPTIMIZE TABLE foo;
+----------+----------+----------+-------------------------------------------------------------------+
| Table    | Op       | Msg_type | Msg_text                                                          |
+----------+----------+----------+-------------------------------------------------------------------+
| test.foo | optimize | note     | Table does not support optimize, doing recreate + analyze instead |
| test.foo | optimize | status   | OK                                                                |
```  

OPTIMIZE TABLE uses online DDL for regular and partitioned InnoDB tables, which reduces downtime for concurrent DML operations. The table rebuild triggered by OPTIMIZE TABLE is completed in place. An exclusive table lock is only taken briefly during the prepare phase and the commit phase of the operation. During the prepare phase, metadata is updated and an intermediate table is created. During the commit phase, table metadata changes are committed.

OPTIMIZE TABLE rebuilds the table using the table copy method under the following conditions:

- When the old_alter_table system variable is enabled.
- When the server is started with the --skip-new option.

OPTIMIZE TABLE using online DDL is not supported for InnoDB tables that contain FULLTEXT indexes. The table copy method is used instead.
**InnoDB** stores data using a page-allocation method and does not suffer from fragmentation in the same way that legacy storage engines (such as **MyISAM**) do. When considering whether or not to run optimize, consider the workload of transactions that your server is expected to process:

- Some level of fragmentation is expected. **InnoDB** only fills pages 93% full, to leave room for updates without having to split pages.
- Delete operations might leave gaps that leave pages less filled than desired, which could make it worthwhile to optimize the table.
- Updates to rows usually rewrite the data within the same page, depending on the data type and row format, when sufficient space is available. See Section 15.9.1.5, “How Compression Works for **InnoDB** Tables” and Section 15.10, “**InnoDB** Row Formats”.
- High-concurrency workloads might leave gaps in indexes over time, as **InnoDB** retains multiple versions of the same data due through its MVCC mechanism. See Section 15.3, “**InnoDB** Multi-Versioning”.

**MyISAM** Details

For **MyISAM** tables, **OPTIMIZE TABLE** works as follows:

1. If the table has deleted or split rows, repair the table.
2. If the index pages are not sorted, sort them.
3. If the table’s statistics are not up to date (and the repair could not be accomplished by sorting the index), update them.

**Other Considerations**

**OPTIMIZE TABLE** is performed online for regular and partitioned **InnoDB** tables. Otherwise, MySQL locks the table during the time **OPTIMIZE TABLE** is running.

**OPTIMIZE TABLE** does not sort R-tree indexes, such as spatial indexes on **POINT** columns. (Bug #23578)

### 13.7.3.5 REPAIR TABLE Statement

```
REPAIR [NO_WRITE_TO_BINLOG | LOCAL]
    TABLE tbl_name [, tbl_name] ...
    [QUICK] [EXTENDED] [USE_FRM]
```

**REPAIR TABLE** repairs a possibly corrupted table, for certain storage engines only.

This statement requires **SELECT** and **INSERT** privileges for the table.

Although normally you should never have to run **REPAIR TABLE**, if disaster strikes, this statement is very likely to get back all your data from a **MyISAM** table. If your tables become corrupted often, try to find the reason for it, to eliminate the need to use **REPAIR TABLE**. See Section B.3.3.3, “What to Do If MySQL Keeps Crashing”, and Section 16.2.4, “**MyISAM** Table Problems”.

**REPAIR TABLE** checks the table to see whether an upgrade is required. If so, it performs the upgrade, following the same rules as **CHECK TABLE ... FOR UPGRADE**. See Section 13.7.3.2, “CHECK TABLE Statement”, for more information.

**Important**

- Make a backup of a table before performing a table repair operation; under some circumstances the operation might cause data loss. Possible causes include but are not limited to file system errors. See Chapter 7, Backup and Recovery.
Table Maintenance Statements

- If the server exits during a `REPAIR TABLE` operation, it is essential after restarting it that you immediately execute another `REPAIR TABLE` statement for the table before performing any other operations on it. In the worst case, you might have a new clean index file without information about the data file, and then the next operation you perform could overwrite the data file. This is an unlikely but possible scenario that underscores the value of making a backup first.

- In the event that a table on the source becomes corrupted and you run `REPAIR TABLE` on it, any resulting changes to the original table are not propagated to replicas.

- **REPAIR TABLE** Storage Engine and Partitioning Support

- **REPAIR TABLE** Options

- **REPAIR TABLE** Output

- Table Repair Considerations

**REPAIR TABLE** Storage Engine and Partitioning Support

`REPAIR TABLE` works for **MyISAM**, **ARCHIVE**, and **CSV** tables. For **MyISAM** tables, it has the same effect as `myisamchk --recover tbl_name` by default. This statement does not work with views.

`REPAIR TABLE` is supported for partitioned tables. However, the **USE_FRM** option cannot be used with this statement on a partitioned table.

You can use `ALTER TABLE ... REPAIR PARTITION` to repair one or more partitions; for more information, see Section 13.1.9, “ALTER TABLE Statement”, and Section 24.3.4, “Maintenance of Partitions”.

**REPAIR TABLE** Options

- **NO_WRITE_TO_BINLOG** or **LOCAL**

  By default, the server writes **REPAIR TABLE** statements to the binary log so that they replicate to replicas. To suppress logging, specify the optional **NO_WRITE_TO_BINLOG** keyword or its alias **LOCAL**.

- **QUICK**

  If you use the **QUICK** option, **REPAIR TABLE** tries to repair only the index file, and not the data file. This type of repair is like that done by `myisamchk --recover --quick`.

- **EXTENDED**

  If you use the **EXTENDED** option, MySQL creates the index row by row instead of creating one index at a time with sorting. This type of repair is like that done by `myisamchk --safe-recover`.

- **USE_FRM**

  The **USE_FRM** option is available for use if the **.MYI** index file is missing or if its header is corrupted. This option tells MySQL not to trust the information in the **.MYI** file header and to re-create it using information from the data dictionary. This kind of repair cannot be done with `myisamchk`.

**Caution**

Use the **USE_FRM** option only if you cannot use regular **REPAIR** modes. Telling the server to ignore the **.MYI** file makes important table metadata
stored in the .MYI unavailable to the repair process, which can have deleterious consequences:

- The current AUTO_INCREMENT value is lost.
- The link to deleted records in the table is lost, which means that free space for deleted records remains unoccupied thereafter.
- The .MYI header indicates whether the table is compressed. If the server ignores this information, it cannot tell that a table is compressed and repair can cause change or loss of table contents. This means that USE_FRM should not be used with compressed tables. That should not be necessary, anyway: Compressed tables are read only, so they should not become corrupt.

If you use USE_FRM for a table that was created by a different version of the MySQL server than the one you are currently running, REPAIR TABLE does not attempt to repair the table. In this case, the result set returned by REPAIR TABLE contains a line with a Msg_type value of error and a Msg_text value of Failed repairing incompatible .FRM file.

If USE_FRM is used, REPAIR TABLE does not check the table to see whether an upgrade is required.

REPAIR TABLE Output

REPAIR TABLE returns a result set with the columns shown in the following table.

<table>
<thead>
<tr>
<th>Column</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table</td>
<td>The table name</td>
</tr>
<tr>
<td>Op</td>
<td>Always repair</td>
</tr>
<tr>
<td>Msg_type</td>
<td>status, error, info, note, or warning</td>
</tr>
<tr>
<td>Msg_text</td>
<td>An informational message</td>
</tr>
</tbody>
</table>

The REPAIR TABLE statement might produce many rows of information for each repaired table. The last row has a Msg_type value of status and Msg_text normally should be OK. For a MyISAM table, if you do not get OK, you should try repairing it with myisamchk --safe-recover. (REPAIR TABLE does not implement all the options of myisamchk. With myisamchk --safe-recover, you can also use options that REPAIR TABLE does not support, such as --max-record-length.)

REPAIR TABLE table catches and throws any errors that occur while copying table statistics from the old corrupted file to the newly created file. For example, if the user ID of the owner of the .MYD or .MYI file is different from the user ID of the mysqld process, REPAIR TABLE generates a "cannot change ownership of the file" error unless mysqld is started by the root user.

Table Repair Considerations

REPAIR TABLE upgrades a table if it contains old temporal columns in pre-5.6.4 format (TIME, DATETIME, and TIMESTAMP columns without support for fractional seconds precision) and the avoid_temporal_upgrade system variable is disabled. If avoid_temporal_upgrade is enabled, REPAIR TABLE ignores the old temporal columns present in the table and does not upgrade them.

To upgrade tables that contain such temporal columns, disable avoid_temporal_upgrade before executing REPAIR TABLE.

You may be able to increase REPAIR TABLE performance by setting certain system variables. See Section 8.6.3, “Optimizing REPAIR TABLE Statements”.
13.7.4 Component, Plugin, and User-Defined Function Statements

13.7.4.1 CREATE FUNCTION Statement for User-Defined Functions

```
CREATE [AGGREGATE] FUNCTION function_name
  RETURNS {STRING|INTEGER|REAL|DECIMAL}
  SONAME shared_library_name
```

This statement loads the user-defined function (UDF) named `function_name`. (CREATE FUNCTION is also used to create stored functions; see Section 13.1.17, “CREATE PROCEDURE and CREATE FUNCTION Statements”.)

A user-defined function is a way to extend MySQL with a new function that works like a native (built-in) MySQL function such as `ABS()` or `CONCAT()`. See Adding a User-Defined Function.

`function_name` is the name that should be used in SQL statements to invoke the function. The RETURNS clause indicates the type of the function's return value. DECIMAL is a legal value after RETURNS, but currently DECIMAL functions return string values and should be written like STRING functions.

The AGGREGATE keyword, if given, signifies that the UDF is an aggregate (group) function. An aggregate UDF works exactly like a native MySQL aggregate function such as `SUM()` or `COUNT()`.

`shared_library_name` is the base name of the shared library file containing the code that implements the function. The file must be located in the plugin directory. This directory is given by the value of the `plugin_dir` system variable. For more information, see Section 5.7.1, “Installing and Uninstalling User-Defined Functions”.

CREATE FUNCTION requires the INSERT privilege for the mysql system schema because it adds a row to the `mysql.func` system table to register the function.

CREATE FUNCTION also adds the function to the Performance Schema user_defined_functions table that provides runtime information about installed UDFs. See Section 27.12.21.8, “The user_defined_functions Table”.

**Note**

Like the `mysql.func` system table, the Performance Schema `user_defined_functions` table lists UDFs installed using CREATE FUNCTION. Unlike the `mysql.func` table, the `user_defined_functions` table also lists UDFs installed automatically by server components or plugins. This difference makes `user_defined_functions` preferable to `mysql.func` for checking which UDFs are installed.

During the normal startup sequence, the server loads UDFs registered in the `mysql.func` table. If the server is started with the `--skip-grant-tables` option, UDFs registered in the table are not loaded and are unavailable.

**Note**

To upgrade the shared library associated with a UDF, issue a DROP FUNCTION statement, upgrade the shared library, and then issue a CREATE FUNCTION statement. If you upgrade the shared library first and then use DROP FUNCTION, the server may unexpectedly shut down.

13.7.4.2 DROP FUNCTION Statement for User-Defined Functions

```
DROP FUNCTION [IF EXISTS] function_name
```

This statement drops the user-defined function (UDF) named `function_name`. (DROP FUNCTION is also used to drop stored functions; see Section 13.1.29, “DROP PROCEDURE and DROP FUNCTION Statements”.)
**DROP FUNCTION** is the complement of **CREATE FUNCTION**. It requires the **DELETE** privilege for the **mysql** system schema because it removes the row from the **mysql.func** system table that registers the function.

**DROP FUNCTION** also removes the function from the Performance Schema **user_defined_functions** table that provides runtime information about installed UDFs. See Section 27.12.21.8, “The **user_defined_functions** Table”.

During the normal startup sequence, the server loads UDFs registered in the **mysql.func** table. Because **DROP FUNCTION** removes the **mysql.func** row for the dropped function, the server does not load the function during subsequent restarts.

**DROP FUNCTION** cannot be used to drop a UDF that is installed automatically by components or plugins rather than by using **CREATE FUNCTION**. Such a UDF is also dropped automatically, when the component or plugin that installed it is uninstalled.

**Note**

To upgrade the shared library associated with a UDF, issue a **DROP FUNCTION** statement, upgrade the shared library, and then issue a **CREATE FUNCTION** statement. If you upgrade the shared library first and then use **DROP FUNCTION**, the server may unexpectedly shut down.

### 13.7.4.3 INSTALL COMPONENT Statement

**INSTALL COMPONENT** *component_name* [, *component_name*] ...

This statement installs one or more components, which become active immediately. A component provides services that are available to the server and other components; see Section 5.5, "MySQL Components". **INSTALL COMPONENT** requires the **INSERT** privilege for the **mysql.component** system table because it adds a row to that table to register the component.

**Example:**

```
INSTALL COMPONENT 'file://component1', 'file://component2';
```

A component is named using a URN that begins with **file://** and indicates the base name of the library file that implements the component, located in the directory named by the **plugin_dir** system variable. Component names do not include any platform-dependent file name suffix such as **.so** or **.dll**. (These naming details are subject to change because component name interpretation is itself performed by a service and the component infrastructure makes it possible to replace the default service implementation with alternative implementations.)

If any error occurs, the statement fails and has no effect. For example, this happens if a component name is erroneous, a named component does not exist or is already installed, or component initialization fails.

A loader service handles component loading, which includes adding installed components to the **mysql.component** system table that serves as a registry. For subsequent server restarts, any components listed in **mysql.component** are loaded by the loader service during the startup sequence. This occurs even if the server is started with the **--skip-grant-tables** option.

If a component depends on services not present in the registry and you attempt to install the component without also installing the component or components that provide the services on which it depends, an error occurs:

```
ERROR 3527 (HY000): Cannot satisfy dependency for service 'component_a' required by component 'component_b'.
```

To avoid this problem, either install all components in the same statement, or install the dependent component after installing any components on which it depends.
### 13.7.4.4 INSTALL PLUGIN Statement

This statement installs a server plugin. It requires the INSERT privilege for the `mysql.plugin` system table because it adds a row to that table to register the plugin.

**plugin_name** is the name of the plugin as defined in the plugin descriptor structure contained in the library file (see [Plugin Data Structures](#)). Plugin names are not case-sensitive. For maximal compatibility, plugin names should be limited to ASCII letters, digits, and underscore because they are used in C source files, shell command lines, M4 and Bourne shell scripts, and SQL environments.

**shared_library_name** is the name of the shared library that contains the plugin code. The name includes the file name extension (for example, `libmyplugin.so`, `libmyplugin.dll`, or `libmyplugin.dylib`).

The shared library must be located in the plugin directory (the directory named by the `plugin_dir` system variable). The library must be in the plugin directory itself, not in a subdirectory. By default, `plugin_dir` is the plugin directory under the directory named by the `pkglibdir` configuration variable, but it can be changed by setting the value of `plugin_dir` at server startup. For example, set its value in a `my.cnf` file:

```
[mysqld]
plugin_dir=/path/to/plugin/directory
```

If the value of `plugin_dir` is a relative path name, it is taken to be relative to the MySQL base directory (the value of the `basedir` system variable).

**INSTALL PLUGIN** loads and initializes the plugin code to make the plugin available for use. A plugin is initialized by executing its initialization function, which handles any setup that the plugin must perform before it can be used. When the server shuts down, it executes the deinitialization function for each plugin that is loaded so that the plugin has a chance to perform any final cleanup.

**INSTALL PLUGIN** also registers the plugin by adding a line that indicates the plugin name and library file name to the `mysql.plugin` system table. During the normal startup sequence, the server loads and initializes plugins registered in `mysql.plugin`. This means that a plugin is installed with **INSTALL PLUGIN** only once, not every time the server starts. If the server is started with the `--skip-grant-tables` option, plugins registered in the `mysql.plugin` table are not loaded and are unavailable.

A plugin library can contain multiple plugins. For each of them to be installed, use a separate **INSTALL PLUGIN** statement. Each statement names a different plugin, but all of them specify the same library name.

**INSTALL PLUGIN** causes the server to read option (`my.cnf`) files just as during server startup. This enables the plugin to pick up any relevant options from those files. It is possible to add plugin options to an option file even before loading a plugin (if the `loose` prefix is used). It is also possible to uninstall a plugin, edit `my.cnf`, and install the plugin again. Restarting the plugin this way enables it to the new option values without a server restart.

For options that control individual plugin loading at server startup, see [Section 5.6.1, “Installing and Uninstalling Plugins”](##). If you need to load plugins for a single server startup when the `--skip-grant-tables` option is given (which tells the server not to read system tables), use the `--plugin-load` option. See [Section 5.1.7, “Server Command Options”](##).

To remove a plugin, use the **UNINSTALL PLUGIN** statement.
For additional information about plugin loading, see Section 5.6.1, “Installing and Uninstalling Plugins”.

To see what plugins are installed, use the SHOW PLUGINS statement or query the INFORMATION_SCHEMA the PLUGINS table.

If you recompile a plugin library and need to reinstall it, you can use either of the following methods:

- Use UNINSTALL PLUGIN to uninstall all plugins in the library, install the new plugin library file in the plugin directory, and then use INSTALL PLUGIN to install all plugins in the library. This procedure has the advantage that it can be used without stopping the server. However, if the plugin library contains many plugins, you must issue many INSTALL PLUGIN and UNINSTALL PLUGIN statements.

- Stop the server, install the new plugin library file in the plugin directory, and restart the server.

### 13.7.4.5 UNINSTALL COMPONENT Statement

**UNINSTALL COMPONENT component_name [, component_name ] ...**

This statement deactivates and uninstalls one or more components. A component provides services that are available to the server and other components; see Section 5.5, “MySQL Components”. UNINSTALL COMPONENT is the complement of INSTALL COMPONENT. It requires the DELETE privilege for the mysql.component system table because it removes the row from that table that registers the component.

**Example:**

UNINSTALL COMPONENT 'file://component1', 'file://component2';

For information about component naming, see Section 13.7.4.3, “INSTALL COMPONENT Statement”.

If any error occurs, the statement fails and has no effect. For example, this happens if a component name is erroneous, a named component is not installed, or cannot be uninstalled because other installed components depend on it.

A loader service handles component unloading, which includes removing uninstalled components from the mysql.component system table that serves as a registry. As a result, unloaded components are not loaded during the startup sequence for subsequent server restarts.

**Note**

This statement has no effect for keyring components, which are loaded using a manifest file and cannot be uninstalled. See Section 6.4.4.2, “Keyring Component Installation”.

### 13.7.4.6 UNINSTALL PLUGIN Statement

**UNINSTALL PLUGIN plugin_name**

This statement removes an installed server plugin. UNINSTALL PLUGIN is the complement of INSTALL PLUGIN. It requires the DELETE privilege for the mysql.plugin system table because it removes the row from that table that registers the plugin.

**plugin_name** must be the name of some plugin that is listed in the mysql.plugin table. The server executes the plugin's deinitialization function and removes the row for the plugin from the mysql.plugin system table, so that subsequent server restarts do not load and initialize the plugin. UNINSTALL PLUGIN does not remove the plugin's shared library file.

You cannot uninstall a plugin if any table that uses it is open.

Plugin removal has implications for the use of associated tables. For example, if a full-text parser plugin is associated with a FULLTEXT index on the table, uninstalling the plugin makes the table unusable.
Any attempt to access the table results in an error. The table cannot even be opened, so you cannot drop an index for which the plugin is used. This means that uninstalling a plugin is something to do with care unless you do not care about the table contents. If you are uninstalling a plugin with no intention of reinstalling it later and you care about the table contents, you should dump the table with `mysqldump` and remove the `WITH PARSER` clause from the dumped `CREATE TABLE` statement so that you can reload the table later. If you do not care about the table, `DROP TABLE` can be used even if any plugins associated with the table are missing.

For additional information about plugin loading, see Section 5.6.1, “Installing and Uninstalling Plugins”.

### 13.7.5 CLONE Statement

```sql
CLONE clone_action

clone_action: {
   LOCAL DATA DIRECTORY [=] 'clone_dir';
   INSTANCE FROM 'user'@'host':port
   IDENTIFIED BY 'password'
   [DATA DIRECTORY [=] 'clone_dir']
   [REQUIRE [NO] SSL]
}
```

The `CLONE` statement is used to clone data locally or from a remote MySQL server instance. To use `CLONE` syntax, the clone plugin must be installed. See Section 5.6.7, “The Clone Plugin”.

**CLONE LOCAL DATA DIRECTORY** syntax clones data from the local MySQL data directory to a directory on the same server or node where the MySQL server instance runs. The `'clone_dir'` directory is the full path of the local directory that data is cloned to. An absolute path is required. The specified directory must not exist, but the specified path must be an existent path. The MySQL server requires the necessary write access to create the specified directory. For more information, see Section 5.6.7.2, “Cloning Data Locally”.

**CLONE INSTANCE** syntax clones data from a remote MySQL server instance (the donor) and transfers it to the MySQL instance where the cloning operation was initiated (the recipient).

- **user** is the clone user on the donor MySQL server instance.
- **host** is the hostname address of the donor MySQL server instance. Internet Protocol version 6 (IPv6) address format is not supported. An alias to the IPv6 address can be used instead. An IPv4 address can be used as is.
- **port** is the port number of the donor MySQL server instance. (The X Protocol port specified by `mysqlx_port` is not supported. Connecting to the donor MySQL server instance through MySQL Router is also not supported.)
- **IDENTIFIED BY 'password'** specifies the password of the clone user on the donor MySQL server instance.
- **DATA DIRECTORY [=] 'clone_dir'** is an optional clause used to specify a directory on the recipient for the data you are cloning. Use this option if you do not want to remove existing data in the recipient data directory. An absolute path is required, and the directory must not exist. The MySQL server must have the necessary write access to create the directory.

When the optional `DATA DIRECTORY [=] 'clone_dir'` clause is not used, a cloning operation removes existing data in the recipient data directory, replaces it with the cloned data, and automatically restarts the server afterward.

- **[REQUIRE [NO] SSL]** explicitly specifies whether an encrypted connection is to be used or not when transferring cloned data over the network. An error is returned if the explicit specification cannot be satisfied. If an SSL clause is not specified, clone attempts to establish an encrypted connection by default, falling back to an insecure connection if the secure connection attempt fails.
A secure connection is required when cloning encrypted data regardless of whether this clause is specified. For more information, see Configuring an Encrypted Connection for Cloning.

For additional information about cloning data from a remote MySQL server instance, see Section 5.6.7.3, “Cloning Remote Data”.

13.7.6 SET Statements

The `SET` statement has several forms. Descriptions for those forms that are not associated with a specific server capability appear in subsections of this section:

- `SET var_name = value` enables you to assign values to variables that affect the operation of the server or clients. See Section 13.7.6.1, “SET Syntax for Variable Assignment”.

- `SET CHARACTER SET` and `SET NAMES` assign values to character set and collation variables associated with the current connection to the server. See Section 13.7.6.2, “SET CHARACTER SET Statement”, and Section 13.7.6.3, “SET NAMES Statement”.

Descriptions for the other forms appear elsewhere, grouped with other statements related to the capability they help implement:

- `SET DEFAULT ROLE` and `SET ROLE` set the default role and current role for user accounts. See Section 13.7.1.9, “SET DEFAULT ROLE Statement”, and Section 13.7.1.11, “SET ROLE Statement”.

- `SET PASSWORD` assigns account passwords. See Section 13.7.1.10, “SET PASSWORD Statement”.

- `SET RESOURCE GROUP` assigns threads to a resource group. See Section 13.7.2.4, “SET RESOURCE GROUP Statement”.

- `SET TRANSACTION ISOLATION LEVEL` sets the isolation level for transaction processing. See Section 13.3.7, “SET TRANSACTION Statement”.

13.7.6.1 SET Syntax for Variable Assignment

```
SET variable = expr [, variable = expr] ...
```

```
variable: { user_var_name
               | param_name
               | local_var_name
               | (GLOBAL | @@GLOBAL.) system_var_name
               | (PERSIST | @@PERSIST.) system_var_name
               | (PERSIST_ONLY | @@PERSIST_ONLY.) system_var_name
               | [SESSION | @@SESSION. | @@] system_var_name
}
```

`SET` syntax for variable assignment enables you to assign values to different types of variables that affect the operation of the server or clients:

- User-defined variables. See Section 9.4, “User-Defined Variables”.

- Stored procedure and function parameters, and stored program local variables. See Section 13.6.4, “Variables in Stored Programs”.

- System variables. See Section 5.1.8, “Server System Variables”. System variables also can be set at server startup, as described in Section 5.1.9, “Using System Variables”.

A `SET` statement that assigns variable values is not written to the binary log, so in replication scenarios it affects only the host on which you execute it. To affect all replication hosts, execute the statement on each host.

The following sections describe `SET` syntax for setting variables. They use the `=` assignment operator, but the `:=` assignment operator is also permitted for this purpose.
SET Statements

- User-Defined Variable Assignment
- Parameter and Local Variable Assignment
- System Variable Assignment
- SET Error Handling
- Multiple Variable Assignment
- System Variable References in Expressions

User-Defined Variable Assignment

User-defined variables are created locally within a session and exist only within the context of that session; see Section 9.4, “User-Defined Variables”.

A user-defined variable is written as \texttt{@var}\texttt{\_name} and is assigned an expression value as follows:

\begin{verbatim}
SET @var\_name = expr;
\end{verbatim}

Examples:

\begin{verbatim}
SET @name = 43;
SET @total\_tax = (SELECT \text{SUM(tax)} FROM taxable\_transactions);
\end{verbatim}

As demonstrated by those statements, \texttt{expr} can range from simple (a literal value) to more complex (the value returned by a scalar subquery).

The Performance Schema \texttt{user\_variables\_by\_thread} table contains information about user-defined variables. See Section 27.12.10, “Performance Schema User-Defined Variable Tables”.

Parameter and Local Variable Assignment

\texttt{SET} applies to parameters and local variables in the context of the stored object within which they are defined. The following procedure uses the \texttt{increment} procedure parameter and \texttt{counter} local variable:

\begin{verbatim}
CREATE PROCEDURE p(increment INT)
BEGIN
  DECLARE counter INT DEFAULT 0;
  WHILE counter < 10 DO
    -- ... do work ...
    SET counter = counter + increment;
  END WHILE;
END;
\end{verbatim}

System Variable Assignment

The MySQL server maintains system variables that configure its operation. A system variable can have a global value that affects server operation as a whole, a session value that affects the current session, or both. Many system variables are dynamic and can be changed at runtime using the \texttt{SET} statement to affect operation of the current server instance. \texttt{SET} can also be used to persist certain system variables to the \texttt{mysqld-auto.cnf} file in the data directory, to affect server operation for subsequent startups.

If you change a session system variable, the value remains in effect within your session until you change the variable to a different value or the session ends. The change has no effect on other sessions.

If you change a global system variable, the value is remembered and used to initialize the session value for new sessions until you change the variable to a different value or the server exits. The change is visible to any client that accesses the global value. However, the change affects the corresponding
session value only for clients that connect after the change. The global variable change does not affect
the session value for any current client sessions (not even the session within which the global value
change occurs).

To make a global system variable setting permanent so that it applies across server restarts, you can
persist it to the `mysqld-auto.cnf` file in the data directory. It is also possible to make persistent
configuration changes by manually modifying a `my.cnf` option file, but that is more cumbersome,
and an error in a manually entered setting might not be discovered until much later. `SET` statements
that persist system variables are more convenient and avoid the possibility of malformed settings
because settings with syntax errors do not succeed and do not change server configuration. For more
information about persisting system variables and the `mysqld-auto.cnf` file, see Section 5.1.9.3,
“Persisted System Variables”.

**Note**

Setting or persisting a global system variable value always requires special
privileges. Setting a session system variable value normally requires no special
privileges and can be done by any user, although there are exceptions. For
more information, see Section 5.1.9.1, “System Variable Privileges”.

The following discussion describes the syntax options for setting and persisting system variables:

- To assign a value to a global system variable, precede the variable name by the `GLOBAL` keyword or
  the `@@GLOBAL.` qualifier:

```sql
SET GLOBAL max_connections = 1000;
SET @@GLOBAL.max_connections = 1000;
```

- To assign a value to a session system variable, precede the variable name by the `SESSION` or
  `LOCAL` keyword, by the `@@SESSION., @@LOCAL.,` or `@@` qualifier, or by no keyword or no modifier at
  all:

```sql
SET SESSION sql_mode = 'TRADITIONAL';
SET LOCAL sql_mode = 'TRADITIONAL';
SET @@SESSION.sql_mode = 'TRADITIONAL';
SET @@LOCAL.sql_mode = 'TRADITIONAL';
SET @@sql_mode = 'TRADITIONAL';
SET sql_mode = 'TRADITIONAL';
```

A client can change its own session variables, but not those of any other client.

- To persist a global system variable to the `mysqld-auto.cnf` option file in the data directory,
  precede the variable name by the `PERSIST` keyword or the `@@PERSIST.` qualifier:

```sql
SET PERSIST max_connections = 1000;
SET @@PERSIST.max_connections = 1000;
```

This `SET` syntax enables you to make configuration changes at runtime that also persist across
server restarts. Like `SET GLOBAL`, `SET PERSIST` sets the global variable runtime value, but also
writes the variable setting to the `mysqld-auto.cnf` file (replacing any existing variable setting if
there is one).

- To persist a global system variable to the `mysqld-auto.cnf` file without setting the global
  variable runtime value, precede the variable name by the `PERSIST_ONLY` keyword or the
  `@@PERSIST_ONLY.` qualifier:

```sql
SET PERSIST_ONLY back_log = 100;
SET @@PERSIST_ONLY.back_log = 100;
```

Like `PERSIST`, `PERSIST_ONLY` writes the variable setting to `mysqld-auto.cnf`. However,
unlike `PERSIST`, `PERSIST_ONLY` does not modify the global variable runtime value. This makes
`PERSIST_ONLY` suitable for configuring read-only system variables that can be set only at server
startup.
To set a global system variable value to the compiled-in MySQL default value or a session system variable to the current corresponding global value, set the variable to the value DEFAULT. For example, the following two statements are identical in setting the session value of `max_join_size` to the current global value:

```
SET @SESSION.max_join_size = DEFAULT;
SET @SESSION.max_join_size = @@GLOBAL.max_join_size;
```

Using `SET` to persist a global system variable to a value of DEFAULT or to its literal default value assigns the variable its default value and adds a setting for the variable to `mysqld-auto.cnf`. To remove the variable from the file, use `RESET PERSIST`.

Some system variables cannot be persisted or are persist-restricted. See Section 5.1.9.4, "Nonpersistible and Persist-Restricted System Variables".

A system variable implemented by a plugin can be persisted if the plugin is installed when the `SET` statement is executed. Assignment of the persisted plugin variable takes effect for subsequent server restarts if the plugin is still installed. If the plugin is no longer installed, the plugin variable no longer exists when the server reads the `mysqld-auto.cnf` file. In this case, the server writes a warning to the error log and continues:

```
currently unknown variable 'var_name'
was read from the persisted config file
```

To display system variable names and values:

- Use the `SHOW VARIABLES` statement; see Section 13.7.7.41, "SHOW VARIABLES Statement".
- Several Performance Schema tables provide system variable information. See Section 27.12.14, "Performance Schema System Variable Tables".
- The Performance Schema `variables_info` table contains information showing when and by which user each system variable was most recently set. See Section 27.12.14.2, "Performance Schema variables_info Table".
- The Performance Schema `persisted_variables` table provides an SQL interface to the `mysqld-auto.cnf` file, enabling its contents to be inspected at runtime using `SELECT` statements. See Section 27.12.14.1, "Performance Schema persisted_variables Table".

**SET Error Handling**

If any variable assignment in a `SET` statement fails, the entire statement fails and no variables are changed, nor is the `mysqld-auto.cnf` file changed.

`SET` produces an error under the circumstances described here. Most of the examples show `SET` statements that use keyword syntax (for example, `GLOBAL` or `SESSION`), but the principles are also true for statements that use the corresponding modifiers (for example, `@@GLOBAL` or `@@SESSION`).

- Use of `SET` (any variant) to set a read-only variable:

  ```
  mysql> SET GLOBAL version = 'abc';
  ERROR 1238 (HY000): Variable 'version' is a read only variable
  ```

- Use of `GLOBAL`, `PERSIST`, or `PERSIST_ONLY` to set a variable that has only a session value:

  ```
  mysql> SET GLOBAL sql_log_bin = ON;
  ERROR 1228 (HY000): Variable 'sql_log_bin' is a SESSION variable and can't be used with SET GLOBAL
  ```

- Use of `SESSION` to set a variable that has only a global value:

  ```
  mysql> SET SESSION max_connections = 1000;
  ERROR 1229 (HY000): Variable 'max_connections' is a
GLOBAL variable and should be set with `SET GLOBAL`

- Omission of `GLOBAL`, `PERSIST`, or `PERSIST_ONLY` to set a variable that has only a global value:

  ```sql
  mysql> SET max_connections = 1000;
  ERROR 1229 (HY000): Variable 'max_connections' is a GLOBAL variable and should be set with `SET GLOBAL`
  ```

- Use of `PERSIST` or `PERSIST_ONLY` to set a variable that cannot be persisted:

  ```sql
  mysql> SET PERSIST port = 3307;
  ERROR 1238 (HY000): Variable 'port' is a read only variable
  mysql> SET PERSIST_ONLY port = 3307;
  ERROR 1238 (HY000): Variable 'port' is a non persistent read only variable
  ```

- The `@@GLOBAL`, `@@PERSIST`, `@@PERSIST_ONLY`, `@@SESSION`, and `@@` modifiers apply only to system variables. An error occurs for attempts to apply them to user-defined variables, stored procedure or function parameters, or stored program local variables.

- Not all system variables can be set to `DEFAULT`. In such cases, assigning `DEFAULT` results in an error.

- An error occurs for attempts to assign `DEFAULT` to user-defined variables, stored procedure or function parameters, or stored program local variables.

### Multiple Variable Assignment

A `SET` statement can contain multiple variable assignments, separated by commas. This statement assigns values to a user-defined variable and a system variable:

```sql
SET @x = 1, SESSION sql_mode = '';
```

If you set multiple system variables in a single statement, the most recent `GLOBAL`, `PERSIST`, `PERSIST_ONLY`, or `SESSION` keyword in the statement is used for following assignments that have no keyword specified.

Examples of multiple-variable assignment:

```sql
SET GLOBAL sort_buffer_size = 1000000, SESSION sort_buffer_size = 1000000;
SET @@GLOBAL.sort_buffer_size = 1000000, @@LOCAL.sort_buffer_size = 1000000;
SET GLOBAL max_connections = 1000, sort_buffer_size = 1000000;
```

The `@@GLOBAL`, `@@PERSIST`, `@@PERSIST_ONLY`, `@@SESSION`, and `@@` modifiers apply only to the immediately following system variable, not any remaining system variables. This statement sets the `sort_buffer_size` global value to 50000 and the session value to 1000000:

```sql
SET @@GLOBAL.sort_buffer_size = 50000, sort_buffer_size = 1000000;
```

### System Variable References in Expressions

To refer to the value of a system variable in expressions, use one of the `@@`-modifiers (except `@@PERSIST` and `@@PERSIST_ONLY`, which are not permitted in expressions). For example, you can retrieve system variable values in a `SELECT` statement like this:

```sql
SELECT @@GLOBAL.sql_mode, @@SESSION.sql_mode, @sql_mode;
```

#### Note

A reference to a system variable in an expression as `@@var_name` (with `@@` rather than `@@GLOBAL`, or `@@SESSION`) returns the session value if it exists and the global value otherwise. This differs from `SET @@var_name = expr`, which always refers to the session value.

### 13.7.6.2 SET CHARACTER SET Statement
SHOW Statements

```
SET {CHARACTER SET | CHARSET}
   {'charset_name' | DEFAULT}
```

This statement maps all strings sent between the server and the current client with the given mapping. `SET CHARACTER SET` sets three session system variables: `character_set_client` and `character_set_results` are set to the given character set, and `character_set_connection` to the value of `character_set_database`. See Section 10.4, "Connection Character Sets and Collations".

`charset_name` may be quoted or unquoted.

The default character set mapping can be restored by using the value `DEFAULT`. The default depends on the server configuration.

Some character sets cannot be used as the client character set. Attempting to use them with `SET CHARACTER SET` produces an error. See Impermissible Client Character Sets.

13.7.6.3 SET NAMES Statement

```
SET NAMES {'charset_name'}
     [COLLATE 'collation_name'] | DEFAULT
```

This statement sets the three session system variables `character_set_client`, `character_set_connection`, and `character_set_results` to the given character set. Setting `character_set_connection` to `charset_name` also sets `collation_connection` to the default collation for `charset_name`. See Section 10.4, "Connection Character Sets and Collations".

The optional `COLLATE` clause may be used to specify a collation explicitly. If given, the collation must one of the permitted collations for `charset_name`.

`charset_name` and `collation_name` may be quoted or unquoted.

The default mapping can be restored by using a value of `DEFAULT`. The default depends on the server configuration.

Some character sets cannot be used as the client character set. Attempting to use them with `SET NAMES` produces an error. See Impermissible Client Character Sets.

13.7.7 SHOW Statements

`SHOW` has many forms that provide information about databases, tables, columns, or status information about the server. This section describes those following:

```
SHOW [BINARY | MASTER] LOGS
SHOW BINLOG EVENTS [IN 'log_name'] [FROM pos] [LIMIT [offset,] row_count]
SHOW CHARACTER SET [like_or_where]
SHOW COLLATION [like_or_where]
SHOW [FULL] COLUMNS FROM tbl_name [FROM db_name] [like_or_where]
SHOW CREATE DATABASE db_name
SHOW CREATE EVENT event_name
SHOW CREATE FUNCTION func_name
SHOW CREATE PROCEDURE proc_name
SHOW CREATE TABLE tbl_name
SHOW CREATE TRIGGER trigger_name
SHOW CREATE VIEW view_name
SHOW DATABASES [like_or_where]
SHOW ENGINE engine_name {STATUS | MUTEX}
SHOW [STORAGE] ENGINES
SHOW ERRORS [LIMIT [offset,] row_count]
SHOW EVENTS
SHOW FUNCTION CODE func_name
SHOW FUNCTION STATUS [like_or_where]
SHOW GRANTS FOR user
SHOW INDEX FROM tbl_name [FROM db_name]
```
SHOW Statements

SHOW MASTER STATUS
SHOW OPEN TABLES [FROM db_name] [like_or_where]
SHOW PLUGINS
SHOW PROCEDURE CODE proc_name
SHOW PROCEDURE STATUS [like_or_where]
SHOW PRIVILEGES
SHOW [FULL] PROCESSLIST
SHOW PROFILE [types] [FOR QUERY n] [OFFSET n] [LIMIT n]
SHOW PROFILES
SHOW RELAYLOG EVENTS [IN 'log_name'] [FROM pos] [LIMIT [offset,] row_count]
SHOW REPLICA | SLAVE HOSTS
SHOW REPLICA | SLAVE STATUS [FOR CHANNEL channel]
SHOW [GLOBAL | SESSION] STATUS [like_or_where]
SHOW [FULL] TABLES [FROM db_name] [like_or_where]
SHOW TRIGGERS [FROM db_name] [like_or_where]
SHOW [GLOBAL | SESSION] VARIABLES [like_or_where]
SHOW [GLOBAL | SESSION] VARIABLES [like_or_where]
SHOW WARNINGS [LIMIT [offset,] row_count]

like_or_where: {
LIKE 'pattern'
WHERE expr
}

If the syntax for a given SHOW statement includes a LIKE 'pattern' part, 'pattern' is a string that can contain the SQL % and _ wildcard characters. The pattern is useful for restricting statement output to matching values.

Several SHOW statements also accept a WHERE clause that provides more flexibility in specifying which rows to display. See Section 26.8, “Extensions to SHOW Statements”.

Many MySQL APIs (such as PHP) enable you to treat the result returned from a SHOW statement as you would a result set from a SELECT; see Chapter 29, Connectors and APIs, or your API documentation for more information. In addition, you can work in SQL with results from queries on tables in the INFORMATION_SCHEMA database, which you cannot easily do with results from SHOW statements. See Chapter 26, INFORMATION_SCHEMA Tables.

13.7.7.1 SHOW BINARY LOGS Statement

SHOW BINARY LOGS
SHOW MASTER LOGS

Lists the binary log files on the server. This statement is used as part of the procedure described in Section 13.4.1.1, “PURGE BINARY LOGS Statement”, that shows how to determine which logs can be purged. SHOW BINARY LOGS requires the REPLICATION CLIENT privilege (or the deprecated SUPER privilege).

Encrypted binary log files have a 512-byte file header that stores information required for encryption and decryption of the file. This is included in the file size displayed by SHOW BINARY LOGS. The Encrypted column shows whether or not the binary log file is encrypted. Binary log encryption is active if binlog_encryption=ON is set for the server. Existing binary log files are not encrypted or decrypted if binary log encryption is activated or deactivated while the server is running.

mysql> SHOW BINARY LOGS;
+---------------+-----------+-----------+
| Log_name      | File_size | Encrypted |
|---------------+-----------+-----------|
| binlog.000015 | 724935    | Yes       |
| binlog.000016 | 733481    | Yes       |
+---------------+-----------+-----------+

SHOW MASTER LOGS is equivalent to SHOW BINARY LOGS.

13.7.7.2 SHOW BINLOG EVENTS Statement

SHOW BINLOG EVENTS
SHOW Statements

[IN 'log_name']
[FROM pos]
[LIMIT [offset,] row_count]

Shows the events in the binary log. If you do not specify 'log_name', the first binary log is displayed.

SHOW BINLOG EVENTS requires the REPLICATION SLAVE privilege.

The LIMIT clause has the same syntax as for the SELECT statement. See Section 13.2.10, “SELECT Statement”.

Note
Issuing a SHOW BINLOG EVENTS with no LIMIT clause could start a very time- and resource-consuming process because the server returns to the client the complete contents of the binary log (which includes all statements executed by the server that modify data). As an alternative to SHOW BINLOG EVENTS, use the mysqlbinlog utility to save the binary log to a text file for later examination and analysis. See Section 4.6.9, “mysqlbinlog — Utility for Processing Binary Log Files”.

SHOW BINLOG EVENTS displays the following fields for each event in the binary log:

- **Log_name**
  The name of the file that is being listed.

- **Pos**
  The position at which the event occurs.

- **Event_type**
  An identifier that describes the event type.

- **Server_id**
  The server ID of the server on which the event originated.

- **End_log_pos**
  The position at which the next event begins, which is equal to Pos plus the size of the event.

- **Info**
  More detailed information about the event type. The format of this information depends on the event type.

For compressed transaction payloads, the Transaction_payload_event is first printed as a single unit, then it is unpacked and each event inside it is printed.

Some events relating to the setting of user and system variables are not included in the output from SHOW BINLOG EVENTS. To get complete coverage of events within a binary log, use mysqlbinlog.

SHOW BINLOG EVENTS does not work with relay log files. You can use SHOW RELAYLOG EVENTS for this purpose.

### 13.7.7.3 SHOW CHARACTER SET Statement

SHOW CHARACTER SET
[LIKE 'pattern' | WHERE expr]

The SHOW CHARACTER SET statement shows all available character sets. The LIKE clause, if present, indicates which character set names to match. The WHERE clause can be given to select rows using
more general conditions, as discussed in Section 26.8, “Extensions to SHOW Statements”. For example:

```
mysql> SHOW CHARACTER SET LIKE 'latin%';
+---------+-----------------------------+-------------------+--------+
| Charset | Description                 | Default collation | Maxlen |
+---------+-----------------------------+-------------------+--------+
| latin1  | cp1252 West European        | latin1_swedish_ci |      1 |
| latin2  | ISO 8859-2 Central European | latin2_general_ci |      1 |
| latin5  | ISO 8859-9 Turkish          | latin5_turkish_ci |      1 |
| latin7  | ISO 8859-13 Baltic          | latin7_general_ci |      1 |
+---------+-----------------------------+-------------------+--------+
```

SHOW CHARACTER SET output has these columns:

- **Charset**
  The character set name.

- **Description**
  A description of the character set.

- **Default collation**
  The default collation for the character set.

- **Maxlen**
  The maximum number of bytes required to store one character.

The filename character set is for internal use only; consequently, SHOW CHARACTER SET does not display it.

Character set information is also available from the INFORMATION_SCHEMA CHARACTER_SETS table. See Section 26.3.4, “The INFORMATION_SCHEMA CHARACTER_SETS Table”.

### 13.7.7.4 SHOW COLLATION Statement

```
SHOW COLLATION
[LIKE 'pattern' | WHERE expr]
```

This statement lists collations supported by the server. By default, the output from SHOW COLLATION includes all available collations. The LIKE clause, if present, indicates which collation names to match. The WHERE clause can be given to select rows using more general conditions, as discussed in Section 26.8, “Extensions to SHOW Statements”. For example:

```
mysql> SHOW COLLATION WHERE Charset = 'latin1';
+-------------------+---------+----+---------+----------+---------+
| Collation          | Charset | Id | Default | Compiled | Sortlen |
+-------------------+---------+----+---------+----------+---------+
| latin1_german1_ci | latin1  |  5 |         | Yes      |       1 |
| latin1_swedish_ci | latin1  |  8 | Yes     | Yes      |       1 |
| latin1_danish_ci  | latin1  | 15 |         | Yes      |       1 |
| latin1_german2_ci | latin1  | 31 |         | Yes      |       2 |
| latin1_general_ci | latin1  | 47 |         | Yes      |       1 |
| latin1_general cs | latin1  | 49 |         | Yes      |       1 |
| latin1_spanish_ci | latin1  | 94 |         | Yes      |       1 |
+-------------------+---------+----+---------+----------+---------+
```

SHOW COLLATION output has these columns:

- **Collation**
  The collation name.
SHOW Statements

- **Charset**
  The name of the character set with which the collation is associated.

- **Id**
  The collation ID.

- **Default**
  Whether the collation is the default for its character set.

- **Compiled**
  Whether the character set is compiled into the server.

- **Sortlen**
  This is related to the amount of memory required to sort strings expressed in the character set.

To see the default collation for each character set, use the following statement. Default is a reserved word, so to use it as an identifier, it must be quoted as such:

```sql
mysql> SHOW COLLATION WHERE `Default` = 'Yes';
```

<table>
<thead>
<tr>
<th>Collation</th>
<th>Charset</th>
<th>Id</th>
<th>Default</th>
<th>Compiled</th>
<th>Sortlen</th>
</tr>
</thead>
<tbody>
<tr>
<td>big5_chinese_ci</td>
<td>big5</td>
<td>1</td>
<td>Yes</td>
<td>Yes</td>
<td>1</td>
</tr>
<tr>
<td>dec8_swedish_ci</td>
<td>dec8</td>
<td>3</td>
<td>Yes</td>
<td>Yes</td>
<td>1</td>
</tr>
<tr>
<td>cp850_general_ci</td>
<td>cp850</td>
<td>4</td>
<td>Yes</td>
<td>Yes</td>
<td>1</td>
</tr>
<tr>
<td>hp8_english_ci</td>
<td>hp8</td>
<td>6</td>
<td>Yes</td>
<td>Yes</td>
<td>1</td>
</tr>
<tr>
<td>koi8r_general_ci</td>
<td>koi8r</td>
<td>7</td>
<td>Yes</td>
<td>Yes</td>
<td>1</td>
</tr>
<tr>
<td>latin1_swedish_ci</td>
<td>latin1</td>
<td>8</td>
<td>Yes</td>
<td>Yes</td>
<td>1</td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Collation information is also available from the INFORMATION_SCHEMA COLLATIONS table. See Section 26.3.6, "The INFORMATION_SCHEMA COLLATIONS Table".

13.7.7.5 SHOW COLUMNS Statement

```sql
SHOW [EXTENDED] [FULL] {COLUMNS | FIELDS}
  {FROM | IN} tbl_name
  [{FROM | IN} db_name]
  [LIKE 'pattern' | WHERE expr]
```

SHOW COLUMNS displays information about the columns in a given table. It also works for views. SHOW COLUMNS displays information only for those columns for which you have some privilege.

```sql
mysql> SHOW COLUMNS FROM City;
```

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Null</th>
<th>Key</th>
<th>Default</th>
<th>Extra</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID</td>
<td>int(11)</td>
<td>NO</td>
<td>PRI</td>
<td>NULL</td>
<td>auto_increment</td>
</tr>
<tr>
<td>Name</td>
<td>char(35)</td>
<td>NO</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>CountryCode</td>
<td>char(3)</td>
<td>NO</td>
<td>MUL</td>
<td></td>
<td></td>
</tr>
<tr>
<td>District</td>
<td>char(20)</td>
<td>NO</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Population</td>
<td>int(11)</td>
<td>NO</td>
<td>0</td>
<td></td>
<td></td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

An alternative to `tbl_name FROM db_name` syntax is `db_name.tbl_name`. These two statements are equivalent:

```sql
SHOW COLUMNS FROM mytable FROM mydb;
SHOW COLUMNS FROM mydb.mytable;
```

The optional EXTENDED keyword causes the output to include information about hidden columns that MySQL uses internally and are not accessible by users.
SHOW Statements

The optional `FULL` keyword causes the output to include the column collation and comments, as well as the privileges you have for each column.

The `LIKE` clause, if present, indicates which column names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in Section 26.8, “Extensions to SHOW Statements”.

The data types may differ from what you expect them to be based on a `CREATE TABLE` statement because MySQL sometimes changes data types when you create or alter a table. The conditions under which this occurs are described in Section 13.1.20.7, “Silent Column Specification Changes”.

`SHOW COLUMNS` displays the following values for each table column:

- **Field**
  The name of the column.

- **Type**
  The column data type.

- **Collation**
  The collation for nonbinary string columns, or `NULL` for other columns. This value is displayed only if you use the `FULL` keyword.

- **Null**
  The column nullability. The value is `YES` if `NULL` values can be stored in the column, `NO` if not.

- **Key**
  Whether the column is indexed:
  - If `Key` is empty, the column either is not indexed or is indexed only as a secondary column in a multiple-column, nonunique index.
  - If `Key` is `PRI`, the column is a `PRIMARY KEY` or is one of the columns in a multiple-column `PRIMARY KEY`.
  - If `Key` is `UNI`, the column is the first column of a `UNIQUE` index. (A `UNIQUE` index permits multiple NULL values, but you can tell whether the column permits NULL by checking the `Null` field.)
  - If `Key` is `MUL`, the column is the first column of a nonunique index in which multiple occurrences of a given value are permitted within the column.

If more than one of the `Key` values applies to a given column of a table, `Key` displays the one with the highest priority, in the order `PRI, UNI, MUL`.

A `UNIQUE` index may be displayed as `PRI` if it cannot contain NULL values and there is no `PRIMARY KEY` in the table. A `UNIQUE` index may display as `MUL` if several columns form a composite `UNIQUE` index; although the combination of the columns is unique, each column can still hold multiple occurrences of a given value.

- **Default**
  The default value for the column. This is `NULL` if the column has an explicit default of `NULL`, or if the column definition includes no `DEFAULT` clause.

- **Extra**
  Any additional information that is available about a given column. The value is nonempty in these cases:
SHOW Statements

- `auto_increment` for columns that have the `AUTO_INCREMENT` attribute.
- `on update CURRENT_TIMESTAMP` for `TIMESTAMP` or `DATETIME` columns that have the `ON UPDATE CURRENT_TIMESTAMP` attribute.
- `VIRTUAL GENERATED` or `VIRTUAL STORED` for generated columns.
- `DEFAULT_GENERATED` for columns that have an expression default value.

**Privileges**

The privileges you have for the column. This value is displayed only if you use the `FULL` keyword.

**Comment**

Any comment included in the column definition. This value is displayed only if you use the `FULL` keyword.

Table column information is also available from the `INFORMATION_SCHEMA.COLUMNS` table. See Section 26.3.8, “The INFORMATION_SCHEMA COLUMNS Table”. The extended information about hidden columns is available only using `SHOW EXTENDED COLUMNS`; it cannot be obtained from the `COLUMNS` table.

You can list a table's columns with the `mysqlshow db_name tbl_name` command.

The `DESCRIBE` statement provides information similar to `SHOW COLUMNS`. See Section 13.8.1, “DESCRIBE Statement”.

The `SHOW CREATE TABLE`, `SHOW TABLE STATUS`, and `SHOW INDEX` statements also provide information about tables. See Section 13.7.7, “SHOW Statements”.

### 13.7.7.6 SHOW CREATE DATABASE Statement

`SHOW CREATE {DATABASE | SCHEMA} [IF NOT EXISTS] db_name`

Shows the `CREATE DATABASE` statement that creates the named database. If the `SHOW` statement includes an `IF NOT EXISTS` clause, the output too includes such a clause. `SHOW CREATE SCHEMA` is a synonym for `SHOW CREATE DATABASE`.

```sql
mysql> SHOW CREATE DATABASE test\G
*************************** 1. row ***************************
Database: test
Create Database: CREATE DATABASE `test` /*!40100 DEFAULT CHARACTER SET utf8mb4 COLLATE utf8mb4_0900_ai_ci */ /*!80014 DEFAULT ENCRYPTION='N' */
```

### 13.7.7.7 SHOW CREATE EVENT Statement

`SHOW CREATE EVENT event_name`

This statement displays the `CREATE EVENT` statement needed to re-create a given event. It requires the `EVENT` privilege for the database from which the event is to be shown. For example (using the same event `e_daily` defined and then altered in Section 13.7.7.18, “SHOW EVENTS Statement”):

```sql
mysql> SHOW CREATE EVENT myschema.e_daily\G
```

`SHOW CREATE DATABASE` quotes table and column names according to the value of the `sql_quote_show_create` option. See Section 5.1.8, “Server System Variables”.

### 13.7.7.8 SHOW DATABASE Statement

This statement provides information about a database. It requires the `DATABASE` privilege for the database to be displayed. For example (using the same database `test` defined and then altered in Section 13.7.7.6, “SHOW CREATE DATABASE Statement”):

```sql
mysql> SHOW DATABASE test\G
```

### 13.7.7.9 SHOW DATABASES Statement

This statement lists all the databases available to the user. It requires the `DATABASE` privilege for any of the databases listed. For example (using the same databases defined and then altered in Section 13.7.7.8, “SHOW DATABASE Statement”):

```sql
mysql> SHOW DATABASES\G
```

### 13.7.7.10 SHOW DEFAULT VALUES Statement

This statement displays the name, data type, and default value for each column in the table. It requires the `SELECT` privilege for the table. For example (using the same table `quotes` defined and then altered in Section 13.7.7.11, “SHOW TABLE STATUS Statement”):

```sql
mysql> SHOW DEFAULT VALUES quotes\G
```
SHOW Statements

*************************** 1. row ***************************
Event: e_daily
sql_mode: ONLY_FULL_GROUP_BY,STRICT_TRANS_TABLES,
NO_ZERO_IN_DATE,NO_ZERO_DATE,
ERROR_FOR_DIVISION_BY ZERO,
NOngine_SUBSTITUTION

CREATE Event: CREATE DEFINER=`jon`@`ghidora` EVENT `e_daily`
ON SCHEDULE EVERY 1 DAY
STARTS CURRENT_TIMESTAMP + INTERVAL 6 HOUR
ON COMPLETION NOT PRESERVE
ENABLE
COMMENT 'Saves total number of sessions then closes the table each day'
DO BEGIN
INSERT INTO site_activity.totals (time, total)
SELECT CURRENT_TIMESTAMP, COUNT(*)
FROM site_activity.sessions;
DELETE FROM site_activity.sessions;
END

character_set_client: utf8mb4
collation_connection: utf8mb4_0900_ai_ci
Database Collation: utf8mb4_0900_ai_ci

character_set_client is the session value of the character_set_client system variable when the event was created. collation_connection is the session value of the collation_connection system variable when the event was created. Database Collation is the collation of the database with which the event is associated.

The output reflects the current status of the event (ENABLE) rather than the status with which it was created.

13.7.7.8 SHOW CREATE FUNCTION Statement

SHOW CREATE FUNCTION func_name

This statement is similar to SHOW CREATE PROCEDURE but for stored functions. See Section 13.7.7.9, “SHOW CREATE PROCEDURE Statement”.

13.7.7.9 SHOW CREATE PROCEDURE Statement

SHOW CREATE PROCEDURE proc_name

This statement is a MySQL extension. It returns the exact string that can be used to re-create the named stored procedure. A similar statement, SHOW CREATE FUNCTION, displays information about stored functions (see Section 13.7.7.8, “SHOW CREATE FUNCTION Statement”).

To use either statement, you must be the user named as the routine DEFINER, have the SHOW Routine privilege, have the SELECT privilege at the global level, or have the CREATE ROUTINE, ALTER ROUTINE, or EXECUTE privilege granted at a scope that includes the routine. The value displayed for the Create Procedure or Create Function field is NULL if you have only CREATE ROUTINE, ALTER ROUTINE, or EXECUTE.

mysql> SHOW CREATE PROCEDURE test.citycount\G
*************************** 1. row ***************************
Procedure: citycount
sql_mode: ONLY_FULL_GROUP_BY,STRICT_TRANS_TABLES,
NO_ZERO_IN_DATE,NO_ZERO_DATE,
ERROR_FOR_DIVISION_BY ZERO,
NOngine_SUBSTITUTION

CREATE DEFINER=`me`@`localhost` PROCEDURE `citycount`(IN country CHAR(3), OUT cities INT)
BEGIN
SELECT COUNT(*) INTO cities FROM world.city
WHERE CountryCode = country;
END

character_set_client: utf8mb4
SHOW Statements

collation_connection: utf8mb4_0900_ai_ci
Database Collation: utf8mb4_0900_ai_ci

mysql> SHOW CREATE FUNCTION test.hello\G
*************************** 1. row ***************************
Function: hello
sql_mode: ONLY_FULL_GROUP_BY,STRICT_TRANS_TABLES,
         NO_ZERO_IN_DATE,NO_ZERO_DATE,
         ERROR_FOR_DIVISION_BY_ZERO,
         NO_ENGINE_SUBSTITUTION
Create Function: CREATE DEFINER=`me`@`localhost`
FUNCTION `hello`(s CHAR(20))
RETURNS char(50) CHARSET utf8mb4
DETERMINISTIC
RETURN CONCAT('Hello, ',s,'!')
character_set_client: utf8mb4
collation_connection: utf8mb4_0900_ai_ci
Database Collation: utf8mb4_0900_ai_ci

character_set_client is the session value of the character_set_client system variable when the routine was created. collation_connection is the session value of the collation_connection system variable when the routine was created. Database Collation is the collation of the database with which the routine is associated.

13.7.7.10 SHOW CREATE TABLE Statement

SHOW CREATE TABLE `tbl_name`

Shows the CREATE TABLE statement that creates the named table. To use this statement, you must have some privilege for the table. This statement also works with views.

mysql> SHOW CREATE TABLE t\G
*************************** 1. row ***************************
Table: t
Create Table: CREATE TABLE `t` (  `id` int(11) NOT NULL AUTO_INCREMENT,  `s` char(60) DEFAULT NULL,  PRIMARY KEY (`id`)) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4

As of MySQL 8.0.16, MySQL implements CHECK constraints and SHOW CREATE TABLE displays them. All CHECK constraints are displayed as table constraints. That is, a CHECK constraint originally specified as part of a column definition displays as a separate clause not part of the column definition. Example:

mysql> CREATE TABLE t1 (  i1 INT CHECK (i1 <> 0), -- column constraint  i2 INT,  CHECK (i2 > i1), -- table constraint  CHECK (i2 <> 0) NOT ENFORCED -- table constraint, not enforced );

mysql> SHOW CREATE TABLE t1\G
*************************** 1. row ***************************
Table: t1
Create Table: CREATE TABLE `t1` (  `i1` int(11) DEFAULT NULL,  `i2` int(11) DEFAULT NULL,  CONSTRAINT `t1_chk_1` CHECK ((`i1` <> 0)),  CONSTRAINT `t1_chk_2` CHECK ((`i2` > `i1`)),  CONSTRAINT `t1_chk_3` CHECK ((`i2` <> 0))/*!80016 NOT ENFORCED */  ) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_0900_ai_ci

SHOW CREATE TABLE quotes table and column names according to the value of the sql_quote_show_create option. See Section 5.1.8, “Server System Variables”.

When altering the storage engine of a table, table options that are not applicable to the new storage engine are retained in the table definition to enable reverting the table with its previously defined
SHOW Statements

options to the original storage engine, if necessary. For example, when changing the storage engine from InnoDB to MyISAM, InnoDB-specific options such as ROW_FORMAT=COMPACT are retained.

```
mysql> CREATE TABLE t1 (c1 INT PRIMARY KEY) ROW_FORMAT=COMPACT ENGINE=InnoDB;
mysql> ALTER TABLE t1 ENGINE=MyISAM;
mysql> SHOW CREATE TABLE t1\G
```
```
*************************** 1. row ***************************
Table: t1
Create Table: CREATE TABLE `t1` (
  `c1` int NOT NULL,
  PRIMARY KEY (`c1`) ) ENGINE=MyISAM DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_0900_ai_ci ROW_FORMAT=COMPACT
```

When creating a table with strict mode disabled, the storage engine's default row format is used if the specified row format is not supported. The actual row format of the table is reported in the Row_format column in response to SHOW TABLE STATUS. SHOW CREATE TABLE shows the row format that was specified in the CREATE TABLE statement.

### 13.7.7.11 SHOW CREATE TRIGGER Statement

SHOW CREATE TRIGGER trigger_name

This statement shows the CREATE TRIGGER statement that creates the named trigger. This statement requires the TRIGGER privilege for the table associated with the trigger.

```
mysql> SHOW CREATE TRIGGER ins_sum\G
```
```
*************************** 1. row ***************************
Trigger: ins_sum
sql_mode: ONLY_FULL_GROUP_BY,STRICT_TRANS_TABLES,
NO_ZERO_IN_DATE,NO_ZERO_DATE,
ERROR_FOR_DIVISION_BY_ZERO,
NO_ENGINE_SUBSTITUTION
SQL Original Statement: CREATE DEFINER=`me`@`localhost` TRIGGER `ins_sum`
BEFORE INSERT ON `account`
FOR EACH ROW SET @sum = @sum + NEW.amount
character_set_client: utf8mb4
collation_connection: utf8mb4_0900_ai_ci
Database Collation: utf8mb4_0900_ai_ci
Created: 2018-08-08 10:10:12.61
```

SHOW CREATE TRIGGER output has these columns:

- **Trigger**: The trigger name.
- **sql_mode**: The SQL mode in effect when the trigger executes.
- **SQL Original Statement**: The CREATE TRIGGER statement that defines the trigger.
- **character_set_client**: The session value of the character_set_client system variable when the trigger was created.
- **collation_connection**: The session value of the collation_connection system variable when the trigger was created.
- **Database Collation**: The collation of the database with which the trigger is associated.
- **Created**: The date and time when the trigger was created. This is a TIMESTAMP(2) value (with a fractional part in hundredths of seconds) for triggers.

Trigger information is also available from the INFORMATION_SCHEMA TRIGGERS table. See Section 26.3.45, "The INFORMATION_SCHEMA TRIGGERS Table".

### 13.7.7.12 SHOW CREATE USER Statement

SHOW CREATE USER user
This statement shows the `CREATE USER` statement that creates the named user. An error occurs if the user does not exist. The statement requires the `SELECT` privilege for the `mysql` system schema, except to see information for the current user. For the current user, the `SELECT` privilege for the `mysql.user` system table is required for display of the password hash in the `IDENTIFIED AS` clause; otherwise, the hash displays as `<secret>`.

To name the account, use the format described in Section 6.2.4, "Specifying Account Names". The host name part of the account name, if omitted, defaults to `'%'`. It is also possible to specify `CURRENT_USER` or `CURRENT_USER()` to refer to the account associated with the current session.

Password hash values displayed in the `IDENTIFIED WITH` clause of output from `SHOW CREATE USER` may contain unprintable characters that have adverse effects on terminal displays and in other environments. Enabling the `print_identified_with_as_hex` system variable (available as of MySQL 8.0.17) causes `SHOW CREATE USER` to display such hash values as hexadecimal strings rather than as regular string literals. Hash values that do not contain unprintable characters still display as regular string literals, even with this variable enabled.

Password hash values displayed in the `IDENTIFIED AS` clause of output from `SHOW CREATE USER` may contain unprintable characters that have adverse effects on terminal displays and in other environments. Enabling the `print_identified_with_as_hex` system variable (available as of MySQL 8.0.17) causes `SHOW CREATE USER` to display such hash values as hexadecimal strings rather than as regular string literals. Hash values that do not contain unprintable characters still display as regular string literals, even with this variable enabled.

```
musl> CREATE USER 'u1'@'localhost' IDENTIFIED BY 'secret';
musl> SET print_identified_with_as_hex = ON;
musl> SHOW CREATE USER 'u1'@'localhost'
```

```
*************************** 1. row ***************************
CREATE USER for u1@localhost: CREATE USER 'u1'@'localhost'
IDENTIFIED WITH 'caching_sha2_password'
AS 0x244124303035240C7745603626313C4C1063E0A104B1E14135A544A7871567245614F487234463546F624F6C7861326932752F45622F4F473273597557627139
REQUIRE NONE PASSWORD EXPIRE DEFAULT ACCOUNT UNLOCK
PASSWORD HISTORY DEFAULT PASSWORD REUSE INTERVAL DEFAULT
PASSWORD REQUIRE CURRENT DEFAULT
```

To display the privileges granted to an account, use the `SHOW GRANTS` statement. See Section 13.7.7.21, "SHOW GRANTS Statement".

### 13.7.7.13 SHOW CREATE VIEW Statement

```
SHOW CREATE VIEW view_name
```

This statement shows the `CREATE VIEW` statement that creates the named view.

```
musl> SHOW CREATE VIEW v
```

```
*************************** 1. row ***************************
View: v
Create View: CREATE ALGORITHM=UNDEFINED
DEFINER=`bob`@`localhost`
SQL SECURITY DEFINER VIEW
`v` AS select 1 AS `a`,2 AS `b`
collation_connection: utf8mb4
```

collation_connection is the session value of the `collation_connection` system variable when the view was created. `collation_connection` is the session value of the `collation_connection` system variable when the view was created.

Use of `SHOW CREATE VIEW` requires the `SHOW VIEW` privilege, and the `SELECT` privilege for the view in question.

View information is also available from the `INFORMATION_SCHEMA VIEWS` table. See Section 26.3.48, "The INFORMATION_SCHEMA VIEWS Table".

MySQL lets you use different `sql_mode` settings to tell the server the type of SQL syntax to support. For example, you might use the `ANSI` SQL mode to ensure MySQL correctly interprets the standard SQL concatenation operator, the double bar (`||`), in your queries. If you then create a view that concatenates items, you might worry that changing the `sql_mode` setting to a value different from `ANSI` could cause the view to become invalid. But this is not the case. No matter how you write out a view definition, MySQL always stores it the same way, in a canonical form. Here is an example that shows how the server converts a double bar concatenation operator to a `CONCAT()` function:
The advantage of storing a view definition in canonical form is that changes made later to the value of `sql_mode` do not affect the results from the view. However an additional consequence is that comments prior to `SELECT` are stripped from the definition by the server.

### 13.7.14 SHOW DATABASES Statement

SHOW {DATABASES | SCHEMAS} [LIKE 'pattern' | WHERE expr]

SHOW DATABASES lists the databases on the MySQL server host. SHOW SCHEMAS is a synonym for SHOW DATABASES. The LIKE clause, if present, indicates which database names to match. The WHERE clause can be given to select rows using more general conditions, as discussed in Section 26.8, “Extensions to SHOW Statements”.

You see only those databases for which you have some kind of privilege, unless you have the global SHOW DATABASES privilege. You can also get this list using the `mysqlshow` command.

If the server was started with the `--skip-show-database` option, you cannot use this statement at all unless you have the SHOW DATABASES privilege.

MySQL implements databases as directories in the data directory, so this statement simply lists directories in that location. However, the output may include names of directories that do not correspond to actual databases.

Database information is also available from the INFORMATION_SCHEMA SCHEMATA table. See Section 26.3.31, “The INFORMATION_SCHEMA SCHEMATA Table”.

#### Caution

Because any static global privilege is considered a privilege for all databases, any static global privilege enables a user to see all database names with SHOW DATABASES or by examining the SCHEMATA table of INFORMATION_SCHEMA, except databases that have been restricted at the database level by partial revokes.

### 13.7.15 SHOW ENGINE Statement

SHOW ENGINE engine_name {STATUS | MUTEX}

SHOW ENGINE displays operational information about a storage engine. It requires the PROCESS privilege. The statement has these variants:

SHOW ENGINE INNODB STATUS
SHOW ENGINE INNODB MUTEX
SHOW ENGINE PERFORMANCE_SCHEMA STATUS

SHOW ENGINE INNODB STATUS displays extensive information from the standard InnoDB Monitor about the state of the InnoDB storage engine. For information about the standard monitor and other InnoDB Monitors that provide information about InnoDB processing, see Section 15.17, “InnoDB Monitors”.

2704
SHOW ENGINE INNODB MUTEX displays InnoDB mutex and rw-lock statistics.

**Note**

InnoDB mutexes and rwlocks can also be monitored using Performance Schema tables. See Section 15.16.2, “Monitoring InnoDB Mutex Waits Using Performance Schema”.

Mutex statistics collection is configured dynamically using the following options:

- To enable the collection of mutex statistics, run:
  ```
  SET GLOBAL innodb_monitor_enable='latch';
  ```

- To reset mutex statistics, run:
  ```
  SET GLOBAL innodb_monitor_reset='latch';
  ```

- To disable the collection of mutex statistics, run:
  ```
  SET GLOBAL innodb_monitor_disable='latch';
  ```

Collection of mutex statistics for SHOW ENGINE INNODB MUTEX can also be enabled by setting `innodb_monitor_enable='all'`, or disabled by setting `innodb_monitor_disable='all'`.

SHOW ENGINE INNODB MUTEX output has these columns:

- **Type**
  Always InnoDB.

- **Name**
  For mutexes, the Name field reports only the mutex name. For rwlocks, the Name field reports the source file where the rwlock is implemented, and the line number in the file where the rwlock is created. The line number is specific to your version of MySQL.

- **Status**
  The mutex status. This field reports the number of spins, waits, and calls. Statistics for low-level operating system mutexes, which are implemented outside of InnoDB, are not reported.
  - **spins** indicates the number of spins.
  - **waits** indicates the number of mutex waits.
  - **calls** indicates how many times the mutex was requested.

SHOW ENGINE INNODB MUTEX does not list mutexes and rw-locks for each buffer pool block, as the amount of output would be overwhelming on systems with a large buffer pool. SHOW ENGINE INNODB MUTEX does, however, print aggregate BUF_BLOCK_MUTEX spin, wait, and call values for buffer pool block mutexes and rw-locks. SHOW ENGINE INNODB MUTEX also does not list any mutexes or rw-locks that have never been waited on (os_waits=0). Thus, SHOW ENGINE INNODB MUTEX only displays information about mutexes and rw-locks outside of the buffer pool that have caused at least one OS-level wait.

Use SHOW ENGINE PERFORMANCE_SCHEMA STATUS to inspect the internal operation of the Performance Schema code:

```sql
mysql> SHOW ENGINE PERFORMANCE_SCHEMA STATUS\G
*************************** 3. row ***************************
Type: performance_schema
```
This statement is intended to help the DBA understand the effects that different Performance Schema options have on memory requirements.

Values consist of two parts, which name an internal buffer and a buffer attribute, respectively. Interpret buffer names as follows:

- An internal buffer that is not exposed as a table is named within parentheses. Examples:

- An internal buffer that is exposed as a table in the `performance_schema` database is named after the table, without parentheses. Examples:
  - `events_waits_history.size`, `mutex_instances.count`.

- A value that applies to the Performance Schema as a whole begins with `performance_schema`. Example:
  - `performance_schema.memory`.

Buffer attributes have these meanings:

- `size` is the size of the internal record used by the implementation, such as the size of a row in a table. `size` values cannot be changed.

- `count` is the number of internal records, such as the number of rows in a table. `count` values can be changed using Performance Schema configuration options.

- For a table, `tbl_name.memory` is the product of `size` and `count`. For the Performance Schema as a whole, `performance_schema.memory` is the sum of all the memory used (the sum of all other `memory` values).

In some cases, there is a direct relationship between a Performance Schema configuration parameter and a `SHOW ENGINE` value. For example, `events_waits_history_long.count` corresponds to `performance_schema_events_waits_history_long_size`. In other cases, the relationship is more complex. For example, `events_waits_history.count` corresponds to `performance_schema_events_waits_history_size` (the number of rows per thread) multiplied by `performance_schema_max_thread_instances` (the number of threads).

**SHOW ENGINE NDB STATUS.** If the server has the `NDB` storage engine enabled, `SHOW ENGINE NDB STATUS` displays cluster status information such as the number of connected data nodes, the cluster connectstring, and cluster binary log epochs, as well as counts of various Cluster API objects created by the MySQL Server when connected to the cluster. Sample output from this statement is shown here:

```
mysql> SHOW ENGINE NDB STATUS;
+------------+-----------------------+--------------------------------------------------+
| Type       | Name                  | Status                                           |
|------------|-----------------------+--------------------------------------------------|
| ndbcluster | connection            | cluster_node_id=7, connected_host=198.51.100.103, connected_port=1186, number_of_data_nodes=4, |
```
The `number_of_ready_data_nodes` and `connect_count` are key metrics that can be used to monitor the status of the NDB cluster. The `number_of_ready_data_nodes` indicates the number of data nodes that are actually running, while `connect_count` shows how many times the mysqld has connected or reconnected to cluster data nodes.

### Status Information

<table>
<thead>
<tr>
<th>Name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>cluster_node_id</code></td>
<td>The node ID of the MySQL server in the cluster</td>
</tr>
<tr>
<td><code>connected_host</code></td>
<td>The host name or IP address of the cluster management server to which the MySQL server is connected</td>
</tr>
<tr>
<td><code>connected_port</code></td>
<td>The port used by the MySQL server to connect to the management server (connected_host)</td>
</tr>
<tr>
<td><code>number_of_data_nodes</code></td>
<td>The number of data nodes configured for the cluster (that is, the number of [ndbd] sections in the cluster config.ini file)</td>
</tr>
<tr>
<td><code>number_of_ready_data_nodes</code></td>
<td>The number of data nodes in the cluster that are actually running</td>
</tr>
<tr>
<td><code>connect_count</code></td>
<td>The number of times this mysqld has connected or reconnected to cluster data nodes</td>
</tr>
</tbody>
</table>

### Binlog Information

The `binlog` row's `Status` column contains information relating to NDB Cluster Replication. The name/value pairs it contains are described in the following table.

<table>
<thead>
<tr>
<th>Name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>latest_epoch</code></td>
<td>The most recent epoch most recently run on this MySQL server (that is, the sequence number of the most recent transaction run on the server)</td>
</tr>
<tr>
<td><code>latest_trans_epoch</code></td>
<td>The most recent epoch processed by the cluster's data nodes</td>
</tr>
<tr>
<td><code>latest_received_binlog_epoch</code></td>
<td>The most recent epoch received by the binary log thread</td>
</tr>
<tr>
<td><code>latest_handled_binlog_epoch</code></td>
<td>The most recent epoch processed by the binary log thread (for writing to the binary log)</td>
</tr>
<tr>
<td><code>latest_applied_binlog_epoch</code></td>
<td>The most recent epoch actually written to the binary log</td>
</tr>
</tbody>
</table>

See Section 23.6, “NDB Cluster Replication”, for more information.

The remaining rows from the output of `SHOW ENGINE NDB STATUS` which are most likely to prove useful in monitoring the cluster are listed here by `Name`:
SHOW Statements

- **NdbTransaction**: The number and size of NdbTransaction objects that have been created. An NdbTransaction is created each time a table schema operation (such as `CREATE TABLE` or `ALTER TABLE`) is performed on an NDB table.

- **NdbOperation**: The number and size of NdbOperation objects that have been created.

- **NdbIndexScanOperation**: The number and size of NdbIndexScanOperation objects that have been created.

- **NdbIndexOperation**: The number and size of NdbIndexOperation objects that have been created.

- **NdbRecAttr**: The number and size of NdbRecAttr objects that have been created. In general, one of these is created each time a data manipulation statement is performed by an SQL node.

- **NdbBlob**: The number and size of NdbBlob objects that have been created. An NdbBlob is created for each new operation involving a BLOB column in an NDB table.

- **NdbReceiver**: The number and size of any NdbReceiver object that have been created. The number in the created column is the same as the number of data nodes in the cluster to which the MySQL server has connected.

**Note**
SHOW ENGINE NDB STATUS returns an empty result if no operations involving NDB tables have been performed during the current session by the MySQL client accessing the SQL node on which this statement is run.

### 13.7.7.16 SHOW ENGINES Statement

SHOW [STORAGE] ENGINES

SHOW ENGINES displays status information about the server's storage engines. This is particularly useful for checking whether a storage engine is supported, or to see what the default engine is.

For information about MySQL storage engines, see Chapter 15, *The InnoDB Storage Engine*, and Chapter 16, *Alternative Storage Engines*.

```sql
mysql> SHOW ENGINES\G
*************************** 1. row ***************************
  Engine: ARCHIVE
  Support: YES
  Comment: Archive storage engine
  Transactions: NO
  XA: NO
  Savepoints: NO
*************************** 2. row ***************************
  Engine: BLACKHOLE
  Support: YES
  Comment: /dev/null storage engine (anything you write to it disappears)
  Transactions: NO
  XA: NO
  Savepoints: NO
*************************** 3. row ***************************
  Engine: MRG_MYISAM
  Support: YES
  Comment: Collection of identical MyISAM tables
  Transactions: NO
  XA: NO
  Savepoints: NO
*************************** 4. row ***************************
  Engine: FEDERATED
  Support: NO
  Comment: Federated MySQL storage engine
  Transactions: NULL
  XA: NULL
  Savepoints: NULL
```
SHOW Statements

The output from `SHOW ENGINES` may vary according to the MySQL version used and other factors.

`SHOW ENGINES` output has these columns:

- **Engine**
  The name of the storage engine.

- **Support**
  The server's level of support for the storage engine, as shown in the following table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>YES</td>
<td>The engine is supported and is active</td>
</tr>
<tr>
<td>DEFAULT</td>
<td>Like YES, plus this is the default engine</td>
</tr>
<tr>
<td>NO</td>
<td>The engine is not supported</td>
</tr>
<tr>
<td>DISABLED</td>
<td>The engine is supported but has been disabled</td>
</tr>
</tbody>
</table>

A value of NO means that the server was compiled without support for the engine, so it cannot be enabled at runtime.

A value of DISABLED occurs either because the server was started with an option that disables the engine, or because not all options required to enable it were given. In the latter case, the error log should contain a reason indicating why the option is disabled. See Section 5.4.2, “The Error Log”.

You might also see DISABLED for a storage engine if the server was compiled to support it, but was started with a `--skip-engine_name` option. For the NDB storage engine, DISABLED means the server was compiled with support for NDB Cluster, but was not started with the `--ndbcluster` option.
All MySQL servers support MyISAM tables. It is not possible to disable MyISAM.

- **Comment**
  
  A brief description of the storage engine.

- **Transactions**
  
  Whether the storage engine supports transactions.

- **XA**
  
  Whether the storage engine supports XA transactions.

- **Savepoints**
  
  Whether the storage engine supports savepoints.

Storage engine information is also available from the INFORMATION_SCHEMA ENGINES table. See Section 26.3.13, "The INFORMATION_SCHEMA ENGINES Table".

### 13.7.7.17 SHOW ERRORS Statement

```sql
SHOW ERRORS [LIMIT [offset,] row_count]
SHOW COUNT(*) ERRORS
```

**SHOW ERRORS** is a diagnostic statement that is similar to **SHOW WARNINGS**, except that it displays information only for errors, rather than for errors, warnings, and notes.

The **LIMIT** clause has the same syntax as for the **SELECT** statement. See Section 13.2.10, "SELECT Statement".

The **SHOW COUNT(*) ERRORS** statement displays the number of errors. You can also retrieve this number from the **error_count** variable:

```sql
SHOW COUNT(*) ERRORS;
SELECT @@error_count;
```

**SHOW ERRORS** and **error_count** apply only to errors, not warnings or notes. In other respects, they are similar to **SHOW WARNINGS** and **warning_count**. In particular, **SHOW ERRORS** cannot display information for more than **max_error_count** messages, and **error_count** can exceed the value of **max_error_count** if the number of errors exceeds **max_error_count**.

For more information, see Section 13.7.7.42, "SHOW WARNINGS Statement".

### 13.7.7.18 SHOW EVENTS Statement

```sql
SHOW EVENTS
[[FROM | IN] schema_name]
[LIKE 'pattern' | WHERE expr]
```

This statement displays information about Event Manager events, which are discussed in Section 25.4, "Using the Event Scheduler". It requires the **EVENT** privilege for the database from which the events are to be shown.

In its simplest form, **SHOW EVENTS** lists all of the events in the current schema:

```sql
mysql> SELECT CURRENT_USER(), SCHEMA();
+----------------+----------+
| CURRENT_USER() | SCHEMA() |
+----------------+----------+
| jon@ghidora    | myschema |
```
SHOW Statements

To see events for a specific schema, use the `FROM` clause. For example, to see events for the `test` schema, use the following statement:

```sql
SHOW EVENTS FROM test;
```

The `LIKE` clause, if present, indicates which event names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in Section 26.8, "Extensions to SHOW Statements".

`SHOW EVENTS` output has these columns:

- **Db**
  The name of the schema (database) to which the event belongs.

- **Name**
  The name of the event.

- **Definer**
  The account of the user who created the event, in `user_name@host_name` format.

- **Time zone**
  The event time zone, which is the time zone used for scheduling the event and that is in effect within the event as it executes. The default value is `SYSTEM`.

- **Type**
  The event repetition type, either `ONE TIME` (transient) or `RECURRING` (repeating).

- **Execute At**
  For a one-time event, this is the `DATETIME` value specified in the `AT` clause of the `CREATE EVENT` statement used to create the event, or of the last `ALTER EVENT` statement that modified the event. The value shown in this column reflects the addition or subtraction of any `INTERVAL` value included in the event's `AT` clause. For example, if an event is created using `ON SCHEDULE AT CURRENT_TIMESTAMP + '1:6' DAY_HOUR`, and the event was created at 2018-02-09 14:05:30, the value shown in this column would be '2018-02-10 20:05:30'. If the event's timing is determined by an `EVERY` clause instead of an `AT` clause (that is, if the event is recurring), the value of this column is `NULL`.

- **Interval Value**
For a recurring event, the number of intervals to wait between event executions. For a transient event, the value of this column is always NULL.

- **Interval Field**

  The time units used for the interval which a recurring event waits before repeating. For a transient event, the value of this column is always NULL.

- **Starts**

  The start date and time for a recurring event. This is displayed as a DATETIME value, and is NULL if no start date and time are defined for the event. For a transient event, this column is always NULL. For a recurring event whose definition includes a STARTS clause, this column contains the corresponding DATETIME value. As with the Execute At column, this value resolves any expressions used. If there is no STARTS clause affecting the timing of the event, this column is NULL.

- **Ends**

  For a recurring event whose definition includes a ENDS clause, this column contains the corresponding DATETIME value. As with the Execute At column, this value resolves any expressions used. If there is no ENDS clause affecting the timing of the event, this column is NULL.

- **Status**

  The event status. One of ENABLED, DISABLED, or SLAVESIDE_DISABLED. SLAVESIDEDisabled indicates that the creation of the event occurred on another MySQL server acting as a replication source and replicated to the current MySQL server which is acting as a replica, but the event is not presently being executed on the replica. For more information, see Section 17.5.1.16, “Replication of Invoked Features”. information.

- **Originator**

  The server ID of the MySQL server on which the event was created; used in replication. This value may be updated by ALTER EVENT to the server ID of the server on which that statement occurs, if executed on a source server. The default value is 0.

- **character_set_client**

  The session value of the character_set_client system variable when the event was created.

- **collation_connection**

  The session value of the collation_connection system variable when the event was created.

- **Database Collation**

  The collation of the database with which the event is associated.

For more information about SLAVESIDE_DISABLED and the Originator column, see Section 17.5.1.16, “Replication of Invoked Features”.

Times displayed by SHOW EVENTS are given in the event time zone, as discussed in Section 25.4.4, “Event Metadata”.

Event information is also available from the INFORMATION_SCHEMA EVENTS table. See Section 26.3.14, “The INFORMATION_SCHEMA EVENTS Table”.

The event action statement is not shown in the output of SHOW EVENTS. Use SHOW CREATE EVENT or the INFORMATION_SCHEMA EVENTS table.

### 13.7.7.19 SHOW FUNCTION CODE Statement
SHOW FUNCTION CODE `func_name`

This statement is similar to `SHOW PROCEDURE CODE` but for stored functions. See Section 13.7.7.27, “SHOW PROCEDURE CODE Statement”.

### 13.7.7.20 SHOW FUNCTION STATUS Statement

```
SHOW FUNCTION STATUS [LIKE 'pattern' | WHERE expr]
```

This statement is similar to `SHOW PROCEDURE STATUS` but for stored functions. See Section 13.7.7.28, “SHOW PROCEDURE STATUS Statement”.

### 13.7.7.21 SHOW GRANTS Statement

```
SHOW GRANTS [FOR user_or_role [USING role ...]]
```

This statement displays the privileges and roles that are assigned to a MySQL user account or role, in the form of `GRANT` statements that must be executed to duplicate the privilege and role assignments.

**Note**

To display nonprivilege information for MySQL accounts, use the `SHOW CREATE USER` statement. See Section 13.7.7.12, “SHOW CREATE USER Statement”.

`SHOW GRANTS` requires the `SELECT` privilege for the `mysql` system schema, except to display privileges and roles for the current user.

To name the account or role for `SHOW GRANTS`, use the same format as for the `GRANT` statement (for example, `'jeffrey'@'localhost'`):

```
mysql> SHOW GRANTS FOR 'jeffrey'@'localhost';
```

```
+------------------------------------------------------------------+
<table>
<thead>
<tr>
<th>Grants for jeffrey@localhost</th>
</tr>
</thead>
<tbody>
<tr>
<td>GRANT USAGE ON <em>.</em> TO <code>jeffrey</code>@<code>localhost</code></td>
</tr>
<tr>
<td>GRANT SELECT, INSERT, UPDATE ON <code>db1</code>.* TO <code>jeffrey</code>@<code>localhost</code></td>
</tr>
</tbody>
</table>
+------------------------------------------------------------------+
```

The host part, if omitted, defaults to `'%'`. For additional information about specifying account and role names, see Section 6.2.4, “Specifying Account Names”, and Section 6.2.5, “Specifying Role Names”.

To display the privileges granted to the current user (the account you are using to connect to the server), you can use any of the following statements:

```
SHOW GRANTS;
SHOW GRANTS FOR CURRENT_USER;
SHOW GRANTS FOR CURRENT_USER();
```

If `SHOW GRANTS FOR CURRENT_USER` (or any equivalent syntax) is used in definer context, such as within a stored procedure that executes with definer rather than invoker privileges, the grants displayed are those of the definer and not the invoker.

In MySQL 8.0 compared to previous series, `SHOW GRANTS` no longer displays `ALL PRIVILEGES` in its global-privileges output because the meaning of `ALL PRIVILEGES` at the global level varies...
depending on which dynamic privileges are defined. Instead, `SHOW GRANTS` explicitly lists each granted global privilege:

```
mysql> SHOW GRANTS FOR 'root'@'localhost';
+---------------------------------------------------------------------+
| Grants for root@localhost                                           |
+---------------------------------------------------------------------+
| GRANT SELECT, INSERT, UPDATE, DELETE, CREATE, DROP, RELOAD,         |
| SHUTDOWN, PROCESS, FILE, REFERENCES, INDEX, ALTER, SHOW DATABASES, |
| SUPER, CREATE TEMPORARY TABLES, LOCK TABLES, EXECUTE, REPLICATION   |
| SLAVE, REPLICATION CLIENT, CREATE VIEW, SHOW VIEW, CREATE ROUTINE, |
| ALTER ROUTINE, CREATE USER, EVENT, TRIGGER, CREATE TABLESPACE,     |
| CREATE ROLE, DROP ROLE ON *.* TO 'root'@'localhost' WITH GRANT      |
| OPTION                                                              |
| GRANT PROXY ON ''@'' TO 'root'@'localhost' WITH GRANT OPTION        |
+---------------------------------------------------------------------+
```

Applications that process `SHOW GRANTS` output should be adjusted accordingly.

At the global level, `GRANT OPTION` applies to all granted static global privileges if granted for any of them, but applies individually to granted dynamic privileges. `SHOW GRANTS` displays global privileges this way:

- One line listing all granted static privileges, if there are any, including `WITH GRANT OPTION` if appropriate.
- One line listing all granted dynamic privileges for which `GRANT OPTION` is granted, if there are any, including `WITH GRANT OPTION`.
- One line listing all granted dynamic privileges for which `GRANT OPTION` is not granted, if there are any, without `WITH GRANT OPTION`.

With the optional `USING` clause, `SHOW GRANTS` enables you to examine the privileges associated with roles for the user. Each role named in the `USING` clause must be granted to the user.

Suppose that user `u1` is assigned roles `r1` and `r2`, as follows:

```
CREATE ROLE 'r1', 'r2';
GRANT SELECT ON db1.* TO 'r1';
GRANT INSERT, UPDATE, DELETE ON db1.* TO 'r2';
CREATE USER 'u1'@'localhost' IDENTIFIED BY 'u1pass';
GRANT 'r1', 'r2' TO 'u1'@'localhost';
```

`SHOW GRANTS` without `USING` shows the granted roles:

```
mysql> SHOW GRANTS FOR 'u1'@'localhost';
+---------------------------------------------+
| Grants for u1@localhost                     |
+---------------------------------------------+
| GRANT USAGE ON *.* TO `u1`@`localhost`      |
| GRANT `r1`@`%`,`r2`@`%` TO `u1`@`localhost` |
+---------------------------------------------+
```

Adding a `USING` clause causes the statement to also display the privileges associated with each role named in the clause:

```
mysql> SHOW GRANTS FOR 'u1'@'localhost' USING 'r1';
+---------------------------------------------+
| Grants for u1@localhost                     |
+---------------------------------------------+
| GRANT USAGE ON *.* TO `u1`@`localhost`      |
| GRANT SELECT ON `db1`.* TO `u1`@`localhost` |
| GRANT `r1`@`%`,`r2`@`%` TO `u1`@`localhost` |
+---------------------------------------------+
```

```
mysql> SHOW GRANTS FOR 'u1'@'localhost' USING 'r2';
+---------------------------------------------+
| Grants for u1@localhost                     |
+---------------------------------------------+
```
Note

A privilege granted to an account is always in effect, but a role is not. The active roles for an account can differ across and within sessions, depending on the value of the `activate_all_roles_on_login` system variable, the account default roles, and whether `SET ROLE` has been executed within a session.

MySQL 8.0.16 and higher supports partial revokes of global privileges, such that a global privilege can be restricted from applying to particular schemas (see Section 6.2.12, “Privilege Restriction Using Partial Revokes”). To indicate which global schema privileges have been revoked for particular schemas, `SHOW GRANTS` output includes `REVOKE` statements:

```sql
mysql> SET PERSIST partial_revokes = ON;
mysql> CREATE USER u1;
mysql> GRANT SELECT, INSERT, DELETE ON *.* TO u1;
mysql> REVOKE SELECT, INSERT ON mysql.* FROM u1;
mysql> REVOKE DELETE ON world.* FROM u1;
mysql> SHOW GRANTS FOR u1;
+--------------------------------------------------+
| Grants for u1@%                                  |
+--------------------------------------------------+
| GRANT SELECT, INSERT, DELETE ON *.* TO `u1`@`%`  |
| REVOKE SELECT, INSERT ON `mysql`.* FROM `u1`@`%` |
| REVOKE DELETE ON `world`.* FROM `u1`@`%`         |
+--------------------------------------------------+
```

`SHOW GRANTS` does not display privileges that are available to the named account but are granted to a different account. For example, if an anonymous account exists, the named account might be able to use its privileges, but `SHOW GRANTS` does not display them.

`SHOW GRANTS` displays mandatory roles named in the `mandatory_roles` system variable value as follows:

- **SHOW GRANTS** without a `FOR` clause displays privileges for the current user, and includes mandatory roles.
- **SHOW GRANTS FOR user** displays privileges for the named user, and does not include mandatory roles.

This behavior is for the benefit of applications that use the output of `SHOW GRANTS FOR user` to determine which privileges are granted explicitly to the named user. Were that output to include mandatory roles, it would be difficult to distinguish roles granted explicitly to the user from mandatory roles.

For the current user, applications can determine privileges with or without mandatory roles by using `SHOW GRANTS` or `SHOW GRANTS FOR CURRENT_USER`, respectively.

### 13.7.7.22 SHOW INDEX Statement

```
SHOW [EXTENDED] {INDEX | INDEXES | KEYS}
  {FROM | IN} tbl_name
  [{FROM | IN} db_name]
  [WHERE expr]
```
SHOW INDEX returns table index information. The format resembles that of the SQLStatistics call in ODBC. This statement requires some privilege for any column in the table.

```
mysql> SHOW INDEX FROM City
*************************** 1. row ***************************
  Table: city
  Non_unique: 0
  Key_name: PRIMARY
  Seq_in_index: 1
  Column_name: ID
  Collation: A
  Cardinality: 4188
  Sub_part: NULL
  Packed: NULL
  Null:             Index_type: BTREE
  Comment:          Index_comment: Visible: YES
  Expression: NULL
*************************** 2. row ***************************
  Table: city
  Non_unique: 1
  Key_name: CountryCode
  Seq_in_index: 1
  Column_name: CountryCode
  Collation: A
  Cardinality: 232
  Sub_part: NULL
  Packed: NULL
  Null:             Index_type: BTREE
  Comment:          Index_comment: Visible: YES
  Expression: NULL
```

An alternative to `tbl_name FROM db_name` syntax is `db_name.tbl_name`. These two statements are equivalent:

```
SHOW INDEX FROM mytable FROM mydb;
SHOW INDEX FROM mydb.mytable;
```

The optional EXTENDED keyword causes the output to include information about hidden indexes that MySQL uses internally and are not accessible by users.

The WHERE clause can be given to select rows using more general conditions, as discussed in Section 26.8, “Extensions to SHOW Statements”.

SHOW INDEX returns the following fields:

- **Table**
  The name of the table.

- **Non_unique**
  0 if the index cannot contain duplicates, 1 if it can.

- **Key_name**
  The name of the index. If the index is the primary key, the name is always PRIMARY.

- **Seq_in_index**
  The column sequence number in the index, starting with 1.

- **Column_name**
SHOW Statements

The column name. See also the description for the Expression column.

* Collation

How the column is sorted in the index. This can have values A (ascending), D (descending), or NULL (not sorted).

* Cardinality

An estimate of the number of unique values in the index. To update this number, run ANALYZE TABLE or (for MyISAM tables) myisamchk -a.

Cardinality is counted based on statistics stored as integers, so the value is not necessarily exact even for small tables. The higher the cardinality, the greater the chance that MySQL uses the index when doing joins.

* Sub_part

The index prefix. That is, the number of indexed characters if the column is only partly indexed, NULL if the entire column is indexed.

Note

Prefix limits are measured in bytes. However, prefix lengths for index specifications in CREATE TABLE, ALTER TABLE, and CREATE INDEX statements are interpreted as number of characters for nonbinary string types (CHAR, VARCHAR, TEXT) and number of bytes for binary string types (BINARY, VARBINARY, BLOB). Take this into account when specifying a prefix length for a nonbinary string column that uses a multibyte character set.

For additional information about index prefixes, see Section 8.3.5, “Column Indexes”, and Section 13.1.15, “CREATE INDEX Statement”.

* Packed

Indicates how the key is packed. NULL if it is not.

* Null

Contains YES if the column may contain NULL values and '' if not.

* Index_type

The index method used (BTREE, FULLTEXT, HASH, RTREE).

* Comment

Information about the index not described in its own column, such as disabled if the index is disabled.

* Index_comment

Any comment provided for the index with a COMMENT attribute when the index was created.

* Visible

Whether the index is visible to the optimizer. See Section 8.3.12, “Invisible Indexes”.

* Expression

MySQL 8.0.13 and higher supports functional key parts (see Functional Key Parts), which affects both the Column_name and Expression columns:
SHOW Statements

- For a nonfunctional key part, Column_name indicates the column indexed by the key part and Expression is NULL.

- For a functional key part, Column_name column is NULL and Expression indicates the expression for the key part.

Information about table indexes is also available from the INFORMATION_SCHEMA STATISTICS table. See Section 26.3.34, “The INFORMATION_SCHEMA STATISTICS Table”. The extended information about hidden indexes is available only using SHOW EXTENDED INDEX; it cannot be obtained from the STATISTICS table.

You can list a table’s indexes with the mysqlshow -k db_name tbl_name command.

13.7.7.23 SHOW MASTER STATUS Statement

SHOW MASTER STATUS

This statement provides status information about the binary log files of the source server. It requires the REPLICATION CLIENT privilege (or the deprecated SUPER privilege).

Example:

```
mysql> SHOW MASTER STATUS\G
*************************** 1. row ***************************
File: source-bin.000002
Position: 1307
Binlog_Do_DB: test
Binlog_Ignore_DB: manual, mysql
Executed_Gtid_Set: 3E11FA47-71CA-11E1-9E33-C80AA9429562:1-5
1 row in set (0.00 sec)
```

When global transaction IDs are in use, Executed_Gtid_Set shows the set of GTIDs for transactions that have been executed on the source. This is the same as the value for the gtid_executed system variable on this server, as well as the value for Executed_Gtid_Set in the output of SHOW REPLICA | SLAVE STATUS on this server.

13.7.7.24 SHOW OPEN TABLES Statement

SHOW OPEN TABLES

SHOW OPEN TABLES [(FROM | IN) db_name]
    [LIKE 'pattern' | WHERE expr]

SHOW OPEN TABLES lists the non-TEMPORARY tables that are currently open in the table cache. See Section 8.4.3.1, “How MySQL Opens and Closes Tables”. The FROM clause, if present, restricts the tables shown to those present in the db_name database. The LIKE clause, if present, indicates which table names to match. The WHERE clause can be given to select rows using more general conditions, as discussed in Section 26.8, "Extensions to SHOW Statements".

SHOW OPEN TABLES output has these columns:

- Database
  The database containing the table.

- Table
  The table name.

- In_use
  The number of table locks or lock requests there are for the table. For example, if one client acquires a lock for a table using LOCK TABLE t1 WRITE, In_use is 1. If another client issues LOCK TABLE t1 WRITE while the table remains locked, the client blocks, waiting for the lock, but the lock request...
SHOW Statements

causes `In_use` to be 2. If the count is zero, the table is open but not currently being used. `In_use` is also increased by the `HANDLER ... OPEN` statement and decreased by `HANDLER ... CLOSE`.

• Name_locked

Whether the table name is locked. Name locking is used for operations such as dropping or renaming tables.

If you have no privileges for a table, it does not show up in the output from `SHOW OPEN TABLES`.

13.7.7.25 SHOW PLUGINS Statement

SHOW PLUGINS

`SHOW PLUGINS` displays information about server plugins.

Example of `SHOW PLUGINS` output:

```
mysql> SHOW PLUGINS\G
*************************** 1. row ***************************
   Name: binlog
  Status: ACTIVE
    Type: STORAGE ENGINE
    Library: NULL
      License: GPL
*************************** 2. row ***************************
   Name: CSV
  Status: ACTIVE
    Type: STORAGE ENGINE
    Library: NULL
      License: GPL
*************************** 3. row ***************************
   Name: MEMORY
  Status: ACTIVE
    Type: STORAGE ENGINE
    Library: NULL
      License: GPL
*************************** 4. row ***************************
   Name: MyISAM
  Status: ACTIVE
    Type: STORAGE ENGINE
    Library: NULL
      License: GPL
...
```

`SHOW PLUGINS` output has these columns:

• Name

The name used to refer to the plugin in statements such as `INSTALL PLUGIN` and `UNINSTALL PLUGIN`.

• Status

The plugin status, one of `ACTIVE`, `INACTIVE`, `DISABLED`, `DELETING`, or `DELETED`.

• Type

The type of plugin, such as `STORAGE ENGINE`, `INFORMATION_SCHEMA`, or `AUTHENTICATION`.

• Library

The name of the plugin shared library file. This is the name used to refer to the plugin file in statements such as `INSTALL PLUGIN` and `UNINSTALL PLUGIN`. This file is located in the directory named by the `plugin_dir` system variable. If the library name is `NULL`, the plugin is compiled in and cannot be uninstalled with `UNINSTALL PLUGIN`. 
• **License**

How the plugin is licensed (for example, GPL).

For plugins installed with `INSTALL PLUGIN`, the Name and Library values are also registered in the `mysql.plugin` system table.

For information about plugin data structures that form the basis of the information displayed by `SHOW PLUGINS`, see The MySQL Plugin API.

Plugin information is also available from the `INFORMATION_SCHEMA.PLUGINS` table. See Section 26.3.22, "The INFORMATION_SCHEMA PLUGINS Table".

### 13.7.7.26 SHOW PRIVILEGES Statement

`SHOW PRIVILEGES` shows the list of system privileges that the MySQL server supports. The privileges displayed include all static privileges, and all currently registered dynamic privileges.

```sql
mysql> SHOW PRIVILEGES
*************************** 1. row ***************************
Privilege: Alter
   Context: Tables
     Comment: To alter the table
*************************** 2. row ***************************
Privilege: Alter routine
   Context: Functions,Procedures
     Comment: To alter or drop stored functions/procedures
*************************** 3. row ***************************
Privilege: Create
   Context: Databases,Tables,Indexes
     Comment: To create new databases and tables
*************************** 4. row ***************************
Privilege: Create routine
   Context: Databases
     Comment: To use CREATE FUNCTION/PROCEDURE
*************************** 5. row ***************************
Privilege: Create temporary tables
   Context: Databases
     Comment: To use CREATE TEMPORARY TABLE
...```

Privileges belonging to a specific user are displayed by the `SHOW GRANTS` statement. See Section 13.7.7.21, "SHOW GRANTS Statement", for more information.

### 13.7.7.27 SHOW PROCEDURE CODE Statement

`SHOW PROCEDURE CODE proc_name`

This statement is a MySQL extension that is available only for servers that have been built with debugging support. It displays a representation of the internal implementation of the named stored procedure. A similar statement, `SHOW FUNCTION CODE`, displays information about stored functions (see Section 13.7.7.19, "SHOW FUNCTION CODE Statement").

To use either statement, you must be the user named as the routine DEFINER, have the SHOW_ROUTINE privilege, or have the SELECT privilege at the global level.

If the named routine is available, each statement produces a result set. Each row in the result set corresponds to one “instruction” in the routine. The first column is Pos, which is an ordinal number beginning with 0. The second column is Instruction, which contains an SQL statement (usually changed from the original source), or a directive which has meaning only to the stored-routine handler.

```sql
mysql> DELIMITER //
mysql> CREATE PROCEDURE p1 ()
```
BEGIN
    DECLARE fanta INT DEFAULT 55;
    DROP TABLE t2;
    LOOP
        INSERT INTO t3 VALUES (fanta);
    END LOOP;
END//
Query OK, 0 rows affected (0.01 sec)

mysql> SHOW PROCEDURE CODE p1//
+-----+----------------------------------------+
| Pos | Instruction                            |
+-----+----------------------------------------+
|   0 | set fanta@0 55                         |
|   1 | stmt 9 "DROP TABLE t2"                 |
|   2 | stmt 5 "INSERT INTO t3 VALUES (fanta)" |
|   3 | jump 2                                 |
+-----+----------------------------------------+
4 rows in set (0.00 sec)

mysql> CREATE FUNCTION test.hello (s CHAR(20))
    RETURNS CHAR(50) DETERMINISTIC
    RETURN CONCAT('Hello, ',s,'!');
Query OK, 0 rows affected (0.00 sec)

mysql> SHOW FUNCTION CODE test.hello;
+-----+---------------------------------------+
| Pos | Instruction                           |
+-----+---------------------------------------+
|   0 | freturn 254 concat('Hello, ',s@0,'!') |
+-----+---------------------------------------+
1 row in set (0.00 sec)

In this example, the nonexecutable BEGIN and END statements have disappeared, and for the DECLARE variable_name statement, only the executable part appears (the part where the default is assigned). For each statement that is taken from source, there is a code word stmt followed by a type (9 means DROP, 5 means INSERT, and so on). The final row contains an instruction jump 2, meaning GOTO instruction #2.

13.7.7.28 SHOW PROCEDURE STATUS Statement

SHOW PROCEDURE STATUS
    [LIKE 'pattern'  | WHERE expr]

This statement is a MySQL extension. It returns characteristics of a stored procedure, such as the database, name, type, creator, creation and modification dates, and character set information. A similar statement, SHOW FUNCTION STATUS, displays information about stored functions (see Section 13.7.7.20, "SHOW FUNCTION STATUS Statement").

To use either statement, you must be the user named as the routine DEFINER, have the SHOW ROUTINE privilege, have the SELECT privilege at the global level, or have the CREATE ROUTINE, ALTER ROUTINE, or EXECUTE privilege granted at a scope that includes the routine.

The LIKE clause, if present, indicates which procedure or function names to match. The WHERE clause can be given to select rows using more general conditions, as discussed in Section 26.8, “Extensions to SHOW Statements”.

mysql> SHOW PROCEDURE STATUS LIKE 'sp1'\G
*************************** 1. row ***************************
Db: test
Name: sp1
Type: PROCEDURE
Definer: testuser@localhost
Modified: 2018-08-08 13:54:11
Created: 2018-08-08 13:54:11
Security_type: DEFINER
Comment:
character_set_client: utf8mb4
SHOW Function Status Like 'hello'\G

<table>
<thead>
<tr>
<th>Db</th>
<th>test</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>hello</td>
</tr>
<tr>
<td>Type</td>
<td>FUNCTION</td>
</tr>
<tr>
<td>Definer</td>
<td>testuser@localhost</td>
</tr>
<tr>
<td>Modified</td>
<td>2020-03-10 11:10:03</td>
</tr>
<tr>
<td>Created</td>
<td>2020-03-10 11:10:03</td>
</tr>
<tr>
<td>Security_type</td>
<td>DEFINER</td>
</tr>
<tr>
<td>Comment</td>
<td></td>
</tr>
</tbody>
</table>

character_set_client is the session value of the character_set_client system variable when the routine was created. collation_connection is the session value of the collation_connection system variable when the routine was created. Database Collation is the collation of the database with which the routine is associated.

Stored routine information is also available from the INFORMATION_SCHEMA PARAMETERS and ROUTINES tables. See Section 26.3.20, “The INFORMATION_SCHEMA PARAMETERS Table”, and Section 26.3.30, “The INFORMATION_SCHEMA ROUTINES Table”.

13.7.7.29 SHOW PROCESSLIST Statement

SHOW [FULL] PROCESSLIST

The MySQL process list indicates the operations currently being performed by the set of threads executing within the server. The SHOW PROCESSLIST statement is one source of process information. For a comparison of this statement with other sources, see Sources of Process Information.

Note

As of MySQL 8.0.22, an alternative implementation for SHOW PROCESSLIST is available based on the Performance Schema processlist table, which, unlike the default SHOW PROCESSLIST implementation, does not require a mutex and has better performance characteristics. For details, see Section 27.12.21.5, “The processlist Table”.

If you have the PROCESS privilege, you can see all threads, even those belonging to other users. Otherwise (without the PROCESS privilege), nonanonymous users have access to information about their own threads but not threads for other users, and anonymous users have no access to thread information.

Without the FULL keyword, SHOW PROCESSLIST displays only the first 100 characters of each statement in the Info field.

The SHOW PROCESSLIST statement is very useful if you get the “too many connections” error message and want to find out what is going on. MySQL reserves one extra connection to be used by accounts that have the CONNECTION_ADMIN privilege (or the deprecated SUPER privilege), to ensure that administrators should always be able to connect and check the system (assuming that you are not giving this privilege to all your users).

Threads can be killed with the KILL statement. See Section 13.7.8.4, “KILL Statement”.

Example of SHOW PROCESSLIST output:

mysql> SHOW FULL PROCESSLIST\G

<table>
<thead>
<tr>
<th>Id</th>
<th>User</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>system user</td>
</tr>
</tbody>
</table>
**SHOW Statements**

<table>
<thead>
<tr>
<th>Host</th>
<th>Command</th>
<th>Time</th>
<th>State</th>
<th>Info</th>
</tr>
</thead>
<tbody>
<tr>
<td>NULL</td>
<td>Connect</td>
<td>1030455</td>
<td>Waiting for master to send event</td>
<td>NULL</td>
</tr>
<tr>
<td>NULL</td>
<td>Connect</td>
<td>1004</td>
<td>Has read all relay log; waiting for the slave I/O thread to update it</td>
<td>NULL</td>
</tr>
<tr>
<td>NULL</td>
<td>Binlog Dump</td>
<td>2144</td>
<td>Has sent all binlog to slave; waiting for binlog to be updated</td>
<td>NULL</td>
</tr>
<tr>
<td>NULL</td>
<td>Binlog Dump</td>
<td>2086</td>
<td>Has sent all binlog to slave; waiting for binlog to be updated</td>
<td>NULL</td>
</tr>
<tr>
<td>localhost</td>
<td>Query</td>
<td>0</td>
<td>NULL</td>
<td>SHOW FULL PROCESSLIST</td>
</tr>
</tbody>
</table>

**SHOW PROCESSLIST** output has these columns:

- **Id**
  
The connection identifier. This is the same value displayed in the **ID** column of the `INFORMATION_SCHEMA.PROCESSLIST` table, displayed in the **PROCESSLIST_ID** column of the Performance Schema `threads` table, and returned by the `CONNECTION_ID()` function within the thread.

- **User**
  
The MySQL user who issued the statement. A value of **system user** refers to a nonclient thread spawned by the server to handle tasks internally, for example, a delayed-row handler thread or an I/O or SQL thread used on replica hosts. For **system user**, there is no host specified in the **Host** column. **unauthenticated user** refers to a thread that has become associated with a client connection but for which authentication of the client user has not yet occurred. **event_scheduler** refers to the thread that monitors scheduled events (see Section 25.4, “Using the Event Scheduler”).

**Note**

A **User** value of **system user** is distinct from the **SYSTEM_USER** privilege. The former designates internal threads. The latter distinguishes the system user and regular user account categories (see Section 6.2.11, “Account Categories”).
SHOW Statements

• **Host**

The host name of the client issuing the statement (except for system user, for which there is no host). The host name for TCP/IP connections is reported in `host_name:client_port` format to make it easier to determine which client is doing what.

• **db**

The default database for the thread, or NULL if none has been selected.

• **Command**

The type of command the thread is executing on behalf of the client, or Sleep if the session is idle. For descriptions of thread commands, see Section 8.14, "Examining Server Thread (Process) Information". The value of this column corresponds to the COM_xxx commands of the client/server protocol and Com_xxx status variables. See Section 5.1.10, “Server Status Variables”.

• **Time**

The time in seconds that the thread has been in its current state. For a replica SQL thread, the value is the number of seconds between the timestamp of the last replicated event and the real time of the replica host. See Section 17.2.3, "Replication Threads".

• **State**

An action, event, or state that indicates what the thread is doing. For descriptions of State values, see Section 8.14, "Examining Server Thread (Process) Information". Most states correspond to very quick operations. If a thread stays in a given state for many seconds, there might be a problem that needs to be investigated.

• **Info**

The statement the thread is executing, or NULL if it is executing no statement. The statement might be the one sent to the server, or an innermost statement if the statement executes other statements. For example, if a CALL statement executes a stored procedure that is executing a SELECT statement, the Info value shows the SELECT statement.

13.7.7.30 SHOW PROFILE Statement

```
SHOW PROFILE [type [, type] ... ]
   [FOR QUERY n]
   [LIMIT row_count [OFFSET offset]]
``` 

type: {
   ALL
   | BLOCK IO
   | CONTEXT SWITCHES
   | CPU
   | IPC
   | MEMORY
   | PAGE FAULTS
   | SOURCE
   | SWAPS
}

The `SHOW PROFILE` and `SHOW PROFILES` statements display profiling information that indicates resource usage for statements executed during the course of the current session.

**Note**

The `SHOW PROFILE` and `SHOW PROFILES` statements are deprecated; expect them to be removed in a future MySQL release. Use the Performance Schema instead; see Section 27.19.1, “Query Profiling Using Performance Schema”.

2724
To control profiling, use the `profiling` session variable, which has a default value of 0 (OFF). Enable profiling by setting `profiling` to 1 or ON:

```sql
mysql> SET profiling = 1;
```

`SHOW PROFILES` displays a list of the most recent statements sent to the server. The size of the list is controlled by the `profiling_history_size` session variable, which has a default value of 15. The maximum value is 100. Setting the value to 0 has the practical effect of disabling profiling.

All statements are profiled except `SHOW PROFILE` and `SHOW PROFILES`, so neither of those statements appears in the profile list. Malformed statements are profiled. For example, `SHOW PROFILING` is an illegal statement, and a syntax error occurs if you try to execute it, but it shows up in the profiling list.

`SHOW PROFILE` displays detailed information about a single statement. Without the `FOR QUERY n` clause, the output pertains to the most recently executed statement. If `FOR QUERY n` is included, `SHOW PROFILE` displays information for statement `n`. The values of `n` correspond to the `Query_ID` values displayed by `SHOW PROFILES`.

The `LIMIT row_count` clause may be given to limit the output to `row_count` rows. If `LIMIT` is given, `OFFSET offset` may be added to begin the output `offset` rows into the full set of rows.

By default, `SHOW PROFILE` displays `Status` and `Duration` columns. The `Status` values are like the `State` values displayed by `SHOW PROCESSLIST`, although there might be some minor differences in interpretation for the two statements for some status values (see Section 8.14, “Examining Server Thread (Process) Information”).

Optional `type` values may be specified to display specific additional types of information:

- `ALL` displays all information
- `BLOCK IO` displays counts for block input and output operations
- `CONTEXT SWITCHES` displays counts for voluntary and involuntary context switches
- `CPU` displays user and system CPU usage times
- `IPC` displays counts for messages sent and received
- `MEMORY` is not currently implemented
- `PAGE FAULTS` displays counts for major and minor page faults
- `SOURCE` displays the names of functions from the source code, together with the name and line number of the file in which the function occurs
- `SWAPS` displays swap counts

Profiling is enabled per session. When a session ends, its profiling information is lost.

```sql
mysql> SELECT @@profiling;
<table>
<thead>
<tr>
<th>@@profiling</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
</tr>
</tbody>
</table>
1 row in set (0.00 sec)

mysql> SET profiling = 1;
Query OK, 0 rows affected (0.00 sec)

mysql> DROP TABLE IF EXISTS t1;
Query OK, 0 rows affected, 1 warning (0.00 sec)
```
SHOW Statements

```sql
mysql> CREATE TABLE T1 (id INT);
Query OK, 0 rows affected (0.01 sec)

mysql> SHOW PROFILES;
+----------+----------+--------------------------+
<table>
<thead>
<tr>
<th>Query_ID</th>
<th>Duration</th>
<th>Query</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0.000088</td>
<td>SET PROFILING = 1</td>
</tr>
<tr>
<td>1</td>
<td>0.000136</td>
<td>DROP TABLE IF EXISTS t1</td>
</tr>
<tr>
<td>2</td>
<td>0.011947</td>
<td>CREATE TABLE t1 (id INT)</td>
</tr>
</tbody>
</table>
+----------+----------+--------------------------+
3 rows in set (0.00 sec)

mysql> SHOW PROFILE;
+----------------------+----------+
| Status               | Duration |
|----------------------+----------|

| creating table      | 0.000056 |
| After create        | 0.011363 |
| query end           | 0.000375 |
| freeing items       | 0.000089 |
| logging slow query  | 0.000019 |
| cleaning up         | 0.000005 |
+----------------------+----------+
7 rows in set (0.00 sec)

mysql> SHOW PROFILE FOR QUERY 1;
+--------------------+----------+
<table>
<thead>
<tr>
<th>Status</th>
<th>Duration</th>
</tr>
</thead>
<tbody>
<tr>
<td>query end</td>
<td>0.000107</td>
</tr>
<tr>
<td>freeing items</td>
<td>0.000008</td>
</tr>
<tr>
<td>logging slow query</td>
<td>0.000015</td>
</tr>
<tr>
<td>cleaning up</td>
<td>0.000006</td>
</tr>
</tbody>
</table>
+--------------------+----------+
4 rows in set (0.00 sec)

mysql> SHOW PROFILE CPU FOR QUERY 2;
+----------------------+----------+----------+------------+
| Status               | Duration | CPU_user | CPU_system |
|----------------------+----------+----------+------------+
| checking permissions | 0.000040 | 0.000038 | 0.000002   |
| creating table      | 0.000056 | 0.000028 | 0.000028   |
| After create        | 0.011363 | 0.000217 | 0.001571   |
| query end           | 0.000375 | 0.000013 | 0.000028   |
| freeing items       | 0.000089 | 0.000010 | 0.000014   |
| logging slow query  | 0.000019 | 0.000009 | 0.000010   |
| cleaning up         | 0.000005 | 0.000003 | 0.000002   |
+----------------------+----------+----------+------------+
7 rows in set (0.00 sec)
```

**Note**

Profiling is only partially functional on some architectures. For values that depend on the `getrusage()` system call, `NULL` is returned on systems such as Windows that do not support the call. In addition, profiling is per process and not per thread. This means that activity on threads within the server other than your own may affect the timing information that you see.

Profiling information is also available from the `INFORMATION_SCHEMA.PROFILING` table. See Section 26.3.24, “The INFORMATION_SCHEMA.PROFILING Table”. For example, the following queries are equivalent:

```sql
SHOW PROFILE FOR QUERY 2;
SELECT STATE, FORMAT(DURATION, 6) AS DURATION
FROM INFORMATION_SCHEMA.PROFILING
WHERE QUERY_ID = 2 ORDER BY SEQ;
```
### 13.7.7.31 SHOW PROFILES Statement

#### SHOW PROFILES

The `SHOW PROFILES` statement, together with `SHOW PROFILE`, displays profiling information that indicates resource usage for statements executed during the course of the current session. For more information, see Section 13.7.7.30, “SHOW PROFILE Statement”.

**Note**

The `SHOW PROFILE` and `SHOW PROFILES` statements are deprecated; expect it to be removed in a future MySQL release. Use the Performance Schema instead; see Section 27.19.1, “Query Profiling Using Performance Schema”.

### 13.7.7.32 SHOW RELAYLOG EVENTS Statement

#### SHOW RELAYLOG EVENTS

```sql
SHOW RELAYLOG EVENTS
    [IN 'log_name']
    [FROM pos]
    [LIMIT [offset], row_count]
    [channel_option]
```

*channel_option:*

```sql
    FOR CHANNEL channel
```

Shows the events in the relay log of a replica. If you do not specify `log_name`, the first relay log is displayed. This statement has no effect on the source. `SHOW RELAYLOG EVENTS` requires the `REPLICATION SLAVE` privilege.

The `LIMIT` clause has the same syntax as for the `SELECT` statement. See Section 13.2.10, “SELECT Statement”.

**Note**

Issuing a `SHOW RELAYLOG EVENTS` with no `LIMIT` clause could start a very time- and resource-consuming process because the server returns to the client the complete contents of the relay log (including all statements modifying data that have been received by the replica).

The optional `FOR CHANNEL channel` clause enables you to name which replication channel the statement applies to. Providing a `FOR CHANNEL channel` clause applies the statement to a specific replication channel. If no channel is named and no extra channels exist, the statement applies to the default channel.

When using multiple replication channels, if a `SHOW RELAYLOG EVENTS` statement does not have a channel defined using a `FOR CHANNEL channel` clause an error is generated. See Section 17.2.2, “Replication Channels” for more information.

`SHOW RELAYLOG EVENTS` displays the following fields for each event in the relay log:

- **Log_name**
  The name of the file that is being listed.

- **Pos**
  The position at which the event occurs.

- **Event_type**
  An identifier that describes the event type.

- **Server_id**
SHOW Statements

The server ID of the server on which the event originated.

- **End_log_pos**
  The value of `End_log_pos` for this event in the source's binary log.

- **Info**
  More detailed information about the event type. The format of this information depends on the event type.

For compressed transaction payloads, the `Transaction_payload_event` is first printed as a single unit, then it is unpacked and each event inside it is printed.

Some events relating to the setting of user and system variables are not included in the output from `SHOW RELAYLOG EVENTS`. To get complete coverage of events within a relay log, use `mysqlbinlog`.

**13.7.7.33 SHOW REPLICAS | SHOW SLAVE HOSTS Statement**

{`SHOW REPLICAS | SHOW SLAVE HOSTS`}

Displays a list of replicas currently registered with the source. From MySQL 8.0.22, use `SHOW REPLICAS` in place of `SHOW SLAVE HOSTS`, which is deprecated from that release. In releases before MySQL 8.0.22, use `SHOW SLAVE HOSTS`. `SHOW REPLICAS | SHOW SLAVE HOSTS` requires the `REPLICATION SLAVE` privilege.

`SHOW REPLICAS | SHOW SLAVE HOSTS` should be executed on a server that acts as a replication source. The statement displays information about servers that are or have been connected as replicas, with each row of the result corresponding to one replica server, as shown here:

```sql
mysql> SHOW REPLICAS;
+------------+-----------+------+-----------+--------------------------------------+
| Server_id  | Host      | Port | Source_id | Replica_UUID                         |
+------------+-----------+------+-----------+--------------------------------------+
|         10 | iconnect2 | 3306 |         3 | 14cb6624-7f93-11e0-b2c0-c80aa9429562 |
|         21 | athena    | 3306 |         3 | 07af4990-f41f-11df-a566-7ac56fda645 |
+------------+-----------+------+-----------+--------------------------------------+
```

- **Server_id**: The unique server ID of the replica server, as configured in the replica server's option file, or on the command line with `--server-id=value`.
- **Host**: The host name of the replica server, as specified on the replica with the `--report-host` option. This can differ from the machine name as configured in the operating system.
- **User**: The replica server user name, as specified on the replica with the `--report-user` option. Statement output includes this column only if the source server is started with the `--show-slave-auth-info` option.
- **Password**: The replica server password, as specified on the replica with the `--report-password` option. Statement output includes this column only if the source server is started with the `--show-slave-auth-info` option.
- **Port**: The port on the source to which the replica server is listening, as specified on the replica with the `--report-port` option.
  A zero in this column means that the replica port (`--report-port`) was not set.
- **Source_id**: The unique server ID of the source server that the replica server is replicating from. This is the server ID of the server on which `SHOW REPLICAS | SHOW SLAVE HOSTS` is executed, so this same value is listed for each row in the result.
- **Replica_UUID**: The globally unique ID of this replica, as generated on the replica and found in the replica's `auto.cnf` file.
SHOW Statements

13.7.7.34 SHOW SLAVE HOSTS | SHOW REPLICAS Statement

{SHOW SLAVE HOSTS | SHOW REPLICAS}

Displays a list of replicas currently registered with the source. From MySQL 8.0.22, SHOW SLAVE HOSTS is deprecated and the alias SHOW REPLICAS should be used instead. The statement works in the same way as before, only the terminology used for the statement and its output has changed. Both versions of the statement update the same status variables when used. Please see the documentation for SHOW REPLICAS for a description of the statement.

13.7.7.35 SHOW REPLICA | SLAVE STATUS Statement

SHOW {REPLICA | SLAVE} STATUS [FOR CHANNEL channel]

This statement provides status information on essential parameters of the replica threads. From MySQL 8.0.22, use SHOW REPLICA STATUS in place of SHOW SLAVE STATUS, which is deprecated from that release. In releases before MySQL 8.0.22, use SHOW SLAVE STATUS. The statement requires the REPLICATION CLIENT privilege (or the deprecated SUPER privilege).

SHOW REPLICA | SLAVE STATUS is nonblocking. When run concurrently with STOP REPLICA | SLAVE, SHOW REPLICA | SLAVE STATUS returns without waiting for STOP REPLICA | SLAVE to finish shutting down the replication SQL thread or replication I/O thread (or both). This permits use in monitoring and other applications where getting an immediate response from SHOW REPLICA | SLAVE STATUS is more important than ensuring that it returned the latest data.

If you issue this statement using the mysql client, you can use a \G statement terminator rather than a semicolon to obtain a more readable vertical layout:

```
mysql> SHOW REPLICA STATUS\G
*************************** 1. row ***************************
Replica_IO_State: Waiting for source to send event
Source_Host: localhost
Source_User: repl
Source_Port: 13000

```

2729
The Performance Schema provides tables that expose replication information. This is similar to the information available from the `SHOW REPLICA | SLAVE STATUS` statement, but represented in table form. For details, see Section 27.12.11, “Performance Schema Replication Tables”.

The following list describes the fields returned by `SHOW REPLICA | SLAVE STATUS`. For additional information about interpreting their meanings, see Section 17.1.7.1, “Checking Replication Status”.

- **Replica_IO_State**
  
  A copy of the `State` field of the `SHOW PROCESSLIST` output for the replica I/O thread. This tells you what the thread is doing: trying to connect to the source, waiting for events from the source, reconnecting to the source, and so on. For a listing of possible states, see Section 8.14.5, “Replication I/O Thread States”.

- **Source_Host**
  
  The source host that the replica is connected to.

- **Source_User**
  
  The user name of the account used to connect to the source.

- **Source_Port**
  
  The port used to connect to the source.

- **Connect_Retry**
  
  The number of seconds between connect retries (default 60). This can be set with a `CHANGE REPLICATION SOURCE TO` statement (from MySQL 8.0.23) or `CHANGE MASTER TO` statement (before MySQL 8.0.23).

- **Source_Log_File**
  
  The name of the source binary log file from which the I/O thread is currently reading.

- **Read_Source_Log_Pos**
  
  The position in the current source binary log file up to which the I/O thread has read.

- **Relay_Log_File**
  
  2730
SHOW Statements

The name of the relay log file from which the SQL thread is currently reading and executing.

- Relay_Log_Pos
  The position in the current relay log file up to which the SQL thread has read and executed.

- Relay_Source_Log_File
  The name of the source binary log file containing the most recent event executed by the SQL thread.

- Replica_IO_Running
  Whether the replication I/O thread is started and has connected successfully to the source. Internally, the state of this thread is represented by one of the following three values:
  - MYSQL_REPLICA_NOT_RUN. The replication I/O thread is not running. For this state, Replica_IO_Running is No.
  - MYSQL_REPLICA_RUN_NOT_CONNECT. The replication I/O thread is running, but is not connected to a replication source. For this state, Replica_IO_Running is Connecting.
  - MYSQL_REPLICA_RUN_CONNECT. The replication I/O thread is running, and is connected to a replication source. For this state, Replica_IO_Running is Yes.

- Replica_SQL_Running
  Whether the replication SQL thread is started.

- Replicate_Do_DB, Replicate_Ignore_DB
  The names of any databases that were specified with the --replicate-do-db and --replicate-ignore-db options, or the CHANGE REPLICATION FILTER statement. If the FOR CHANNEL clause was used, the channel specific replication filters are shown. Otherwise, the replication filters for every replication channel are shown.

- Replicate_Do_Table, Replicate_Ignore_Table, Replicate_Wild_Do_Table, Replicate_Wild_Ignore_Table
  The names of any tables that were specified with the --replicate-do-table, --replicate-ignore-table, --replicate-wild-do-table, and --replicate-wild-ignore-table options, or the CHANGE REPLICATION FILTER statement. If the FOR CHANNEL clause was used, the channel specific replication filters are shown. Otherwise, the replication filters for every replication channel are shown.

- Last_Errno, Last_Error
  These columns are aliases for Last_SQL_Errno and Last_SQL_Error.
  Issuing RESET MASTER or RESET REPLICA | SLAVE resets the values shown in these columns.

  **Note**
  When the replication SQL thread receives an error, it reports the error first, then stops the SQL thread. This means that there is a small window of time during which SHOW REPLICA | SLAVE STATUS shows a nonzero value for Last_SQL_Errno even though Replica_SQL_Running still displays Yes.

- Skip_Counter
  The current value of the sql_slave_skip_counter system variable. See SET GLOBAL sql_slave_skip_counter Statement.
SHOW Statements

- **Exec_Source_Log_Pos**

  The position in the current source binary log file to which the replication SQL thread has read and executed, marking the start of the next transaction or event to be processed. You can use this value with the `CHANGE REPLICATION SOURCE TO` statement's `SOURCE_LOG_POS` option (from MySQL 8.0.23) or the `CHANGE MASTER TO` statement's `MASTER_LOG_POS` option (before MySQL 8.0.23) when starting a new replica from an existing replica, so that the new replica reads from this point. The coordinates given by `(Relay_Source_Log_File, Exec_Source_Log_Pos)` in the source's binary log correspond to the coordinates given by `(Relay_Log_File, Relay_Log_Pos)` in the relay log.

  Inconsistencies in the sequence of transactions from the relay log which have been executed can cause this value to be a “low-water mark”. In other words, transactions appearing before the position are guaranteed to have committed, but transactions after the position may have committed or not. If these gaps need to be corrected, use `START REPLICA | SLAVE UNTIL SQL_AFTER_MTS_GAPS`. See Section 17.5.1.34, “Replication and Transaction Inconsistencies” for more information.

- **Relay_Log_Space**

  The total combined size of all existing relay log files.

- **Until_Condition, Until_Log_File, Until_Log_Pos**

  The values specified in the `UNTIL` clause of the `START REPLICA | SLAVE` statement.

  `Until_Condition` has these values:
  - **None** if no `UNTIL` clause was specified.
  - **Source** if the replica is reading until a given position in the source's binary log.
  - **Relay** if the replica is reading until a given position in its relay log.
  - **SQL_BEFORE_GTIDS** if the replication SQL thread is processing transactions until it has reached the first transaction whose GTID is listed in the `gtid_set`.
  - **SQL_AFTER_GTIDS** if the replication threads are processing all transactions until the last transaction in the `gtid_set` has been processed by both threads.
  - **SQL_AFTER_MTS_GAPS** if a multithreaded replica's SQL threads are running until no more gaps are found in the relay log.

  `Until_Log_File` and `Until_Log_Pos` indicate the log file name and position that define the coordinates at which the replication SQL thread stops executing.

  For more information on `UNTIL` clauses, see Section 13.4.2.8, “START SLAVE | REPLICA Statement”.

- **Source_SSL_Allowed, Source_SSL_CA_File, Source_SSL_CA_Path, Source_SSL_Cert, Source_SSL_Cipher, Source_SSL_CRL_File, Source_SSL_CRL_Path, Source_SSL_Key, Source_SSL_Verify_Server_Cert**

  These fields show the SSL parameters used by the replica to connect to the source, if any.

  `Source_SSL_Allowed` has these values:
  - **Yes** if an SSL connection to the source is permitted.
  - **No** if an SSL connection to the source is not permitted.
  - **Ignored** if an SSL connection is permitted but the replica server does not have SSL support enabled.
SHOW Statements

The values of the other SSL-related fields correspond to the values of the `SOURCE_SSL_*` options of the `CHANGE REPLICAlevision SOURCE TO` statement (from MySQL 8.0.23), or the `MASTER_SSL_*` options of the `CHANGE MASTER TO` statement (before MySQL 8.0.23). See Section 13.4.2.1, “CHANGE MASTER TO Statement”.

- **Seconds_Behind_Source**

  This field is an indication of how “late” the replica is:

  - When the replica is actively processing updates, this field shows the difference between the current timestamp on the replica and the original timestamp logged on the source for the event currently being processed on the replica.

  - When no event is currently being processed on the replica, this value is 0.

  In essence, this field measures the time difference in seconds between the replication SQL thread and the replication I/O thread. If the network connection between source and replica is fast, the replication I/O thread is very close to the source, so this field is a good approximation of how late the replication SQL thread is compared to the source. If the network is slow, this is not a good approximation; the replication SQL thread may quite often be caught up with the slow-reading replication I/O thread, so `Seconds_Behind_Source` often shows a value of 0, even if the replication I/O thread is late compared to the source. In other words, *this column is useful only for fast networks*.

  This time difference computation works even if the source and replica do not have identical clock times, provided that the difference, computed when the replica I/O thread starts, remains constant from then on. Any changes, including NTP updates, can lead to clock skews that can make calculation of `Seconds_Behind_Source` less reliable.

  In MySQL 8.0, this field is NULL (undefined or unknown) if the replication SQL thread is not running, or if the SQL thread has consumed all of the relay log and the replication I/O thread is not running. (In older versions of MySQL, this field was NULL if the replication SQL thread or the replication I/O thread was not running or was not connected to the source.) If the replication I/O thread is running but the relay log is exhausted, `Seconds_Behind_Source` is set to 0.

  The value of `Seconds_Behind_Source` is based on the timestamps stored in events, which are preserved through replication. This means that if a source M1 is itself a replica of M0, any event from M1’s binary log that originates from M0’s binary log has M0’s timestamp for that event. This enables MySQL to replicate `TIMESTAMP` successfully. However, the problem for `Seconds_Behind_Source` is that if M1 also receives direct updates from clients, the `Seconds_Behind_Source` value randomly fluctuates because sometimes the last event from M1 originates from M0 and sometimes is the result of a direct update on M1.

  When using a multithreaded replica, you should keep in mind that this value is based on `Exec_Source_Log_Pos`, and so may not reflect the position of the most recently committed transaction.

- **Last_IO_Errno, Last_IO_Error**

  The error number and error message of the most recent error that caused the replication I/O thread to stop. An error number of 0 and message of the empty string mean “no error.” If the `Last_IO_Error` value is not empty, the error values also appear in the replica’s error log.

  I/O error information includes a timestamp showing when the most recent I/O thread error occurred. This timestamp uses the format `YYYYMMDD hh:mm:ss`, and appears in the `Last_IO_Error_Timestamp` column.

  Issuing `RESET MASTER` or `RESET REPLICA` | `SLAVE` resets the values shown in these columns.

- **Last_SQL_Errno, Last_SQL_Error**
The error number and error message of the most recent error that caused the replication SQL thread to stop. An error number of 0 and message of the empty string mean "no error." If the Last_SQL_Error value is not empty, the error values also appear in the replica's error log.

If the replica is multithreaded, the replication SQL thread is the coordinator for worker threads. In this case, the Last_SQL_Error field shows exactly what the Last_Error_Message column in the Performance Schema replication_applier_status_by_coordinator table shows. The field value is modified to suggest that there may be more failures in the other worker threads which can be seen in the replication_applier_status_by_worker table that shows each worker thread's status. If that table is not available, the replica error log can be used. The log or the replication_applier_status_by_worker table should also be used to learn more about the failure shown by SHOW REPLICA | SLAVE STATUS or the coordinator table.

SQL error information includes a timestamp showing when the most recent SQL thread error occurred. This timestamp uses the format YYMMDD hh:mm:ss, and appears in the Last_SQL_Error_Timestamp column.

Issuing RESET MASTER or RESET REPLICA | SLAVE resets the values shown in these columns.

In MySQL 8.0, all error codes and messages displayed in the Last_SQL_Errno and Last_SQL_Error columns correspond to error values listed in Server Error Message Reference. This was not always true in previous versions. (Bug #11760365, Bug #52768)

- Replicate_Ignore_Server_Ids

Any server IDs that have been specified using the IGNORE_SERVER_IDS option of the CHANGE REPLICA | SLAVE STATUS command, so that the replica ignores events from these servers. This option is used in a circular or other multi-source replication setup when one of the servers is removed. If any server IDs have been set in this way, a comma-delimited list of one or more numbers is shown. If no server IDs have been set, the field is blank.

Note

The Ignored_server_ids value in the slave_master_info table also shows the server IDs to be ignored, but as a space-delimited list, preceded by the total number of server IDs to be ignored. For example, if a CHANGE REPLICA | SLAVE STATUS command containing the IGNORE_SERVER_IDS = (2, 6, 9) option has been issued to tell a replica to ignore sources having the server ID 2, 6, or 9, that information appears as shown here:

| Replicate_Ignore_Server_Ids: 2, 6, 9 |
| Ignored_server_ids: 3, 2, 6, 9 |

Replicate_Ignore_Server_Ids filtering is performed by the I/O thread, rather than by the SQL thread, which means that events which are filtered out are not written to the relay log. This differs from the filtering actions taken by server options such --replicate-do-table, which apply to the SQL thread.

Note

From MySQL 8.0, a deprecation warning is issued if SET GTID_MODE=ON is issued when any channel has existing server IDs set with IGNORE_SERVER_IDS. Before starting GTID-based replication, use SHOW REPLICA | SLAVE STATUS to check for and clear all ignored server ID lists on the servers involved. You can clear a list by issuing a CHANGE REPLICA | SLAVE STATUS command containing the IGNORE_SERVER_IDS option with an empty list.
SHOW Statements

- **Source_Server_Id**
  The server_id value from the source.

- **Source_UUID**
  The server_uuid value from the source.

- **Source_Info_File**
  The location of the master.info file, the use of which is now deprecated. By default from MySQL 8.0, a table is used instead for the replica's connection metadata repository.

- **SQL_Delay**
  The number of seconds that the replica must lag the source.

- **SQL_Remaining_Delay**
  When Replica_SQL_Running_State is Waiting until MASTER_DELAY seconds after source executed event, this field contains the number of delay seconds remaining. At other times, this field is NULL.

- **Replica_SQL_Running_State**
  The state of the SQL thread (analogous to Replica_IO_State). The value is identical to the State value of the SQL thread as displayed by SHOW PROCESSLIST. Section 8.14.6, “Replication SQL Thread States”, provides a listing of possible states.

- **Source_Retry_Count**
  The number of times the replica can attempt to reconnect to the source in the event of a lost connection. This value can be set using the SOURCE_RETRY_COUNT | MASTER_RETRY_COUNT option of the CHANGE_REPLICATION_SOURCE_TO statement (from MySQL 8.0.23) or CHANGE_MASTER_TO statement (before MySQL 8.0.23), or the older --master-retry-count server option (still supported for backward compatibility).

- **Source_Bind**
  The network interface that the replica is bound to, if any. This is set using the SOURCE_BIND | MASTER_BIND option for the CHANGE_REPLICATION_SOURCE_TO statement (from MySQL 8.0.23) or CHANGE_MASTER_TO statement (before MySQL 8.0.23).

- **Last_IO_Error_Timestamp**
  A timestamp in YYMMDD hh:mm:ss format that shows when the most recent I/O error took place.

- **Last_SQL_Error_Timestamp**
  A timestamp in YYMMDD hh:mm:ss format that shows when the most recent SQL error occurred.

- **Retrieved_Gtid_Set**
  The set of global transaction IDs corresponding to all transactions received by this replica. Empty if GTIDs are not in use. See GTID Sets for more information.

  This is the set of all GTIDs that exist or have existed in the relay logs. Each GTID is added as soon as the Gtid_log_event is received. This can cause partially transmitted transactions to have their GTIDs included in the set.

  When all relay logs are lost due to executing RESET REPLICA | SLAVE or CHANGE_REPLICATION_SOURCE_TO | CHANGE_MASTER_TO, or due to the effects of the --relay-log-
**recovery** option, the set is cleared. When *relay_log_purge = 1*, the newest relay log is always kept, and the set is not cleared.

- **Executed_Gtid_Set**

  The set of global transaction IDs written in the binary log. This is the same as the value for the global *gtid_executed* system variable on this server, as well as the value for Executed_Gtid_Set in the output of *SHOW MASTER STATUS* on this server. Empty if GTIDs are not in use. See **GTID Sets** for more information.

- **Auto_Position**

  1 if GTID auto-positioning is in use for the channel, otherwise 0.

- **Replicate_Rewrite_DB**

  The *Replicate_Rewrite_DB* value displays any replication filtering rules that were specified. For example, if the following replication filter rule was set:

  ```
  CHANGE REPLICATION FILTER REPLICATE_REWRITE_DB=((db1,db2), (db3,db4));
  ```

  the *Replicate_Rewrite_DB* value displays:

  ```
  Replicate_Rewrite_DB: (db1,db2),(db3,db4)
  ```

  For more information, see **Section 13.4.2.2, “CHANGE REPLICATION FILTER Statement”**.

- **Channel_name**

  The replication channel which is being displayed. There is always a default replication channel, and more replication channels can be added. See **Section 17.2.2, “Replication Channels”** for more information.

- **Master_TLS_Version**

  The TLS version used on the source. For TLS version information, see **Section 6.3.2, “Encrypted Connection TLS Protocols and Ciphers”**.

- **Source_public_key_path**

  The path name to a file containing a replica-side copy of the public key required by the source for RSA key pair-based password exchange. The file must be in PEM format. This column applies to replicas that authenticate with the *sha256_password* or *caching_sha2_password* authentication plugin.

  If *Source_public_key_path* is given and specifies a valid public key file, it takes precedence over *Get_source_public_key*.

- **Get_source_public_key**

  Whether to request from the source the public key required for RSA key pair-based password exchange. This column applies to replicas that authenticate with the *caching_sha2_password* authentication plugin. For that plugin, the source does not send the public key unless requested.

  If *Source_public_key_path* is given and specifies a valid public key file, it takes precedence over *Get_source_public_key*.

- **Network_Namespace**

  The network namespace name; empty if the connection uses the default (global) namespace. For information about network namespaces, see **Section 5.1.14, “Network Namespace Support”**. This column was added in MySQL 8.0.22.
SHOW Statements

13.7.7.36 SHOW SLAVE | REPLICA STATUS Statement

```
SHOW {SLAVE | REPLICA} STATUS [FOR CHANNEL channel]
```

This statement provides status information on essential parameters of the replica threads. From MySQL 8.0.22, `SHOW SLAVE STATUS` is deprecated and the alias `SHOW REPLICA STATUS` should be used instead. The statement works in the same way as before, only the terminology used for the statement and its output has changed. Both versions of the statement update the same status variables when used. Please see the documentation for `SHOW REPLICA STATUS` for a description of the statement.

13.7.7.37 SHOW STATUS Statement

```
SHOW [GLOBAL | SESSION] STATUS
[LIKE 'pattern' | WHERE expr]
```

`SHOW STATUS` provides server status information (see Section 5.1.10, “Server Status Variables”). This statement does not require any privilege. It requires only the ability to connect to the server.

Status variable information is also available from these sources:

- Performance Schema tables. See Section 27.12.15, “Performance Schema Status Variable Tables”.
- The `mysqladmin extended-status` command. See Section 4.5.2, “mysqladmin — A MySQL Server Administration Program”.

For `SHOW STATUS`, a `LIKE` clause, if present, indicates which variable names to match. A `WHERE` clause can be given to select rows using more general conditions, as discussed in Section 26.8, “Extensions to SHOW Statements”.

`SHOW STATUS` accepts an optional `GLOBAL` or `SESSION` variable scope modifier:

- With a `GLOBAL` modifier, the statement displays the global status values. A global status variable may represent status for some aspect of the server itself (for example, `Aborted_connects`), or the aggregated status over all connections to MySQL (for example, `Bytes_received` and `Bytes_sent`). If a variable has no global value, the session value is displayed.
- With a `SESSION` modifier, the statement displays the status variable values for the current connection. If a variable has no session value, the global value is displayed. `LOCAL` is a synonym for `SESSION`.
- If no modifier is present, the default is `SESSION`.

The scope for each status variable is listed at Section 5.1.10, “Server Status Variables”.

Each invocation of the `SHOW STATUS` statement uses an internal temporary table and increments the global `Created_tmp_tables` value.

Partial output is shown here. The list of names and values may differ for your server. The meaning of each variable is given in Section 5.1.10, “Server Status Variables”.

```
mysql> SHOW STATUS;
+--------------------------+------------+
| Variable_name            | Value      |
+--------------------------+------------+
| Aborted_clients          | 0          |
| Aborted_connects         | 0          |
| Bytes_received           | 155372598  |
| Bytes_sent               | 1176560426 |
| Connections              | 30023      |
| Created_tmp_disk_tables  | 0          |
| Created_tmp_tables       | 8340       |
| Created_tmp_files        | 60         |
| ...                      |            |
```
SHOW Statements

<table>
<thead>
<tr>
<th>Open_tables</th>
<th>1</th>
</tr>
</thead>
<tbody>
<tr>
<td>Open_files</td>
<td>2</td>
</tr>
<tr>
<td>Open_streams</td>
<td>0</td>
</tr>
<tr>
<td>Opened_tables</td>
<td>44600</td>
</tr>
<tr>
<td>Questions</td>
<td>2026873</td>
</tr>
<tr>

</tbody>
</table>

With a `LIKE` clause, the statement displays only rows for those variables with names that match the pattern:

```
mysql> SHOW STATUS LIKE 'Key%';
+--------------------+----------+
| Variable_name      | Value    |
+--------------------+----------+
| Key_blocks_used    | 14955    |
| Key_read_requests  | 96854827 |
| Key_reads          | 162040   |
| Key_write_requests | 7589728  |
| Key_writes         | 3813196  |
+--------------------+----------+
```

13.7.7.38 SHOW TABLE STATUS Statement

```
SHOW TABLE STATUS
[WHERE expr]
[LIKE 'pattern']
```

`SHOW TABLE STATUS` works like `SHOW TABLES`, but provides a lot of information about each non-TEMPORARY table. You can also get this list using the `mysqlshow --status db_name` command. The `LIKE` clause, if present, indicates which table names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in Section 26.8, “Extensions to SHOW Statements”.

This statement also displays information about views.

`SHOW TABLE STATUS` output has these columns:

- **Name**
  The name of the table.

- **Engine**

  For partitioned tables, `Engine` shows the name of the storage engine used by all partitions.

- **Version**
  This column is unused. With the removal of .frm files in MySQL 8.0, this column now reports a hardcoded value of 10, which is the last .frm file version used in MySQL 5.7.

- **Row_format**
  The row-storage format (Fixed, Dynamic, Compressed, Redundant, Compact). For MyISAM tables, `Dynamic` corresponds to what `myisamchk -dvv` reports as Packed.

- **Rows**
The number of rows. Some storage engines, such as MyISAM, store the exact count. For other storage engines, such as InnoDB, this value is an approximation, and may vary from the actual value by as much as 40% to 50%. In such cases, use `SELECT COUNT(*)` to obtain an accurate count.

The `Rows` value is NULL for INFORMATION_SCHEMA tables.

For InnoDB tables, the row count is only a rough estimate used in SQL optimization. (This is also true if the InnoDB table is partitioned.)

- **Avg_row_length**
  
The average row length.

- **Data_length**
  
  For MyISAM, `Data_length` is the length of the data file, in bytes.

  For InnoDB, `Data_length` is the approximate amount of space allocated for the clustered index, in bytes. Specifically, it is the clustered index size, in pages, multiplied by the InnoDB page size.

  Refer to the notes at the end of this section for information regarding other storage engines.

- **Max_data_length**
  
  For MyISAM, `Max_data_length` is maximum length of the data file. This is the total number of bytes of data that can be stored in the table, given the data pointer size used.

  Unused for InnoDB.

  Refer to the notes at the end of this section for information regarding other storage engines.

- **Index_length**
  
  For MyISAM, `Index_length` is the length of the index file, in bytes.

  For InnoDB, `Index_length` is the approximate amount of space allocated for non-clustered indexes, in bytes. Specifically, it is the sum of non-clustered index sizes, in pages, multiplied by the InnoDB page size.

  Refer to the notes at the end of this section for information regarding other storage engines.

- **Data_free**
  
The number of allocated but unused bytes.

  InnoDB tables report the free space of the tablespace to which the table belongs. For a table located in the shared tablespace, this is the free space of the shared tablespace. If you are using multiple tablespaces and the table has its own tablespace, the free space is for only that table. Free space means the number of bytes in completely free extents minus a safety margin. Even if free space displays as 0, it may be possible to insert rows as long as new extents need not be allocated.

  For NDB Cluster, `Data_free` shows the space allocated on disk for, but not used by, a Disk Data table or fragment on disk. (In-memory data resource usage is reported by the `Data_length` column.)

  For partitioned tables, this value is only an estimate and may not be absolutely correct. A more accurate method of obtaining this information in such cases is to query the INFORMATION_SCHEMA PARTITIONS table, as shown in this example:

  ```sql
  SELECT SUM(Data_free)
  FROM INFORMATION_SCHEMA.PARTITIONS
  ```
SHOW Statements

WHERE TABLE_SCHEMA = 'mydb'
AND   TABLE_NAME   = 'mytable';

For more information, see Section 26.3.21, “The INFORMATION_SCHEMA PARTITIONS Table”.

• **Auto_increment**  
The next AUTO_INCREMENT value.

• **Create_time**  
When the table was created.

• **Update_time**  
When the data file was last updated. For some storage engines, this value is NULL. For example, InnoDB stores multiple tables in its system tablespace and the data file timestamp does not apply. Even with file-per-table mode with each InnoDB table in a separate .ibd file, change buffering can delay the write to the data file, so the file modification time is different from the time of the last insert, update, or delete. For MyISAM, the data file timestamp is used; however, on Windows the timestamp is not updated by updates, so the value is inaccurate.

Update_time displays a timestamp value for the last UPDATE, INSERT, or DELETE performed on InnoDB tables that are not partitioned. For MVCC, the timestamp value reflects the COMMIT time, which is considered the last update time. Timestamps are not persisted when the server is restarted or when the table is evicted from the InnoDB data dictionary cache.

• **Check_time**  
When the table was last checked. Not all storage engines update this time, in which case, the value is always NULL.

For partitioned InnoDB tables, Check_time is always NULL.

• **Collation**  
The table default collation. The output does not explicitly list the table default character set, but the collation name begins with the character set name.

• **Checksum**  
The live checksum value, if any.

• **Create_options**  
Extra options used with CREATE TABLE.

Create_options shows partitioned for a partitioned table.

Prior to MySQL 8.0.16, Create_options shows the ENCRYPTION clause specified for tables created in file-per-table tablespaces. As of MySQL 8.0.16, it shows the encryption clause for file-per-table tablespaces if the table is encrypted or if the specified encryption differs from the schema encryption. The encryption clause is not shown for tables created in general tablespaces. To identify encrypted file-per-table and general tablespaces, query the INNODB_TABLESPACES ENCRYPTION column.

When creating a table with strict mode disabled, the storage engine's default row format is used if the specified row format is not supported. The actual row format of the table is reported in the
Row_format column. Create_options shows the row format that was specified in the CREATE TABLE statement.

When altering the storage engine of a table, table options that are not applicable to the new storage engine are retained in the table definition to enable reverting the table with its previously defined options to the original storage engine, if necessary. Create_options may show retained options.

- **Comment**

  The comment used when creating the table (or information as to why MySQL could not access the table information).

**Notes**

- For InnoDB tables, SHOW TABLE STATUS does not give accurate statistics except for the physical size reserved by the table. The row count is only a rough estimate used in SQL optimization.

- For NDB tables, the output of this statement shows appropriate values for the Avg_row_length and Data_length columns, with the exception that BLOB columns are not taken into account.

- For NDB tables, Data_length includes data stored in main memory only; the Max_data_length and Data_free columns apply to Disk Data.

- For NDB Cluster Disk Data tables, Max_data_length shows the space allocated for the disk part of a Disk Data table or fragment. (In-memory data resource usage is reported by the Data_length column.)

- For MEMORY tables, the Data_length, Max_data_length, and Index_length values approximate the actual amount of allocated memory. The allocation algorithm reserves memory in large amounts to reduce the number of allocation operations.

- For views, most columns displayed by SHOW TABLE STATUS are 0 or NULL except that Name indicates the view name, Create_time indicates the creation time, and Comment says VIEW.

Table information is also available from the INFORMATION_SCHEMA TABLES table. See Section 26.3.38, “The INFORMATION_SCHEMA TABLES Table”.

### 13.7.7.39 SHOW TABLES Statement

```sql
SHOW [EXTENDED] [FULL] TABLES
    [[FROM | IN] db_name]
    [LIKE 'pattern' | WHERE expr]
```

SHOW TABLES lists the non-TEMPORARY tables in a given database. You can also get this list using the mysqlshow db_name command. The LIKE clause, if present, indicates which table names to match. The WHERE clause can be given to select rows using more general conditions, as discussed in Section 26.8, “Extensions to SHOW Statements”.

Matching performed by the LIKE clause is dependent on the setting of the lower_case_table_names system variable.

The optional EXTENDED modifier causes SHOW TABLES to list hidden tables created by failed ALTER TABLE statements. These temporary tables have names beginning with #sql and can be dropped using DROP TABLE.

This statement also lists any views in the database. The optional FULL modifier causes SHOW TABLES to display a second output column with values of BASE TABLE for a table, VIEW for a view, or SYSTEM VIEW for an INFORMATION_SCHEMA table.

If you have no privileges for a base table or view, it does not show up in the output from SHOW TABLES or mysqlshow db_name.
Table information is also available from the `INFORMATION_SCHEMA TABLES` table. See Section 26.3.38, “The INFORMATION_SCHEMA TABLES Table”.

### 13.7.7.40 SHOW TRIGGERS Statement

```sql
SHOW TRIGGERS
[([FROM | IN] db_name]
[LIKE 'pattern' | WHERE expr]
```

`SHOW TRIGGERS` lists the triggers currently defined for tables in a database (the default database unless a `FROM` clause is given). This statement returns results only for databases and tables for which you have the `TRIGGER` privilege. The `LIKE` clause, if present, indicates which table names (not trigger names) to match and causes the statement to display triggers for those tables. The `WHERE` clause can be given to select rows using more general conditions, as discussed in Section 26.8, “Extensions to SHOW Statements”.

For the `ins_sum` trigger defined in Section 25.3, “Using Triggers”, the output of `SHOW TRIGGERS` is as shown here:

```sql
mysql> SHOW TRIGGERS LIKE 'acc%'\G
*************************** 1. row ***************************
Trigger: ins_sum
Event: INSERT
Table: account
Statement: SET @sum = @sum + NEW.amount
Timing: BEFORE
Created: 2018-08-08 10:10:12.61
sql_mode: ONLY_FULL_GROUP_BY,STRICT_TRANS_TABLES,
          NO_ZERO_IN_DATE,NO_ZERO_DATE,
          ERROR_FOR_DIVISION_BY_ZERO,
          NO_ENGINE_SUBSTITUTION
Definer: me@localhost
character_set_client: utf8mb4
collation_connection: utf8mb4_0900_ai_ci
Database Collation: utf8mb4_0900_ai_ci
```

`SHOW TRIGGERS` output has these columns:

- **Trigger**
  The name of the trigger.

- **Event**
  The trigger event. This is the type of operation on the associated table for which the trigger activates. The value is `INSERT` (a row was inserted), `DELETE` (a row was deleted), or `UPDATE` (a row was modified).

- **Table**
  The table for which the trigger is defined.

- **Statement**
  The trigger body; that is, the statement executed when the trigger activates.

- **Timing**
  Whether the trigger activates before or after the triggering event. The value is `BEFORE` or `AFTER`.

- **Created**
  The date and time when the trigger was created. This is a `TIMESTAMP(2)` value (with a fractional part in hundredths of seconds) for triggers.

- **sql_mode**
  2742
SHOW Statements

The SQL mode in effect when the trigger was created, and under which the trigger executes. For the permitted values, see Section 5.1.11, “Server SQL Modes”.

- **Definer**
  The account of the user who created the trigger, in `user_name@host_name` format.

- **character_set_client**
  The session value of the `character_set_client` system variable when the trigger was created.

- **collation_connection**
  The session value of the `collation_connection` system variable when the trigger was created.

- **Database Collation**
  The collation of the database with which the trigger is associated.

Trigger information is also available from the `INFORMATION_SCHEMA TRIGGERS` table. See Section 26.3.45, “The INFORMATION_SCHEMA TRIGGERS Table”.

### 13.7.7.41 SHOW VARIABLES Statement

```
SHOW [GLOBAL | SESSION] VARIABLES
[LIKE 'pattern' | WHERE expr]
```

**SHOW VARIABLES** shows the values of MySQL system variables (see Section 5.1.8, “Server System Variables”). This statement does not require any privilege. It requires only the ability to connect to the server.

System variable information is also available from these sources:

- The `mysqladmin variables` command. See Section 4.5.2, “mysqladmin — A MySQL Server Administration Program”.

For **SHOW VARIABLES**, a **LIKE** clause, if present, indicates which variable names to match. A **WHERE** clause can be given to select rows using more general conditions, as discussed in Section 26.8, “Extensions to SHOW Statements”.

**SHOW VARIABLES** accepts an optional **GLOBAL** or **SESSION** variable scope modifier:

- With a **GLOBAL** modifier, the statement displays global system variable values. These are the values used to initialize the corresponding session variables for new connections to MySQL. If a variable has no global value, no value is displayed.

- With a **SESSION** modifier, the statement displays the system variable values that are in effect for the current connection. If a variable has no session value, the global value is displayed. **LOCAL** is a synonym for **SESSION**.

- If no modifier is present, the default is **SESSION**.

The scope for each system variable is listed at Section 5.1.8, “Server System Variables”.

**SHOW VARIABLES** is subject to a version-dependent display-width limit. For variables with very long values that are not completely displayed, use **SELECT** as a workaround. For example:

```
SELECT @@GLOBAL.innodb_data_file_path;
```
Most system variables can be set at server startup (read-only variables such as `version_comment` are exceptions). Many can be changed at runtime with the `SET` statement. See Section 5.1.9, “Using System Variables”, and Section 13.7.6.1, “SET Syntax for Variable Assignment”.

Partial output is shown here. The list of names and values may differ for your server. Section 5.1.8, “Server System Variables”, describes the meaning of each variable, and Section 5.1.1, “Configuring the Server”, provides information about tuning them.

```
mysql> SHOW VARIABLES;
+--------------------------------------------+------------------------------+
| Variable_name                              | Value                        |
+--------------------------------------------+------------------------------+
| activate_all_roles_on_login                | OFF                          |
| auto_generate_certs                        | ON                           |

With a **LIKE** clause, the statement displays only rows for those variables with names that match the pattern. To obtain the row for a specific variable, use a **LIKE** clause as shown:

SHOW VARIABLES LIKE 'max_join_size';
SHOW SESSION VARIABLES LIKE 'max_join_size';

To get a list of variables whose name match a pattern, use the % wildcard character in a **LIKE** clause:

SHOW VARIABLES LIKE '%size%';
SHOW GLOBAL VARIABLES LIKE '%size%';

Wildcard characters can be used in any position within the pattern to be matched. Strictly speaking, because _is a wildcard that matches any single character, you should escape it as \_ to match it literally. In practice, this is rarely necessary.

### 13.7.7.42 SHOW WARNINGS Statement

SHOW WARNINGS [LIMIT [offset,] row_count]
SHOW COUNT(*) WARNINGS

**SHOW WARNINGS** is a diagnostic statement that displays information about the conditions (errors, warnings, and notes) resulting from executing a statement in the current session. Warnings are generated for DML statements such as INSERT, UPDATE, and LOAD DATA as well as DDL statements such as CREATE TABLE and ALTER TABLE.

The **LIMIT** clause has the same syntax as for the **SELECT** statement. See Section 13.2.10, “SELECT Statement”.

**SHOW WARNINGS** is also used following **EXPLAIN**, to display the extended information generated by **EXPLAIN**. See Section 8.8.3, “Extended EXPLAIN Output Format”.

**SHOW WARNINGS** displays information about the conditions resulting from execution of the most recent nondiagnostic statement in the current session. If the most recent statement resulted in an error during parsing, **SHOW WARNINGS** shows the resulting conditions, regardless of statement type (diagnostic or nondiagnostic).

The **SHOW COUNT(*) WARNINGS** diagnostic statement displays the total number of errors, warnings, and notes. You can also retrieve this number from the **warning_count** system variable:

SHOW COUNT(*) WARNINGS;
SELECT @warning_count;

A difference in these statements is that the first is a diagnostic statement that does not clear the message list. The second, because it is a **SELECT** statement is considered nondiagnostic and does clear the message list.

A related diagnostic statement, **SHOW ERRORS**, shows only error conditions (it excludes warnings and notes), and **SHOW COUNT(*) ERRORS** statement displays the total number of errors. See Section 13.7.7.17, “SHOW ERRORS Statement”. **GET DIAGNOSTICS** can be used to examine information for individual conditions. See Section 13.6.7.3, “GET DIAGNOSTICS Statement”.

2745
Here is a simple example that shows data-conversion warnings for `INSERT`. The example assumes that strict SQL mode is disabled. With strict mode enabled, the warnings would become errors and terminate the `INSERT`.

```sql
SHOW Statements
```

```sql
mysql> CREATE TABLE t1 (a TINYINT NOT NULL, b CHAR(4));
Query OK, 0 rows affected (0.05 sec)

mysql> INSERT INTO t1 VALUES(10,'mysql'), (NULL,'test'), (300,'xyz');
Query OK, 3 rows affected, 3 warnings (0.00 sec)
Records: 3  Duplicates: 0  Warnings: 3

mysql> SHOW WARNINGS\G
*************************** 1. row ***************************
<table>
<thead>
<tr>
<th>Level</th>
<th>Code</th>
<th>Message</th>
</tr>
</thead>
<tbody>
<tr>
<td>Warning</td>
<td>1265</td>
<td>Data truncated for column 'b' at row 1</td>
</tr>
</tbody>
</table>

```

The `max_error_count` system variable controls the maximum number of error, warning, and note messages for which the server stores information, and thus the number of messages that `SHOW WARNINGS` displays. To change the number of messages the server can store, change the value of `max_error_count`.

`max_error_count` controls only how many messages are stored, not how many are counted. The value of `warning_count` is not limited by `max_error_count`, even if the number of messages generated exceeds `max_error_count`. The following example demonstrates this. The `ALTER TABLE` statement produces three warning messages (strict SQL mode is disabled for the example to prevent an error from occurring after a single conversion issue). Only one message is stored and displayed because `max_error_count` has been set to 1, but all three are counted (as shown by the value of `warning_count`):

```sql
mysql> SHOW VARIABLES LIKE 'max_error_count';
+-----------------+-------+
| Variable_name   | Value |
+-----------------+-------+
| max_error_count | 1024  |
+-----------------+-------+
1 row in set (0.00 sec)

mysql> SET max_error_count=1, sql_mode = '';
Query OK, 0 rows affected (0.00 sec)

mysql> ALTER TABLE t1 MODIFY b CHAR;
Query OK, 3 rows affected, 3 warnings (0.00 sec)
Records: 3  Duplicates: 0  Warnings: 3

mysql> SHOW WARNINGS;
*************************** 1. row ***************************
<table>
<thead>
<tr>
<th>Level</th>
<th>Code</th>
<th>Message</th>
</tr>
</thead>
<tbody>
<tr>
<td>Warning</td>
<td>1263</td>
<td>Data truncated for column 'b' at row 1</td>
</tr>
</tbody>
</table>

1 row in set (0.00 sec)

mysql> SELECT @@warning_count;
+-----------------+
| @@warning_count |
+-----------------+
| 3               |
+-----------------+
1 row in set (0.01 sec)
```
To disable message storage, set `max_error_count` to 0. In this case, `warning_count` still indicates how many warnings occurred, but messages are not stored and cannot be displayed.

The `sql_notes` system variable controls whether note messages increment `warning_count` and whether the server stores them. By default, `sql_notes` is 1, but if set to 0, notes do not increment `warning_count` and the server does not store them:

```sql
mysql> SET sql_notes = 1;
mysql> DROP TABLE IF EXISTS test.no_such_table;
Query OK, 0 rows affected, 1 warning (0.00 sec)
mysql> SHOW WARNINGS;
+-------+---------+------------------------------------+
| Level | Code    | Message                           |
+-------+---------+------------------------------------+
| Note  | 1051    | Unknown table 'test.no_such_table' |
+-------+---------+------------------------------------+
1 row in set (0.00 sec)
mysql> SET sql_notes = 0;
mysql> DROP TABLE IF EXISTS test.no_such_table;
Query OK, 0 rows affected (0.00 sec)
mysql> SHOW WARNINGS;
Empty set (0.00 sec)
```

The MySQL server sends to each client a count indicating the total number of errors, warnings, and notes resulting from the most recent statement executed by that client. From the C API, this value can be obtained by calling `mysql_warning_count()`. See `mysql_warning_count()`.

In the `mysql` client, you can enable and disable automatic warnings display using the `warnings` and `nowarning` commands, respectively, or their shortcuts, `\W` and `\w` (see Section 4.5.1.2, "mysql Client Commands"). For example:

```sql
mysql> \W
Show warnings enabled.
mysql> SELECT 1/0;
| 1/0  |
| NULL |
+------+
1 row in set, 1 warning (0.03 sec)
Warning (Code 1365): Division by 0
mysql> \w
Show warnings disabled.
```

## 13.7.8 Other Administrative Statements

### 13.7.8.1 BINLOG Statement

**BINLOG 'str'**

BINLOG is an internal-use statement. It is generated by the `mysqlbinlog` program as the printable representation of certain events in binary log files. (See Section 4.6.9, "mysqlbinlog — Utility for Processing Binary Log Files"). The 'str' value is a base 64-encoded string that the server decodes to determine the data change indicated by the corresponding event.

To execute BINLOG statements when applying `mysqlbinlog` output, a user account requires the `BINLOG_ADMIN` privilege (or the deprecated `SUPER` privilege), or the `REPLICATION_APPLIER` privilege plus the appropriate privileges to execute each log event.

This statement can execute only format description events and row events.

### 13.7.8.2 CACHE INDEX Statement

**CACHE INDEX {**

```sql
tbl_index_list [, tbl_index_list] ...```

**}`**

The `CACHE INDEX` statement assigns table indexes to a specific key cache. It applies only to MyISAM tables, including partitioned MyISAM tables. After the indexes have been assigned, they can be preloaded into the cache if desired with `LOAD INDEX INTO CACHE`.

The following statement assigns indexes from the tables `t1`, `t2`, and `t3` to the key cache named `hot_cache`:

```
mysql> CACHE INDEX t1, t2, t3 IN hot_cache;
```

```
+---------+-------------------+---------+----------+
| Table   | Op                 | Msg_type| Msg_text |
|---------+-------------------+---------+----------+
| test.t1 | assign_to_keycache| status  | OK       |
| test.t2 | assign_to_keycache| status  | OK       |
| test.t3 | assign_to_keycache| status  | OK       |
```

The syntax of `CACHE INDEX` enables you to specify that only particular indexes from a table should be assigned to the cache. However, the implementation assigns all the table's indexes to the cache, so there is no reason to specify anything other than the table name.

The key cache referred to in a `CACHE INDEX` statement can be created by setting its size with a parameter setting statement or in the server parameter settings. For example:

```
SET GLOBAL keycache1.key_buffer_size=128*1024;
```

Key cache parameters are accessed as members of a structured system variable. See Section 5.1.9.5, “Structured System Variables”.

A key cache must exist before you assign indexes to it, or an error occurs:

```
mysql> CACHE INDEX t1 IN non_existent_cache;
ERROR 1284 (HY000): Unknown key cache 'non_existent_cache'
```

By default, table indexes are assigned to the main (default) key cache created at the server startup. When a key cache is destroyed, all indexes assigned to it are reassigned to the default key cache.

Index assignment affects the server globally: If one client assigns an index to a given cache, this cache is used for all queries involving the index, no matter which client issues the queries.

`CACHE INDEX` is supported for partitioned MyISAM tables. You can assign one or more indexes for one, several, or all partitions to a given key cache. For example, you can do the following:

```
CREATE TABLE pt (c1 INT, c2 VARCHAR(50), INDEX i(c1)) ENGINE=MyISAM
PARTITION BY HASH(c1)
PARTITIONS 4;
```

```
SET GLOBAL kc_fast.key_buffer_size = 128 * 1024;
SET GLOBAL kc_slow.key_buffer_size = 128 * 1024;
```

```
CACHE INDEX pt PARTITION (p0) IN kc_fast;
CACHE INDEX pt PARTITION (p1, p3) IN kc_slow;
```

The previous set of statements performs the following actions:

- Creates a partitioned table with 4 partitions; these partitions are automatically named `p0`, ..., `p3`; this table has an index named `i` on column `c1`. 

• Creates 2 key caches named `kc_fast` and `kc_slow`.

• Assigns the index for partition `p0` to the `kc_fast` key cache and the index for partitions `p1` and `p3` to the `kc_slow` key cache; the index for the remaining partition (`p2`) uses the server’s default key cache.

If you wish instead to assign the indexes for all partitions in table `pt` to a single key cache named `kc_all`, you can use either of the following two statements:

```sql
CACHE INDEX pt PARTITION (ALL) IN kc_all;
CACHE INDEX pt IN kc_all;
```

The two statements just shown are equivalent, and issuing either one has exactly the same effect. In other words, if you wish to assign indexes for all partitions of a partitioned table to the same key cache, the `PARTITION (ALL)` clause is optional.

When assigning indexes for multiple partitions to a key cache, the partitions need not be contiguous, and you need not list their names in any particular order. Indexes for any partitions not explicitly assigned to a key cache automatically use the server default key cache.

Index preloading is also supported for partitioned MyISAM tables. For more information, see Section 13.7.8.5, “LOAD INDEX INTO CACHE Statement”.

### 13.7.8.3 FLUSH Statement

```sql
FLUSH [NO_WRITE_TO_BINLOG | LOCAL] {  
  flush_option [, flush_option] ...  
}  

tables_option: {  
  TABLES  
  | TABLES tbl_name [, tbl_name] ...  
  | TABLES WITH READ LOCK  
  | TABLES tbl_name [, tbl_name] ... WITH READ LOCK  
  | TABLES tbl_name [, tbl_name] ... FOR EXPORT  
}
```

The `FLUSH` statement has several variant forms that clear or reload various internal caches, flush tables, or acquire locks. Each `FLUSH` operation requires the privileges indicated in its description.

**Note**

It is not possible to issue `FLUSH` statements within stored functions or triggers. However, you may use `FLUSH` in stored procedures, so long as these are not called from stored functions or triggers. See Section 25.8, “Restrictions on Stored Programs”.

By default, the server writes `FLUSH` statements to the binary log so that they replicate to replicas. To suppress logging, specify the optional `NO_WRITE_TO_BINLOG` keyword or its alias `LOCAL`. 

2749
**Note**

FLUSH LOGS, FLUSH BINARY LOGS, FLUSH TABLES WITH READ LOCK (with or without a table list), and FLUSH TABLES tbl_name ... FOR EXPORT are not written to the binary log in any case because they would cause problems if replicated to a replica.

The FLUSH statement causes an implicit commit. See Section 13.3.3, “Statements That Cause an Implicit Commit”.

The mysqladmin utility provides a command-line interface to some flush operations, using commands such as flush-hosts, flush-logs, flush-privileges, flush-status, and flush-tables. See Section 4.5.2, “mysqladmin — A MySQL Server Administration Program”.

Sending a SIGHUP or SIGUSR1 signal to the server causes several flush operations to occur that are similar to various forms of the FLUSH statement. Signals can be sent by the root system account or the system account that owns the server process. This enables the flush operations to be performed without having to connect to the server, which requires a MySQL account that has privileges sufficient for those operations. See Section 4.10, “Unix Signal Handling in MySQL”.

The RESET statement is similar to FLUSH. See Section 13.7.8.6, “RESET Statement”, for information about using RESET with replication.

The following list describes the permitted FLUSH statement flush_option values. For descriptions of the permitted tables_option values, see FLUSH TABLES Syntax.

- **FLUSH BINARY LOGS**

  Closes and reopening any binary log file to which the server is writing. If binary logging is enabled, the sequence number of the binary log file is incremented by one relative to the previous file.

  This operation requires the RELOAD privilege.

- **FLUSH ENGINE LOGS**

  Closes and reopening any flushable logs for installed storage engines. This causes InnoDB to flush its logs to disk.

  This operation requires the RELOAD privilege.

- **FLUSH ERROR LOGS**

  Closes and reopening any error log file to which the server is writing.

  This operation requires the RELOAD privilege.

- **FLUSH GENERAL LOGS**

  Closes and reopening any general query log file to which the server is writing.

  This operation requires the RELOAD privilege.

  This operation has no effect on tables used for the general query log (see Section 5.4.1, “Selecting General Query Log and Slow Query Log Output Destinations”).

- **FLUSH HOSTS**

  Empties the host cache and the Performance Schema host_cache table that exposes the cache contents, and unblocks any blocked hosts.

  This operation requires the RELOAD privilege.
For information about why host cache flushing might be advisable or desirable, see Section 5.1.12.3, “DNS Lookups and the Host Cache”.

**Note**

`FLUSH HOSTS` is deprecated as of MySQL 8.0.23; expect it to be removed in a future MySQL release. Instead, truncate the Performance Schema `host_cache` table:

```
TRUNCATE TABLE performance_schema.host_cache;
```

The `TRUNCATE TABLE` operation requires the `DROP` privilege for the table rather than the `RELOAD` privilege.

- **FLUSH LOGS**

Closes and reopens any log file to which the server is writing.

This operation requires the `RELOAD` privilege.

The effect of this operation is equivalent to the combined effects of these operations:

```
FLUSH BINARY LOGS
FLUSH ENGINE LOGS
FLUSH ERROR LOGS
FLUSH GENERAL LOGS
FLUSH RELAY LOGS
FLUSH SLOW LOGS
```

- **FLUSH OPTIMIZER_COSTS**

Re-reads the cost model tables so that the optimizer starts using the current cost estimates stored in them.

This operation requires the `FLUSH_OPTIMIZER_COSTS` or `RELOAD` privilege.

The server writes a warning to the error log for any unrecognized cost model table entries. For information about these tables, see Section 8.9.5, “The Optimizer Cost Model”. This operation affects only sessions that begin subsequent to the flush. Existing sessions continue to use the cost estimates that were current when they began.

- **FLUSH PRIVILEGES**

Re-reads the privileges from the grant tables in the `mysql` system schema. As part of this operation, the server reads the `global_grants` table containing dynamic privilege assignments and registers any unregistered privileges found there.

This operation requires the `RELOAD` privilege.

If the `--skip-grant-tables` option was specified at server startup to disable the MySQL privilege system, `FLUSH PRIVILEGES` provides a way to enable the privilege system at runtime.

Resets failed-login tracking (or enables it if the server was started with `--skip-grant-tables`) and unlocks any temporarily locked accounts. See Section 6.2.15, “Password Management”.

Frees memory cached by the server as a result of `GRANT, CREATE_USER, CREATE_SERVER, and INSTALL PLUGIN` statements. This memory is not released by the corresponding `REVOKE, DROP_USER, DROP_SERVER, and UNINSTALL PLUGIN` statements, so for a server that executes many
instances of the statements that cause caching, there is an increase in cached memory use unless it is freed with FLUSH PRIVILEGES.

Casts the in-memory cache used by the caching_sha2_password authentication plugin. See Cache Operation for SHA-2 Pluggable Authentication.

**FLUSH RELAY LOGS [FOR CHANNEL channel]**

Closes and reopens any relay log file to which the server is writing. If relay logging is enabled, the sequence number of the relay log file is incremented by one relative to the previous file.

This operation requires the RELOAD privilege.

The FOR CHANNEL channel clause enables you to name which replication channel the operation applies to. Execute FLUSH RELAY LOGS FOR CHANNEL channel to flush the relay log for a specific replication channel. If no channel is named and no extra replication channels exist, the operation applies to the default channel. If no channel is named and multiple replication channels exist, the operation applies to all replication channels. For more information, see Section 17.2.2, “Replication Channels”.

**FLUSH SLOW LOGS**

Closes and reopens any slow query log file to which the server is writing.

This operation requires the RELOAD privilege.

This operation has no effect on tables used for the slow query log (see Section 5.4.1, “Selecting General Query Log and Slow Query Log Output Destinations”).

**FLUSH STATUS**

Flushes status indicators.

This operation requires the FLUSH_STATUS or RELOAD privilege.

This operation adds the session status from all active sessions to the global status variables, resets the status of all active sessions, and resets account, host, and user status values aggregated from disconnected sessions. See Section 27.12.15, “Performance Schema Status Variable Tables”. This information may be of use when debugging a query. See Section 1.6, “How to Report Bugs or Problems”.

**FLUSH USER_RESOURCES**

Resets all per-hour user resource indicators to zero.

This operation requires the FLUSH_USER_RESOURCES or RELOAD privilege.

Resetting resource indicators enables clients that have reached their hourly connection, query, or update limits to resume activity immediately. FLUSH_USER_RESOURCES does not apply to the limit on maximum simultaneous connections that is controlled by the max_user_connections system variable. See Section 6.2.20, “Setting Account Resource Limits”.

**FLUSH TABLES Syntax**

FLUSH TABLES flushes tables, and, depending on the variant used, acquires locks. Any TABLES variant used in a FLUSH statement must be the only option used. FLUSH TABLE is a synonym for FLUSH TABLES.

**Note**

The descriptions here that indicate tables are flushed by closing them apply differently for InnoDB, which flushes table contents to disk but leaves them
open. This still permits table files to be copied while the tables are open, as long as other activity does not modify them.

- **FLUSH TABLES**

Closes all open tables, forces all tables in use to be closed, and flushes the prepared statement cache.

This operation requires the `FLUSH_TABLES` or `RELOAD` privilege.

For information about prepared statement caching, see Section 8.10.3, “Caching of Prepared Statements and Stored Programs”.

`FLUSH TABLES` is not permitted when there is an active `LOCK TABLES ... READ`. To flush and lock tables, use `FLUSH TABLES tbl_name ... WITH READ LOCK` instead.

- **FLUSH TABLES** `tbl_name [, tbl_name]` ...

With a list of one or more comma-separated table names, this operation is like `FLUSH TABLES` with no names except that the server flushes only the named tables. If a named table does not exist, no error occurs.

This operation requires the `FLUSH_TABLES` or `RELOAD` privilege.

- **FLUSH TABLES WITH READ LOCK**

Closes all open tables and locks all tables for all databases with a global read lock.

This operation requires the `FLUSH_TABLES` or `RELOAD` privilege.

This operation is a very convenient way to get backups if you have a file system such as Veritas or ZFS that can take snapshots in time. Use `UNLOCK TABLES` to release the lock.

`FLUSH TABLES WITH READ LOCK` acquires a global read lock rather than table locks, so it is not subject to the same behavior as `LOCK TABLES` and `UNLOCK TABLES` with respect to table locking and implicit commits:

- **UNLOCK TABLES** implicitly commits any active transaction only if any tables currently have been locked with `LOCK TABLES`. The commit does not occur for `UNLOCK TABLES` following `FLUSH TABLES WITH READ LOCK` because the latter statement does not acquire table locks.

- Beginning a transaction causes table locks acquired with `LOCK TABLES` to be released, as though you had executed `UNLOCK TABLES`. Beginning a transaction does not release a global read lock acquired with `FLUSH TABLES WITH READ LOCK`.

`FLUSH TABLES WITH READ LOCK` does not prevent the server from inserting rows into the log tables (see Section 5.4.1, “Selecting General Query Log and Slow Query Log Output Destinations”).

- **FLUSH TABLES** `tbl_name [, tbl_name]` ... WITH READ LOCK

Flushes and acquires read locks for the named tables.

This operation requires the `FLUSH_TABLES` or `RELOAD` privilege. Because it acquires table locks, it also requires the `LOCK TABLES` privilege for each table.

The operation first acquires exclusive metadata locks for the tables, so it waits for transactions that have those tables open to complete. Then the operation flushes the tables from the table cache, reopens the tables, acquires table locks (like `LOCK TABLES ... READ`), and downgrades the
metadata locks from exclusive to shared. After the operation acquires locks and downgrades the metadata locks, other sessions can read but not modify the tables.

This operation applies only to existing base (non-TEMPORARY) tables. If a name refers to a base table, that table is used. If it refers to a TEMPORARY table, it is ignored. If a name applies to a view, an ER_WRONG_OBJECT error occurs. Otherwise, an ER_NO SUCH_TABLE error occurs.

Use UNLOCK TABLES to release the locks, LOCK TABLES to release the locks and acquire other locks, or START TRANSACTION to release the locks and begin a new transaction.

This FLUSH TABLES variant enables tables to be flushed and locked in a single operation. It provides a workaround for the restriction that FLUSH TABLES is not permitted when there is an active LOCK TABLES ... READ.

This operation does not perform an implicit UNLOCK TABLES, so an error results if you perform the operation while there is any active LOCK TABLES or use it a second time without first releasing the locks acquired.

If a flushed table was opened with HANDLER, the handler is implicitly flushed and loses its position.

- FLUSH TABLES tbl_name [, tbl_name] ... FOR EXPORT

This FLUSH TABLES variant applies to InnoDB tables. It ensures that changes to the named tables have been flushed to disk so that binary table copies can be made while the server is running.

This operation requires the FLUSH_TABLES or RELOAD privilege. Because it acquires locks on tables in preparation for exporting them, it also requires the LOCK TABLES and SELECT privileges for each table.

The operation works like this:

1. It acquires shared metadata locks for the named tables. The operation blocks as long as other sessions have active transactions that have modified those tables or hold table locks for them. When the locks have been acquired, the operation blocks transactions that attempt to update the tables, while permitting read-only operations to continue.

2. It checks whether all storage engines for the tables support FOR EXPORT. If any do not, an ER_ILLEGAL_HA error occurs and the operation fails.

3. The operation notifies the storage engine for each table to make the table ready for export. The storage engine must ensure that any pending changes are written to disk.

4. The operation puts the session in lock-tables mode so that the metadata locks acquired earlier are not released when the FOR EXPORT operation completes.

This operation applies only to existing base (non-TEMPORARY) tables. If a name refers to a base table, that table is used. If it refers to a TEMPORARY table, it is ignored. If a name applies to a view, an ER_WRONG_OBJECT error occurs. Otherwise, an ER_NO_SUCH_TABLE error occurs.

InnoDB supports FOR EXPORT for tables that have their own .ibd file file (that is, tables created with the innodb_file_per_table setting enabled). InnoDB ensures when notified by the FOR EXPORT operation that any changes have been flushed to disk. This permits a binary copy of table contents to be made while the FOR EXPORT operation is in effect because the .ibd file is transaction consistent and can be copied while the server is running. FOR EXPORT does not apply to InnoDB system tablespace files, or to InnoDB tables that have FULLTEXT indexes.

FLUSH TABLES ... FOR EXPORT is supported for partitioned InnoDB tables.

When notified by FOR EXPORT, InnoDB writes to disk certain kinds of data that is normally held in memory or in separate disk buffers outside the tablespace files. For each table, InnoDB also
produces a file named `table_name.cfg` in the same database directory as the table. The `.cfg` file contains metadata needed to reimport the tablespace files later, into the same or different server.

When the `FOR EXPORT` operation completes, InnoDB has flushed all dirty pages to the table data files. Any change buffer entries are merged prior to flushing. At this point, the tables are locked and quiescent: The tables are in a transactionally consistent state on disk and you can copy the `.ibd` tablespace files along with the corresponding `.cfg` files to get a consistent snapshot of those tables.

For the procedure to reimport the copied table data into a MySQL instance, see Section 15.6.1.3, “Importing InnoDB Tables”.

After you are done with the tables, use `UNLOCK TABLES` to release the locks, `LOCK TABLES` to release the locks and acquire other locks, or `START TRANSACTION` to release the locks and begin a new transaction.

While any of these statements is in effect within the session, attempts to use `FLUSH TABLES ... FOR EXPORT` produce an error:

```sql
FLUSH TABLES ... WITH READ LOCK
FLUSH TABLES ... FOR EXPORT
LOCK TABLES ... READ
LOCK TABLES ... WRITE
```

While `FLUSH TABLES ... FOR EXPORT` is in effect within the session, attempts to use any of these statements produce an error:

```sql
FLUSH TABLES WITH READ LOCK
FLUSH TABLES ... WITH READ LOCK
FLUSH TABLES ... FOR EXPORT
```

### 13.7.8.4 KILL Statement

`KILL [CONNECTION | QUERY] processlist_id`

Each connection to `mysqld` runs in a separate thread. You can kill a thread with the `KILL processlist_id` statement.

Thread processlist identifiers can be determined from the `ID` column of the `INFORMATION_SCHEMA PROCESSLIST` table, the `Id` column of `SHOW PROCESSLIST` output, and the `PROCESSLIST_ID` column of the Performance Schema `threads` table. The value for the current thread is returned by the `CONNECTION_ID()` function.

`KILL` permits an optional `CONNECTION` or `QUERY` modifier:

- `KILL CONNECTION` is the same as `KILL` with no modifier: It terminates the connection associated with the given `processlist_id`, after terminating any statement the connection is executing.
- `KILL QUERY` terminates the statement the connection is currently executing, but leaves the connection itself intact.

The ability to see which threads are available to be killed depends on the `PROCESS` privilege:

- Without `PROCESS`, you can see only your own threads.
- With `PROCESS`, you can see all threads.

The ability to kill threads and statements depends on the `CONNECTION_ADMIN` privilege and the deprecated `SUPER` privilege:

- Without `CONNECTION_ADMIN` or `SUPER`, you can kill only your own threads and statements.
- With `CONNECTION_ADMIN` or `SUPER`, you can kill all threads and statements, except that to affect a thread or statement that is executing with the `SYSTEM_USER` privilege, your own session must additionally have the `SYSTEM_USER` privilege.
You can also use the `mysqladmin processlist` and `mysqladmin kill` commands to examine and kill threads.

When you use `KILL`, a thread-specific kill flag is set for the thread. In most cases, it might take some time for the thread to die because the kill flag is checked only at specific intervals:

- During `SELECT` operations, for `ORDER BY` and `GROUP BY` loops, the flag is checked after reading a block of rows. If the kill flag is set, the statement is aborted.
- `ALTER TABLE` operations that make a table copy check the kill flag periodically for each few copied rows read from the original table. If the kill flag was set, the statement is aborted and the temporary table is deleted.

The `KILL` statement returns without waiting for confirmation, but the kill flag check aborts the operation within a reasonably small amount of time. Aborting the operation to perform any necessary cleanup also takes some time.

- During `UPDATE` or `DELETE` operations, the kill flag is checked after each block read and after each updated or deleted row. If the kill flag is set, the statement is aborted. If you are not using transactions, the changes are not rolled back.
- `GET_LOCK()` aborts and returns `NULL`.
- If the thread is in the table lock handler (state: Locked), the table lock is quickly aborted.
- If the thread is waiting for free disk space in a write call, the write is aborted with a “disk full” error message.
- `EXPLAIN ANALYZE` aborts and prints the first row of output. This works in MySQL 8.0.20 and later.

**Warning**

Killing a `REPAIR TABLE` or `OPTIMIZE TABLE` operation on a MyISAM table results in a table that is corrupted and unusable. Any reads or writes to such a table fail until you optimize or repair it again (without interruption).

### 13.7.8.5 LOAD INDEX INTO CACHE Statement

```
LOAD INDEX INTO CACHE
tbl_index_list [, tbl_index_list] ...

tbl_index_list:
  tbl_name
    [PARTITION (partition_list)]
    [{INDEX|KEY} (index_name[, index_name] ...)]
    [IGNORE LEAVES]

partition_list: { 
  partition_name[, partition_name] ...
  | ALL 
}
```

The `LOAD INDEX INTO CACHE` statement preloads a table index into the key cache to which it has been assigned by an explicit `CACHE INDEX` statement, or into the default key cache otherwise.

`LOAD INDEX INTO CACHE` applies only to MyISAM tables, including partitioned MyISAM tables. In addition, indexes on partitioned tables can be preloaded for one, several, or all partitions.

The `IGNORE LEAVES` modifier causes only blocks for the nonleaf nodes of the index to be preloaded.

`IGNORE LEAVES` is also supported for partitioned MyISAM tables.

The following statement preloads nodes (index blocks) of indexes for the tables `t1` and `t2`:

```
mysql> LOAD INDEX INTO CACHE t1, t2 IGNORE LEAVES;
```
This statement preloads all index blocks from \texttt{t1}. It preloads only blocks for the nonleaf nodes from \texttt{t2}.

The syntax of \texttt{LOAD INDEX INTO CACHE} enables you to specify that only particular indexes from a table should be preloaded. However, the implementation preloads all the table's indexes into the cache, so there is no reason to specify anything other than the table name.

It is possible to preload indexes on specific partitions of partitioned \texttt{MyISAM} tables. For example, of the following 2 statements, the first preloads indexes for partition \texttt{p0} of a partitioned table \texttt{pt}, while the second preloads the indexes for partitions \texttt{p1} and \texttt{p3} of the same table:

\begin{verbatim}
LOAD INDEX INTO CACHE pt PARTITION (p0);
LOAD INDEX INTO CACHE pt PARTITION (p1, p3);
\end{verbatim}

To preload the indexes for all partitions in table \texttt{pt}, you can use either of the following two statements:

\begin{verbatim}
LOAD INDEX INTO CACHE pt PARTITION (ALL);
LOAD INDEX INTO CACHE pt;
\end{verbatim}

The two statements just shown are equivalent, and issuing either one has exactly the same effect.

When preloading indexes for multiple partitions, the partitions need not be contiguous, and you need not list their names in any particular order.

\texttt{LOAD INDEX INTO CACHE ... IGNORE LEAVES} fails unless all indexes in a table have the same block size. To determine index block sizes for a table, use \texttt{myisamchk -dv} and check the \texttt{Blocksize} column.

### 13.7.8.6 RESET Statement

<table>
<thead>
<tr>
<th>reset_option</th>
<th>\texttt{RESET}</th>
<th>\texttt{RELOAD}</th>
</tr>
</thead>
</table>
\begin{verbatim}
RESET reset_option [, reset_option] ...

reset_option: {
  MASTER
  | REPLICA
  | SLAVE
}
\end{verbatim}

The \texttt{RESET} statement is used to clear the state of various server operations. You must have the \texttt{RELOAD} privilege to execute \texttt{RESET}.

For information about the \texttt{RESET PERSIST} statement that removes persisted global system variables, see Section 13.7.8.7, “\texttt{RESET PERSIST} Statement”.

\texttt{RESET} acts as a stronger version of the \texttt{FLUSH} statement. See Section 13.7.8.3, “\texttt{FLUSH} Statement”.

The \texttt{RESET} statement causes an implicit commit. See Section 13.3.3, “Statements That Cause an Implicit Commit”.

The following list describes the permitted \texttt{RESET} statement \texttt{reset_option} values:

- \texttt{RESET MASTER}

  Deletes all binary logs listed in the index file, resets the binary log index file to be empty, and creates a new binary log file.
Other Administrative Statements

- **RESET REPLICA | SLAVE**

  Makes the replica forget its replication position in the source binary logs. Also resets the relay log by deleting any existing relay log files and beginning a new one. Use `RESET REPLICA` in place of `RESET SLAVE` from MySQL 8.0.22.

### 13.7.8.7 RESET PERSIST Statement

```sql
RESET PERSIST [[IF EXISTS] system_var_name]
```

`RESET PERSIST` removes persisted global system variable settings from the `mysqld-auto.cnf` option file in the data directory. Removing a persisted system variable causes the variable no longer to be initialized from `mysqld-auto.cnf` at server startup. For more information about persisting system variables and the `mysqld-auto.cnf` file, see Section 5.1.9.3, “Persisted System Variables”.

The privileges required for `RESET PERSIST` depend on the type of system variable to be removed:

- For dynamic system variables, this statement requires the `SYSTEM_VARIABLES_ADMIN` privilege (or the deprecated `SUPER` privilege).
- For read-only system variables, this statement requires the `SYSTEM_VARIABLES_ADMIN` and `PERSIST_RO_VARIABLES_ADMIN` privileges.

See Section 5.1.9.1, “System Variable Privileges”.

Depending on whether the variable name and `IF EXISTS` clauses are present, the `RESET PERSIST` statement has these forms:

- To remove all persisted variables from `mysqld-auto.cnf`, use `RESET PERSIST` without naming any system variable:

  ```sql
  RESET PERSIST;
  ```

  You must have privileges for removing both dynamic and read-only system variables if `mysqld-auto.cnf` contains both kinds of variables.

- To remove a specific persisted variable from `mysqld-auto.cnf`, name it in the statement:

  ```sql
  RESET PERSIST system_var_name;
  ```

  This includes plugin system variables, even if the plugin is not currently installed. If the variable is not present in the file, an error occurs.

- To remove a specific persisted variable from `mysqld-auto.cnf`, but produce a warning rather than an error if the variable is not present in the file, add an `IF EXISTS` clause to the previous syntax:

  ```sql
  RESET PERSIST IF EXISTS system_var_name;
  ```

`RESET PERSIST` is not affected by the value of the `persisted_globals_load` system variable.

`RESET PERSIST` affects the contents of the Performance Schema `persisted_variables` table because the table contents correspond to the contents of the `mysqld-auto.cnf` file. On the other hand, because `RESET PERSIST` does not change variable values, it has no effect on the contents of the Performance Schema `variables_info` table until the server is restarted.

For information about `RESET` statement variants that clear the state of other server operations, see Section 13.7.8.6, “RESET Statement”.

### 13.7.8.8 RESTART Statement

```sql
RESTART
```

This statement stops and restarts the MySQL server. It requires the `SHUTDOWN` privilege.
One use for **RESTART** is when it is not possible or convenient to gain command-line access to the MySQL server on the server host to restart it. For example, **SET PERSIST_ONLY** can be used at runtime to make configuration changes to system variables that can be set only at server startup, but the server must still be restarted for those changes to take effect. The **RESTART** statement provides a way to do so from within client sessions, without requiring command-line access on the server host.

**Note**

After executing a **RESTART** statement, the client can expect the current connection to be lost. If auto-reconnect is enabled, the connection is reestablished after the server restarts. Otherwise, the connection must be reestablished manually.

A successful **RESTART** operation requires **mysqld** to be running in an environment that has a monitoring process available to detect a server shutdown performed for restart purposes:

- In the presence of a monitoring process, **RESTART** causes **mysqld** to terminate such that the monitoring process can determine that it should start a new **mysqld** instance.
- If no monitoring process is present, **RESTART** fails with an error.

These platforms provide the necessary monitoring support for the **RESTART** statement:

- Windows, when **mysqld** is started as a Windows service or standalone. (**mysqld** forks, and one process acts as a monitor to the other, which acts as the server.)
- Unix and Unix-like systems that use systemd or **mysqld_safe** to manage **mysqld**.

To configure a monitoring environment such that **mysqld** enables the **RESTART** statement:

1. Set the **MYSQLD_PARENT_PID** environment variable to the value of the process ID of the process that starts **mysqld**, before starting **mysqld**.
2. When **mysqld** performs a shutdown due to use of the **RESTART** statement, it returns exit code 16.
3. When the monitoring process detects an exit code of 16, it starts **mysqld** again. Otherwise, it exits.

Here is a minimal example as implemented in the **bash** shell:

```bash
#!/bin/bash
export MYSQLD_PARENT_PID=$$
export MYSQLD_RESTART_EXIT=16
while true ; do
  bin/mysqld mysql options here
  if [ $? -ne $MYSQLD_RESTART_EXIT ]; then
    break
  fi
done
```

On Windows, the forking used to implement **RESTART** makes determining the server process to attach to for debugging more difficult. To alleviate this, starting the server with **--gdb** suppresses forking, in addition to its other actions done to set up a debugging environment. In non-debug settings, **--no-monitor** may be used for the sole purpose of suppressing forking the monitor process. For a server started with either **--gdb** or **--no-monitor**, executing **RESTART** causes the server to simply exit without restarting.

The **Com_restart** status variable tracks the number of **RESTART** statements. Because status variables are initialized for each server startup and do not persist across restarts, **Com_restart** normally has a value of zero, but can be nonzero if **RESTART** statements were executed but failed.

**13.7.8.9 SHUTDOWN Statement**
Utility Statements

**13.8 Utility Statements**

**13.8.1 DESCRIBE Statement**

The `DESCRIBE` and `EXPLAIN` statements are synonyms, used either to obtain information about table structure or query execution plans. For more information, see Section 13.7.7.5, “SHOW COLUMNS Statement”, and Section 13.8.2, “EXPLAIN Statement”.

**13.8.2 EXPLAIN Statement**

```yaml
{EXPLAIN | DESCRIBE | DESC}
  tbl_name [col_name | wild]
{EXPLAIN | DESCRIBE | DESC}
  [explain_type]
    {explainable_stmt | FOR CONNECTION connection_id}
{EXPLAIN | DESCRIBE | DESC} ANALYZE [FORMAT = TREE] select_statement
```

`explain_type`:

```yaml
  { FORMAT = format_name
  }
```

`format_name`:

```yaml
  { TRADITIONAL
    | JSON
    | TREE
  }
```

`explainable_stmt`:

```yaml
  { SELECT statement
    | TABLE statement
    | DELETE statement
    | INSERT statement
    | REPLACE statement
    | UPDATE statement
  }
```

The `DESCRIBE` and `EXPLAIN` statements are synonyms. In practice, the `DESCRIBE` keyword is more often used to obtain information about table structure, whereas `EXPLAIN` is used to obtain a query execution plan (that is, an explanation of how MySQL would execute a query).

The following discussion uses the `DESCRIBE` and `EXPLAIN` keywords in accordance with those uses, but the MySQL parser treats them as completely synonymous.

- Obtaining Table Structure Information
- Obtaining Execution Plan Information
- Obtaining Information with `EXPLAIN ANALYZE`
Obtaining Table Structure Information

DESCRIBE provides information about the columns in a table:

```sql
mysql> DESCRIBE City;
+----------+----------+------+-----+---------+----------------+
| Field    | Type     | Null | Key | Default | Extra          |
|----------+----------+------+-----+---------+----------------+
| Id       | int(11)  | NO   | PRI | NULL    | auto_increment |
| Name     | char(35) | NO   |     |         |                |
| Country  | char(3)  | NO   | UNI |         |                |
| District | char(20) | YES  | MUL |         |                |
| Population | int(11) | NO   |     | 0       |                |
+----------+----------+------+-----+---------+----------------+
```

DESCRIBE is a shortcut for SHOW COLUMNS. These statements also display information for views.

The description for SHOW COLUMNS provides more information about the output columns. See Section 13.7.7.5, “SHOW COLUMNS Statement”.

By default, DESCRIBE displays information about all columns in the table. col_name, if given, is the name of a column in the table. In this case, the statement displays information only for the named column. wild, if given, is a pattern string. It can contain the SQL % and _ wildcard characters. In this case, the statement displays output only for the columns with names matching the string. There is no need to enclose the string within quotation marks unless it contains spaces or other special characters.

The DESCRIBE statement is provided for compatibility with Oracle.

The SHOW CREATE TABLE, SHOW TABLE STATUS, and SHOW INDEX statements also provide information about tables. See Section 13.7.7, “SHOW Statements”.

Obtaining Execution Plan Information

The EXPLAIN statement provides information about how MySQL executes statements:

- EXPLAIN works with SELECT, DELETE, INSERT, REPLACE, and UPDATE statements. In MySQL 8.0.19 and later, it also works with TABLE statements.
- When EXPLAIN is used with an explainable statement, MySQL displays information from the optimizer about the statement execution plan. That is, MySQL explains how it would process the statement, including information about how tables are joined and in which order. For information about using EXPLAIN to obtain execution plan information, see Section 8.8.2, “EXPLAIN Output Format”.
- When EXPLAIN is used with FOR CONNECTION connection_id rather than an explainable statement, it displays the execution plan for the statement executing in the named connection. See Section 8.8.4, “Obtaining Execution Plan Information for a Named Connection”.
- For explainable statements, EXPLAIN produces additional execution plan information that can be displayed using SHOW WARNINGS. See Section 8.8.3, “Extended EXPLAIN Output Format”.
- EXPLAIN is useful for examining queries involving partitioned tables. See Section 24.3.5, “Obtaining Information About Partitions”.
- The FORMAT option can be used to select the output format. TRADITIONAL presents the output in tabular format. This is the default if no FORMAT option is present. JSON format displays the information in JSON format. In MySQL 8.0.16 and later, TREE provides tree-like output with more precise descriptions of query handling than the TRADITIONAL format; it is the only format which shows hash join usage (see Section 8.2.1.4, “Hash Join Optimization”) and is always used for EXPLAIN ANALYZE.

EXPLAIN requires the same privileges required to execute the explained statement. Additionally, EXPLAIN also requires the SHOW VIEW privilege for any explained view. EXPLAIN ... FOR
**EXPLAIN Statement**

`CONNECTION` also requires the `PROCESS` privilege if the specified connection belongs to a different user.

With the help of `EXPLAIN`, you can see where you should add indexes to tables so that the statement executes faster by using indexes to find rows. You can also use `EXPLAIN` to check whether the optimizer joins the tables in an optimal order. To give a hint to the optimizer to use a join order corresponding to the order in which the tables are named in a `SELECT` statement, begin the statement with `SELECT STRAIGHT_JOIN` rather than just `SELECT`. (See Section 13.2.10, “SELECT Statement”.)

The optimizer trace may sometimes provide information complementary to that of `EXPLAIN`. However, the optimizer trace format and content are subject to change between versions. For details, see *MySQL Internals: Tracing the Optimizer*.

If you have a problem with indexes not being used when you believe that they should be, run `ANALYZE TABLE` to update table statistics, such as cardinality of keys, that can affect the choices the optimizer makes. See Section 13.7.3.1, “ANALYZE TABLE Statement”.

**Note**

MySQL Workbench has a Visual Explain capability that provides a visual representation of `EXPLAIN` output. See Tutorial: Using Explain to Improve Query Performance.

**Obtaining Information with EXPLAIN ANALYZE**

MySQL 8.0.18 introduces `EXPLAIN ANALYZE`, which runs a statement and produces `EXPLAIN` output along with timing and additional, iterator-based, information about how the optimizer’s expectations matched the actual execution. For each iterator, the following information is provided:

- Estimated execution cost
  (Some iterators are not accounted for by the cost model, and so are not included in the estimate.)
- Estimated number of returned rows
- Time to return first row
- Time to return all rows (actual cost), in milliseconds
  (When there are multiple loops, this figure shows the average time per loop.)
- Number of rows returned by the iterator
- Number of loops

The query execution information is displayed using the `TREE` output format, in which nodes represent iterators. `EXPLAIN ANALYZE` always uses the `TREE` output format. In MySQL 8.0.21 and later, this can optionally be specified explicitly using `FORMAT=TREE`; formats other than `TREE` remain unsupported.

`EXPLAIN ANALYZE` can be used with `SELECT` statements, as well as with multi-table `UPDATE` and `DELETE` statements. Beginning with MySQL 8.0.19, it can also be used with `TABLE` statements.

Beginning with MySQL 8.0.20, you can terminate this statement using `KILL QUERY` or `CTRL-C`.

`EXPLAIN ANALYZE` cannot be used with `FOR CONNECTION`.

Example output:

```
mysql> EXPLAIN ANALYZE SELECT * FROM t1 JOIN t2 ON (t1.c1 = t2.c2)
+-----------------+-----------------+-----------------+
| EXPLAIN:  | Inner hash join | (t2.c2 = t1.c1) |
| cost=4.70     | 4.70            | 4.70            |
| rows=6        | 6               | 6               |
```

2762
The tables used in the example output were created by the statements shown here:

```sql
CREATE TABLE t1 (  
c1 INTEGER DEFAULT NULL,  
c2 INTEGER DEFAULT NULL
);
CREATE TABLE t2 (  
c1 INTEGER DEFAULT NULL,  
c2 INTEGER DEFAULT NULL
);
CREATE TABLE t3 (  
  pk INTEGER NOT NULL PRIMARY KEY,  
i INTEGER DEFAULT NULL
);
```

Values shown for `actual time` in the output of this statement are expressed in milliseconds.

### 13.8.3 HELP Statement

The **HELP** statement returns online information from the MySQL Reference Manual. Its proper operation requires that the help tables in the `mysql` database be initialized with help topic information (see Section 5.1.17, "Server-Side Help Support").

The **HELP** statement searches the help tables for the given search string and displays the result of the search. The search string is not case-sensitive.

The search string can contain the wildcard characters `%` and `_`. These have the same meaning as for pattern-matching operations performed with the `LIKE` operator. For example, `HELP 'rep%'` returns a list of topics that begin with `rep`.

The **HELP** statement understands several types of search strings:

- **At the most general level, use `contents` to retrieve a list of the top-level help categories:**

  ```sql
  HELP 'contents'
  ```

- **For a list of topics in a given help category, such as Data Types, use the category name:**

  ```sql
  HELP 'data types'
  ```

- **For help on a specific help topic, such as the ASCII() function or the CREATE TABLE statement, use the associated keyword or keywords:**

  ```sql
  HELP 'ascii'
  ```
HELP 'ascii'
HELP 'create table'

In other words, the search string matches a category, many topics, or a single topic. You cannot necessarily tell in advance whether a given search string returns a list of items or the help information for a single help topic. However, you can tell what kind of response HELP returned by examining the number of rows and columns in the result set.

The following descriptions indicate the forms that the result set can take. Output for the example statements is shown using the familiar “tabular” or “vertical” format that you see when using the mysql client, but note that mysql itself reformats HELP result sets in a different way.

- Empty result set
  No match could be found for the search string.

- Result set containing a single row with three columns
  This means that the search string yielded a hit for the help topic. The result has three columns:
  - **name**: The topic name.
  - **description**: Descriptive help text for the topic.
  - **example**: Usage example or examples. This column might be blank.

  **Example**: HELP 'replace'

  **Yields**:

<table>
<thead>
<tr>
<th>name</th>
<th>description</th>
<th>example</th>
</tr>
</thead>
<tbody>
<tr>
<td>REPLACE</td>
<td>Syntax: REPLACE(str,from_str,to_str)</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Returns the string str with all occurrences of the string from_str replaced by the string to_str. REPLACE() performs a case-sensitive match when searching for from_str.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>example: mysql&gt; SELECT REPLACE('www.mysql.com', 'w', 'Ww');</td>
<td></td>
</tr>
<tr>
<td></td>
<td>-&gt; 'WwWwWw.mysql.com'</td>
<td></td>
</tr>
</tbody>
</table>

- Result set containing multiple rows with two columns
  This means that the search string matched many help topics. The result set indicates the help topic names:
  - **name**: The help topic name.
  - **is_it_category**: Y if the name represents a help category, N if it does not. If it does not, the name value when specified as the argument to the HELP statement should yield a single-row result set containing a description for the named item.

  **Example**: HELP 'status'

  **Yields**:

<table>
<thead>
<tr>
<th>name</th>
<th>is_it_category</th>
</tr>
</thead>
<tbody>
<tr>
<td>SHOW</td>
<td>N</td>
</tr>
<tr>
<td>SHOW ENGINE</td>
<td>N</td>
</tr>
<tr>
<td>SHOW MASTER STATUS</td>
<td>N</td>
</tr>
<tr>
<td>SHOW PROCEDURE STATUS</td>
<td>N</td>
</tr>
<tr>
<td>SHOW SLAVE STATUS</td>
<td>N</td>
</tr>
<tr>
<td>SHOW STATUS</td>
<td>N</td>
</tr>
<tr>
<td>SHOW TABLE STATUS</td>
<td>N</td>
</tr>
</tbody>
</table>
• Result set containing multiple rows with three columns

This means the search string matches a category. The result set contains category entries:

• source_category_name: The help category name.

• name: The category or topic name

• is_it_category: Y if the name represents a help category, N if it does not. If it does not, the name value when specified as the argument to the HELP statement should yield a single-row result set containing a description for the named item.

Example: HELP 'functions'

Yields:

<table>
<thead>
<tr>
<th>source_category_name</th>
<th>name</th>
<th>is_it_category</th>
</tr>
</thead>
<tbody>
<tr>
<td>Functions</td>
<td>CREATE FUNCTION</td>
<td>N</td>
</tr>
<tr>
<td>Functions</td>
<td>DROP FUNCTION</td>
<td>N</td>
</tr>
<tr>
<td>Functions</td>
<td>Bit Functions</td>
<td>Y</td>
</tr>
<tr>
<td>Functions</td>
<td>Comparison operators</td>
<td>Y</td>
</tr>
<tr>
<td>Functions</td>
<td>Control flow functions</td>
<td>Y</td>
</tr>
<tr>
<td>Functions</td>
<td>Date and Time Functions</td>
<td>Y</td>
</tr>
<tr>
<td>Functions</td>
<td>Encryption Functions</td>
<td>Y</td>
</tr>
<tr>
<td>Functions</td>
<td>Information Functions</td>
<td>Y</td>
</tr>
<tr>
<td>Functions</td>
<td>Logical operators</td>
<td>Y</td>
</tr>
<tr>
<td>Functions</td>
<td>Miscellaneous Functions</td>
<td>Y</td>
</tr>
<tr>
<td>Functions</td>
<td>Numeric Functions</td>
<td>Y</td>
</tr>
<tr>
<td>Functions</td>
<td>String Functions</td>
<td>Y</td>
</tr>
</tbody>
</table>

13.8.4 USE Statement

USE db_name

The USE statement tells MySQL to use the named database as the default (current) database for subsequent statements. This statement requires some privilege for the database or some object within it.

The named database remains the default until the end of the session or another USE statement is issued:

USE db1;
SELECT COUNT(*) FROM mytable; # selects from db1.mytable
USE db2;
SELECT COUNT(*) FROM mytable; # selects from db2.mytable

The database name must be specified on a single line. Newlines in database names are not supported.

Making a particular database the default by means of the USE statement does not preclude accessing tables in other databases. The following example accesses the author table from the db1 database and the editor table from the db2 database:

USE db1;
SELECT author_name,editor_name FROM author,db2.editor
WHERE author.editor_id = db2.editor.editor_id;

14.8 Data Dictionary Limitations .......................................................... 2774

MySQL Server incorporates a transactional data dictionary that stores information about database objects. In previous MySQL releases, dictionary data was stored in metadata files, nontransactional tables, and storage engine-specific data dictionaries.

This chapter describes the main features, benefits, usage differences, and limitations of the data dictionary. For other implications of the data dictionary feature, refer to the “Data Dictionary Notes” section in the MySQL 8.0 Release Notes.

Benefits of the MySQL data dictionary include:

• Simplicity of a centralized data dictionary schema that uniformly stores dictionary data. See Section 14.1, “Data Dictionary Schema”.

• Transactional, crash-safe storage of dictionary data. See Section 14.3, “Transactional Storage of Dictionary Data”.

• Uniform and centralized caching for dictionary objects. See Section 14.4, “Dictionary Object Cache”.

• A simpler and improved implementation for some INFORMATION_SCHEMA tables. See Section 14.5, “INFORMATION_SCHEMA and Data Dictionary Integration”.

• Atomic DDL. See Section 13.1.1, “Atomic Data Definition Statement Support”.

Important
A data dictionary-enabled server entails some general operational differences compared to a server that does not have a data dictionary; see Section 14.7, “Data Dictionary Usage Differences”. Also, for upgrades to MySQL 8.0, the upgrade procedure differs somewhat from previous MySQL releases and requires that you verify the upgrade readiness of your installation by checking specific prerequisites. For more information, see Section 2.11, “Upgrading MySQL”, particularly Section 2.11.5, “Preparing Your Installation for Upgrade”.

14.1 Data Dictionary Schema

Data dictionary tables are protected and may only be accessed in debug builds of MySQL. However, MySQL supports access to data stored in data dictionary tables through INFORMATION_SCHEMA tables and SHOW statements. For an overview of the tables that comprise the data dictionary, see Data Dictionary Tables.

MySQL system tables still exist in MySQL 8.0 and can be viewed by issuing a SHOW TABLES statement on the mysql system database. Generally, the difference between MySQL data dictionary
tables and system tables is that data dictionary tables contain metadata required to execute SQL queries, whereas system tables contain auxiliary data such as time zone and help information. MySQL system tables and data dictionary tables also differ in how they are upgraded. The MySQL server manages data dictionary upgrades. SQL server. See How the Data Dictionary is Upgraded. Upgrading MySQL system tables requires running the full MySQL upgrade procedure. See Section 2.11.3, “What the MySQL Upgrade Process Upgrades”.

How the Data Dictionary is Upgraded

New versions of MySQL may include changes to data dictionary table definitions. Such changes are present in newly installed versions of MySQL, but when performing an in-place upgrade of MySQL binaries, changes are applied when the MySQL server is restarted using the new binaries. At startup, the data dictionary version of the server is compared to the version information stored in the data dictionary to determine if data dictionary tables should be upgraded. If an upgrade is necessary and supported, the server creates data dictionary tables with updated definitions, copies persisted metadata to the new tables, atomically replaces the old tables with the new ones, and reinitializes the data dictionary. If an upgrade is not necessary, startup continues without updating the data dictionary tables.

Upgrade of data dictionary tables is an atomic operation, which means that all of the data dictionary tables are upgraded as necessary or the operation fails. If the upgrade operation fails, server startup fails with an error. In this case, the old server binaries can be used with the old data directory to start the server. When the new server binaries are used again to start the server, the data dictionary upgrade is reattempted.

Generally, after data dictionary tables are successfully upgraded, it is not possible to restart the server using the old server binaries. As a result, downgrading MySQL server binaries to a previous MySQL version is not supported after data dictionary tables are upgraded.

The `mysqld --no-dd-upgrade` option can be used to prevent automatic upgrade of data dictionary tables at startup. When `--no-dd-upgrade` is specified, and the server finds that the data dictionary version of the server is different from the version stored in the data dictionary, startup fails with an error stating that the data dictionary upgrade is prohibited.

Viewing Data Dictionary Tables Using a Debug Build of MySQL

Data dictionary tables are protected by default but can be accessed by compiling MySQL with debugging support (using the `-DWITH_DEBUG=1` CMake option) and specifying the `+d,skip_dd_table_access_check` debug option and modifier. For information about compiling debug builds, see Section 5.9.1.1, “Compiling MySQL for Debugging”.

Warning
Modifying or writing to data dictionary tables directly is not recommended and may render your MySQL instance inoperable.

After compiling MySQL with debugging support, use this `SET` statement to make data dictionary tables visible to the `mysql` client session:

```sql
mysql> SET SESSION debug='+d,skip_dd_table_access_check';
```

Use this query to retrieve a list of data dictionary tables:

```sql
mysql> SELECT name, schema_id, hidden, type FROM mysql.tables where schema_id=1 AND hidden='System';
```

Use `SHOW CREATE TABLE` to view data dictionary table definitions. For example:

```sql
mysql> SHOW CREATE TABLE mysql.catalogs\G
```

14.2 Removal of File-based Metadata Storage

In previous MySQL releases, dictionary data was partially stored in metadata files. Issues with file-based metadata storage included expensive file scans, susceptibility to file system-related bugs,
complex code for handling of replication and crash recovery failure states, and a lack of extensibility that made it difficult to add metadata for new features and relational objects.

The metadata files listed below are removed from MySQL. Unless otherwise noted, data previously stored in metadata files is now stored in data dictionary tables.

- **.frm** files: Table metadata files. With the removal of `.frm` files:
  - The 64KB table definition size limit imposed by the `.frm` file structure is removed.
  - The `INFORMATION_SCHEMA.TABLES` `VERSION` column reports a hardcoded value of 10, which is the last `.frm` file version used in MySQL 5.7.
- **.par** files: Partition definition files. InnoDB stopped using partition definition files in MySQL 5.7 with the introduction of native partitioning support for InnoDB tables.
- **.TRN** files: Trigger namespace files.
- **.TRG** files: Trigger parameter files.
- **.isl** files: InnoDB Symbolic Link files containing the location of `file-per-table` tablespace files created outside of the data directory.
- **db.opt** files: Database configuration files. These files, one per database directory, contained database default character set attributes.
- **ddl_log.log** file: The file contained records of metadata operations generated by data definition statements such as `DROP TABLE` and `ALTER TABLE`.

### 14.3 Transactional Storage of Dictionary Data

The data dictionary schema stores dictionary data in transactional (InnoDB) tables. Data dictionary tables are located in the `mysql` database together with non-data dictionary system tables.

Data dictionary tables are created in a single InnoDB tablespace named `mysql.ibd`, which resides in the MySQL data directory. The `mysql.ibd` tablespace file must reside in the MySQL data directory and its name cannot be modified or used by another tablespace.

Dictionary data is protected by the same commit, rollback, and crash-recovery capabilities that protect user data that is stored in InnoDB tables.

### 14.4 Dictionary Object Cache

The dictionary object cache is a shared global cache that stores previously accessed data dictionary objects in memory to enable object reuse and minimize disk I/O. Similar to other cache mechanisms used by MySQL, the dictionary object cache uses an LRU-based eviction strategy to evict least recently used objects from memory.

The dictionary object cache comprises cache partitions that store different object types. Some cache partition size limits are configurable, whereas others are hardcoded.

- **tablespace definition cache partition**: Stores tablespace definition objects. The `tablespace_definition_cache` option sets a limit for the number of tablespace definition objects that can be stored in the dictionary object cache. The default value is 256.
- **schema definition cache partition**: Stores schema definition objects. The `schema_definition_cache` option sets a limit for the number of schema definition objects that can be stored in the dictionary object cache. The default value is 256.
- **table definition cache partition**: Stores table definition objects. The object limit is set to the value of `max_connections`, which has a default value of 151.
The table definition cache partition exists in parallel with the table definition cache that is configured using the `table_definition_cache` configuration option. Both caches store table definitions but serve different parts of the MySQL server. Objects in one cache have no dependence on the existence of objects in the other.

- **stored program definition cache partition**: Stores stored program definition objects. The `stored_program_definition_cache` option sets a limit for the number of stored program definition objects that can be stored in the dictionary object cache. The default value is 256.

  The stored program definition cache partition exists in parallel with the stored procedure and stored function caches that are configured using the `stored_program_cache` option.

  The `stored_program_cache` option sets a soft upper limit for the number of cached stored procedures or functions per connection, and the limit is checked each time a connection executes a stored procedure or function. The stored program definition cache partition, on the other hand, is a shared cache that stores stored program definition objects for other purposes. The existence of objects in the stored program definition cache partition has no dependence on the existence of objects in the stored procedure cache or stored function cache, and vice versa.

- **character set definition cache partition**: Stores character set definition objects and has a hardcoded object limit of 256.

- **collation definition cache partition**: Stores collation definition objects and has a hardcoded object limit of 256.

For information about valid values for dictionary object cache configuration options, refer to Section 5.1.8, “Server System Variables”.

### 14.5 INFORMATION_SCHEMA and Data Dictionary Integration

With the introduction of the data dictionary, the following `INFORMATION_SCHEMA` tables are implemented as views on data dictionary tables:

- `CHARACTER_SETS`
- `CHECK_CONSTRAINTS`
- `COLLATIONS`
- `COLLATION_CHARACTER_SET_APPLICABILITY`
- `COLUMNS`
- `COLUMN_STATISTICS`
- `EVENTS`
- `FILES`
- `INNODB_COLUMNS`
- `INNODB_DATAFILES`
- `INNODB_FIELDS`
- `INNODB_FOREIGN`
- `INNODB_FOREIGN_COLS`
- `INNODB_INDEXES`
- `INNODB_TABLES`
- `INNODB_TABLESPACES`
Queries on those tables are now more efficient because they obtain information from data dictionary tables rather than by other, slower means. In particular, for each INFORMATION_SCHEMA table that is a view on data dictionary tables:

- The server no longer must create a temporary table for each query of the INFORMATION_SCHEMA table.

- When the underlying data dictionary tables store values previously obtained by directory scans (for example, to enumerate database names or table names within databases) or file-opening operations (for example, to read information from .frm files), INFORMATION_SCHEMA queries for those values now use table lookups instead. (Additionally, even for a non-view INFORMATION_SCHEMA table, values such as database and table names are retrieved by lookups from the data dictionary and do not require directory or file scans.)

- Indexes on the underlying data dictionary tables permit the optimizer to construct efficient query execution plans, something not true for the previous implementation that processed the INFORMATION_SCHEMA table using a temporary table per query.

The preceding improvements also apply to SHOW statements that display information corresponding to the INFORMATION_SCHEMA tables that are views on data dictionary tables. For example, SHOW DATABASES displays the same information as the SCHEMATA table.

In addition to the introduction of views on data dictionary tables, table statistics contained in the STATISTICS and TABLES tables is now cached to improve INFORMATION_SCHEMA query performance. The information_schema_stats_expiry system variable defines the period of time before cached table statistics expire. The default is 86400 seconds (24 hours). If there are no cached statistics or statistics have expired, statistics are retrieved from storage engine when querying table statistics columns. To update cached values at any time for a given table, use ANALYZE TABLE
Serialized Dictionary Information (SDI)

**information_schema_stats_expiry** can be set to 0 to have **INFORMATION_SCHEMA** queries retrieve the latest statistics directly from the storage engine, which is not as fast as retrieving cached statistics.

For more information, see Section 8.2.3, “Optimizing INFORMATION_SCHEMA Queries”.

**INFORMATION_SCHEMA** tables in MySQL 8.0 are closely tied to the data dictionary, resulting in several usage differences. See Section 14.7, “Data Dictionary Usage Differences”.

### 14.6 Serialized Dictionary Information (SDI)

In addition to storing metadata about database objects in the data dictionary, MySQL stores it in serialized form. This data is referred to as serialized dictionary information (SDI). InnoDB stores SDI data within its tablespace files. NDBCLUSTER stores SDI data in the NDB dictionary. Other storage engines store SDI data in .sdi files that are created for a given table in the table’s database directory. SDI data is generated in a compact JSON format.

Serialized dictionary information (SDI) is present in all InnoDB tablespace files except for temporary tablespace and undo tablespace files. SDI records in an InnoDB tablespace file only describe table and tablespace objects contained within the tablespace.

SDI data is updated by DDL operations on a table or **CHECK TABLE FOR UPGRADE**. SDI data is not updated when the MySQL server is upgraded to a new release or version.

The presence of SDI data provides metadata redundancy. For example, if the data dictionary becomes unavailable, object metadata can be extracted directly from InnoDB tablespace files using the ibd2sdi tool.

For InnoDB, an SDI record requires a single index page, which is 16KB in size by default. However, SDI data is compressed to reduce the storage footprint.

For partitioned InnoDB tables comprised of multiple tablespaces, SDI data is stored in the tablespace file of the first partition.

The MySQL server uses an internal API that is accessed during DDL operations to create and maintain SDI records.

The **IMPORT TABLE** statement imports MyISAM tables based on information contained in .sdi files. For more information, see Section 13.2.5, “IMPORT TABLE Statement”.

### 14.7 Data Dictionary Usage Differences

Use of a data dictionary-enabled MySQL server entails some operational differences compared to a server that does not have a data dictionary:

- Previously, enabling the **innodb_read_only** system variable prevented creating and dropping tables only for the InnoDB storage engine. As of MySQL 8.0, enabling **innodb_read_only** prevents these operations for all storage engines. Table creation and drop operations for any storage engine modify data dictionary tables in the mysql system database, but those tables use the InnoDB storage engine and cannot be modified when **innodb_read_only** is enabled. The same principle applies to other table operations that require modifying data dictionary tables. Examples:
  - **ANALYZE TABLE** fails because it updates table statistics, which are stored in the data dictionary.
  - **ALTER TABLE tbl_name ENGINE=engine_name** fails because it updates the storage engine designation, which is stored in the data dictionary.

**Note**

Enabling **innodb_read_only** also has important implications for non-data dictionary tables in the mysql system database. For details, see the...
Data Dictionary Usage Differences

Previously, tables in the mysql system database were visible to DML and DDL statements. As of MySQL 8.0, data dictionary tables are invisible and cannot be modified or queried directly. However, in most cases there are corresponding INFORMATION_SCHEMA tables that can be queried instead. This enables the underlying data dictionary tables to be changed as server development proceeds, while maintaining a stable INFORMATION_SCHEMA interface for application use.

INFORMATION_SCHEMA tables in MySQL 8.0 are closely tied to the data dictionary, resulting in several usage differences:

- Previously, INFORMATION_SCHEMA queries for table statistics in the STATISTICS and TABLES tables retrieved statistics directly from storage engines. As of MySQL 8.0, cached table statistics are used by default. The information_schema_stats_expiry system variable defines the period of time before cached table statistics expire. The default is 86400 seconds (24 hours). (To update the cached values at any time for a given table, use ANALYZE TABLE.) If there are no cached statistics or statistics have expired, statistics are retrieved from storage engines when querying table statistics columns. To always retrieve the latest statistics directly from storage engines, set information_schema_stats_expiry to 0. For more information, see Section 8.2.3, “Optimizing INFORMATION_SCHEMA Queries”.

- Several INFORMATION_SCHEMA tables are views on data dictionary tables, which enables the optimizer to use indexes on those underlying tables. Consequently, depending on optimizer choices, the row order of results for INFORMATION_SCHEMA queries might differ from previous results. If a query result must have specific row ordering characteristics, include an ORDER BY clause.

- Queries on INFORMATION_SCHEMA tables may return column names in a different lettercase than in earlier MySQL series. Applications should test result set column names in case-insensitive fashion. If that is not feasible, a workaround is to use column aliases in the select list that return column names in the required lettercase. For example:

```sql
SELECT TABLE_SCHEMA AS table_schema, TABLE_NAME AS table_name
FROM INFORMATION_SCHEMA.TABLES WHERE TABLE_NAME = 'users';
```

| mysqldump and mysqlpump no longer dump the INFORMATION_SCHEMA database, even if explicitly named on the command line. |

| CREATE TABLE dst_tbl LIKE src_tbl requires that src_tbl be a base table and fails if it is an INFORMATION_SCHEMA table that is a view on data dictionary tables. |

| Previously, result set headers of columns selected from INFORMATION_SCHEMA tables used the capitalization specified in the query. This query produces a result set with a header of table_name: |

```sql
SELECT table_name FROM INFORMATION_SCHEMA.TABLES;
```

As of MySQL 8.0, these headers are capitalized; the preceding query produces a result set with a header of TABLE_NAME. If necessary, a column alias can be used to achieve a different lettercase. For example:

```sql
SELECT table_name AS 'table_name' FROM INFORMATION_SCHEMA.TABLES;
```
• The data directory affects how `mysqldump` and `mysqlpump` dump information from the `mysql` system database:

• Previously, it was possible to dump all tables in the `mysql` system database. As of MySQL 8.0, `mysqldump` and `mysqlpump` dump only non-data dictionary tables in that database.

• Previously, the `--routines` and `--events` options were not required to include stored routines and events when using the `--all-databases` option: The dump included the `mysql` system database, and therefore also the `proc` and `event` tables containing stored routine and event definitions. As of MySQL 8.0, the `event` and `proc` tables are not used. Definitions for the corresponding objects are stored in data dictionary tables, but those tables are not dumped. To include stored routines and events in a dump made using `--all-databases`, use the `--routines` and `--events` options explicitly.

• Previously, the `--routines` option required the `SELECT` privilege for the `proc` table. As of MySQL 8.0, that table is not used; `--routines` requires the global `SELECT` privilege instead.

• Previously, it was possible to dump stored routine and event definitions together with their creation and modification timestamps, by dumping the `proc` and `event` tables. As of MySQL 8.0, those tables are not used, so it is not possible to dump timestamps.

• Previously, creating a stored routine that contains illegal characters produced a warning. As of MySQL 8.0, this is an error.

14.8 Data Dictionary Limitations

This section describes temporary limitations introduced with the MySQL data dictionary.

• Manual creation of database directories under the data directory (for example, with `mkdir`) is unsupported. Manually created database directories are not recognized by the MySQL Server.

• DDL operations take longer due to writing to storage, undo logs, and redo logs instead of `.frm` files.

15.1 Introduction to InnoDB

InnoDB is a general-purpose storage engine that balances high reliability and high performance. In MySQL 8.0, InnoDB is the default MySQL storage engine. Unless you have configured a different default storage engine, issuing a `CREATE TABLE` statement without an `ENGINE` clause creates an InnoDB table.

Key Advantages of InnoDB

- Its DML operations follow the ACID model, with transactions featuring commit, rollback, and crash-recovery capabilities to protect user data. See Section 15.2, “InnoDB and the ACID Model”.
InnoDB Enhancements and New Features

- Row-level locking and Oracle-style consistent reads increase multi-user concurrency and performance. See Section 15.7, “InnoDB Locking and Transaction Model”.

- InnoDB tables arrange your data on disk to optimize queries based on primary keys. Each InnoDB table has a primary key index called the clustered index that organizes the data to minimize I/O for primary key lookups. See Section 15.6.2.1, “Clustered and Secondary Indexes”.

- To maintain data integrity, InnoDB supports FOREIGN KEY constraints. With foreign keys, inserts, updates, and deletes are checked to ensure they do not result in inconsistencies across related tables. See Section 13.1.20.5, “FOREIGN KEY Constraints”.

Table 15.1 InnoDB Storage Engine Features

<table>
<thead>

To compare the features of InnoDB with other storage engines provided with MySQL, see the Storage Engine Features table in Chapter 16, Alternative Storage Engines.

InnoDB Enhancements and New Features

For information about InnoDB enhancements and new features, refer to:

- The InnoDB enhancements list in Section 1.3, “What Is New in MySQL 8.0”.
Additional InnoDB Information and Resources

- The Release Notes.

Additional InnoDB Information and Resources

- For InnoDB-related terms and definitions, see the MySQL Glossary.
- For a forum dedicated to the InnoDB storage engine, see MySQL Forums::InnoDB.
- InnoDB is published under the same GNU GPL License Version 2 (of June 1991) as MySQL. For more information on MySQL licensing, see http://www.mysql.com/company/legal/licensing/.

15.1.1 Benefits of Using InnoDB Tables

InnoDB tables have the following benefits:

- If the server unexpectedly exits because of a hardware or software issue, regardless of what was happening in the database at the time, you don't need to do anything special after restarting the database. InnoDB crash recovery automatically finalizes changes that were committed before the time of the crash, and undoes changes that were in process but not committed, permitting you to restart and continue from where you left off. See Section 15.18.2, “InnoDB Recovery”.

- The InnoDB storage engine maintains its own buffer pool that caches table and index data in main memory as data is accessed. Frequently used data is processed directly from memory. This cache applies to many types of information and speeds up processing. On dedicated database servers, up to 80% of physical memory is often assigned to the buffer pool. See Section 15.5.1, “Buffer Pool”.

- If you split up related data into different tables, you can set up foreign keys that enforce referential integrity. See Section 13.1.20.5, “FOREIGN KEY Constraints”.

- If data becomes corrupted on disk or in memory, a checksum mechanism alerts you to the bogus data before you use it. The innodb_checksum_algorithm variable defines the checksum algorithm used by InnoDB.

- When you design a database with appropriate primary key columns for each table, operations involving those columns are automatically optimized. It is very fast to reference the primary key columns in WHERE clauses, ORDER BY clauses, GROUP BY clauses, and join operations. See Section 15.6.2.1, “Clustered and Secondary Indexes”.

- Inserts, updates, and deletes are optimized by an automatic mechanism called change buffering. InnoDB not only allows concurrent read and write access to the same table, it caches changed data to streamline disk I/O. See Section 15.5.2, “Change Buffer”.

- Performance benefits are not limited to large tables with long-running queries. When the same rows are accessed over and over from a table, the Adaptive Hash Index takes over to make these lookups even faster, as if they came out of a hash table. See Section 15.5.3, “Adaptive Hash Index”.

- You can compress tables and associated indexes. See Section 15.9, “InnoDB Table and Page Compression”.

- You can encrypt your data. See Section 15.13, “InnoDB Data-at-Rest Encryption”.

- You can create and drop indexes and perform other DDL operations with much less impact on performance and availability. See Section 15.12.1, “Online DDL Operations”.

- Truncating a file-per-table tablespace is very fast and can free up disk space for the operating system to reuse rather than only InnoDB. See Section 15.6.3.2, “File-Per-Table Tablespaces”.

- The storage layout for table data is more efficient for BLOB and long text fields, with the DYNAMIC row format. See Section 15.10, “InnoDB Row Formats”.

- You can monitor the internal workings of the storage engine by querying INFORMATION_SCHEMA tables. See Section 15.15, “InnoDB INFORMATION_SCHEMA Tables”.

2778
• You can monitor the performance details of the storage engine by querying Performance Schema tables. See Section 15.16, "InnoDB Integration with MySQL Performance Schema".

• You can mix InnoDB tables with tables from other MySQL storage engines, even within the same statement. For example, you can use a join operation to combine data from InnoDB and MEMORY tables in a single query.

• InnoDB has been designed for CPU efficiency and maximum performance when processing large data volumes.

• InnoDB tables can handle large quantities of data, even on operating systems where file size is limited to 2GB.

For InnoDB-specific tuning techniques you can apply to your MySQL server and application code, see Section 8.5, "Optimizing for InnoDB Tables".

15.1.2 Best Practices for InnoDB Tables

This section describes best practices when using InnoDB tables.

• Specify a primary key for every table using the most frequently queried column or columns, or an auto-increment value if there is no obvious primary key.

• Use joins wherever data is pulled from multiple tables based on identical ID values from those tables. For fast join performance, define foreign keys on the join columns, and declare those columns with the same data type in each table. Adding foreign keys ensures that referenced columns are indexed, which can improve performance. Foreign keys also propagate deletes and updates to all affected tables, and prevent insertion of data in a child table if the corresponding IDs are not present in the parent table.

• Turn off autocommit. Committing hundreds of times a second puts a cap on performance (limited by the write speed of your storage device).

• Group sets of related DML operations into transactions by bracketing them with START TRANSACTION and COMMIT statements. While you don't want to commit too often, you also don't want to issue huge batches of INSERT, UPDATE, or DELETE statements that run for hours without committing.

• Do not use LOCK TABLES statements. InnoDB can handle multiple sessions all reading and writing to the same table at once without sacrificing reliability or high performance. To get exclusive write access to a set of rows, use the SELECT ... FOR UPDATE syntax to lock just the rows you intend to update.

• Enable the innodb_file_per_table variable or use general tablespaces to put the data and indexes for tables into separate files instead of the system tablespace. The innodb_file_per_table variable is enabled by default.

• Evaluate whether your data and access patterns benefit from the InnoDB table or page compression features. You can compress InnoDB tables without sacrificing read/write capability.

• Run the server with the --sql_mode=NO_ENGINE_SUBSTITUTION option to prevent tables from being created with storage engines that you do not want to use.

15.1.3 Verifying that InnoDB is the Default Storage Engine

Issue the SHOW ENGINES statement to view the available MySQL storage engines. Look for DEFAULT in the SUPPORT column.

```
mysql> SHOW ENGINES;

Alternatively, query the INFORMATION_SCHEMA.ENGINES table.

mysql> SELECT * FROM INFORMATION_SCHEMA.ENGINES;
```
15.1.4 Testing and Benchmarking with InnoDB

If InnoDB is not the default storage engine, you can determine if your database server and applications work correctly with InnoDB by restarting the server with `--default-storage-engine=InnoDB` defined on the command line or with `default-storage-engine=innodb` defined in the [mysqld] section of the MySQL server option file.

Since changing the default storage engine only affects newly created tables, run your application installation and setup steps to confirm that everything installs properly, then exercise the application features to make sure the data loading, editing, and querying features work. If a table relies on a feature that is specific to another storage engine, you receive an error. In this case, add the `ENGINE=other_engine_name` clause to the `CREATE TABLE` statement to avoid the error.

If you did not make a deliberate decision about the storage engine, and you want to preview how certain tables work when created using InnoDB, issue the command `ALTER TABLE table_name ENGINE=InnoDB;` for each table. Alternatively, to run test queries and other statements without disturbing the original table, make a copy:

```sql
CREATE TABLE ... ENGINE=InnoDB AS SELECT * FROM other_engine_table;
```

To assess performance with a full application under a realistic workload, install the latest MySQL server and run benchmarks.

Test the full application lifecycle, from installation, through heavy usage, and server restart. Kill the server process while the database is busy to simulate a power failure, and verify that the data is recovered successfully when you restart the server.

Test any replication configurations, especially if you use different MySQL versions and options on the source server and replicas.

15.2 InnoDB and the ACID Model

The ACID model is a set of database design principles that emphasize aspects of reliability that are important for business data and mission-critical applications. MySQL includes components such as the InnoDB storage engine that adhere closely to the ACID model so that data is not corrupted and results are not distorted by exceptional conditions such as software crashes and hardware malfunctions. When you rely on ACID-compliant features, you do not need to reinvent the wheel of consistency checking and crash recovery mechanisms. In cases where you have additional software safeguards, ultra-reliable hardware, or an application that can tolerate a small amount of data loss or inconsistency, you can adjust MySQL settings to trade some of the ACID reliability for greater performance or throughput.

The following sections discuss how MySQL features, in particular the InnoDB storage engine, interact with the categories of the ACID model:

- **A**: atomicity.
- **C**: consistency.
- **I**: isolation.
- **D**: durability.

**Atomicity**

The atomicity aspect of the ACID model mainly involves InnoDB transactions. Related MySQL features include:

- The `autocommit` setting.
- The `COMMIT` statement.
- The `ROLLBACK` statement.
Consistency

The consistency aspect of the ACID model mainly involves internal InnoDB processing to protect data from crashes. Related MySQL features include:

- The InnoDB doublewrite buffer. See Section 15.6.4, “Doublewrite Buffer”.
- InnoDB crash recovery. See InnoDB Crash Recovery.

Isolation

The isolation aspect of the ACID model mainly involves InnoDB transactions, in particular the isolation level that applies to each transaction. Related MySQL features include:

- The autocommit setting.
- Transaction isolation levels and the SET TRANSACTION statement. See Section 15.7.2.1, “Transaction Isolation Levels”.
- The low-level details of InnoDB locking. Details can be viewed in the INFORMATION_SCHEMA tables (see Section 15.15.2, “InnoDB INFORMATION_SCHEMA Transaction and Locking Information”) and Performance Schema data_locks and data_lock_waits tables.

Durability

The durability aspect of the ACID model involves MySQL software features interacting with your particular hardware configuration. Because of the many possibilities depending on the capabilities of your CPU, network, and storage devices, this aspect is the most complicated to provide concrete guidelines for. (And those guidelines might take the form of “buy new hardware”.) Related MySQL features include:

- The InnoDB doublewrite buffer. See Section 15.6.4, “Doublewrite Buffer”.
- The innodb_flush_log_at_trx_commit variable.
- The sync_binlog variable.
- The innodb_file_per_table variable.
- The write buffer in a storage device, such as a disk drive, SSD, or RAID array.
- A battery-backed cache in a storage device.
- The operating system used to run MySQL, in particular its support for the fsync() system call.
- An uninterruptible power supply (UPS) protecting the electrical power to all computer servers and storage devices that run MySQL servers and store MySQL data.
- Your backup strategy, such as frequency and types of backups, and backup retention periods.
- For distributed or hosted data applications, the particular characteristics of the data centers where the hardware for the MySQL servers is located, and network connections between the data centers.

15.3 InnoDB Multi-Versioning

InnoDB is a multi-version storage engine. It keeps information about old versions of changed rows to support transactional features such as concurrency and rollback. This information is stored in undo tablespaces in a data structure called a rollback segment. See Section 15.6.3.4, “Undo Tablespaces”. InnoDB uses the information in the rollback segment to perform the undo operations needed in a transaction rollback. It also uses the information to build earlier versions of a row for a consistent read. See Section 15.7.2.3, “Consistent Nonlocking Reads”.

2781
Internally, InnoDB adds three fields to each row stored in the database:

- A 6-byte \texttt{DB_TRX_ID} field indicates the transaction identifier for the last transaction that inserted or updated the row. Also, a deletion is treated internally as an update where a special bit in the row is set to mark it as deleted.

- A 7-byte \texttt{DB_ROLL_PTR} field called the roll pointer. The roll pointer points to an undo log record written to the rollback segment. If the row was updated, the undo log record contains the information necessary to rebuild the content of the row before it was updated.

- A 6-byte \texttt{DB_ROW_ID} field contains a row ID that increases monotonically as new rows are inserted. If InnoDB generates a clustered index automatically, the index contains row ID values. Otherwise, the \texttt{DB_ROW_ID} column does not appear in any index.

Undo logs in the rollback segment are divided into insert and update undo logs. Insert undo logs are needed only in transaction rollback and can be discarded as soon as the transaction commits. Update undo logs are used also in consistent reads, but they can be discarded only after there is no transaction present for which InnoDB has assigned a snapshot that in a consistent read could require the information in the update undo log to build an earlier version of a database row. For additional information about undo logs, see Section 15.6.6, “Undo Logs”.

It is recommended that you commit transactions regularly, including transactions that issue only consistent reads. Otherwise, InnoDB cannot discard data from the update undo logs, and the rollback segment may grow too big, filling up the undo tablespace in which it resides. For information about managing undo tablespaces, see Section 15.6.3.4, “Undo Tablespaces”.

The physical size of an undo log record in the rollback segment is typically smaller than the corresponding inserted or updated row. You can use this information to calculate the space needed for your rollback segment.

In the InnoDB multi-versioning scheme, a row is not physically removed from the database immediately when you delete it with an SQL statement. InnoDB only physically removes the corresponding row and its index records when it discards the update undo log record written for the deletion. This removal operation is called a purge, and it is quite fast, usually taking the same order of time as the SQL statement that did the deletion.

If you insert and delete rows in smallish batches at about the same rate in the table, the purge thread can start to lag behind and the table can grow bigger and bigger because of all the “dead” rows, making everything disk-bound and very slow. In such cases, throttle new row operations, and allocate more resources to the purge thread by tuning the \texttt{innodb_max_purge_lag} system variable. For more information, see Section 15.8.9, “Purge Configuration”.

**Multi-Versioning and Secondary Indexes**

InnoDB multiversion concurrency control (MVCC) treats secondary indexes differently than clustered indexes. Records in a clustered index are updated in-place, and their hidden system columns point undo log entries from which earlier versions of records can be reconstructed. Unlike clustered index records, secondary index records do not contain hidden system columns nor are they updated in-place.

When a secondary index column is updated, old secondary index records are delete-marked, new records are inserted, and delete-marked records are eventually purged. When a secondary index record is delete-marked or the secondary index page is updated by a newer transaction, InnoDB looks up the database record in the clustered index. In the clustered index, the record’s \texttt{DB_TRX_ID} is checked, and the correct version of the record is retrieved from the undo log if the record was modified after the reading transaction was initiated.

If a secondary index record is marked for deletion or the secondary index page is updated by a newer transaction, the covering index technique is not used. Instead of returning values from the index structure, InnoDB looks up the record in the clustered index.
However, if the **index condition pushdown (ICP)** optimization is enabled, and parts of the **WHERE** condition can be evaluated using only fields from the index, the MySQL server still pushes this part of the **WHERE** condition down to the storage engine where it is evaluated using the index. If no matching records are found, the clustered index lookup is avoided. If matching records are found, even among delete-marked records, **InnoDB** looks up the record in the clustered index.

### 15.4 InnoDB Architecture

The following diagram shows in-memory and on-disk structures that comprise the **InnoDB** storage engine architecture. For information about each structure, see Section 15.5, “**InnoDB In-Memory Structures**”, and Section 15.6, “**InnoDB On-Disk Structures**”.

#### Figure 15.1 InnoDB Architecture

---

### 15.5 InnoDB In-Memory Structures

This section describes **InnoDB** in-memory structures and related topics.

#### 15.5.1 Buffer Pool

The buffer pool is an area in main memory where **InnoDB** caches table and index data as it is accessed. The buffer pool permits frequently used data to be accessed directly from memory, which speeds up processing. On dedicated servers, up to 80% of physical memory is often assigned to the buffer pool.

For efficiency of high-volume read operations, the buffer pool is divided into pages that can potentially hold multiple rows. For efficiency of cache management, the buffer pool is implemented as a linked list of pages; data that is rarely used is aged out of the cache using a variation of the least recently used (LRU) algorithm.
Knowing how to take advantage of the buffer pool to keep frequently accessed data in memory is an important aspect of MySQL tuning.

**Buffer Pool LRU Algorithm**

The buffer pool is managed as a list using a variation of the LRU algorithm. When room is needed to add a new page to the buffer pool, the least recently used page is evicted and a new page is added to the middle of the list. This midpoint insertion strategy treats the list as two sublists:

- At the head, a sublist of new (“young”) pages that were accessed recently
- At the tail, a sublist of old pages that were accessed less recently

**Figure 15.2 Buffer Pool List**

The algorithm keeps frequently used pages in the new sublist. The old sublist contains less frequently used pages; these pages are candidates for eviction.

By default, the algorithm operates as follows:

- 3/8 of the buffer pool is devoted to the old sublist.
• The midpoint of the list is the boundary where the tail of the new sublist meets the head of the old sublist.

• When InnoDB reads a page into the buffer pool, it initially inserts it at the midpoint (the head of the old sublist). A page can be read because it is required for a user-initiated operation such as an SQL query, or as part of a read-ahead operation performed automatically by InnoDB.

• Accessing a page in the old sublist makes it "young", moving it to the head of the new sublist. If the page was read because it was required by a user-initiated operation, the first access occurs immediately and the page is made young. If the page was read due to a read-ahead operation, the first access does not occur immediately and might not occur at all before the page is evicted.

• As the database operates, pages in the buffer pool that are not accessed “age” by moving toward the tail of the list. Pages in both the new and old sublists age as other pages are made new. Pages in the old sublist also age as pages are inserted at the midpoint. Eventually, a page that remains unused reaches the tail of the old sublist and is evicted.

By default, pages read by queries are immediately moved into the new sublist, meaning they stay in the buffer pool longer. A table scan, performed for a `mysqldump` operation or a `SELECT` statement with no `WHERE` clause, for example, can bring a large amount of data into the buffer pool and evict an equivalent amount of older data, even if the new data is never used again. Similarly, pages that are loaded by the read-ahead background thread and accessed only once are moved to the head of the new list. These situations can push frequently used pages to the old sublist where they become subject to eviction. For information about optimizing this behavior, see Section 15.8.3.3, "Making the Buffer Pool Scan Resistant", and Section 15.8.3.4, "Configuring InnoDB Buffer Pool Prefetching (Read-Ahead)".

InnoDB Standard Monitor output contains several fields in the BUFFER POOL AND MEMORY section regarding operation of the buffer pool LRU algorithm. For details, see Monitoring the Buffer Pool Using the InnoDB Standard Monitor.

Buffer Pool Configuration

You can configure the various aspects of the buffer pool to improve performance.

• Ideally, you set the size of the buffer pool to as large a value as practical, leaving enough memory for other processes on the server to run without excessive paging. The larger the buffer pool, the more InnoDB acts like an in-memory database, reading data from disk once and then accessing the data from memory during subsequent reads. See Section 15.8.3.1, "Configuring InnoDB Buffer Pool Size".

• On 64-bit systems with sufficient memory, you can split the buffer pool into multiple parts to minimize contention for memory structures among concurrent operations. For details, see Section 15.8.3.2, "Configuring Multiple Buffer Pool Instances".

• You can keep frequently accessed data in memory regardless of sudden spikes of activity from operations that would bring large amounts of infrequently accessed data into the buffer pool. For details, see Section 15.8.3.3, "Making the Buffer Pool Scan Resistant".

• You can control how and when to perform read-ahead requests to prefetch pages into the buffer pool asynchronously in anticipation of impending need for them. For details, see Section 15.8.3.4, "Configuring InnoDB Buffer Pool Prefetching (Read-Ahead)".

• You can control when background flushing occurs and whether or not the rate of flushing is dynamically adjusted based on workload. For details, see Section 15.8.3.5, "Configuring Buffer Pool Flushing".

• You can configure how InnoDB preserves the current buffer pool state to avoid a lengthy warmup period after a server restart. For details, see Section 15.8.3.6, "Saving and Restoring the Buffer Pool State".
**InnoDB** Standard Monitor output, which can be accessed using `SHOW ENGINE INNODB STATUS`, provides metrics regarding operation of the buffer pool. Buffer pool metrics are located in the **BUFFER POOL AND MEMORY** section of **InnoDB** Standard Monitor output:

```sql
BUFFER POOL AND MEMORY
----------------------
Total large memory allocated 2198863872
Dictionary memory allocated 776332
Buffer pool size 131072
Free buffers 124908
Database pages 5720
Old database pages 2071
Modified db pages 910
Pending reads 0
Pending writes: LRU 0, flush list 0, single page 0
Pages made young 4, not young 0
0.10 youngs/s, 0.00 non-youngs/s
Pages read 197, created 5523, written 5060
0.00 reads/s, 190.89 creates/s, 244.94 writes/s
Buffer pool hit rate 1000 / 1000, young-making rate 0 / 1000 not
0 / 1000
Pages read ahead 0.00/s, evicted without access 0.00/s, Random read
ahead 0.00/s
LRU len: 5720, unzip_LRU len: 0
I/O sum[0]:cur[0], unzip sum[0]:cur[0]
```

The following table describes buffer pool metrics reported by the **InnoDB** Standard Monitor.

Per second averages provided in **InnoDB** Standard Monitor output are based on the elapsed time since **InnoDB** Standard Monitor output was last printed.

**Table 15.2 InnoDB Buffer Pool Metrics**

<table>
<thead>
<tr>
<th>Name</th>

</tr>
<tr>
<td>I/O unzip cur</td>
<td>The total number of buffer pool unzip_LRU list pages decompressed in the current interval.</td>
</tr>
</tbody>
</table>

Notes:

- The **youngs/s** metric is applicable only to old pages. It is based on the number of page accesses. There can be multiple accesses for a given page, all of which are counted. If you see very low **youngs/s** values when there are no large scans occurring, consider reducing the delay time or increasing the percentage of the buffer pool used for the old sublist. Increasing the percentage makes the old sublist larger so that it takes longer for pages in that sublist to move to the tail, which increases the likelihood that those pages are accessed again and made young. See Section 15.8.3.3, “Making the Buffer Pool Scan Resistant”.

- The **non-youngs/s** metric is applicable only to old pages. It is based on the number of page accesses. There can be multiple accesses for a given page, all of which are counted. If you do not see a higher **non-youngs/s** value when performing large table scans (and a higher **youngs/s** value), increase the delay value. See Section 15.8.3.3, “Making the Buffer Pool Scan Resistant”.

- The **young-making** rate accounts for all buffer pool page accesses, not just accesses for pages in the old sublist. The **young-making** rate and **not** rate do not normally add up to the overall buffer pool hit rate. Page hits in the old sublist cause pages to move to the new sublist, but page hits in the
new sublist cause pages to move to the head of the list only if they are a certain distance from the head.

- **not (young-making rate)** is the average hit rate at which page accesses have not resulted in making pages young due to the delay defined by `innodb_old_blocks_time` not being met, or due to page hits in the new sublist that did not result in pages being moved to the head. This rate accounts for all buffer pool page accesses, not just accesses for pages in the old sublist.

Buffer pool server status variables and the `INNODB_BUFFER_POOL_STATS` table provide many of the same buffer pool metrics found in InnoDB Standard Monitor output. For more information, see Example 15.10, “Querying the INNODB_BUFFER_POOL_STATS Table”.

### 15.5.2 Change Buffer

The change buffer is a special data structure that caches changes to secondary index pages when those pages are not in the buffer pool. The buffered changes, which may result from INSERT, UPDATE, or DELETE operations (DML), are merged later when the pages are loaded into the buffer pool by other read operations.

**Figure 15.3 Change Buffer**

![Change Buffer Diagram]

Unlike clustered indexes, secondary indexes are usually nonunique, and inserts into secondary indexes happen in a relatively random order. Similarly, deletes and updates may affect secondary index pages that are not adjacently located in an index tree. Merging cached changes at a later time, when affected pages are read into the buffer pool by other operations, avoids substantial random access I/O that would be required to read secondary index pages into the buffer pool from disk.

Periodically, the purge operation that runs when the system is mostly idle, or during a slow shutdown, writes the updated index pages to disk. The purge operation can write disk blocks for a series of index values more efficiently than if each value were written to disk immediately.

Change buffer merging may take several hours when there are many affected rows and numerous secondary indexes to update. During this time, disk I/O is increased, which can cause a significant slowdown for disk-bound queries. Change buffer merging may also continue to occur after a transaction is committed, and even after a server shutdown and restart (see Section 15.21.2, “Forcing InnoDB Recovery” for more information).
In memory, the change buffer occupies part of the buffer pool. On disk, the change buffer is part of the system tablespace, where index changes are buffered when the database server is shut down.

The type of data cached in the change buffer is governed by the `innodb_change_buffering` variable. For more information, see Configuring Change Buffering. You can also configure the maximum change buffer size. For more information, see Configuring the Change Buffer Maximum Size.

Change buffering is not supported for a secondary index if the index contains a descending index column or if the primary key includes a descending index column.

For answers to frequently asked questions about the change buffer, see Section A.16, “MySQL 8.0 FAQ: InnoDB Change Buffer”.

### Configuring Change Buffering

When `INSERT`, `UPDATE`, and `DELETE` operations are performed on a table, the values of indexed columns (particularly the values of secondary keys) are often in an unsorted order, requiring substantial I/O to bring secondary indexes up to date. The change buffer caches changes to secondary index entries when the relevant page is not in the buffer pool, thus avoiding expensive I/O operations by not immediately reading in the page from disk. The buffered changes are merged when the page is loaded into the buffer pool, and the updated page is later flushed to disk. The InnoDB main thread merges buffered changes when the server is nearly idle, and during a slow shutdown.

Because it can result in fewer disk reads and writes, change buffering is most valuable for workloads that are I/O-bound; for example, applications with a high volume of DML operations such as bulk inserts benefit from change buffering.

However, the change buffer occupies a part of the buffer pool, reducing the memory available to cache data pages. If the working set almost fits in the buffer pool, or if your tables have relatively few secondary indexes, it may be useful to disable change buffering. If the working data set fits entirely within the buffer pool, change buffering does not impose extra overhead, because it only applies to pages that are not in the buffer pool.

The `innodb_change_buffering` variable controls the extent to which InnoDB performs change buffering. You can enable or disable buffering for inserts, delete operations (when index records are initially marked for deletion) and purge operations (when index records are physically deleted). An update operation is a combination of an insert and a delete. The default `innodb_change_buffering` value is `all`.

Permitted `innodb_change_buffering` values include:

- **all**
  
  The default value: buffer inserts, delete-marking operations, and purges.

- **none**
  
  Do not buffer any operations.

- **inserts**
  
  Buffer insert operations.

- **deletes**
  
  Buffer delete-marking operations.

- **changes**
  
  Buffer both inserts and delete-marking operations.

- **purges**
  
  Buffer purges.
Buffer the physical deletion operations that happen in the background.

You can set the `innodb_change_buffering` variable in the MySQL option file (`my.cnf` or `my.ini`) or change it dynamically with the `SET GLOBAL` statement, which requires privileges sufficient to set global system variables. See Section 5.1.9.1, “System Variable Privileges”. Changing the setting affects the buffering of new operations; the merging of existing buffered entries is not affected.

**Configuring the Change Buffer Maximum Size**

The `innodb_change_buffer_max_size` variable permits configuring the maximum size of the change buffer as a percentage of the total size of the buffer pool. By default, `innodb_change_buffer_max_size` is set to 25. The maximum setting is 50.

Consider increasing `innodb_change_buffer_max_size` on a MySQL server with heavy insert, update, and delete activity, where change buffer merging does not keep pace with new change buffer entries, causing the change buffer to reach its maximum size limit.

Consider decreasing `innodb_change_buffer_max_size` on a MySQL server with static data used for reporting, or if the change buffer consumes too much of the memory space shared with the buffer pool, causing pages to age out of the buffer pool sooner than desired.

Test different settings with a representative workload to determine an optimal configuration. The `innodb_change_buffer_max_size` variable is dynamic, which permits modifying the setting without restarting the server.

**Monitoring the Change Buffer**

The following options are available for change buffer monitoring:

- **InnoDB** Standard Monitor output includes change buffer status information. To view monitor data, issue the `SHOW ENGINE INNODB STATUS` statement.

  ```
mysql> SHOW ENGINE INNODB STATUS\G
```

  Change buffer status information is located under the INSERT BUFFER AND ADAPTIVE HASH INDEX heading and appears similar to the following:

  ```
  -------------------------------------
  INSERT BUFFER AND ADAPTIVE HASH INDEX
  -------------------------------------
  Ibuf: size 1, free list len 0, seg size 2, 0 merges
  merged operations:
  insert 0, delete mark 0, delete 0
  discarded operations:
  insert 0, delete mark 0, delete 0
  Hash table size 4425293, used cells 32, node heap has 1 buffer(s)
  13577.57 hash searches/s, 202.47 non-hash searches/s
  ```

  For more information, see Section 15.17.3, “InnoDB Standard Monitor and Lock Monitor Output”.

- **The INFORMATION_SCHEMA.INNODB_METRICS** table provides most of the data points found in InnoDB Standard Monitor output plus other data points. To view change buffer metrics and a description of each, issue the following query:

  ```
mysql> SELECT NAME, COMMENT FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME LIKE '%ibuf%'
```

  For `INNODB_METRICS` table usage information, see Section 15.15.6, “InnoDB INFORMATION_SCHEMA Metrics Table”.

- **The INFORMATION_SCHEMA.INNODB_BUFFER_PAGE** table provides metadata about each page in the buffer pool, including change buffer index and change buffer bitmap pages. Change buffer pages are identified by `PAGE_TYPE`, `IBUF_INDEX` is the page type for change buffer index pages, and `IBUF_BITMAP` is the page type for change buffer bitmap pages.
Warning

Querying the `INNODB_BUFFER_PAGE` table can introduce significant performance overhead. To avoid impacting performance, reproduce the issue you want to investigate on a test instance and run your queries on the test instance.

For example, you can query the `INNODB_BUFFER_PAGE` table to determine the approximate number of `IBUF_INDEX` and `IBUF_BITMAP` pages as a percentage of total buffer pool pages.

```sql
mysql> SELECT (SELECT COUNT(*) FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE WHERE PAGE_TYPE LIKE 'IBUF%') AS change_buffer_pages,
               (SELECT COUNT(*) FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE) AS total_pages,
               ((change_buffer_pages/total_pages)*100) AS change_buffer_page_percentage;
+---------------------+-------------+-------------------------------+
| change_buffer_pages | total_pages | change_buffer_page_percentage |
+---------------------+-------------+-------------------------------+
|                  25  |        8192 |                        0.3052 |
+---------------------+-------------+-------------------------------+
```

For information about other data provided by the `INNODB_BUFFER_PAGE` table, see Section 26.4.2, “The INFORMATION_SCHEMA INNODB_BUFFER_PAGE Table”. For related usage information, see Section 15.15.5, “InnoDB INFORMATION_SCHEMA Buffer Pool Tables”.

- Performance Schema provides change buffer mutex wait instrumentation for advanced performance monitoring. To view change buffer instrumentation, issue the following query:

```sql
mysql> SELECT * FROM performance_schema.setup_instruments
       WHERE NAME LIKE '%wait/synch/mutex/innodb/ibuf%';
+-------------------------------------------------------+---------+-------+
| NAME                                                  | ENABLED | TIMED |
+-------------------------------------------------------+---------+-------+
| wait/synch/mutex/innodb/ibuf_bitmap_mutex             | YES     | YES   |
| wait/synch/mutex/innodb/ibuf_mutex                    | YES     | YES   |
| wait/synch/mutex/innodb/ibuf_pessimistic_insert_mutex | YES     | YES   |
+-------------------------------------------------------+---------+-------+
```

For information about monitoring InnoDB mutex waits, see Section 15.16.2, “Monitoring InnoDB Mutex Waits Using Performance Schema”.

### 15.5.3 Adaptive Hash Index

The adaptive hash index enables InnoDB to perform more like an in-memory database on systems with appropriate combinations of workload and sufficient memory for the buffer pool without sacrificing transactional features or reliability. The adaptive hash index is enabled by the `innodb_adaptive_hash_index` variable, or turned off at server startup by `--skip-innodb-adaptive-hash-index`.

Based on the observed pattern of searches, a hash index is built using a prefix of the index key. The prefix can be any length, and it may be that only some values in the B-tree appear in the hash index.

Hash indexes are built on demand for the pages of the index that are accessed often.

If a table fits almost entirely in main memory, a hash index speeds up queries by enabling direct lookup of any element, turning the index value into a sort of pointer. InnoDB has a mechanism that monitors index searches. If InnoDB notices that queries could benefit from building a hash index, it does so automatically.

With some workloads, the speedup from hash index lookups greatly outweighs the extra work to monitor index lookups and maintain the hash index structure. Access to the adaptive hash index can sometimes become a source of contention under heavy workloads, such as multiple concurrent joins.

Queries with `LIKE` operators and `%` wildcards also tend not to benefit. For workloads that do not benefit from the adaptive hash index, turning it off reduces unnecessary performance overhead. Because it is
difficult to predict in advance whether the adaptive hash index is appropriate for a particular system and workload, consider running benchmarks with it enabled and disabled.

The adaptive hash index feature is partitioned. Each index is bound to a specific partition, and each partition is protected by a separate latch. Partitioning is controlled by the `innodb_adaptive_hash_index_parts` variable. The `innodb_adaptive_hash_index_parts` variable is set to 8 by default. The maximum setting is 512.

You can monitor adaptive hash index use and contention in the `SHOW ENGINE INNODB STATUS` output. If there are numerous threads waiting on rw-latches created in `btr0sea.c`, consider increasing the number of adaptive hash index partitions or disabling the adaptive hash index.

For information about the performance characteristics of hash indexes, see Section 8.3.9, “Comparison of B-Tree and Hash Indexes”.

15.5.4 Log Buffer

The log buffer is the memory area that holds data to be written to the log files on disk. Log buffer size is defined by the `innodb_log_buffer_size` variable. The default size is 16MB. The contents of the log buffer are periodically flushed to disk. A large log buffer enables large transactions to run without the need to write redo log data to disk before the transactions commit. Thus, if you have transactions that update, insert, or delete many rows, increasing the size of the log buffer saves disk I/O.

The `innodb_flush_log_at_trx_commit` variable controls how the contents of the log buffer are written and flushed to disk. The `innodb_flush_log_at_timeout` variable controls log flushing frequency.

For related information, see Memory Configuration, and Section 8.5.4, “Optimizing InnoDB Redo Logging”.

15.6 InnoDB On-Disk Structures

This section describes InnoDB on-disk structures and related topics.

15.6.1 Tables

This section covers topics related to InnoDB tables.

15.6.1.1 Creating InnoDB Tables

InnoDB tables are created using the `CREATE TABLE` statement; for example:

```
CREATE TABLE t1 (a INT, b CHAR (20), PRIMARY KEY (a)) ENGINE=InnoDB;
```

The `ENGINE=InnoDB` clause is not required when InnoDB is defined as the default storage engine, which it is by default. However, the `ENGINE` clause is useful if the `CREATE TABLE` statement is to be replayed on a different MySQL Server instance where the default storage engine is not InnoDB or is unknown. You can determine the default storage engine on a MySQL Server instance by issuing the following statement:

```
mysql> SELECT @@default_storage_engine;
+--------------------------+
| @@default_storage_engine |
+--------------------------+
| InnoDB                   |
+--------------------------+
```

InnoDB tables are created in file-per-table tablespaces by default. To create an InnoDB table in the InnoDB system tablespace, disable the `innodb_file_per_table` variable before creating the table. To create an InnoDB table in a general tablespace, use `CREATE TABLE ... TABLESPACE` syntax. For more information, see Section 15.6.3, “Tablespaces”.

Row Formats

2792
The row format of an InnoDB table determines how its rows are physically stored on disk. InnoDB supports four row formats, each with different storage characteristics. Supported row formats include REDUNDANT, COMPACT, DYNAMIC, and COMPRESSED. The DYNAMIC row format is the default. For information about row format characteristics, see Section 15.10, “InnoDB Row Formats”.

The innodb_default_row_format variable defines the default row format. The row format of a table can also be defined explicitly using the ROW_FORMAT table option in a CREATE TABLE or ALTER TABLE statement. See Defining the Row Format of a Table.

Primary Keys

It is recommended that you define a primary key for each table that you create. When selecting primary key columns, choose columns with the following characteristics:

• Columns that are referenced by the most important queries.
• Columns that are never left blank.
• Columns that never have duplicate values.
• Columns that rarely if ever change value once inserted.

For example, in a table containing information about people, you would not create a primary key on (firstname, lastname) because more than one person can have the same name, a name column may be left blank, and sometimes people change their names. With so many constraints, often there is not an obvious set of columns to use as a primary key, so you create a new column with a numeric ID to serve as all or part of the primary key. You can declare an auto-increment column so that ascending values are filled in automatically as rows are inserted:

```sql
# The value of ID can act like a pointer between related items in different tables.
CREATE TABLE t5 (id INT AUTO_INCREMENT, b CHAR (20), PRIMARY KEY (id));

# The primary key can consist of more than one column. Any autoinc column must come first.
CREATE TABLE t6 (id INT AUTO_INCREMENT, a INT, b CHAR (20), PRIMARY KEY (id,a));
```

For more information about auto-increment columns, see Section 15.6.1.6, “AUTO_INCREMENT Handling in InnoDB”.

Although a table works correctly without defining a primary key, the primary key is involved with many aspects of performance and is a crucial design aspect for any large or frequently used table. It is recommended that you always specify a primary key in the CREATE TABLE statement. If you create the table, load data, and then run ALTER TABLE to add a primary key later, that operation is much slower than defining the primary key when creating the table. For more information about primary keys, see Section 15.6.2.1, “Clustered and Secondary Indexes”.

Viewing InnoDB Table Properties

To view the properties of an InnoDB table, issue a SHOW TABLE STATUS statement:

```sql
mysql> SHOW TABLE STATUS FROM test LIKE 't%';
*************************** 1. row ***************************
Name: t1
Engine: InnoDB
Version: 10
Row_format: Dynamic
Rows: 0

15.6.1.2 Creating Tables Externally

There are different reasons for creating InnoDB tables externally; that is, creating tables outside of the data directory. Those reasons might include space management, I/O optimization, or placing tables on a storage device with particular performance or capacity characteristics, for example.

InnoDB supports the following methods for creating tables externally:

- **Using the DATA DIRECTORY Clause**
- **Using CREATE TABLE ... TABLESPACE Syntax**
- **Creating a Table in an External General Tablespace**

### Using the DATA DIRECTORY Clause

You can create an InnoDB table in an external directory by specifying a `DATA DIRECTORY` clause in the `CREATE TABLE` statement.

```
CREATE TABLE t1 (c1 INT PRIMARY KEY) DATA DIRECTORY = '/external/directory';
```

The `DATA DIRECTORY` clause is supported for tables created in file-per-table tablespaces. Tables are implicitly created in file-per-table tablespaces when the `innodb_file_per_table` variable is enabled, which it is by default.

```
mysql> SELECT @@innodb_file_per_table;
+-------------------------+
<table>
<thead>
<tr>
<th>@@innodb_file_per_table</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
</tr>
</tbody>
</table>
+-------------------------+
```

For more information about file-per-table tablespaces, see Section 15.6.3.2, “File-Per-Table Tablespaces”.

When you specify a `DATA DIRECTORY` clause in a `CREATE TABLE` statement, the table's data file (`table_name.ibd`) is created in a schema directory under the specified directory.

As of MySQL 8.0.21, tables and table partitions created outside of the data directory using the `DATA DIRECTORY` clause are restricted to directories known to InnoDB. This requirement permits database administrators to control where tablespace data files are created and ensures that data files can be
found during recovery (see Tablespace Discovery During Crash Recovery). Known directories are those defined by the \texttt{datadir}, \texttt{innodb\_data\_home\_dir}, and \texttt{innodb\_directories} variables. You can use the following statement to check those settings:

```
mysql> SELECT @@datadir,@@innodb\_data\_home\_dir,@@innodb\_directories;
```

If the directory you want to use is unknown, add it to the \texttt{innodb\_directories} setting before you create the table. The \texttt{innodb\_directories} variable is read-only. Configuring it requires restarting the server. For general information about setting system variables, see Section 5.1.9, “Using System Variables”.

The following example demonstrates creating a table in an external directory using the \texttt{DATA DIRECTORY} clause. It is assumed that the \texttt{innodb\_file\_per\_table} variable is enabled and that the directory is known to InnoDB.

```
mysql> USE test;
Database changed
mysql> CREATE TABLE t1 (c1 INT PRIMARY KEY) DATA DIRECTORY = '/external/directory';
```

Usage Notes:

- MySQL initially holds the tablespace data file open, preventing you from dismounting the device, but might eventually close the file if the server is busy. Be careful not to accidentally dismount an external device while MySQL is running, or start MySQL while the device is disconnected. Attempting to access a table when the associated data file is missing causes a serious error that requires a server restart.

A server restart might fail if the data file is not found at the expected path. In this case, you can restore the tablespace data file from a backup or drop the table to remove the information about it from the data dictionary.

- Before placing a table on an NFS-mounted volume, review potential issues outlined in Using NFS with MySQL.

- If using an LVM snapshot, file copy, or other file-based mechanism to back up the table's data file, always use the \texttt{FLUSH TABLES ... FOR EXPORT} statement first to ensure that all changes buffered in memory are flushed to disk before the backup occurs.

- Using the \texttt{DATA DIRECTORY} clause to create a table in an external directory is an alternative to using symbolic links, which InnoDB does not support.

- The \texttt{DATA DIRECTORY} clause is not supported in a replication environment where the source and replica reside on the same host. The \texttt{DATA DIRECTORY} clause requires a full directory path. Replicating the path in this case would cause the source and replica to create the table in the same location.

- As of MySQL 8.0.21, tables created in file-per-table tablespaces can no longer be created in the undo tablespace directory (\texttt{innodb\_undo\_directory}) unless that directly is known to InnoDB. Known directories are those defined by the \texttt{datadir}, \texttt{innodb\_data\_home\_dir}, and \texttt{innodb\_directories} variables.

Using \texttt{CREATE TABLE ... TABLESPACE} Syntax

\texttt{CREATE TABLE ... TABLESPACE} syntax can be used in combination with the \texttt{DATA DIRECTORY} clause to create a table in an external directory. To do so, specify \texttt{innodb\_file\_per\_table} as the tablespace name.
This method is supported only for tables created in file-per-table tablespaces, but does not require the `innodb_file_per_table` variable to be enabled. In all other respects, this method is equivalent to the `CREATE TABLE ... DATA DIRECTORY` method described above. The same usage notes apply.

Creating a Table in an External General Tablespace

You can create a table in a general tablespace that resides in an external directory.

- For information about creating a general tablespace in an external directory, see Creating a General Tablespace.
- For information about creating a table in a general tablespace, see Adding Tables to a General Tablespace.

15.6.1.3 Importing InnoDB Tables

This section describes how to import tables using the Transportable Tablespaces feature, which permits importing tables, partitioned tables, or individual table partitions that reside in file-per-table tablespaces. There are many reasons why you might want to import tables:

- To run reports on a non-production MySQL server instance to avoid placing extra load on a production server.
- To copy data to a new replica server.
- To restore a table from a backed-up tablespace file.
- As a faster way of moving data than importing a dump file, which requires reinserting data and rebuilding indexes.
- To move a data to a server with storage media that is better suited to your storage requirements. For example, you might move busy tables to an SSD device, or move large tables to a high-capacity HDD device.

The Transportable Tablespaces feature is described under the following topics in this section:

- Prerequisites
- Importing Tables
- Importing Partitioned Tables
- Importing Table Partitions
- Limitations
- Usage Notes
- Internals

Prerequisites

- The `innodb_file_per_table` variable must be enabled, which it is by default.
- The page size of the tablespace must match the page size of the destination MySQL server instance. InnoDB page size is defined by the `innodb_page_size` variable, which is configured when initializing a MySQL server instance.
- If the table has a foreign key relationship, `foreign_key_checks` must be disabled before executing `DISCARD TABLESPACE`. Also, you should export all foreign key related tables at the same logical point in time, as `ALTER TABLE ... IMPORT TABLESPACE` does not enforce foreign key
Tables

constraints on imported data. To do so, stop updating the related tables, commit all transactions, acquire shared locks on the tables, and perform the export operations.

- When importing a table from another MySQL server instance, both MySQL server instances must have General Availability (GA) status and must be the same version. Otherwise, the table must be created on the same MySQL server instance into which it is being imported.

- If the table was created in an external directory by specifying the DATA DIRECTORY clause in the CREATE TABLE statement, the table that you replace on the destination instance must be defined with the same DATA DIRECTORY clause. A schema mismatch error is reported if the clauses do not match. To determine if the source table was defined with a DATA DIRECTORY clause, use SHOW CREATE TABLE to view the table definition. For information about using the DATA DIRECTORY clause, see Section 15.6.1.2, “Creating Tables Externally”.

- If a ROW_FORMAT option is not defined explicitly in the table definition or ROW_FORMAT=DEFAULT is used, the innodb_default_row_format setting must be the same on the source and destination instances. Otherwise, a schema mismatch error is reported when you attempt the import operation. Use SHOW CREATE TABLE to check the table definition. Use SHOW VARIABLES to check the innodb_default_row_format setting. For related information, see Defining the Row Format of a Table.

Importing Tables

This example demonstrates how to import a regular non-partitioned table that resides in a file-per-table tablespace.

1. On the destination instance, create a table with the same definition as the table you intend to import. (You can obtain the table definition using SHOW CREATE TABLE syntax.) If the table definition does not match, a schema mismatch error is reported when you attempt the import operation.

   ```sql
   mysql> USE test;
   mysql> CREATE TABLE t1 (c1 INT) ENGINE=INNODB;
   ```

2. On the destination instance, discard the tablespace of the table that you just created. (Before importing, you must discard the tablespace of the receiving table.)

   ```sql
   mysql> ALTER TABLE t1 DISCARD TABLESPACE;
   ```

3. On the source instance, run FLUSH TABLES ... FOR EXPORT to quiesce the table you intend to import. When a table is quiesced, only read-only transactions are permitted on the table.

   ```sql
   mysql> USE test;
   mysql> FLUSH TABLES t1 FOR EXPORT;
   ```

   FLUSH TABLES ... FOR EXPORT ensures that changes to the named table are flushed to disk so that a binary table copy can be made while the server is running. When FLUSH TABLES ... FOR EXPORT is run, InnoDB generates a .cfg metadata file in the schema directory of the table. The .cfg file contains metadata that is used for schema verification during the import operation.

4. Copy the .ibd file and .cfg metadata file from the source instance to the destination instance. For example:

   ```shell
   shell> scp /path/to/datadir/test/t1.{ibd,cfg} destination-server:/path/to/datadir/test
   ```

   The .ibd file and .cfg file must be copied before releasing the shared locks, as described in the next step.

   Note

   If you are importing a table from an encrypted tablespace, InnoDB generates a .cfp file in addition to a .cfg metadata file. The .cfp file...
Tables

must be copied to the destination instance together with the .cfg file. The .cfg file contains a transfer key and an encrypted tablespace key. On import, InnoDB uses the transfer key to decrypt the tablespace key. For related information, see Section 15.13, “InnoDB Data-at-Rest Encryption”.

5. On the source instance, use `UNLOCK TABLES` to release the locks acquired by the `FLUSH TABLES ... FOR EXPORT` statement:

```sql
mysql> USE test;
mysql> UNLOCK TABLES;
```

6. On the destination instance, import the tablespace:

```sql
mysql> USE test;
mysql> ALTER TABLE t1 IMPORT TABLESPACE;
```

Importing Partitioned Tables

This example demonstrates how to import a partitioned table, where each table partition resides in a file-per-table tablespace.

1. On the destination instance, create a partitioned table with the same definition as the partitioned table that you want to import. (You can obtain the table definition using `SHOW CREATE TABLE` syntax.) If the table definition does not match, a schema mismatch error is reported when you attempt the import operation.

```sql
mysql> USE test;
mysql> CREATE TABLE t1 (i int) ENGINE = InnoDB PARTITION BY KEY (i) PARTITIONS 3;
```

In the `datadir/test` directory, there is a tablespace .ibd file for each of the three partitions.

```bash
mysql> ! ls /path/to/datadir/test/
t1#p#p0.ibd  t1#p#p1.ibd  t1#p#p2.ibd
```

2. On the destination instance, discard the tablespace for the partitioned table. (Before the import operation, you must discard the tablespace of the receiving table.)

```sql
mysql> ALTER TABLE t1 DISCARD TABLESPACE;
```

The three tablespace .ibd files of the partitioned table are discarded from the `datadir/test` directory.

3. On the source instance, run `FLUSH TABLES ... FOR EXPORT` to quiesce the partitioned table that you intend to import. When a table is quiesced, only read-only transactions are permitted on the table.

```sql
mysql> USE test;
mysql> FLUSH TABLES t1 FOR EXPORT;
```

`FLUSH TABLES ... FOR EXPORT` ensures that changes to the named table are flushed to disk so that binary table copy can be made while the server is running. When `FLUSH TABLES ... FOR EXPORT` is run, InnoDB generates .cfg metadata files in the schema directory of the table for each of the table's tablespace files.

```bash
mysql> ! ls /path/to/datadir/test/
t1#p#p0.ibd  t1#p#p1.ibd  t1#p#p2.ibd
t1#p#p0.cfg  t1#p#p1.cfg  t1#p#p2.cfg
```

The .cfg files contain metadata that is used for schema verification when importing the tablespace. `FLUSH TABLES ... FOR EXPORT` can only be run on the table, not on individual table partitions.

4. Copy the .ibd and .cfg files from the source instance schema directory to the destination instance schema directory. For example:
shell> scp /path/to/datadir/test/t1*.{ibd,cfg} destination-server:/path/to/datadir/test

The .ibd and .cfg files must be copied before releasing the shared locks, as described in the next step.

Note
If you are importing a table from an encrypted tablespace, InnoDB generates a .cfp files in addition to a .cfg metadata files. The .cfp files must be copied to the destination instance together with the .cfg files. The .cfp files contain a transfer key and an encrypted tablespace key. On import, InnoDB uses the transfer key to decrypt the tablespace key. For related information, see Section 15.13, "InnoDB Data-at-Rest Encryption".

5. On the source instance, use `UNLOCK TABLES` to release the locks acquired by `FLUSH TABLES ... FOR EXPORT`:

```sql
mysql> USE test;
mysql> USE test;
```

6. On the destination instance, import the tablespace of the partitioned table:

```sql
mysql> USE test;
mysql> USE test;
```

Importing Table Partitions

This example demonstrates how to import individual table partitions, where each partition resides in a file-per-table tablespace file.

In the following example, two partitions (p2 and p3) of a four-partition table are imported.

1. On the destination instance, create a partitioned table with the same definition as the partitioned table that you want to import partitions from. (You can obtain the table definition using `SHOW CREATE TABLE` syntax.) If the table definition does not match, a schema mismatch error is reported when you attempt the import operation.

```sql
mysql> USE test;
mysql> USE test;
```

In the `/datadir/test` directory, there is a tablespace .ibd file for each of the four partitions.

```sql
mysql> /! ls /path/to/datadir/test/
t1#p#p0.ibd  t1#p#p1.ibd  t1#p#p2.ibd t1#p#p3.ibd
```

2. On the destination instance, discard the partitions that you intend to import from the source instance. (Before importing partitions, you must discard the corresponding partitions from the receiving partitioned table.)

```sql
mysql> ALTER TABLE t1 DISCARD PARTITION p2, p3 TABLESPACE;
```

The tablespace .ibd files for the two discarded partitions are removed from the `/datadir/test` directory on the destination instance, leaving the following files:

```sql
mysql> /! ls /path/to/datadir/test/
t1#p#p0.ibd  t1#p#p1.ibd
```

Note
When `ALTER TABLE ... DISCARD PARTITION ... TABLESPACE` is run on subpartitioned tables, both partition and subpartition table names are permitted. When a partition name is specified, subpartitions of that partition are included in the operation.
3. On the source instance, run `FLUSH TABLES ... FOR EXPORT` to quiesce the partitioned table. When a table is quiesced, only read-only transactions are permitted on the table.

```sql
mysql> USE test;
mysql> FLUSH TABLES t1 FOR EXPORT;
```

`FLUSH TABLES ... FOR EXPORT` ensures that changes to the named table are flushed to disk so that binary table copy can be made while the instance is running. When `FLUSH TABLES ... FOR EXPORT` is run, InnoDB generates a `.cfg` metadata file for each of the table's tablespace files in the schema directory of the table.

```sql
mysql> \ls /path/to/datadir/test/
t1#p#p0.ibd  t1#p#p1.ibd  t1#p#p2.ibd  t1#p#p3.ibd
t1#p#p0.cfg  t1#p#p1.cfg  t1#p#p2.cfg  t1#p#p3.cfg
```

The `.cfg` files contain metadata that used for schema verification during the import operation. `FLUSH TABLES ... FOR EXPORT` can only be run on the table, not on individual table partitions.

4. Copy the `.ibd` and `.cfg` files for partition `p2` and partition `p3` from the source instance schema directory to the destination instance schema directory.

```shell
scp t1#p#p2.ibd t1#p#p2.cfg t1#p#p3.ibd t1#p#p3.cfg destination-server:/path/to/datadir/test
```

The `.ibd` and `.cfg` files must be copied before releasing the shared locks, as described in the next step.

**Note**

If you are importing partitions from an encrypted tablespace, InnoDB generates a `.cfp` files in addition to a `.cfg` metadata files. The `.cfp` files must be copied to the destination instance together with the `.cfg` files. The `.cfp` files contain a transfer key and an encrypted tablespace key. On import, InnoDB uses the transfer key to decrypt the tablespace key. For related information, see Section 15.13, “InnoDB Data-at-Rest Encryption”.

5. On the source instance, use `UNLOCK TABLES` to release the locks acquired by `FLUSH TABLES ... FOR EXPORT`:

```sql
mysql> USE test;
mysql> UNLOCK TABLES;
```

6. On the destination instance, import table partitions `p2` and `p3`:

```sql
mysql> USE test;
mysql> ALTER TABLE t1 IMPORT PARTITION p2, p3 TABLESPACE;
```

**Note**

When `ALTER TABLE ... IMPORT PARTITION ... TABLESPACE` is run on subpartitioned tables, both partition and subpartition table names are permitted. When a partition name is specified, subpartitions of that partition are included in the operation.

**Limitations**

- The *Transportable Tablespaces* feature is only supported for tables that reside in file-per-table tablespaces. It is not supported for the tables that reside in the system tablespace or general tablespaces. Tables in shared tablespaces cannot be quiesced.

- `FLUSH TABLES ... FOR EXPORT` is not supported on tables with a `FULLTEXT` index, as full-text search auxiliary tables cannot be flushed. After importing a table with a `FULLTEXT` index, run `OPTIMIZE TABLE` to rebuild the `FULLTEXT` indexes. Alternatively, drop `FULLTEXT` indexes before the export operation and recreate the indexes after importing the table on the destination instance.
Tables

- Due to a `.cfg` metadata file limitation, schema mismatches are not reported for partition type or partition definition differences when importing a partitioned table. Column differences are reported.

- Prior to MySQL 8.0.19, index key part sort order information is not stored to the `.cfg` metadata file used during a tablespace import operation. The index key part sort order is therefore assumed to be ascending, which is the default. As a result, records could be sorted in an unintended order if one table involved in the import operation is defined with a DESC index key part sort order and the other table is not. The workaround is to drop and recreate affected indexes. For information about index key part sort order, see Section 13.1.15, “CREATE INDEX Statement”.

The `.cfg` file format was updated in MySQL 8.0.19 to include index key part sort order information. The issue described above does not affect import operations between MySQL 8.0.19 server instances or higher.

Usage Notes

- `ALTER TABLE ... IMPORT TABLESPACE` does not require a `.cfg` metadata file to import a table. However, metadata checks are not performed when importing without a `.cfg` file, and a warning similar to the following is issued:

```
Message: InnoDB: IO Read error: (2, No such file or directory) Error opening './test\t.cfg', will attempt to import without schema verification
1 row in set (0.00 sec)
```

Importing a table without a `.cfg` metadata file should only be considered if no schema mismatches are expected. The ability to import without a `.cfg` file could be useful in crash recovery scenarios where metadata is not accessible.

- On Windows, InnoDB stores database, tablespace, and table names internally in lowercase. To avoid import problems on case-sensitive operating systems such as Linux and Unix, create all databases, tablespaces, and tables using lowercase names. A convenient way to ensure that names are created in lowercase is to set `lower_case_table_names` to 1 before initializing the server. (It is prohibited to start the server with a `lower_case_table_names` setting that is different from the setting used when the server was initialized.)

```
[mysqld]
lower_case_table_names=1
```

- When running `ALTER TABLE ... DISCARD PARTITION ... TABLESPACE` and `ALTER TABLE ... IMPORT PARTITION ... TABLESPACE` on subpartitioned tables, both partition and subpartition table names are permitted. When a partition name is specified, subpartitions of that partition are included in the operation.

Internals

The following information describes internals and messages written to the error log during a table import procedure.

When `ALTER TABLE ... DISCARD TABLESPACE` is run on the destination instance:

- The table is locked in X mode.
- The tablespace is detached from the table.

When `FLUSH TABLES ... FOR EXPORT` is run on the source instance:

- The table being flushed for export is locked in shared mode.
- The purge coordinator thread is stopped.
- Dirty pages are synchronized to disk.
- Table metadata is written to the binary `.cfg` file.
Tables

Expected error log messages for this operation:

- [Note] InnoDB: Sync to disk of "test"."t1" started.
- [Note] InnoDB: Stopping purge
- [Note] InnoDB: Writing table metadata to './test/t1.cfg'
- [Note] InnoDB: Table "test"."t1" flushed to disk

When `UNLOCK TABLES` is run on the source instance:

- The binary `.cfg` file is deleted.
- The shared lock on the table or tables being imported is released and the purge coordinator thread is restarted.

Expected error log messages for this operation:

- [Note] InnoDB: Deleting the meta-data file './test/t1.cfg'
- [Note] InnoDB: Resuming purge

When `ALTER TABLE ... IMPORT TABLESPACE` is run on the destination instance, the import algorithm performs the following operations for each tablespace being imported:

- Each tablespace page is checked for corruption.
- The space ID and log sequence numbers (LSNs) on each page are updated.
- Flags are validated and LSN updated for the header page.
- Btree pages are updated.
- The page state is set to dirty so that it is written to disk.

Expected error log messages for this operation:

- [Note] InnoDB: Importing tablespace for table 'test/t1' that was exported from host 'host_name'
- [Note] InnoDB: Phase I - Update all pages
- [Note] InnoDB: Sync to disk
- [Note] InnoDB: Sync to disk - done!
- [Note] InnoDB: Phase III - Flush changes to disk
- [Note] InnoDB: Phase IV - Flush complete

**Note**

You may also receive a warning that a tablespace is discarded (if you discarded the tablespace for the destination table) and a message stating that statistics could not be calculated due to a missing `.ibd` file:

- [Warning] InnoDB: Table "test"."t1" tablespace is set as discarded. 7f34d9a37700 InnoDB: cannot calculate statistics for table "test"."t1" because the .ibd file is missing. For help, please refer to http://dev.mysql.com/doc/refman/8.0/en/innodb-troubleshooting.html

### 15.6.1.4 Moving or Copying InnoDB Tables

This section describes techniques for moving or copying some or all InnoDB tables to a different server or instance. For example, you might move an entire MySQL instance to a larger, faster server; you might clone an entire MySQL instance to a new replica server; you might copy individual tables to another instance to develop and test an application, or to a data warehouse server to produce reports.

On Windows, InnoDB always stores database and table names internally in lowercase. To move databases in a binary format from Unix to Windows or from Windows to Unix, create all databases and tables using lowercase names. A convenient way to accomplish this is to add the following line to the `[mysqld]` section of your `my.cnf` or `my.ini` file before creating any databases or tables:

- [mysqld]
It is prohibited to start the server with a `lower_case_table_names` setting that is different from the setting used when the server was initialized.

Techniques for moving or copying InnoDB tables include:

- Importing Tables
- MySQL Enterprise Backup
- Copying Data Files (Cold Backup Method)
- Restoring from a Logical Backup

**Importing Tables**

A table that resides in a file-per-table tablespace can be imported from another MySQL server instance or from a backup using the *Transportable Tablespace* feature. See Section 15.6.1.3, "Importing InnoDB Tables".

**MySQL Enterprise Backup**

The MySQL Enterprise Backup product lets you back up a running MySQL database with minimal disruption to operations while producing a consistent snapshot of the database. When MySQL Enterprise Backup is copying tables, reads and writes can continue. In addition, MySQL Enterprise Backup can create compressed backup files, and back up subsets of tables. In conjunction with the MySQL binary log, you can perform point-in-time recovery. MySQL Enterprise Backup is included as part of the MySQL Enterprise subscription.

For more details about MySQL Enterprise Backup, see Section 30.2, “MySQL Enterprise Backup Overview”.

**Copying Data Files (Cold Backup Method)**

You can move an InnoDB database simply by copying all the relevant files listed under "Cold Backups" in Section 15.18.1, “InnoDB Backup”.

**InnoDB** data and log files are binary-compatible on all platforms having the same floating-point number format. If the floating-point formats differ but you have not used `FLOAT` or `DOUBLE` data types in your tables, then the procedure is the same: simply copy the relevant files.

When you move or copy file-per-table `.ibd` files, the database directory name must be the same on the source and destination systems. The table definition stored in the InnoDB shared tablespace includes the database name. The transaction IDs and log sequence numbers stored in the tablespace files also differ between databases.

To move an `.ibd` file and the associated table from one database to another, use a `RENAME TABLE` statement:

```
RENAME TABLE db1.tbl_name TO db2.tbl_name;
```

If you have a “clean” backup of an `.ibd` file, you can restore it to the MySQL installation from which it originated as follows:

1. The table must not have been dropped or truncated since you copied the `.ibd` file, because doing so changes the table ID stored inside the tablespace.

2. Issue this `ALTER TABLE` statement to delete the current `.ibd` file:
3. Copy the backup `.ibd` file to the proper database directory.

4. Issue this `ALTER TABLE` statement to tell InnoDB to use the new `.ibd` file for the table:

   ```sql
   ALTER TABLE tbl_name IMPORT TABLESPACE;
   ```

   **Note**
   
   The `ALTER TABLE ... IMPORT TABLESPACE` feature does not enforce foreign key constraints on imported data.

In this context, a “clean” `.ibd` file backup is one for which the following requirements are satisfied:

- There are no uncommitted modifications by transactions in the `.ibd` file.
- There are no unmerged insert buffer entries in the `.ibd` file.
- Purge has removed all delete-marked index records from the `.ibd` file.
- `mysqlld` has flushed all modified pages of the `.ibd` file from the buffer pool to the file.

You can make a clean backup `.ibd` file using the following method:

1. Stop all activity from the `mysqlld` server and commit all transactions.

2. Wait until `SHOW ENGINE INNODB STATUS` shows that there are no active transactions in the database, and the main thread status of InnoDB is `Waiting for server activity`. Then you can make a copy of the `.ibd` file.

Another method for making a clean copy of an `.ibd` file is to use the MySQL Enterprise Backup product:

1. Use MySQL Enterprise Backup to back up the InnoDB installation.

2. Start a second `mysqlld` server on the backup and let it clean up the `.ibd` files in the backup.

### Restoring from a Logical Backup

You can use a utility such as `mysqldump` to perform a logical backup, which produces a set of SQL statements that can be executed to reproduce the original database object definitions and table data for transfer to another SQL server. Using this method, it does not matter whether the formats differ or if your tables contain floating-point data.

To improve the performance of this method, disable `autocommit` when importing data. Perform a commit only after importing an entire table or segment of a table.

### 15.6.1.5 Converting Tables from MyISAM to InnoDB

If you have MyISAM tables that you want to convert to InnoDB for better reliability and scalability, review the following guidelines and tips before converting.

**Note**

Partitioned MyISAM tables created in previous versions of MySQL are not compatible with MySQL 8.0. Such tables must be prepared prior to upgrade, either by removing the partitioning, or by converting them to InnoDB. See Section 24.6.2, “Partitioning Limitations Relating to Storage Engines”, for more information.

- Adjusting Memory Usage for MyISAM and InnoDB
• Handling Too-Long Or Too-Short Transactions
• Handling Deadlocks
• Storage Layout
• Converting an Existing Table
• Cloning the Structure of a Table
• Transferring Data
• Storage Requirements
• Defining Primary Keys
• Application Performance Considerations
• Understanding Files Associated with InnoDB Tables

Adjusting Memory Usage for MyISAM and InnoDB

As you transition away from MyISAM tables, lower the value of the key_buffer_size configuration option to free memory no longer needed for caching results. Increase the value of the innodb_buffer_pool_size configuration option, which performs a similar role of allocating cache memory for InnoDB tables. The InnoDB buffer pool caches both table data and index data, speeding up lookups for queries and keeping query results in memory for reuse. For guidance regarding buffer pool size configuration, see Section 8.12.3.1, “How MySQL Uses Memory”.

Handling Too-Long Or Too-Short Transactions

Because MyISAM tables do not support transactions, you might not have paid much attention to the autocommit configuration option and the COMMIT and ROLLBACK statements. These keywords are important to allow multiple sessions to read and write InnoDB tables concurrently, providing substantial scalability benefits in write-heavy workloads.

While a transaction is open, the system keeps a snapshot of the data as seen at the beginning of the transaction, which can cause substantial overhead if the system inserts, updates, and deletes millions of rows while a stray transaction keeps running. Thus, take care to avoid transactions that run for too long:

• If you are using a mysql session for interactive experiments, always COMMIT (to finalize the changes) or ROLLBACK (to undo the changes) when finished. Close down interactive sessions rather than leave them open for long periods, to avoid keeping transactions open for long periods by accident.

• Make sure that any error handlers in your application also ROLLBACK incomplete changes or COMMIT completed changes.

• ROLLBACK is a relatively expensive operation, because INSERT, UPDATE, and DELETE operations are written to InnoDB tables prior to the COMMIT, with the expectation that most changes are committed successfully and rollbacks are rare. When experimenting with large volumes of data, avoid making changes to large numbers of rows and then rolling back those changes.

• When loading large volumes of data with a sequence of INSERT statements, periodically COMMIT the results to avoid having transactions that last for hours. In typical load operations for data warehousing, if something goes wrong, you truncate the table (using TRUNCATE TABLE) and start over from the beginning rather than doing a ROLLBACK.

The preceding tips save memory and disk space that can be wasted during too-long transactions. When transactions are shorter than they should be, the problem is excessive I/O. With each COMMIT, MySQL makes sure each change is safely recorded to disk, which involves some I/O.
For most operations on InnoDB tables, you should use the setting `autocommit=0`. From an efficiency perspective, this avoids unnecessary I/O when you issue large numbers of consecutive `INSERT`, `UPDATE`, or `DELETE` statements. From a safety perspective, this allows you to issue a `ROLLBACK` statement to recover lost or garbled data if you make a mistake on the `mysql` command line, or in an exception handler in your application.

`autocommit=1` is suitable for InnoDB tables when running a sequence of queries for generating reports or analyzing statistics. In this situation, there is no I/O penalty related to `COMMIT` or `ROLLBACK`, and InnoDB can automatically optimize the read-only workload.

If you make a series of related changes, finalize all the changes at once with a single `COMMIT` at the end. For example, if you insert related pieces of information into several tables, do a single `COMMIT` after making all the changes. Or if you run many consecutive `INSERT` statements, do a single `COMMIT` after all the data is loaded; if you are doing millions of `INSERT` statements, perhaps split up the huge transaction by issuing a `COMMIT` every ten thousand or hundred thousand records, so the transaction does not grow too large.

Remember that even a `SELECT` statement opens a transaction, so after running some report or debugging queries in an interactive `mysql` session, either issue a `COMMIT` or close the `mysql` session.

For related information, see Section 15.7.2.2, “autocommit, Commit, and Rollback”.

### Handling Deadlocks

You might see warning messages referring to “deadlocks” in the MySQL error log, or the output of `SHOW ENGINE INNODB STATUS`. A deadlock is not a serious issue for InnoDB tables, and often does not require any corrective action. When two transactions start modifying multiple tables, accessing the tables in a different order, they can reach a state where each transaction is waiting for the other and neither can proceed. When deadlock detection is enabled (the default), MySQL immediately detects this condition and cancels (rolls back) the “smaller” transaction, allowing the other to proceed. If deadlock detection is disabled using the `innodb_deadlock_detect` configuration option, InnoDB relies on the `innodb_lock_wait_timeout` setting to roll back transactions in case of a deadlock.

Either way, your applications need error-handling logic to restart a transaction that is forcibly cancelled due to a deadlock. When you re-issue the same SQL statements as before, the original timing issue no longer applies. Either the other transaction has already finished and yours can proceed, or the other transaction is still in progress and your transaction waits until it finishes.

If deadlock warnings occur constantly, you might review the application code to reorder the SQL operations in a consistent way, or to shorten the transactions. You can test with the `innodb_print_all_deadlocks` option enabled to see all deadlock warnings in the MySQL error log, rather than only the last warning in the `SHOW ENGINE INNODB STATUS` output.

For more information, see Section 15.7.5, “Deadlocks in InnoDB”.

### Storage Layout

To get the best performance from InnoDB tables, you can adjust a number of parameters related to storage layout.

When you convert MyISAM tables that are large, frequently accessed, and hold vital data, investigate and consider the `innodb_file_per_table` and `innodb_page_size` variables, and the `ROW_FORMAT` and `KEY_BLOCK_SIZE` clauses of the `CREATE TABLE` statement.

During your initial experiments, the most important setting is `innodb_file_per_table`. When this setting is enabled, which is the default, new InnoDB tables are implicitly created in file-per-table tablespaces. In contrast with the InnoDB system tablespace, file-per-table tablespaces allow disk space to be reclaimed by the operating system when a table is truncated or dropped. File-per-table tablespaces also support `DYNAMIC` and `COMPRESSED` row formats and associated features such as...
table compression, efficient off-page storage for long variable-length columns, and large index prefixes. For more information, see Section 15.6.3.2, “File-Per-Table Tablespaces”.

You can also store InnoDB tables in a shared general tablespace, which support multiple tables and all row formats. For more information, see Section 15.6.3.3, “General Tablespaces”.

Converting an Existing Table

To convert a non-InnoDB table to use InnoDB use ALTER TABLE:

\[\text{ALTER TABLE } \text{table_name} \ \text{ENGINE=InnoDB;}\]

Cloning the Structure of a Table

You might make an InnoDB table that is a clone of a MyISAM table, rather than using ALTER TABLE to perform conversion, to test the old and new table side-by-side before switching.

Create an empty InnoDB table with identical column and index definitions. Use SHOW CREATE TABLE \text{table_name}\G to see the full CREATE TABLE statement to use. Change the ENGINE clause to ENGINE=INNODB.

Transferring Data

To transfer a large volume of data into an empty InnoDB table created as shown in the previous section, insert the rows with INSERT INTO \text{innodb_table} SELECT * FROM \text{myisam_table} ORDER BY primary_key_columns.

You can also create the indexes for the InnoDB table after inserting the data. Historically, creating new secondary indexes was a slow operation for InnoDB, but now you can create the indexes after the data is loaded with relatively little overhead from the index creation step.

If you have UNIQUE constraints on secondary keys, you can speed up a table import by turning off the uniqueness checks temporarily during the import operation:

\[\text{SET unique_checks=0;}\]
\[\text{... import operation ...}\]
\[\text{SET unique_checks=1;}\]

For big tables, this saves disk I/O because InnoDB can use its change buffer to write secondary index records as a batch. Be certain that the data contains no duplicate keys. unique_checks permits but does not require storage engines to ignore duplicate keys.

For better control over the insertion process, you can insert big tables in pieces:

\[\text{INSERT INTO } \text{newtable} \ \text{SELECT * FROM } \text{oldtable} \ \text{WHERE yourkey > something AND yourkey <= somethingelse;}\]

After all records are inserted, you can rename the tables.

During the conversion of big tables, increase the size of the InnoDB buffer pool to reduce disk I/O. Typically, the recommended buffer pool size is 50 to 75 percent of system memory. You can also increase the size of InnoDB log files.

Storage Requirements

If you intend to make several temporary copies of your data in InnoDB tables during the conversion process, it is recommended that you create the tables in file-per-table tablespaces so that you can reclaim the disk space when you drop the tables. When the innodb_file_per_table configuration option is enabled (the default), newly created InnoDB tables are implicitly created in file-per-table tablespaces.

Whether you convert the MyISAM table directly or create a cloned InnoDB table, make sure that you have sufficient disk space to hold both the old and new tables during the process. InnoDB tables
Tables

require more disk space than MyISAM tables. If an ALTER TABLE operation runs out of space, it
starts a rollback, and that can take hours if it is disk-bound. For inserts, InnoDB uses the insert buffer
to merge secondary index records to indexes in batches. That saves a lot of disk I/O. For rollback, no
such mechanism is used, and the rollback can take 30 times longer than the insertion.

In the case of a runaway rollback, if you do not have valuable data in your database, it may be
advisable to kill the database process rather than wait for millions of disk I/O operations to complete.
For the complete procedure, see Section 15.21.2, “Forcing InnoDB Recovery”.

Defining Primary Keys

The PRIMARY KEY clause is a critical factor affecting the performance of MySQL queries and the
space usage for tables and indexes. The primary key uniquely identifies a row in a table. Every row in
the table should have a primary key value, and no two rows can have the same primary key value.

These are guidelines for the primary key, followed by more detailed explanations.

• Declare a PRIMARY KEY for each table. Typically, it is the most important column that you refer to in
WHERE clauses when looking up a single row.

• Declare the PRIMARY KEY clause in the original CREATE TABLE statement, rather than adding it
later through an ALTER TABLE statement.

• Choose the column and its data type carefully. Prefer numeric columns over character or string ones.

• Consider using an auto-increment column if there is not another stable, unique, non-null, numeric
column to use.

• An auto-increment column is also a good choice if there is any doubt whether the value of the
primary key column could ever change. Changing the value of a primary key column is an expensive
operation, possibly involving rearranging data within the table and within each secondary index.

Consider adding a primary key to any table that does not already have one. Use the smallest practical
numeric type based on the maximum projected size of the table. This can make each row slightly more
compact, which can yield substantial space savings for large tables. The space savings are multiplied
if the table has any secondary indexes, because the primary key value is repeated in each secondary
index entry. In addition to reducing data size on disk, a small primary key also lets more data fit into the
buffer pool, speeding up all kinds of operations and improving concurrency.

If the table already has a primary key on some longer column, such as a VARCHAR, consider adding a
new unsigned AUTO_INCREMENT column and switching the primary key to that, even if that column is
not referenced in queries. This design change can produce substantial space savings in the secondary
indexes. You can designate the former primary key columns as UNIQUE NOT NULL to enforce the
same constraints as the PRIMARY KEY clause, that is, to prevent duplicate or null values across all
those columns.

If you spread related information across multiple tables, typically each table uses the same column for
its primary key. For example, a personnel database might have several tables, each with a primary
key of employee number. A sales database might have some tables with a primary key of customer
number, and other tables with a primary key of order number. Because lookups using the primary key
are very fast, you can construct efficient join queries for such tables.

If you leave the PRIMARY KEY clause out entirely, MySQL creates an invisible one for you. It is a 6-
byte value that might be longer than you need, thus wasting space. Because it is hidden, you cannot
refer to it in queries.

Application Performance Considerations

The reliability and scalability features of InnoDB require more disk storage than equivalent MyISAM
tables. You might change the column and index definitions slightly, for better space utilization, reduced
I/O and memory consumption when processing result sets, and better query optimization plans making efficient use of index lookups.

If you set up a numeric ID column for the primary key, use that value to cross-reference with related values in any other tables, particularly for join queries. For example, rather than accepting a country name as input and doing queries searching for the same name, do one lookup to determine the country ID, then do other queries (or a single join query) to look up relevant information across several tables. Rather than storing a customer or catalog item number as a string of digits, potentially using up several bytes, convert it to a numeric ID for storing and querying. A 4-byte unsigned INT column can index over 4 billion items (with the US meaning of billion: 1000 million). For the ranges of the different integer types, see Section 11.1.2, "Integer Types (Exact Value) - INTEGER, INT, SMALLINT, TINYINT, MEDIUMINT, BIGINT".

Understanding Files Associated with InnoDB Tables

InnoDB files require more care and planning than MyISAM files do.

- You must not delete the ibdata files that represent the InnoDB system tablespace.
- Methods of moving or copying InnoDB tables to a different server are described in Section 15.6.1.4, "Moving or Copying InnoDB Tables".

15.6.1.6 AUTO_INCREMENT Handling in InnoDB

InnoDB provides a configurable locking mechanism that can significantly improve scalability and performance of SQL statements that add rows to tables with AUTO_INCREMENT columns. To use the AUTO_INCREMENT mechanism with an InnoDB table, an AUTO_INCREMENT column must be defined as part of an index such that it is possible to perform the equivalent of an indexed SELECT MAX(ai_col) lookup on the table to obtain the maximum column value. Typically, this is achieved by making the AUTO_INCREMENT column the first column of some table index.

This section describes the AUTO_INCREMENT lock modes, usage implications of different AUTO_INCREMENT lock mode settings, and how InnoDB initializes the AUTO_INCREMENT counter.

- InnoDB AUTO_INCREMENT Lock Modes
- InnoDB AUTO_INCREMENT Lock Mode Usage Implications
- InnoDB AUTO_INCREMENT Counter Initialization
- Notes

InnoDB AUTO_INCREMENT Lock Modes

This section describes the AUTO_INCREMENT lock modes used to generate auto-increment values, and how each lock mode affects replication. The auto-increment lock mode is configured at startup using the innodb_autoinc_lock_mode variable.

The following terms are used in describing innodb_autoinc_lock_mode settings:

- "INSERT-like" statements

All statements that generate new rows in a table, including INSERT, INSERT ... SELECT, REPLACE, REPLACE ... SELECT, and LOAD DATA. Includes "simple-inserts", "bulk-inserts", and "mixed-mode" inserts.

- "Simple inserts"

Statements for which the number of rows to be inserted can be determined in advance (when the statement is initially processed). This includes single-row and multiple-row INSERT and REPLACE statements that do not have a nested subquery, but not INSERT ... ON DUPLICATE KEY UPDATE.
• “Bulk inserts”

Statements for which the number of rows to be inserted (and the number of required auto-
increment values) is not known in advance. This includes \texttt{INSERT ... SELECT}, \texttt{REPLACE ... SELECT}, and \texttt{LOAD DATA} statements, but not plain \texttt{INSERT}. InnoDB assigns new values for the \texttt{AUTO_INCREMENT} column one at a time as each row is processed.

• “Mixed-mode inserts”

These are “simple insert” statements that specify the auto-increment value for some (but not all) of the new rows. An example follows, where \texttt{c1} is an \texttt{AUTO_INCREMENT} column of table \texttt{t1}:

\begin{verbatim}
INSERT INTO t1 (c1,c2) VALUES (1,'a'), (NULL,'b'), (5,'c'), (NULL,'d');
\end{verbatim}

Another type of “mixed-mode insert” is \texttt{INSERT ... ON DUPLICATE KEY UPDATE}, which in the worst case is in effect an \texttt{INSERT} followed by a \texttt{UPDATE}, where the allocated value for the \texttt{AUTO_INCREMENT} column may or may not be used during the update phase.

There are three possible settings for the \texttt{innodb_autoinc_lock_mode} variable. The settings are 0, 1, or 2, for “traditional”, “consecutive”, or “interleaved” lock mode, respectively. As of MySQL 8.0, interleaved lock mode \texttt{(innodb_autoinc_lock_mode=2)} is the default setting. Prior to MySQL 8.0, consecutive lock mode is the default \texttt{(innodb_autoinc_lock_mode=1)}.
