no longer use version 8.0.18 or earlier to administer the cluster.

To upgrade a cluster's metadata, connect MySQL Shell's global session to your cluster and use the
dba.upgradeMetadata() operation to upgrade the cluster's metadata to the new metadata. For
example:

```bash
mysql-js> \connect user@example.com:3306
mysql-js> dba.upgradeMetadata()
InnoDB Cluster Metadata Upgrade
The cluster you are connected to is using an outdated metadata schema version
1.0.1 and needs to be upgraded to 2.0.0.
Without doing this upgrade, no AdminAPI calls except read only operations will
be allowed.
The grants for the MySQL Router accounts that were created automatically when
bootstrapping need to be updated to match the new metadata version’s
requirements. Updating router accounts...
NOTE: 2 router accounts have been updated.
Upgrading metadata at 'example.com:3306' from version 1.0.1 to version 2.0.0.
Creating backup of the metadata schema...
Step 1 of 1: upgrading from 1.0.1 to 2.0.0...
Removing metadata backup...
Upgrade process successfully finished, metadata schema is now on version 2.0.0
```

If you encounter an error related to the cluster administration user missing privileges, use the
Cluster.setupAdminAccount() operation with the update option to grant the user the correct
privileges. See Configuring Users for InnoDB Cluster.

**21.3.3 Troubleshooting InnoDB cluster Upgrades**

This section covers trouble shooting the upgrade process.

**Handling Host Name Changes**

MySQL Shell uses the host value of the provided connection parameters as the target hostname
used for AdminAPI operations, namely to register the instance in the metadata (for the
dba.createCluster() and Cluster.addInstance() operations). However, the actual host
used for the connection parameters might not match the hostname that is used or reported by
Group Replication, which uses the value of the `report_host` system variable when it is defined (in other words it is not `NULL`), otherwise the value of `hostname` is used. Therefore, AdminAPI now follows the same logic to register the target instance in the metadata and as the default value for the `group_replication_local_address` variable on instances, instead of using the host value from the instance connection parameters. When the `report_host` variable is set to empty, Group Replication uses an empty value for the host but AdminAPI (for example in commands such as `dba.checkInstanceConfiguration()`, `dba.configureInstance()`, `dba.createCluster()`, and so on) reports the hostname as the value used which is inconsistent with the value reported by Group Replication. If an empty value is set for the `report_host` system variable, an error is generated. (Bug #28285389)

For a cluster created using a MySQL Shell version earlier than 8.0.16, an attempt to reboot the cluster from a complete outage performed using version 8.0.16 or higher results in this error. This is caused by a mismatch of the Metadata values with the `report_host` or `hostname` values reported by the instances. The workaround is to:

1. Identify which of the instances is the “seed”, in other words the one with the most recent GTID set. The `dba.rebootClusterFromCompleteOutage()` operation detects whether the instance is a seed and the operation generates an error if the current session is not connected to the most up-to-date instance.

2. Set the `report_host` system variable to the value that is stored in the Metadata schema for the target instance. This value is the `hostname:port` pair used in the instance definition upon cluster creation. The value can be consulted by querying the `mysql_innodb_cluster_metadata.instances` table.

For example, suppose a cluster was created using the following sequence of commands:

```
mysql-ja> \c clusterAdmin@localhost:3306
mysql-ja> dba.createCluster("myCluster")
```

Therefore the hostname value stored in the metadata is “localhost” and for that reason, `report_host` must be set to “localhost” on the seed.

3. Reboot the cluster using only the seed instance. At the interactive prompts do not add the remaining instances to the cluster.

4. Use `Cluster.rescan()` to add the other instances back to the cluster.

5. Remove the seed instance from the cluster

6. Stop mysql on the seed instance and either remove the forced `report_host` setting (step 2), or replace it with the value previously stored in the Metadata value.

7. Restart the seed instance and add it back to the cluster using `Cluster.addInstance()`

This allows a smooth and complete upgrade of the cluster to the latest MySQL Shell version. Another possibility, that depends on the use-case, is to simply set the value of `report_host` on all cluster members to match what has been registered in the Metadata schema upon cluster creation.

### 21.4 Using MySQL Router with InnoDB Cluster

This section describes how to use MySQL Router with InnoDB cluster to achieve high availability. Regardless of whether you have deployed a sandbox or production cluster, MySQL Router can configure itself based on the InnoDB cluster’s metadata using the `--bootstrap` option. This configures MySQL Router automatically to route connections to the cluster’s server instances. Client applications connect to the ports MySQL Router provides, without any need to be aware of the InnoDB cluster topology. In the event of a unexpected failure, the InnoDB cluster adjusts itself automatically and MySQL Router detects the change. This removes the need for your client application to handle failover. For more information, see Routing for MySQL InnoDB cluster.
Note

Do not attempt to configure MySQL Router manually to redirect to the ports of an InnoDB cluster. Always use the `--bootstrap` option as this ensures that MySQL Router takes its configuration from the InnoDB cluster's metadata. See Cluster Metadata and State.

The recommended deployment of MySQL Router is on the same host as the application. When using a sandbox deployment, everything is running on a single host, therefore you deploy MySQL Router to the same host. When using a production deployment, we recommend deploying one MySQL Router instance to each machine used to host one of your client applications. It is also possible to deploy MySQL Router to a common machine through which your application instances connect.

Assuming MySQL Router is already installed (see Installing MySQL Router), use the `--bootstrap` option to provide the location of a server instance that belongs to the InnoDB cluster. MySQL Router uses the included metadata cache plugin to retrieve the InnoDB cluster's metadata, consisting of a list of server instance addresses which make up the InnoDB cluster and their role in the cluster. You pass the URI-like connection string of the server that MySQL Router should retrieve the InnoDB cluster metadata from. For example:

```
shell> mysqlrouter --bootstrap icadmin@ic-1:3306 --user=mysqlrouter
```

You are prompted for the instance password and encryption key for MySQL Router to use. This encryption key is used to encrypt the instance password used by MySQL Router to connect to the cluster. The ports you can use to connect to the InnoDB cluster are also displayed. The MySQL Router bootstrap process creates a `mysqlrouter.conf` file, with the settings based on the cluster metadata retrieved from the address passed to the `--bootstrap` option, in the above example `icadmin@ic-1:3306`. Based on the InnoDB cluster metadata retrieved, MySQL Router automatically configures the `mysqlrouter.conf` file, including a `metadata_cache` section. If you are using MySQL Router 8.0.14 and later, the `--bootstrap` option automatically configures MySQL Router to track and store active MySQL InnoDB cluster Metadata server addresses at the path configured by `dynamic_state`. This ensures that when MySQL Router is restarted it knows which MySQL InnoDB cluster Metadata server addresses are current. For more information see the `dynamic_state` documentation.

In earlier MySQL Router versions, metadata server information was defined during Router's initial bootstrap operation and stored statically as `bootstrap_server_addresses` in the configuration file, which contained the addresses for all server instances in the cluster. For example:

```
[metadata_cache:prodCluster]
router_id=1
bootstrap_server_addresses=mysql://icadmin@ic-1:3306,mysql://icadmin@ic-2:3306,mysql://icadmin@ic-3:3306
user=mysql_router1_jy95yozko3k2
metadata_cluster=prodCluster
ttl=300
```

Tip

If using MySQL Router 8.0.13 or earlier, when you change the topology of a cluster by adding another server instance after you have bootstrapped MySQL Router, you need to update `bootstrap_server_addresses` based on the updated metadata. Either restart MySQL Router using the `--bootstrap` option, or manually edit the `bootstrap_server_addresses` section of the `mysqlrouter.conf` file and restart MySQL Router.

The generated MySQL Router configuration creates TCP ports which you use to connect to the cluster. By default, ports for communicating with the cluster using both classic MySQL protocol and X Protocol are created. To use X Protocol the server instances must have X Plugin installed and configured, which is the default for MySQL 8.0 and later. The default available TCP ports are:

- `6446` - for classic MySQL protocol read-write sessions, which MySQL Router redirects incoming connections to primary server instances.
• **6447** - for classic MySQL protocol read-only sessions, which MySQL Router redirects incoming connections to one of the secondary server instances.

• **64460** - for X Protocol read-write sessions, which MySQL Router redirects incoming connections to primary server instances.

• **64470** - for X Protocol read-only sessions, which MySQL Router redirects incoming connections to one of the secondary server instances.

Depending on your MySQL Router configuration the port numbers might be different to the above. For example if you use the **--conf-base-port** option, or the **group_replication_single_primary_mode** variable. The exact ports are listed when you start MySQL Router.

The way incoming connections are redirected depends on the type of cluster being used. When using a single-primary cluster, by default MySQL Router publishes a X Protocol and a classic MySQL protocol port, which clients connect to for read-write sessions and which are redirected to the cluster's single primary. With a multi-primary cluster read-write sessions are redirected to one of the primary instances in a round-robin fashion. For example, this means that the first connection to port 6446 would be redirected to the ic-1 instance, the second connection to port 6446 would be redirected to the ic-2 instance, and so on. For incoming read-only connections MySQL Router redirects connections to one of the secondary instances, also in a round-robin fashion. To modify this behavior see the **routing_strategy** option.

Once bootstrapped and configured, start MySQL Router. If you used a system wide install with the **--bootstrap** option then issue:

```
shell> mysqlrouter &
```

If you installed MySQL Router to a directory using the **--directory** option, use the **start.sh** script found in the directory you installed to. Alternatively set up a service to start MySQL Router automatically when the system boots, see Starting MySQL Router. You can now connect a MySQL client, such as MySQL Shell to one of the incoming MySQL Router ports as described above and see how the client gets transparently connected to one of the InnoDB cluster instances.

```
shell> mysqlsh --uri root@localhost:6442
```

To verify which instance you are actually connected to, simply issue an SQL query against the **port** status variable.

```
mysql-js> \sql
Switching to SQL mode... Commands end with ;
mysql-js> select @@port;
<table>
<thead>
<tr>
<th>@port</th>
</tr>
</thead>
<tbody>
<tr>
<td>3310</td>
</tr>
</tbody>
</table>
```

**Testing High Availability**

To test if high availability works, simulate an unexpected halt by killing an instance. The cluster detects the fact that the instance left the cluster and reconfigures itself. Exactly how the cluster reconfigures itself depends on whether you are using a single-primary or multi-primary cluster, and the role the instance serves within the cluster.

In single-primary mode:

• If the current primary leaves the cluster, one of the secondary instances is elected as the new primary, with instances prioritized by the lowest **server_uuid**. MySQL Router redirects read-write connections to the newly elected primary.
• If a current secondary leaves the cluster, MySQL Router stops redirecting read-only connections to
the instance.

For more information see Section 18.1.3.1, “Single-Primary Mode”.

In multi-primary mode:

• If a current "R/W" instance leaves the cluster, MySQL Router redirects read-write connections
to other primaries. If the instance which left was the last primary in the cluster then the cluster is
completely gone and you cannot connect to any MySQL Router port.

For more information see Section 18.1.3.2, “Multi-Primary Mode”.

There are various ways to simulate an instance leaving a cluster, for example you can forcibly stop
the MySQL server on an instance, or use the AdminAPI `dba.killSandboxInstance()` if testing a
sandbox deployment. In this example assume there is a single-primary sandbox cluster deployment
with three server instances and the instance listening at port 3310 is the current primary. Simulate the
instance leaving the cluster unexpectedly:

```
mysql-js> dba.killSandboxInstance(3310)
```

The cluster detects the change and elects a new primary automatically. Assuming your session is
connected to port 6446, the default read-write classic MySQL protocol port, MySQL Router should
detect the change to the cluster's topology and redirect your session to the newly elected primary. To
verify this, switch to SQL mode in MySQL Shell using the `\sql` command and select the instance’s
port variable to check which instance your session has been redirected to. Notice that the first
SELECT statement fails as the connection to the original primary was lost. This means the current
session has been closed, MySQL Shell automatically reconnects for you and when you issue the
command again the new port is confirmed.

```
mysql-js> \sql
Switching to SQL mode... Commands end with ;
mysql-sql> SELECT @@port;
ERROR: 2013 (HY000): Lost connection to MySQL server during query
The global session got disconnected.
Attempting to reconnect to 'root@localhost:6446'...
The global session was successfully reconnected.
mysql-sql> SELECT @@port;
+--------+
| @@port |
+--------+
| 3330   |
+--------+
1 row in set (0.00 sec)
```

In this example, the instance at port 3330 has been elected as the new primary. This shows that the
InnoDB cluster provided us with automatic failover, that MySQL Router has automatically reconnected
us to the new primary instance, and that we have high availability.

MySQL Router and Metadata Servers

When MySQL Router is bootstrapped against a cluster, it records the server instance’s addresses in
its configuration file. If any additional instances are added to the cluster after bootstrapping the MySQL
Router, they are not automatically detected and therefore are not used for connection routing.

To ensure that newly added instances are routed to correctly you must bootstrap MySQL Router
against the cluster to read the updated metadata. This means that you must restart MySQL Router and
include the `--bootstrap` option.

Working with a Cluster's Routers

You can bootstrap multiple instances of MySQL Router against a cluster or replica set. From version
8.0.19, to show a list of all registered MySQL Router instances, issue:
Working with a Cluster's Routers

Cluster.listRouters()

The result provides information about each registered MySQL Router instance, such as its name in the metadata, the hostname, ports, and so on. For example, issue:

```javascript
mysql-js> Cluster.listRouters()
{
    "clusterName": "example",
    "routers": {
        "ic-1:3306": {
            "hostname": "ic-1:3306",
            "lastCheckIn": "2020-01-16 11:43:45",
            "roPort": 6447,
            "roXPort": 64470,
            "rwPort": 6446,
            "rwXPort": 64460,
            "version": "8.0.19"
        }
    }
}
```

The returned information shows:

- The name of the MySQL Router instance.
- Last check-in timestamp, which is generated by a periodic ping from the MySQL Router stored in the metadata.
- Hostname where the MySQL Router instance is running.
- Read-Only and Read-Write ports which the MySQL Router publishes for classic MySQL protocol connections.
- Read-Only and Read-Write ports which the MySQL Router publishes for X Protocol connections.
- Version of this MySQL Router instance. The support for returning `version` was added in 8.0.19. If this operation is run against an earlier version of MySQL Router, the version field is `null`.

Additionally, the `Cluster.listRouters()` operation can show a list of instances that do not support the metadata version supported by MySQL Shell. Use the `onlyUpgradeRequired` option, for example by issuing `Cluster.listRouters({'onlyUpgradeRequired': 'true'})`. The returned list shows only the MySQL Router instances registered with the `Cluster` which require an upgrade of their metadata. See Section 21.3.2, "Upgrading InnoDB cluster Metadata".

MySQL Router instances are not automatically removed from the metadata, so for example as you bootstrap more instances the InnoDB cluster metadata contains a growing number of references to instances. To remove a registered MySQL Router instance from a cluster's metadata, use the `Cluster.removeRouterMetadata(router)` operation, added in version 8.0.19. Use the `Cluster.listRouters()` operation to get the name of the MySQL Router instance you want to remove, and pass it in as `router`. For example suppose your MySQL Router instances registered with a cluster were:

```javascript
mysql-js> Cluster.listRouters()
{
    "clusterName": "testCluster",
    "routers": {
        "myRouter1": {
            "hostname": "example1.com",
            "lastCheckIn": null,
            "routerId": "1",
            "roPort": "6447",
            "rwPort": "6446"
            "version": null
        },
        "myRouter2": {
            "hostname": "example2.com",
            "lastCheckIn": "2019-11-27 16:25:00",
```

...
Configuring the MySQL Router User

Based on the fact that the instance named “myRouter1” has null for “lastCheckIn” and “version”, we decide to remove this old instance from the metadata by issuing:

```sql
mysql-js> cluster.removeRouterMetadata('myRouter1')
```

The MySQL Router instance specified is unregistered from the cluster by removing it from the InnoDB cluster metadata.

**Configuring the MySQL Router User**

When MySQL Router connects to an InnoDB cluster or InnoDB ReplicaSet, it requires a user account which has the correct privileges. From MySQL Router version 8.0.19 this internal user can be specified using the `--account` option. In previous versions, MySQL Router created internal accounts at each bootstrap of the cluster, which could result in a number of accounts building up over time. From MySQL Shell version 8.0.20, you can use AdminAPI to set up the user account required for MySQL Router.

Use the `setupRouterAccount(user, [options])` operation to create a MySQL user account or upgrade an existing account so that it that can be used by MySQL Router to operate on an InnoDB cluster or InnoDB ReplicaSet. This is the recommended method of configuring MySQL Router with InnoDB cluster and InnoDB ReplicaSet.

To add a new MySQL Router account named `myRouter1` to the InnoDB cluster referenced by the variable `testCluster`, issue:

```sql
mysqlsh> testCluster.setupRouterAccount(myRouter1)
```

In this case, no domain is specified and so the account is created with the wildcard (%) character, which ensures that the created user can connect from any domain. To limit the account to only be able to connect from the `example.com` domain, issue:

```sql
mysqlsh> testCluster.setupRouterAccount(myRouter1@example.com)
```

The operation prompts for a password, and then sets up the MySQL Router user with the correct privileges. If the InnoDB cluster or InnoDB ReplicaSet has multiple instances, the created MySQL Router user is propagated to all of the instances. Once you have a user set up, you can use it to bootstrap MySQL Router using the `--account` option. For example, suppose you created a cluster administrator named `adminAccount` using the `setupAdminAccount()` operation. To bootstrap MySQL Router using the `myRouter1` user created by the `setupRouterAccount()` operation, issue:

```bash
mysqlrouter --bootstrap adminAccount@ic-1:3306 --account=myRouter1
```

When you already have a MySQL Router user configured, for example if you were using a version prior to 8.0.20, you can use the `setupRouterAccount()` operation to reconfigure the existing user. In this case, pass in the `update` option set to true. For example, to reconfigure the `myOldRouter` user, issue:

```sql
mysqlsh> testCluster.setupRouterAccount(myOldRouter, {'update':1})
```

### 21.5 Working with InnoDB Cluster

This section explains how to work with InnoDB cluster, and how to handle common administration tasks.

- **Using** `dba.checkInstanceConfiguration()`
- **Configuring Instances with** `dba.configureLocalInstance()`
Using `dba.checkInstanceConfiguration()`

Before creating a production deployment from server instances you need to check that MySQL on each instance is correctly configured. In addition to `dba.configureInstance()`, which checks the configuration as part of configuring an instance, you can use the `dba.checkInstanceConfiguration()` function. This ensures that the instance satisfies...
Configuring Instances with `dba.configureLocalInstance()`

Instances which do not support persisting configuration changes automatically (see Persisting Settings) require you to connect to the server, run MySQL Shell, connect to the instance locally and issue
Retrieving an InnoDB cluster with `dba.getCluster()`

dba.configureLocalInstance(). This enables MySQL Shell to modify the instance's option file after running the following commands against a remote instance:

- `dba.configureInstance()`
- `dba.createCluster()`
- `Cluster.addInstance()`
- `Cluster.removeInstance()`
- `Cluster.rejoinInstance()`

**Important**
Failing to persist configuration changes to an instance's option file can result in the instance not rejoining the cluster after the next restart.

The recommended method is to log in to the remote machine, for example using SSH, run MySQL Shell as the root user and then connect to the local MySQL server. For example, use the `--uri` option to connect to the local instance:

```shell
sudo -i mysqlsh --uri=instance
```

Alternatively use the `\connect` command to log in to the local instance. Then issue `dba.configureInstance(instance)`, where `instance` is the connection information to the local instance, to persist any changes made to the local instance's option file.

```mysql-js
dba.configureLocalInstance('icadmin@ic-2:3306')
```

Repeat this process for each instance in the cluster which does not support persisting configuration changes automatically. For example if you add 2 instances to a cluster which do not support persisting configuration changes automatically, you must connect to each server and persist the configuration changes required for InnoDB cluster before the instance restarts. Similarly if you modify the cluster structure, for example changing the number of instances, you need to repeat this process for each server instance to update the InnoDB cluster metadata accordingly for each instance in the cluster.

**Retrieving an InnoDB cluster with `dba.getCluster()`**

When you create a cluster using `dba.createCluster()`, the operation returns a Cluster object which can be assigned to a variable. You use this object to work with the cluster, for example to add instances or check the cluster's status. If you want to retrieve a cluster again at a later date, for example after restarting MySQL Shell, use the `dba.getCluster([name],[options])` function. For example:

```mysql-js
var cluster1 = dba.getCluster()
```

If you do not specify a cluster `name` then the default cluster is returned. By default MySQL Shell attempts to connect to the primary instance of the cluster when you use `dba.getCluster()`. Set the `connectToPrimary` option to configure this behavior. If `connectToPrimary` is `true` and the active global MySQL Shell session is not to a primary instance, the cluster is queried for the primary member and the cluster object connects to it. If there is no quorum in the cluster, the operation fails. If `connectToPrimary` is `false`, the cluster object uses the active session, in other words the same instance as the MySQL Shell's current global session. If `connectToPrimary` is not specified, MySQL Shell treats `connectToPrimary` as `true`, and falls back to `connectToPrimary` being `false`.

To force connecting to a secondary when getting a cluster, establish a connection to the secondary member of the cluster and use the `connectToPrimary` option by issuing:

```mysql-js
shell.connect(secondary_member)
```
Finding the Primary

When you are working with a single-primary InnoDB cluster or an InnoDB ReplicaSet, you need to connect to the primary instance for administration tasks so that configuration changes can be written to the metadata. To find the current primary you can:

- use the `--redirect-primary` option at MySQL Shell start up to ensure that the target server is part of an InnoDB cluster or InnoDB ReplicaSet. If the target instance is not the primary, MySQL Shell finds the primary and connects to it.

- use the `shell.connectToPrimary([instance, password])` operation (added in version 8.0.20), which checks whether the target instance belongs to a cluster or replica set. If so, MySQL Shell opens a new session to the primary, sets the active global MySQL Shell session to the established session and returns it.

  If an `instance` is not provided, the operation attempts to use the active global MySQL Shell session. If an `instance` is not provided and there is no active global MySQL Shell session, an exception is thrown. If the target instance does not belong to a cluster or replica set the operation fails with an error.

- use the status operation, find the primary in the result, and manually connect to that instance.

Using `cluster.describe()`

To get information about the structure of the InnoDB cluster itself, use the `Cluster.describe()` function:

```javascript
mysql-j> cluster.describe();
{
    "clusterName": "testCluster",
    "defaultReplicaSet": {
        "name": "default",
        "topology": [
            {
                "address": "ic-1:3306",
                "label": "ic-1:3306",
                "role": "HA"
            },
            {
                "address": "ic-2:3306",
                "label": "ic-2:3306",
                "role": "HA"
            },
            {
                "address": "ic-3:3306",
                "label": "ic-3:3306",
                "role": "HA"
            }
        ]
    }
}
```

The output from this function shows the structure of the InnoDB cluster including all of its configuration information, and so on. The address, label and role values match those described at Checking a cluster's Status with `Cluster.status()`.

Checking a cluster's Status with `Cluster.status()`
Checking a cluster’s Status with `Cluster.status()`

Cluster objects provide the `status()` method that enables you to check how a cluster is running. Before you can check the status of the InnoDB cluster, you need to get a reference to the InnoDB cluster object by connecting to any of its instances. However, if you want to make changes to the configuration of the cluster, you must connect to a "R/W" instance. Issuing `status()` retrieves the status of the cluster based on the view of the cluster which the server instance you are connected to is aware of and outputs a status report.

**Important**

The instance’s state in the cluster directly influences the information provided in the status report. Therefore ensure the instance you are connected to has a status of **ONLINE**.

For information about how the InnoDB cluster is running, use the cluster’s `status()` method:

```sql
mysql-ja> var cluster = dba.getCluster()
mysql-ja> cluster.status()
```

```json
{   "clusterName": "testcluster",   "defaultReplicaSet": {     "name": "default",     "primary": "ic-1:3306",     "ssl": "REQUIRED",     "status": "OK",     "statusText": "Cluster is ONLINE and can tolerate up to ONE failure.",     "topology": {       "ic-1:3306": {         "address": "ic-1:3306",         "mode": "R/W",         "readReplicas": {},         "role": "HA",         "status": "ONLINE"       },       "ic-2:3306": {         "address": "ic-2:3306",         "mode": "R/O",         "readReplicas": {},         "role": "HA",         "status": "ONLINE"       },       "ic-3:3306": {         "address": "ic-3:3306",         "mode": "R/O",         "readReplicas": {},         "role": "HA",         "status": "ONLINE"       }     },     "groupInformationSourceMember": "mysql://icadmin@ic-1:3306"
}
```

The output of `Cluster.status()` provides the following information:

- **clusterName**: name assigned to this cluster during `dba.createCluster()`.
- **defaultReplicaSet**: the server instances which belong to an InnoDB cluster and contain the data set.
- **primary**: displayed when the cluster is operating in single-primary mode only. Shows the address of the current primary instance. If this field is not displayed, the cluster is operating in multi-primary mode.
- **ssl**: whether secure connections are used by the cluster or not. Shows values of **REQUIRED** or **DISABLED**, depending on how the `memberSslMode` option was configured during either `createCluster()` or `addInstance()`. The value returned by this parameter corresponds to the
Checking a cluster's Status with `Cluster.status()`

value of the `group_replication_ssl_mode` server variable on the instance. See Securing your Cluster.

- **status**: The status of this element of the cluster. For the overall cluster this describes the high availability provided by this cluster. The status is one of the following:
  - **ONLINE**: The instance is online and participating in the cluster.
  - **OFFLINE**: The instance has lost connection to the other instances.
  - **RECOVERING**: The instance is attempting to synchronize with the cluster by retrieving transactions it needs before it can become an **ONLINE** member.
  - **UNREACHABLE**: The instance has lost communication with the cluster.
  - **ERROR**: The instance has encountered an error during the recovery phase or while applying a transaction.

  **Important**

  Once an instance enters **ERROR** state, the `super_read_only` option is set to **ON**. To leave the **ERROR** state you must manually configure the instance with `super_read_only=OFF`.

- **(MISSING)**: The state of an instance which is part of the configured cluster, but is currently unavailable.

  **Note**

  The **MISSING** state is specific to InnoDB cluster, it is not a state generated by Group Replication. MySQL Shell uses this state to indicate instances that are registered in the metadata, but cannot be found in the live cluster view.

- **topology**: The instances which have been added to the cluster.

- **Host name of instance**: The host name of an instance, for example localhost:3310.

- **role**: what function this instance provides in the cluster. Currently only HA, for high availability.

- **mode**: whether the server is read-write ("R/W") or read-only ("R/O"). From version 8.0.17, this is derived from the current state of the `super_read_only` variable on the instance, and whether the cluster has quorum. In previous versions the value of mode was derived from whether the instance was serving as a primary or secondary instance. Usually if the instance is a primary, then the mode is "R/W", and if the instance is a secondary the mode is "R/O". Any instances in a cluster that have no visible quorum are marked as "R/O", regardless of the state of the `super_read_only` variable.

- **groupInformationSourceMember**: the internal connection used to get information about the cluster, shown as a URI-like connection string. Usually the connection initially used to create the cluster.

To display more information about the cluster use the `extended` option. From version 8.0.17, the `extended` option supports integer or Boolean values. To configure the additional information that `Cluster.status({"extended":value})` provides, use the following values:

- **0**: disables the additional information, the default
- **1**: includes information about the Group Replication Protocol Version, Group name, cluster member UUIDs, cluster member roles and states as reported by Group Replication, and the list of fenced system variables
- **2**: includes information about transactions processed by connection and applier
Checking a cluster's Status with `Cluster.status()`

- 3: includes more detailed statistics about the replication performed by each cluster member.

Setting `extended` using Boolean values is the equivalent of setting the integer values 0 and 1. In versions prior to 8.0.17, the `extended` option was only Boolean. Similarly prior versions used the `queryMembers` Boolean option to provide more information about the instances in the cluster, which is the equivalent of setting `extended` to 3. The `queryMembers` option is deprecated and scheduled to be removed in a future release.

When you issue `Cluster.status({'extended':1})`, or the `extended` option is set to `true`, the output includes:

- the following additional attributes for the `defaultReplicaSet` object:
  - `GRProtocolVersion` is the Group Replication Protocol Version being used in the cluster.
  - `groupName` is the group's name, a UUID.
  - the following additional attributes for each object of the `topology` object:
    - `fenceSysVars` a list containing the name of the fenced system variables which are enabled. Currently the fenced system variables considered are `read_only`, `super_read_only` and `offline_mode`.
    - `memberId` Each cluster member UUID.
    - `memberRole` the Member Role as reported by the Group Replication plugin, see the `MEMBER_ROLE` column of the `replication_group_members` table.
    - `memberState` the Member State as reported by the Group Replication plugin, see the `MEMBER_STATE` column of the `replication_group_members` table.

To see information about recovery and regular transaction I/O, applier worker thread statistics and any lags; applier coordinator statistics, if parallel apply is enabled; error, and other information from I/O and applier threads issue use the values 2 and 3. A value of 3 is the equivalent of setting the deprecated `queryMembers` option to `true`. When you use these values, a connection to each instance in the cluster is opened so that additional instance specific statistics can be queried. The exact statistics that are included in the output depend on the state and configuration of the instance and the server version. This information matches that shown in the `replication_group_member_stats` table, see the descriptions of the matching columns for more information. Instances which are `ONLINE` have a `transactions` section included in the output. Instances which are `RECOVERING` have a `recovery` section included in the output. When you set `extended` to 2, in either case, these sections can contain the following:

- `appliedCount`: see `COUNT_TRANSACTONS_REMOTE_APPLIED`
- `checkedCount`: see `COUNT_TRANSACTONS_CHECKED`
- `committedAllMembers`: see `TRANSACTIONS_COMMITTED_ALL_MEMBERS`
- `conflictsDetectedCount`: see `COUNT_CONFLICTS_DETECTED`
- `inApplierQueueCount`: see `COUNT_TRANSACTONS_REMOTE_IN_APPLIER_QUEUE`
- `inQueueCount`: see `COUNT_TRANSACTONS_IN_QUEUE`
- `lastConflictFree`: see `LAST_CONFLICT_FREE_TRANSACTION`
Checking a cluster's Status with `Cluster.status()`

- `proposedCount`: see `COUNT_TRANSACTIONS_LOCAL_PROPOSED`
- `rollbackCount`: see `COUNT_TRANSACTIONS_LOCAL_ROLLBACK`

When you set `extended` to 3, the `connection` section shows information from the `replication_connection_status` table. The `connection` section can contain the following:

The `currentlyQueueing` section has information about the transactions currently queued:

- `immediateCommitTimestamp`: see `QUEUEING_TRANSACTION_IMMEDIATE_COMMIT_TIMESTAMP`
- `immediateCommitToNowTime`: see `QUEUEING_TRANSACTION_IMMEDIATE_COMMIT_TIMESTAMP minus NOW()`
- `originalCommitTimestamp`: see `QUEUEING_TRANSACTION_ORIGINAL_COMMIT_TIMESTAMP`
- `originalCommitToNowTime`: see `QUEUEING_TRANSACTION_ORIGINAL_COMMIT_TIMESTAMP minus NOW()`
- `startTimestamp`: see `QUEUEING_TRANSACTION_START_QUEUE_TIMESTAMP`
- `transaction`: see `QUEUEING_TRANSACTION`
- `lastHeartbeatTimestamp`: see `LAST_HEARTBEAT_TIMESTAMP`

The `lastQueued` section has information about the most recently queued transaction:

- `endTimestamp`: see `LAST_QUEUED_TRANSACTION_END_QUEUE_TIMESTAMP`
- `immediateCommitTimestamp`: see `LAST_QUEUED_TRANSACTION_IMMEDIATE_COMMIT_TIMESTAMP`
- `immediateCommitToEndTime`: `LAST_QUEUED_TRANSACTION_IMMEDIATE_COMMIT_TIMESTAMP minus NOW()`
- `originalCommitTimestamp`: see `LAST_QUEUED_TRANSACTION_ORIGINAL_COMMIT_TIMESTAMP`
- `originalCommitToEndTime`: `LAST_QUEUED_TRANSACTION_ORIGINAL_COMMIT_TIMESTAMP minus NOW()`
- `queueTime`: `LAST_QUEUED_TRANSACTION_END_QUEUE_TIMESTAMP minus LAST_QUEUED_TRANSACTION_START_QUEUE_TIMESTAMP`
- `startTimestamp`: see `LAST_QUEUED_TRANSACTION_START_QUEUE_TIMESTAMP`
- `transaction`: see `LAST_QUEUED_TRANSACTION`
- `receivedHeartbeats`: see `COUNT_RECEIVED_HEARTBEATS`
- `receivedTransactionSet`: see `RECEIVED_TRANSACTION_SET`
- `threadId`: see `THREAD_ID`

Instances which are using a multithreaded slave have a `workers` section which contains information about the worker threads, and matches the information shown by the `replication_applier_status_by_worker` table.

The `lastApplied` section shows the following information about the last transaction applied by the worker:

- `applyTime`: see `LAST_APPLIED_TRANSACTION_END_APPLY_TIMESTAMP minus LAST_APPLIED_TRANSACTION_START_APPLY_TIMESTAMP`
Checking a cluster’s Status with `Cluster.status()`

- `endTimestamp`: see `LAST_APPLIED_TRANSACTION_END_APPLY_TIMESTAMP`
- `immediateCommitTimestamp`: see `LAST_APPLIED_TRANSACTION_IMMEDIATE_COMMIT_TIMESTAMP`
- `immediateCommitToEndTime`: see `LAST_APPLIED_TRANSACTION_IMMEDIATE_COMMIT_TIMESTAMP` minus `NOW()`
- `originalCommitTimestamp`: see `LAST_APPLIED_TRANSACTION_ORIGINAL_COMMIT_TIMESTAMP`
- `originalCommitToEndTime`: see `LAST_APPLIED_TRANSACTION_ORIGINAL_COMMIT_TIMESTAMP` minus `NOW()`
- `startTimestamp`: see `LAST_APPLIED_TRANSACTION_START_APPLY_TIMESTAMP`
- `transaction`: see `LAST_APPLIED_TRANSACTION`

The `currentlyApplying` section shows the following information about the transaction currently being applied by the worker:

- `immediateCommitTimestamp`: see `APPLYING_TRANSACTION_IMMEDIATE_COMMIT_TIMESTAMP`
- `immediateCommitToNowTime`: see `APPLYING_TRANSACTION_IMMEDIATE_COMMIT_TIMESTAMP` minus `NOW()`
- `originalCommitTimestamp`: see `APPLYING_TRANSACTION_ORIGINAL_COMMIT_TIMESTAMP`
- `originalCommitToNowTime`: see `APPLYING_TRANSACTION_ORIGINAL_COMMIT_TIMESTAMP` minus `NOW()`
- `startTimestamp`: see `APPLYING_TRANSACTION_START_APPLY_TIMESTAMP`
- `transaction`: see `APPLYING_TRANSACTION`

The `lastProcessed` section has the following information about the last transaction processed by the worker:

- `bufferTime`: `LAST_PROCESSED_TRANSACTION_END_BUFFER_TIMESTAMP` minus `LAST_PROCESSED_TRANSACTION_START_BUFFER_TIMESTAMP`
- `endTimestamp`: see `LAST_PROCESSED_TRANSACTION_END_BUFFER_TIMESTAMP`
- `immediateCommitTimestamp`: see `LAST_PROCESSED_TRANSACTION_IMMEDIATE_COMMIT_TIMESTAMP`
- `immediateCommitToEndTime`: see `LAST_PROCESSED_TRANSACTION_IMMEDIATE_COMMIT_TIMESTAMP` minus `LAST_PROCESSED_TRANSACTION_END_BUFFER_TIMESTAMP`
- `originalCommitTimestamp`: see `LAST_PROCESSED_TRANSACTION_ORIGINAL_COMMIT_TIMESTAMP`
- `originalCommitToEndTime`: see `LAST_PROCESSED_TRANSACTION_ORIGINAL_COMMIT_TIMESTAMP` minus `LAST_PROCESSED_TRANSACTION_END_BUFFER_TIMESTAMP`
- `startTimestamp`: see `LAST_PROCESSED_TRANSACTION_START_BUFFER_TIMESTAMP`
- `transaction`: see `LAST_PROCESSED_TRANSACTION`

If parallel applier workers are enabled, then the number of objects in the workers array in `transactions` or `recovery` matches the number of configured workers and an additional
coordinator object is included. The information shown matches the information in the replication_applier_status_by_coordinator table. The object can contain:

The currentlyProcessing section has the following information about the transaction being processed by the worker:

- **immediateCommitTimestamp**: see `PROCESSING_TRANSACTION_IMMEDIATE_COMMIT_TIMESTAMP`
- **immediateCommitToNowTime**: `PROCESSING_TRANSACTION_IMMEDIATE_COMMIT_TIMESTAMP` minus `NOW()`
- **originalCommitTimestamp**: see `PROCESSING_TRANSACTION_ORIGINAL_COMMIT_TIMESTAMP`
- **originalCommitToNowTime**: `PROCESSING_TRANSACTION_ORIGINAL_COMMIT_TIMESTAMP` minus `NOW()`
- **startTimestamp**: see `PROCESSING_TRANSACTION_START_BUFFER_TIMESTAMP`
- **transaction**: see `PROCESSING_TRANSACTION`

worker objects have the following information if an error was detected in the replication_applier_status_by_worker table:

- **lastErrno**: see `LAST_ERROR_NUMBER`
- **lastError**: see `LAST_ERROR_MESSAGE`
- **lastErrorTimestamp**: see `LAST_ERROR_TIMESTAMP`

connection objects have the following information if an error was detected in the replication_connection_status table:

- **lastErrno**: see `LAST_ERROR_NUMBER`
- **lastError**: see `LAST_ERROR_MESSAGE`
- **lastErrorTimestamp**: see `LAST_ERROR_TIMESTAMP`

coordinator objects have the following information if an error was detected in the replication_applier_status_by_coordinator table:

- **lastErrno**: see `LAST_ERROR_NUMBER`
- **lastError**: see `LAST_ERROR_MESSAGE`
- **lastErrorTimestamp**: see `LAST_ERROR_TIMESTAMP`

**Monitoring Recovery Operations**

The output of `Cluster.status()` shows information about the progress of recovery operations for instances in `RECOVERING` state. Information is shown for instances recovering using either MySQL Clone, or incremental recovery. Monitor these fields:

- The **recoveryStatusText** field includes information about the type of recovery being used. When MySQL Clone is working the field shows “Cloning in progress”. When incremental recovery is working the field shows “Distributed recovery in progress”.
- When MySQL Clone is being used, the **recovery** field includes a dictionary with the following fields:
  - **cloneStartTime**: The timestamp of the start of the clone process
  - **cloneState**: The state of the clone progress
• **currentStage**: The current stage which the clone process has reached

• **currentStageProgress**: The current stage progress as a percentage of completion

• **currentStageState**: The current stage state

Example `Cluster.status()` output, trimmed for brevity:

```
...,
  "recovery": {
    "cloneState": "In Progress",
    "currentStage": "FILE COPY",
    "currentStageProgress": 61.726837675213865,
    "currentStageState": "In Progress",
  },
  "recoveryStatusText": "Cloning in progress",
...,
```

• When incremental recovery is being used, the `recovery` field includes a dictionary with the following field:

• **state**: The state of the `group_replication_recovery` channel

Example output `Cluster.status()`, trimmed for brevity:

```
...,
  "recovery": {
    "state": "ON",
  },
...,
```

**InnoDB cluster and Group Replication Protocol**

From MySQL 8.0.16, Group Replication has the concept of a communication protocol for the group, see [Section 18.4.1.4, “Setting a Group’s Communication Protocol Version”](#) for background information. The Group Replication communication protocol version usually has to be managed explicitly, and set to accommodate the oldest MySQL Server version that you want the group to support. However, InnoDB cluster automatically and transparently manages the communication protocol versions of its members, whenever the cluster topology is changed using AdminAPI operations. A cluster always uses the most recent communication protocol version that is supported by all the instances that are currently part of the cluster or joining it.

• When an instance is added to, removed from, or rejoins the cluster, or a rescan or reboot operation is carried out on the cluster, the communication protocol version is automatically set to a version supported by the instance that is now at the earliest MySQL Server version.

• When you carry out a rolling upgrade by removing instances from the cluster, upgrading them, and adding them back into the cluster, the communication protocol version is automatically upgraded when the last remaining instance at the old MySQL Server version is removed from the cluster prior to its upgrade.

To see the communication protocol version being used in a cluster, use the `Cluster.status()` function with the `extended` option enabled. The communication protocol version is returned in the `GRProtocolVersion` field, provided that the cluster has quorum and no cluster members are unreachable.

**Checking the MySQL Version on Instances**

The following operations can report information about the MySQL Server version running on the instance:
• `Cluster.status()`

• `Cluster.describe()`

• `Cluster.rescan()`

The behavior varies depending on the MySQL Server version of the `Cluster` object session.

• `Cluster.status()`

If either of the following requirements are met, a `version` string attribute is returned for each instance JSON object of the `topology` object:

• The `Cluster` object's current session is version 8.0.11 or later.

• The `Cluster` object's current session is running a version earlier than version 8.0.11 but the `extended` option is set to 3 (or the deprecated `queryMembers` is true).

For example on an instance running version 8.0.16:

```
"topology": {
  "ic-1:3306": {
    "address": "ic-1:3306",
    "mode": "R/W",
    "readReplicas": {},
    "role": "HA",
    "status": "ONLINE",
    "version": "8.0.16"
  }
}
```

For example on an instance running version 5.7.24:

```
"topology": {
  "ic-1:3306": {
    "address": "ic-1:3306",
    "mode": "R/W",
    "readReplicas": {},
    "role": "HA",
    "status": "ONLINE",
    "version": "5.7.24"
  }
}
```

• `Cluster.describe()`

If the `Cluster` object's current session is version 8.0.11 or later, a `version` string attribute is returned for each instance JSON object of the `topology` object.

For example on an instance running version 8.0.16:

```
"topology": [
  {
    "address": "ic-1:3306",
    "label": "ic-1:3306",
    "role": "HA",
    "version": "8.0.16"
  }
]
```

• `Cluster.rescan()`

If the `Cluster` object's current session is version 8.0.11 or later, and the `Cluster.rescan()` operation detects instances which do not belong to the cluster, a `version` string attribute is returned for each instance JSON object of the `newlyDiscoveredInstance` object.

For example on an instance running version 8.0.16:

```
"newlyDiscoveredInstances": [
```
Super Read-only and Instances

Whenever Group Replication stops, the `super_read_only` variable is set to `ON` to ensure no writes are made to the instance. When you try to use such an instance with the following AdminAPI commands you are given the choice to set `super_read_only=OFF` on the instance:

- `dba.configureInstance()`
- `dba.configureLocalInstance()`
- `dba.dropMetadataSchema()`

When AdminAPI encounters an instance which has `super_read_only=ON`, in interactive mode you are given the choice to set `super_read_only=OFF`. For example:

```plaintext
mysql-js> var myCluster = dba.dropMetadataSchema()
Are you sure you want to remove the Metadata? [y/N]: y
The MySQL instance at 'localhost:3310' currently has the super_read_only system variable set to protect it from inadvertent updates from applications. You must first unset it to be able to perform any changes to this instance.
For more information see:
Do you want to disable super_read_only and continue? [y/N]: y
Metadata Schema successfully removed.
```

The number of current active sessions to the instance is shown. You must ensure that no applications can write to the instance inadvertently. By answering `y` you confirm that AdminAPI can write to the instance. If there is more than one open session to the instance listed, exercise caution before permitting AdminAPI to set `super_read_only=OFF`.

To force the function to set `super_read_only=OFF` in a script, pass the `clearReadOnly` option set to `true`. For example `dba.configureInstance(instance, {clearReadOnly: true})`.

Configuring Users for InnoDB Cluster

Working with instances that belong to an InnoDB cluster or InnoDB ReplicaSet requires that you connect to the instances with a user that has the correct privileges to administer the instances. AdminAPI provides the following ways to administer suitable users:

- In version 8.0.20 and later, use the `setupAdminAccount(user)` operation, which creates or upgrades a MySQL user account with the necessary privileges to administer an InnoDB cluster or InnoDB ReplicaSet.
- In versions prior to 8.0.20, the preferred method to create users for administration is using the `clusterAdmin` option with the `dba.configureInstance()` operation.

For more information, see User Privileges. If you want to manually configure an administration user, that user requires the following privileges, all with `GRANT OPTION`:

- Global privileges on `*.*` for `RELOAD`, `SHUTDOWN`, `PROCESS`, `FILE`, `SELECT`, `SUPER`, `REPLICATION_SLAVE`, `REPLICATION_CLIENT`, `REPLICATION_APPLIER`, `CREATE_USER`, `SYSTEM_VARIABLES_ADMIN`, `PERIST_RO_VARIABLES_ADMIN`, `BACKUP_ADMIN`, `CLONE_ADMIN`, and `EXECUTE`. 
Note
SUPER includes the following required privileges:
SYSTEM_VARIABLES_ADMIN, SESSION_VARIABLES_ADMIN,
REPLICATION_SLAVE_ADMIN, GROUP_REPLICATION_ADMIN,
REPLICATION_SLAVE_ADMIN, ROLE_ADMIN.

• Schema specific privileges for mysql_innodb_cluster_metadata.*, mysql_innodb_cluster_metadata_bkp.*, and mysql_innodb_cluster_metadata_previous.* are ALTER, ALTER ROUTINE, CREATE,
CREATE ROUTINE, CREATE TEMPORARY TABLES, CREATE VIEW, DELETE, DROP, EVENT,
EXECUTE, INDEX, INSERT, LOCK TABLES, REFERENCES, SHOW VIEW, TRIGGER, UPDATE; and for mysql.* are INSERT, UPDATE, DELETE.

Note
This list of privileges is based on the current version of MySQL Shell. The privileges are subject to change between releases. Therefore the recommended way to administer accounts is using the operations described at User Privileges.

If only read operations are needed, for example to create a user for monitoring purposes, an account with more restricted privileges can be used. To give the user your_user the privileges needed to monitor InnoDB cluster issue:

```sql
GRANT SELECT ON mysql_innodb_cluster_metadata.* TO your_user@'%';
GRANT SELECT ON performance_schema.global_status TO your_user@'%';
GRANT SELECT ON performance_schema.replication_applier_status TO your_user@'%';
GRANT SELECT ON performance_schema.replication_applier_status_by_coordinator TO your_user@'%';
GRANT SELECT ON performance_schema.replication_applier_status_by_worker TO your_user@'%';
GRANT SELECT ON performance_schema.replication_applier_status_configuration TO your_user@'%';
GRANT SELECT ON performance_schema.replication_connection_configuration TO your_user@'%';
GRANT SELECT ON performance_schema.replication_connection_status TO your_user@'%';
GRANT SELECT ON performance_schema.replication_group_member_stats TO your_user@'%';
GRANT SELECT ON performance_schema.replication_group_members TO your_user@'%' WITH GRANT OPTION;
GRANT SELECT ON performance_schema.threads TO your_user@'%' WITH GRANT OPTION;
```

For more information, see Section 13.7.1, “Account Management Statements”.

Resetting Recovery Account Passwords

From version 8.0.18, you can use the `Cluster.resetRecoveryAccountsPassword()` operation to reset the passwords for the internal recovery accounts created by InnoDB cluster, for example to follow a custom password lifetime policy. Use the `Cluster.resetRecoveryAccountsPassword()` operation to reset the passwords for all internal recovery accounts used by the cluster. The operation sets a new random password for the internal recovery account on each instance which is online. If an instance cannot be reached, the operation fails. You can use the `force` option to ignore such instances, but this is not recommended, and it is safer to bring the instance back online before using this operation. This operation only applies to the passwords created by InnoDB cluster and cannot be used to update manually created passwords.

Note
The user which executes this operation must have all the required `clusterAdmin` privileges, in particular `CREATE USER`, in order to ensure that the password of recovery accounts can be changed regardless of the password verification-required policy. In other words, independent of whether the `password_require_current` system variable is enabled or not.

Configuring Automatic Rejoin of Instances

Instances running MySQL 8.0.16 and later support the Group Replication automatic rejoin functionality, which enables you to configure instances to automatically rejoin the cluster after being expelled. See
Section 18.6.6, “Responses to Failure Detection and Network Partitioning” for background information. AdminAPI provides the `autoRejoinTries` option to configure the number of tries instances make to rejoin the cluster after being expelled. By default instances do not automatically rejoin the cluster. You can configure the `autoRejoinTries` option at either the cluster level or for an individual instance using the following commands:

- `dba.createCluster()`
- `Cluster.addInstance()`
- `Cluster.setOption()`
- `Cluster.setInstanceOption()`

The `autoRejoinTries` option accepts positive integer values between 0 and 2016 and the default value is 0, which means that instances do not try to automatically rejoin. When you are using the automatic rejoin functionality, your cluster is more tolerant to faults, especially temporary ones such as unreliable networks. But if quorum has been lost, you should not expect members to automatically rejoin the cluster, because majority is required to rejoin instances.

Instances running MySQL version 8.0.12 and later have the `group_replication_exit_state_action` variable, which you can configure using the AdminAPI `exitStateAction` option. This controls what instances do in the event of leaving the cluster unexpectedly. By default the `exitStateAction` option is `READ_ONLY`, which means that instances which leave the cluster unexpectedly become read-only. If `exitStateAction` is set to `OFFLINE_MODE` (available from MySQL 8.0.18), instances which leave the cluster unexpectedly become read-only and also enter offline mode, where they disconnect existing clients and do not accept new connections (except from clients with administrator privileges). If `exitStateAction` is set to `ABORT_SERVER` then in the event of leaving the cluster unexpectedly, the instance shuts down MySQL, and it has to be started again before it can rejoin the cluster. Note that when you are using the automatic rejoin functionality, the action configured by the `exitStateAction` option only happens in the event that all attempts to rejoin the cluster fail.

There is a chance you might connect to an instance and try to configure it using the AdminAPI, but at that moment the instance could be rejoining the cluster. This could happen whenever you use any of these operations:

- `Cluster.status()`
- `dba.getCluster()`
- `Cluster.rejoinInstance()`
- `Cluster.addInstance()`
- `Cluster.removeInstance()`
- `Cluster.rescan()`
- `Cluster.checkInstanceState()`

These operations might provide extra information while the instance is automatically rejoining the cluster. In addition, when you are using `Cluster.removeInstance()`, if the target instance is automatically rejoining the cluster the operation aborts unless you pass in `force:true`.

Managing Sandbox Instances

Once a sandbox instance is running, it is possible to change its status at any time using the following:

- To stop a sandbox instance use `dba.stopSandboxInstance(instance)`. This stops the instance gracefully, unlike `dba.killSandboxInstance(instance)`.
- To start a sandbox instance use `dba.startSandboxInstance(instance)`.
InnoDB Cluster and Binary Log Purging

In MySQL 8, the binary log is automatically purged (as defined by `binlog_expire_logs_seconds`). This means that a cluster which has been running for a longer time than `binlog_expire_logs_seconds` could eventually not contain an instance with a complete binary log that contains all of the transactions applied by the instances. This could result in instances needing to be provisioned automatically, for example using MySQL Enterprise Backup, before they could join the cluster. Instances running 8.0.17 and later support the MySQL Clone plugin, which resolves this issue by providing an automatic provisioning solution which does not rely on incremental recovery, see Section 21.2.5, “Using MySQL Clone with InnoDB cluster”. Instances running a version earlier than 8.0.17 only support incremental recovery, and the result is that, depending on which version of MySQL the instance is running, instances might have to be provisioned automatically. Otherwise operations which rely on distributed recovery, such as `Cluster.addInstance()` and so on might fail.

On instances running earlier versions of MySQL the following rules are used for binary log purging:

- Instances running a version earlier than 8.0.1 have no automatic binary log purging because the default value of `expire_logs_days` is 0.
- Instances running a version later than 8.0.1 but earlier than 8.0.4 purge the binary log after 30 days because the default value of `expire_logs_days` is 30.
- Instances running a version later than 8.0.10 purge the binary log after 30 days because the default value of `binlog_expire_logs_seconds` is 2592000 and the default value of `expire_logs_days` is 0.

Thus, depending on how long the cluster has been running binary logs could have been purged and you might have to provision instances manually. Similarly, if you manually purged binary logs you could encounter the same situation. Therefore you are strongly advised to upgrade to a version of MySQL later than 8.0.17 to take full advantage of the automatic provisioning provided by MySQL Clone for distributed recovery, and to minimize downtime while provisioning instances for your InnoDB cluster.

Removing Instances from the InnoDB Cluster

You can remove an instance from a cluster at any time should you wish to do so. This can be done with the `Cluster.removeInstance(instance)` method, as in the following example:

```sql
mysql-j> cluster.removeInstance('root@localhost:3310')
```

The instance will be removed from the InnoDB cluster. Depending on the instance being the Seed or not, the Metadata session might become invalid. If so, please start a new session to the Metadata Storage R/W instance.

```
Attempting to leave from the Group Replication group...
```

```
The instance 'localhost:3310' was successfully removed from the cluster.
```

You can optionally pass in the `interactive` option to control whether you are prompted to confirm the removal of the instance from the cluster. In interactive mode, you are prompted to continue with the removal of the instance (or not) in case it is not reachable. The `cluster.removeInstance()` operation ensures that the instance is removed from the metadata of all the cluster members which are ONLINE, and the instance itself.

When the instance being removed has transactions which still need to be applied, AdminAPI waits for up to the number of seconds configured by the MySQL Shell `dba.gtidWaitTimeout` option for
transactions (GTIDs) to be applied. The MySQL Shell `dba.gtidWaitTimeout` option has a default value of 60 seconds, see Configuring MySQL Shell Options for information on changing the default. If the timeout value defined by `dba.gtidWaitTimeout` is reached when waiting for transactions to be applied and the `force` option is `false` (or not defined) then an error is issued and the remove operation is aborted. If the timeout value defined by `dba.gtidWaitTimeout` is reached when waiting for transactions to be applied and the `force` option is set to `true` then the operation continues without an error and removes the instance from the cluster.

### Important

The `force` option should only be used with `Cluster.removeInstance(instance)` when you want to ignore any errors, for example unprocessed transactions or an instance being UNREACHABLE, and do not plan to reuse the instance with the cluster. Ignoring errors when removing an instance from the cluster could result in an instance which is not in synchrony with the cluster, preventing it from rejoining the cluster at a later time. Only use the `force` option when you plan to no longer use the instance with the cluster, in all other cases you should always try to recover the instance and only remove it when it is available and healthy, in other words with the status ONLINE.

### Customizing InnoDB clusters

When you create a cluster and add instances to it, values such as the group name, the local address, and the seed instances are configured automatically by AdminAPI. These default values are recommended for most deployments, but advanced users can override the defaults by passing the following options to the `dba.createCluster()` and `Cluster.addInstance()`.

To customize the name of the replication group created by InnoDB cluster, pass the `groupName` option to the `dba.createCluster()` command. This sets the `group_replication_group_name` system variable. The name must be a valid UUID.

To customize the address which an instance provides for connections from other instances, pass the `localAddress` option to the `dba.createCluster()` and `cluster.addInstance()` commands. Specify the address in the format `host:port`. This sets the `group_replication_local_address` system variable on the instance. The address must be accessible to all instances in the cluster, and must be reserved for internal cluster communication only. In other words do not use this address for communication with the instance.

To customize the instances used as seeds when an instance joins the cluster, pass the `groupSeeds` option to the `dba.createCluster()` and `cluster.addInstance()` commands. Seed instances are contacted when a new instance joins a cluster and used to provide data to the new instance. The addresses are specified as a comma separated list such as `host1:port1,host2:port2`. This configures the `group_replication_group_seeds` system variable.

For more information see the documentation of the system variables configured by these AdminAPI options.

### Rejoining a Cluster

If an instance leaves the cluster, for example because it lost connection, and for some reason it could not automatically rejoin the cluster, it might be necessary to rejoin it to the cluster at a later stage. To rejoin an instance to a cluster issue `Cluster.rejoinInstance(instance)`.

### Tip

If the instance has `super_read_only=ON` then you might need to confirm that AdminAPI can set `super_read_only=OFF`. See Super Read-only and Instances for more information.
In the case where an instance has not had its configuration persisted (see Persisting Settings), upon restart the instance does not rejoin the cluster automatically. The solution is to issue `cluster.rejoinInstance()` so that the instance is added to the cluster again and ensure the changes are persisted. Once the InnoDB cluster configuration is persisted to the instance’s option file it rejoins the cluster automatically.

If you are rejoining an instance which has changed in some way then you might have to modify the instance to make the rejoin process work correctly. For example, when you restore a MySQL Enterprise Backup backup, the `server_uuid` changes. Attempting to rejoin such an instance fails because InnoDB cluster instances are identified by the `server_uuid` variable. In such a situation, information about the instance’s old `server_uuid` must be removed from the InnoDB cluster metadata and then a `Cluster.rescan()` must be executed to add the instance to the metadata using its new `server_uuid`. For example:

```javascript
cluster.removeInstance("root@instanceWithOldUUID:3306", {force: true})
cluster.rescan()
```

In this case you must pass the `force` option to the `Cluster.removeInstance()` method because the instance is unreachable from the cluster’s perspective and we want to remove it from the InnoDB cluster metadata anyway.

## Restoring a Cluster from Quorum Loss

If an instance (or instances) fail, then a cluster can lose its quorum, which is the ability to vote in a new primary. This can happen when there is a failure of enough instances that there is no longer a majority of the instances which make up the cluster to vote on Group Replication operations. When a cluster loses quorum you can no longer process write transactions with the cluster, or change the cluster’s topology, for example by adding, rejoining, or removing instances. However if you have an instance online which contains the InnoDB cluster metadata, it is possible to restore a cluster with quorum. This assumes you can connect to an instance that contains the InnoDB cluster metadata, and that instance can contact the other instances you want to use to restore the cluster.

> **Important**
> This operation is potentially dangerous because it can create a split-brain scenario if incorrectly used and should be considered a last resort. Make absolutely sure that there are no partitions of this group that are still operating somewhere in the network, but not accessible from your location.

Connect to an instance which contains the cluster’s metadata, then use the `Cluster.forceQuorumUsingPartitionOf(instance)` operation, which restores the cluster based on the metadata on `instance`, and then all the instances that are `ONLINE` from the point of view of the given instance definition are added to the restored cluster.

```
mysql-ja> cluster.forceQuorumUsingPartitionOf("icadmin@ic-1:3306")
```

In the event that an instance is not automatically added to the cluster, for example if its settings were not persisted, use `Cluster.rejoinInstance()` to manually add the instance back to the cluster.

The restored cluster might not, and does not have to, consist of all of the original instances which made up the cluster. For example, if the original cluster consisted of the following five instances:
Rebooting a Cluster from a Major Outage

and the cluster experiences a split-brain scenario, with ic-1, ic-2, and ic-3 forming one partition while ic-4 and ic-5 form another partition. If you connect to ic-1 and issue `Cluster.forceQuorumUsingPartitionOf('icadmin@ic-1:3306')` to restore the cluster the resulting cluster would consist of these three instances:

- ic-1
- ic-2
- ic-3

because ic-1 sees ic-2 and ic-3 as ONLINE and does not see ic-4 and ic-5.

Rebooting a Cluster from a Major Outage

If your cluster suffers from a complete outage, you can ensure it is reconfigured correctly using `dba.rebootClusterFromCompleteOutage()`. This operation takes the instance which MySQL Shell is currently connected to and uses its metadata to recover the cluster. In the event that a cluster's instances have completely stopped, the instances must be started and only then can the cluster be started. For example if the machine a sandbox cluster was running on has been restarted, and the instances were at ports 3310, 3320 and 3330, issue:

```sql
mysql-js> dba.startSandboxInstance(3310)
mymysql-js> dba.startSandboxInstance(3320)
mymysql-js> dba.startSandboxInstance(3330)
```

This ensures the sandbox instances are running. In the case of a production deployment you would have to start the instances outside of MySQL Shell. Once the instances have started, you need to connect to an instance with the GTID superset, which means the instance which had applied the most transaction before the outage. If you are unsure which instance contains the GTID superset, connect to any instance and follow the interactive messages from the `dba.rebootClusterFromCompleteOutage()`, which detects if the instance you are connected to contains the GTID superset. Reboot the cluster by issuing:

```sql
mysql-js> var cluster = dba.rebootClusterFromCompleteOutage();
```

The `dba.rebootClusterFromCompleteOutage()` operation then follows these steps to ensure the cluster is correctly reconfigured:

- The InnoDB cluster metadata found on the instance which MySQL Shell is currently connected to is checked to see if it contains the GTID superset, in other words the transactions applied by the cluster. If the currently connected instance does not contain the GTID superset, the operation aborts with that information. See the subsequent paragraphs for more information.

- If the instance contains the GTID superset, the cluster is recovered based on the metadata of the instance.

- Assuming you are running MySQL Shell in interactive mode, a wizard is run that checks which instances of the cluster are currently reachable and asks if you want to rejoin any discovered instances to the rebooted cluster.
Rescanning a Cluster

- Similarly, in interactive mode the wizard also detects instances which are currently not reachable and asks if you would like to remove such instances from the rebooted cluster.

If you are not using MySQL Shell’s interactive mode, you can use the `rejoinInstances` and `removeInstances` options to manually configure instances which should be joined or removed during the reboot of the cluster.

If you encounter an error such as `The active session instance isn't the most updated in comparison with the ONLINE instances of the Cluster's metadata.`, then the instance you are connected to does not have the GTID superset of transactions applied by the cluster. In this situation, connect MySQL Shell to the instance suggested in the error message and issue `dba.rebootClusterFromCompleteOutage()` from that instance.

**Tip**

To manually detect which instance has the GTID superset rather than using the interactive wizard, check the `gtid_executed` variable on each instance. For example issue:

```sql
mysql-sql> SHOW VARIABLES LIKE 'gtid_executed';
```

The instance which has applied the largest GTID set of transactions contains the GTID superset.

If this process fails, and the cluster metadata has become badly corrupted, you might need to drop the metadata and create the cluster again from scratch. You can drop the cluster metadata using `dba.dropMetadataSchema()`.

**Warning**

The `dba.dropMetadataSchema()` method should only be used as a last resort, when it is not possible to restore the cluster. It cannot be undone.

---

### Rescanning a Cluster

If you make configuration changes to a cluster outside of the AdminAPI commands, for example by changing an instance’s configuration manually to resolve configuration issues or after the loss of an instance, you need to update the InnoDB cluster metadata so that it matches the current configuration of instances. In these cases, use the `Cluster.rescan()` operation, which enables you to update the InnoDB cluster metadata either manually or using an interactive wizard. The `Cluster.rescan()` operation can detect new active instances that are not registered in the metadata and add them, or obsolete instances (no longer active) still registered in the metadata, and remove them. You can automatically update the metadata depending on the instances found by the command, or you can specify a list of instance addresses to either add to the metadata or remove from the metadata. You can also update the topology mode stored in the metadata, for example after changing from single-primary mode to multi-primary mode outside of AdminAPI.

The syntax of the command is `Cluster.rescan([options])`. The `options` dictionary supports the following:

- **interactive**: boolean value used to disable or enable the wizards in the command execution. Controls whether prompts and confirmations are provided. The default value is equal to MySQL Shell wizard mode, specified by `shell.options.useWizards`.

- **addInstances**: list with the connection data of the new active instances to add to the metadata, or “auto” to automatically add missing instances to the metadata. The value “auto” is case-insensitive.

- Instances specified in the list are added to the metadata, without prompting for confirmation.

- In interactive mode, you are prompted to confirm the addition of newly discovered instances that are not included in the `addInstances` option.
Checking Instance State

- In non-interactive mode, newly discovered instances that are not included in the `addInstances` option are reported in the output, but you are not prompted to add them.

- `removeInstances`: list with the connection data of the obsolete instances to remove from the metadata, or “auto” to automatically remove obsolete instances from the metadata.

- Instances specified in the list are removed from the metadata, without prompting for confirmation.

- In interactive mode, you are prompted to confirm the removal of obsolete instances that are not included in the `removeInstances` option.

- In non-interactive mode, obsolete instances that are not included in the `removeInstances` option are reported in the output but you are not prompted to remove them.

- `updateTopologyMode`: boolean value used to indicate if the topology mode (single-primary or multi-primary) in the metadata should be updated (true) or not (false) to match the one being used by the cluster. By default, the metadata is not updated (false).

  - If the value is `true` then the InnoDB cluster metadata is compared to the current mode being used by Group Replication, and the metadata is updated if necessary. Use this option to update the metadata after making changes to the topology mode of your cluster outside of AdminAPI.

  - If the value is `false` then InnoDB cluster metadata about the cluster’s topology mode is not updated even if it is different from the topology used by the cluster's Group Replication group.

  - If the option is not specified and the topology mode in the metadata is different from the topology used by the cluster’s Group Replication group, then:

    - In interactive mode, you are prompted to confirm the update of the topology mode in the metadata.

    - In non-interactive mode, if there is a difference between the topology used by the cluster's Group Replication group and the InnoDB cluster metadata, it is reported and no changes are made to the metadata.

    - When the metadata topology mode is updated to match the Group Replication mode, the auto-increment settings on all instances are updated as described at InnoDB cluster and Auto-increment.

Checking Instance State

The `cluster.checkInstanceState()` function can be used to verify the existing data on an instance does not prevent it from joining a cluster. This process works by validating the instance’s global transaction identifier (GTID) state compared to the GTIDs already processed by the cluster. For more information on GTIDs see Section 17.1.3.1, “GTID Format and Storage”. This check enables you to determine if an instance which has processed transactions can be added to the cluster.

The following demonstrates issuing this in a running MySQL Shell:

```javascript
mysql-ja> cluster.checkInstanceState('icadmin@ic-4:3306')
```

The output of this function can be one of the following:

- OK new: the instance has not executed any GTID transactions, therefore it cannot conflict with the GTIDs executed by the cluster.

- OK recoverable: the instance has executed GTIDs which do not conflict with the executed GTIDs of the cluster seed instances.

- ERROR diverged: the instance has executed GTIDs which diverge with the executed GTIDs of the cluster seed instances.
• ERROR lost_transactions: the instance has more executed GTIDs than the executed GTIDs of the cluster seed instances

Instances with an OK status can be added to the cluster because any data on the instance is consistent with the cluster. In other words the instance being checked has not executed any transactions which conflict with the GTIDs executed by the cluster, and can be recovered to the same state as the rest of the cluster instances.

Dissolving an InnoDB Cluster

To dissolve an InnoDB cluster you connect to a read-write instance, for example the primary in a single-primary cluster, and use the `Cluster.dissolve()` command. This removes all metadata and configuration associated with the cluster, and disables Group Replication on the instances. Any data that was replicated between the instances is not removed.

Important

There is no way to undo the dissolving of a cluster. To create it again use `dba.createCluster()`.

The `Cluster.dissolve()` operation can only configure instances which are ONLINE or reachable. If members of a cluster cannot be reached by the member where you issued the `Cluster.dissolve()` command you have to decide how the dissolve operation should proceed. If there is any chance you want to rejoin any instances that are identified as missing from the cluster, it is strongly recommended to cancel the dissolve operation and first bring the missing instances back online, before proceeding with a dissolve operation. This ensures that all instances can have their metadata updated correctly, and that there is no chance of a split-brain situation. However, if the instances from the cluster which cannot be reached have permanently left the cluster there could be no choice but to force the dissolve operation, which means that the missing instances are ignored and only online instances are affected by the operation.

Warning

Forcing the dissolve operation to ignore cluster instances can result in instances which could not be reached during the dissolve operation continuing to operate, creating the risk of a split-brain situation. Only ever force a dissolve operation to ignore missing instances if you are sure there is no chance of the instance coming online again.

In interactive mode, if members of a cluster are not reachable during a dissolve operation then an interactive prompt is displayed, for example:

```
mysql-js> Cluster.dissolve()
The cluster still has the following registered instances:
{
  "clusterName": "testCluster",
  "defaultReplicaSet": {
    "name": "default",
    "topology": [
      {
        "address": "ic-1:3306",
        "label": "ic-1:3306",
        "role": "HA"
      },
      {
        "address": "ic-2:3306",
        "label": "ic-2:3306",
        "role": "HA"
      },
      {
        "address": "ic-3:3306",
        "label": "ic-3:3306",
        "role": "HA"
      }
    ]
  }
```
Securing your Cluster

Server instances can be configured to use secure connections. For general information on using SSL with MySQL see Section 6.3, “Using Encrypted Connections”. This section explains how to configure a cluster to use SSL. An additional security possibility is to configure which servers can access the cluster, see Creating a Whitelist of Servers.

Note

After issuing `cluster.dissolve()`, any variable assigned to the `Cluster` object is no longer valid.
Creating a Whitelist of Servers

Important

Once you have configured a cluster to use SSL you must add the servers to the `ipWhitelist`.

When using `dba.createCluster()` to set up a cluster, if the server instance provides SSL encryption then it is automatically enabled on the seed instance. Pass the `memberSslMode` option to the `dba.createCluster()` method to specify a different SSL mode. The SSL mode of a cluster can only be set at the time of creation. The `memberSslMode` option is a string that configures the SSL mode to be used, it defaults to `AUTO`. The permitted values are `DISABLED`, `REQUIRED`, and `AUTO`. These modes are defined as:

- Setting `createCluster({memberSslMode:'DISABLED'})` ensures SSL encryption is disabled for the seed instance in the cluster.
- Setting `createCluster({memberSslMode:'REQUIRED'})` then SSL encryption is enabled for the seed instance in the cluster. If it cannot be enabled an error is raised.
- Setting `createCluster({memberSslMode:'AUTO'})` (the default) then SSL encryption is automatically enabled if the server instance supports it, or disabled if the server does not support it.

Note

When using the commercial version of MySQL, SSL is enabled by default and you might need to configure the whitelist for all instances. See Creating a Whitelist of Servers.

When you issue the `cluster.addInstance()` and `cluster.rejoinInstance()` commands, SSL encryption on the instance is enabled or disabled based on the setting found for the seed instance.

When using `createCluster()` with the `adoptFromGR` option to adopt an existing Group Replication group, no SSL settings are changed on the adopted cluster:

- `memberSslMode` cannot be used with `adoptFromGR`.
- If the SSL settings of the adopted cluster are different from the ones supported by the MySQL Shell, in other words SSL for Group Replication recovery and Group Communication, both settings are not modified. This means you are not be able to add new instances to the cluster, unless you change the settings manually for the adopted cluster.

MySQL Shell always enables or disables SSL for the cluster for both Group Replication recovery and Group Communication, see Section 18.5.2, “Group Replication Secure Socket Layer (SSL) Support”. A verification is performed and an error issued in case those settings are different for the seed instance (for example as the result of a `dba.createCluster()` using `adoptFromGR`) when adding a new instance to the cluster. SSL encryption must be enabled or disabled for all instances in the cluster. Verifications are performed to ensure that this invariant holds when adding a new instance to the cluster.

The `dba.deploySandboxInstance()` command attempts to deploy sandbox instances with SSL encryption support by default. If it is not possible, the server instance is deployed without SSL support. Use the `ignoreSslError` option set to false to ensure that sandbox instances are deployed with SSL support, issuing an error if SSL support cannot be provided. When `ignoreSslError` is true, which is the default, no error is issued during the operation if the SSL support cannot be provided and the server instance is deployed without SSL support.

Creating a Whitelist of Servers

When using a cluster's `createCluster()`, `addInstance()`, and `rejoinInstance()` methods you can optionally specify a list of approved servers that belong to the cluster, referred to as a whitelist. By specifying the whitelist explicitly in this way you can increase the security of your cluster because
only servers in the whitelist can connect to the cluster. Using the `ipWhitelist` option configures the `group_replication_ip_whitelist` system variable on the instance. By default, if not specified explicitly, the whitelist is automatically set to the private network addresses that the server has network interfaces on. To configure the whitelist, specify the servers to add with the `ipWhitelist` option when using the method. IP addresses must be specified in IPv4 format. Pass the servers as a comma separated list, surrounded by quotes. For example:

```sql
mysql-js> cluster.addInstance("icadmin@ic-3:3306", {ipWhitelist: "203.0.113.0/24, 198.51.100.110"})
```

This configures the instance to only accept connections from servers at addresses 203.0.113.0/24 and 198.51.100.110. The whitelist can also include host names, which are resolved only when a connection request is made by another server.

**Warning**

Host names are inherently less secure than IP addresses in a whitelist. MySQL carries out FCrDNS verification, which provides a good level of protection, but can be compromised by certain types of attack. Specify host names in your whitelist only when strictly necessary, and ensure that all components used for name resolution, such as DNS servers, are maintained under your control. You can also implement name resolution locally using the hosts file, to avoid the use of external components.

---

**Scripting AdminAPI**

You can automate cluster configuration with scripts, which can be run using MySQL Shell. For example:

```bash
shell> mysqlsh -f setup-innodb-cluster.js
```

**Note**

Any command line options specified after the script file name are passed to the script and not to MySQL Shell. You can access those options using the `os.argv` array in JavaScript, or the `sys.argv` array in Python. In both cases, the first option picked up in the array is the script name.

The contents of an example script file is shown here:

```javascript
print('InnoDB cluster sandbox set up
');
print('==================================
');
print('Setting up a MySQL InnoDB cluster with 3 MySQL Server sandbox instances.
');
print('The instances will be installed in ~/mysql-sandboxes.
');
print('They will run on ports 3310, 3320 and 3330.

');
var dbPass = shell.prompt('Please enter a password for the MySQL root account: ', {type:"password"});
try {
  try {
    printf(\nDeployment of the sandbox instances.\n);  
dba.deploySandboxInstance(3310, {password: dbPass});
  printf(\n);  
dba.deploySandboxInstance(3320, {password: dbPass});
  printf(\n);  
dba.deploySandboxInstance(3330, {password: dbPass});
  printf(\nSandbox instances deployed successfully.\n
');
  printf(\nSetting up InnoDB cluster...
');
  shell.connect('root@localhost:3310', dbPass);
  var cluster = dba.createCluster("prodCluster");
  printf(\nAdding instances to the cluster.\n);  
  cluster.addInstance({user: "root", host: "localhost", port: 3320, password: dbPass});
  printf(\n);  
  cluster.addInstance({user: "root", host: "localhost", port: 3330, password: dbPass});
  printf(\nInstances successfully added to the cluster.\n);
```

3491
Configuring the Election Process

You can optionally configure how a single-primary cluster elects a new primary, for example to prefer one instance as the new primary to fail over to. Use the `memberWeight` option and pass it to the `dba.createCluster()` and `Cluster.addInstance()` methods when creating your cluster. The `memberWeight` option accepts an integer value between 0 and 100, which is a percentage weight for automatic primary election on failover. When an instance has a higher percentage number set by `memberWeight`, it is more likely to be elected as primary in a single-primary cluster. When a primary election takes place, if multiple instances have the same `memberWeight` value, the instances are then prioritized based on their server UUID in lexicographical order (the lowest) and by picking the first one.

Setting the value of `memberWeight` configures the `group_replication_member_weight` system variable on the instance. Group Replication limits the value range from 0 to 100, automatically adjusting it if a higher or lower value is provided. Group Replication uses a default value of 50 if no value is provided. See Section 18.1.3.1, “Single-Primary Mode” for more information.

For example to configure a cluster where `ic-3` is the preferred instance to fail over to in the event that `ic-1`, the current primary, leaves the cluster unexpectedly use `memberWeight` as follows:

```javascript
dba.createCluster('cluster1', {memberWeight:35})
var mycluster = dba.getCluster()
mycluster.addInstance('icadmin@ic2', {memberWeight:25})
mycluster.addInstance('icadmin@ic3', {memberWeight:50})
```

Configuring Failover Consistency

Group Replication provides the ability to specify the failover guarantees (eventual or “read your writes”) if a primary failover happens in single-primary mode (see Section 18.4.2.2, “Configuring Transaction Consistency Guarantees”). You can configure the failover guarantees of an InnoDB cluster at creation by passing the `consistency` option (prior to version 8.0.16 this option was the `failoverConsistency` option, which is now deprecated) to the `dba.createCluster()` operation, which configures the `group_replication_consistency` system variable on the seed instance. This option defines the behavior of a new fencing mechanism used when a new primary is elected in a single-primary group. The fencing restricts connections from writing and reading from the new primary until it has applied any pending backlog of changes that came from the old primary (sometimes referred to as “read your writes”). While the fencing mechanism is in place, applications effectively do not see time going backward for a short period of time while any backlog is applied. This ensures that applications do not read stale information from the newly elected primary.

The `consistency` option is only supported if the target MySQL server version is 8.0.14 or later, and instances added to a cluster which has been configured with the `consistency` option are automatically configured to have `group_replication_consistency` the same on all cluster members that have support for the option. The variable default value is controlled by Group Replication and is `EVENTUAL`, change the `consistency` option to `BEFORE_ON_PRIMARY_FAILOVER` to enable the fencing mechanism. Alternatively use `consistency=0` for `EVENTUAL` and `consistency=1` for `BEFORE_ON_PRIMARY_FAILOVER`.

**Note**

Using the `consistency` option on a multi-primary InnoDB cluster has no effect but is allowed because the cluster can later be changed into single-primary mode with the `Cluster.switchToSinglePrimaryMode()` operation.

Changing a Cluster's Topology

3492
By default, an InnoDB cluster runs in single-primary mode, where the cluster has one primary server that accepts read and write queries (R/W), and all of the remaining instances in the cluster accept only read queries (R/O). When you configure a cluster to run in multi-primary mode, all of the instances in the cluster are primaries, which means that they accept both read and write queries (R/W). If a cluster has all of its instances running MySQL server version 8.0.15 or later, you can make changes to the topology of the cluster while the cluster is online. In previous versions it was necessary to completely dissolve and re-create the cluster to make the configuration changes. This uses the group action coordinator exposed through the UDFs described at Section 18.4.1, “Configuring an Online Group”, and as such you should observe the rules for configuring online groups.

**Note**

multi-primary mode is considered an advanced mode

Usually a single-primary cluster elects a new primary when the current primary leaves the cluster unexpectedly, for example due to an unexpected halt. The election process is normally used to choose which of the current secondaries becomes the new primary. To override the election process and force a specific server to become the new primary, use the `Cluster.setPrimaryInstance(instance)` function, where `instance` specifies the connection to the instance which should become the new primary. This enables you to configure the underlying Group Replication group to choose a specific instance as the new primary, bypassing the election process.

You can change the mode (sometimes described as the topology) which a cluster is running in between single-primary and multi-primary using the following operations:

- `Cluster.switchToMultiPrimaryMode()`, which switches the cluster to multi-primary mode. All instances become primaries.

- `Cluster.switchToSinglePrimaryMode([instance])`, which switches the cluster to single-primary mode. If `instance` is specified, it becomes the primary and all the other instances become secondaries. If `instance` is not specified, the new primary is the instance with the highest member weight (and the lowest UUID in case of a tie on member weight).

### Setting Options for InnoDB cluster

You can check and modify the settings in place for an InnoDB cluster while the instances are online. To check the current settings of a cluster, use the following operation:

- `Cluster.options()`, which lists the configuration options for the cluster and its instances. A boolean option `all` can also be specified to include information about all Group Replication system variables in the output.

You can configure the options of an InnoDB cluster at a cluster level or instance level, while instances remain online. This avoids the need to remove, reconfigure and then again add the instance to change InnoDB cluster options. Use the following operations:

- `Cluster.setOption(option, value)` to change the settings of all cluster instances globally or cluster global settings such as `clusterName`.

- `Cluster.setInstanceOption(instance, option, value)` to change the settings of individual cluster instances

The way which you use InnoDB cluster options with the operations listed depends on whether the option can be changed to be the same on all instances or not. These options are changeable at both the cluster (all instances) and per instance level:

- `exitStateAction`

- `memberWeight`

This option is changeable at the per instance level only:
InnoDB cluster and Auto-increment

- label

These options are changeable at the cluster level only:

- consistency
- expelTimeout
- clusterName

InnoDB cluster and Auto-increment

When you are using an instance as part of an InnoDB cluster, the `auto_increment_increment` and `auto_increment_offset` variables are configured to avoid the possibility of auto increment collisions for multi-primary clusters up to a size of 9 (the maximum supported size of a Group Replication group). The logic used to configure these variables can be summarized as:

- If the group is running in single-primary mode, then set `auto_increment_increment` to 1 and `auto_increment_offset` to 2.

- If the group is running in multi-primary mode, then when the cluster has 7 instances or less set `auto_increment_increment` to 7 and `auto_increment_offset` to `1 + server_id % 7`. If a multi-primary cluster has 8 or more instances set `auto_increment_increment` to the number of instances and `auto_increment_offset` to `1 + server_id % (number of instances)`.

21.6 InnoDB ReplicaSet

This section documents InnoDB ReplicaSet, added in version 8.0.19.

21.6.1 InnoDB ReplicaSet Introduction

The AdminAPI includes support for InnoDB ReplicaSet, that enables you to administer a set of MySQL instances running asynchronous GTID-based replication in a similar way to InnoDB cluster. An InnoDB ReplicaSet consists of a single primary and multiple secondaries (traditionally referred to as the MySQL replication master and slaves). You administer your replica sets using a ReplicaSet object and the AdminAPI operations, for example to check the status of the InnoDB ReplicaSet, and manually failover to a new primary in the event of a failure. Similar to InnoDB cluster, MySQL Router supports bootstrapping against InnoDB ReplicaSet, which means you can automatically configure MySQL Router to use your InnoDB ReplicaSet without having to manually configure it. This makes InnoDB ReplicaSet a quick and easy way to get MySQL replication and MySQL Router up and running, making it well suited to scaling out reads, and provides manual failover capabilities in use cases that do not require the high availability offered by InnoDB cluster.

In addition to deploying an InnoDB ReplicaSet using AdminAPI, you can adopt an existing replication setup. AdminAPI configures the InnoDB ReplicaSet based on the topology of the replication setup. Once the replication setup has been adopted, you administer it in the same way as an InnoDB ReplicaSet deployed from scratch. This enables you to take advantage of AdminAPI and MySQL Router without the need to create a new replica set. For more information see Section 21.6.4, “Adopting an Existing Replication Set Up”.

InnoDB ReplicaSet Limitations

An InnoDB ReplicaSet has several limitations compared to a InnoDB cluster and thus, it is recommended that you deploy InnoDB cluster wherever possible. Generally, a InnoDB ReplicaSet on its own does not provide high availability. Among the limitations of InnoDB ReplicaSet are:

- No automatic failover. In events where the primary becomes unavailable, a failover needs to be triggered manually using AdminAPI before any changes are possible again. However, secondary instances remain available for reads.
• No protection from partial data loss due to an unexpected halt or unavailability. Transactions that have not yet been applied by the time of the halt could become lost.

• No protection against inconsistencies after a crash or unavailability. If a failover promotes a secondary while the former primary is still available (for example due to a network partition), inconsistencies could be introduced because of the split-brain.

21.6.2 Deploying InnoDB ReplicaSet

You deploy InnoDB ReplicaSet in a similar way to InnoDB cluster. First you configure some MySQL server instances, the minimum is two instances. One functions as the primary, in this tutorial rs-1; the other instance functions as the secondary, in this tutorial rs-2; which replicates the transactions applied by the primary. This is the equivalent of the master and slave known from asynchronous MySQL replication. Then you connect to one of the instances using MySQL Shell, and create a replica set. Once the replica set has been created, you can add instances to it.

InnoDB ReplicaSet is compatible with sandbox instances, which you can use to deploy locally, for example for testing purposes. See Deploying Sandbox Instances for instructions. However, this tutorial assumes you are deploying a production InnoDB ReplicaSet, where each instance is running on a different host.

InnoDB ReplicaSet Prerequisites

To use InnoDB ReplicaSet you should be aware of the following prerequisites:

• Only instances running MySQL version 8.0 and later are supported

• Only GTID-based replication is supported, binary log file position replication is not compatible with InnoDB ReplicaSet

• Only Row Based Replication (RBR) is supported, Statement Based Replication (SBR) is unsupported

• Replication filters are not supported

• Unmanaged replication channels are not allowed in any instance

• A replica set consists of maximum one primary instance, and one or multiple secondaries are supported. Although there is no limit to the number of secondaries you can add to a replica set, each MySQL Router connected to a replica set monitors each instance. Therefore, the more instances that are added to a replica set, the more monitoring has to be done.

• The replica set must be entirely managed by MySQL Shell. For example, the replication account is created and managed by MySQL Shell. Making configuration changes to the instance outside of MySQL Shell, for example using SQL statements directly to change the primary, is not supported. Always use MySQL Shell to work with InnoDB ReplicaSet.

AdminAPI and InnoDB ReplicaSet enable you to work with MySQL replication without a deep understanding of the underlying concepts. However, for background information see Chapter 17, Replication.

Configuring InnoDB Replica Set Instances

Use \texttt{dba.configureReplicaSetInstance(instance)} to configure each instance you want to use in your replica set. MySQL Shell can either connect to an instance and then configure it, or you can pass in \texttt{instance} to configure a specific remote instance. To use an instance in a replica set, it must supportpersisting settings. See Persisting Settings.

The \texttt{dba.configureReplicaSetInstance()} function can optionally create an administrator account, if the \texttt{clusterAdmin} option is provided. The account is created with the correct set of privileges required to manage InnoDB cluster and InnoDB ReplicaSet. The preferred method to create users to administer a replica set is using the \texttt{clusterAdmin} option.
Deploying InnoDB ReplicaSet

Tip
The administrator account must have the same user name and password across all instances of the same cluster or replica set.

To configure the instance at rs-1:3306, with a cluster administrator named rsadmin issue:

```javascript
mysql-ja> dba.configureReplicaSetInstance('root@rs-1:3306', {clusterAdmin: "'rsadmin'@'rs-1%'"});
```

The interactive prompt requests the password required by the specified user. To configure the instance MySQL Shell is currently connected to, you can specify a null instance definition. For example issue:

```javascript
mysql-ja> dba.configureReplicaSetInstance('', {clusterAdmin: "'rsadmin'@'rs-1%'"});
```

The interactive prompt requests the password required by the specified user. This checks the instance which MySQL Shell is currently connected to is valid for use in a InnoDB ReplicaSet. Settings which are not compatible with InnoDB ReplicaSet are configured if possible. The cluster administrator account is created with the privileges required for InnoDB ReplicaSet.

Creating an InnoDB Replica Set

Once you have configured your instances, connect to an instance and use `dba.createReplicaSet()` to create a managed replica set that uses MySQL asynchronous replication, as opposed to MySQL Group Replication used by InnoDB cluster. The MySQL instance which MySQL Shell is currently connected to is used as the initial primary of the replica set.

The `dba.createReplicaSet()` operation performs several checks to ensure that the instance state and configuration are compatible with a managed replica set and if so, a metadata schema is initialized on the instance. If you want to check the operation but not actually make any changes to the instances, use the `dryRun` option. This checks and shows what actions the MySQL Shell would take to create the replica set. If the replica set is created successfully, a `ReplicaSet` object is returned. Therefore it is best practice to assign the returned `ReplicaSet` to a variable. This enables you to work with the replica set, for example by calling the `ReplicaSet.status()` operation. To create a replica set named `example` on instance `rs-1` and assign it to the `rs` variable, issue:

```javascript
mysql-ja> \connect root@rs-1:3306
...
mysql-ja> var rs = dba.createReplicaSet("example")
A new replicaset with instance 'rs-1:3306' will be created.
* Checking MySQL instance at rs-1:3306
This instance reports its own address as rs-1:3306
rs-1:3306: Instance configuration is suitable.
* Updating metadata...
ReplicaSet object successfully created for rs-1:3306.
Use rs.add_instance() to add more asynchronously replicated instances to this replicaset and rs.status() to check its status.
```

To verify that the operation was successful, you work with the returned `ReplicaSet` object. For example this provides the `ReplicaSet.status()` operation, which displays information about the replica set. We already assigned the returned `ReplicaSet` to the variable `rs`, so issue:

```javascript
mysql-ja> rs.status()
{
  "replicaSet": {
    "name": "example",
    "primary": "rs-1:3306",
    "status": "AVAILABLE",
    "statusText": "All instances available.",
    "topology": {
      "rs-1:3306": {
        "address": "rs-1:3306",
        "instanceRole": "PRIMARY",
```
Adding Instances to a Replica Set

When you have created a replica set you can use the `ReplicaSet.addInstance()` operation to add an instance as a read-only secondary replica of the current primary of the replica set. Therefore, the primary of the replica set must be reachable and available during this operation. MySQL Replication is configured between the added instance and the primary, using an automatically created MySQL account with a random password. Once the instance is added to the replica set, the operation waits for the newly added instance to apply all transactions that have been previously applied by the primary. This process is called recovery, and MySQL Shell supports different methods which you configure with the `recoveryMethod` option.

MySQL Shell connects to the target instance using the same user name and password used to obtain the `ReplicaSet` handle object. All instances of the replica set are expected to have the same administrator account with the same grants and passwords. A custom administrator account with the required grants can be created while an instance is configured with `dba.configureReplicaSetInstance()`. See Configuring InnoDB Replica Set Instances.

When an instance is joining a replica set, distributed recovery is used in much the same way that it is in InnoDB cluster. This means that you can choose between MySQL Clone and incremental recovery. For more information, see Section 21.2.5, “Using MySQL Clone with InnoDB cluster”. This section covers the differences when adding instances to a replica set.

Prerequisites

For an instance to be able to join a replica set, the following prerequisites must be satisfied. They are automatically checked by `ReplicaSet.addInstance()`, and the operation fails if any issues are found.

- binary log and replication related options must have been at least validated and also possibly configured by `dba.configureReplicaSetInstance()`

If the selected recovery method is incremental:

- the transaction set on the instance being added must not contain transactions that do not exist on the primary
- the transaction set on the instance being added must not be missing
- transactions that have been purged from the binary log of the primary

If MySQL Clone is available on both the primary and the instance you want to add to the replica set, the prerequisites listed above can be overcome by using clone as the recovery method.

Adding Instances to a ReplicaSet

Once you have created a replica set and assigned it to a variable, use the `ReplicaSet.addInstance(instance)` operation to add secondary instances to the replica set. You specify the instance as a URI-like connection string, see Section 4.2.5, “Connecting to the Server Using URI-Like Strings or Key-Value Pairs”. The user you specify must have the privileges...
Adding Instances to a Replica Set

required and must be the same on all instances in the replica set, see Configuring InnoDB Replica Set Instances. If you want to check the operation but not actually make any changes, use the dryRun option. This shows what actions the MySQL Shell would take to add the instance to the replica set.

For example to add the instance at rs-2 with user rsadmin, issue:

```sql
mysql-js> rs.addInstance('rsadmin@rs-2')
```

Adding instance to the replicaset...

* Performing validation checks

This instance reports its own address as rsadmin@rs-2
rsadmin@rs-2: Instance configuration is suitable.

* Checking async replication topology...

* Checking transaction state of the instance...

NOTE: The target instance 'rsadmin@rs-2' has not been pre-provisioned (GTID set is empty). The Shell is unable to decide whether replication can completely recover its state. The safest and most convenient way to provision a new instance is through automatic clone provisioning, which will completely overwrite the state of 'rsadmin@rs-2' with a physical snapshot from an existing replicaset member. To use this method by default, set the 'recoveryMethod' option to 'clone'.

WARNING: It should be safe to rely on replication to incrementally recover the state of the new instance if you are sure all updates ever executed in the replicaset were done with GTIDs enabled, there are no purged transactions and the new instance contains the same GTID set as the replicaset or a subset of it. To use this method by default, set the 'recoveryMethod' option to 'incremental'. Please select a recovery method [C]lone/[I]ncremental recovery/[A]bort (default Clone):

In this case we did not specify the recovery method, so the operation advises you on how to best proceed. In this example we choose the clone option because we do not have any existing transactions on the instance joining the replicaset. Therefore there is no risk of deleting data from the joining instance.

```sql
Please select a recovery method [C]lone/[I]ncremental recovery/[A]bort (default Clone): C
```

* Updating topology

Waiting for clone process of the new member to complete. Press ^C to abort the operation.

* Waiting for clone to finish...

NOTE: rsadmin@rs-2 is being cloned from rsadmin@rs-1
** Stage DROP DATA: Completed
** Clone Transfer
FILE COPY ################################################################### 100% Completed
PAGE COPY ################################################################### 100% Completed
REDO COPY ################################################################### 100% Completed
** Stage RECOVERY: \\
NOTE: rsadmin@rs-2 is shutting down...

* Waiting for server restart... ready
* rsadmin@rs-2 has restarted, waiting for clone to finish...
* Clone process has finished: 59.63 MB transferred in about 1 second (~1.00 B/s)

** Configuring rsadmin@rs-2 to replicate from rsadmin@rs-1
** Waiting for new instance to synchronize with PRIMARY...

The instance 'rsadmin@rs-2' was added to the replicaset and is replicating from rsadmin@rs-1.

Assuming the instance is valid for InnoDB ReplicaSet usage, distributed recovery proceeds. In this case the newly joining instance uses MySQL Clone to copy all of the transactions it has not yet applied from the primary, then it joins the replica as an online instance. To verify, use the ReplicaSet.status() operation:

```sql
mysql-js> rs.status()
{
  "replicaSet": {
    "name": "example",
```
Adopting an Existing Replication Set Up

"primary": "rs-1:3306",
"status": "AVAILABLE",
"statusText": "All instances available.",
"topology": {
"rs-1:3306": {
"address": "rs-1:3306",
"instanceRole": "PRIMARY",
"mode": "R/W",
"status": "ONLINE"
},
"rs-2:3306": {
"address": "rs-2:3306",
"instanceRole": "SECONDARY",
"mode": "R/O",
"replication": {
"applierStatus": "APPLIED_ALL",
"applierThreadState": "Slave has read all relay log; waiting for more updates",
"receiverStatus": "ON",
"receiverThreadState": "Waiting for master to send event",
"replicationLag": null
},
"status": "ONLINE"
}
},
"type": "ASYNC"
}
}

This output shows that the replica set named example now consists of two MySQL instances, and
that the primary is rs-1. Currently there is one secondary instance at rs-2, which is a replica of the
primary. The replica set is online, which means that the primary and secondary are in synchrony. At
this point the replica set is ready to process transactions.
If you want to override the interactive MySQL Shell mode trying to choose the most suitable recovery
method, use the recoveryMethod option to configure how the instance recovers the data required
to be able to join the replica set. For more information, see Section 21.2.5, “Using MySQL Clone with
InnoDB cluster”.

21.6.4 Adopting an Existing Replication Set Up
As an alternative to creating a new InnoDB ReplicaSet, you can also adopt an existing replication setup
using the adoptFromAR option with dba.createReplicaSet(). The replication setup is scanned,
and if it is compatible with the InnoDB ReplicaSet prerequisites, AdminAPI creates the necessary
metadata. Once the replication setup has been adopted, you can only use AdminAPI to administer the
InnoDB ReplicaSet.
To convert an existing replication setup to a InnoDB ReplicaSet connect to the primary, also referred
to as the master. The replication topology is automatically scanned and validated, starting from the
instance MySQL Shell's global session is connected to. The configuration of all instances is checked
during adoption, to ensure they are compatible with InnoDB ReplicaSet usage. All replication channels
must be active and their transaction sets as verified through GTID sets must be consistent. Instances
are assumed to have the same state or be able to converge. All instances that are part of the topology
are automatically added to the replica set. The only changes made by this operation to an adopted
replica set are the creation of the metadata schema. Existing replication channels are not changed
during adoption, although they could be changed during subsequent primary switch operations.
For example, to adopt a replication topology consisting of the MySQL server instances on example1
and example2 to an InnoDB ReplicaSet, connect to the primary at example1 and issue:
mysql-js> rs = dba.createReplicaSet('testadopt', {'adoptFromAR':1})
A new replicaset with the topology visible from 'example1:3306' will be created.
* Scanning replication topology...
** Scanning state of instance example1:3306
** Scanning state of instance example2:3306

3499


Working with InnoDB ReplicaSet

* Discovering async replication topology starting with example1:3306

Discovered topology:
- example1:3306: uuid=00371d66-3c45-11ea-804b-080027337932 read_only=no
- example2:3306: uuid=59e4f26e-3c3c-11ea-8b65-080027337932 read_only=no
  - replicates from example1:3306
  source="localhost:3310" channel= status=ON receiver=ON applier=ON

* Checking configuration of discovered instances...

This instance reports its own address as example1:3306
example1:3306: Instance configuration is suitable.

This instance reports its own address as example2:3306
example2:3306: Instance configuration is suitable.

* Checking discovered replication topology...

example1:3306 detected as the PRIMARY.
Replication state of example2:3306 is OK.

Validations completed successfully.

* Updating metadata...

ReplicaSet object successfully created for example1:3306.
Use rs.add_instance() to add more asynchronously replicated instances to
this replicaset and rs.status() to check its status.

Once the InnoDB ReplicaSet has been adopted, you can use it in the same way that you would use a
replica set which was created from scratch. From this point you must administer the InnoDB ReplicaSet
using only AdminAPI.

21.6.5 Working with InnoDB ReplicaSet

You work with an InnoDB ReplicaSet in much the same way as you would work with an InnoDB cluster.
For example as seen in Adding Instances to a ReplicaSet, you assign a ReplicaSet object to a
variable and call operations that administer the replica set, such as ReplicaSet.addInstance() to
add instances, which is the equivalent of Cluster.addInstance() in InnoDB cluster. Thus, much of
the documentation at Section 21.5, “Working with InnoDB Cluster” also applies to InnoDB ReplicaSet.
The following operations are supported by ReplicaSet objects:

- You get online help for ReplicaSet objects, and the AdminAPI, using \help ReplicaSet or
  ReplicaSet.help() and \help dba or dba.help(). See Using AdminAPI.

- You can quickly check the name of a ReplicaSet object using either name or
  ReplicaSet.getName(). For example the following are equivalent:

```bash
mysql-j> rs.name
example
mysql-j> rs.getName()
example
```

- You check information about a replica set using the ReplicaSet.status() operation, which
  supports the extended option to get different levels of detail. For example:

  • the default for extended is 0, a regular level of details. Only basic information about the status
    of the instance and replication is included, in addition to non-default or unexpected replication
    settings and status.

  • setting extended to 1 includes Metadata Version, server UUID and the raw information used to
    derive the status of the instance, size of the applier queue, value of system variables that protect
    against unexpected writes and so on.

  • setting extended to 2 includes important replication related configuration settings, such as SSL,
    worker threads, replication delay and heartbeat delay.

  See Checking a cluster’s Status with Cluster.status().
Working with InnoDB ReplicaSet

- You change the instances being used for a replica set using the `ReplicaSet.addInstance()` and `ReplicaSet.removeInstance()` operations. See Adding Instances to a ReplicaSet, and Removing Instances from the InnoDB Cluster.

- In the event of an instance leaving the replica set, for example due to an unexpected halt, use the `ReplicaSet.rejoinInstance()` operation. See Rejoining a Cluster.

- You work with the MySQL Router instances which have been bootstrapped against a replica set in exactly the same way as with InnoDB cluster. See Working with a Cluster’s Routers for information on `ReplicaSet.listRouters()` and `ReplicaSet.removeRouterMetadata()`. For specific information on using MySQL Router with InnoDB ReplicaSet see Section 21.6.6, “Using Replica Sets with MySQL Router”.

For more information, see the linked InnoDB cluster sections.

The following operations are specific to InnoDB ReplicaSet and can only be called against a `ReplicaSet` object:

**Planned Changes of the Replica Set Primary**

Use the `ReplicaSet.setPrimaryInstance()` operation to safely perform a change of the primary of a replica set to another instance. The current primary is demoted to a secondary and made read-only, while the promoted instance becomes the new primary and is made read-write. All other secondary instances are updated to replicate from the new primary. MySQL Router instances which have been bootstrapped against the replica set automatically start redirecting read-write clients to the new primary.

For a safe change of the primary to be possible, all replica set instances must be reachable by MySQL Shell and have consistent `GTID_EXECUTED` sets. If the primary is not available, and there is no way to restore it, a forced failover might be the only option instead, see Forcing the Primary Instance in a Replica Set.

During a change of primary, the promoted instance is synchronized with the old primary, ensuring that all transactions present on the primary are applied before the topology change is committed. If this synchronization step takes too long or is not possible on any of the secondary instances, the operation is aborted. In such a situation, these problematic secondary instances must be either repaired or removed from the replica set for the fail over to be possible.

**Forcing the Primary Instance in a Replica Set**

Unlike InnoDB cluster, which supports automatic failover in the event of an unexpected failure of the primary, InnoDB ReplicaSet does not have automatic failure detection or a consensus based protocol such as that provided by Group Replication. If the primary is not available, a manual failover is required. An InnoDB ReplicaSet which has lost its primary is effectively read-only, and for any write changes to be possible a new primary must be chosen. In the event that you cannot connect to the primary, and you cannot use `ReplicaSet.setPrimaryInstance()` to safely perform a switchover to a new primary as described at Planned Changes of the Replica Set Primary, use the `ReplicaSet.forcePrimaryInstance()` operation to perform a forced failover of the primary. This is a last resort operation that must only be used in a disaster type scenario where the current primary is unavailable and cannot be restored in any way.

**Warning**

A forced failover is a potentially destructive action and must be used with caution.

If a target instance is not given (or is null), the most up-to-date instance is automatically selected and promoted to be the new primary. If a target instance is provided, it is promoted to a primary, while other reachable secondary instances are switched to replicate from the new primary. The target instance must have the most up-to-date `GTID_EXECUTED` set among reachable instances, otherwise the operation fails.
A failover is different from a planned primary change because it promotes a secondary instance without synchronizing with or updating the old primary. That has the following major consequences:

- Any transactions that had not yet been applied by a secondary primary to a secondary at the time the old primary failed are lost.
- If the old primary is actually still running and processing transactions, there is a split-brain and the datasets of the old and new primaries diverge.

If the last known primary is still reachable, the `ReplicaSet.forcePrimary()` operation fails, to reduce the risk of split-brain situations. But it is the administrator's responsibility to ensure that the old primary it is not reachable by the other instances to prevent or minimize such scenarios.

After a forced failover, the old primary is considered invalid by the new primary and can no longer be part of the replica set. If at a later date you find a way to recover the instance, it must be removed from the replica set and re-added as a new instance. If there were any secondary instances that could not be switched to the new primary during the failover, they are also considered invalid.

Data loss is possible after a failover, because the old primary might have had transactions that were not yet replicated to the secondary being promoted. Moreover, if the instance that was presumed to have failed is still able to process transactions, for example because the network where it is located is still functioning but unreachable from MySQL Shell, it continues diverging from the promoted instances. Recovering once transaction sets on instances have diverged requires manual intervention and could not be possible in some situations, even if the failed instances can be recovered. In many cases, the fastest and simplest way to recover from a disaster that required a forced failover is by discarding such diverged transactions and re-provisioning a new instance from the newly promoted primary.

**InnoDB ReplicaSet Locking**

From version 8.0.20, AdminAPI uses a locking mechanism to avoid different operations from performing changes on an InnoDB ReplicaSet simultaneously. Previously, different instances of MySQL Shell could connect to an InnoDB ReplicaSet at the same time and execute AdminAPI operations simultaneously. This could lead to inconsistent instance states and errors, for example if `ReplicaSet.addInstance()` and `ReplicaSet.setPrimary()` were executed in parallel.

The InnoDB ReplicaSet operations have the following locking:

- `dba.upgradeMetadata()` and `dba.createReplicaSet()` are globally exclusive operations. This means that if MySQL Shell executes these operations on an InnoDB ReplicaSet, no other operations can be executed against the InnoDB ReplicaSet or any of its instances.

- `ReplicaSet.forcePrimaryInstance()` and `ReplicaSet.setPrimaryInstance()` are operations that change the primary. This means that if MySQL Shell executes these operations against an InnoDB ReplicaSet, no other operations which change the primary, or instance change operations can be executed until the first operation completes.

- `ReplicaSet.addInstance()`, `ReplicaSet.rejoinInstance()`, and `ReplicaSet.removeInstance()` are operations that change an instance. This means that if MySQL Shell executes these operations on an instance, the instance is locked for any further instance change operations. However, this lock is only at the instance level and multiple instances in an InnoDB ReplicaSet can each execute one of this type of operation simultaneously. In other words, at most one instance change operation can be executed at a time, per instance in the InnoDB ReplicaSet.

- `dba.getReplicaSet()` and `ReplicaSet.status()` are InnoDB ReplicaSet read operations and do not require any locking.

In practice, if you try to execute an InnoDB ReplicaSet related operation while another operation that cannot be executed concurrently is still running, you get an error indicating that a lock on a needed resource failed to be acquired. In this case, you should wait for the running operation which holds the lock to complete, and only then try to execute the next operation. For example:
Using Replica Sets with MySQL Router

```sql
mysql> rs.addInstance("admin@rs2:3306");
```

ERROR: The operation cannot be executed because it failed to acquire the lock on instance 'rs1:3306'. Another operation requiring exclusive access to the instance is still in progress, please wait for it to finish and try again.

ReplicaSet.addInstance: Failed to acquire lock on instance 'rs1:3306' (MYSQLSH 51400)

In this example, the `ReplicaSet.addInstance()` operation failed because the lock on the primary instance (rs1:3306) could not be acquired, for example because a `ReplicaSet.setPrimaryInstance()` operation (or other similar operation) was still running.

### 21.6.6 Using Replica Sets with MySQL Router

You can use MySQL Router 8.0.19 and later to bootstrap against a replica set, in the same way that InnoDB cluster can be bootstrapped. See Section 21.4, “Using MySQL Router with InnoDB Cluster”. The only difference in the generated MySQL Router configuration file is the addition of the `cluster_type` option. When MySQL Router is bootstrapped against a replica set, the generated configuration file includes:

```
cluster_type=rs
```

When you use MySQL Router with a replica set, be aware that:

- The read-write port of MySQL Router directs client connections to the primary instance of the replica set
- The read-only port of MySQL Router directs client connections to a secondary instance of the replica set, although it could also direct them to the primary
- MySQL Router obtains information about the replica set's topology from the primary instance
- MySQL Router automatically recovers when the primary instance becomes unavailable and a different instance is promoted

You work with the MySQL Router instances which have been bootstrapped against a replica set in exactly the same way as with InnoDB cluster. See Working with a Cluster's Routers for information on `ReplicaSet.listRouters()` and `ReplicaSet.removeRouterMetadata()`.

### 21.7 Known Limitations

This section describes the known limitations of InnoDB cluster. As InnoDB cluster uses Group Replication, you should also be aware of its limitations, see Section 18.9.2, “Group Replication Limitations”.

- If a session type is not specified when creating the global session, MySQL Shell provides automatic protocol detection which attempts to first create a NodeSession and if that fails it tries to create a ClassicSession. With an InnoDB cluster that consists of three server instances, where there is one read-write port and two read-only ports, this can cause MySQL Shell to only connect to one of the read-only instances. Therefore it is recommended to always specify the session type when creating the global session.
- When adding non-sandbox server instances (instances which you have configured manually rather than using `dba.deploySandboxInstance()`) to a cluster, MySQL Shell is not able to persist any configuration changes in the instance's configuration file. This leads to one or both of the following scenarios:
  1. The Group Replication configuration is not persisted in the instance's configuration file and upon restart the instance does not rejoin the cluster.
  2. The instance is not valid for cluster usage. Although the instance can be verified with `dba.checkInstanceConfiguration()`, and MySQL Shell makes the required configuration
known Limitations

changes in order to make the instance ready for cluster usage, those changes are not persisted
in the configuration file and so are lost once a restart happens.

If only a happens, the instance does not rejoin the cluster after a restart.

If b also happens, and you observe that the instance did not rejoin the cluster after a restart, you
cannot use the recommended `dba.rebootClusterFromCompleteOutage()` in this situation to
get the cluster back online. This is because the instance loses any configuration changes made by
MySQL Shell, and because they were not persisted, the instance reverts to the previous state before
being configured for the cluster. This causes Group Replication to stop responding, and eventually
the command times out.

To avoid this problem it is strongly recommended to use `dba.configureInstance()` before
adding instances to a cluster in order to persist the configuration changes.

• The use of the `--defaults-extra-file` option to specify an option file is not supported by
InnoDB cluster server instances. InnoDB cluster only supports a single option file on instances and
no extra option files are supported. Therefore for any operation working with the instance's option
file the main one should be specified. If you want to use multiple option files you have to configure
the files manually and make sure they are updated correctly considering the precedence rules of the
use of multiple option files and ensuring that the desired settings are not incorrectly overwritten by
options in an extra unrecognized option file.

• Attempting to use instances with a host name that resolves to an IP address which does not match a
real network interface fails with an error that This instance reports its own address as
the hostname. This is not supported by the Group Replication communication layer. On Debian
based instances this means instances cannot use addresses such as `user@localhost` because
localhost resolves to a non-existent IP (such as `127.0.0.1`). This impacts on using a sandbox
deployment, which usually uses local instances on a single machine.

A workaround is to configure the `report_host` system variable on each instance to use the actual
IP address of your machine. Retrieve the IP of your machine and add `report_host=IP of your
machine` to the `my.cnf` file of each instance. You need to ensure the instances are then restarted to
make the change.

• When executing `dba.createCluster()` or adding an instance to an existing InnoDB cluster by
running `Cluster.addInstance()`, the following errors are logged to MySQL error log:

2020-02-10T10:53:43.727246Z 12 [ERROR] [MY-011685] [Repl] Plugin
group_replication reported: 'The group name option is mandatory'
2020-02-10T10:53:43.727292Z 12 [ERROR] [MY-011660] [Repl] Plugin
group_replication reported: 'Unable to start Group Replication on boot.'

These messages are harmless and relate to the way AdminAPI starts Group Replication.

• When using a sandbox deployment, each sandbox instance uses a copy of the `mysqld` binary found
in the $PATH in the local mysql-sandboxes directory. If the version of `mysqld` changes, for example
after an upgrade, sandboxes based on the previous version fail to start. This is because the sandbox
binary is outdated compared to the dependencies found under the `basedir`. Sandbox instances
are not designed for production, therefore they are considered transient and are not supported for
upgrade.

A workaround for this issue is to manually copy the upgraded `mysqld` binary into the bin directory
of each sandbox. Then start the sandbox by issuing `dba.startSandboxInstance()`. The
operation fails with a timeout, and the error log contains:

2020-03-26T11:43:12.969131Z 5 [System] [MY-013381] [Server] Server upgrade
from '80019' to '80020' started.
2020-03-26T11:44:03.543082Z 5 [System] [MY-013381] [Server] Server upgrade
from '80019' to '80020' completed.

Although the operation seems to fail with a timeout, the sandbox has started successfully.

MySQL NDB Cluster is a high-availability, high-redundancy version of MySQL adapted for the distributed computing environment. The most recent NDB Cluster release series uses version 8 of the NDB storage engine (also known as NDDBCLUSTER) to enable running several computers with MySQL servers and other software in a cluster. NDB Cluster 8.0, now available as a General Availability (GA) release beginning with version 8.0.19, incorporates version 8.0 of the NDB storage engine. NDB Cluster 7.6 and NDB Cluster 7.5, still available as GA releases, use versions 7.6 and 7.5 of NDB, respectively. Previous GA releases still available for use in production, NDB Cluster 7.4 and NDB Cluster 7.3, incorporate NDB versions 7.4 and 7.3, respectively. NDB 7.2 and older release series are no longer supported or maintained.

Support for the NDB storage engine is not included in standard MySQL Server 8.0 binaries built by Oracle. Instead, users of NDB Cluster binaries from Oracle should upgrade to the most recent binary release of NDB Cluster for supported platforms—these include RPMs that should work with most Linux distributions. NDB Cluster 8.0 users who build from source should use the sources provided for MySQL 8.0 and build with the options required to provide NDB support. (Locations where the sources can be obtained are listed later in this section.)

Important

MySQL NDB Cluster does not support InnoDB cluster, which must be deployed using MySQL Server 8.0 with the InnoDB storage engine as well as additional applications that are not included in the NDB Cluster distribution. MySQL Server
8.0 binaries cannot be used with MySQL NDB Cluster. For more information about deploying and using InnoDB cluster, see Chapter 21, *InnoDB Cluster*, Section 22.1.6, “MySQL Server Using InnoDB Compared with NDB Cluster”, discusses differences between the NDB and InnoDB storage engines.

This chapter contains information about NDB Cluster 8.0 releases through 8.0.20, now available (beginning with NDB 8.0.19) as a General Availability release, and recommended for new deployments. NDB Cluster 7.6 and 7.5 are previous GA releases still supported in production; for information about NDB Cluster 7.6, see What is New in NDB Cluster 7.6. For similar information about NDB Cluster 7.5, see What is New in NDB Cluster 7.5. NDB Cluster 7.4 and 7.3 are previous GA releases still supported in production, although we recommend that new deployments for production use NDB Cluster 8.0; see MySQL NDB Cluster 7.3 and NDB Cluster 7.4.

**Supported Platforms.** NDB Cluster is currently available and supported on a number of platforms. For exact levels of support available for on specific combinations of operating system versions, operating system distributions, and hardware platforms, please refer to https://www.mysql.com/support/supportedplatforms/cluster.html.

**Availability.** NDB Cluster binary and source packages are available for supported platforms from https://dev.mysql.com/downloads/cluster/.

**NDB Cluster release numbers.** NDB 8.0 follows the same release pattern as the MySQL Server 8.0 series of releases, beginning with MySQL 8.0.13 and MySQL NDB Cluster 8.0.13. In this *Manual* and other MySQL documentation, we identify these and later NDB Cluster releases employing a version number that begins with “NDB” . This version number is that of the `NDBCLUSTER` storage engine used in the NDB 8.0 release, and is the same as the MySQL 8.0 server version on which the NDB Cluster 8.0 release is based.

**Version strings used in NDB Cluster software.** The version string displayed by the `mysql` client supplied with the MySQL NDB Cluster distribution uses this format:  

```
mysql-<mysql_server_version>-cluster
```

`mysql_server_version` represents the version of the MySQL Server on which the NDB Cluster release is based. For all NDB Cluster 8.0 releases, this is `8.0.n`, where `n` is the release number. Building from source using `-DWITH_NDBCLUSTER` or the equivalent adds the `-cluster` suffix to the version string. (See Section 22.2.2.4, “Building NDB Cluster from Source on Linux”, and Section 22.2.3.2, “Compiling and Installing NDB Cluster from Source on Windows”.) You can see this format used in the `mysql` client, as shown here:

```
shell> mysql
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 2
Server version: 8.0.20-cluster Source distribution
Type 'help;' or '\h' for help. Type '\c' to clear the buffer.
mysql> SELECT VERSION()\G
*************************** 1. row ***************************
VERSION(): 8.0.20-cluster
1 row in set (0.00 sec)
```

The first General Availability release of NDB Cluster using MySQL 8.0 is NDB 8.0.19, using MySQL 8.0.19.

The version string displayed by other NDB Cluster programs not normally included with the MySQL 8.0 distribution uses this format:

```
mysql-<mysql_server_version> ndb-<ndb_engine_version>
```

`mysql_server_version` represents the version of the MySQL Server on which the NDB Cluster release is based. For all NDB Cluster 8.0 releases, this is `8.0.n`, where `n` is the release number.
**ndb_engine_version** is the version of the **NDB** storage engine used by this release of the NDB Cluster software. For all NDB 8.0 releases, this number is the same as the MySQL Server version. You can see this format used in the output of the `SHOW` command in the `ndb_mgm` client, like this:

```
ndb_mgm> SHOW
Connected to Management Server at: localhost:1186
Cluster Configuration
---------------------
[Ndbd]     2 node(s)
id=1    @10.0.10.6  (mysql-8.0.22 ndb-8.0.20, Nodegroup: 0, *)
id=2    @10.0.10.8  (mysql-8.0.22 ndb-8.0.20, Nodegroup: 0)

[Ndb_mgmd] 1 node(s)
id=3    @10.0.10.2  (mysql-8.0.22 ndb-8.0.20)

[mysqld(API)]   2 node(s)
id=4    @10.0.10.10  (mysql-8.0.22 ndb-8.0.20)
id=5 (not connected, accepting connect from any host)
```

**Compatibility with standard MySQL 8.0 releases.** While many standard MySQL schemas and applications can work using NDB Cluster, it is also true that unmodified applications and database schemas may be slightly incompatible or have suboptimal performance when run using NDB Cluster (see Section 22.1.7, “Known Limitations of NDB Cluster”). Most of these issues can be overcome, but this also means that you are very unlikely to be able to switch an existing application datastore—that currently uses, for example, MyISAM or InnoDB—to use the NDB storage engine without allowing for the possibility of changes in schemas, queries, and applications. A `mysqld` compiled without NDB support (that is, built without `-DWITH_NDBCLUSTER_STORAGE_ENGINE` or its alias `-DWITH_NDBCLUSTER`) cannot function as a drop-in replacement for a `mysqld` that is built with it.

**NDB Cluster development source trees.** NDB Cluster development trees can also be accessed from https://github.com/mysql/mysql-server.

The NDB Cluster development sources maintained at https://github.com/mysql/mysql-server are licensed under the GPL. For information about obtaining MySQL sources using Git and building them yourself, see Section 2.9.5, “Installing MySQL Using a Development Source Tree”.

---

**Note**

As with MySQL Server 8.0, NDB Cluster 8.0 releases are built using **CMake**.

NDB Cluster 8.0 is available beginning with NDB 8.0.19 as a General Availability release, and is recommended for new deployments. NDB Cluster 7.6 and 7.5 are previous GA releases still supported in production; for information about NDB Cluster 7.6, see What is New in NDB Cluster 7.6. For similar information about NDB Cluster 7.5, see What is New in NDB Cluster 7.5. NDB Cluster 7.4 and 7.3 are previous GA releases still supported in production, although we recommend that new deployments for production use NDB Cluster 8.0; see MySQL NDB Cluster 7.3 and NDB Cluster 7.4.

The contents of this chapter are subject to revision as NDB Cluster continues to evolve. Additional information regarding NDB Cluster can be found on the MySQL website at http://www.mysql.com/products/cluster/.

**Additional Resources.** More information about NDB Cluster can be found in the following places:

- For answers to some commonly asked questions about NDB Cluster, see Section A.10, “MySQL 8.0 FAQ: NDB Cluster”.
- Many NDB Cluster users and developers blog about their experiences with NDB Cluster, and make feeds of these available through PlanetMySQL.

---

## 22.1 NDB Cluster Overview
**NDB Cluster** is a technology that enables clustering of in-memory databases in a shared-nothing system. The shared-nothing architecture enables the system to work with very inexpensive hardware, and with a minimum of specific requirements for hardware or software.

NDB Cluster is designed not to have any single point of failure. In a shared-nothing system, each component is expected to have its own memory and disk, and the use of shared storage mechanisms such as network shares, network file systems, and SANs is not recommended or supported.

NDB Cluster integrates the standard MySQL server with an in-memory clustered storage engine called **NDB** (which stands for "Network DataBase"). In our documentation, the term **NDB** refers to the part of the setup that is specific to the storage engine, whereas "MySQL NDB Cluster" refers to the combination of one or more MySQL servers with the NDB storage engine.

An NDB Cluster consists of a set of computers, known as hosts, each running one or more processes. These processes, known as nodes, may include MySQL servers (for access to NDB data), data nodes (for storage of the data), one or more management servers, and possibly other specialized data access programs. The relationship of these components in an NDB Cluster is shown here:

**Figure 22.1 NDB Cluster Components**

All these programs work together to form an NDB Cluster (see Section 22.4, “NDB Cluster Programs”. When data is stored by the NDB storage engine, the tables (and table data) are stored in the data nodes. Such tables are directly accessible from all other MySQL servers (SQL nodes) in the cluster. Thus, in a payroll application storing data in a cluster, if one application updates the salary of an employee, all other MySQL servers that query this data can see this change immediately.

Although an NDB Cluster SQL node uses the mysql server daemon, it differs in a number of critical respects from the mysql binary supplied with the MySQL 8.0 distributions, and the two versions of mysql are not interchangeable.

In addition, a MySQL server that is not connected to an NDB Cluster cannot use the NDB storage engine and cannot access any NDB Cluster data.

The data stored in the data nodes for NDB Cluster can be mirrored; the cluster can handle failures of individual data nodes with no other impact than that a small number of transactions are aborted due to losing the transaction state. Because transactional applications are expected to handle transaction failure, this should not be a source of problems.

Individual nodes can be stopped and restarted, and can then rejoin the system (cluster). Rolling restarts (in which all nodes are restarted in turn) are used in making configuration changes and software upgrades (see Section 22.5.5, “Performing a Rolling Restart of an NDB Cluster”). Rolling
restarts are also used as part of the process of adding new data nodes online (see Section 22.5.15, “Adding NDB Cluster Data Nodes Online”). For more information about data nodes, how they are organized in an NDB Cluster, and how they handle and store NDB Cluster data, see Section 22.1.2, “NDB Cluster Nodes, Node Groups, Replicas, and Partitions”.

Backing up and restoring NDB Cluster databases can be done using the NDB-native functionality found in the NDB Cluster management client and the `ndb_restore` program included in the NDB Cluster distribution. For more information, see Section 22.5.3, “Online Backup of NDB Cluster”, and Section 22.4.23, “ndb_restore — Restore an NDB Cluster Backup”. You can also use the standard MySQL functionality provided for this purpose in `mysqldump` and the MySQL server. See Section 4.5.4, “mysqldump — A Database Backup Program”, for more information.

NDB Cluster nodes can employ different transport mechanisms for inter-node communications; TCP/IP over standard 100 Mbps or faster Ethernet hardware is used in most real-world deployments.

### 22.1.1 NDB Cluster Core Concepts

`NDBCLUSTER` (also known as `NDB`) is an in-memory storage engine offering high-availability and data-persistence features.

The `NDBCLUSTER` storage engine can be configured with a range of failover and load-balancing options, but it is easiest to start with the storage engine at the cluster level. NDB Cluster's `NDB` storage engine contains a complete set of data, dependent only on other data within the cluster itself.

The “Cluster” portion of NDB Cluster is configured independently of the MySQL servers. In an NDB Cluster, each part of the cluster is considered to be a node.

**Note**

In many contexts, the term “node” is used to indicate a computer, but when discussing NDB Cluster it means a process. It is possible to run multiple nodes on a single computer; for a computer on which one or more cluster nodes are being run we use the term *cluster host*.

There are three types of cluster nodes, and in a minimal NDB Cluster configuration, there will be at least three nodes, one of each of these types:

- **Management node**: The role of this type of node is to manage the other nodes within the NDB Cluster, performing such functions as providing configuration data, starting and stopping nodes, and running backups. Because this node type manages the configuration of the other nodes, a node of this type should be started first, before any other node. An MGM node is started with the command `ndb_mgmd`.

- **Data node**: This type of node stores cluster data. There are as many data nodes as there are replicas, times the number of fragments (see Section 22.1.2, “NDB Cluster Nodes, Node Groups, Replicas, and Partitions”). For example, with two replicas, each having two fragments, you need four data nodes. One replica is sufficient for data storage, but provides no redundancy; therefore, it is recommended to have 2 (or more) replicas to provide redundancy, and thus high availability. A data node is started with the command `ndbd` (see Section 22.4.1, “ndbd — The NDB Cluster Data Node Daemon”) or `ndbmtd` (see Section 22.4.3, “ndbmtd — The NDB Cluster Data Node Daemon (Multi-Threaded)”).

NDB Cluster tables are normally stored completely in memory rather than on disk (this is why we refer to NDB Cluster as an in-memory database). However, some NDB Cluster data can be stored on disk; see Section 22.5.13, “NDB Cluster Disk Data Tables”, for more information.

- **SQL node**: This is a node that accesses the cluster data. In the case of NDB Cluster, an SQL node is a traditional MySQL server that uses the `NDBCLUSTER` storage engine. An SQL node is a `mysqld` process started with the `--ndbcluster` and `--ndb-connectstring` options, which are explained elsewhere in this chapter, possibly with additional MySQL server options as well.
An SQL node is actually just a specialized type of API node, which designates any application which accesses NDB Cluster data. Another example of an API node is the `ndb_restore` utility that is used to restore a cluster backup. It is possible to write such applications using the NDB API. For basic information about the NDB API, see Getting Started with the NDB API.

**Important**

It is not realistic to expect to employ a three-node setup in a production environment. Such a configuration provides no redundancy; to benefit from NDB Cluster's high-availability features, you must use multiple data and SQL nodes. The use of multiple management nodes is also highly recommended.

For a brief introduction to the relationships between nodes, node groups, replicas, and partitions in NDB Cluster, see Section 22.1.2, "NDB Cluster Nodes, Node Groups, Replicas, and Partitions".

Configuration of a cluster involves configuring each individual node in the cluster and setting up individual communication links between nodes. NDB Cluster is currently designed with the intention that data nodes are homogeneous in terms of processor power, memory space, and bandwidth. In addition, to provide a single point of configuration, all configuration data for the cluster as a whole is located in one configuration file.

The management server manages the cluster configuration file and the cluster log. Each node in the cluster retrieves the configuration data from the management server, and so requires a way to determine where the management server resides. When interesting events occur in the data nodes, the nodes transfer information about these events to the management server, which then writes the information to the cluster log.

In addition, there can be any number of cluster client processes or applications. These include standard MySQL clients, NDB-specific API programs, and management clients. These are described in the next few paragraphs.

**Standard MySQL clients.** NDB Cluster can be used with existing MySQL applications written in PHP, Perl, C, C++, Java, Python, Ruby, and so on. Such client applications send SQL statements to and receive responses from MySQL servers acting as NDB Cluster SQL nodes in much the same way that they interact with standalone MySQL servers.

MySQL clients using an NDB Cluster as a data source can be modified to take advantage of the ability to connect with multiple MySQL servers to achieve load balancing and failover. For example, Java clients using Connector/J 5.0.6 and later can use `jdbc:mysql:loadbalance://` URLs (improved in Connector/J 5.1.7) to achieve load balancing transparently; for more information about using Connector/J with NDB Cluster, see Using Connector/J with NDB Cluster.

**NDB client programs.** Client programs can be written that access NDB Cluster data directly from the `NDBCLUSTER` storage engine, bypassing any MySQL Servers that may be connected to the cluster, using the NDB API, a high-level C++ API. Such applications may be useful for specialized purposes where an SQL interface to the data is not needed. For more information, see The NDB API.

NDB-specific Java applications can also be written for NDB Cluster using the NDB Cluster Connector for Java. This NDB Cluster Connector includes ClusterJ, a high-level database API similar to object-relational mapping persistence frameworks such as Hibernate and JPA that connect directly to `NDBCLUSTER`, and so does not require access to a MySQL Server. Support is also provided in NDB Cluster for ClusterJPA, an OpenJPA implementation for NDB Cluster that leverages the strengths of ClusterJ and JDBC; ID lookups and other fast operations are performed using ClusterJ (bypassing the MySQL Server), while more complex queries that can benefit from MySQL's query optimizer are sent through the MySQL Server, using JDBC. See Java and NDB Cluster, and The ClusterJ API and Data Object Model, for more information.

NDB Cluster also supports applications written in JavaScript using Node.js. The MySQL Connector for JavaScript includes adapters for direct access to the `NDB` storage engine and as well as for the MySQL Server. Applications using this Connector are typically event-driven and use a domain object...
model similar in many ways to that employed by ClusterJ. For more information, see MySQL NoSQL Connector for JavaScript.

The Memcache API for NDB Cluster, implemented as the loadable ndbmemcache storage engine for memcached version 1.6 and later, can be used to provide a persistent NDB Cluster data store, accessed using the memcache protocol.

The standard memcached caching engine is included in the NDB Cluster 8.0 distribution. Each memcached server has direct access to data stored in NDB Cluster, but is also able to cache data locally and to serve (some) requests from this local cache.

For more information, see ndbmemcache—Memcache API for NDB Cluster.

**Management clients.** These clients connect to the management server and provide commands for starting and stopping nodes gracefully, starting and stopping message tracing (debug versions only), showing node versions and status, starting and stopping backups, and so on. An example of this type of program is the ndb_mgm management client supplied with NDB Cluster (see Section 22.4.5, "ndb_mgm — The NDB Cluster Management Client"). Such applications can be written using the MGM API, a C-language API that communicates directly with one or more NDB Cluster management servers. For more information, see The MGM API.

Oracle also makes available MySQL Cluster Manager, which provides an advanced command-line interface simplifying many complex NDB Cluster management tasks, such as restarting an NDB Cluster with a large number of nodes. The MySQL Cluster Manager client also supports commands for getting and setting the values of most node configuration parameters as well as mysqld server options and variables relating to NDB Cluster. MySQL Cluster Manager 1.4.8 provides experimental support for NDB 8.0. See MySQL™ Cluster Manager 1.4.8 User Manual, for more information.

**Event logs.** NDB Cluster logs events by category (startup, shutdown, errors, checkpoints, and so on), priority, and severity. A complete listing of all reportable events may be found in Section 22.5.6, “Event Reports Generated in NDB Cluster”. Event logs are of the two types listed here:

- *Cluster log*: Keeps a record of all desired reportable events for the cluster as a whole.
- *Node log*: A separate log which is also kept for each individual node.

**Note**

Under normal circumstances, it is necessary and sufficient to keep and examine only the cluster log. The node logs need be consulted only for application development and debugging purposes.

**Checkpoint.** Generally speaking, when data is saved to disk, it is said that a checkpoint has been reached. More specific to NDB Cluster, a checkpoint is a point in time where all committed transactions are stored on disk. With regard to the NDB storage engine, there are two types of checkpoints which work together to ensure that a consistent view of the cluster's data is maintained. These are shown in the following list:

- *Local Checkpoint (LCP)*: This is a checkpoint that is specific to a single node; however, LCPs take place for all nodes in the cluster more or less concurrently. An LCP usually occurs every few minutes; the precise interval varies, and depends upon the amount of data stored by the node, the level of cluster activity, and other factors.

  NDB 8.0 supports partial LCPs, which can significantly improve performance under some conditions. See the descriptions of the EnablePartialLcp and RecoveryWork configuration parameters which enable partial LCPs and control the amount of storage they use.

- *Global Checkpoint (GCP)*: A GCP occurs every few seconds, when transactions for all nodes are synchronized and the redo-log is flushed to disk.

For more information about the files and directories created by local checkpoints and global checkpoints, see NDB Cluster Data Node File System Directory.
22.1.2 NDB Cluster Nodes, Node Groups, Replicas, and Partitions

This section discusses the manner in which NDB Cluster divides and duplicates data for storage.

A number of concepts central to an understanding of this topic are discussed in the next few paragraphs.

Data node. An ndbd or ndbmtd process, which stores one or more replicas—that is, copies of the partitions (discussed later in this section) assigned to the node group of which the node is a member.

Each data node should be located on a separate computer. While it is also possible to host multiple data node processes on a single computer, such a configuration is not usually recommended.

It is common for the terms “node” and “data node” to be used interchangeably when referring to an ndbd or ndbmtd process; where mentioned, management nodes (ndb_mgmd processes) and SQL nodes (mysqld processes) are specified as such in this discussion.

Node group. A node group consists of one or more nodes, and stores partitions, or sets of replicas (see next item).

The number of node groups in an NDB Cluster is not directly configurable; it is a function of the number of data nodes and of the number of replicas (NoOfReplicas configuration parameter), as shown here:

\[
\text{[# of node groups]} = \frac{\text{[# of data nodes]}}{\text{NoOfReplicas}}
\]

Thus, an NDB Cluster with 4 data nodes has 4 node groups if NoOfReplicas is set to 1 in the config.ini file, 2 node groups if NoOfReplicas is set to 2, and 1 node group if NoOfReplicas is set to 4. Replicas are discussed later in this section; for more information about NoOfReplicas, see Section 22.3.3.6, “Defining NDB Cluster Data Nodes”.

Note
All node groups in an NDB Cluster must have the same number of data nodes.

You can add new node groups (and thus new data nodes) online, to a running NDB Cluster; see Section 22.5.15, “Adding NDB Cluster Data Nodes Online”, for more information.

Partition. This is a portion of the data stored by the cluster. Each node is responsible for keeping at least one copy of any partitions assigned to it (that is, at least one replica) available to the cluster.

The number of partitions used by default by NDB Cluster depends on the number of data nodes and the number of LDM threads in use by the data nodes, as shown here:

\[
\text{[# of partitions]} = \text{[# of data nodes]} \times \text{[# of LDM threads]}
\]

When using data nodes running ndbmtd, the number of LDM threads is controlled by the setting for MaxNoOfExecutionThreads. When using ndbd there is a single LDM thread, which means that there are as many cluster partitions as nodes participating in the cluster. This is also the case when using ndbmtd with MaxNoOfExecutionThreads set to 3 or less. (You should be aware that the number of LDM threads increases with the value of this parameter, but not in a strictly linear fashion, and that there are additional constraints on setting it; see the description of MaxNoOfExecutionThreads for more information.)

NDB and user-defined partitioning. NDB Cluster normally partitions NDDBCLUSTER tables automatically. However, it is also possible to employ user-defined partitioning with NDDBCLUSTER tables. This is subject to the following limitations:

1. Only the KEY and LINEAR KEY partitioning schemes are supported in production with NDB tables.

2. The maximum number of partitions that may be defined explicitly for any NDB table is \(8 \times \text{[number of LDM threads]} \times \text{[number of node groups]}\), the number of node groups in an NDB Cluster being determined as discussed previously in this section. When running ndbd...
for data node processes, setting the number of LDM threads has no effect (since ThreadConfig applies only to ndbmtd); in such cases, this value can be treated as though it were equal to 1 for purposes of performing this calculation.

See Section 22.4.3, “ndbmtd — The NDB Cluster Data Node Daemon (Multi-Threaded)”, for more information.

For more information relating to NDB Cluster and user-defined partitioning, see Section 22.1.7, “Known Limitations of NDB Cluster”, and Section 23.6.2, “Partitioning Limitations Relating to Storage Engines”.

**Replica.** This is a copy of a cluster partition. Each node in a node group stores a replica. Also sometimes known as a *partition replica*. The number of replicas is equal to the number of nodes per node group.

A replica belongs entirely to a single node; a node can (and usually does) store several replicas.

The following diagram illustrates an NDB Cluster with four data nodes running ndbd, arranged in two node groups of two nodes each; nodes 1 and 2 belong to node group 0, and nodes 3 and 4 belong to node group 1.

---

**Note**

Only data nodes are shown here; although a working NDB Cluster requires an ndb_mgmd process for cluster management and at least one SQL node to access the data stored by the cluster, these have been omitted from the figure for clarity.

**Figure 22.2 NDB Cluster with Two Node Groups**

The data stored by the cluster is divided into four partitions, numbered 0, 1, 2, and 3. Each partition is stored—in multiple copies—on the same node group. Partitions are stored on alternate node groups as follows:

- Partition 0 is stored on node group 0; a *primary replica* (primary copy) is stored on node 1, and a *backup replica* (backup copy of the partition) is stored on node 2.
NDB Cluster Hardware, Software, and Networking Requirements

- Partition 1 is stored on the other node group (node group 1); this partition's primary replica is on node 3, and its backup replica is on node 4.

- Partition 2 is stored on node group 0. However, the placing of its two replicas is reversed from that of Partition 0; for Partition 2, the primary replica is stored on node 2, and the backup on node 1.

- Partition 3 is stored on node group 1, and the placement of its two replicas are reversed from those of partition 1. That is, its primary replica is located on node 4, with the backup on node 3.

What this means regarding the continued operation of an NDB Cluster is this: so long as each node group participating in the cluster has at least one node operating, the cluster has a complete copy of all data and remains viable. This is illustrated in the next diagram.

Figure 22.3 Nodes Required for a 2x2 NDB Cluster

In this example, the cluster consists of two node groups each consisting of two data nodes. Each data node is running an instance of ndbd. Any combination of at least one node from node group 0 and at least one node from node group 1 is sufficient to keep the cluster “alive”. However, if both nodes from a single node group fail, the combination consisting of the remaining two nodes in the other node group is not sufficient. In this situation, the cluster has lost an entire partition and so can no longer provide access to a complete set of all NDB Cluster data.

The maximum number of node groups supported for a single NDB Cluster instance is 48.

22.1.3 NDB Cluster Hardware, Software, and Networking Requirements

One of the strengths of NDB Cluster is that it can be run on commodity hardware and has no unusual requirements in this regard, other than for large amounts of RAM, due to the fact that all live data storage is done in memory. (It is possible to reduce this requirement using Disk Data tables—see Section 22.5.13, “NDB Cluster Disk Data Tables”, for more information about these.) Naturally, multiple and faster CPUs can enhance performance. Memory requirements for other NDB Cluster processes are relatively small.

The software requirements for NDB Cluster are also modest. Host operating systems do not require any unusual modules, services, applications, or configuration to support NDB Cluster. For supported operating systems, a standard installation should be sufficient. The MySQL software requirements are simple: all that is needed is a production release of NDB Cluster. It is not strictly necessary to compile MySQL yourself merely to be able to use NDB Cluster. We assume that you are using the binaries appropriate to your platform, available from the NDB Cluster software downloads page at https://dev.mysql.com/downloads/cluster/.
For communication between nodes, NDB Cluster supports TCP/IP networking in any standard topology, and the minimum expected for each host is a standard 100 Mbps Ethernet card, plus a switch, hub, or router to provide network connectivity for the cluster as a whole. We strongly recommend that an NDB Cluster be run on its own subnet which is not shared with machines not forming part of the cluster for the following reasons:

- **Security.** Communications between NDB Cluster nodes are not encrypted or shielded in any way. The only means of protecting transmissions within an NDB Cluster is to run your NDB Cluster on a protected network. If you intend to use NDB Cluster for Web applications, the cluster should definitely reside behind your firewall and not in your network's De-Militarized Zone (DMZ) or elsewhere. See Section 22.5.12.1, “NDB Cluster Security and Networking Issues”, for more information.

- **Efficiency.** Setting up an NDB Cluster on a private or protected network enables the cluster to make exclusive use of bandwidth between cluster hosts. Using a separate switch for your NDB Cluster not only helps protect against unauthorized access to NDB Cluster data, it also ensures that NDB Cluster nodes are shielded from interference caused by transmissions between other computers on the network. For enhanced reliability, you can use dual switches and dual cards to remove the network as a single point of failure; many device drivers support failover for such communication links.

**Network communication and latency.** NDB Cluster requires communication between data nodes and API nodes (including SQL nodes), as well as between data nodes and other data nodes, to execute queries and updates. Communication latency between these processes can directly affect the observed performance and latency of user queries. In addition, to maintain consistency and service despite the silent failure of nodes, NDB Cluster uses heartbeating and timeout mechanisms which treat an extended loss of communication from a node as node failure. This can lead to reduced redundancy. Recall that, to maintain data consistency, an NDB Cluster shuts down when the last node in a node group fails. Thus, to avoid increasing the risk of a forced shutdown, breaks in communication between nodes should be avoided wherever possible.

The failure of a data or API node results in the abort of all uncommitted transactions involving the failed node. Data node recovery requires synchronization of the failed node's data from a surviving data node, and re-establishment of disk-based redo and checkpoint logs, before the data node returns to service. This recovery can take some time, during which the Cluster operates with reduced redundancy.

Heartbeating relies on timely generation of heartbeat signals by all nodes. This may not be possible if the node is overloaded, has insufficient machine CPU due to sharing with other programs, or is experiencing delays due to swapping. If heartbeat generation is sufficiently delayed, other nodes treat the node that is slow to respond as failed.

This treatment of a slow node as a failed one may or may not be desirable in some circumstances, depending on the impact of the node's slowed operation on the rest of the cluster. When setting timeout values such as `HeartbeatIntervalDbDb` and `HeartbeatIntervalDbApi` for NDB Cluster, care must be taken care to achieve quick detection, failover, and return to service, while avoiding potentially expensive false positives.

Where communication latencies between data nodes are expected to be higher than would be expected in a LAN environment (on the order of 100 µs), timeout parameters must be increased to ensure that any allowed periods of latency periods are well within configured timeouts. Increasing timeouts in this way has a corresponding effect on the worst-case time to detect failure and therefore time to service recovery.

LAN environments can typically be configured with stable low latency, and such that they can provide redundancy with fast failover. Individual link failures can be recovered from with minimal and controlled latency visible at the TCP level (where NDB Cluster normally operates). WAN environments may offer a range of latencies, as well as redundancy with slower failover times. Individual link failures may require route changes to propagate before end-to-end connectivity is restored. At the TCP level this
can appear as large latencies on individual channels. The worst-case observed TCP latency in these scenarios is related to the worst-case time for the IP layer to reroute around the failures.

22.1.4 What is New in NDB Cluster

The following sections describe changes in the implementation of NDB Cluster in MySQL NDB Cluster 8.0 through 8.0.20, as compared to earlier release series. NDB Cluster 8.0 is available as a General Availability (GA) release, beginning with NDB 8.0.19. NDB Cluster 7.6 and 7.5 are previous GA releases still supported in production; for information about NDB Cluster 7.6, see What is New in NDB Cluster 7.6. For similar information about NDB Cluster 7.5, see What is New in NDB Cluster 7.5. NDB Cluster 7.4 and 7.3 are previous GA releases still supported in production, although we recommend that new deployments for production use NDB Cluster 8.0; see MySQL NDB Cluster 7.3 and NDB Cluster 7.4.

What is New in NDB Cluster 8.0

Major changes and new features in NDB Cluster 8.0 which are likely to be of interest are shown in the following list:

- **Compatibility enhancements.** The following changes reduce longstanding nonessential differences in NDB behavior as compared to that of other MySQL storage engines:
  - **Development in parallel with MySQL server.** Beginning with this release, MySQL NDB Cluster is being developed in parallel with the standard MySQL 8.0 server under a new unified release model with the following features:
    - NDB 8.0 is developed in, built from, and released with the MySQL 8.0 source code tree.
    - The numbering scheme for NDB Cluster 8.0 releases follows the scheme for MySQL 8.0, starting with version 8.0.13.
    - Building the source with NDB support appends `--cluster` to the version string returned by `mysql --version`, as shown here:
      ```
      $ mysql --version
      mysql Ver 8.0.20-cluster for Linux on x86_64 (Source distribution)
      
      NDB binaries continue to display both the MySQL Server version and the NDB engine version, like this:
      ```
      ```
      $ ndb_mgm --version
      MySQL distrib mysql-8.0.20 ndb-8.0.20, for Linux (x86_64)
      ```
      In MySQL Cluster NDB 8.0, these two version numbers are always the same.
      
      To build the MySQL 8.0.13 (or later) source with NDB Cluster support, use the CMake option `-DWITH_NDBCLUSTER`.

- **Database and table names.** As of NDB 8.0.18, the 63-byte limit on identifiers for databases and tables is removed. These identifiers can now use up to 64 bytes, as for such objects using other MySQL storage engines. See Section 22.1.7.11, “Previous NDB Cluster Issues Resolved in NDB Cluster 8.0”.

- **Generated names for foreign keys.** NDB (version 8.0.18 and later) now uses the pattern `tbl_name_fk_N` for naming internally generated foreign keys. This is similar to the pattern used by InnoDB.

- **Schema and metadata distribution and synchronization.** NDB 8.0 makes use of the MySQL data dictionary to distribute schema information to SQL nodes joining a cluster and to synchronize new schema changes between existing SQL nodes. The following list describes individual enhancements relating to this integration work:
What is New in NDB Cluster

- **Schema distribution enhancements.** The NDB schema distribution coordinator, which handles schema operations and tracks their progress, has been extended in NDB 8.0.17 to ensure that resources used during a schema operation are released at its conclusion. Previously, some of this work was done by the schema distribution client; this has been changed due to the fact that the client did not always have all needed state information, which could lead to resource leaks when the client decided to abandon the schema operation prior to completion and without informing the coordinator.

  To help fix this issue, schema operation timeout detection has been moved from the schema distribution client to the coordinator, providing the coordinator with an opportunity to clean up any resources used during the schema operation. The coordinator now checks ongoing schema operations for timeout at regular intervals, and marks participants that have not yet completed a given schema operation as failed when detecting timeout. It also provides suitable warnings whenever a schema operation timeout occurs. (It should be noted that, after such a timeout is detected, the schema operation itself continues.) Additional reporting is done by printing a list of active schema operations at regular intervals whenever one or more of these operations is ongoing.

  As an additional part of this work, a new `mysqld` option `--ndb-schema-dist-timeout` makes it possible to set the length of time to wait until a schema operation is marked as having timed out.

- **Disk data file distribution.** Beginning with NDB Cluster 8.0.14, NDB uses the MySQL data dictionary to make sure that disk data files and related constructs such as tablespaces and log file groups are correctly distributed between all connected SQL nodes.

- **Schema synchronization of tablespace objects.** When a MySQL Server connects as an SQL node to an NDB cluster, it checks its data dictionary against the information found in the NDB dictionary.

  Previously, the only NDB objects synchronized on connection of a new SQL node were databases and tables; MySQL NDB Cluster 8.0.14 and later also implement schema synchronization of disk data objects including tablespaces and log file groups. Among other benefits, this eliminates the possibility of a mismatch between the MySQL data dictionary and the NDB dictionary following a native backup and restore, in which tablespaces and log file groups were restored to the NDB dictionary, but not to the MySQL Server’s data dictionary.

  It is also no longer possible to issue a `CREATE TABLE` statement that refers to a nonexistent tablespace. Such a statement now fails with an error.

- **Database DDL synchronization enhancements.** Work done in NDB 8.0.17 insures that synchronization of databases by newly joined (or rejoined) SQL nodes with those on existing SQL nodes now makes proper use of the data dictionary so that any database-level operations (`CREATE DATABASE`, `ALTER DATABASE`, or `DROP DATABASE`) that may have been misssed by this SQL node are now correctly duplicated on it when it connects (or reconnects) to the cluster.

  As part of the schema synchronization procedure performed when starting, an SQL node now compares all databases on the cluster’s data nodes with those in its own data dictionary, and if any of these is found to be missing from the SQL node’s data dictionary, the SQL Node installs it locally by executing a `CREATE DATABASE` statement. A database thus created uses the default MySQL Server database properties (such as those as determined by `character_set_database` and `collation_database`) that are in effect on this SQL node at the time the statement is executed.

- **NDB metadata change detection and synchronization.** NDB 8.0.16 implements a new mechanism for detection of updates to metadata for data objects such as tables, tablespaces, and log file groups with the MySQL data dictionary. This is done using a thread, the NDB metadata
What is New in NDB Cluster

change monitor thread, which runs in the background and checks periodically for inconsistencies between the NDB dictionary and the MySQL data dictionary.

The monitor performs metadata checks every 60 seconds by default. The polling interval can be adjusted by setting the value of the `ndb_metadata_check_interval` system variable; polling can be disabled altogether by setting the `ndb_metadata_check` system variable to `OFF`. A status variable (also added in NDB 8.0.16) `Ndb_metadata_detected_count` shows the number of times since `mysqld` was last started that inconsistencies have been detected.

Beginning in version 8.0.18, NDB ensures that NDB table, log file group, and tablespace objects submitted by the metadata change monitor thread during operations following startup are automatically checked for mismatches and synchronized by the NDB binlog thread.

NDB 8.0.18 also adds two status variables relating to automatic synchronization:
- `Ndb_metadata_synced_count` shows the number of objects synchronized automatically;
- `Ndb_metadata_blacklist_size` indicates the number of objects for which synchronization has failed. In addition, you can see which objects have been synchronized by inspecting the cluster log.

NDB 8.0.19 further enhances this functionality by adding databases to those objects in which changes are detected and synchronized. Only databases actually used by NDB tables are so handled; other databases which may be present in the MySQL data dictionary are ignored. This eliminates a previous requirement, for the case when a table existed in NDB but the table and the database to which it belonged did not exist on the SQL node, to create this database manually; now in such cases, the database and all NDB tables belonging to it should be created on the SQL node automatically.

Beginning with NDB 8.0.21, more detailed information about the current state of automatic synchronization than can be obtained from log messages or status variables is provided by two new tables added to the MySQL Performance Schema. The tables are listed here:

- `ndb_sync_pending_objects`: Contains information about database objects for which mismatches have been detected between the NDB dictionary and the MySQL data dictionary (and which have not been blacklisted from automatic synchronization).
- `ndb_sync_excluded_objects`: Contains information about NDB database objects which have been blacklisted because they cannot be synchronized between the NDB dictionary and the MySQL data dictionary, and thus require manual intervention.

A row in one of these tables provides the database object's parent schema, name, and type. Types of objects include schemas, tablespaces, log file groups, and tables. (If the object is a log file group or tablespace, the parent schema is `NULL`.) In addition, the `ndb_sync_excluded_objects` table shows the reason for which the object has been blacklisted.

These tables are present only if NDBCLUSTER storage engine support is enabled. For more information about these tables, see Section 26.12.12, “Performance Schema NDB Cluster Tables”.

- **Changes in NDB table extra metadata.** In NDB 8.0.14 and later, the extra metadata property of an NDB table is used for storing serialized metadata from the MySQL data dictionary, rather than storing the binary representation of the table as in previous versions. (This was a `.frm` file, no longer used by the MySQL Server—see Chapter 14, MySQL Data Dictionary.) As part of the work to support this change, the available size of the table's extra metadata has been increased. This means that NDB tables created in NDB Cluster 8.0.14 and later are not compatible with previous
NDB Cluster releases. Tables created in previous releases can be used with NDB 8.0.14 and later, but cannot be opened afterwards by an earlier version.

This metadata is accessible using the NDB API methods `getExtraMetadata()` and `setExtraMetadata()` that were implemented in NDB 8.0.13.

For more information, see Section 22.2.8, “Upgrading and Downgrading NDB Cluster”.

• On-the-fly upgrades of tables using .frm files. A table created in NDB 7.6 and earlier contains metadata in the form of a compressed .frm file, which is no longer supported in MySQL 8.0. To facilitate online upgrades to NDB 8.0, NDB performs on-the-fly translation of this metadata and writes it into the MySQL Server’s data dictionary, which enables the `mysqld` in NDB Cluster 8.0 to work with the table without preventing subsequent use of the table by a previous version of the NDB software.

Important

Once a table’s structure has been modified in NDB 8.0, its metadata is stored using the data dictionary, and it can no longer be accessed by NDB 7.6 and earlier.

This enhancement also makes it possible to restore an NDB backup made using an earlier version to a cluster running NDB 8.0 (or later).

• Synchronization of user privileges with NDB_STORED_USER. A new mechanism for sharing and synchronizing users, roles, and privileges between SQL nodes is available beginning with NDB 8.0.18, using the NDB_STORED_USER privilege. Distributed privileges as implemented in NDB 7.6 and earlier (see Distributed Privileges Using Shared Grant Tables) are no longer supported.

Once a user account is created on an SQL node, the user and its privileges can be stored in NDB and thus shared between all SQL nodes in the cluster by issuing a `GRANT` statement such as this one:

```sql
GRANT NDB_STORED_USER ON *.* TO 'jon'@'localhost';
```

NDB_STORED_USER always has global scope and must be granted using `ON *.*`. System reserved accounts such as `mysql.session@localhost` or `mysql.infoschema@localhost` cannot be assigned this privilege.

Roles can also be shared between SQL nodes by issuing the appropriate `GRANT NDB_STORED_USER` statement. Assigning such a role to a user does not cause the user to be shared; the NDB_STORED_USER privilege must be granted to each user explicitly.

A user or role having NDB_STORED_USER, along with its privileges, is shared with all SQL nodes as soon as they join a given NDB Cluster. Changes to the privileges of the user or role are synchronized immediately with all connected SQL nodes. It is possible to make such changes from any connected SQL node, but recommended practice is to do so from a designated SQL node only, since the order of execution of statements affecting privileges from different SQL nodes cannot be guaranteed to be the same on all SQL nodes.

Implications for upgrades. Due to changes in the MySQL server’s privilege system (see Section 6.2.3, “Grant Tables”), privilege tables using the NDB storage engine do not function correctly in NDB 8.0. It is safe but not necessary to retain such privilege tables created in NDB 7.6 or earlier, but they are no longer used for access control. Beginning with NDB 8.0.16, a `mysqld` acting as an SQL node and detecting such tables in NDB writes a warning to the MySQL server log, and creates InnoDB shadow tables local to itself; such shadow tables are created on each MySQL server connected to the cluster. When performing an upgrade from NDB 7.6 or earlier, the privilege tables
using NDB can be removed safely using ndb_drop_table once all MySQL servers acting as SQL nodes have been upgraded (see Section 22.2.8, “Upgrading and Downgrading NDB Cluster”).

The ndb_restore utility's --restore-privilege-tables option is deprecated but continues to be honored in NDB 8.0, and can still be used to restore distributed privilege tables present in a backup taken from a previous release of NDB Cluster to a cluster running NDB 8.0. These tables are handled as described in the preceding paragraph.

Shared users and grants are stored in the ndb_sql_metadata table, which in NDB 8.0.19 and later ndb_restore by default does not restore; you can specify the --include-stored-grants option to cause it to do so.

• INFORMATION_SCHEMA changes. The following changes are made in the display of information regarding Disk Data files in the INFORMATION_SCHEMA.FILES table:

  • Tablespaces and log file groups are no longer represented in the FILES table. (These constructs are not actually files.)
  
  • Each data file is now represented by a single row in the FILES table. Each undo log file is also now represented in this table by one row only. (Previously, a row was displayed for each copy of each of these files on each data node.)

  In addition, INFORMATION_SCHEMA tables are now populated with tablespace statistics for MySQL Cluster tables. (Bug #27167728)

• Error information with ndb_perror. The deprecated --ndb option for perror has been removed. Instead, use ndb_perror to obtain error message information from NDB error codes. (Bug #81704, Bug #81705, Bug #23523926, Bug #23523957)

• Condition pushdown enhancements. Previously, condition pushdown was limited to predicate terms referring to column values from the same table to which the condition was being pushed. In NDB 8.0.16, this restriction is removed such that column values from tables earlier in the query plan can also be referred to from pushed conditions. As of NDB 8.0.18, joins comparing column expressions are supported, as are comparisons between columns in the same table. Columns and column expressions to be compared must be of exactly the same type; this means they must also be of the same signedness, length, character set, precision, and scale, whenever these attributes apply.

  Pushing down larger parts of a condition allows more rows to be filtered out by the data nodes, thereby reducing the number of rows which mysqld must handle during join processing. Another benefit of these enhancements is that filtering can be performed in parallel in the LDM threads, rather than in a single mysqld process on an SQL node; this has the potential to improve query performance significantly.

  Existing rules for type compatibility between column values being compared continue to apply (see Section 8.2.1.5, “Engine Condition Pushdown Optimization”).

• Increase in maximum row size. NDB 8.0.18 increases the maximum number of bytes that can be stored in an NDBCLUSTER table from 14000 to 30000 bytes.

  A BLOB or TEXT column continues to use 264 bytes of this total, as before.

  The maximum offset for a fixed-width column of an NDB table is 8188 bytes; this is also unchanged from releases previous to 8.0.18.

  See Section 22.1.7.5, “Limits Associated with Database Objects in NDB Cluster”, for more information.

• ndb_mgm SHOW command and single user mode. Beginning with NDB 8.0.17, when the cluster in single user mode, the output of the management client SHOW command indicates which API or SQL node has exclusive access while this mode is in effect.
• **Online column renames.** Beginning with NDB 8.0.18, columns of NDB tables can be renamed online, using `ALGORITHM=INPLACE`. See Section 22.5.14, “Online Operations with ALTER TABLE in NDB Cluster”, for more information.

• **Improved ndb_mgmd startup times.** Start times for management nodes daemon have been significantly improved in NDB 8.0.18 and later, in the following ways:

  - Due to replacing the list data structure formerly used by `ndb_mgmd` for handling node properties from configuration data with a hash table, overall startup times for the management server have been decreased by a factor of 6 or more.

  - In addition, in cases where data and SQL node host names not present in the management server’s `hosts` file are used in the cluster configuration file, `ndb_mgmd` start times can be up to 20 times shorter than was previously the case.

• **NDB API enhancements.** Beginning with NDB 8.0.18, `NdbScanFilter::cmp()` and several comparison methods of `NdbInterpretedCode` can be used to compare table column values with each other. The affected `NdbInterpretedCode` methods are listed here:

  - `branch_col_eq()`
  - `branch_col_ge()`
  - `branch_col_gt()`
  - `branch_col_le()`
  - `branch_col_lt()`
  - `branch_col_ne()`

  For all of the methods just listed, table column values to be compared must be of exactly matching types, including with respect to length, precision, signedness, scale, character set, and collation, as applicable.

  See the descriptions of the individual API methods for more information.

• **Offline multithreaded index builds.** It is now possible to specify a set of cores to be used for I/O threads performing offline multithreaded builds of ordered indexes, as opposed to normal I/O duties such as file I/O, compression, or decompression. “Offline” in this context refers to building of ordered indexes performed when the parent table is not being written to; such building takes place when an NDB cluster performs a node or system restart, or as part of restoring a cluster from backup using `ndb_restore --rebuild-indexes`.

  In addition, the default behaviour for offline index build work is modified to use all cores available to `ndbmtd`, rather limiting itself to the core reserved for the I/O thread. Doing so can improve restart and restore times and performance, availability, and the user experience.

  This enhancement is implemented as follows:

  1. The default value for `BuildIndexThreads` is changed from 0 to 128. This means that offline ordered index builds are now multithreaded by default.

  2. The default value for `TwoPassInitialNodeRestartCopy` is changed from `false` to `true`. This means that an initial node restart first copies all data from a “live” node to one that is starting—without creating any indexes—builds ordered indexes offline, and then again synchronizes its data with the live node, that is, synchronizing twice and building indexes offline between the two synchronizations. This causes an initial node restart to behave more like the normal restart of a node, and reduces the time required for building indexes.
3. A new thread type \texttt{(idxbld)} is defined for the \texttt{ThreadConfig} configuration parameter, to allow locking of offline index build threads to specific CPUs.

In addition, \texttt{NDB} now distinguishes the thread types that are accessible to \texttt{ThreadConfig} by these two criteria:

1. Whether the thread is an execution thread. Threads of types \texttt{main}, \texttt{ldm}, \texttt{recv}, \texttt{rep}, \texttt{tc}, and \texttt{send} are execution threads; thread types \texttt{io}, \texttt{watchdog}, and \texttt{idxbld} are not.

2. Whether the allocation of the thread to a given task is permanent or temporary. Currently all thread types except \texttt{idxbld} are permanent.

For additional information, see the descriptions of the indicated parameters in the Manual. (Bug \#25835748, Bug \#26928111)

- **logbuffers table backup process information.** When performing an NDB backup, the \texttt{ndbinfo.logbuffers} table now displays information regarding buffer usage by the backup process on each data node. This is implemented as rows reflecting two new log types in addition to \texttt{REDO} and \texttt{DD-UNDO}. One of these rows has the log type \texttt{BACKUP-DATA}, which shows the amount of data buffer used during backup to copy fragments to backup files. The other row has the log type \texttt{BACKUP-LOG}, which displays the amount of log buffer used during the backup to record changes made after the backup has started. One each of these \texttt{log_type} rows is shown in the \texttt{logbuffers} table for each data node in the cluster. Rows having these two log types are present in the table only while an NDB backup is currently in progress. (Bug \#25822988)

- **ndbinfo.processes table on Windows.** The process ID of the monitor process used on Windows platforms by \texttt{RESTART} to spawn and restart a \texttt{mysqld} is now shown in the \texttt{processes} table as an \texttt{angel_pid}.

- **String hashing improvements.** Prior to NDB 8.0, all string hashing was based on first transforming the string into a normalized form, then MD5-hashing the resulting binary image. This could give rise to some performance problems, for the following reasons:

  - The normalized string is always space padded to its full length. For a \texttt{VARCHAR}, this often involved adding more spaces than there were characters in the original string.

  - The string libraries were not optimized for this space padding, which added considerable overhead in some use cases.

  - The padding semantics varied between character sets, some of which were not padded to their full length.

  - The transformed string could become quite large, even without space padding; some Unicode 9.0 collations can transform a single code point into 100 bytes or more of character data.

  - Subsequent MD5 hashing consisted mainly of padding with spaces, and was not particularly efficient, possibly causing additional performance penalties by flushing significant portions of the L1 cache.

A collation provides its own hash function, which hashes the string directly without first creating a normalized string. In addition, for a Unicode 9.0 collation, the hash is computed without padding. \texttt{NDB} now takes advantage of this built-in function whenever hashing a string identified as using a Unicode 9.0 collation.

Since, for other collations, there are existing databases which are hash partitioned on the transformed string, \texttt{NDB} continues to employ the previous method for hashing strings that use these, to maintain compatibility. (Bug \#89590, Bug \#89604, Bug \#89609, Bug \#27515000, Bug \#27523758, Bug \#27522732)
What is New in NDB Cluster

- **RESET MASTER changes.** Because the MySQL Server now executes \texttt{RESET MASTER} with a global read lock, the behavior of this statement when used with NDB Cluster has changed in the following two respects:

  - It is no longer guaranteed to be synchronous; that is, it is now possible that a read coming immediately before \texttt{RESET MASTER} is issued may not be logged until after the binary log has been rotated.
  
  - It now behaves in exactly the same fashion, whether the statement is issued on the same SQL node that is writing the binary log, or on a different SQL node in the same cluster.

  
  \textbf{Note}\n  
  \texttt{SHOW BINLOG EVENTS}, \texttt{FLUSH LOGS}, and most data definition statements continue, as they did in previous NDB versions, to operate in a synchronous fashion.

- **\texttt{ndb_restore} option usage.** Beginning with NDB 8.0.16, the \texttt{--nodeid} and \texttt{--backupid} options are both required when invoking \texttt{ndb_restore}.

- **\texttt{ndb_log_bin} default.** Beginning with NDB 8.0.16, the default value of the \texttt{ndb_log_bin} system variable has changed from \texttt{TRUE} to \texttt{FALSE}.

- **Dynamic transactional resource allocation.** Allocation of resources in the transaction coordinator (see \textit{The DBTC Block}) is now performed using dynamic memory pools. This means that resource allocation determined by data node configuration parameters such as \texttt{MaxDMLOperationsPerTransaction}, \texttt{MaxNoOfConcurrentIndexOperations}, \texttt{MaxNoOfConcurrentOperations}, \texttt{MaxNoOfConcurrentScans}, \texttt{MaxNoOfConcurrentTransactions}, \texttt{MaxNoOfFiredTriggers}, \texttt{MaxNoOfLocalScans}, and \texttt{TransactionBufferMemory} is now done in such a way that, if the load represented by each of these parameters is within the target load for all such resources, others of these resources can be limited so as not to exceed the total resources available.

As part of this work, several new data node parameters controlling transactional resources in \textit{DBTC}, listed here, have been added:

  - ReservedConcurrentIndexOperations
  - ReservedConcurrentOperations
  - ReservedConcurrentScans
  - ReservedConcurrentTransactions
  - ReservedFiredTriggers
  - ReservedLocalScans
  - ReservedTransactionBufferMemory.

  See the descriptions of the parameters just listed for further information.

- **Backups using multiple LDMs per data node.** NDB backups can now be performed in a parallel fashion on individual data nodes using multiple local data managers (LDMs). (Previously, backups were done in parallel across data nodes, but were always serial within data node processes.) No special syntax is required for the \texttt{START BACKUP} command in the \texttt{ndb_mgm} client to enable this feature, but all data nodes must be using multiple LDMs. This means that data nodes must be running \texttt{ndbmtd} (\texttt{ndbd} is single-threaded and thus always has only one LDM) and they must be configured to use multiple LDMs before taking the backup; you can do this by choosing an appropriate setting for one of the multi-threaded data node configuration parameters \texttt{MaxNoOfExecutionThreads} or \texttt{ThreadConfig}. 

3524
Backups using multiple LDMs create subdirectories, one per LDM, under the BACKUP/BACKUP-backup_id/ directory. ndb_restore now detects these subdirectories automatically, and if they exist, attempts to restore the backup in parallel; see Section 22.4.23.2, “Restoring from a backup taken in parallel”, for details. (Single-threaded backups are restored as in previous versions of NDB.) It is also possible to restore backups taken in parallel using an ndb_restore binary from a previous version of NDB Cluster by modifying the usual restore procedure; Restoring a parallel backup serially, provides information on how to do this.

- **ARM support (source only).** Beginning with NDB 8.0.18, it is possible to build NDB from source for 64-bit ARM CPUs. Currently, this support is source-only, and we do not provide any precompiled binaries for this platform.

- **Binary configuration file enhancements.** Beginning with NDB 8.0.18, a new format is used for the management server's binary configuration file. Previously, a maximum of 16381 sections could appear in the cluster configuration file; now the maximum number of sections is 4G. This is intended to support larger numbers of nodes in a cluster than was possible before this change.

  Upgrades to the new format are relatively seamless, and should seldom if ever require manual intervention, as the management server continues to be able to read the old format without issue. A downgrade from NDB 8.0.18 (or later) to an older version of the NDB Cluster software requires manual removal of any binary configuration files or, alternatively, starting the older management server binary with the --initial option.

  For more information, see Section 22.2.8, “Upgrading and Downgrading NDB Cluster”.

- **Increased number of data nodes.** NDB 8.0.18 increases the maximum number of data nodes supported per cluster to 144 (previously, this was 48). Data nodes can now use node IDs in the range 1 to 144, inclusive.

  Previously, the recommended node IDs for management nodes were 49 and 50. These are still supported for management nodes, but using them as such limits the maximum number of data nodes to 142; for this reason, it is now recommended that node IDs 145 and 146 are used for management nodes.

- **RedoOverCommitCounter and RedoOverCommitLimit changes.** Due to ambiguities in the semantics for setting them to 0, the minimum value for each of the data node configuration parameters RedoOverCommitCounter and RedoOverCommitLimit has been increased to 1, beginning with NDB 8.0.19.

- **ndb_autoincrement_prefetch_sz changes.** In NDB 8.0.19, the default value of the ndb_autoincrement_prefetch_sz server system variable is increased to 512.

- **Changes in parameter maximimums and defaults.** NDB 8.0.19 makes the following changes in configuration parameter maximum and default values:
  - The maximum for DataMemory is increased to 16 terabytes.
  - The maximum for DiskPageBufferMemory is also increased to 16 terabytes.
  - The default value for StringMemory is increased to 25%.
  - The default for LcpScanProgressTimeout is increased to 180 seconds.

- **Disk Data checkpointing improvements.** NDB Cluster 8.0.19 provides a number of new enhancements which help to reduce the latency of checkpoints of Disk Data tables and tablespaces when using non-volatile memory devices such as solid-state drives and the NVMe specification for such devices. These improvements include those in the following list:
  - Avoiding bursts of checkpoint disk writes
  - Speeding up checkpoints for disk data tablespaces when the redo log or the undo log becomes full
What is New in NDB Cluster

- Balancing checkpoints to disk and in-memory checkpoints against one other, when necessary
- Protecting disk devices from overload to help ensure low latency under high loads

As part of this work, NDB 8.0.19 introduces two new data node configuration parameters. \texttt{MaxDiskDataLatency} places a ceiling on the degree of latency permitted for disk access and causes transactions taking longer than this length of time to be aborted. \texttt{DiskDataUsingSameDisk} makes it possible to take advantage of housing Disk Data tablespaces on separate disks by increasing the rate at which checkpoints of such tablespaces can be performed.

In addition, three new tables in the \texttt{ndbinfo} database, also added in NDB 8.0.19 and listed here, provide information about Disk Data performance:

- The \texttt{diskstat} table reports on writes to Disk Data tablespaces during the past second
- The \texttt{diskstats_1sec} table reports on writes to Disk Data tablespaces for each of the last 20 seconds
- The \texttt{pgman_time_track_stats} table reports on the latency of disk operations relating to Disk Data tablespaces

**Memory allocation and \texttt{TransactionMemory}**. NDB 8.0.19 introduces a new \texttt{TransactionMemory} parameter which simplifies allocation of data node memory for transactions as part of the work done to pool transactional and Local Data Manager (LDM) memory. This parameter is intended to replace several older transactional memory parameters which have been deprecated.

Transaction memory can now be set in any of the three ways listed here:

- Several deprecated configuration parameters are incompatible with \texttt{TransactionMemory}. If any of these are set, \texttt{TransactionMemory} cannot be set (see Parameters incompatible with \texttt{TransactionMemory}), and the data node’s transaction memory is determined as it was previous to NDB 8.0.19.

\begin{Verbatim}
\textbf{Note}
\end{Verbatim}

Attempting to set \texttt{TransactionMemory} and any of the deprecated parameters concurrently in the \texttt{config.ini} file prevents the management server from starting.

- If \texttt{TransactionMemory} is set, this value is used for determining transaction memory. \texttt{TransactionMemory} cannot be set if any of the incompatible deprecated parameters mentioned in the previous item have also been set.

- If none of the incompatible parameters are set and \texttt{TransactionMemory} is also not set, transaction memory is set by NDB.

For more information, see the description of \texttt{TransactionMemory}, as well as Section 22.3.3.13, “Data Node Memory Management”.

- **Support for additional replicas**. NDB 8.0.19 increases the maximum number of replicas supported in production from 2 to 4. (Previously, it was possible to set \texttt{NoOfReplicas} to 3 or 4, but this was not officially supported or verified in testing.)
• **Restoring by slices.** Beginning with NDB 8.0.20, it is possible to divide a backup into roughly equal portions (slices) and to restore these slices in parallel using two new options implemented for `ndb_restore`:

  - `--num-slices` determines the number of slices into which the backup should be divided.
  - `--slice-id` provides the ID of the slice to be restored by the current instance of `ndb_restore`.

This makes it possible to employ multiple instances of `ndb_restore` to restore subsets of the backup in parallel, potentially reducing the amount of time required to perform the restore operation.

For more information, see the description of the `ndb_restore --num-slices` option.

• **Read from any replica enabled.** Beginning with NDB 8.0.19, read from any replica is enabled by default for all NDB tables. This means that the default value for the `ndb_read_backup` system variable is now ON, and that the value of the `NDB_TABLE` comment option `READ_BACKUP` is 1 when creating a new NDB table. Enabling read from any replica significantly improves performance for reads from NDB tables, with minimal impact on writes.

For more information, see the description of the `ndb_read_backup` system variable, and Section 13.1.20.10, “Setting NDB_TABLE Options”.

• **ndb_blob_tool enhancements.** Beginning with NDB 8.0.20, the `ndb_blob_tool` utility can detect missing blob parts for which inline parts exist and replace these with placeholder blob parts (consisting of space characters) of the correct length. To check whether there are missing blob parts, use the `--check-missing` option with this program. To replace any missing blob parts with placeholders, use the `--add-missing` option.

For more information, see Section 22.4.6, “ndb_blob_tool — Check and Repair BLOB and TEXT columns of NDB Cluster Tables”.

• **ndbinfo versioning.** NDB 8.0.20 and later supports versioning for `ndbinfo` tables, and maintains the current definitions for its tables internally. At startup, NDB compares its supported `ndbinfo` version with the version stored in the data dictionary. If the versions differ, NDB drops any old `ndbinfo` tables and recreates them using the current definitions.

• **Support for Fedora Linux.** Beginning with NDB 8.0.20, Fedora Linux is a supported platform for NDB Cluster Community releases and can be installed using the RPMs supplied for this purpose by Oracle. These can be obtained from the NDB Cluster downloads page.

• **NDB programs—NDBT dependency removal.** The dependency of a number of NDB utility programs on the NDBT library has been removed. This library is used internally for development, and is not required for normal use; its inclusion in these programs could lead to unwanted issues when testing.

Affected programs are listed here, along with the NDB versions in which the dependency was removed:

  - `ndb_delete_all`, in NDB 8.0.18
  - `ndb_show_tables`, in NDB 8.0.20
  - `ndb_waiter`, in NDB 8.0.20

The principal effect of this change for users is that these programs no longer print `NDBT_ProgramExit - status` following completion of a run. Applications that depend upon such behavior should be updated to reflect the change when upgrading to the indicated versions.

• **Pushdown of outer joins and semijoins.** Work done in NDB 8.0.20 allows many outer joins and semijoins, and not only those using a primary key or unique key lookup, to be pushed down to the data nodes (see Section 8.2.1.5, “Engine Condition Pushdown Optimization”).

...
Outer joins using scans which can now be pushed include those which meet the following conditions:

- There are no unpushed conditions on the table
- There are no unpushed conditions on other tables in the same join nest, or in upper join nests on which it depends
- All other tables in the same join nest, or in upper join nests on which it depends, are also pushed

A semijoin that uses an index scan can now be pushed if it meets the the conditions just noted for a pushed outer join, and it uses the firstMatch strategy (see Section 8.2.2.1, “Optimizing IN and EXISTS Subquery Predicates with Semijoin Transformations”).

When a join cannot be pushed, EXPLAIN should provide the reason or reasons.

- **Foreign keys and lettercasing.** NDB stores the names of foreign keys using the case with which they were defined. Formerly, when the value of the lower_case_table_names system variable was set to 0, it performed case-sensitive comparisons of foreign key names as used in SELECT and other SQL statements with the names as stored. Beginning with NDB 8.0.20, such comparisons are now always performed in a case-insensitive fashion, regardless of the value of lower_case_table_names.

- **Multiple transporters.** NDB 8.0.20 introduces support for multiple transporters to handle node-to-node communication between pairs of data nodes. This facilitates higher rates of update operations for each node group in the cluster, and helps avoid constraints imposed by system or other limitations on inter-node communications using a single socket.

  By default, NDB now uses a number of transporters based on the number of local data management (LDM) threads or the number of transaction coordinator (TC) threads, whichever is greater. By default, the number of transporters is equal to half of this number. While the default should perform well for most workloads, it is possible to adjust the number of transporters employed by each node group by setting the NodeGroupTransporters data node configuration parameter (also introduced in NDB 8.0.20), up a maximum of the greater of the number of LDM threads or the number of TC threads. Setting it to 0 causes the number of transporters to be the same as the number of LDM threads.

- **ndb_restore: primary key schema changes.** NDB 8.0.21 (and later) supports different primary key definitions for source and target tables when restoring an NDB native backup with ndb_restore when it is run with the --allow-pk-changes option. Both increasing and decreasing the number of columns making up the original primary key are supported.

  When the primary key is extended with an additional column or columns, any columns added must be defined as NOT NULL, and no values in any such columns may be changed during the time that the backup is being taken. Because some applications set all column values in a row when updating it, whether or not all values are actually changed, this can cause a restore operation to fail even if no values in the column to be added to the primary key have changed. You can override this behavior using the --ignore-extended-pk-updates option also added in NDB 8.0.21; in this case, you must ensure that no such values are changed.

  A column can be removed from the table’s primary key whether or not this column remains part of the table.

  For more information, see the description of the --allow-pk-changes option for ndb_restore.

- **Merging backups with ndb_restore.** In some cases, it may be desirable to consolidate data originally stored in different instances of NDB Cluster (all using the same schema) into a single target NDB Cluster. This is now supported when using backups created in the ndb_mgm client (see Section 22.5.3.2, “Using The NDB Cluster Management Client to Create a Backup”) and restoring them with ndb_restore, using the --remap-column option added in NDB 8.0.21 along with --restore-data (and possibly additional compatible options as needed or desired). --remap-
column can be employed to handle cases in which primary and unique key values are overlapping between source clusters, and it is necessary that they do not overlap in the target cluster, as well as to preserve other relationships between tables such as foreign keys.

--remap-column takes as its argument a string having the format db.tbl.col:fn:args, where db, tbl, and col are, respectively, the names of the database, table, and column, fn is the name of a remapping function, and args is one or more arguments to fn. There is no default value. Only offset is supported as the function name, with args as the integer offset to be applied to the value of the column when inserting it into the target table from the backup. The column must use one of the MySQL integer types (see Section 11.1.2, “Integer Types (Exact Value) - INTEGER, INT, SMALLINT, TINYINT, MEDIUMINT, BIGINT”); the allowed range of the offset value is the same as the signed version of that type (this allows the offset to be negative if desired).

The new option can be used multiple times in the same invocation of ndb_restore, so that you can remap to new values multiple columns of the same table, different tables, or both. The offset value does not have to be the same for all instances of the option.

In addition, two new options are provided for ndb_desc, also beginning in NDB 8.0.21:

• --auto-inc (short form -a): Includes the the next auto-increment value in the output, if the table has an AUTO_INCREMENT column.

• --context (short form -x): Provides extra information about the table, including the schema, database name, table name, and internal ID.

For more information and examples, see the description of the --remap-column option.

• **Send thread improvements.** As of NDB 8.0.20, each send thread now handles sends to a subset of transporters, and each block thread now assists only one send thread, resulting in more send threads, and thus better performance and data node scalability.

• **Adaptive spin control using SpinMethod.** NDB 8.0.20 introduces a simple interface for setting up adaptive CPU spin on platforms supporting it, using the SpinMethod data node parameter. This parameter has four settings, one each for static spinning, cost-based adaptive spinning, latency-optimized adaptive spinning, and adaptive spinning optimized for database machines on which each thread has its own CPU. Each of these settings causes the data node to use a set of predetermined values for one or more spin parameters which enable adaptive spinning, set spin timing, and set spin overhead, as appropriate to a given scenario, thus obviating the need to set these directly for common use cases.

For fine-tuning spin behavior, it is also possible to set these and additional spin parameters directly, using the existing SchedulerSpinTimer data node configuration parameter as well as the following DUMP commands in the ndb_mgm client:

• DUMP 104000 (SetSchedulerSpinTimerAll): Sets spin time for all threads

• DUMP 104001 (SetSchedulerSpinTimerThread): Sets spin time for a specified thread

• DUMP 104002 (SetAllowedSpinOverhead): Sets spin overhead as the number of units of CPU time allowed to gain 1 unit of latency

• DUMP 104003 (SetSpintimePerCall): Sets the time for a call to spin
Options, Variables, and Parameters Added, Deprecated or Removed in NDB 8.0

- **DUMP 104004 (EnableAdaptiveSpinning)**: Enables or disables adaptive spinning.

NDB 8.0.20 also adds a new TCP configuration parameter `TcpSpinTime` which sets the time to spin for a given TCP connection.

The `ndb_top` tool is also enhanced to provide spin time information per thread.

For additional information, see the description of the `SpinMethod` parameter, the listed `DUMP` commands, and Section 22.4.29, “`ndb_top` — View CPU usage information for NDB threads”.

MySQL Cluster Manager 1.4.8 also provides experimental support for NDB Cluster 8.0. MySQL Cluster Manager has an advanced command-line interface that can simplify many complex NDB Cluster management tasks. See MySQL™ Cluster Manager 1.4.8 User Manual, for more information.

### 22.1.5 Options, Variables, and Parameters Added, Deprecated or Removed in NDB 8.0

- **Node Configuration Parameters Introduced in NDB 8.0**
- **Node Configuration Parameters Deprecated in NDB 8.0**
- **Node Configuration Parameters Removed in NDB 8.0**
- **MySQL Server Options and Variables Introduced in NDB 8.0**
- **MySQL Server Options and Variables Deprecated in NDB 8.0**
- **MySQL Server Options and Variables Removed in NDB 8.0**

The next few sections contain information about NDB node configuration parameters and NDB-specific `mysqld` options and variables that have been added to, deprecated in, or removed from NDB 8.0.

#### Node Configuration Parameters Introduced in NDB 8.0

The following node configuration parameters have been added in NDB 8.0.

- **DiskDataUsingSameDisk**: Set to false if Disk Data tablespaces are located on separate physical disks. Added in NDB 8.0.19.
- **MaxDiskDataLatency**: Maximum allowed mean latency of disk access (ms) before starting to abort transactions. Added in NDB 8.0.19.
- **NodeGroupTransporters**: Number of transporters to use between nodes in same node group. Added in NDB 8.0.20.
- **ReservedConcurrentIndexOperations**: Number of simultaneous index operations having dedicated resources on one data node. Added in NDB 8.0.16.
- **ReservedConcurrentOperations**: Number of simultaneous operations having dedicated resources in transaction coordinators on one data node. Added in NDB 8.0.16.
- **ReservedConcurrentScans**: Number of simultaneous scans having dedicated resources on one data node. Added in NDB 8.0.16.
- **ReservedConcurrentTransactions**: Number of simultaneous transactions having dedicated resources on one data node. Added in NDB 8.0.16.
- **ReservedFiredTriggers**: Number of triggers having dedicated resources on one data node. Added in NDB 8.0.16.
- **ReservedLocalScans**: Number of simultaneous fragment scans having dedicated resources on one data node. Added in NDB 8.0.16.
Options, Variables, and Parameters Added, Deprecated or Removed in NDB 8.0

- **ReservedTransactionBufferMemory**: Dynamic buffer space (in bytes) for key and attribute data allocated to each data node. Added in NDB 8.0.16.

- **SpinMethod**: Determines spin method used by data node; see documentation for details. Added in NDB 8.0.20.

- **TcpSpinTime**: Time to spin before going to sleep when receiving. Added in NDB 8.0.20.

- **TransactionMemory**: Memory allocated for transactions on each data node. Added in NDB 8.0.19.

### Node Configuration Parameters Deprecated in NDB 8.0

The following node configuration parameters have been deprecated in NDB 8.0.

- **BatchSizePerLocalScan**: Used to calculate number of lock records for scan with hold lock. Deprecated as of NDB 8.0.19.

- **MaxNoOfConcurrentIndexOperations**: Total number of index operations that can execute simultaneously on one data node. Deprecated as of NDB 8.0.19.

- **MaxNoOfConcurrentOperations**: Maximum number of operation records in transaction coordinator. Deprecated as of NDB 8.0.19.

- **MaxNoOfConcurrentScans**: Maximum number of scans executing concurrently on data node. Deprecated as of NDB 8.0.19.

- **MaxNoOfConcurrentTransactions**: Maximum number of transactions executing concurrently on this data node, total number of transactions that can be executed concurrently is this value times number of data nodes in cluster. Deprecated as of NDB 8.0.19.

- **MaxNoOfFiredTriggers**: Total number of triggers that can fire simultaneously on one data node. Deprecated as of NDB 8.0.19.

- **MaxNoOfLocalOperations**: Maximum number of operation records defined on this data node. Deprecated as of NDB 8.0.19.

- **MaxNoOfLocalScans**: Maximum number of fragment scans in parallel on this data node. Deprecated as of NDB 8.0.19.

- **ReservedTransactionBufferMemory**: Dynamic buffer space (in bytes) for key and attribute data allocated to each data node. Deprecated as of NDB 8.0.19.

### Node Configuration Parameters Removed in NDB 8.0

No node configuration parameters have been removed from NDB 8.0.

### MySQL Server Options and Variables Introduced in NDB 8.0

The following `mysqld` system variables, status variables, and options have been added in NDB 8.0.

- **Ndb_metadata_blacklist_size**: Number of NDB metadata objects that NDB binlog thread has failed to synchronize. Added in NDB 8.0.18.

- **Ndb_metadata_detected_count**: Number of times NDB metadata change monitor thread has detected changes. Added in NDB 8.0.16.

- **Ndb_metadata_synced_count**: Number of NDB metadata objects which have been synchronized. Added in NDB 8.0.18.

- **Ndb_trans_hint_count_session**: Number of transactions using hints that have been started in this session. Added in NDB 8.0.17.

- **ndb-schema-dist-timeout**: How long to wait before detecting timeout during schema distribution. Added in NDB 8.0.17.
MySQL Server Using InnoDB Compared with NDB Cluster

- **ndb_dbg_check SHARES**: Check for any lingering shares (debug builds only). Added in NDB 8.0.13.

- **ndb_metadata_check**: Enable auto-detection of NDB metadata changes with respect to MySQL data dictionary; enabled by default. Added in NDB 8.0.16.

- **ndb_metadata_check_interval**: Interval in seconds to perform check for NDB metadata changes with respect to MySQL data dictionary. Added in NDB 8.0.16.

- **ndb_schema_dist_lock_wait_timeout**: Time during schema distribution to wait for lock before returning error. Added in NDB 8.0.18.

- **ndb_schema_dist_timeout**: Time to wait before detecting timeout during schema distribution. Added in NDB 8.0.16.

- **ndb_schema_dist_upgrade_allowed**: Allow schema distribution table upgrade when connecting to NDB. Added in NDB 8.0.17.

- **ndbinfo**: Enable ndbinfo plugin, if supported. Added in NDB 8.0.13.

**MySQL Server Options and Variables Deprecated in NDB 8.0**

No system variables, status variables, or options have been deprecated in NDB 8.0.

**MySQL Server Options and Variables Removed in NDB 8.0**

No system variables, status variables, or options have been removed from NDB 8.0.

### 22.1.6 MySQL Server Using InnoDB Compared with NDB Cluster

MySQL Server offers a number of choices in storage engines. Since both NDB and InnoDB can serve as transactional MySQL storage engines, users of MySQL Server sometimes become interested in NDB Cluster. They see NDB as a possible alternative or upgrade to the default InnoDB storage engine in MySQL 8.0. While NDB and InnoDB share common characteristics, there are differences in architecture and implementation, so that some existing MySQL Server applications and usage scenarios can be a good fit for NDB Cluster, but not all of them.

In this section, we discuss and compare some characteristics of the NDB storage engine used by NDB 8.0 with InnoDB used in MySQL 8.0. The next few sections provide a technical comparison. In many instances, decisions about when and where to use NDB Cluster must be made on a case-by-case basis, taking all factors into consideration. While it is beyond the scope of this documentation to provide specifics for every conceivable usage scenario, we also attempt to offer some very general guidance on the relative suitability of some common types of applications for NDB as opposed to InnoDB back ends.

NDB Cluster 8.0 uses a *mysqld* based on MySQL 8.0, including support for InnoDB 1.1. While it is possible to use InnoDB tables with NDB Cluster, such tables are not clustered. It is also not possible to use programs or libraries from an NDB Cluster 8.0 distribution with MySQL Server 8.0, or the reverse.

While it is also true that some types of common business applications can be run either on NDB Cluster or on MySQL Server (most likely using the InnoDB storage engine), there are some important architectural and implementation differences. Section 22.1.6.1, “Differences Between the NDB and InnoDB Storage Engines”, provides a summary of the these differences. Due to the differences, some usage scenarios are clearly more suitable for one engine or the other; see Section 22.1.6.2, “NDB and InnoDB Workloads”. This in turn has an impact on the types of applications that better suited for use with NDB or InnoDB. See Section 22.1.6.3, “NDB and InnoDB Feature Usage Summary”, for a comparison of the relative suitability of each for use in common types of database applications.

For information about the relative characteristics of the NDB and MEMORY storage engines, see When to Use MEMORY or NDB Cluster.

See Chapter 16, Alternative Storage Engines, for additional information about MySQL storage engines.
22.1.6.1 Differences Between the NDB and InnoDB Storage Engines

The NDB storage engine is implemented using a distributed, shared-nothing architecture, which causes it to behave differently from InnoDB in a number of ways. For those unaccustomed to working with NDB, unexpected behaviors can arise due to its distributed nature with regard to transactions, foreign keys, table limits, and other characteristics. These are shown in the following table:

<table>
<thead>
<tr>
<th>Feature</th>
<th>InnoDB (MySQL 8.0)</th>
<th>NDB 8.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL Server Version</td>
<td>8.0</td>
<td>8.0</td>
</tr>
<tr>

#### 22.1.6.2 NDB and InnoDB Workloads

NDB Cluster has a range of unique attributes that make it ideal to serve applications requiring high availability, fast failover, high throughput, and low latency. Due to its distributed architecture and multi-node implementation, NDB Cluster also has specific constraints that may keep some workloads from performing well. A number of major differences in behavior between the NDB and InnoDB storage engines with regard to some common types of database-driven application workloads are shown in the following table:

**Table 22.2 Differences between InnoDB and NDB storage engines, common types of data-driven application workloads.**

#### 22.1.6.3 NDB and InnoDB Feature Usage Summary

When comparing application feature requirements to the capabilities of InnoDB with NDB, some are clearly more compatible with one storage engine than the other.

The following table lists supported application features according to the storage engine to which each feature is typically better suited.

**Table 22.3 Supported application features according to the storage engine to which each feature is typically better suited**

- **Preferred application requirements for InnoDB**
  - Foreign keys

- **Preferred application requirements for NDB**
  - Write scaling
22.1.7 Known Limitations of NDB Cluster

In the sections that follow, we discuss known limitations in current releases of NDB Cluster as compared with the features available when using the MyISAM and InnoDB storage engines. If you check the "Cluster" category in the MySQL bugs database at http://bugs.mysql.com, you can find known bugs in the following categories under "MySQL Server:" in the MySQL bugs database at http://bugs.mysql.com, which we intend to correct in upcoming releases of NDB Cluster:

- NDB Cluster
- Cluster Direct API (NDBAPI)
- Cluster Disk Data
- Cluster Replication
- ClusterJ

This information is intended to be complete with respect to the conditions just set forth. You can report any discrepancies that you encounter to the MySQL bugs database using the instructions given in Section 1.7, "How to Report Bugs or Problems". If we do not plan to fix the problem in NDB Cluster 8.0, we will add it to the list.

See Section 22.1.7.11, "Previous NDB Cluster Issues Resolved in NDB Cluster 8.0" for a list of issues in earlier releases that have been resolved in NDB Cluster 8.0.

Note

Limitations and other issues specific to NDB Cluster Replication are described in Section 22.6.3, "Known Issues in NDB Cluster Replication".

22.1.7.1 Noncompliance with SQL Syntax in NDB Cluster

Some SQL statements relating to certain MySQL features produce errors when used with NDB tables, as described in the following list:

- **Temporary tables.** Temporary tables are not supported. Trying either to create a temporary table that uses the NDB storage engine or to alter an existing temporary table to use NDB fails with the error `Table storage engine 'ndbcluster' does not support the create option 'TEMPORARY'`.

- **Indexes and keys in NDB tables.** Keys and indexes on NDB Cluster tables are subject to the following limitations:
Known Limitations of NDB Cluster

- **Column width.** Attempting to create an index on an NDB table column whose width is greater than 3072 bytes succeeds, but only the first 3072 bytes are actually used for the index. In such cases, a warning `Specified key was too long; max key length is 3072 bytes` is issued, and a `SHOW CREATE TABLE` statement shows the length of the index as 3072.

- **TEXT and BLOB columns.** You cannot create indexes on NDB table columns that use any of the TEXT or BLOB data types.

- **FULLTEXT indexes.** The NDB storage engine does not support FULLTEXT indexes, which are possible for MyISAM and InnoDB tables only. However, you can create indexes on VARCHAR columns of NDB tables.

- **USING HASH keys and NULL.** Using nullable columns in unique keys and primary keys means that queries using these columns are handled as full table scans. To work around this issue, make the column **NOT NULL**, or re-create the index without the USING HASH option.

- **Prefixes.** There are no prefix indexes; only entire columns can be indexed. (The size of an NDB column index is always the same as the width of the column in bytes, up to and including 3072 bytes, as described earlier in this section. Also see Section 22.1.7.6, “Unsupported or Missing Features in NDB Cluster”, for additional information.)

- **BIT columns.** A BIT column cannot be a primary key, unique key, or index, nor can it be part of a composite primary key, unique key, or index.

- **AUTO_INCREMENT columns.** Like other MySQL storage engines, the NDB storage engine can handle a maximum of one AUTO_INCREMENT column per table. However, in the case of an NDB table with no explicit primary key, an AUTO_INCREMENT column is automatically defined and used as a “hidden” primary key. For this reason, you cannot define a table that has an explicit AUTO_INCREMENT column unless that column is also declared using the PRIMARY KEY option. Attempting to create a table with an AUTO_INCREMENT column that is not the table’s primary key, and using the NDB storage engine, fails with an error.

- **Restrictions on foreign keys.** Support for foreign key constraints in NDB 8.0 is comparable to that provided by InnoDB, subject to the following restrictions:
  
  - Every column referenced as a foreign key requires an explicit unique key, if it is not the table’s primary key.
  
  - **ON UPDATE CASCADE** is not supported when the reference is to the parent table’s primary key. This is because an update of a primary key is implemented as a delete of the old row (containing the old primary key) plus an insert of the new row (with a new primary key). This is not visible to the NDB kernel, which views these two rows as being the same, and thus has no way of knowing that this update should be cascaded.
  
  - As of NDB 8.0.16: **ON DELETE CASCADE** is not supported where the child table contains one or more columns of any of the TEXT or BLOB types. (Bug #89511, Bug #27484882)
  
  - **SET DEFAULT** is not supported. (Also not supported by InnoDB.)
  
  - The **NO ACTION** keyword is accepted but treated as **RESTRICT**, which is a standard SQL keyword, is the default in MySQL 8.0. (Also the same as with InnoDB.)
  
  - In earlier versions of NDB Cluster, when creating a table with foreign key referencing an index in another table, it sometimes appeared possible to create the foreign key even if the order of the columns in the indexes did not match, due to the fact that an appropriate error was not always returned internally. A partial fix for this issue improved the error used internally to work in most...
Known Limitations of NDB Cluster

cases: however, it remains possible for this situation to occur in the event that the parent index is a

unique index. (Bug #18094360)

For more information, see Section 13.1.20.5, “FOREIGN KEY Constraints”, and Section 1.8.3.2,

“FOREIGN KEY Constraints”.

• NDB Cluster and geometry data types.

Geometry data types (WKT and WKB) are supported for NDB tables. However, spatial indexes are not

supported.

• Character sets and binary log files. Currently, the ndb_apply_status and

ndb_binlog_index tables are created using the latin1 (ASCII) character set. Because names

of binary logs are recorded in this table, binary log files named using non-Latin characters are

not referenced correctly in these tables. This is a known issue, which we are working to fix. (Bug

#50226)

To work around this problem, use only Latin-1 characters when naming binary log files or setting any

the --basedir, --log-bin, or --log-bin-index options.

• Creating NDB tables with user-defined partitioning. Support for user-defined partitioning

in NDB Cluster is restricted to [LINEAR] KEY partitioning. Using any other partitioning type with

ENGINE=NDB or ENGINE=NDBCluster in a CREATE TABLE statement results in an error.

It is possible to override this restriction, but doing so is not supported for use in production settings.
For details, see User-defined partitioning and the NDB storage engine (NDB Cluster).

Default partitioning scheme. All NDB Cluster tables are by default partitioned by KEY using

the table’s primary key as the partitioning key. If no primary key is explicitly set for the table, the

“hidden” primary key automatically created by the NDB storage engine is used instead. For additional
discussion of these and related issues, see Section 23.2.5, “KEY Partitioning”.

CREATE TABLE and ALTER TABLE statements that would cause a user-partitioned NDBCLUSTER

table not to meet either or both of the following two requirements are not permitted, and fail with an

error:

1. The table must have an explicit primary key.

2. All columns listed in the table’s partitioning expression must be part of the primary key.

Exception. If a user-partitioned NDBCLUSTER table is created using an empty column-list (that is,

using PARTITION BY [LINEAR] KEY()), then no explicit primary key is required.

Maximum number of partitions for NDBCLUSTER tables. The maximum number of partitions

that can defined for a NDBCLUSTER table when employing user-defined partitioning is 8 per node

group. (See Section 22.1.2, “NDB Cluster Nodes, Node Groups, Replicas, and Partitions”, for more

information about NDB Cluster node groups.

DROP PARTITION not supported. It is not possible to drop partitions from NDB tables using

ALTER TABLE ... DROP PARTITION. The other partitioning extensions to ALTER TABLE—ADD

PARTITION, REORGANIZE PARTITION, and COALESCE PARTITION—are supported for NDB

tables, but use copying and so are not optimized. See Section 23.3.1, “Management of RANGE and

LIST Partitions” and Section 13.1.9, “ALTER TABLE Statement”.

• Row-based replication.

When using row-based replication with NDB Cluster, binary logging cannot be disabled. That is, the

NDB storage engine ignores the value of sql_log_bin.

• JSON data type. The MySQL JSON data type is supported for NDB tables in the mysql supplied

with NDB 8.0.

An NDB table can have a maximum of 3 JSON columns.
The NDB API has no special provision for working with JSON data, which it views simply as BLOB data. Handling data as JSON must be performed by the application.

22.1.7.2 Limits and Differences of NDB Cluster from Standard MySQL Limits

In this section, we list limits found in NDB Cluster that either differ from limits found in, or that are not found in, standard MySQL.

**Memory usage and recovery.** Memory consumed when data is inserted into an NDB table is not automatically recovered when deleted, as it is with other storage engines. Instead, the following rules hold true:

- A **DELETE** statement on an NDB table makes the memory formerly used by the deleted rows available for re-use by inserts on the same table only. However, this memory can be made available for general re-use by performing **OPTIMIZE TABLE**.

  A rolling restart of the cluster also frees any memory used by deleted rows. See Section 22.5.5, “Performing a Rolling Restart of an NDB Cluster”.

- A **DROP TABLE** or **TRUNCATE TABLE** operation on an NDB table frees the memory that was used by this table for re-use by any NDB table, either by the same table or by another NDB table.

  **Note**

  Recall that **TRUNCATE TABLE** drops and re-creates the table. See Section 13.1.37, “TRUNCATE TABLE Statement”.

- **Limits imposed by the cluster's configuration.**

  A number of hard limits exist which are configurable, but available main memory in the cluster sets limits. See the complete list of configuration parameters in Section 22.3.3, “NDB Cluster Configuration Files”. Most configuration parameters can be upgraded online. These hard limits include:

  - Database memory size and index memory size (**DataMemory** and **IndexMemory**, respectively).

    **DataMemory** is allocated as 32KB pages. As each **DataMemory** page is used, it is assigned to a specific table; once allocated, this memory cannot be freed except by dropping the table.

    See Section 22.3.3.6, “Defining NDB Cluster Data Nodes”, for more information.

  - The maximum number of operations that can be performed per transaction is set using the configuration parameters **MaxNoOfConcurrentOperations** and **MaxNoOfLocalOperations**.

    **Note**

    Bulk loading, **TRUNCATE TABLE**, and **ALTER TABLE** are handled as special cases by running multiple transactions, and so are not subject to this limitation.

  - Different limits related to tables and indexes. For example, the maximum number of ordered indexes in the cluster is determined by **MaxNoOfOrderedIndexes**, and the maximum number of ordered indexes per table is 16.

  - **Node and data object maximums.** The following limits apply to numbers of cluster nodes and metadata objects:

    - As of NDB 8.0.18, the maximum number of data nodes is 145. (Previously, this was 48.)

      A data node must have a node ID in the range of 1 to 144, inclusive. (In NDB 8.0.17 and earlier releases, this was 1 to 48, inclusive.)
Management and API nodes may use node IDs in the range 1 to 255, inclusive.

- The total maximum number of nodes in an NDB Cluster is 255. This number includes all SQL nodes (MySQL Servers), API nodes (applications accessing the cluster other than MySQL servers), data nodes, and management servers.

- The maximum number of metadata objects in current versions of NDB Cluster is 20320. This limit is hard-coded.

See Section 22.1.7.11, “Previous NDB Cluster Issues Resolved in NDB Cluster 8.0”, for more information.

### 22.1.7.3 Limits Relating to Transaction Handling in NDB Cluster

A number of limitations exist in NDB Cluster with regard to the handling of transactions. These include the following:

- **Transaction isolation level.** The NDBCLUSTER storage engine supports only the READ COMMITTED transaction isolation level. (InnoDB, for example, supports READ COMMITTED, READ UNCOMMITTED, REPEATABLE READ, and SERIALIZABLE.) You should keep in mind that NDB implements READ COMMITTED on a per-row basis; when a read request arrives at the data node storing the row, what is returned is the last committed version of the row at that time.

Uncommitted data is never returned, but when a transaction modifying a number of rows commits concurrently with a transaction reading the same rows, the transaction performing the read can observe “before” values, “after” values, or both, for different rows among these, due to the fact that a given row read request can be processed either before or after the commit of the other transaction.

To ensure that a given transaction reads only before or after values, you can impose row locks using `SELECT ... LOCK IN SHARE MODE`. In such cases, the lock is held until the owning transaction is committed. Using row locks can also cause the following issues:

- Increased frequency of lock wait timeout errors, and reduced concurrency

- Increased transaction processing overhead due to reads requiring a commit phase

- Possibility of exhausting the available number of concurrent locks, which is limited by `MaxNoOfConcurrentOperations`

NDB uses READ COMMITTED for all reads unless a modifier such as LOCK IN SHARE MODE or FOR UPDATE is used. LOCK IN SHARE MODE causes shared row locks to be used; FOR UPDATE causes exclusive row locks to be used. Unique key reads have their locks upgraded automatically by NDB to ensure a self-consistent read; BLOB reads also employ extra locking for consistency.

See Section 22.5.3.4, “NDB Cluster Backup Troubleshooting”, for information on how NDB Cluster's implementation of transaction isolation level can affect backup and restoration of NDB databases.

- **Transactions and BLOB or TEXT columns.** NDBCLUSTER stores only part of a column value that uses any of MySQL's BLOB or TEXT data types in the table visible to MySQL; the remainder of the BLOB or TEXT is stored in a separate internal table that is not accessible to MySQL. This gives rise to two related issues of which you should be aware whenever executing SELECT statements on tables that contain columns of these types:

1. For any SELECT from an NDB Cluster table: If the SELECT includes a BLOB or TEXT column, the READ COMMITTED transaction isolation level is converted to a read with read lock. This is done to guarantee consistency.

2. For any SELECT which uses a unique key lookup to retrieve any columns that use any of the BLOB or TEXT data types and that is executed within a transaction, a shared read lock is held on
Known Limitations of NDB Cluster

the table for the duration of the transaction—that is, until the transaction is either committed or aborted.

This issue does not occur for queries that use index or table scans, even against NDB tables having BLOB or TEXT columns.

For example, consider the table \( t \) defined by the following CREATE TABLE statement:

```sql
CREATE TABLE t (
    a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    b INT NOT NULL,
    c INT NOT NULL,
    d TEXT,
    INDEX i(b),
    UNIQUE KEY u(c)
) ENGINE = NDB,
```

The following query on \( t \) causes a shared read lock, because it uses a unique key lookup:

```sql
SELECT * FROM t WHERE c = 1;
```

However, none of the four queries shown here causes a shared read lock:

```sql
SELECT * FROM t WHERE b = 1;
SELECT * FROM t WHERE d = '1';
SELECT * FROM t;
SELECT b,c WHERE a = 1;
```

This is because, of these four queries, the first uses an index scan, the second and third use table scans, and the fourth, while using a primary key lookup, does not retrieve the value of any BLOB or TEXT columns.

You can help minimize issues with shared read locks by avoiding queries that use unique key lookups that retrieve BLOB or TEXT columns, or, in cases where such queries are not avoidable, by committing transactions as soon as possible afterward.

- **Unique key lookups and transaction isolation.** Unique indexes are implemented in NDB using a hidden index table which is maintained internally. When a user-created NDB table is accessed using a unique index, the hidden index table is first read to find the primary key that is then used to read the user-created table. To avoid modification of the index during this double-read operation, the row found in the hidden index table is locked. When a row referenced by a unique index in the user-created NDB table is updated, the hidden index table is subject to an exclusive lock by the transaction in which the update is performed. This means that any read operation on the same (user-created) NDB table must wait for the update to complete. This is true even when the transaction level of the read operation is READ COMMITTED.

One workaround which can be used to bypass potentially blocking reads is to force the SQL node to ignore the unique index when performing the read. This can be done by using the IGNORE_INDEX index hint as part of the SELECT statement reading the table (see Section 8.9.4, “Index Hints”). Because the MySQL server creates a shadowing ordered index for every unique index created in NDB, this lets the ordered index be read instead, and avoids unique index access locking. The resulting read is as consistent as a committed read by primary key, returning the last committed value at the time the row is read.

Reading via an ordered index makes less efficient use of resources in the cluster, and may have higher latency.

It is also possible to avoid using the unique index for access by querying for ranges rather than for unique values.
Known Limitations of NDB Cluster

• **Rollbacks.** There are no partial transactions, and no partial rollbacks of transactions. A duplicate key or similar error causes the entire transaction to be rolled back.

This behavior differs from that of other transactional storage engines such as InnoDB that may roll back individual statements.

• **Transactions and memory usage.**

As noted elsewhere in this chapter, NDB Cluster does not handle large transactions well; it is better to perform a number of small transactions with a few operations each than to attempt a single large transaction containing a great many operations. Among other considerations, large transactions require very large amounts of memory. Because of this, the transactional behavior of a number of MySQL statements is affected as described in the following list:

• **TRUNCATE TABLE** is not transactional when used on NDB tables. If a TRUNCATE TABLE fails to empty the table, then it must be re-run until it is successful.

• **DELETE FROM (even with no WHERE clause) is transactional.** For tables containing a great many rows, you may find that performance is improved by using several DELETE FROM ... LIMIT ... statements to “chunk” the delete operation. If your objective is to empty the table, then you may wish to use TRUNCATE TABLE instead.

• **LOAD DATA statements.** LOAD DATA is not transactional when used on NDB tables.

![Important]

When executing a LOAD DATA statement, the NDB engine performs commits at irregular intervals that enable better utilization of the communication network. It is not possible to know ahead of time when such commits take place.

• **ALTER TABLE and transactions.** When copying an NDB table as part of an ALTER TABLE, the creation of the copy is nontransactional. (In any case, this operation is rolled back when the copy is deleted.)

• **Transactions and the COUNT() function.** When using NDB Cluster Replication, it is not possible to guarantee the transactional consistency of the COUNT() function on the slave. In other words, when performing on the master a series of statements (INSERT, DELETE, or both) that changes the number of rows in a table within a single transaction, executing SELECT COUNT(*) FROM table queries on the slave may yield intermediate results. This is due to the fact that SELECT COUNT(...) may perform dirty reads, and is not a bug in the NDB storage engine. (See Bug #31321 for more information.)

22.1.7.4 NDB Cluster Error Handling

Starting, stopping, or restarting a node may give rise to temporary errors causing some transactions to fail. These include the following cases:

• **Temporary errors.** When first starting a node, it is possible that you may see Error 1204 Temporary failure, distribution changed and similar temporary errors.

• **Errors due to node failure.** The stopping or failure of any data node can result in a number of different node failure errors. (However, there should be no aborted transactions when performing a planned shutdown of the cluster.)

In either of these cases, any errors that are generated must be handled within the application. This should be done by retrying the transaction.

See also Section 22.1.7.2, “Limits and Differences of NDB Cluster from Standard MySQL Limits”.

22.1.7.5 Limits Associated with Database Objects in NDB Cluster
Some database objects such as tables and indexes have different limitations when using the NDBCLUSTER storage engine:

- **Number of database objects.** The maximum number of all NDB database objects in a single NDB Cluster—including databases, tables, and indexes—is limited to 20320.

- **Attributes per table.** The maximum number of attributes (that is, columns and indexes) that can belong to a given table is 512.

- **Attributes per key.** The maximum number of attributes per key is 32.

- **Row size.** Beginning with NDB 8.0.18, the maximum permitted size of any one row is 30000 bytes, in NDB 8.0.17 and earlier releases, this limit is 14000 bytes.

  Each BLOB or TEXT column contributes $256 + 8 = 264$ bytes to this total; this includes JSON columns. See String Type Storage Requirements, as well as JSON Storage Requirements, for more information relating to these types.

  In addition, the maximum offset for a fixed-width column of an NDB table is 8188 bytes; attempting to create a table that violates this limitation fails with NDB error 851 Maximum offset for fixed-size columns exceeded. For memory-based columns, you can work around this limitation by using a variable-width column type such as VARCHAR or defining the column as COLUMN_FORMAT=DYNAMIC; this does not work with columns stored on disk. For disk-based columns, you may be able to do so by reordering one or more of the table’s disk-based columns such that the combined width of all but the disk-based column defined last in the CREATE TABLE statement used to create the table does not exceed 8188 bytes, less any possible rounding performed for some data types such as CHAR or VARCHAR; otherwise it is necessary to use memory-based storage for one or more of the offending column or columns instead.

- **BIT column storage per table.** The maximum combined width for all BIT columns used in a given NDB table is 4096.

- **FIXED column storage.** NDB Cluster 8.0 supports a maximum of 128 TB per fragment of data in FIXED columns.

**22.1.7.6 Unsupported or Missing Features in NDB Cluster**

A number of features supported by other storage engines are not supported for NDB tables. Trying to use any of these features in NDB Cluster does not cause errors in or of itself; however, errors may occur in applications that expects the features to be supported or enforced. Statements referencing such features, even if effectively ignored by NDB, must be syntactically and otherwise valid.

- **Index prefixes.** Prefixes on indexes are not supported for NDB tables. If a prefix is used as part of an index specification in a statement such as CREATE TABLE, ALTER TABLE, or CREATE INDEX, the prefix is not created by NDB.

  A statement containing an index prefix, and creating or modifying an NDB table, must still be syntactically valid. For example, the following statement always fails with Error 1089 Incorrect prefix key; the used key part isn't a string, the used length is longer than the key part, or the storage engine doesn't support unique prefix keys, regardless of storage engine:

  ```sql
  CREATE TABLE t1 (    c1 INT NOT NULL,    c2 VARCHAR(100),    INDEX i1 (c2(500))  );
  ```

  This happens on account of the SQL syntax rule that no index may have a prefix larger than itself.

- **Savepoints and rollbacks.** Savepoints and rollbacks to savepoints are ignored as in MyISAM.
Known Limitations of NDB Cluster

- **Durability of commits.** There are no durable commits on disk. Commits are replicated, but there is no guarantee that logs are flushed to disk on commit.

- **Replication.** Statement-based replication is not supported. Use `--binlog-format=ROW` (or `--binlog-format=MIXED`) when setting up cluster replication. See Section 22.6, "NDB Cluster Replication", for more information.

Replication using global transaction identifiers (GTIDs) is not compatible with NDB Cluster, and is not supported in NDB Cluster 8.0. Do not enable GTIDs when using the NDB storage engine, as this is very likely to cause problems up to and including failure of NDB Cluster Replication.

Semisynchronous replication is not supported in NDB Cluster.

- **Generated columns.** The NDB storage engine does not support indexes on virtual generated columns.

As with other storage engines, you can create an index on a stored generated column, but you should bear in mind that NDB uses DataMemory for storage of the generated column as well as IndexMemory for the index. See JSON columns and indirect indexing in NDB Cluster, for an example.

NDB Cluster writes changes in stored generated columns to the binary log, but does log not those made to virtual columns. This should not effect NDB Cluster Replication or replication between NDB and other MySQL storage engines.

**Note**

See Section 22.1.7.3, “Limits Relating to Transaction Handling in NDB Cluster”, for more information relating to limitations on transaction handling in NDB.

### 22.1.7.7 Limitations Relating to Performance in NDB Cluster

The following performance issues are specific to or especially pronounced in NDB Cluster:

- **Range scans.** There are query performance issues due to sequential access to the NDB storage engine; it is also relatively more expensive to do many range scans than it is with either MyISAM or InnoDB.

- **Reliability of Records in range.** The Records in range statistic is available but is not completely tested or officially supported. This may result in nonoptimal query plans in some cases. If necessary, you can employ USE INDEX or FORCE INDEX to alter the execution plan. See Section 8.9.4, “Index Hints”, for more information on how to do this.

- **Unique hash indexes.** Unique hash indexes created with USING HASH cannot be used for accessing a table if NULL is given as part of the key.

### 22.1.7.8 Issues Exclusive to NDB Cluster

The following are limitations specific to the NDB storage engine:

- **Machine architecture.** All machines used in the cluster must have the same architecture. That is, all machines hosting nodes must be either big-endian or little-endian, and you cannot use a mixture of both. For example, you cannot have a management node running on a PowerPC which directs a data node that is running on an x86 machine. This restriction does not apply to machines simply running mysql or other clients that may be accessing the cluster’s SQL nodes.

- **Binary logging.**

  NDB Cluster has the following limitations or restrictions with regard to binary logging:

  - `sql_log_bin` has no effect on data operations; however, it is supported for schema operations.
Known Limitations of NDB Cluster

- NDB Cluster cannot produce a binary log for tables having BLOB columns but no primary key.

- Only the following schema operations are logged in a cluster binary log which is not on the mysqld executing the statement:
  - CREATE TABLE
  - ALTER TABLE
  - DROP TABLE
  - CREATE DATABASE / CREATE SCHEMA
  - DROP DATABASE / DROP SCHEMA
  - CREATE TABLESPACE
  - ALTER TABLESPACE
  - DROP TABLESPACE
  - CREATE LOGFILE GROUP
  - ALTER LOGFILE GROUP
  - DROP LOGFILE GROUP

- Schema operations. Schema operations (DDL statements) are rejected while any data node restarts. Schema operations are also not supported while performing an online upgrade or downgrade.

- Number of replicas. The number of replicas, as determined by the NoOfReplicas data node configuration parameter, is the number of copies of all data stored by NDB Cluster. Setting this parameter to 1 means there is only a single copy; in this case, no redundancy is provided, and the loss of a data node entails loss of data. To guarantee redundancy, and thus preservation of data even if a data node fails, set this parameter to 2, which is the default and recommended value in production.

  Setting NoOfReplicas to a value greater than 2 is supported (to a maximum of 4) but unnecessary to guard against loss of data.

  See also Section 22.1.7.10, “Limitations Relating to Multiple NDB Cluster Nodes”.

### 22.1.7.9 Limitations Relating to NDB Cluster Disk Data Storage

#### Disk Data object maximums and minimums.

Disk data objects are subject to the following maximums and minimums:

- Maximum number of tablespaces: $2^{32}$ (4294967296)
- Maximum number of data files per tablespace: $2^{16}$ (65536)
- The minimum and maximum possible sizes of extents for tablespace data files are 32K and 2G, respectively. See Section 13.1.21, “CREATE TABLESPACE Statement”, for more information.

In addition, when working with NDB Disk Data tables, you should be aware of the following issues regarding data files and extents:

- Data files use DataMemory. Usage is the same as for in-memory data.
- Data files use file descriptors. It is important to keep in mind that data files are always open, which means the file descriptors are always in use and cannot be re-used for other system tasks.
• Extents require sufficient DiskPageBufferMemory; you must reserve enough for this parameter to account for all memory used by all extents (number of extents times size of extents).

Disk Data tables and diskless mode. Use of Disk Data tables is not supported when running the cluster in diskless mode.

22.1.7.10 Limitations Relating to Multiple NDB Cluster Nodes

Multiple SQL nodes.
The following are issues relating to the use of multiple MySQL servers as NDB Cluster SQL nodes, and are specific to the NDBCLUSTER storage engine:

• No distributed table locks. A LOCK TABLES works only for the SQL node on which the lock is issued; no other SQL node in the cluster “sees” this lock. This is also true for a lock issued by any statement that locks tables as part of its operations. (See next item for an example.)

• ALTER TABLE operations. ALTER TABLE is not fully locking when running multiple MySQL servers (SQL nodes). (As discussed in the previous item, NDB Cluster does not support distributed table locks.)

Multiple management nodes.
When using multiple management servers:

• If any of the management servers are running on the same host, you must give nodes explicit IDs in connection strings because automatic allocation of node IDs does not work across multiple management servers on the same host. This is not required if every management server resides on a different host.

• When a management server starts, it first checks for any other management server in the same NDB Cluster, and upon successful connection to the other management server uses its configuration data. This means that the management server --reload and --initial startup options are ignored unless the management server is the only one running. It also means that, when performing a rolling restart of an NDB Cluster with multiple management nodes, the management server reads its own configuration file if (and only if) it is the only management server running in this NDB Cluster. See Section 22.5.5, “Performing a Rolling Restart of an NDB Cluster”, for more information.

Multiple network addresses. Multiple network addresses per data node are not supported. Use of these is liable to cause problems: In the event of a data node failure, an SQL node waits for confirmation that the data node went down but never receives it because another route to that data node remains open. This can effectively make the cluster inoperable.

Note
It is possible to use multiple network hardware interfaces (such as Ethernet cards) for a single data node, but these must be bound to the same address. This also means that it not possible to use more than one [tcp] section per connection in the config.ini file. See Section 22.3.3.10, “NDB Cluster TCP/IP Connections”, for more information.

22.1.7.11 Previous NDB Cluster Issues Resolved in NDB Cluster 8.0

A number of limitations and related issues that existed in earlier versions of NDB Cluster have been resolved in NDB 8.0. These are described briefly in the following list:

Database and table names. Prior to NDB 8.0.18, when using the NDB storage engine, the maximum allowed length both for database names and for table names is 63 characters, and a statement using a database name or table name longer than this limit failed with an appropriate error. As of NDB 8.0.18, this restriction is lifted and identifiers for NDB databases and tables may now use up to 64 bytes, as with other MySQL database and table names.

22.2 NDB Cluster Installation
This section describes the basics for planning, installing, configuring, and running an NDB Cluster. Whereas the examples in Section 22.3, “Configuration of NDB Cluster” provide more in-depth information on a variety of clustering options and configuration, the result of following the guidelines and procedures outlined here should be a usable NDB Cluster which meets the minimum requirements for availability and safeguarding of data.

This section covers hardware and software requirements; networking issues; installation of NDB Cluster; basic configuration issues; starting, stopping, and restarting the cluster; loading of a sample database; and performing queries.

NDB Cluster also provides the NDB Cluster Auto-Installer, a web-based graphical installer, as part of the NDB Cluster distribution. The Auto-Installer can be used to perform basic installation and setup of an NDB Cluster on one (for testing) or more host computers. See Section 22.2.1, “The NDB Cluster Auto-Installer”, for more information.

Assumptions. The following sections make a number of assumptions regarding the cluster’s physical and network configuration. These assumptions are discussed in the next few paragraphs.

Cluster nodes and host computers. The cluster consists of four nodes, each on a separate host computer, and each with a fixed network address on a typical Ethernet network as shown here:

<table>
<thead>
<tr>
<th>Node</th>
<th>IP Address</th>
</tr>
</thead>
<tbody>
<tr>
<td>Management node (mgmd)</td>
<td>198.51.100.10</td>
</tr>
<tr>
<td>SQL node (mysql)</td>
<td>198.51.100.20</td>
</tr>
<tr>
<td>Data node “A” (ndbd)</td>
<td>198.51.100.30</td>
</tr>
<tr>
<td>Data node “B” (ndbd)</td>
<td>198.51.100.40</td>
</tr>
</tbody>
</table>

This setup is also shown in the following diagram:

**Figure 22.4 NDB Cluster Multi-Computer Setup**

Network addressing. In the interest of simplicity (and reliability), this How-To uses only numeric IP addresses. However, if DNS resolution is available on your network, it is possible to use host names in lieu of IP addresses in configuring Cluster. Alternatively, you can use the hosts file (typically /etc/hosts for Linux and other Unix-like operating systems, C:\WINDOWS\system32\drivers\etc\hosts on Windows, or your operating system’s equivalent) for providing a means to do host lookup if such is available.
NDB Cluster Installation

**Potential hosts file issues.** A common problem when trying to use host names for Cluster nodes arises because of the way in which some operating systems (including some Linux distributions) set up the system's own host name in the `/etc/hosts` during installation. Consider two machines with the host names `ndb1` and `ndb2`, both in the `cluster` network domain. Red Hat Linux (including some derivatives such as CentOS and Fedora) places the following entries in these machines’ `/etc/hosts` files:

```bash
# ndb1 /etc/hosts:
127.0.0.1   ndb1.cluster ndb1 localhost.localdomain localhost
# ndb2 /etc/hosts:
127.0.0.1   ndb2.cluster ndb2 localhost.localdomain localhost
```

SUSE Linux (including OpenSUSE) places these entries in the machines’ `/etc/hosts` files:

```bash
# ndb1 /etc/hosts:
127.0.0.1       localhost
127.0.0.2       ndb1.cluster ndb1
# ndb2 /etc/hosts:
127.0.0.1       localhost
127.0.0.2       ndb2.cluster ndb2
```

In both instances, `ndb1` routes `ndb1.cluster` to a loopback IP address, but gets a public IP address from DNS for `ndb2.cluster`, while `ndb2` routes `ndb2.cluster` to a loopback address and obtains a public address for `ndb1.cluster`. The result is that each data node connects to the management server, but cannot tell when any other data nodes have connected, and so the data nodes appear to hang while starting.

![Caution](image)

You cannot mix `localhost` and other host names or IP addresses in `config.ini`. For these reasons, the solution in such cases (other than to use IP addresses for all `config.ini HostName` entries) is to remove the fully qualified host names from `/etc/hosts` and use these in `config.ini` for all cluster hosts.

**Host computer type.** Each host computer in our installation scenario is an Intel-based desktop PC running a supported operating system installed to disk in a standard configuration, and running no unnecessary services. The core operating system with standard TCP/IP networking capabilities should be sufficient. Also for the sake of simplicity, we also assume that the file systems on all hosts are set up identically. In the event that they are not, you should adapt these instructions accordingly.

**Network hardware.** Standard 100 Mbps or 1 gigabit Ethernet cards are installed on each machine, along with the proper drivers for the cards, and that all four hosts are connected through a standard-issue Ethernet networking appliance such as a switch. (All machines should use network cards with the same throughput. That is, all four machines in the cluster should have 100 Mbps cards or all four machines should have 1 Gbps cards.) NDB Cluster works in a 100 Mbps network; however, gigabit Ethernet provides better performance.

![Important](image)

NDB Cluster is *not* intended for use in a network for which throughput is less than 100 Mbps or which experiences a high degree of latency. For this reason (among others), attempting to run an NDB Cluster over a wide area network such as the Internet is not likely to be successful, and is not supported in production.

**Sample data.** We use the `world` database which is available for download from the MySQL website (see [https://dev.mysql.com/doc/index-other.html](https://dev.mysql.com/doc/index-other.html)). We assume that each machine has sufficient memory for running the operating system, required NDB Cluster processes, and (on the data nodes) storing the database.
For general information about installing MySQL, see *Chapter 2, Installing and Upgrading MySQL*. For information about installation of NDB Cluster on Linux and other Unix-like operating systems, see *Section 22.2.2, “Installation of NDB Cluster on Linux”*. For information about installation of NDB Cluster on Windows operating systems, see *Section 22.2.3, “Installing NDB Cluster on Windows”*.

For general information about NDB Cluster hardware, software, and networking requirements, see *Section 22.1.3, “NDB Cluster Hardware, Software, and Networking Requirements”*.

### 22.2.1 The NDB Cluster Auto-Installer

This section describes the web-based graphical configuration installer included as part of the NDB Cluster distribution. Topics discussed include an overview of the installer and its parts, software and other requirements for running the installer, navigating the GUI, and using the installer to set up and start or stop an NDB Cluster on one or more host computers.

The NDB Cluster Auto-Installer is made up of two components. The front end is a GUI client implemented as a Web page that loads and runs in a standard Web browser such as Firefox or Microsoft Internet Explorer. The back end is a server process (`ndb_setup.py`) that runs on the local machine or on another host to which you have access.

These two components (client and server) communicate with each other using standard HTTP requests and responses. The back end can manage NDB Cluster software programs on any host where the back end user has granted access. If the NDB Cluster software is on a different host, the back end relies on SSH for access.

#### 22.2.1.1 NDB Cluster Auto-Installer Requirements

This section provides information on supported operating platforms and software, required software, and other prerequisites for running the NDB Cluster Auto-Installer.

**Supported platforms.** The NDB Cluster Auto-Installer is available with NDB 8.0 distributions for recent versions of Linux, Windows, Solaris, and macOS. For more detailed information about platform support for NDB Cluster and the NDB Cluster Auto-Installer, see [https://www.mysql.com/support/supportedplatforms/cluster.html](https://www.mysql.com/support/supportedplatforms/cluster.html).

**Supported web browsers.** The web-based installer is supported with recent versions of Firefox and Microsoft Internet Explorer. It should also work with recent versions of Opera, Safari, and Chrome, although we have not thoroughly tested for compatibility with these browsers.

**Required software—setup host.** The following software must be installed on the host where the Auto-Installer is run:

- **Python 2.6 or higher.** The Auto-Installer requires the Python interpreter and standard libraries. If these are not already installed on the system, you may be able to add them using the system’s package manager. Otherwise, you can download them from [http://python.org/download/](http://python.org/download/).

- **Paramiko 2 or higher.** You can download this from [http://www.lag.net/paramiko/](http://www.lag.net/paramiko/) if it is not available from your system’s package manager.

- **Pycrypto version 1.9 or higher.** This cryptography module is required by Paramiko, and can be installed using `pip install cryptography`. If `pip` is not installed, and the module is not available using your system's package manager, you can download it from [https://www.dlitz.net/software/pycrypto/](https://www.dlitz.net/software/pycrypto/).

All of the software in the preceding list is included in the Windows version of the configuration tool, and does not need to be installed separately.

**Required software—remote hosts.** The only software required for remote hosts where you wish to deploy NDB Cluster nodes is the SSH server, which is usually installed by default on Linux and...
Solaris systems. Several alternatives are available for Windows; for an overview of these, see http://en.wikipedia.org/wiki/Comparison_of_SSH_servers.

An additional requirement when using multiple hosts is that it is possible to authenticate to any of the remote hosts using SSH and the proper keys or user credentials, as discussed in the next few paragraphs:

**Authentication and security.** Three basic security or authentication mechanisms for remote access are available to the Auto-Installer, which we list and describe here:

- **SSH.** A secure shell connection is used to enable the back end to perform actions on remote hosts. For this reason, an SSH server must be running on the remote host. In addition, the operating system user running the installer must have access to the remote server, either with a user name and password, or by using public and private keys.

  **Important**
  You should never use the system `root` account for remote access, as this is extremely insecure. In addition, `mysql` cannot normally be started by system `root`. For these and other reasons, you should provide SSH credentials for a regular user account on the target system, and not for system `root`. For more information about this issue, see Section 6.1.5, “How to Run MySQL as a Normal User”.

- **HTTPS.** Remote communication between the Web browser front end and the back end is not encrypted by default, which means that information such as the user’s SSH password is transmitted as cleartext that is readable to anyone. For communication from a remote client to be encrypted, the back end must have a certificate, and the front end must communicate with the back end using HTTPS rather than HTTP. Enabling HTTPS is accomplished most easily through issuing a self-signed certificate. Once the certificate is issued, you must make sure that it is used. You can do this by starting `ndb_setup.py` from the command line with the `--use-https (-S)` and `--cert-file (-c)` options.

  A sample certificate file `cfg.pem` is included and is used by default. This file is located in the `mcc` directory under the installation share directory; on Linux, the full path to the file is normally `/usr/share/mysql/mcc/cfg.pem`. On Windows systems, this is usually `C:\Program Files\MySQL\MySQL Server 8.0\share\mcc\cfg.pem`. Letting the default be used means that, for testing purposes, you can simply start the installer with the `-S` option to use an HTTPS connection between the browser and the back end.

  The Auto-Installer saves the configuration file for a given cluster `mycluster01` as `mycluster01.mcc` in the home directory of the user invoking the `ndb_setup.py` executable. This file is encrypted with a passphrase supplied by the user (using Fernet); because HTTP transmits the passphrase in the clear, it is strongly recommended that you always use an HTTPS connection to access the Auto-Installer on a remote host.

- **Certificate-based authentication.** The back end `ndb_setup.py` process can execute commands on the local host as well as remote hosts. This means that anyone connecting to the back end can take charge of how commands are executed. To reject unwanted connections to the back end, a certificate may be required for authentication of the client. In this case, a certificate must be issued by the user, installed in the browser, and made available to the back end for authentication purposes. You can enact this requirement (together with or in place of password or key authentication) by starting `ndb_setup.py` with the `--ca-certs-file (-a)` option.

  There is no need or requirement for secure authentication when the client browser is running on the same host as the Auto-Installer back end.

  See also Section 22.5.12, “NDB Cluster Security Issues”, which discusses security considerations to take into account when deploying NDB Cluster, as well as Chapter 6, Security, for more general MySQL security information.
22.2.1.2 Using the NDB Cluster Auto-Installer

The NDB Cluster Auto-Installer interface is made up of several pages, each corresponding to a step in the process used to configure and deploy an NDB Cluster. These pages are listed here, in order:

- **Welcome**: Begin using the Auto-Installer by choosing either to configure a new NDB Cluster, or to continue configuring an existing one.

- **Define Cluster**: Set basic information about the cluster as a whole, such as name, hosts, and load type. Here you can also set the SSH authentication type for accessing remote hosts, if needed.

- **Define Hosts**: Identify the hosts where you intend to run NDB Cluster processes.

- **Define Processes**: Assign one or more processes of a given type or types to each cluster host.

- **Define Parameters**: Set configuration attributes for processes or types of processes.

- **Deploy Configuration**: Deploy the cluster with the configuration set previously; start and stop the deployed cluster.

### NDB Cluster Installer Settings and Help Menus

These menus are shown on all screens except for the **Welcome** screen. They provide access to installer settings and information. The Settings menu is shown here in more detail:

**Figure 22.5 NDB Cluster Auto-Installer Settings menu**

The Settings menu has the following entries:

- **Automatically save configuration as cookies**: Save your configuration information—such as host names, process data, and parameter values—as a cookie in the browser. When this option is chosen, all information except any SSH password is saved. This means that you can quit and restart the browser, and continue working on the same configuration from where you left off at the end of the previous session. This option is enabled by default.

  The SSH password is never saved; if you use one, you must supply it at the beginning of each new session.

- **Show advanced configuration options**: Shows by default advanced configuration parameters where available.

  Once set, the advanced parameters continue to be used in the configuration file until they are explicitly changed or reset. This is regardless of whether the advanced parameters are currently visible in the installer; in other words, disabling the menu item does not reset the values of any of these parameters.
You can also toggle the display of advanced parameters for individual processes on the Define Parameters screen.

This option is disabled by default.

- **Automatically get resource information for new hosts**: Query new hosts automatically for hardware resource information to pre-populate a number of configuration options and values. In this case, the suggested values are not mandatory, but they are used unless explicitly changed using the appropriate editing options in the installer.

  This option is enabled by default.

The installer Help menu is shown here:

**Figure 22.6 NDB Cluster Auto-Installer Help menu**

The Help menu provides several options, described in the following list:

- **Contents**: Show the built-in user guide. This is opened in a separate browser window, so that it can be used simultaneously with the installer without interrupting workflow.

- **Current page**: Open the built-in user guide to the section describing the page currently displayed in the installer.

- **About**: Open a dialog displaying the installer name and the version number of the NDB Cluster distribution with which it was supplied.

The Auto-Installer also provides context-sensitive help in the form of tooltips for most input widgets.

In addition, the names of most NDB configuration parameters are linked to their descriptions in the online documentation. The documentation is displayed in a separate browser window.

The next section discusses starting the Auto-Installer. The sections immediately following it describe in greater detail the purpose and function of each of these pages in the order listed previously.

**Starting the NDB Cluster Auto-Installer**

The Auto-Installer is provided together with the NDB Cluster software. Separate RPM and .deb packages containing only the Auto-Installer are also available for many Linux distributions. (See Section 22.2, “NDB Cluster Installation”.)

The present section explains how to start the installer. You can do by invoking the `ndb_setup.py` executable.
The NDB Cluster Auto-Installer

## User and privileges

You should run the `ndb_setup.py` as a normal user; no special privileges are needed to do so. You should not run this program as the `mysql` user, or using the system `root` or Administrator account; doing so may cause the installation to fail.

`ndb_setup.py` is found in the `bin` within the NDB Cluster installation directory; a typical location might be `/usr/local/mysql/bin` on a Linux system or `C:\Program Files\MySQL\MySQL Server 8.0\bin` on a Windows system. This can vary according to where the NDB Cluster software is installed on your system, and the installation method.

On Windows, you can also start the installer by running `setup.bat` in the NDB Cluster installation directory. When invoked from the command line, this batch file accepts the same options as `ndb_setup.py`.

`ndb_setup.py` can be started with any of several options that affect its operation, but it is usually sufficient to allow the default settings be used, in which case you can start `ndb_setup.py` by either of the following two methods:

1. Navigate to the NDB Cluster `bin` directory in a terminal and invoke it from the command line, without any additional arguments or options, like this:

```
shell> ndb_setup.py
Running out of install dir: /usr/local/mysql/bin
Starting web server on port 8081
URL is https://localhost:8081/welcome.html
deathkey=627876
Press CTRL+C to stop web server.
The application should now be running in your browser.
(Alternatively you can navigate to https://localhost:8081/welcome.html to start it)
```

This works regardless of operating platform.

2. Navigate to the NDB Cluster `bin` directory in a file browser (such as Windows Explorer on Windows, or Konqueror, Dolphin, or Nautilus on Linux) and activate (usually by double-clicking) the `ndb_setup.py` file icon. This works on Windows, and should work with most common Linux desktops as well.

On Windows, you can also navigate to the NDB Cluster installation directory and activate the `setup.bat` file icon.

In either case, once `ndb_setup.py` is invoked, the Auto-Installer's Welcome screen should open in the system's default web browser. If not, you should be able to open the page `http://localhost:8081/welcome.html` or `https://localhost:8081/welcome.html` manually in the browser.

In some cases, you may wish to use non-default settings for the installer, such as specifying HTTPS for connections, or a different port for the Auto-Installer’s included web server to run on, in which case you must invoke `ndb_setup.py` with one or more startup options with values overriding the necessary defaults. The same startup options can be used on Windows systems with the `setup.bat` file supplied for such platforms in the NDB Cluster software distribution. This can be done using the command line, but if you want or need to start the installer from a desktop or file browser while employing one or more of these options, it is also possible to create a script or batch file containing the proper invocation, then to double-click its file icon in the file browser to start the installer. (On Linux systems, you might also need to make the script file executable first.) If you plan to use the Auto-Installer from a remote host, you should start using the `-S` option. For information about this and other advanced startup options for the NDB Cluster Auto-Installer, see Section 22.4.26, "ndb_setup.py — Start browser-based Auto-Installer for NDB Cluster".

## NDB Cluster Auto-Installer Welcome Screen

3552
The Welcome screen is loaded in the default browser when `ndb_setup.py` is invoked. The first time the Auto-Installer is run (or if for some other reason there are no existing configurations), this screen appears as shown here:

**Figure 22.7 The NDB Cluster Auto-Installer Welcome screen, first run**

In this case, the only choice of cluster listed is for configuration of a new cluster, and both the View Cfg and Continue buttons are inactive.

To create a new configuration, enter and confirm a passphrase in the text boxes provided. When this has been done, you can click Continue to proceed to the Define Cluster screen where you can assign a name to the new cluster.

If you have previously created one or more clusters with the Auto-Installer, they are listed by name. This example shows an existing cluster named `mycluster-1`:
The NDB Cluster Auto-Installer

Figure 22.8 The NDB Cluster Auto-Installer Welcome screen, with previously created cluster mycluster-1

To view the configuration for and work with a given cluster, select the radiobutton next to its name in the list, then enter and confirm the passphrase that was used to create it. When you have done this correctly, you can click View Cfg to view and edit this cluster's configuration.

NDB Cluster Auto-Installer Define Cluster Screen

The Define Cluster screen is appears following the Welcome screen, and is used for setting general properties of the cluster. The layout of the Define Cluster screen is shown here:

Figure 22.9 The NDB Cluster Auto-Installer Define Cluster screen

Cluster Type and SSH Credentials
MySQL Cluster is able to operate in various configurations. Please specify the settings below to define the right cluster type that fits your use case. If you intend to use remote hosts for deploying MySQL Cluster, SSH must be enabled. Unless key based SSH is possible, you must submit your user name and password below:

<table>
<thead>
<tr>
<th>Cluster property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cluster name</td>
<td>mycluster-1</td>
</tr>
<tr>
<td>Hostlist</td>
<td></td>
</tr>
<tr>
<td>Application area</td>
<td>simple testing</td>
</tr>
<tr>
<td>Virtual add</td>
<td></td>
</tr>
</tbody>
</table>

SSH property (Cluster-wide) | Value
---------------------------|-------------------|
| Key based SSH (Y/N)       | N                  |
| Username (Y/N)             | N                  |
| Password (Y/N)             | N                  |

Install properties (Cluster-wide) | Value
---------------------------------|-------------------|
| Key user (Y/N)               | N                  |
| Key passphrase (Y/N)         | N                  |
| Key file (Y/N)               | N                  |
This screen and subsequent screens also include Settings and Help menus which are described later in this section; see NDB Cluster Installer Settings and Help Menus.

The Define Cluster screen allows you to set three sorts of properties for the cluster: cluster properties, SSH properties, and installation properties.

Cluster properties that can be set on this screen are listed here:

- **Cluster name**: A name that identifies the cluster; in this example, this is *mycluster-1*. The name is set on the previous screen and cannot be changed here.

- **Host list**: A comma-delimited list of one or more hosts where cluster processes should run. By default, this is *127.0.0.1*. If you add remote hosts to the list, you must be able to connect to them using the credentials supplied as SSH properties.

- **Application type**: Choose one of the following:
  1. **Simple testing**: Minimal resource usage for small-scale testing. This is the default. *Not intended for production environments.*
  2. **Web**: Maximize performance for the given hardware.
  3. **Real-time**: Maximize performance while maximizing sensitivity to timeouts in order to minimize the time needed to detect failed cluster processes.

- **Write load**: Choose a level for the anticipated number of writes for the cluster as a whole. You can choose any one of the following levels:
  1. **Low**: The expected load includes fewer than 100 write transactions per second.
  2. **Medium**: The expected load includes 100 to 1000 write transactions per second; this is the default.
  3. **High**: The expected load includes more than 1000 write transactions per second.

SSH properties are described in the following list:

- **Key-Based SSH**: Check this box to use key-enabled login to the remote host. If checked, the key user and passphrase must also be supplied; otherwise, a user and password for a remote login account are needed.

- **User**: Name of user with remote login access.

- **Password**: Password for remote user.

- **Key user**: Name of the user for whom the key is valid, if not the same as the operating system user.

- **Key passphrase**: Passphrase for the key, if required.

- **Key file**: Path to the key file. The default is *~/.ssh/id_rsa*.

The SSH properties set on this page apply to all hosts in the cluster. They can be overridden for a given host by editing that host's properties on the Define Hosts screen.

Two installation properties can also be set on this screen:

- **Install MySQL Cluster**: This setting determines the source from which the Auto-Installer installs NDB Cluster software, if any, on the cluster hosts. Possible values and their effects are listed here:
  1. **DOCKER**: Try to install the MySQL Cluster Docker image from [https://hub.docker.com/r/mysql/mysql-cluster/](https://hub.docker.com/r/mysql/mysql-cluster/) on each host
  2. **REPO**: Try to install the NDB Cluster software from the MySQL Repositories on each host
3. **BOTH**: Try to install either the Docker image or the software from the repository on each host, giving preference to the repository

4. **NONE**: Do not install the NDB Cluster software on the hosts; this is the default

- **Open FW Ports**: Check this checkbox to have the installer attempt to open ports required by NDB Cluster processes on all hosts.

The next figure shows the **Define Cluster** page with settings for a small test cluster with all nodes running on `localhost`:

**Figure 22.10 The NDB Cluster Auto-Installer Define Cluster screen, with settings for a test cluster**

After making the desired settings, you can save them to the configuration file and proceed to the **Define Hosts** screen by clicking the **Save & Next** button.

If you exit the installer without saving, no changes are made to the configuration file.

**NDB Cluster Auto-Installer Define Hosts Screen**

The **Define Hosts** screen, shown here, provides a means of viewing and specifying several key properties of each cluster host:
Properties shown include the following:

- **Host**: Name or IP address of this host
- **Res.info**: Shows OK if the installer was able to retrieve requested resource information from this host
- **Platform**: Operating system or platform
- **Memory (MB)**: Amount of RAM on this host
- **Cores**: Number of CPU cores available on this host
- **MySQL Cluster install directory**: Path to directory where the NDB Cluster software is installed on this host; defaults to `/usr/local/bin`
- **MySQL Cluster data directory**: Path to directory used for data by NDB Cluster processes on this host; defaults to `/var/lib/mysql-cluster`
- **DiskFree**: Free disk space in bytes
  
  For hosts with multiple disks, only the space available on the disk used for the data directory is shown.

This screen also provides an extended view for each host that includes the following properties:

- **FDQN**: This host’s fully qualified domain name, used by the installer to connect with it, distribute configuration information to it, and start and stop cluster processes on it.
- **Internal IP**: The IP address used for communication with cluster processes running on this host by processes running elsewhere.
- **OS Details**: Detailed operating system name and version information.
- **Open FW**: If this checkbox is enabled, the installer attempts to open ports in the host’s firewall needed by cluster processes.
- **REPO URL**: URL for MySQL NDB Cluster repository
- **DOCKER URL**: URL for MySQL NDB Cluster Docker images; for NDB 8.0, this is `mysql/mysql-cluster:8.0`.
- **Install**: If this checkbox is enabled, the Auto-Installer attempts to install the NDB Cluster software on this host.
The extended view is shown here:

**Figure 22.12 NDB Cluster Define Hosts screen, extended host info view**

All cells in the display are editable, with the exceptions of those in the **Host**, **Res.info**, and **FQDN** columns.

Be aware that it may take some time for information to be retrieved from remote hosts. Fields for which no value could be retrieved are indicated with an ellipsis (...). You can retry the fetching of resource information from one or more hosts by selecting the hosts in the list and then clicking the **Refresh selected host(s)** button.

**Adding and Removing Hosts**

You can add one or more hosts by clicking the **Add Host** button and entering the required properties where indicated in the **Add new host** dialog, shown here:
The NDB Cluster Auto-Installer

Figure 22.13 NDB Cluster Add Host dialog

This dialog includes the following fields:

- **Host name**: A comma-separated list of one or more host names, IP addresses, or both. These must be accessible from the host where the Auto-Installer is running.

- **Host internal IP (VPN)**: If you are setting up the cluster to run on a VPN or other internal network, enter the IP address or addresses used for contact by cluster nodes on other hosts.
The NDB Cluster Auto-Installer

- **Key-based auth**: If checked, enables key-based authentication. You can enter any additional needed information in the User, Passphrase, and Key file fields.

- **Ordinary login**: If accessing this host using a password-based login, enter the appropriate information in the User and Password fields.

- **Open FW ports**: Selecting this checkbox allows the installer try opening any ports needed by cluster processes in this host's firewall.

- **Configure installation**: Checking this allows the Auto-Install to attempt to set up the NDB Cluster software on this host.

To save the new host and its properties, click **Add**. If you wish to cancel without saving any changes, click **Cancel** instead.

Similarly, you can remove one or more hosts using the button labelled **Remove selected host(s)**. **When you remove a host, any process which was configured for that host is also removed.**

**Warning**

*Remove selected host(s)* acts immediately. There is no confirmation dialog. If you remove a host in error, you must re-enter its name and properties manually using **Add host**.

If the SSH user credentials on the *Define Cluster screen* are changed, the Auto-Installer attempts to refresh the resource information from any hosts for which information is missing.

You can edit the host's platform name, hardware resource information, installation directory, and data directory by clicking the corresponding cell in the grid, by selecting one or more hosts and clicking the button labelled **Edit selected host(s)**. This causes a dialog box to appear, in which these fields can be edited, as shown here:

**Figure 22.14 NDB Cluster Auto-Installer Edit Hosts dialog**

When more than one host is selected, any edited values are applied to all selected hosts.
Once you have entered all desired host information, you can use the **Save & Next** button to save the information to the cluster's configuration file and proceed to the **Define Processes** screen, where you can set up NDB Cluster processes on one or more hosts.

### NDB Cluster Auto-Installer Define Processes Screen

The **Define Processes** screen, shown here, provides a way to assign NDB Cluster processes (nodes) to cluster hosts:

**Figure 22.15 NDB Cluster Auto-Installer Define Processes dialog**

This screen contains a process tree showing cluster hosts and processes set up to run on each one, as well as a panel which displays information about the item currently selected in the tree.

When this screen is accessed for the first time for a given cluster, a default set of processes is defined for you, based on the number of hosts. If you later return to the **Define Hosts** screen, remove all hosts, and add new hosts, this also causes a new default set of processes to be defined.

NDB Cluster processes are of the types described in this list:

- **Management node.** Performs administrative tasks such as stopping individual data nodes, querying node and cluster status, and making backups. Executable: `ndb_mgmd`.
- **Single-threaded data node.** Stores data and executes queries. Executable: `ndbd`.
- **Multi threaded data node.** Stores data and executes queries with multiple worker threads executing in parallel. Executable: `ndbmtc.d`.
- **SQL node.** MySQL server for executing SQL queries against NDB. Executable: `mysqld`.
- **API node.** A client accessing data in NDB by means of the NDB API or other low-level client API, rather than by using SQL. See MySQL NDB Cluster API Developer Guide, for more information.

For more information about process (node) types, see Section 22.1.1, “NDB Cluster Core Concepts”.

Processes shown in the tree are numbered sequentially by type, for each host—for example, **SQL node 1**, **SQL node 2**, and so on—to simplify identification.
Each management node, data node, or SQL process must be assigned to a specific host, and is not allowed to run on any other host. An API node may be assigned to a single host, but this is not required. Instead, you can assign it to the special Any host entry which the tree also contains in addition to any other hosts, and which acts as a placeholder for processes that are allowed to run on any host. Only API processes may use this Any host entry.

**Adding processes.** To add a new process to a given host, either right-click that host's entry in the tree, then select the Add process popup when it appears, or select a host in the process tree, and press the Add process button below the process tree. Performing either of these actions opens the add process dialog, as shown here:

![Figure 22.16 NDB Cluster Auto-Installer Add Process Dialog](image)

Here you can select from among the available process types described earlier this section; you can also enter an arbitrary process name to take the place of the suggested value, if desired.

**Removing processes.** To delete a process, select that process in the tree and use the Del process button.

When you select a process in the process tree, information about that process is displayed in the information panel, where you can change the process name and possibly its type. You can change a multi-threaded data node (ndbmt.c) to a single-threaded data node (ndbd), or the reverse, only; no other process type changes are allowed. *If you want to make a change between any other process types, you must delete the original process first, then add a new process of the desired type.*

**NDB Cluster Auto-Installer Define Parameters Screen**

Like the Define Processes screen, this screen includes a process tree; the Define Parameters process tree is organized by process or node type, in groups labelled Management Layer, Data Layer, SQL Layer, and API Layer. An information panel displays information regarding the item currently selected. The Define Attributes screen is shown here:
The checkbox labelled Show advanced configuration, when checked, makes advanced options for data node and SQL node processes visible in the information pane. These options are set and used whether or not they are visible. You can also enable this behavior globally by checking Show advanced configuration options under Settings (see NDB Cluster Installer Settings and Help Menus).

You can edit attributes for a single process by selecting that process from the tree, or for all processes of the same type in the cluster by selecting one of the Layer folders. A per-process value set for a given attribute overrides any per-group setting for that attribute that would otherwise apply to the process in question. An example of such an information panel (for an SQL process) is shown here:
Attributes whose values can be overridden are shown in the information panel with a button bearing a plus sign. This + button activates an input widget for the attribute, enabling you to change its value. When the value has been overridden, this button changes into a button showing an X. The X button undoes any changes made to a given attribute, which immediately reverts to the predefined value.

All configuration attributes have predefined values calculated by the installer, based such factors as host name, node ID, node type, and so on. In most cases, these values may be left as they are. If you are not familiar with it already, it is highly recommended that you read the applicable documentation before making changes to any of the attribute values. To make finding this information easier, each attribute name shown in the information panel is linked to its description in the online NDB Cluster documentation.

**NDB Cluster Auto-Installer Deploy Configuration Screen**

This screen allows you to perform the following tasks:

- Review process startup commands and configuration files to be applied
- Distribute configuration files by creating any necessary files and directories on all cluster hosts—that is, *deploy* the cluster as presently configured
- Start and stop the cluster

The **Deploy Configuration** screen is shown here:
Like the Define Parameters screen, this screen features a process tree which is organized by process type. Next to each process in the tree is a status icon indicating the current status of the process: connected (CONNECTED), starting (STARTING), running (STARTED), stopping (STOPPING), or disconnected (NO_CONTACT). The icon shows green if the process is connected or running; yellow if it is starting or stopping; red if the process is stopped or cannot be contacted by the management server.

This screen also contains two information panels, one showing the startup command or commands needed to start the selected process. (For some processes, more than one command may be required—for example, if initialization is necessary.) The other panel shows the contents of the configuration file, if any, for the given process.

This screen also contains four buttons, labelled as and performing the functions described in the following list:

- **Install cluster**: Nonfunctional in this release; implementation intended for a future release.
- **Deploy cluster**: Verify that the configuration is valid. Create any directories required on the cluster hosts, and distribute the configuration files onto the hosts. A progress bar shows how far the deployment has proceeded, as shown here, and a dialog is displayed when the deployment has completed, as shown here:
Figure 22.20 Cluster Deployment Process
• **Start cluster**: The cluster is deployed as with *Deploy cluster*, after which all cluster processes are started in the correct order.

Starting these processes may take some time. If the estimated time to completion is too large, the installer provides an opportunity to cancel or to continue of the startup procedure. A progress bar indicates the current status of the startup procedure, as shown here:

**Figure 22.21 Cluster Startup Process with Progress Bar**

![Cluster Startup Process with Progress Bar](image)

The process status icons next to the items shown in the process tree also update with the status of each process.

A confirmation dialog is shown when the startup process has completed, as shown here:

**Figure 22.22 Cluster Startup, Process Completed Dialog**

![Cluster Startup, Process Completed Dialog](image)

• **Stop cluster**: After the cluster has been started, you can stop it using this. As with starting the cluster, cluster shutdown is not instantaneous, and may require some time complete. A progress bar, similar to that displayed during cluster startup, shows the approximate current status of the cluster...
shutdown procedure, as do the process status icons adjoining the process tree. The progress bar is shown here:

**Figure 22.23 Cluster Shutdown Process, with Progress Bar**

The Auto-Installer generates a `config.ini` file containing NDB node parameters for each management node, as well as a `my.cnf` file containing the appropriate options for each `mysqld` process in the cluster. No configuration files are created for data nodes or API nodes.

### 22.2.2 Installation of NDB Cluster on Linux

This section covers installation methods for NDB Cluster on Linux and other Unix-like operating systems. While the next few sections refer to a Linux operating system, the instructions and procedures given there should be easily adaptable to other supported Unix-like platforms. For manual installation and setup instructions specific to Windows systems, see Section 22.2.3, “Installing NDB Cluster on Windows”.

Each NDB Cluster host computer must have the correct executable programs installed. A host running an SQL node must have installed on it a MySQL Server binary (`mysqld`). Management nodes require the management server daemon (`ndb_mgm`); data nodes require the data node daemon (`ndbd` or `ndbdm`), and control node hosts. It is not necessary to install the MySQL Server binary on management node hosts and data node hosts. It is recommended that you also install the management client (`ndb_mgm`) on the management server host.
Installation of NDB Cluster on Linux can be done using precompiled binaries from Oracle (downloaded as a .tar.gz archive), with RPM packages (also available from Oracle), or from source code. All three of these installation methods are described in the section that follow.

Regardless of the method used, it is still necessary following installation of the NDB Cluster binaries to create configuration files for all cluster nodes, before you can start the cluster. See Section 22.2.4, “Initial Configuration of NDB Cluster”.

### 22.2.2.1 Installing an NDB Cluster Binary Release on Linux

This section covers the steps necessary to install the correct executables for each type of Cluster node from precompiled binaries supplied by Oracle.

For setting up a cluster using precompiled binaries, the first step in the installation process for each cluster host is to download the binary archive from the NDB Cluster downloads page. (For the most recent 64-bit NDB 8.0 release, this is `mysql-cluster-gpl-8.0.20-linux-glibc2.12-x86_64.tar.gz`.) We assume that you have placed this file in each machine’s `/var/tmp` directory.

If you require a custom binary, see Section 2.9.5, “Installing MySQL Using a Development Source Tree”.

**Note**

After completing the installation, do not yet start any of the binaries. We show you how to do so following the configuration of the nodes (see Section 22.2.4, “Initial Configuration of NDB Cluster”).

#### SQL nodes

On each of the machines designated to host SQL nodes, perform the following steps as the system root user:

1. Check your `/etc/passwd` and `/etc/group` files (or use whatever tools are provided by your operating system for managing users and groups) to see whether there is already a `mysql` group and `mysql` user on the system. Some OS distributions create these as part of the operating system installation process. If they are not already present, create a new `mysql` user group, and then add a `mysql` user to this group:

   ```shell
   groupadd mysql
   useradd -g mysql -s /bin/false mysql
   ```

   The syntax for `useradd` and `groupadd` may differ slightly on different versions of Unix, or they may have different names such as `adduser` and `addgroup`.

2. Change location to the directory containing the downloaded file, unpack the archive, and create a symbolic link named `mysql` to the `mysql` directory.

   ```shell
   cd /var/tmp
   tar -C /usr/local -xzvf mysql-cluster-gpl-8.0.20-linux-glibc2.12-x86_64.tar.gz
   ln -s /usr/local/mysql-cluster-gpl-8.0.20-linux-glibc2.12-x86_64 /usr/local/mysql
   ```

3. Change location to the `mysql` directory and set up the system databases using `mysqld --initialize` as shown here:

   ```shell
   cd mysql
   mysqld --initialize
   ```

   This generates a random password for the MySQL root account. If you do not want the random password to be generated, you can substitute the `--initialize-insecure` option for `--initialize`. In either case, you should review Section 2.10.1, “Initializing the Data
Installation of NDB Cluster on Linux

4. Set the necessary permissions for the MySQL server and data directories:

```
shell> chown -R root .
shell> chown -R mysql data
shell> chgrp -R mysql .
```

5. Copy the MySQL startup script to the appropriate directory, make it executable, and set it to start when the operating system is booted up:

```
shell> cp support-files/mysql.server /etc/rc.d/init.d/
shell> chmod +x /etc/rc.d/init.d/mysql.server
shell> chkconfig --add mysql.server
```

(The startup scripts directory may vary depending on your operating system and version—for example, in some Linux distributions, it is `/etc/init.d`.)

Here we use Red Hat's `chkconfig` for creating links to the startup scripts; use whatever means is appropriate for this purpose on your platform, such as `update-rc.d` on Debian.

Remember that the preceding steps must be repeated on each machine where an SQL node is to reside.

**Data nodes.** Installation of the data nodes does not require the `mysqld` binary. Only the NDB Cluster data node executable `ndbd` (single-threaded) or `ndbmtd` (multithreaded) is required. These binaries can also be found in the `.tar.gz` archive. Again, we assume that you have placed this archive in `/var/tmp`.

As system `root` (that is, after using `sudo`, `su root`, or your system's equivalent for temporarily assuming the system administrator account's privileges), perform the following steps to install the data node binaries on the data node hosts:

1. Change location to the `/var/tmp` directory, and extract the `ndbd` and `ndbmtd` binaries from the archive into a suitable directory such as `/usr/local/bin`:

```
shell> cd /var/tmp
shell> tar -zxvf mysql-cluster-gpl-8.0.20-linux-glibc2.12-x86_64.tar.gz
shell> cd mysql-cluster-gpl-8.0.20-linux-glibc2.12-x86_64
shell> cp bin/ndbd /usr/local/bin/ndbd
shell> cp bin/ndbmtd /usr/local/bin/ndbmtd
```

(You can safely delete the directory created by unpacking the downloaded archive, and the files it contains, from `/var/tmp` once `ndb_mgm` and `ndb_mgmd` have been copied to the executables directory.)

2. Change location to the directory into which you copied the files, and then make both of them executable:

```
shell> cd /usr/local/bin
shell> chmod +x ndb*
```

The preceding steps should be repeated on each data node host.

Although only one of the data node executables is required to run an NDB Cluster data node, we have shown you how to install both `ndbd` and `ndbmtd` in the preceding instructions. We recommend that you do this when installing or upgrading NDB Cluster, even if you plan to use only one of them, since this will save time and trouble in the event that you later decide to change from one to the other.

---

**Note**

The data directory on each machine hosting a data node is `/usr/local/mysql/data`. This piece of information is essential when configuring the management node. (See Section 22.2.4, “Initial Configuration of NDB Cluster”.)
Management nodes. Installation of the management node does not require the mysqld binary. Only the NDB Cluster management server (ndb_mgmd) is required; you most likely want to install the management client (ndb_mgm) as well. Both of these binaries also be found in the .tar.gz archive. Again, we assume that you have placed this archive in /var/tmp.

As system root, perform the following steps to install ndb_mgm and ndb_mgmd on the management node host:

1. Change location to the /var/tmp directory, and extract the ndb_mgm and ndb_mgmd from the archive into a suitable directory such as /usr/local/bin:

   ```
   shell> cd /var/tmp
   shell> tar -zxvf mysql-cluster-gpl-8.0.20-linux-glibc2.12-x86_64.tar.gz
   shell> cd mysql-cluster-gpl-8.0.20-linux-glibc2.12-x86_64
   shell> cp bin/ndb_mgm* /usr/local/bin
   ```

   (You can safely delete the directory created by unpacking the downloaded archive, and the files it contains, from /var/tmp once ndb_mgm and ndb_mgmd have been copied to the executables directory.)

2. Change location to the directory into which you copied the files, and then make both of them executable:

   ```
   shell> cd /usr/local/bin
   shell> chmod +x ndb_mgm*
   ```

In Section 22.2.4, “Initial Configuration of NDB Cluster“, we create configuration files for all of the nodes in our example NDB Cluster.

### 22.2.2.2 Installing NDB Cluster from RPM

This section covers the steps necessary to install the correct executables for each type of NDB Cluster 8.0 node using RPM packages supplied by Oracle. For information about RPMs for previous versions of NDB Cluster, see Installation using old-style RPMs (NDB 7.5.3 and earlier).

As an alternative to the method described in this section, Oracle provides MySQL Repositories for NDB Cluster that are compatible with many common Linux distributions. Two repositories, listed here, are available for RPM-based distributions:

- For distributions using `yum` or `dnf`, you can use the MySQL Yum Repository for NDB Cluster. See Installing MySQL NDB Cluster Using the Yum Repository, for instructions and additional information.
- For SLES, you can use the MySQL SLES Repository for NDB Cluster. See Installing MySQL NDB Cluster Using the SLES Repository, for instructions and additional information.

RPMs are available for both 32-bit and 64-bit Linux platforms. The filenames for these RPMs use the following pattern:

```
mysql-cluster-community-data-node-8.0.20-1.el7.x86_64.rpm
mysql-cluster-license-component-ver-rev.distro.arch.rpm
```

- `license`: {commercial | community}
- `component`: {management-server | data-node | server | client | other—see text}
- `ver`: major.minor.release
- `rev`: major.[minor]
- `distro`: {el6 | el7 | sles12}
- `arch`: {i686 | x86_64}

`license` indicates whether the RPM is part of a Commercial or Community release of NDB Cluster. In the remainder of this section, we assume for the examples that you are installing a Community release.
Possible values for component, with descriptions, can be found in the following table:

**Table 22.5 Components of the NDB Cluster RPM distribution**

<table>
<thead>
<tr>
<th>Component</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>auto-installer</td>
<td>NDB Cluster Auto Installer program; see Section 22.2.1, “The NDB Cluster Auto-Installer”, for usage</td>
</tr>
<tr>
<td>client</td>

</tr>
<tr>
<td>test</td>
<td>mysqltest, other MySQL test programs, and support files</td>
</tr>
</tbody>
</table>

A single bundle (.tar file) of all NDB Cluster RPMs for a given platform and architecture is also available. The name of this file follows the pattern shown here:

```
mysql-cluster-license-ver-rev.distro.arch.rpm-bundle.tar
```

You can extract the individual RPM files from this file using `tar` or your preferred tool for extracting archives.

The components required to install the three major types of NDB Cluster nodes are given in the following list:
Installation of NDB Cluster on Linux

- **Management node**: management-server
- **Data node**: data-node
- **SQL node**: server and common

In addition, the client RPM should be installed to provide the ndb_mgm management client on at least one management node. You may also wish to install it on SQL nodes, to have mysql and other MySQL client programs available on these. We discuss installation of nodes by type later in this section.

**ver** represents the three-part NDB storage engine version number in 8.0.x format, shown as 8.0.20 in the examples. **rev** provides the RPM revision number in major.minor format. In the examples shown in this section, we use 1.1 for this value.

The **distro** (Linux distribution) is one of rhel5 (Oracle Linux 5, Red Hat Enterprise Linux 4 and 5), el6 (Oracle Linux 6, Red Hat Enterprise Linux 6), el7 (Oracle Linux 7, Red Hat Enterprise Linux 7), or sles12 (SUSE Enterprise Linux 12). For the examples in this section, we assume that the host runs Oracle Linux 7, Red Hat Enterprise Linux 7, or the equivalent (el7).

**arch** is i686 for 32-bit RPMs and x86_64 for 64-bit versions. In the examples shown here, we assume a 64-bit platform.

The NDB Cluster version number in the RPM file names (shown here as 8.0.20) can vary according to the version which you are actually using. *It is very important that all of the Cluster RPMs to be installed have the same version number.* The architecture should also be appropriate to the machine on which the RPM is to be installed; in particular, you should keep in mind that 64-bit RPMs (x86_64) cannot be used with 32-bit operating systems (use i686 for the latter).

**Data nodes.** On a computer that is to host an NDB Cluster data node it is necessary to install only the data-node RPM. To do so, copy this RPM to the data node host, and run the following command as the system root user, replacing the name shown for the RPM as necessary to match that of the RPM downloaded from the MySQL website:

```
shell> rpm -Uhv mysql-cluster-community-data-node-8.0.20-1.el7.x86_64.rpm
```

This installs the ndbd and ndbmtd data node binaries in /usr/sbin. Either of these can be used to run a data node process on this host.

**SQL nodes.** Copy the server and common RPMs to each machine to be used for hosting an NDB Cluster SQL node (server requires common). Install the server RPM by executing the following command as the system root user, replacing the name shown for the RPM as necessary to match the name of the RPM downloaded from the MySQL website:

```
shell> rpm -Uhv mysql-cluster-community-server-8.0.20-1.el7.x86_64.rpm
```

This installs the MySQL server binary (mysqld), with NDB storage engine support, in the /usr/sbin directory. It also installs all needed MySQL Server support files and useful MySQL server programs, including the mysql.server and mysqld_safe startup scripts (in /usr/share/mysql and /usr/bin, respectively). The RPM installer should take care of general configuration issues (such as creating the mysql user and group, if needed) automatically.

**Important**

You must use the versions of these RPMs released for NDB Cluster; those released for the standard MySQL server do not provide support for the NDB storage engine.

To administer the SQL node (MySQL server), you should also install the client RPM, as shown here:

```
shell> rpm -Uhv mysql-cluster-community-client-8.0.20-1.el7.x86_64.rpm
```
Installation of NDB Cluster on Linux

This installs the mysql client and other MySQL client programs, such as mysqladmin and mysqldump, to /usr/bin.

**Management nodes.** To install the NDB Cluster management server, it is necessary only to use the management-server RPM. Copy this RPM to the computer intended to host the management node, and then install it by running the following command as the system root user (replace the name shown for the RPM as necessary to match that of the management-server RPM downloaded from the MySQL website):

```
shell> rpm -Uvh mysql-cluster-commercial-management-server-8.0.20-1.el7.x86_64.rpm
```

This RPM installs the management server binary ndb_mgmd in the /usr/sbin directory. While this is the only program actually required for running a management node, it is also a good idea to have the ndb_mgm NDB Cluster management client available as well. You can obtain this program, as well as other NDB client programs such as ndb_desc and ndb_config, by installing the client RPM as described previously.

See Section 2.5.4, “Installing MySQL on Linux Using RPM Packages from Oracle”, for general information about installing MySQL using RPMs supplied by Oracle.

After installing from RPM, you still need to configure the cluster; see Section 22.2.4, “Initial Configuration of NDB Cluster”, for the relevant information.

It is very important that all of the Cluster RPMs to be installed have the same version number. The architecture designation should also be appropriate to the machine on which the RPM is to be installed; in particular, you should keep in mind that 64-bit RPMs cannot be used with 32-bit operating systems.

**Data nodes.** On a computer that is to host a cluster data node it is necessary to install only the server RPM. To do so, copy this RPM to the data node host, and run the following command as the system root user, replacing the name shown for the RPM as necessary to match that of the RPM downloaded from the MySQL website:

```
shell> rpm -Uvh MySQL-Cluster-server-gpl-8.0.20-1.sles11.i386.rpm
```

Although this installs all NDB Cluster binaries, only the program ndbd or ndbmd (both in /usr/sbin) is actually needed to run an NDB Cluster data node.

**SQL nodes.** On each machine to be used for hosting a cluster SQL node, install the server RPM by executing the following command as the system root user, replacing the name shown for the RPM as necessary to match the name of the RPM downloaded from the MySQL website:

```
shell> rpm -Uvh MySQL-Cluster-server-gpl-8.0.20-1.sles11.i386.rpm
```

This installs the MySQL server binary (mysqld) with NDB storage engine support in the /usr/sbin directory, as well as all needed MySQL Server support files. It also installs the mysql.server and mysqld_safe startup scripts (in /usr/share/mysql and /usr/bin, respectively). The RPM installer should take care of general configuration issues (such as creating the mysql user and group, if needed) automatically.

To administer the SQL node (MySQL server), you should also install the client RPM, as shown here:

```
shell> rpm -Uvh MySQL-Cluster-client-gpl-8.0.20-1.sles11.i386.rpm
```

This installs the mysql client program.

**Management nodes.** To install the NDB Cluster management server, it is necessary only to use the server RPM. Copy this RPM to the computer intended to host the management node, and then install it by running the following command as the system root user (replace the name shown for the RPM as necessary to match that of the server RPM downloaded from the MySQL website):

```
```
Installation of NDB Cluster on Linux

```shell
rpm -Uvh MySQL-Cluster-server-gpl-8.0.20-1.sles11.i386.rpm
```

Although this RPM installs many other files, only the management server binary `ndb_mgmd` (in the `/usr/sbin` directory) is actually required for running a management node. The server RPM also installs `ndb_mgm`, the NDB management client.

See Section 22.2.4, “Initial Configuration of NDB Cluster”, for information about required post-installation configuration.

### 22.2.2.3 Installing NDB Cluster Using .deb Files

The section provides information about installing NDB Cluster on Debian and related Linux distributions such as Ubuntu using the `.deb` files supplied by Oracle for this purpose.

Oracle also provides an NDB Cluster APT repository for Debian and other distributions. See Installing MySQL NDB Cluster Using the APT Repository, for instructions and additional information.

Oracle provides `.deb` installer files for NDB Cluster for 32-bit and 64-bit platforms. For a Debian-based system, only a single installer file is necessary. This file is named using the pattern shown here, according to the applicable NDB Cluster version, Debian version, and architecture:

```
mysql-cluster-gpl-ndbver-debianver-debian-source-arch.deb
```

Here, `ndbver` is the 3-part NDB engine version number, `debianver` is the major version of Debian (8 or 9), and `arch` is one of `i686` or `x86_64`. In the examples that follow, we assume you wish to install NDB 8.0.20 on a 64-bit Debian 9 system; in this case, the installer file is named `mysql-cluster-gpl-8.0.20-debian9-x86_64.deb-bundle.tar`.

Once you have downloaded the appropriate `.deb` file, you can untar it, and then install it from the command line using `dpkg`, like this:

```shell
dpkg -i mysql-cluster-gpl-8.0.20-debian9-i686.deb
```

You can also remove it using `dpkg` as shown here:

```shell
dpkg -r mysql
```

The installer file should also be compatible with most graphical package managers that work with `.deb` files, such as GDebi for the Gnome desktop.

The `.deb` file installs NDB Cluster under `/opt/mysql/server-version/`, where `version` is the 2-part release series version for the included MySQL server. For NDB 8.0, this is always `5.7`. The directory layout is the same as that for the generic Linux binary distribution (see Table 2.3, "MySQL Installation Layout for Generic Unix/Linux Binary Package"), with the exception that startup scripts and configuration files are found in `support-files` instead of `share`. All NDB Cluster executables, such as `ndb_mgm`, `ndbd`, and `ndb_mgmd`, are placed in the `bin` directory.

### 22.2.2.4 Building NDB Cluster from Source on Linux

This section provides information about compiling NDB Cluster on Linux and other Unix-like platforms. Building NDB Cluster from source is similar to building the standard MySQL Server, although it differs in a few key respects discussed here. For general information about building MySQL from source, see Section 2.9, “Installing MySQL from Source”. For information about compiling NDB Cluster on Windows platforms, see Section 22.2.3.2, “Compiling and Installing NDB Cluster from Source on Windows”.

Building MySQL NDB Cluster 8.0 requires using the MySQL Server 8.0 sources. These are available from the MySQL downloads page at [https://dev.mysql.com/downloads/](https://dev.mysql.com/downloads/). The archived source file should have a name similar to `mysql-8.0.20.tar.gz`. You can also obtain the sources from GitHub at [https://github.com/mysql/mysql-server](https://github.com/mysql/mysql-server).
Note
In previous versions, building of NDB Cluster from standard MySQL Server sources was not supported. In MySQL 8.0 and NDB Cluster 8.0, this is no longer the case—both products are now built from the same sources.

The `WITH_NDBCLUSTER` option for CMake causes the binaries for the management nodes, data nodes, and other NDB Cluster programs to be built; it also causes `mysqld` to be compiled with NDB storage engine support. This option (or one of its aliases `WITH_NDBCLUSTER_STORAGE_ENGINE` and `WITH_PLUGIN_NDBCLUSTER`) is required when building NDB Cluster.

Important
The `WITH_NDB_JAVA` option is enabled by default. This means that, by default, if CMake cannot find the location of Java on your system, the configuration process fails; if you do not wish to enable Java and ClusterJ support, you must indicate this explicitly by configuring the build using `-DWITH_NDB_JAVA=OFF`. Use `WITH_CLASSPATH` to provide the Java classpath if needed.

For more information about CMake options specific to building NDB Cluster, see Options for Compiling NDB Cluster.

After you have run `make && make install` (or your system's equivalent), the result is similar to what is obtained by unpacking a precompiled binary to the same location.

Management nodes. When building from source and running the default `make install`, the management server and management client binaries (`ndb_mgmd` and `ndb_mgm`) can be found in `/usr/local/mysql/bin`. Only `ndb_mgmd` is required to be present on a management node host; however, it is also a good idea to have `ndb_mgm` present on the same host machine. Neither of these executables requires a specific location on the host machine's file system.

Data nodes. The only executable required on a data node host is the data node binary `ndbd` or `ndbmtd`. (`mysqld`, for example, does not have to be present on the host machine.) By default, when building from source, this file is placed in the directory `/usr/local/mysql/bin`. For installing on multiple data node hosts, only `ndbd` or `ndbmtd` need be copied to the other host machine or machines. (This assumes that all data node hosts use the same architecture and operating system; otherwise you may need to compile separately for each different platform.) The data node binary need not be in any particular location on the host's file system, as long as the location is known.

When compiling NDB Cluster from source, no special options are required for building multithreaded data node binaries. Configuring the build with `NDB` storage engine support causes `ndbmtd` to be built automatically; `make install` places the `ndbmtd` binary in the installation `bin` directory along with `mysqld`, `ndbd`, and `ndb_mgm`.

SQL nodes. If you compile MySQL with clustering support, and perform the default installation (using `make install` as the system root user), `mysqld` is placed in `/usr/local/mysql/bin`. Follow the steps given in Section 2.9, “Installing MySQL from Source” to make `mysqld` ready for use. If you want to run multiple SQL nodes, you can use a copy of the same `mysqld` executable and its associated support files on several machines. The easiest way to do this is to copy the entire `/usr/local/mysql` directory and all directories and files contained within it to the other SQL node host or hosts, then repeat the steps from Section 2.9, “Installing MySQL from Source” on each machine. If you configure the build with a nondefault `PREFIX` option, you must adjust the directory accordingly.

In Section 22.2.4, “Initial Configuration of NDB Cluster”, we create configuration files for all of the nodes in our example NDB Cluster.

22.2.3 Installing NDB Cluster on Windows

This section describes installation procedures for NDB Cluster on Windows hosts. NDB Cluster 8.0 binaries for Windows can be obtained from https://dev.mysql.com/downloads/cluster/. For
Installing NDB Cluster on Windows

information about installing NDB Cluster on Windows from a binary release provided by Oracle, see Section 22.2.3.1, “Installing NDB Cluster on Windows from a Binary Release”.

It is also possible to compile and install NDB Cluster from source on Windows using Microsoft Visual Studio. For more information, see Section 22.2.3.2, “Compiling and Installing NDB Cluster from Source on Windows”.

22.2.3.1 Installing NDB Cluster on Windows from a Binary Release

This section describes a basic installation of NDB Cluster on Windows using a binary “no-install” NDB Cluster release provided by Oracle, using the same 4-node setup outlined in the beginning of this section (see Section 22.2, “NDB Cluster Installation”), as shown in the following table:

Table 22.6 Network addresses of nodes in example cluster

<table>
<thead>
<tr>
<th>Node</th>
<th>IP Address</th>
</tr>
</thead>
<tbody>
<tr>
<td>Management node</td>
<td>198.51.100.10</td>
</tr>
<tr>
<td>mgmd</td>
<td></td>

<td>Data node &quot;B&quot;</td>
<td>198.51.100.40</td>
</tr>
<tr>
<td>ndbd</td>
<td></td>
</tr>
</tbody>
</table>

As on other platforms, the NDB Cluster host computer running an SQL node must have installed on it a MySQL Server binary (mysqld.exe). You should also have the MySQL client (mysql.exe) on this host. For management nodes and data nodes, it is not necessary to install the MySQL Server binary; however, each management node requires the management server daemon (ndb_mgmd.exe); each data node requires the data node daemon (ndbd.exe or ndbuniversal.exe). For this example, we refer to ndbd.exe as the data node executable, but you can install ndbuniversal.exe, the multithreaded version of this program, instead, in exactly the same way. You should also install the management client (ndb_mgm.exe) on the management server host. This section covers the steps necessary to install the correct Windows binaries for each type of NDB Cluster node.

Note

As with other Windows programs, NDB Cluster executables are named with the .exe file extension. However, it is not necessary to include the .exe extension when invoking these programs from the command line. Therefore, we often simply refer to these programs in this documentation as mysqld, mysql, ndb_mgmd, and so on. You should understand that, whether we refer (for example) to mysqld or mysqld.exe, either name means the same thing (the MySQL Server program).

For setting up an NDB Cluster using Oracle’s no-install binaries, the first step in the installation process is to download the latest NDB Cluster Windows ZIP binary archive from https://dev.mysql.com/downloads/cluster/. This archive has a filename of the mysql-cluster-gpl-ver-winarch.zip, where ver is the NDB storage engine version (such as 8.0.20), and arch is the architecture (32 for 32-bit binaries, and 64 for 64-bit binaries). For example, the NDB Cluster 8.0.20 archive for 64-bit Windows systems is named mysql-cluster-gpl-8.0.20-win64.zip.

You can run 32-bit NDB Cluster binaries on both 32-bit and 64-bit versions of Windows; however, 64-bit NDB Cluster binaries can be used only on 64-bit versions of Windows. If you are using a 32-bit version of Windows on a computer that has a 64-bit CPU, then you must use the 32-bit NDB Cluster binaries.

To minimize the number of files that need to be downloaded from the Internet or copied between machines, we start with the computer where you intend to run the SQL node.

SQL node. We assume that you have placed a copy of the archive in the directory C:\Documents and Settings\username\My Documents\Downloads on the computer having the IP address
Installing NDB Cluster on Windows

198.51.100.20, where username is the name of the current user. (You can obtain this name using ECHO %USERNAME% on the command line.) To install and run NDB Cluster executables as Windows services, this user should be a member of the Administrators group.

Extract all the files from the archive. The Extraction Wizard integrated with Windows Explorer is adequate for this task. (If you use a different archive program, be sure that it extracts all files and directories from the archive, and that it preserves the archive’s directory structure.) When you are asked for a destination directory, enter C:\, which causes the Extraction Wizard to extract the archive to the directory C:\mysql-cluster-gpl-ver-winarch. Rename this directory to C:\mysql.

It is possible to install the NDB Cluster binaries to directories other than C:\mysql\bin; however, if you do so, you must modify the paths shown in this procedure accordingly. In particular, if the MySQL Server (SQL node) binary is installed to a location other than C:\mysql or C:\Program Files\MySQL\MySQL Server 8.0, or if the SQL node’s data directory is in a location other than C:\mysql\data or C:\Program Files\MySQL\MySQL Server 8.0\data, extra configuration options must be used on the command line or added to the my.ini or my.cnf file when starting the SQL node. For more information about configuring a MySQL Server to run in a nonstandard location, see Section 2.3.4, “Installing MySQL on Microsoft Windows Using a noinstall ZIP Archive”.

For a MySQL Server with NDB Cluster support to run as part of an NDB Cluster, it must be started with the options --ndbcluster and --ndb-connectstring. While you can specify these options on the command line, it is usually more convenient to place them in an option file. To do this, create a new text file in Notepad or another text editor. Enter the following configuration information into this file:

```
[mysqld]
# Options for mysqld process:
ndbcluster                       # run NDB storage engine
ndb-connectstring=198.51.100.10  # location of management server
```

You can add other options used by this MySQL Server if desired (see Section 2.3.4.2, “Creating an Option File”), but the file must contain the options shown, at a minimum. Save this file as C:\mysql\my.ini. This completes the installation and setup for the SQL node.

Data nodes. An NDB Cluster data node on a Windows host requires only a single executable, one of either ndbd.exe or ndbmtd.exe. For this example, we assume that you are using ndbd.exe, but the same instructions apply when using ndbmtd.exe. On each computer where you wish to run a data node (the computers having the IP addresses 198.51.100.30 and 198.51.100.40), create the directories C:\mysql, C:\mysql\bin, and C:\mysql\cluster-data; then, on the computer where you downloaded and extracted the no-install archive, locate ndbd.exe in the C:\mysql\bin directory. Copy this file to the C:\mysql\bin directory on each of the two data node hosts.

To function as part of an NDB Cluster, each data node must be given the address or hostname of the management server. You can supply this information on the command line using the --ndb-connectstring or -c option when starting each data node process. However, it is usually preferable to put this information in an option file. To do this, create a new text file in Notepad or another text editor and enter the following text:

```
[mysql_cluster]
# Options for data node process:
ndb-connectstring=198.51.100.10  # location of management server
```

Save this file as C:\mysql\my.ini on the data node host. Create another text file containing the same information and save it on as C:\mysql\my.ini on the other data node host, or copy the my.ini file from the first data node host to the second one, making sure to place the copy in the second data node’s C:\mysql directory. Both data node hosts are now ready to be used in the NDB Cluster, which leaves only the management node to be installed and configured.

Management node. The only executable program required on a computer used for hosting an NDB Cluster management node is the management server program ndb_mgmd.exe. However, in order to administer the NDB Cluster once it has been started, you should also install the NDB Cluster management client program ndb_mgm.exe on the same machine as the management server. Locate
Installing NDB Cluster on Windows

these two programs on the machine where you downloaded and extracted the no-install archive; this should be the directory C:\mysql\bin on the SQL node host. Create the directory C:\mysql\bin on the computer having the IP address 198.51.100.10, then copy both programs to this directory.

You should now create two configuration files for use by ndb_mgmd.exe:

1. A local configuration file to supply configuration data specific to the management node itself. Typically, this file needs only to supply the location of the NDB Cluster global configuration file (see item 2).

   To create this file, start a new text file in Notepad or another text editor, and enter the following information:

   [mysql_cluster]
   # Options for management node process
   config-file=C:\mysql\bin\config.ini

   Save this file as the text file C:\mysql\bin\my.ini.

2. A global configuration file from which the management node can obtain configuration information governing the NDB Cluster as a whole. At a minimum, this file must contain a section for each node in the NDB Cluster, and the IP addresses or hostnames for the management node and all data nodes (HostName configuration parameter). It is also advisable to include the following additional information:

   - The IP address or hostname of any SQL nodes
   - The data memory and index memory allocated to each data node (DataMemory and IndexMemory configuration parameters)
   - The number of replicas, using the NoOfReplicas configuration parameter (see Section 22.1.2, “NDB Cluster Nodes, Node Groups, Replicas, and Partitions”)
   - The directory where each data node stores its data and log file, and the directory where the management node keeps its log files (in both cases, the DataDir configuration parameter)

   Create a new text file using a text editor such as Notepad, and input the following information:

   [ndbd default]
   # Options affecting ndbd processes on all data nodes:
   NoOfReplicas=2                      # Number of replicas
   DataDir=C:\mysql/cluster-data       # Directory for each data node's data files
   # Forward slashes used in directory path,
   # rather than backslashes. This is correct;
   # see Important note in text
   DataMemory=80M    # Memory allocated to data storage
   IndexMemory=18M   # Memory allocated to index storage
   # For DataMemory and IndexMemory, we have used the
   # default values. Since the "world" database takes up
   # only about 500KB, this should be more than enough for
   # this example Cluster setup.

   [ndbd]
   # Options for data node "A":
   # (one [ndbd] section per data node)
   HostName=198.51.100.30          # Hostname or IP address

   [ndbd]
   # Options for data node "B":
   HostName=198.51.100.40          # Hostname or IP address

   [mysqld]
# Installing NDB Cluster on Windows

## 22.2.3.2 Compiling and Installing NDB Cluster from Source on Windows

Oracle provides precompiled NDB Cluster binaries for Windows which should be adequate for most users. However, if you wish, it is also possible to compile NDB Cluster for Windows from source code. The procedure for doing this is almost identical to the procedure used to compile the standard MySQL Server binaries for Windows, and uses the same tools. However, there are two major differences:

- Building MySQL NDB Cluster 8.0 requires using the MySQL Server 8.0 sources. These are available from the MySQL downloads page at [https://dev.mysql.com/downloads/](https://dev.mysql.com/downloads/). The archived source file should have a name similar to `mysql-8.0.20.tar.gz`. You can also obtain the sources from GitHub at [https://github.com/mysql/mysql-server](https://github.com/mysql/mysql-server).

- You must configure the build using the `WITH_NDBCLUSTER` option in addition to any other build options you wish to use with `CMake`. `WITH_NDBCLUSTER_STORAGE_ENGINE` and `WITH_PLUGIN_NDBCLUSTER` are supported as aliases for `WITH_NDBCLUSTER`, and work in exactly the same way.

### Important

The `WITH_NDB_JAVA` option is enabled by default. This means that, by default, if `CMake` cannot find the location of Java on your system, the configuration process fails; if you do not wish to enable Java and ClusterJ support, you must indicate this explicitly by configuring the build using `-DWITH_NDB_JAVA=OFF`. (Bug #12379735) Use `WITH_CLASSPATH` to provide the Java classpath if needed.

For more information about `CMake` options specific to building NDB Cluster, see Options for Compiling NDB Cluster.

Once the build process is complete, you can create a Zip archive containing the compiled binaries; Section 2.9.4, “Installing MySQL Using a Standard Source Distribution” provides the commands needed to perform this task on Windows systems. The NDB Cluster binaries can be found in the `bin` directory of the resulting archive, which is equivalent to the `no-install` archive, and which can be installed and configured in the same manner. For more information, see Section 22.2.3.1, “Installing NDB Cluster on Windows from a Binary Release”.

---

### SQL node options:

| HostName=198.51.100.20 | # Hostname or IP address |

Save this file as the text file `C:\mysql\bin\config.ini`.

### Important

A single backslash character (`\`) cannot be used when specifying directory paths in program options or configuration files used by NDB Cluster on Windows. Instead, you must either escape each backslash character with a second backslash (`\\`), or replace the backslash with a forward slash character (`/`). For example, the following line from the `[ndb_mgmd]` section of an NDB Cluster `config.ini` file does not work:

```
DataDir=C:\mysql\bin\cluster-logs
```

Instead, you may use either of the following:

```
DataDir=C:\\mysql\bin\cluster-logs # Escaped backslashes
DataDir=C:/mysql/bin/cluster-logs     # Forward slashes
```

For reasons of brevity and legibility, we recommend that you use forward slashes in directory paths used in NDB Cluster program options and configuration files on Windows.
Installing NDB Cluster on Windows

22.2.3.3 Initial Startup of NDB Cluster on Windows

Once the NDB Cluster executables and needed configuration files are in place, performing an initial start of the cluster is simply a matter of starting the NDB Cluster executables for all nodes in the cluster. Each cluster node process must be started separately, and on the host computer where it resides. The management node should be started first, followed by the data nodes, and then finally by any SQL nodes.

1. On the management node host, issue the following command from the command line to start the management node process. The output should appear similar to what is shown here:

   C:\mysql\bin> ndb_mgmd
   2010-06-23 07:53:34 [MgmtSrvr] INFO -- Reading cluster configuration from 'config.ini'

   The management node process continues to print logging output to the console. This is normal, because the management node is not running as a Windows service. (If you have used NDB Cluster on a Unix-like platform such as Linux, you may notice that the management node's default behavior in this regard on Windows is effectively the opposite of its behavior on Unix systems, where it runs by default as a Unix daemon process. This behavior is also true of NDB Cluster data node processes running on Windows.) For this reason, do not close the window in which ndb_mgmd.exe is running; doing so kills the management node process. (See Section 22.2.3.4, “Installing NDB Cluster Processes as Windows Services”, where we show how to install and run NDB Cluster processes as Windows services.)

   The required -f option tells the management node where to find the global configuration file (config.ini). The long form of this option is --config-file.

   Important
   An NDB Cluster management node caches the configuration data that it reads from config.ini; once it has created a configuration cache, it ignores the config.ini file on subsequent starts unless forced to do otherwise. This means that, if the management node fails to start due to an error in this file, you must make the management node re-read config.ini after you have corrected any errors in it. You can do this by starting ndb_mgmd.exe with the --reload or --initial option on the command line. Either of these options works to refresh the configuration cache.

   It is not necessary or advisable to use either of these options in the management node's my.ini file.

   For additional information about options which can be used with ndb_mgmd, see Section 22.4.4, "ndb_mgmd — The NDB Cluster Management Server Daemon", as well as Section 22.4.31, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

2. On each of the data node hosts, run the command shown here to start the data node processes:

   C:\mysql\bin> ndbd

   In each case, the first line of output from the data node process should resemble what is shown in the preceding example, and is followed by additional lines of logging output. As with the management node process, this is normal, because the data node is not running as a Windows service. For this reason, do not close the console window in which the data node process is running; doing so kills ndbd.exe. (For more information, see Section 22.2.3.4, "Installing NDB Cluster Processes as Windows Services").

3. Do not start the SQL node yet; it cannot connect to the cluster until the data nodes have finished starting, which may take some time. Instead, in a new console window on the management node
Installing NDB Cluster on Windows

host, start the NDB Cluster management client ndb_mgm.exe, which should be in C:\mysql\bin on the management node host. (Do not try to re-use the console window where ndb_mgmd.exe is running by typing CTRL+C, as this kills the management node.) The resulting output should look like this:

C:\mysql\bin> ndb_mgm
-- NDB Cluster -- Management Client --
ndb_mgm>

When the prompt ndb_mgm> appears, this indicates that the management client is ready to receive NDB Cluster management commands. You can observe the status of the data nodes as they start by entering ALL STATUS at the management client prompt. This command causes a running report of the data nodes's startup sequence, which should look something like this:

ndb_mgm> ALL STATUS
Connected to Management Server at: localhost:1186
Node 2: starting (Last completed phase 3) (mysql-8.0.20-ndb-8.0.20)
Node 3: starting (Last completed phase 3) (mysql-8.0.20-ndb-8.0.20)

Node 2: starting (Last completed phase 4) (mysql-8.0.20-ndb-8.0.20)
Node 3: starting (Last completed phase 4) (mysql-8.0.20-ndb-8.0.20)

Node 2: Started (version 8.0.20)
Node 3: Started (version 8.0.20)
ndb_mgm>

Note

Commands issued in the management client are not case-sensitive; we use uppercase as the canonical form of these commands, but you are not required to observe this convention when inputting them into the ndb_mgm client. For more information, see Section 22.5.2, "Commands in the NDB Cluster Management Client".

The output produced by ALL STATUS is likely to vary from what is shown here, according to the speed at which the data nodes are able to start, the release version number of the NDB Cluster software you are using, and other factors. What is significant is that, when you see that both data nodes have started, you are ready to start the SQL node.

You can leave ndb_mgm.exe running; it has no negative impact on the performance of the NDB Cluster, and we use it in the next step to verify that the SQL node is connected to the cluster after you have started it.

4. On the computer designated as the SQL node host, open a console window and navigate to the directory where you unpacked the NDB Cluster binaries (if you are following our example, this is C:\mysql\bin).

Start the SQL node by invoking mysqld.exe from the command line, as shown here:

C:\mysql\bin> mysqld --console

The --console option causes logging information to be written to the console, which can be helpful in the event of problems. (Once you are satisfied that the SQL node is running in a satisfactory manner, you can stop it and restart it out without the --console option, so that logging is performed normally.)

In the console window where the management client (ndb_mgm.exe) is running on the management node host, enter the SHOW command, which should produce output similar to what is shown here:

ndb_mgm> SHOW
Connected to Management Server at: localhost:1186
Cluster Configuration
Installing NDB Cluster on Windows

---

You can also verify that the SQL node is connected to the NDB Cluster in the `mysql` client (`mysql.exe`) using the `SHOW ENGINE NDB STATUS` statement.

You should now be ready to work with database objects and data using NDB Cluster’s `NDBCluster` storage engine. See Section 22.2.6, “NDB Cluster Example with Tables and Data”, for more information and examples.

You can also install `ndb_mgmd.exe`, `ndbd.exe`, and `ndbmtd.exe` as Windows services. For information on how to do this, see Section 22.2.3.4, “Installing NDB Cluster Processes as Windows Services”.

### 22.2.3.4 Installing NDB Cluster Processes as Windows Services

Once you are satisfied that NDB Cluster is running as desired, you can install the management nodes and data nodes as Windows services, so that these processes are started and stopped automatically whenever Windows is started or stopped. This also makes it possible to control these processes from the command line with the appropriate `SC START` and `SC STOP` commands, or using the Windows graphical `Services` utility. `NET START` and `NET STOP` commands can also be used.

Installing programs as Windows services usually must be done using an account that has Administrator rights on the system.

To install the management node as a service on Windows, invoke `ndb_mgmd.exe` from the command line on the machine hosting the management node, using the `--install` option, as shown here:

```
C:\> C:\mysql\bin\ndb_mgmd.exe --install
Installing service 'NDB Cluster Management Server'
   as '"C:\mysql\bin\ndbd.exe" "--service=ndb_mgmd"'
Service successfully installed.
```

**Important**

When installing an NDB Cluster program as a Windows service, you should always specify the complete path; otherwise the service installation may fail with the error *The system cannot find the file specified.*

The `--install` option must be used first, ahead of any other options that might be specified for `ndb_mgmd.exe`. However, it is preferable to specify such options in an options file instead. If your options file is not in one of the default locations as shown in the output of `ndb_mgmd.exe --help`, you can specify the location using the `--config-file` option.

Now you should be able to start and stop the management server like this:

```
C:\> SC START ndb_mgmd
C:\> SC STOP ndb_mgmd
```

**Note**

If using `NET` commands, you can also start or stop the management server as a Windows service using the descriptive name, as shown here:

```
C:\> NET START 'NDB Cluster Management Server'
The NDB Cluster Management Server service is starting.
The NDB Cluster Management Server service was started successfully.
```
Installing NDB Cluster on Windows

C:\> NET STOP 'NDB Cluster Management Server'
The NDB Cluster Management Server service is stopping..
The NDB Cluster Management Server service was stopped successfully.

It is usually simpler to specify a short service name or to permit the default service name to be used when installing the service, and then reference that name when starting or stopping the service. To specify a service name other than ndb_mgmd, append it to the --install option, as shown in this example:

C:\> C:\mysql\bin\ndb_mgmd.exe --install=mgmd1
Installing service 'NDB Cluster Management Server' as '"C:\mysql\bin\ndb_mgmd.exe"' '--service=mgmd1'"'
Service successfully installed.

Now you should be able to start or stop the service using the name you have specified, like this:

C:\> SC START mgmd1
C:\> SC STOP mgmd1

To remove the management node service, use SC DELETE service_name:

C:\> SC DELETE mgmd1

Alternatively, invoke ndb_mgmd.exe with the --remove option, as shown here:

C:\> C:\mysql\bin\ndb_mgmd.exe --remove
Removing service 'NDB Cluster Management Server'
Service successfully removed.

If you installed the service using a service name other than the default, pass the service name as the value of the ndb_mgmd.exe --remove option, like this:

C:\> C:\mysql\bin\ndb_mgmd.exe --remove=mgmd1
Removing service 'mgmd1'
Service successfully removed.

Installation of an NDB Cluster data node process as a Windows service can be done in a similar fashion, using the --install option for ndbd.exe (or ndbmtd.exe), as shown here:

C:\> C:\mysql\bin\ndbd.exe --install
Installing service 'NDB Cluster Data Node Daemon' as '"C:\mysql\bin\ndbd.exe"' '--service=ndbd'"'
Service successfully installed.

Now you can start or stop the data node as shown in the following example:

C:\> SC START ndbd
C:\> SC STOP ndbd

To remove the data node service, use SC DELETE service_name:

C:\> SC DELETE ndbd

Alternatively, invoke ndbd.exe with the --remove option, as shown here:

C:\> C:\mysql\bin\ndbd.exe --remove
Removing service 'NDB Cluster Data Node Daemon'
Service successfully removed.

As with ndb_mgmd.exe (and mysqld.exe), when installing ndbd.exe as a Windows service, you can also specify a name for the service as the value of --install, and then use it when starting or stopping the service, like this:

C:\> C:\mysql\bin\ndbd.exe --install=dnode1
Installing service 'dnode1' as '"C:\mysql\bin\ndbd.exe"' '--service=dnode1'"'
Service successfully installed.

C:\> SC START dnode1
Initial Configuration of NDB Cluster

22.2.4 Initial Configuration of NDB Cluster

In this section, we discuss manual configuration of an installed NDB Cluster by creating and editing configuration files.

NDB Cluster also provides a GUI installer which can be used to perform the configuration without the need to edit text files in a separate application. For more information, see Section 22.2.1, “The NDB Cluster Auto-Installer”.

For our four-node, four-host NDB Cluster (see Cluster nodes and host computers), it is necessary to write four configuration files, one per node host.

- Each data node or SQL node requires a \texttt{my.cnf} file that provides two pieces of information: a connection string that tells the node where to find the management node, and a line telling the MySQL server on this host (the machine hosting the data node) to enable the \texttt{NDBCLUSTER} storage engine.

  For more information on connection strings, see Section 22.3.3.3, “NDB Cluster Connection Strings”.

- The management node needs a \texttt{config.ini} file telling it how many replicas to maintain, how much memory to allocate for data and indexes on each data node, where to find the data nodes, where to save data to disk on each data node, and where to find any SQL nodes.

Configuring the data nodes and SQL nodes. The \texttt{my.cnf} file needed for the data nodes is fairly simple. The configuration file should be located in the \texttt{/etc} directory and can be edited using any text editor. (Create the file if it does not exist.) For example:

\begin{verbatim}
shell> vi /etc/my.cnf
\end{verbatim}

\begin{itemize}
  \item For each data node and SQL node in our example setup, \texttt{my.cnf} should look like this:

\begin{verbatim}
[mysqld]
# Options for mysqld process:
nbdcluster  # run NDB storage engine

[mysql_cluster]
# Options for NDB Cluster processes:
nbd-connectstring=198.51.100.10  # location of management server
\end{verbatim}

After entering the preceding information, save this file and exit the text editor. Do this for the machines hosting data node “A”, data node “B”, and the SQL node.

Note
We show \texttt{vi} being used here to create the file, but any text editor should work just as well.
Important

Once you have started a mysqld process with the ndbcluster and ndb-connectstring parameters in the [mysqld] and [mysql_cluster] sections of the my.cnf file as shown previously, you cannot execute any CREATE TABLE or ALTER TABLE statements without having actually started the cluster. Otherwise, these statements will fail with an error. This is by design.

Configuring the management node. The first step in configuring the management node is to create the directory in which the configuration file can be found and then to create the file itself. For example (running as root):

```shell
mkdir /var/lib/mysql-cluster
cd /var/lib/mysql-cluster
vi config.ini
```

For our representative setup, the config.ini file should read as follows:

```ini
[ndbd default]
# Options affecting ndbd processes on all data nodes:
NoOfReplicas=2    # Number of replicas
DataMemory=98M    # How much memory to allocate for data storage

[ndbd_mgmd]
# Management process options:
HostName=198.51.100.10          # Hostname or IP address of MGM node
DataDir=/var/lib/mysql-cluster  # Directory for MGM node log files

[ndbd]
# Options for data node "A":
HostName=198.51.100.30          # Hostname or IP address
NodeId=2                        # Node ID for this data node
DataDir=/usr/local/mysql/data   # Directory for this data node's data files

[ndbd]
# Options for data node "B":
HostName=198.51.100.40          # Hostname or IP address
NodeId=3                        # Node ID for this data node
DataDir=/usr/local/mysql/data   # Directory for this data node's data files

[mysqld]
# SQL node options:
HostName=198.51.100.20          # Hostname or IP address
# (additional mysqld connections can be
# specified for this node for various
# purposes such as running ndb_restore)
```

Note

The world database can be downloaded from https://dev.mysql.com/doc/index-other.html.

After all the configuration files have been created and these minimal options have been specified, you are ready to proceed with starting the cluster and verifying that all processes are running. We discuss how this is done in Section 22.2.5, “Initial Startup of NDB Cluster”.

For more detailed information about the available NDB Cluster configuration parameters and their uses, see Section 22.3.3, “NDB Cluster Configuration Files”, and Section 22.3, “Configuration of NDB Cluster”. For configuration of NDB Cluster as relates to making backups, see Section 22.5.3.3, “Configuration for NDB Cluster Backups”.

Note

The default port for Cluster management nodes is 1186; the default port for data nodes is 2202. However, the cluster can automatically allocate ports for data nodes from those that are already free.
22.2.5 Initial Startup of NDB Cluster

Starting the cluster is not very difficult after it has been configured. Each cluster node process must be started separately, and on the host where it resides. The management node should be started first, followed by the data nodes, and then finally by any SQL nodes:

1. On the management host, issue the following command from the system shell to start the management node process:

```
shell> ndb_mgmd -f /var/lib/mysql-cluster/config.ini
```

The first time that it is started, `ndb_mgmd` must be told where to find its configuration file, using the `-f` or `--config-file` option. (See Section 22.4.4, "ndb_mgmd — The NDB Cluster Management Server Daemon", for details.)

For additional options which can be used with `ndb_mgmd`, see Section 22.4.31, "Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs".

2. On each of the data node hosts, run this command to start the `ndbd` process:

```
shell> ndbd
```

3. If you used RPM files to install MySQL on the cluster host where the SQL node is to reside, you can (and should) use the supplied startup script to start the MySQL server process on the SQL node.

If all has gone well, and the cluster has been set up correctly, the cluster should now be operational. You can test this by invoking the `ndb_mgm` management node client. The output should look like that shown here, although you might see some slight differences in the output depending upon the exact version of MySQL that you are using:

```
shell> ndb_mgm
-- NDB Cluster -- Management Client --
ndb_mgm> SHOW
Connected to Management Server at: localhost:1186
Cluster Configuration
---------------------
[ndbd(NDB)] 2 node(s)
id=2 @198.51.100.30 (Version: 8.0.20-ndb-8.0.20, Nodegroup: 0, *)
id=3 @198.51.100.40 (Version: 8.0.20-ndb-8.0.20, Nodegroup: 0)

[ndb_mgmd(MGM)] 1 node(s)
id=1 @198.51.100.10 (Version: 8.0.20-ndb-8.0.20)

[mysqld(API)] 1 node(s)
id=4 @198.51.100.20 (Version: 8.0.20-ndb-8.0.20)
```

The SQL node is referenced here as `[mysqld(API)]`, which reflects the fact that the `mysqld` process is acting as an NDB Cluster API node.

**Note**

The IP address shown for a given NDB Cluster SQL or other API node in the output of `SHOW` is the address used by the SQL or API node to connect to the cluster data nodes, and not to any management node.

You should now be ready to work with databases, tables, and data in NDB Cluster. See Section 22.2.6, "NDB Cluster Example with Tables and Data", for a brief discussion.

22.2.6 NDB Cluster Example with Tables and Data

**Note**

The information in this section applies to NDB Cluster running on both Unix and Windows platforms.
Working with database tables and data in NDB Cluster is not much different from doing so in standard MySQL. There are two key points to keep in mind:

- For a table to be replicated in the cluster, it must use the NDBCLUSTER storage engine. To specify this, use the ENGINE=NDBCLUSTER option when creating the table:

  ```sql
  CREATE TABLE tbl_name (col_name column_definitions) ENGINE=NDBCLUSTER;
  ```

  Alternatively, for an existing table that uses a different storage engine, use `ALTER TABLE` to change the table to use NDBCLUSTER:

  ```sql
  ALTER TABLE tbl_name ENGINE=NDBCLUSTER;
  ```

- Every NDBCLUSTER table has a primary key. If no primary key is defined by the user when a table is created, the NDBCLUSTER storage engine automatically generates a hidden one. Such a key takes up space just as does any other table index. (It is not uncommon to encounter problems due to insufficient memory for accommodating these automatically created indexes.)

If you are importing tables from an existing database using the output of `mysqldump`, you can open the SQL script in a text editor and add the `ENGINE` option to any table creation statements, or replace any existing `ENGINE` options. Suppose that you have the `world` sample database on another MySQL server that does not support NDB Cluster, and you want to export the `City` table:

```
shell> mysqldump --add-drop-table world City > city_table.sql
```

The resulting `city_table.sql` file will contain this table creation statement (and the `INSERT` statements necessary to import the table data):

```sql
DROP TABLE IF EXISTS `City`;
CREATE TABLE `City` (  
  `ID` int(11) NOT NULL auto_increment,  
  `Name` char(35) NOT NULL default '',  
  `CountryCode` char(3) NOT NULL default '',  
  `District` char(20) NOT NULL default '',  
  `Population` int(11) NOT NULL default '0',  
  PRIMARY KEY  (`ID`)  
) ENGINE=MyISAM DEFAULT CHARSET=latin1;
```

```
INSERT INTO `City` VALUES (1,'Kabul','AFG','Kabol',1780000);
INSERT INTO `City` VALUES (2,'Qandahar','AFG','Qandahar',237500);
INSERT INTO `City` VALUES (3,'Herat','AFG','Herat',186800);  
```

You need to make sure that MySQL uses the NDBCLUSTER storage engine for this table. There are two ways that this can be accomplished. One of these is to modify the table definition before importing it into the Cluster database. Using the `City` table as an example, modify the `ENGINE` option of the definition as follows:

```sql
DROP TABLE IF EXISTS `City`;
CREATE TABLE `City` (  
  `ID` int(11) NOT NULL auto_increment,  
  `Name` char(35) NOT NULL default '',  
  `CountryCode` char(3) NOT NULL default '',  
  `District` char(20) NOT NULL default '',  
  `Population` int(11) NOT NULL default '0',  
  PRIMARY KEY  (`ID`)  
) ENGINE=NDBCLUSTER DEFAULT CHARSET=latin1;
```

```
INSERT INTO `City` VALUES (1,'Kabul','AFG','Kabol',1780000);
INSERT INTO `City` VALUES (2,'Qandahar','AFG','Qandahar',237500);
INSERT INTO `City` VALUES (3,'Herat','AFG','Herat',186800);  
```

This must be done for the definition of each table that is to be part of the clustered database. The easiest way to accomplish this is to do a search-and-replace on the file that contains the definitions and replace all instances of `TYPE=engine_name` or `ENGINE=engine_name` with `ENGINE=NDBCLUSTER`. If you do not want to modify the file, you can use the unmodified file to create the tables, and then use `ALTER TABLE` to change their storage engine. The particulars are given later in this section.
Assuming that you have already created a database named `world` on the SQL node of the cluster, you can then use the `mysql` command-line client to read `city_table.sql`, and create and populate the corresponding table in the usual manner:

```
shell> mysql world < city_table.sql
```

It is very important to keep in mind that the preceding command must be executed on the host where the SQL node is running (in this case, on the machine with the IP address `198.51.100.20`).

To create a copy of the entire `world` database on the SQL node, use `mysqldump` on the noncluster server to export the database to a file named `world.sql` (for example, in the `/tmp` directory). Then modify the table definitions as just described and import the file into the SQL node of the cluster like this:

```
shell> mysql world < /tmp/world.sql
```

If you save the file to a different location, adjust the preceding instructions accordingly.

Running `SELECT` queries on the SQL node is no different from running them on any other instance of a MySQL server. To run queries from the command line, you first need to log in to the MySQL Monitor in the usual way (specify the root password at the Enter password: prompt):

```
shell> mysql -u root -p
```

```
Enter password:
Welcome to the MySQL monitor. Commands end with ; or \g.
Your MySQL connection id is 1 to server version: 8.0.20-ndb-8.0.20
```

```
Type 'help;' or '\h' for help. Type '\c' to clear the buffer.
```

```
mysql>
```

We simply use the MySQL server’s root account and assume that you have followed the standard security precautions for installing a MySQL server, including setting a strong root password. For more information, see Section 2.10.4, “Securing the Initial MySQL Account”.

It is worth taking into account that NDB Cluster nodes do not make use of the MySQL privilege system when accessing one another. Setting or changing MySQL user accounts (including the root account) effects only applications that access the SQL node, not interaction between nodes. See Section 22.5.12.2, “NDB Cluster and MySQL Privileges”, for more information.

If you did not modify the ENGINE clauses in the table definitions prior to importing the SQL script, you should run the following statements at this point:

```
mysql> USE world;
mysql> ALTER TABLE City ENGINE=NDBCLUSTER;
mysql> ALTER TABLE Country ENGINE=NDBCLUSTER;
mysql> ALTER TABLE CountryLanguage ENGINE=NDBCLUSTER;
```

Selecting a database and running a `SELECT` query against a table in that database is also accomplished in the usual manner, as is exiting the MySQL Monitor:

```
mysql> USE world;
mysql> SELECT Name, Population FROM City ORDER BY Population DESC LIMIT 5;
+-----------+------------+
<table>
<thead>
<tr>
<th>Name</th>
<th>Population</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bombay</td>
<td>10500000</td>
</tr>
<tr>
<td>Seoul</td>
<td>9981619</td>
</tr>
<tr>
<td>São Paulo</td>
<td>9968485</td>
</tr>
<tr>
<td>Shanghai</td>
<td>9696300</td>
</tr>
<tr>
<td>Jakarta</td>
<td>9604900</td>
</tr>
</tbody>
</table>
+-----------+------------+
5 rows in set (0.34 sec)
```

```
mysql> \q
```

Bye
Applications that use MySQL can employ standard APIs to access NDB tables. It is important to remember that your application must access the SQL node, and not the management or data nodes. This brief example shows how we might execute the SELECT statement just shown by using the PHP 5.X mysqli extension running on a Web server elsewhere on the network:

```php
<?php
# connect to SQL node:
$link = new mysqli('198.51.100.20', 'root', 'root_password', 'world');
# parameters for mysqli constructor are:
# host, user, password, database
if( mysqli_connect_errno() )
die("Connect failed: ", mysqli_connect_error());
$query = "SELECT Name, Population
        FROM City
        ORDER BY Population DESC
        LIMIT 5";

# if no errors...
if( $result = $link->query($query) )
{
    ?><table border="1" width="40%" cellpadding="4" cellspacing ="1">
    <tbody>
    <tr>
        <th width="10">City</th>
        <th>Population</th>
    </tr>
    <?
    # then display the results...
    while($row = $result->fetch_object())
        printf("<tr>
            <td>$row->Name</td><td>%d</td>
            </tr>", $row->Population);
    ?></tbody>
    </table>
    <?
    # ...and verify the number of rows that were retrieved
    printf("<p>Affected rows: %d</p>
    $link->affected_rows);
} else
    # otherwise, tell us what went wrong
    echo mysqli_error();

# free the result set and the mysqli connection object
$result->close();
$link->close();
?>
</body>
</html>

We assume that the process running on the Web server can reach the IP address of the SQL node.

In a similar fashion, you can use the MySQL C API, Perl-DBI, Python-mysql, or MySQL Connectors to perform the tasks of data definition and manipulation just as you would normally with MySQL.

### 22.2.7 Safe Shutdown and Restart of NDB Cluster
To shut down the cluster, enter the following command in a shell on the machine hosting the management node:

```
shell> ndb_mgm -e shutdown
```

The `-e` option here is used to pass a command to the `ndb_mgm` client from the shell. (See Section 22.4.31, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”, for more information about this option.) The command causes the `ndb_mgm`, `ndb_mgmd`, and any `ndbd` or `ndbmtd` processes to terminate gracefully. Any SQL nodes can be terminated using `mysqladmin shutdown` and other means. On Windows platforms, assuming that you have installed the SQL node as a Windows service, you can use `SC STOP service_name` or `NET STOP service_name`.

To restart the cluster on Unix platforms, run these commands:

- On the management host (`198.51.100.10` in our example setup):
  
  ```
  shell> ndb_mgmd -f /var/lib/mysql-cluster/config.ini
  ```

- On each of the data node hosts (`198.51.100.30` and `198.51.100.40`):
  
  ```
  shell> ndbd
  ```

- Use the `ndb_mgm` client to verify that both data nodes have started successfully.

- On the SQL host (`198.51.100.20`):
  
  ```
  shell> mysqld_safe &
  ```

On Windows platforms, assuming that you have installed all NDB Cluster processes as Windows services using the default service names (see Section 22.2.3.4, “Installing NDB Cluster Processes as Windows Services”), you can restart the cluster as follows:

- On the management host (`198.51.100.10` in our example setup), execute the following command:
  
  ```
  C:\> SC START ndb_mgmd
  ```

- On each of the data node hosts (`198.51.100.30` and `198.51.100.40`), execute the following command:
  
  ```
  C:\> SC START ndbd
  ```

- On the management node host, use the `ndb_mgm` client to verify that the management node and both data nodes have started successfully (see Section 22.2.3.3, “Initial Startup of NDB Cluster on Windows”).

- On the SQL node host (`198.51.100.20`), execute the following command:
  
  ```
  C:\> SC START mysql
  ```

In a production setting, it is usually not desirable to shut down the cluster completely. In many cases, even when making configuration changes, or performing upgrades to the cluster hardware or software (or both), which require shutting down individual host machines, it is possible to do so without shutting down the cluster as a whole by performing a rolling restart of the cluster. For more information about doing this, see Section 22.5.5, “Performing a Rolling Restart of an NDB Cluster”.

### 22.2.8 Upgrading and Downgrading NDB Cluster

This section provides information about NDB Cluster software and table file compatibility between different NDB Cluster 8.0 releases with regard to performing upgrades and downgrades as well as compatibility matrices and notes. You should already be familiar with installing and configuring NDB Cluster prior to attempting an upgrade or downgrade. See Section 22.3, “Configuration of NDB Cluster.”
Upgrading and Downgrading NDB Cluster

Schema operations, including SQL DDL statements, cannot be performed while any data nodes are restarting, and thus during an online upgrade or downgrade of the cluster. For other information regarding the rolling restart procedure used to perform an online upgrade, see Section 22.5.5, “Performing a Rolling Restart of an NDB Cluster”.

**Important**

Only compatibility between MySQL versions with regard to NDBCLUSTER is taken into account in this section, and there are likely other issues to be considered. As with any other MySQL software upgrade or downgrade, you are strongly encouraged to review the relevant portions of the MySQL Manual for the MySQL versions from which and to which you intend to migrate, before attempting an upgrade or downgrade of the NDB Cluster software. See Section 2.11, “Upgrading MySQL”.

The table shown here provides information on NDB Cluster upgrade and downgrade compatibility among different releases of NDB 8.0. Additional notes about upgrades and downgrades to, from, or within the NDB Cluster 8.0 release series can be found following the table.

### Upgrades and Downgrades, NDB Cluster 8.0

**Figure 22.25 NDB Cluster Upgrade and Downgrade Compatibility, MySQL NDB Cluster 8.0**

**Version support.** The following versions of NDB Cluster are supported for upgrades to GA releases of NDB Cluster 8.0 (8.0.19 and later):

- NDB Cluster 7.6: NDB 7.6.4 and later
- NDB Cluster 7.5: NDB 7.5.4 and later
- NDB Cluster 7.4: NDB 7.4.6 and later

To upgrade from a release series previous to NDB 7.4, you must upgrade in stages, first to one of the versions just listed, and then from that version to the latest NDB 8.0 release. In such cases, upgrading to the latest NDB 7.6 release is recommended as the first step.
Known Issues.  The following issues are known to occur when upgrading to or between NDB 8.0 releases:

• Online downgrades from NDB 8.0.14 to previous releases are not supported. Tables created in NDB 8.0.14 are not backwards compatible with previous releases. This is due to a change in usage of the extra metadata property implemented by NDB tables to provide full support for the MySQL data dictionary.

For more information, see Changes in NDB table extra metadata. See also Chapter 14, MySQL Data Dictionary.

• Distributed privileges shared between MySQL servers as implemented in prior release series (see Distributed Privileges Using Shared Grant Tables) are not supported in NDB Cluster 8.0. When started, the mysqld supplied with NDB 8.0.16 and later checks for the existence of any grant tables which use the NDB storage engine; if it finds any, it creates local copies (“shadow tables”) of these using InnoDB. This is true for each MySQL server connected to NDB Cluster. After this has been performed on all MySQL servers acting as NDB Cluster SQL nodes, the NDB grant tables may be safely removed using the ndb_drop_table utility supplied with the NDB Cluster distribution, like this:

```
ndb_drop_table -d mysql user db columns_priv tables_priv proxies_priv procs_priv
```

It is safe to retain the NDB grant tables, but they are not used for access control and are effectively ignored.

For more information about the MySQL privileges system used in NDB 8.0, see Section 22.5.16, “Distributed MySQL Privileges with NDB_STORED_USER”, as well as Section 6.2.3, “Grant Tables”.

• In NDB 8.0.18, the binary configuration file format has been enhanced to provide support for greater numbers of nodes than in previous versions. The new format is not accessible to 8.0.17 and older nodes, although newer management servers can detect older nodes and communicate with them using the appropriate format.

Upgrades to NDB 8.0.18 or later from 8.0.17 and earlier should not be problematic in this regard. In the case of downgrades from NDB 8.0.18 or later to 8.0.17 or earlier, because older management servers cannot read the newer binary configuration file format, some manual intervention is required. When performing such a downgrade, it is necessary to remove any cached binary configuration files prior to starting the management using the older NDB software version, and to have the plaintext configuration file available for the management server to read. Alternatively, you can start the older management server using the --initial option (again, it is necessary to have the config.ini available). If the cluster uses multiple management servers, one of these two things must be done for each management server binary.

Also in connection with support for increased numbers of nodes, due to incompatible changes implemented in NDB 8.0.18 in the data node LCP Sysfile, it is necessary, when performing an online downgrade from NDB 8.0.18 (or later) to any prior release, to restart all data nodes using the --initial option.

Restarting the data nodes with --initial is also required when upgrading any release prior to NDB 7.6.4 to any NDB 8.0 release.

• Direct downgrades of clusters running more than 48 data nodes, or with data nodes using node IDs greater than 48, to NDB versions 8.0.17 and earlier from NDB 8.0.18 or later are not supported. It is necessary in such cases to reduce the number of data nodes, change the configurations for all data nodes such that they use node IDs less than or equal to 48, or both, as required not to exceed the old maximums.

• If you are downgrading from NDB 8.0 to NDB 7.5 or NDB 7.4, you must set an explicit value for IndexMemory in the cluster configuration file if none is already present. This is because NDB 8.0 does not use this parameter (which was removed in NDB 7.6) and sets it to 0 by default, whereas it is required in NDB 7.5 and NDB 7.4, in both of which the cluster refuses to start with Invalid
configuration received from Management Server... if IndexMemory is not set to a nonzero value.

Setting IndexMemory is not required for downgrades from NDB 8.0 to NDB 7.6.

22.3 Configuration of NDB Cluster

A MySQL server that is part of an NDB Cluster differs in one chief respect from a normal (nonclustered) MySQL server, in that it employs the NDB storage engine. This engine is also referred to sometimes as NDBCLUSTER, although NDB is preferred.

To avoid unnecessary allocation of resources, the server is configured by default with the NDB storage engine disabled. To enable NDB, you must modify the server's my.cnf configuration file, or start the server with the --ndbcluster option.

This MySQL server is a part of the cluster, so it also must know how to access a management node to obtain the cluster configuration data. The default behavior is to look for the management node on localhost. However, should you need to specify that its location is elsewhere, this can be done in my.cnf, or with the mysql client. Before the NDB storage engine can be used, at least one management node must be operational, as well as any desired data nodes.

For more information about --ndbcluster and other mysqld options specific to NDB Cluster, see MySQL Server Options for NDB Cluster.

You can use also the NDB Cluster Auto-Installer to set up and deploy an NDB Cluster on one or more hosts using a browser-based GUI. For more information, see The NDB Cluster Auto-Installer (NDB 7.5).

For general information about installing NDB Cluster, see Section 22.2, "NDB Cluster Installation".

22.3.1 Quick Test Setup of NDB Cluster

To familiarize you with the basics, we will describe the simplest possible configuration for a functional NDB Cluster. After this, you should be able to design your desired setup from the information provided in the other relevant sections of this chapter.

First, you need to create a configuration directory such as /var/lib/mysql-cluster, by executing the following command as the system root user:

```
shell> mkdir /var/lib/mysql-cluster
```

In this directory, create a file named config.ini that contains the following information. Substitute appropriate values for HostName and DataDir as necessary for your system.

```ini
# file "config.ini" - showing minimal setup consisting of 1 data node, 1 management server, and 3 MySQL servers.
# The empty default sections are not required, and are shown only for the sake of completeness.
# Data nodes must provide a hostname but MySQL Servers are not required to do so.
# If you don't know the hostname for your machine, use localhost.
# The DataDir parameter also has a default value, but it is recommended to set it explicitly.
# Note: [db], [api], and [mgm] are aliases for [ndbd], [mysqld], and [ndb_mgmd], respectively. [db] is deprecated and should not be used in new installations.

[ndbd default]
NoOfReplicas= 1

[mysqld default]
[ndb_mgmd default]
[tcp default]

[ndb_mgmd]
HostName= myhost.example.com
```

3594
Quick Test Setup of NDB Cluster

You can now start the `ndb_mgmd` management server. By default, it attempts to read the `config.ini` file in its current working directory, so change location into the directory where the file is located and then invoke `ndb_mgmd`:

```
shell> cd /var/lib/mysql-cluster
shell> ndb_mgmd
```

Then start a single data node by running `ndbd`:

```
shell> ndbd
```

For command-line options which can be used when starting `ndbd`, see Section 22.4.31, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

By default, `ndbd` looks for the management server at `localhost` on port 1186.

**Note**

If you have installed MySQL from a binary tarball, you will need to specify the path of the `ndb_mgmd` and `ndbd` servers explicitly. (Normally, these will be found in `/usr/local/mysql/bin`).

Finally, change location to the MySQL data directory (usually `/var/lib/mysql` or `/usr/local/mysql/data`), and make sure that the `my.cnf` file contains the option necessary to enable the NDB storage engine:

```
[mysqld]
ndbcluster
```

You can now start the MySQL server as usual:

```
shell> mysqld_safe --user=mysql &
```

Wait a moment to make sure the MySQL server is running properly. If you see the notice `mysql ended`, check the server's `.err` file to find out what went wrong.

If all has gone well so far, you now can start using the cluster. Connect to the server and verify that the `NDBCLUSTER` storage engine is enabled:

```
shell> mysql
Welcome to the MySQL monitor. Commands end with ; or \g.
Your MySQL connection id is 1 to server version: 8.0.22

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SHOW ENGINES\G
... **************************** 12. row ***************************
Engine: NDBCLUSTER
Support: YES
Comment: Clustered, fault-tolerant, memory-based tables
... **************************** 13. row ***************************
Engine: NDB
Support: YES
Comment: Alias for NDBCLUSTER
...
```

The row numbers shown in the preceding example output may be different from those shown on your system, depending upon how your server is configured.
Try to create an `NDBCLUSTER` table:

```shell
mysql
USE test;
CREATE TABLE ctest (i INT) ENGINE=NDBCLUSTER;
```

Query OK, 0 rows affected (0.09 sec)

```shell
SHOW CREATE TABLE ctest \G
*************************** 1. row ***************************
Table: ctest
Create Table: CREATE TABLE `ctest` (
`i` int(11) default NULL
) ENGINE=ndbcluster DEFAULT CHARSET=latin1
1 row in set (0.00 sec)
```

To check that your nodes were set up properly, start the management client:

```shell
ndb_mgm
```

Use the `SHOW` command from within the management client to obtain a report on the cluster’s status:

```
ndb_mgm> SHOW
Cluster Configuration
-------------
[ndbd(NDB)] 1 node(s)
id=2 @127.0.0.1 (Version: 8.0.20-ndb-8.0.20, Nodegroup: 0, *)
[ndb_mgmd(MGM)] 1 node(s)
id=1 @127.0.0.1 (Version: 8.0.20-ndb-8.0.20)
[mysqld(API)] 3 node(s)
id=3 @127.0.0.1 (Version: 8.0.20-ndb-8.0.20)
id=4 (not connected, accepting connect from any host)
id=5 (not connected, accepting connect from any host)
```

At this point, you have successfully set up a working NDB Cluster. You can now store data in the cluster by using any table created with `ENGINE=NDBCLUSTER` or its alias `ENGINE=NDB`.

### 22.3.2 Overview of NDB Cluster Configuration Parameters, Options, and Variables

The next several sections provide summary tables of NDB Cluster node configuration parameters used in the `config.ini` file to govern various aspects of node behavior, as well as of options and variables read by `mysqld` from a `my.cnf` file or from the command line when run as an NDB Cluster process. Each of the node parameter tables lists the parameters for a given type (`ndbd`, `ndb_mgmd`, `mysqld`, `computer`, `tcp`, or `shm`). All tables include the data type for the parameter, option, or variable, as well as its default, minimum, and maximum values as applicable.

#### Considerations when restarting nodes

For node parameters, these tables also indicate what type of restart is required (node restart or system restart)—and whether the restart must be done with `--initial`—to change the value of a given configuration parameter. When performing a node restart or an initial node restart, all of the cluster's data nodes must be restarted in turn (also referred to as a rolling restart). It is possible to update cluster configuration parameters marked as node online—that is, without shutting down the cluster—in this fashion. An initial node restart requires restarting each `ndbd` process with the `--initial` option.

A system restart requires a complete shutdown and restart of the entire cluster. An initial system restart requires taking a backup of the cluster, wiping the cluster file system after shutdown, and then restoring from the backup following the restart.

In any cluster restart, all of the cluster’s management servers must be restarted for them to read the updated configuration parameter values.
Overview of NDB Cluster Configuration Parameters, Options, and Variables

Important

Values for numeric cluster parameters can generally be increased without any problems, although it is advisable to do so progressively, making such adjustments in relatively small increments. Many of these can be increased online, using a rolling restart.

However, decreasing the values of such parameters—whether this is done using a node restart, node initial restart, or even a complete system restart of the cluster—is not to be undertaken lightly; it is recommended that you do so only after careful planning and testing. This is especially true with regard to those parameters that relate to memory usage and disk space, such as MaxNoOfTables, MaxNoOfOrderedIndexes, and MaxNoOfUniqueHashIndexes. In addition, it is generally the case that configuration parameters relating to memory and disk usage can be raised using a simple node restart, but they require an initial node restart to be lowered.

Because some of these parameters can be used for configuring more than one type of cluster node, they may appear in more than one of the tables.

Note

4294967039 often appears as a maximum value in these tables. This value is defined in the NDBCLUSTER sources as MAX_INT_RNIL and is equal to 0xFFFFFEFF, or $2^{32} - 2^8 - 1$.

22.3.2.1 NDB Cluster Data Node Configuration Parameters

The listings in this section provide information about parameters used in the [ndbd] or [ndbd default] sections of a config.ini file for configuring NDB Cluster data nodes. For detailed descriptions and other additional information about each of these parameters, see Section 22.3.3.6, “Defining NDB Cluster Data Nodes”.

These parameters also apply to ndbmtd, the multithreaded version of ndbd. For more information, see Section 22.4.3, "ndbmtd — The NDB Cluster Data Node Daemon (Multi-Threaded)".

- **Arbitration**: How arbitration should be performed to avoid split-brain issues in event of node failure.
- **ArbitrationTimeout**: Maximum time (milliseconds) database partition waits for arbitration signal.
- **BackupDataBufferSize**: Default size of databuffer for a backup (in bytes).
- **BackupDataDir**: Path to where to store backups. Note that string '/BACKUP' is always appended to this setting, so that “effective” default is FileSystemPath/BACKUP.
- **BackupDiskWriteSpeedPct**: Sets percentage of data node's allocated maximum write speed (MaxDiskWriteSpeed) to reserve for LCPs when starting a backup.
- **BackupLogBufferSize**: Default size of log buffer for a backup (in bytes).
- **BackupMaxWriteSize**: Maximum size of file system writes made by backup (in bytes).
- **BackupMemory**: Total memory allocated for backups per node (in bytes).
- **BackupReportFrequency**: Frequency of backup status reports during backup in seconds.
- **BackupWriteSize**: Default size of file system writes made by backup (in bytes).
- **BatchSizePerLocalScan**: Used to calculate number of lock records for scan with hold lock.
Overview of NDB Cluster Configuration Parameters, Options, and Variables

- **BuildIndexThreads**: Number of threads to use for building ordered indexes during a system or node restart. Also applies when running ndb_restore --rebuild-indexes. Setting this parameter to 0 disables multithreaded building of ordered indexes.

- **CompressedBackup**: Use zlib to compress backups as they are written.

- **CompressedLCP**: Write compressed LCPs using zlib.

- **ConnectCheckIntervalDelay**: Time between data node connectivity check stages. Data node is considered suspect after 1 interval and dead after 2 intervals with no response.

- **CrashOnCorruptedTuple**: When enabled, forces node to shut down whenever it detects a corrupted tuple.

- **DataDir**: Data directory for this node.

- **DataMemory**: Number of bytes on each data node allocated for storing data; subject to available system RAM and size of IndexMemory.

- **DefaultHashMapSize**: Set size (in buckets) to use for table hash maps. Three values are supported: 0, 240, and 3840.

- **DictTrace**: Enable DBDICT debugging; for NDB development.

- **DiskDataUsingSameDisk**: Set to false if Disk Data tablespaces are located on separate physical disks.

- **DiskIOThreadPool**: Number of unbound threads for file access, applies to disk data only.

- **Diskless**: Run without using disk.

- **DiskPageBufferEntries**: Memory to allocate in DiskPageBufferMemory; very large disk transactions may require increasing this value.

- **DiskPageBufferMemory**: Number of bytes on each data node allocated for disk page buffer cache.

- **DiskSyncSize**: Amount of data written to file before a synch is forced.

- **EnablePartialLcp**: Enable partial LCP (true); if this is disabled (false), all LCPs write full checkpoints.

- **EnableRedoControl**: Enable adaptive checkpointing speed for controlling redo log usage.

- **EventLogBufferSize**: Size of circular buffer for NDB log events within data nodes.

- **ExecuteOnComputer**: String referencing an earlier defined COMPUTER.

- **ExtraSendBufferMemory**: Memory to use for send buffers in addition to any allocated by TotalSendBufferMemory or SendBufferMemory. Default (0) allows up to 16MB.

- **FileSystemPath**: Path to directory where data node stores its data (directory must exist).

- **FileSystemPathDataFiles**: Path to directory where data node stores its Disk Data files. The default value is FilesystemPathDD, if set; otherwise, FilesystemPath is used if it is set; otherwise, value of DataDir is used.

- **FileSystemPathDD**: Path to directory where data node stores its Disk Data and undo files. Default value is FilesystemPath, if set; otherwise, value of DataDir is used.

- **FileSystemPathUndoFiles**: Path to directory where data node stores its undo files for Disk Data. Default value is FilesystemPathDD, if set; otherwise, FilesystemPath is used if it is set; otherwise, value of DataDir is used.

- **FragmentLogFileSize**: Size of each redo log file.
Overview of NDB Cluster Configuration Parameters, Options, and Variables

- **HeartbeatIntervalDbApi**: Time between API node-data node heartbeats. (API connection closed after 3 missed heartbeats).

- **HeartbeatIntervalDbDb**: Time between data node-to-data node heartbeats; data node considered dead after 3 missed heartbeats.

- **HeartbeatOrder**: Sets order in which data nodes check each others’ heartbeats for determining whether given node is still active and connected to cluster. Must be zero for all data nodes or distinct nonzero values for all data nodes; see documentation for further guidance.

- **HostName**: Host name or IP address for this data node.

- **IndexMemory**: Number of bytes on each data node allocated for storing indexes; subject to available system RAM and size of DataMemory.

- **IndexStatAutoCreate**: Enable/disable automatic statistics collection when indexes are created.

- **IndexStatAutoUpdate**: Monitor indexes for changes and trigger automatic statistics updates.

- **IndexStatSaveScale**: Scaling factor used in determining size of stored index statistics.

- **IndexStatSaveSize**: Maximum size in bytes for saved statistics per index.

- **IndexStatTriggerPct**: Threshold percent change in DML operations for index statistics updates. Value is scaled down by IndexStatTriggerScale.

- **IndexStatTriggerScale**: Scale down IndexStatTriggerPct by this amount, multiplied by base 2 logarithm of index size, for a large index. Set to 0 to disable scaling.

- **IndexStatUpdateDelay**: Minimum delay between automatic index statistics updates for a given index. 0 means no delay.

- **InitFragmentLogFiles**: Initialize fragment logfiles (sparse/full).

- **InitialLogFileGroup**: Describes a log file group that is created during an initial start. See documentation for format.

- **InitialNoOfOpenFiles**: Initial number of files open per data node. (One thread is created per file).

- **InitialTablespace**: Describes a tablespace that is created during an initial start. See documentation for format.

- **InsertRecoveryWork**: Percentage of RecoveryWork used for inserted rows; has no effect unless partial local checkpoints are in use.

- **LateAlloc**: Allocate memory after connection to management server has been established.

- **LcpScanProgressTimeout**: Maximum time that local checkpoint fragment scan can be stalled before node is shut down to ensure systemwide LCP progress. Use 0 to disable.

- **LockExecuteThreadToCPU**: A comma-delimited list of CPU IDs.

- **LockMaintThreadsToCPU**: CPU ID indicating which CPU runs maintenance threads.

- **LockPagesInMainMemory**: 0=disable locking, 1=lock after memory allocation, 2=lock before memory allocation.

- **LogLevelCheckpoint**: Log level of local and global checkpoint information printed to stdout.

- **LogLevelCongestion**: Level of congestion information printed to stdout.

- **LogLevelConnection**: Level of node connect/disconnect information printed to stdout.

- **LogLevelError**: Transporter, heartbeat errors printed to stdout.
Overview of NDB Cluster Configuration Parameters, Options, and Variables

- **LogLevelInfo**: Heartbeat and log information printed to stdout.
- **LogLevelNodeRestart**: Level of node restart and node failure information printed to stdout.
- **LogLevelShutdown**: Level of node shutdown information printed to stdout.
- **LogLevelStartup**: Level of node startup information printed to stdout.
- **LogLevelStatistic**: Level of transaction, operation, and transporter information printed to stdout.
- **LongMessageBuffer**: Number of bytes allocated on each data node for internal long messages.
- **MaxAllocate**: Maximum size of allocation to use when allocating memory for tables.
- **MaxBufferedEpochs**: Allowed number of epochs that a subscribing node can lag behind (unprocessed epochs). Exceeding will cause lagging subscribers to be disconnected.
- **MaxBufferedEpochBytes**: Total number of bytes allocated for buffering epochs.
- **MaxDiskDataLatency**: Maximum allowed mean latency of disk access (ms) before starting to abort transactions.
- **MaxDiskWriteSpeed**: Maximum number of bytes per second that can be written by LCP and backup when no restarts are ongoing.
- **MaxDiskWriteSpeedOtherNodeRestart**: Maximum number of bytes per second that can be written by LCP and backup when another node is restarting.
- **MaxDiskWriteSpeedOwnRestart**: Maximum number of bytes per second that can be written by LCP and backup when this node is restarting.
- **MaxFKBuildBatchSize**: Maximum scan batch size to use for building foreign keys. Increasing this value may speed up builds of foreign keys but impacts ongoing traffic as well.
- **MaxDMLOperationsPerTransaction**: Limit size of a transaction; aborts transaction if it requires more than this many DML operations. Set to 0 to disable.
- **MaxLCPStartDelay**: Time in seconds that LCP polls for checkpoint mutex (to allow other data nodes to complete metadata synchronization), before putting itself in lock queue for parallel recovery of table data.
- **MaxNoOfAttributes**: Suggests a total number of attributes stored in database (sum over all tables).
- **MaxNoOfConcurrentIndexOperations**: Total number of index operations that can execute simultaneously on one data node.
- **MaxNoOfConcurrentOperations**: Maximum number of operation records in transaction coordinator.
- **MaxNoOfConcurrentScans**: Maximum number of scans executing concurrently on data node.
- **MaxNoOfConcurrentSubOperations**: Maximum number of concurrent subscriber operations.
- **MaxNoOfConcurrentTransactions**: Maximum number of transactions executing concurrently on this data node, total number of transactions that can be executed concurrently is this value times number of data nodes in cluster.
- **MaxNoOfFiredTriggers**: Total number of triggers that can fire simultaneously on one data node.
- **MaxNoOfLocalOperations**: Maximum number of operation records defined on this data node.
- **MaxNoOfLocalScans**: Maximum number of fragment scans in parallel on this data node.
- **MaxNoOfOpenFiles**: Maximum number of files open per data node. (One thread is created per file).
Overview of NDB Cluster Configuration Parameters, Options, and Variables

- **MaxNoOfOrderedIndexes**: Total number of ordered indexes that can be defined in system.
- **MaxNoOfSavedMessages**: Maximum number of error messages to write in error log and maximum number of trace files to retain.
- **MaxNoOfSubscribers**: Maximum number of subscribers (default 0 = MaxNoOfTables * 2).
- **MaxNoOfSubscriptions**: Maximum number of subscriptions (default 0 = MaxNoOfTables).
- **MaxNoOfTables**: Suggests a total number of NDB tables stored in database.
- **MaxNoOfTriggers**: Total number of triggers that can be defined in system.
- **MaxNoOfUniqueHashIndexes**: Total number of unique hash indexes that can be defined in the system.
- **MaxParallelCopyInstances**: Number of parallel copies during node restarts. Default is 0, which uses number of LDMs on both nodes, to a maximum of 16.
- **MaxParallelScansPerFragment**: Maximum number of parallel scans per fragment. Once this limit is reached, scans are serialized.
- **MaxReorgBuildBatchSize**: Maximum scan batch size to use for reorganization of table partitions. Increasing this value may speed up table partition reorganization but impacts ongoing traffic as well.
- **MaxStartFailRetries**: Maximum retries when data node fails on startup, requires StopOnError = 0. Setting to 0 causes start attempts to continue indefinitely.
- **MaxUIBuildBatchSize**: Maximum scan batch size to use for building unique keys. Increasing this value may speed up builds of unique keys but impacts ongoing traffic as well.
- **MemReportFrequency**: Frequency of memory reports in seconds; 0 = report only when exceeding percentage limits.
- **MinDiskWriteSpeed**: Minimum number of bytes per second that can be written by LCP and backup.
- **MinFreePct**: Percentage of memory resources to keep in reserve for restarts.
- **NodeGroup**: Node group to which data node belongs; used only during initial start of cluster.
- **NodeGroupTransporters**: Number of transporters to use between nodes in same node group.
- **NodeId**: Number uniquely identifying data node among all nodes in cluster.
- **NoOfFragmentLogFiles**: Number of 16 MB redo log files in each of 4 file sets belonging to data node.
- **NoOfReplicas**: Number of copies of all data in database.
- **Numa**: (Linux only; requires libnuma) Controls NUMA support. Setting to 0 permits system to determine use of interleaving by data node process; 1 means that it is determined by data node.
- **ODirect**: Use O_DIRECT file reads and writes when possible.
- **ODirectSyncFlag**: O_DIRECT writes are treated as synchronized writes; ignored when ODirect is not enabled, InitFragmentLogFiles is set to SPARSE, or both.
- **RealtimeScheduler**: When true, data node threads are scheduled as real-time threads. Default is false.
- **RecoveryWork**: Percentage of storage overhead for LCP files: greater value means less work in normal operations, more work during recovery.
- **RedoBuffer**: Number of bytes on each data node allocated for writing redo logs.
• **RedoOverCommitCounter**: When RedoOverCommitLimit has been exceeded this many times, transactions are aborted, and operations are handled as specified by DefaultOperationRedoProblemAction.

• **RedoOverCommitLimit**: Each time that flushing current redo buffer takes longer than this many seconds, number of times that this has happened is compared to RedoOverCommitCounter.

• **ReservedConcurrentIndexOperations**: Number of simultaneous index operations having dedicated resources on one data node.

• **ReservedConcurrentOperations**: Number of simultaneous operations having dedicated resources in transaction coordinators on one data node.

• **ReservedConcurrentScans**: Number of simultaneous scans having dedicated resources on one data node.

• **ReservedConcurrentTransactions**: Number of simultaneous transactions having dedicated resources on one data node.

• **ReservedFiredTriggers**: Number of triggers having dedicated resources on one data node.

• **ReservedLocalScans**: Number of simultaneous fragment scans having dedicated resources on one data node.

• **ReservedTransactionBufferMemory**: Dynamic buffer space (in bytes) for key and attribute data allocated to each data node.

• **RestartOnErrorInsert**: Control type of restart caused by inserting an error (when StopOnError is enabled).

• **SchedulerExecutionTimer**: Number of microseconds to execute in scheduler before sending.

• **SchedulerResponsiveness**: Set NDB scheduler response optimization 0-10; higher values provide better response time but lower throughput.

• **SchedulerSpinTimer**: Number of microseconds to execute in scheduler before sleeping.

• **ServerPort**: Port used to set up transporter for incoming connections from API nodes.

• **SharedGlobalMemory**: Total number of bytes on each data node allocated for any use.

• **SpinMethod**: Determines spin method used by data node; see documentation for details.

• **StartFailRetryDelay**: Delay in seconds after start failure prior to retry; requires StopOnError = 0.

• **StartFailureTimeout**: Milliseconds to wait before terminating. (0=Wait forever).

• **StartNoNodeGroupTimeout**: Time to wait for nodes without a nodegroup before trying to start (0=forever).

• **StartPartialTimeout**: Milliseconds to wait before trying to start without all nodes. (0=Wait forever).

• **StartPartitionedTimeout**: Milliseconds to wait before trying to start partitioned. (0=Wait forever).

• **StartupStatusReportFrequency**: Frequency of status reports during startup.

• **StopOnError**: When set to 0, data node automatically restarts and recovers following node failures.

• **StringMemory**: Default size of string memory (0 to 100 = % of maximum, 101+ = actual bytes).

• **TcpBind_INADDR_ANY**: Bind IP_ADDR_ANY so that connections can be made from anywhere (for autogenerated connections).
Overview of NDB Cluster Configuration Parameters, Options, and Variables

• **TimeBetweenEpochs**: Time between epochs (synchronization used for replication).

• **TimeBetweenEpochsTimeout**: Timeout for time between epochs. Exceeding will cause node shutdown.

• **TimeBetweenGlobalCheckpoints**: Time between group commits of transactions to disk.

• **TimeBetweenGlobalCheckpointsTimeout**: Minimum timeout for group commit of transactions to disk.

• **TimeBetweenInactiveTransactionAbortCheck**: Time between checks for inactive transactions.

• **TimeBetweenLocalCheckpoints**: Time between taking snapshots of database (expressed in base-2 logarithm of bytes).

• **TimeBetweenWatchDogCheck**: Time between execution checks inside a data node.

• **TimeBetweenWatchDogCheckInitial**: Time between execution checks inside a data node (early start phases when memory is allocated).

• **TotalSendBufferMemory**: Total memory to use for all transporter send buffers.

• **TransactionBufferMemory**: Dynamic buffer space (in bytes) for key and attribute data allocated for each data node.

• **TransactionDeadlockDetectionTimeout**: Time transaction can spend executing within a data node. This is the time that transaction coordinator waits for each data node participating in transaction to execute a request. If data node takes more than this amount of time, transaction is aborted.

• **TransactionInactiveTimeout**: Milliseconds that application waits before executing another part of transaction. This is the time transaction coordinator waits for application to execute or send another part (query, statement) of transaction. If application takes too much time, then transaction is aborted. Timeout = 0 means that application never times out.

• **TransactionMemory**: Memory allocated for transactions on each data node.

• **TwoPassInitialNodeRestartCopy**: Copy data in 2 passes during initial node restart, which enables multithreaded building of ordered indexes for such restarts.

• **UndoDataBuffer**: Number of bytes on each data node allocated for writing data undo logs.

• **UndoIndexBuffer**: Number of bytes on each data node allocated for writing index undo logs.

• **UseShm**: Use shared memory connections between this data node and API node also running on this host.

The following parameters are specific to ndbmtd:

• **MaxNoOfExecutionThreads**: For ndbmtd only, specify maximum number of execution threads.

• **NoOfFragmentLogParts**: Number of redo log file groups belonging to this data node.

• **ThreadConfig**: Used for configuration of multithreaded data nodes (ndbmtd). Default is an empty string; see documentation for syntax and other information.

### 22.3.2.2 NDB Cluster Management Node Configuration Parameters

The listing in this section provides information about parameters used in the [ndb_mgmd] or [mgm] section of a config.ini file for configuring NDB Cluster management nodes. For detailed descriptions and other additional information about each of these parameters, see Section 22.3.3.5, “Defining an NDB Cluster Management Server”.

• **ArbitrationDelay**: When asked to arbitrate, arbitrator waits this long before voting (milliseconds).
Overview of NDB Cluster Configuration Parameters, Options, and Variables

• **ArbitrationRank**: If 0, then management node is not arbitrator. Kernel selects arbitrators in order 1, 2.

• **DataDir**: Data directory for this node.

• **ExecuteOnComputer**: String referencing an earlier defined COMPUTER.

• **ExtraSendBufferMemory**: Memory to use for send buffers in addition to any allocated by TotalSendBufferMemory or SendBufferMemory. Default (0) allows up to 16MB.

• **HeartbeatIntervalMgmdMgmd**: Time between management-node-to-management-node heartbeats; connection between management nodes is considered lost after 3 missed heartbeats.

• **HeartbeatThreadPriority**: Set heartbeat thread policy and priority for management nodes; see manual for allowed values.

• **HostName**: Host name or IP address for this management node.

• **Id**: Number identifying management node. Now deprecated; use NodeId instead.

• **LogDestination**: Where to send log messages: console, system log, or specified log file.

• **NodeId**: Number uniquely identifying management node among all nodes in cluster.

• **PortNumber**: Port number to send commands to and fetch configuration from management server.

• **PortNumberStats**: Port number used to get statistical information from a management server.

• **TotalSendBufferMemory**: Total memory to use for all transporter send buffers.

• **wan**: Use WAN TCP setting as default.

**Note**
After making changes in a management node’s configuration, it is necessary to perform a rolling restart of the cluster for the new configuration to take effect. See Section 22.3.3.5, “Defining an NDB Cluster Management Server”, for more information.

To add new management servers to a running NDB Cluster, it is also necessary to perform a rolling restart of all cluster nodes after modifying any existing config.ini files. For more information about issues arising when using multiple management nodes, see Section 22.1.7.10, “Limitations Relating to Multiple NDB Cluster Nodes”.

### 22.3.2.3 NDB Cluster SQL Node and API Node Configuration Parameters

The listing in this section provides information about parameters used in the [mysqld] and [api] sections of a config.ini file for configuring NDB Cluster SQL nodes and API nodes. For detailed descriptions and other additional information about each of these parameters, see Section 22.3.3.7, “Defining SQL and Other API Nodes in an NDB Cluster”.

• **ApiVerbose**: Enable NDB API debugging; for NDB development.

• **ArbitrationDelay**: When asked to arbitrate, arbitrator waits this many milliseconds before voting.

• **ArbitrationRank**: If 0, then API node is not arbitrator. Kernel selects arbitrators in order 1, 2.

• **AutoReconnect**: Specifies whether an API node should reconnect fully when disconnected from cluster.

• **BatchByteSize**: Default batch size in bytes.

• **BatchSize**: Default batch size in number of records.
Overview of NDB Cluster Configuration Parameters, Options, and Variables

- **ConnectBackoffMaxTime**: Specifies longest time in milliseconds (~100ms resolution) to allow between connection attempts to any given data node by this API node. Excludes time elapsed while connection attempts are ongoing, which in worst case can take several seconds. Disable by setting to 0. If no data nodes are currently connected to this API node, StartConnectBackoffMaxTime is used instead.

- **ConnectionMap**: Specifies which data nodes to connect.

- **DefaultHashMapSize**: Set size (in buckets) to use for table hash maps. Three values are supported: 0, 240, and 3840.

- **DefaultOperationRedoProblemAction**: How operations are handled in event that RedoOverCommitCounter is exceeded.

- **ExecuteOnComputer**: String referencing an earlier defined COMPUTER.

- **ExtraSendBufferMemory**: Memory to use for send buffers in addition to any allocated by TotalSendBufferMemory or SendBufferMemory. Default (0) allows up to 16MB.

- **HeartbeatThreadPriority**: Set heartbeat thread policy and priority for API nodes; see manual for allowed values.

- **HostName**: Host name or IP address for this SQL or API node.

- **Id**: Number identifying MySQL server or API node (Id). Now deprecated; use NodeId instead.

- **MaxScanBatchSize**: Maximum collective batch size for one scan.

- **NodeId**: Number uniquely identifying SQL node or API node among all nodes in cluster.

- **StartConnectBackoffMaxTime**: Same as ConnectBackoffMaxTime except that this parameter is used in its place if no data nodes are connected to this API node.

- **TotalSendBufferMemory**: Total memory to use for all transporter send buffers.

- **wan**: Use WAN TCP setting as default.

For a discussion of MySQL server options for NDB Cluster, see MySQL Server Options for NDB Cluster. For information about MySQL server system variables relating to NDB Cluster, see NDB Cluster System Variables.

<table>
<thead>
<tr>
<th>Note</th>
</tr>
</thead>
</table>

To add new SQL or API nodes to the configuration of a running NDB Cluster, it is necessary to perform a rolling restart of all cluster nodes after adding new [mysqld] or [api] sections to the config.ini file (or files, if you are using more than one management server). This must be done before the new SQL or API nodes can connect to the cluster.

It is not necessary to perform any restart of the cluster if new SQL or API nodes can employ previously unused API slots in the cluster configuration to connect to the cluster.

### 22.3.2.4 Other NDB Cluster Configuration Parameters

The listings in this section provide information about parameters used in the [computer], [tcp], and [shm] sections of a config.ini file for configuring NDB Cluster. For detailed descriptions and additional information about individual parameters, see Section 22.3.3.10, “NDB Cluster TCP/IP Connections”, or Section 22.3.3.12, “NDB Cluster Shared-Memory Connections”, as appropriate.

The following parameters apply to the config.ini file's [computer] section:

- **HostName**: Host name or IP address of this computer.
Overview of NDB Cluster Configuration Parameters, Options, and Variables

- **Id**: A unique identifier for this computer.

The following parameters apply to the `config.ini` file's `[tcp]` section:

- **Checksum**: If checksum is enabled, all signals between nodes are checked for errors.
- **Group**: Used for group proximity; smaller value is interpreted as being closer.
- **NodeId1**: ID of node (data node, API node, or management node) on one side of connection.
- **NodeId2**: ID of node (data node, API node, or management node) on one side of connection.
- **NodeIdServer**: Set server side of TCP connection.
- **OverloadLimit**: When more than this many unsent bytes are in send buffer, connection is considered overloaded.
- **PreSendChecksum**: If this parameter and Checksum are both enabled, perform pre-send checksum checks, and check all TCP signals between nodes for errors.
- **Proxy**:
- **ReceiveBufferMemory**: Bytes of buffer for signals received by this node.
- **SendBufferMemory**: Bytes of TCP buffer for signals sent from this node.
- **SendSignalId**: Sends ID in each signal. Used in trace files. Defaults to true in debug builds.
- **TCP_MAXSEG_SIZE**: Value used for TCP_MAXSEG.
- **TCP_RCV_BUF_SIZE**: Value used for SO_RCVBUF.
- **TCP_SND_BUF_SIZE**: Value used for SO_SNDBUF.
- **TcpBind_INADDR_ANY**: Bind INADDRAny instead of host name for server part of connection.

The following parameters apply to the `config.ini` file's `[shm]` section:

- **Checksum**: If checksum is enabled, all signals between nodes are checked for errors.
- **Group**: Used for group proximity; smaller value is interpreted as being closer.
- **NodeId1**: ID of node (data node, API node, or management node) on one side of connection.
- **NodeId2**: ID of node (data node, API node, or management node) on one side of connection.
- **NodeIdServer**: Set server side of SHM connection.
- **OverloadLimit**: When more than this many unsent bytes are in send buffer, connection is considered overloaded.
- **PreSendChecksum**: If this parameter and Checksum are both enabled, perform pre-send checksum checks, and check all SHM signals between nodes for errors.
- **SendBufferMemory**: Bytes in shared memory buffer for signals sent from this node.
- **SendSignalId**: Sends ID in each signal. Used in trace files.
- **ShmKey**: A shared memory key; when set to 1, this is calculated by NDB.
- **ShmSpinTime**: When receiving, number of microseconds to spin before sleeping.
- **ShmSize**: Size of shared memory segment.
- **Signum**: Signal number to be used for signalling.
22.3.2.5 NDB Cluster `mysqld` Option and Variable Reference

The following table provides a list of the command-line options, server and status variables applicable within `mysqld` when it is running as an SQL node in an NDB Cluster. For a table showing all command-line options, server and status variables available for use with `mysqld`, see Section 5.1.4, “Server Option, System Variable, and Status Variable Reference”.

- **Com_show_ndb_status**: Count of SHOW NDB STATUS statements.
- **Handler_discover**: Number of times that tables have been discovered.
- **ndb-batch-size**: Size (in bytes) to use for NDB transaction batches.
- **ndb-blob-read-batch-bytes**: Specifies size in bytes that large BLOB reads should be batched into. 0 = no limit.
- **ndb-blob-write-batch-bytes**: Specifies size in bytes that large BLOB writes should be batched into. 0 = no limit.
- **ndb-cluster-connection-pool**: Number of connections to the cluster used by MySQL.
- **ndb-cluster-connection-pool-nodeids**: Comma-separated list of node IDs for connections to the cluster used by MySQL; the number of nodes in the list must be the same as the value set for --ndb-cluster-connection-pool.
- **ndb-connectstring**: Point to the management server that distributes the cluster configuration.
- **ndb-default-column-format**: Use this value (FIXED or DYNAMIC) by default for COLUMN_FORMAT and ROW_FORMAT options when creating or adding columns to a table.
- **ndb-deferred-constraints**: Specifies that constraint checks on unique indexes (where these are supported) should be deferred until commit time. Not normally needed or used; for testing purposes only.
- **ndb-distribution**: Default distribution for new tables in NDBCLUSTER (KEYHASH or LINHASH, default is KEYHASH).
- **ndb-log-apply-status**: Cause a MySQL server acting as a slave to log mysql.ndb_apply_status updates received from its immediate master in its own binary log, using its own server ID. Effective only if the server is started with the --ndbcluster option.
- **ndb-log-empty-epochs**: When enabled, causes epochs in which there were no changes to be written to the ndb_apply_status and ndb_binlog_index tables, even when --log-slave-updates is enabled.
- **ndb-log-empty-update**: When enabled, causes updates that produced no changes to be written to the ndb_apply_status and ndb_binlog_index tables, even when --log-slave-updates is enabled.
- **ndb-log-exclusive-reads**: Log primary key reads with exclusive locks; allow conflict resolution based on read conflicts.
- **ndb-log-orig**: Log originating server id and epoch in mysql.ndb_binlog_index table.
- **ndb-log-transaction-id**: Write NDB transaction IDs in the binary log. Requires --log-bin-v1-events=OFF.
- **ndb-log-update-as-write**: Toggles logging of updates on the master between updates (OFF) and writes (ON).
- **ndb-mgmd-host**: Set the host (and port, if desired) for connecting to management server.
- **ndb-nodeid**: NDB Cluster node ID for this MySQL server.
• **ndb-transid-mysql-connection-map**: Enable or disable the ndb_transid_mysql_connection_map plugin; that is, enable or disable the INFORMATION_SCHEMA table having that name.

• **ndb-wait-connected**: Time (in seconds) for the MySQL server to wait for connection to cluster management and data nodes before accepting MySQL client connections.

• **ndb-wait-setup**: Time (in seconds) for the MySQL server to wait for NDB engine setup to complete.

• **ndb-allow-copying-alter-table**: Set to OFF to keep ALTER TABLE from using copying operations on NDB tables.

• **Ndb_api_bytes_received_count**: Amount of data (in bytes) received from the data nodes by this MySQL Server (SQL node).

• **Ndb_api_bytes_received_count_session**: Amount of data (in bytes) received from the data nodes in this client session.

• **Ndb_api_bytes_received_count_slave**: Amount of data (in bytes) received from the data nodes by this slave.

• **Ndb_api_bytes_sent_count**: Amount of data (in bytes) sent to the data nodes by this MySQL Server (SQL node).

• **Ndb_api_bytes_sent_count_session**: Amount of data (in bytes) sent to the data nodes in this client session.

• **Ndb_api_bytes_sent_count_slave**: Amount of data (in bytes) sent to the data nodes by this slave.

• **Ndb_api_event_bytes_count**: Number of bytes of events received by this MySQL Server (SQL node).

• **Ndb_api_event_bytes_count_injector**: Number of bytes of events received by the NDB binary log injector thread.

• **Ndb_api_event_data_count**: Number of row change events received by this MySQL Server (SQL node).

• **Ndb_api_event_data_count_injector**: Number of row change events received by the NDB binary log injector thread.

• **Ndb_api_event_nondata_count**: Number of events received, other than row change events, by this MySQL Server (SQL node).

• **Ndb_api_event_nondata_count_injector**: Number of events received, other than row change events, by the NDB binary log injector thread.

• **Ndb_api_pk_op_count**: Number of operations based on or using primary keys by this MySQL Server (SQL node).

• **Ndb_api_pk_op_count_session**: Number of operations based on or using primary keys in this client session.

• **Ndb_api_pk_op_count_slave**: Number of operations based on or using primary keys by this slave.

• **Ndb_api_pruned_scan_count**: Number of scans that have been pruned to a single partition by this MySQL Server (SQL node).

• **Ndb_api_pruned_scan_count_session**: Number of scans that have been pruned to a single partition in this client session.
Overview of NDB Cluster Configuration Parameters, Options, and Variables

- **Ndb_api_pruned_scan_count_slave**: Number of scans that have been pruned to a single partition by this slave.

- **Ndb_api_range_scan_count**: Number of range scans that have been started by this MySQL Server (SQL node).

- **Ndb_api_range_scan_count_session**: Number of range scans that have been started in this client session.

- **Ndb_api_range_scan_count_slave**: Number of range scans that have been started by this slave.

- **Ndb_api_read_row_count**: Total number of rows that have been read by this MySQL Server (SQL node).

- **Ndb_api_read_row_count_session**: Total number of rows that have been read in this client session.

- **Ndb_api_read_row_count_slave**: Total number of rows that have been read by this slave.

- **Ndb_api_scan_batch_count**: Number of batches of rows received by this MySQL Server (SQL node).

- **Ndb_api_scan_batch_count_session**: Number of batches of rows received in this client session.

- **Ndb_api_scan_batch_count_slave**: Number of batches of rows received by this slave.

- **Ndb_api_table_scan_count**: Number of table scans that have been started, including scans of internal tables, by this MySQL Server (SQL node).

- **Ndb_api_table_scan_count_session**: Number of table scans that have been started, including scans of internal tables, in this client session.

- **Ndb_api_table_scan_count_slave**: Number of table scans that have been started, including scans of internal tables, by this slave.

- **Ndb_api_trans_abort_count**: Number of transactions aborted by this MySQL Server (SQL node).

- **Ndb_api_trans_abort_count_session**: Number of transactions aborted in this client session.

- **Ndb_api_trans_abort_count_slave**: Number of transactions aborted by this slave.

- **Ndb_api_trans_close_count**: Number of transactions aborted (may be greater than the sum of TransCommitCount and TransAbortCount) by this MySQL Server (SQL node).

- **Ndb_api_trans_close_count_session**: Number of transactions aborted (may be greater than the sum of TransCommitCount and TransAbortCount) in this client session.

- **Ndb_api_trans_close_count_slave**: Number of transactions aborted (may be greater than the sum of TransCommitCount and TransAbortCount) by this slave.

- **Ndb_api_trans_commit_count**: Number of transactions committed by this MySQL Server (SQL node).

- **Ndb_api_trans_commit_count_session**: Number of transactions committed in this client session.

- **Ndb_api_trans_commit_count_slave**: Number of transactions committed by this slave.

- **Ndb_api_trans_local_read_row_count**: Total number of rows that have been read by this MySQL Server (SQL node).
Overview of NDB Cluster Configuration Parameters, Options, and Variables

- **Ndb_api_trans_local_read_row_count_session**: Total number of rows that have been read in this client session.

- **Ndb_api_trans_local_read_row_count_slave**: Total number of rows that have been read by this slave.

- **Ndb_api_trans_start_count**: Number of transactions started by this MySQL Server (SQL node).

- **Ndb_api_trans_start_count_session**: Number of transactions started in this client session.

- **Ndb_api_trans_start_count_slave**: Number of transactions started by this slave.

- **Ndb_api_uk_op_count**: Number of operations based on or using unique keys by this MySQL Server (SQL node).

- **Ndb_api_uk_op_count_session**: Number of operations based on or using unique keys in this client session.

- **Ndb_api_uk_op_count_slave**: Number of operations based on or using unique keys by this slave.

- **Ndb_api_wait_exec_complete_count**: Number of times thread has been blocked while waiting for execution of an operation to complete by this MySQL Server (SQL node).

- **Ndb_api_wait_exec_complete_count_session**: Number of times thread has been blocked while waiting for execution of an operation to complete in this client session.

- **Ndb_api_wait_exec_complete_count_slave**: Number of times thread has been blocked while waiting for execution of an operation to complete by this slave.

- **Ndb_api_wait_meta_request_count**: Number of times thread has been blocked waiting for a metadata-based signal by this MySQL Server (SQL node).

- **Ndb_api_wait_meta_request_count_session**: Number of times thread has been blocked waiting for a metadata-based signal in this client session.

- **Ndb_api_wait_meta_request_count_slave**: Number of times thread has been blocked waiting for a metadata-based signal by this slave.

- **Ndb_api_wait_nanos_count**: Total time (in nanoseconds) spent waiting for some type of signal from the data nodes by this MySQL Server (SQL node).

- **Ndb_api_wait_nanos_count_session**: Total time (in nanoseconds) spent waiting for some type of signal from the data nodes in this client session.

- **Ndb_api_wait_nanos_count_slave**: Total time (in nanoseconds) spent waiting for some type of signal from the data nodes by this slave.

- **Ndb_api_wait_scan_result_count**: Number of times thread has been blocked while waiting for a scan-based signal by this MySQL Server (SQL node).

- **Ndb_api_wait_scan_result_count_session**: Number of times thread has been blocked while waiting for a scan-based signal in this client session.

- **Ndb_api_wait_scan_result_count_slave**: Number of times thread has been blocked while waiting for a scan-based signal by this slave.

- **ndb_autoincrement_prefetch_sz**: NDB auto-increment prefetch size.

- **ndb_cache_check_time**: Number of milliseconds between checks of cluster SQL nodes made by the MySQL query cache.
• **ndb_clear_apply_status**: Causes RESET SLAVE to clear all rows from the ndb_apply_status table; ON by default.

• **Ndb_cluster_node_id**: If the server is acting as an NDB Cluster node, then the value of this variable is its node ID in the cluster.

• **Ndb_config_from_host**: The host name or IP address of the Cluster management server. Formerly Ndb_connected_host.

• **Ndb_config_from_port**: The port for connecting to Cluster management server. Formerly Ndb_connected_port.

• **Ndb_conflict_fn_epoch**: Number of rows that have been found in conflict by the NDB$EPOCH() conflict detection function.

• **Ndb_conflict_fn_epoch2**: Number of rows that have been found in conflict by the NDB $EPOCH2() conflict detection function.

• **Ndb_conflict_fn_epoch2_trans**: Number of rows that have been found in conflict by the NDB $EPOCH2_TRANS() conflict detection function.

• **Ndb_conflict_fn_epoch_trans**: Number of rows that have been found in conflict by the NDB $EPOCH_TRANS() conflict detection function.

• **Ndb_conflict_fn_max**: If the server is part of an NDB Cluster involved in cluster replication, the value of this variable indicates the number of times that conflict resolution based on "greater timestamp wins" has been applied.

• **Ndb_conflict_fn_old**: If the server is part of an NDB Cluster involved in cluster replication, the value of this variable indicates the number of times that "same timestamp wins" conflict resolution has been applied.

• **Ndb_conflict_last_conflict_epoch**: Most recent NDB epoch on this slave in which a conflict was detected.

• **Ndb_conflict_last_stable_epoch**: Number of rows found to be in conflict by a transactional conflict function.

• **Ndb_conflict_reflected_op_discard_count**: Number of reflected operations that were not applied due an error during execution.

• **Ndb_conflict_reflected_op_prepare_count**: Number of reflected operations received that have been prepared for execution.

• **Ndb_conflict_refresh_op_count**: Number of refresh operations that have been prepared.

• **Ndb_conflict_trans_conflict_commit_count**: Number of epoch transactions committed after requiring transactional conflict handling.

• **Ndb_conflict_trans_detect_iter_count**: Number of internal iterations required to commit an epoch transaction. Should be (slightly) greater than or equal to Ndb_conflict_trans_conflict_commit_count.

• **Ndb_conflict_trans_reject_count**: Number of transactions rejected after being found in conflict by a transactional conflict function.

• **Ndb_conflict_trans_row_conflict_count**: Number of rows found in conflict by a transactional conflict function. Includes Ndb_conflict_trans_row_conflict_count and any rows included in or dependent on conflicting transactions.

• **Ndb_conflict_trans_row_reject_count**: Total number of rows realigned after being found in conflict by a transactional conflict function. Includes Ndb_conflict_trans_row_conflict_count and any rows included in or dependent on conflicting transactions.
Overview of NDB Cluster Configuration Parameters, Options, and Variables

- **ndb_data_node_neighbour**: Specifies cluster data node "closest" to this MySQL Server, for transaction hinting and fully replicated tables.

- **ndb_default_column_format**: Sets default row format and column format (FIXED or DYNAMIC) used for new NDB tables.

- **ndb_deferred_constraints**: Specifies that constraint checks should be deferred (where these are supported). Not normally needed or used; for testing purposes only.

- **ndb_dbg_check_shares**: Check for any lingering shares (debug builds only).

- **ndb-schema-dist-timeout**: How long to wait before detecting timeout during schema distribution.

- **ndb_distribution**: Default distribution for new tables in NDBCLUSTER (KEYHASH or LINHASH, default is KEYHASH).

- **Ndb_epoch_delete_delete_count**: Number of delete-delete conflicts detected (delete operation is applied, but row does not exist).

- **ndb_eventbuffer_free_percent**: Percentage of free memory that should be available in event buffer before resumption of buffering, after reaching limit set by ndb_eventbuffer_max_alloc.

- **ndb_eventbuffer_max_alloc**: Maximum memory that can be allocated for buffering events by the NDB API. Defaults to 0 (no limit).

- **Ndb_execute_count**: Provides the number of round trips to the NDB kernel made by operations.

- **ndb_extra_logging**: Controls logging of NDB Cluster schema, connection, and data distribution events in the MySQL error log.

- **ndb_force_send**: Forces sending of buffers to NDB immediately, without waiting for other threads.

- **ndb_fully_replicated**: Whether new NDB tables are fully replicated.

- **ndb_index_stat_enable**: Use NDB index statistics in query optimization.

- **ndb_index_stat_option**: Comma-separated list of tunable options for NDB index statistics; the list should contain no spaces.

- **ndb_join_pushdown**: Enables pushing down of joins to data nodes.

- **Ndb_last_commit_epoch_server**: Epoch most recently committed by NDB.

- **Ndb_last_commit_epoch_session**: Epoch most recently committed by this NDB client.

- **ndb_log_apply_status**: Whether or not a MySQL server acting as a slave logs mysql.ndb_apply_status updates received from its immediate master in its own binary log, using its own server ID.

- **ndb_log_bin**: Write updates to NDB tables in the binary log. Effective only if binary logging is enabled with --log-bin.

- **ndb_log_binlog_index**: Insert mapping between epochs and binary log positions into the ndb_binlog_index table. Defaults to ON. Effective only if binary logging is enabled on the server.

- **ndb_log_empty_epochs**: When enabled, epochs in which there were no changes are written to the ndb_apply_status and ndb_binlog_index tables, even when log_slave_updates is enabled.

- **ndb_log_empty_update**: When enabled, updates which produce no changes are written to the ndb_apply_status and ndb_binlog_index tables, even when log_slave_updates is enabled.

- **ndb_log_exclusive_reads**: Log primary key reads with exclusive locks; allow conflict resolution based on read conflicts.
• **ndb_log_orig**: Whether the id and epoch of the originating server are recorded in the mysql.ndb_binlog_index table. Set using the --ndb-log-orig option when starting mysqld.

• **ndb_log_transaction_id**: Whether NDB transaction IDs are written into the binary log (Read-only.).

• **ndb-log-update-minimal**: Log updates in a minimal format.

• **ndb-log-updated-only**: Log complete rows (ON) or updates only (OFF).

• **ndb_metadata_check**: Enable auto-detection of NDB metadata changes with respect to MySQL data dictionary; enabled by default.

• **Ndb_metadata_blacklist_size**: Number of NDB metadata objects that NDB binlog thread has failed to synchronize.

• **ndb_metadata_check_interval**: Interval in seconds to perform check for NDB metadata changes with respect to MySQL data dictionary.

• **Ndb_metadata_detected_count**: Number of times NDB metadata change monitor thread has detected changes.

• **Ndb_metadata_synced_count**: Number of NDB metadata objects which have been synchronized.

• **Ndb_number_of_data_nodes**: If the server is part of an NDB Cluster, the value of this variable is the number of data nodes in the cluster.

• **ndb-optimization-delay**: Sets the number of milliseconds to wait between processing sets of rows by OPTIMIZE TABLE on NDB tables.

• **ndb_optimized_node_selection**: Determines how an SQL node chooses a cluster data node to use as transaction coordinator.

• **Ndb_pruned_scan_count**: Number of scans executed by NDB since the cluster was last started where partition pruning could be used.

• **Ndb_pushed_queries_defined**: Number of joins that API nodes have attempted to push down to the data nodes.

• **Ndb_pushed_queries_dropped**: Number of joins that API nodes have tried to push down, but failed.

• **Ndb_pushed_queries_executed**: Number of joins successfully pushed down and executed on the data nodes.

• **Ndb_pushed_reads**: Number of reads executed on the data nodes by pushed-down joins.

• **ndb_read_backup**: Enable read from any replica for all NDB tables; use NDB_TABLE=READ_BACKUP=0|1 with CREATE TABLE or ALTER TABLE to enable or disable for individual NDB tables.

• **ndb_recv_thread_activation_threshold**: Activation threshold when receive thread takes over the polling of the cluster connection (measured in concurrently active threads).

• **ndb_recv_thread_cpu_mask**: CPU mask for locking receiver threads to specific CPUs; specified as hexadecimal. See documentation for details.

• **ndb_report_thresh_binlog_epoch_slip**: NDB 7.5.4 and later: Threshold for number of epochs completely buffered, but not yet consumed by binlog injector thread which when exceeded generates BUFFERED_EPOCHS_OVER_THRESHOLD event buffer status message; prior to NDB 7.5.4: Threshold for number of epochs to lag behind before reporting binary log status.
Overview of NDB Cluster Configuration Parameters, Options, and Variables

- **ndb_report_thresh_binlog_mem_usage**: This is a threshold on the percentage of free memory remaining before reporting binary log status.

- **ndb_row_checksum**: When enabled, set row checksums; enabled by default.

- **Ndb_scan_count**: The total number of scans executed by NDB since the cluster was last started.

- **ndb_schema_dist_lock_wait_timeout**: Time during schema distribution to wait for lock before returning error.

- **ndb_schema_dist_timeout**: Time to wait before detecting timeout during schema distribution.

- **ndb_schema_dist_upgrade_allowed**: Allow schema distribution table upgrade when connecting to NDB.

- **ndb_show_foreign_key_mock_tables**: Show the mock tables used to support foreign_key_checks=0.

- **ndb_slave_conflict_role**: Role for slave to play in conflict detection and resolution. Value is one of PRIMARY, SECONDARY, PASS, or NONE (default). Can be changed only when slave SQL thread is stopped. See documentation for further information.

- **Ndb_slave_max_replicated_epoch**: The most recently committed NDB epoch on this slave. When this value is greater than or equal to Ndb_conflict_last_conflict_epoch, no conflicts have yet been detected.

- **Ndb_system_name**: Configured cluster system name; empty if server not connected to NDB.

- **ndb_table_no_logging**: NDB tables created when this setting is enabled are not checkpointed to disk (although table schema files are created). The setting in effect when the table is created with or altered to use NDDBCCLUSTER persists for the lifetime of the table.

- **ndb_table_temporary**: NDB tables are not persistent on disk: no schema files are created and the tables are not logged.

- **Ndb_trans_hint_count_session**: Number of transactions using hints that have been started in this session.

- **ndb_use_copying_alter_table**: Use copying ALTER TABLE operations in NDB Cluster.

- **ndb_use_exact_count**: Use exact row count when planning queries.

- **ndb_use_transactions**: Forces NDB to use a count of records during SELECT COUNT(*) query planning to speed up this type of query.

- **ndb_version**: Shows build and NDB engine version as an integer.

- **ndb_version_string**: Shows build information including NDB engine version in ndb-x.y.z format.

- **ndbcluster**: Enable NDB Cluster (if this version of MySQL supports it). Disabled by --skip-ndbcluster.

- **ndbinfo**: Enable ndbinfo plugin, if supported.

- **ndbinfo_database**: The name used for the NDB information database; read only.

- **ndbinfo_max_bytes**: Used for debugging only.

- **ndbinfo_max_rows**: Used for debugging only.

- **ndbinfo_offline**: Put the ndbinfo database into offline mode, in which no rows are returned from tables or views.

- **ndbinfo_show_hidden**: Whether to show ndbinfo internal base tables in the mysql client. The default is OFF.
• **ndbinfo_table_prefix**: The prefix to use for naming ndbinfo internal base tables.

• **ndbinfo_version**: The version of the ndbinfo engine; read only.

• **server_id_bits**: Sets the number of least significant bits in the server_id actually used for identifying the server, permitting NDB API applications to store application data in the most significant bits. server_id must be less than 2 to the power of this value.

• **skip-ndbcluster**: Disable the NDB Cluster storage engine.

• **slave_allow_batching**: Turns update batching on and off for a replication slave.

• **transaction_allow_batching**: Allows batching of statements within a transaction. Disable AUTOCOMMIT to use.

### 22.3.3 NDB Cluster Configuration Files

Configuring NDB Cluster requires working with two files:

• **my.cnf**: Specifies options for all NDB Cluster executables. This file, with which you should be familiar with from previous work with MySQL, must be accessible by each executable running in the cluster.

• **config.ini**: This file, sometimes known as the *global configuration file*, is read only by the NDB Cluster management server, which then distributes the information contained therein to all processes participating in the cluster. *config.ini* contains a description of each node involved in the cluster. This includes configuration parameters for data nodes and configuration parameters for connections between all nodes in the cluster. For a quick reference to the sections that can appear in this file, and what sorts of configuration parameters may be placed in each section, see [Sections of the config.ini File](#).

#### Caching of configuration data

NDB uses *stateful configuration*. Rather than reading the global configuration file every time the management server is restarted, the management server caches the configuration the first time it is started, and thereafter, the global configuration file is read only when one of the following conditions is true:

- **The management server is started using the --initial option.** When `--initial` is used, the global configuration file is re-read, any existing cache files are deleted, and the management server creates a new configuration cache.

- **The management server is started using the --reload option.** The `--reload` option causes the management server to compare its cache with the global configuration file. If they differ, the management server creates a new configuration cache; any existing configuration cache is preserved, but not used. If the management server's cache and the global configuration file contain the same configuration data, then the existing cache is used, and no new cache is created.

- **The management server is started using --config-cache=FALSE.** This disables `--config-cache` (enabled by default), and can be used to force the management server to bypass configuration caching altogether. In this case, the management server ignores any configuration files that may be present, always reading its configuration data from the config.ini file instead.

- **No configuration cache is found.** In this case, the management server reads the global configuration file and creates a cache containing the same configuration data as found in the file.

#### Configuration cache files

The management server by default creates configuration cache files in a directory named `mysql-cluster` in the MySQL installation directory. (If you build NDB Cluster from source on a Unix system, the default location is `/usr/local/mysql-cluster`.) This can be overridden at runtime by starting the management server with the `--configdir` option. Configuration cache files are binary files named according to the pattern `ndb_node_id_config.bin.seq_id`, where `node_id` is the management server's node ID in the cluster, and `seq_id` is a cache identifier. Cache files are numbered sequentially using `seq_id`, in the order in which they are created. The management server uses the latest cache file as determined by the `seq_id`. 

3615
Note
It is possible to roll back to a previous configuration by deleting later configuration cache files, or by renaming an earlier cache file so that it has a higher `seq_id`. However, since configuration cache files are written in a binary format, you should not attempt to edit their contents by hand.

For more information about the `--configdir`, `--config-cache`, `--initial`, and `--reload` options for the NDB Cluster management server, see Section 22.4.4, “ndb_mgmd — The NDB Cluster Management Server Daemon”.

We are continuously making improvements in Cluster configuration and attempting to simplify this process. Although we strive to maintain backward compatibility, there may be times when introduce an incompatible change. In such cases we will try to let Cluster users know in advance if a change is not backward compatible. If you find such a change and we have not documented it, please report it in the MySQL bugs database using the instructions given in Section 1.7, “How to Report Bugs or Problems”.

### 22.3.3.1 NDB Cluster Configuration: Basic Example

To support NDB Cluster, you will need to update `my.cnf` as shown in the following example. You may also specify these parameters on the command line when invoking the executables.

```sh
# my.cnf
# example additions to my.cnf for NDB Cluster
# (valid in MySQL 8.0)
# enable ndbcluster storage engine, and provide connection string for
# management server host (default port is 1186)
[mysqld]
ndbcluster
ndb-connectstring=ndb_mgmd.mysql.com

# provide connection string for management server host (default port: 1186)
[ndbd]
connect-string=ndb_mgmd.mysql.com

# provide connection string for management server host (default port: 1186)
[ndb_mgm]
connect-string=ndb_mgmd.mysql.com

# provide location of cluster configuration file
[ndb_mgmd]
config-file=/etc/config.ini

(For more information on connection strings, see Section 22.3.3.3, “NDB Cluster Connection Strings”.)

# my.cnf
# example additions to my.cnf for NDB Cluster
# (will work on all versions)
# enable ndbcluster storage engine, and provide connection string for management
# server host to the default port 1186
[mysqld]
ndbcluster
ndb-connectstring=ndb_mgmd.mysql.com:1186

Important
Once you have started a `mysqld` process with the `NDBCLUSTER` and `ndb-connectstring` parameters in the `[mysqld]` in the `my.cnf` file as shown
You may also use a separate [mysql_cluster] section in the cluster my.cnf file for settings to be read and used by all executables:

```
# cluster-specific settings
[mysql_cluster]
ndb-connectstring=ndb_mgmd.mysql.com:1186
```

For additional NDB variables that can be set in the my.cnf file, see NDB Cluster System Variables.

The NDB Cluster global configuration file is by convention named config.ini (but this is not required). If needed, it is read by ndb_mgmd at startup and can be placed in any location that can be read by it. The location and name of the configuration are specified using --config-file=path_name with ndb_mgmd on the command line. This option has no default value, and is ignored if ndb_mgmd uses the configuration cache.

The global configuration file for NDB Cluster uses INI format, which consists of sections preceded by section headings (surrounded by square brackets), followed by the appropriate parameter names and values. One deviation from the standard INI format is that the parameter name and value can be separated by a colon (:) as well as the equal sign (=); however, the equal sign is preferred. Another deviation is that sections are not uniquely identified by section name. Instead, unique sections (such as two different nodes of the same type) are identified by a unique ID specified as a parameter within the section.

Default values are defined for most parameters, and can also be specified in config.ini. To create a default value section, simply add the word default to the section name. For example, an [ndbd] section contains parameters that apply to a particular data node, whereas an [ndbd default] section contains parameters that apply to all data nodes. Suppose that all data nodes should use the same data memory size. To configure them all, create an [ndbd default] section that contains a DataMemory line to specify the data memory size.

If used, the [ndbd default] section must precede any [ndbd] sections in the configuration file. This is also true for default sections of any other type.

**Note**

In some older releases of NDB Cluster, there was no default value for NoOfReplicas, which always had to be specified explicitly in the [ndbd default] section. Although this parameter now has a default value of 2, which is the recommended setting in most common usage scenarios, it is still recommended practice to set this parameter explicitly.

The global configuration file must define the computers and nodes involved in the cluster and on which computers these nodes are located. An example of a simple configuration file for a cluster consisting of one management server, two data nodes and two MySQL servers is shown here:

```
# file "config.ini" - 2 data nodes and 2 SQL nodes
# This file is placed in the startup directory of ndb_mgmd (the
# management server)
# The first MySQL Server can be started from any host. The second
# can be started only on the host mysql_5.mysql.com

[ndbd default]
NoOfReplicas= 2
DataDir= /var/lib/mysql-cluster

[ndbd]
Hostname= ndbd_2.mysql.com
DataDir= /var/lib/mysql-cluster
```

```
NDB Cluster Configuration Files

[ndbd]
HostName= ndbd_3.mysql.com

[mysqld]

[mysqld]
HostName= mysqld_5.mysql.com

Note
The preceding example is intended as a minimal starting configuration for purposes of familiarization with NDB Cluster, and is almost certain not to be sufficient for production settings. See Section 22.3.3.2, “Recommended Starting Configuration for NDB Cluster”, which provides a more complete example starting configuration.

Each node has its own section in the config.ini file. For example, this cluster has two data nodes, so the preceding configuration file contains two [ndbd] sections defining these nodes.

Note
Do not place comments on the same line as a section heading in the config.ini file; this causes the management server not to start because it cannot parse the configuration file in such cases.

Sections of the config.ini File

There are six different sections that you can use in the config.ini configuration file, as described in the following list:

• [computer]: Defines cluster hosts. This is not required to configure a viable NDB Cluster, but may be used as a convenience when setting up a large cluster. See Section 22.3.3.4, “Defining Computers in an NDB Cluster”, for more information.

• [ndbd]: Defines a cluster data node (ndbd process). See Section 22.3.3.6, “Defining NDB Cluster Data Nodes”, for details.

• [mysqld]: Defines the cluster’s MySQL server nodes (also called SQL or API nodes). For a discussion of SQL node configuration, see Section 22.3.3.7, “Defining SQL and Other API Nodes in an NDB Cluster”.

• [mgm] or [ndb_mgmd]: Defines a cluster management server (MGM) node. For information concerning the configuration of management nodes, see Section 22.3.3.5, “Defining an NDB Cluster Management Server”.

• [tcp]: Defines a TCP/IP connection between cluster nodes, with TCP/IP being the default connection protocol. Normally, [tcp] or [tcp default] sections are not required to set up an NDB Cluster, as the cluster handles this automatically; however, it may be necessary in some situations to override the defaults provided by the cluster. See Section 22.3.3.10, “NDB Cluster TCP/IP Connections”, for information about available TCP/IP configuration parameters and how to use them. (You may also find Section 22.3.3.11, “NDB Cluster TCP/IP Connections Using Direct Connections” to be of interest in some cases.)

• [shm]: Defines shared-memory connections between nodes. In MySQL 8.0, it is enabled by default, but should still be considered experimental. For a discussion of SHM interconnects, see Section 22.3.3.12, “NDB Cluster Shared-Memory Connections”.

• [sci]: Defines Scalable Coherent Interface connections between cluster data nodes. Not supported in NDB 8.0.

You can define default values for each section. If used, a default section should come before any other sections of that type. For example, an [ndbd default] section should appear in the configuration file before any [ndbd] sections.
NDB Cluster parameter names are case-insensitive, unless specified in MySQL Server my.cnf or my.ini files.

22.3.3.2 Recommended Starting Configuration for NDB Cluster

Achieving the best performance from an NDB Cluster depends on a number of factors including the following:

- NDB Cluster software version
- Numbers of data nodes and SQL nodes
- Hardware
- Operating system
- Amount of data to be stored
- Size and type of load under which the cluster is to operate

Therefore, obtaining an optimum configuration is likely to be an iterative process, the outcome of which can vary widely with the specifics of each NDB Cluster deployment. Changes in configuration are also likely to be indicated when changes are made in the platform on which the cluster is run, or in applications that use the NDB Cluster’s data. For these reasons, it is not possible to offer a single configuration that is ideal for all usage scenarios. However, in this section, we provide a recommended base configuration.

Starting config.ini file. The following config.ini file is a recommended starting point for configuring a cluster running NDB Cluster 8.0:

```ini
# TCP PARAMETERS
[tcp default] SendBufferMemory=2M
ReceiveBufferMemory=2M

# Increasing the sizes of these 2 buffers beyond the default values helps prevent bottlenecks due to slow disk I/O.

# MANAGEMENT NODE PARAMETERS
[ndb_mgmd default]
DataDir = path/to/management/server/data/directory

# It is possible to use a different data directory for each management server, but for ease of administration it is preferable to be consistent.
[ndb_mgmd]
HostName = management-server-A-hostname
NodeId = management-server-A-nodeid

[ndb_mgmd]
HostName = management-server-B-hostname
NodeId = management-server-B-nodeid

# Using 2 management servers helps guarantee that there is always an arbitrator in the event of network partitioning, and so is recommended for high availability. Each management server must be identified by a HostName. You may for the sake of convenience specify a NodeId for any management server, although one will be allocated for it automatically; if you do so, it must be in the range 1-255 inclusive and must be unique among all IDs specified for cluster nodes.

# DATA NODE PARAMETERS
[ndbd default]
NoOfReplicas = 2
```

3619
NDB Cluster Configuration Files

# Using 2 replicas is recommended to guarantee availability of data;
# using only 1 replica does not provide any redundancy, which means
# that the failure of a single data node causes the entire cluster to
# shut down. As of NDB 8.0.19, it is also possible (but not required) to
# use more than 2 replicas, although 2 replicas are sufficient to provide
# high availability.

LockPagesInMainMemory=1

# On Linux and Solaris systems, setting this parameter locks data node
# processes into memory. Doing so prevents them from swapping to disk,
# which can severely degrade cluster performance.

DataMemory=3456M

# The value provided for DataMemory assumes 4 GB RAM
# per data node. However, for best results, you should first calculate
# the memory that would be used based on the data you actually plan to
# store (you may find the ndb_size.pl utility helpful in estimating
# this), then allow an extra 20% over the calculated values. Naturally,
# you should ensure that each data node host has at least as much
# physical memory as the sum of these two values.

ODirect=1

# Enabling this parameter causes NDBCLUSTER to try using O_DIRECT
# writes for local checkpoints and redo logs; this can reduce load on
# CPUs. We recommend doing so when using NDB Cluster on systems running
# Linux kernel 2.6 or later.

NoOfFragmentLogFiles=300
DataDir=path/to/data/node/data/directory
MaxNoOfConcurrentOperations=100000

SchedulerSpinTimer=400
SchedulerExecutionTimer=100
RealTimeScheduler=1

# Setting these parameters allows you to take advantage of real-time scheduling
# of NDB threads to achieve increased throughput when using ndbd. They
# are not needed when using ndbmtd; in particular, you should not set
# RealTimeScheduler for ndbmtd data nodes.

TimeBetweenGlobalCheckpoints=1000
TimeBetweenEpochs=200
RedoBuffer=32M

# CompressedLCP=1
# CompressedBackup=1
# Enabling CompressedLCP and CompressedBackup causes, respectively, local
# checkpoint files and backup files to be compressed, which can result in a space
# savings of up to 50% over noncompressed LCPs and backups.

# MaxNoOfLocalScans=64
MaxNoOfSizeTables=1024
MaxNoOfOrderedIndexes=256

[ndbd]
HostName=data-node-A-hostname
# NodeId=data-node-A-nodeid

LockExecuteThreadToCPU=1
LockMaintThreadsToCPU=0

# On systems with multiple CPUs, these parameters can be used to lock NDBCLUSTER
# threads to specific CPUs

[ndbd]
HostName=data-node-B-hostname
# NodeId=data-node-B-nodeid

LockExecuteThreadToCPU=1
LockMaintThreadsToCPU=0
You must have an [ndbd] section for every data node in the cluster; each of these sections must include a HostName. Each section may optionally include a NodeId for convenience, but in most cases, it is sufficient to allow the cluster to allocate node IDs dynamically. If you do specify the node ID for a data node, it must be in the range 1 to 144 inclusive and must be unique among all IDs specified for cluster nodes. (Previous to NDB 8.0.18, this range was 1 to 48 inclusive.)

SQL NODE / API NODE PARAMETERS

[mysqld]
HostName=sql-node-A-hostname
NodeId=sql-node-A-nodeid

[mysqld]

Each API or SQL node that connects to the cluster requires a [mysqld] or [api] section of its own. Each such section defines a connection "slot"; you should have at least as many of these sections in the config.ini file as the total number of API nodes and SQL nodes that you wish to have connected to the cluster at any given time. There is no performance or other penalty for having extra slots available in case you find later that you want or need more API or SQL nodes to connect to the cluster at the same time.

If no HostName is specified for a given [mysqld] or [api] section, then any API or SQL node may use that slot to connect to the cluster. You may wish to use an explicit HostName for one connection slot to guarantee that an API or SQL node from that host can always connect to the cluster. If you wish to prevent API or SQL nodes from connecting from other than a desired host or hosts, then use a HostName for every [mysqld] or [api] section in the config.ini file. You can if you wish define a node ID (NodeId parameter) for any API or SQL node, but this is not necessary; if you do so, it must be in the range 1 to 255 inclusive and must be unique among all IDs specified for cluster nodes.

Recommended my.cnf options for SQL nodes. MySQL Servers acting as NDB Cluster SQL nodes must always be started with the --ndbcluster and --ndb-connectstring options, either on the command line or in my.cnf. In addition, set the following options for all mysqld processes in the cluster, unless your setup requires otherwise:

- --ndb-use-exact-count=0
- --ndb-index-stat-enable=0
- --ndb-force-send=1
- --optimizer-switch=engine_condition_pushdown=on

22.3.3.3 NDB Cluster Connection Strings

With the exception of the NDB Cluster management server (ndb_mgmd), each node that is part of an NDB Cluster requires a connection string that points to the management server's location. This connection string is used in establishing a connection to the management server as well as in performing other tasks depending on the node's role in the cluster. The syntax for a connection string is as follows:

```
[nodeid=node_id, ]host-definition[, host-definition[, ...]]
```

```
host-definition:
    host_name[:port_number]
```

`node_id` is an integer greater than or equal to 1 which identifies a node in config.ini.host_name is a string representing a valid Internet host name or IP address. `port_number` is an integer referring to a TCP/IP port number.
**NDB Cluster Configuration Files**

**example 1 (long):** "nodeid=2,myhost1:1100,myhost2:1100,198.51.100.3:1200"

**example 2 (short):** "myhost1"

**localhost:1186** is used as the default connection string value if none is provided. If **port_num** is omitted from the connection string, the default port is 1186. This port should always be available on the network because it has been assigned by IANA for this purpose (see [http://www.iana.org/assignments/port-numbers](http://www.iana.org/assignments/port-numbers) for details).

By listing multiple host definitions, it is possible to designate several redundant management servers. An NDB Cluster data or API node attempts to contact successive management servers on each host in the order specified, until a successful connection has been established.

It is also possible to specify in a connection string one or more bind addresses to be used by nodes having multiple network interfaces for connecting to management servers. A bind address consists of a hostname or network address and an optional port number. This enhanced syntax for connection strings is shown here:

```
[nodeid=node_id, ]
[bind-address=host-definition, ]
  host-definition[; bind-address=host-definition]
  host-definition[; bind-address=host-definition]
[, ...]
host-definition:
  host_name:[port_number]
```

If a single bind address is used in the connection string prior to specifying any management hosts, then this address is used as the default for connecting to any of them (unless overridden for a given management server; see later in this section for an example). For example, the following connection string causes the node to use **198.51.100.242** regardless of the management server to which it connects:

```
bind-address=198.51.100.242, poseidon:1186, perch:1186
```

If a bind address is specified *following* a management host definition, then it is used only for connecting to that management node. Consider the following connection string:

```
poseidon:1186;bind-address=localhost, perch:1186;bind-address=198.51.100.242
```

In this case, the node uses **localhost** to connect to the management server running on the host named **poseidon** and **198.51.100.242** to connect to the management server running on the host named **perch**.

You can specify a default bind address and then override this default for one or more specific management hosts. In the following example, **localhost** is used for connecting to the management server running on host **poseidon**; since **198.51.100.242** is specified first (before any management server definitions), it is the default bind address and so is used for connecting to the management servers on hosts **perch** and **orca**:

```
bind-address=198.51.100.242,poseidon:1186;bind-address=localhost,perch:1186,orca:2200
```

There are a number of different ways to specify the connection string:

- Each executable has its own command-line option which enables specifying the management server at startup. (See the documentation for the respective executable.)

- It is also possible to set the connection string for all nodes in the cluster at once by placing it in a [mysql_cluster] section in the management server's **my.cnf** file.

- For backward compatibility, two other options are available, using the same syntax:
  1. Set the **NDB_CONNECTSTRING** environment variable to contain the connection string.
2. Write the connection string for each executable into a text file named `Ndb.cfg` and place this file in the executable’s startup directory.

However, these are now deprecated and should not be used for new installations.

The recommended method for specifying the connection string is to set it on the command line or in the `my.cnf` file for each executable.

### 22.3.3.4 Defining Computers in an NDB Cluster

The `[computer]` section has no real significance other than serving as a way to avoid the need of defining host names for each node in the system. All parameters mentioned here are required.

- **Id**

  Table 22.7 This table provides type and value information for the Id computer configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>string</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td></td>
</tr>
<tr>
<td>Restart Type</td>
<td>IS</td>
</tr>
</tbody>
</table>

This is a unique identifier, used to refer to the host computer elsewhere in the configuration file.

**Important**

The computer ID is *not* the same as the node ID used for a management, API, or data node. Unlike the case with node IDs, you cannot use `NodeId` in place of `Id` in the `[computer]` section of the `config.ini` file.

- **HostName**

  Table 22.8 This table provides type and value information for the HostName computer configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>name or IP address</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td></td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This is the computer’s hostname or IP address.

**Restart types.** Information about the restart types used by the parameter descriptions in this section is shown in the following table:

#### Table 22.9 NDB Cluster restart types

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Restart Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>N</td>
<td>Node</td>
<td>The parameter can be updated using a rolling restart (see Section 22.5.5, “Performing a Rolling Restart of an NDB Cluster”)</td>
</tr>
</tbody>
</table>
### 22.3.3.5 Defining an NDB Cluster Management Server

The `[ndb_mgmd]` section is used to configure the behavior of the management server. If multiple management servers are employed, you can specify parameters common to all of them in an `[ndb_mgmd default]` section. `[mgm]` and `[mgm default]` are older aliases for these, supported for backward compatibility.

All parameters in the following list are optional and assume their default values if omitted.

![Note]

If neither the `ExecuteOnComputer` nor the `HostName` parameter is present, the default value `localhost` will be assumed for both.

- **Id**

  Table 22.10 This table provides type and value information for the Id management node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 255</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>IS</td>
</tr>
</tbody>
</table>

Each node in the cluster has a unique identity. For a management node, this is represented by an integer value in the range 1 to 255, inclusive. This ID is used by all internal cluster messages for addressing the node, and so must be unique for each NDB Cluster node, regardless of the type of node.

![Note]

Data node IDs must be less than 145. If you plan to deploy a large number of data nodes, it is a good idea to limit the node IDs for management nodes (and API nodes) to values greater than 144. (In NDB 8.0.17 and earlier, the maximum value for a data node ID was 48.)

The use of the `Id` parameter for identifying management nodes is deprecated in favor of `NodeId`. Although `Id` continues to be supported for backward compatibility, it now generates a warning and is subject to removal in a future version of NDB Cluster.

- **NodeId**

  Table 22.11 This table provides type and value information for the NodeId management node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
</tbody>
</table>
Each node in the cluster has a unique identity. For a management node, this is represented by an integer value in the range 1 to 255 inclusive. This ID is used by all internal cluster messages for addressing the node, and so must be unique for each NDB Cluster node, regardless of the type of node.

**Note**

As of NDB 8.0.18, data node IDs must be less than 145. (Previously, this was less than 49.) If you plan to deploy a large number of data nodes, it is a good idea to limit the node IDs for management nodes (and API nodes) to values greater than 144.

**NodeId** is the preferred parameter name to use when identifying management nodes. Although the older **Id** continues to be supported for backward compatibility, it is now deprecated and generates a warning when used; it is also subject to removal in a future NDB Cluster release.

* **ExecuteOnComputer**

  Table 22.12 This table provides type and value information for the ExecuteOnComputer management node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>name</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>S</td>
</tr>
</tbody>
</table>

This refers to the **Id** set for one of the computers defined in a [computer] section of the config.ini file.

**Important**

This parameter is deprecated, and is subject to removal in a future release. Use the **HostName** parameter instead.

* **PortNumber**

  Table 22.13 This table provides type and value information for the PortNumber management node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>1186</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 64K</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>S</td>
</tr>
</tbody>
</table>

This is the port number on which the management server listens for configuration requests and management commands.

* **HostName**
### Table 22.14 This table provides type and value information for the HostName management node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>name or IP address</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Specifying this parameter defines the hostname of the computer on which the management node is to reside. To specify a hostname other than `localhost`, either this parameter or `ExecuteOnComputer` is required.

- **LocationDomainId**

### Table 22.15 This table provides type and value information for the LocationDomainId management node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 16</td>
</tr>
<tr>
<td>Restart Type</td>
<td>S</td>
</tr>
</tbody>
</table>

Assigns a management node to a specific availability domain (also known as an availability zone) within a cloud. By informing `NDB` which nodes are in which availability domains, performance can be improved in a cloud environment in the following ways:

- If requested data is not found on the same node, reads can be directed to another node in the same availability domain.

- Communication between nodes in different availability domains are guaranteed to use `NDB` transporters' WAN support without any further manual intervention.

- The transporter's group number can be based on which availability domain is used, such that also SQL and other API nodes communicate with local data nodes in the same availability domain whenever possible.

- The arbitrator can be selected from an availability domain in which no data nodes are present, or, if no such availability domain can be found, from a third availability domain.

`LocationDomainId` takes an integer value between 0 and 16 inclusive, with 0 being the default; using 0 is the same as leaving the parameter unset.

- **LogDestination**

### Table 22.16 This table provides type and value information for the LogDestination management node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>{CONSOLE</td>
</tr>
</tbody>
</table>
This parameter specifies where to send cluster logging information. There are three options in this regard—CONSOLE, SYSLOG, and FILE—with FILE being the default:

- **CONSOLE** outputs the log to `stdout`:
  ```
  CONSOLE
  ```

- **SYSLOG** sends the log to a syslog facility, possible values being one of `auth`, `authpriv`, `cron`, `daemon`, `ftp`, `kern`, `lpr`, `mail`, `news`, `syslog`, `user`, `uucp`, `local0`, `local1`, `local2`, `local3`, `local4`, `local5`, `local6`, or `local7`.

  ```
  SYSLOG:facility=syslog
  ```

- **FILE** pipes the cluster log output to a regular file on the same machine. The following values can be specified:
  - **filename**: The name of the log file.
    
    The default log file name used in such cases is `ndb_nodeid_cluster.log`.
  - **maxsize**: The maximum size (in bytes) to which the file can grow before logging rolls over to a new file. When this occurs, the old log file is renamed by appending `.N` to the file name, where `N` is the next number not yet used with this name.
  - **maxfiles**: The maximum number of log files.

  ```
  FILE:filename=cluster.log,maxsize=1000000,maxfiles=6
  ```

  The default value for the **FILE** parameter is
  ```
  FILE:filename=ndb_node_id_cluster.log,maxsize=1000000,maxfiles=6, where node_id is the ID of the node.
  ```

  It is possible to specify multiple log destinations separated by semicolons as shown here:

  ```
  CONSOLE;SYSLOG:facility=local0;FILE:filename=/var/log/mgmd
  ```

- **ArbitrationRank**

### Table 22.17

This table provides type and value information for the ArbitrationRank management node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>0-2</td>
</tr>
<tr>
<td>Default</td>
<td>1</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 2</td>
</tr>
</tbody>
</table>
This parameter is used to define which nodes can act as arbitrators. Only management nodes and SQL nodes can be arbitrators. `ArbitrationRank` can take one of the following values:

- **0**: The node will never be used as an arbitrator.
- **1**: The node has high priority; that is, it will be preferred as an arbitrator over low-priority nodes.
- **2**: Indicates a low-priority node which be used as an arbitrator only if a node with a higher priority is not available for that purpose.

Normally, the management server should be configured as an arbitrator by setting its `ArbitrationRank` to 1 (the default for management nodes) and those for all SQL nodes to 0 (the default for SQL nodes).

You can disable arbitration completely either by setting `ArbitrationRank` to 0 on all management and SQL nodes, or by setting the `Arbitration` parameter in the `[ndbd default]` section of the `config.ini` global configuration file. Setting `Arbitration` causes any settings for `ArbitrationRank` to be disregarded.

- **ArbitrationDelay**

Table 22.18 This table provides type and value information for the ArbitrationDelay management node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>

<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

An integer value which causes the management server's responses to arbitration requests to be delayed by that number of milliseconds. By default, this value is 0; it is normally not necessary to change it.

- **DataDir**

Table 22.19 This table provides type and value information for the DataDir management node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>path</td>
</tr>
<tr>
<td>Default</td>
<td>.</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This specifies the directory where output files from the management server will be placed. These files include cluster log files, process output files, and the daemon's process ID (PID) file. (For log files, this location can be overridden by setting the `FILE` parameter for `LogDestination` as discussed previously in this section.)

The default value for this parameter is the directory in which `ndb_mgmd` is located.
• **PortNumberStats**

Table 22.20 This table provides type and value information for the PortNumberStats management node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 64K</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter specifies the port number used to obtain statistical information from an NDB Cluster management server. It has no default value.

• **Wan**

Table 22.21 This table provides type and value information for the wan management node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Use WAN TCP setting as default.

• **HeartbeatThreadPriority**

Table 22.22 This table provides type and value information for the HeartbeatThreadPriority management node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>string</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>S</td>
</tr>
</tbody>
</table>

Set the scheduling policy and priority of heartbeat threads for management and API nodes.

The syntax for setting this parameter is shown here:

```
HeartbeatThreadPriority = policy[, priority]
policy:
  (FIFO | RR)
```

When setting this parameter, you must specify a policy. This is one of **FIFO** (first in, first out) or **RR** (round robin). The policy value is followed optionally by the priority (an integer).
- **ExtraSendBufferMemory**

  Table 22.23 This table provides type and value information for the ExtraSendBufferMemory management node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 32G</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter specifies the amount of transporter send buffer memory to allocate in addition to any that has been set using `TotalSendBufferMemory`, `SendBufferMemory`, or both.

- **TotalSendBufferMemory**

  Table 22.24 This table provides type and value information for the TotalSendBufferMemory management node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>256K - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter is used to determine the total amount of memory to allocate on this node for shared send buffer memory among all configured transporters.

If this parameter is set, its minimum permitted value is 256KB; 0 indicates that the parameter has not been set. For more detailed information, see Section 22.3.3.14, "Configuring NDB Cluster Send Buffer Parameters".

- **HeartbeatIntervalMgmdMgmd**

  Table 22.25 This table provides type and value information for the HeartbeatIntervalMgmdMgmd management node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>1500</td>
</tr>
<tr>
<td>Range</td>
<td>100 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Specify the interval between heartbeat messages used to determine whether another management node is on contact with this one. The management node waits after 3 of these intervals to declare the connection dead; thus, the default setting of 1500 milliseconds causes the management node to wait for approximately 1600 ms before timing out.

**Note**

After making changes in a management node's configuration, it is necessary to perform a rolling restart of the cluster for the new configuration to take effect.
To add new management servers to a running NDB Cluster, it is also necessary to perform a rolling restart of all cluster nodes after modifying any existing `config.ini` files. For more information about issues arising when using multiple management nodes, see Section 22.1.7.10, “Limitations Relating to Multiple NDB Cluster Nodes”.

### Restart types

Information about the restart types used by the parameter descriptions in this section is shown in the following table:

**Table 22.26 NDB Cluster restart types**

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Restart Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>N</td>

<tr>
<td>S</td>
<td>System</td>
<td>All cluster nodes must be shut down completely, then restarted, to effect a change in this parameter</td>
</tr>
<tr>
<td>I</td>
<td>Initial</td>
<td>Data nodes must be restarted using the <code>--initial</code> option</td>
</tr>
</tbody>
</table>

#### 22.3.3.6 Defining NDB Cluster Data Nodes

The `ndbd` and `ndbd default` sections are used to configure the behavior of the cluster’s data nodes.

`[ndbd]` and `ndbd default` are always used as the section names whether you are using `ndbd` or `ndbmtd` binaries for the data node processes.

There are many parameters which control buffer sizes, pool sizes, timeouts, and so forth. The only mandatory parameter is either one of `ExecuteOnComputer` or `HostName`; this must be defined in the local `[ndbd]` section.

The parameter `NoOfReplicas` should be defined in the `ndbd default` section, as it is common to all Cluster data nodes. It is not strictly necessary to set `NoOfReplicas`, but it is good practice to set it explicitly.

Most data node parameters are set in the `ndbd default` section. Only those parameters explicitly stated as being able to set local values are permitted to be changed in the `[ndbd]` section. Where present, `HostName`, `NodeId` and `ExecuteOnComputer` must be defined in the local `[ndbd]` section, and not in any other section of `config.ini`. In other words, settings for these parameters are specific to one data node.

For those parameters affecting memory usage or buffer sizes, it is possible to use `K`, `M`, or `G` as a suffix to indicate units of 1024, 1024×1024, or 1024×1024×1024. (For example, `100K` means 100 × 1024 = 102400.)

Parameter names and values are case-insensitive, unless used in a MySQL Server `my.cnf` or `my.ini` file, in which case they are case sensitive.

Information about configuration parameters specific to NDB Cluster Disk Data tables can be found later in this section (see Disk Data Configuration Parameters).

All of these parameters also apply to `ndbmtd` (the multithreaded version of `ndbd`). Three additional data node configuration parameters—`MaxNoOfExecutionThreads`, `ThreadConfig`, and `NoOfFragmentLogParts`—apply to `ndbmtd` only; these have no effect when used with `ndbd`. For more information, see Multi-Threading Configuration Parameters (ndbmtd). See also Section 22.4.3, “ndbmtd — The NDB Cluster Data Node Daemon (Multi-Threaded)”.

3631
Identifying data nodes. The NodeId or Id value (that is, the data node identifier) can be allocated on the command line when the node is started or in the configuration file.

- **NodeId**

  Table 22.27 This table provides type and value information for the NodeId data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 48</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>IS</td>
</tr>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.18</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 144</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>IS</td>
</tr>
</tbody>
</table>

A unique node ID is used as the node’s address for all cluster internal messages. For data nodes, this is an integer in the range 1 to 144 inclusive. (In NDB 8.0.17 and earlier, this was 1 to 48 inclusive.) Each node in the cluster must have a unique identifier.

NodeId is the only supported parameter name to use when identifying data nodes.

- **ExecuteOnComputer**

  Table 22.28 This table provides type and value information for the ExecuteOnComputer data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>name</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>S</td>
</tr>
</tbody>
</table>

This refers to the Id set for one of the computers defined in a [computer] section.

⚠️ Important

This parameter is deprecated, and is subject to removal in a future release. Use the HostName parameter instead.

- **HostName**

  Table 22.29 This table provides type and value information for the HostName data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>name or IP address</td>
</tr>
<tr>
<td>Default</td>
<td>localhost</td>
</tr>
</tbody>
</table>
Specifying this parameter defines the hostname of the computer on which the data node is to reside. To specify a hostname other than *localhost*, either this parameter or *ExecuteOnComputer* is required.

**ServerPort**

Table 22.30 This table provides type and value information for the ServerPort data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 64K</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>S</td>
</tr>
</tbody>
</table>

Each node in the cluster uses a port to connect to other nodes. By default, this port is allocated dynamically in such a way as to ensure that no two nodes on the same host computer receive the same port number, so it should normally not be necessary to specify a value for this parameter.

However, if you need to be able to open specific ports in a firewall to permit communication between data nodes and API nodes (including SQL nodes), you can set this parameter to the number of the desired port in an [*ndbd*] section or (if you need to do this for multiple data nodes) the [*ndbd default*] section of the *config.ini* file, and then open the port having that number for incoming connections from SQL nodes, API nodes, or both.

**Note**

Connections from data nodes to management nodes is done using the *ndb_mgmd* management port (the management server's *PortNumber*) so outgoing connections to that port from any data nodes should always be permitted.

**TcpBind_INADDR_ANY**

Setting this parameter to *TRUE* or 1 binds *IP_ADDR_ANY* so that connections can be made from anywhere (for autogenerated connections). The default is *FALSE* (0).

**NodeGroup**

Table 22.31 This table provides type and value information for the NodeGroup data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td></td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 65536</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>IS</td>
</tr>
</tbody>
</table>

This parameter can be used to assign a data node to a specific node group. It is read only when the cluster is started for the first time, and cannot be used to reassign a data node to a different node.
group online. It is generally not desirable to use this parameter in the [ndbd default] section of the config.ini file, and care must be taken not to assign nodes to node groups in such a way that an invalid numbers of nodes are assigned to any node groups.

The NodeGroup parameter is chiefly intended for use in adding a new node group to a running NDB Cluster without having to perform a rolling restart. For this purpose, you should set it to 65536 (the maximum value). You are not required to set a NodeGroup value for all cluster data nodes, only for those nodes which are to be started and added to the cluster as a new node group at a later time. For more information, see Section 22.5.15.3, “Adding NDB Cluster Data Nodes Online: Detailed Example”.

- **LocationDomainId**

  Table 22.32 This table provides type and value information for the LocationDomainId data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 16</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>S</td>
</tr>
</tbody>
</table>

Assigns a data node to a specific availability domain (also known as an availability zone) within a cloud. By informing NDB which nodes are in which availability domains, performance can be improved in a cloud environment in the following ways:

- If requested data is not found on the same node, reads can be directed to another node in the same availability domain.

- Communication between nodes in different availability domains are guaranteed to use NDB transporters' WAN support without any further manual intervention.

- The transporter's group number can be based on which availability domain is used, such that also SQL and other API nodes communicate with local data nodes in the same availability domain whenever possible.

- The arbitrator can be selected from an availability domain in which no data nodes are present, or, if no such availability domain can be found, from a third availability domain.

  LocationDomainId takes an integer value between 0 and 16 inclusive, with 0 being the default; using 0 is the same as leaving the parameter unset.

- **NoOfReplicas**

  Table 22.33 This table provides type and value information for the NoOfReplicas data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>2</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 2</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>IS</td>
</tr>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.19</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
</tbody>
</table>
This global parameter can be set only in the `[ndbd default]` section, and defines the number of replicas for each table stored in the cluster. This parameter also specifies the size of node groups. A node group is a set of nodes all storing the same information.

Node groups are formed implicitly. The first node group is formed by the set of data nodes with the lowest node IDs, the next node group by the set of the next lowest node identities, and so on. By way of example, assume that we have 4 data nodes and that `NoOfReplicas` is set to 2. The four data nodes have node IDs 2, 3, 4 and 5. Then the first node group is formed from nodes 2 and 3, and the second node group by nodes 4 and 5. It is important to configure the cluster in such a manner that nodes in the same node groups are not placed on the same computer because a single hardware failure would cause the entire cluster to fail.

If no node IDs are provided, the order of the data nodes will be the determining factor for the node group. Whether or not explicit assignments are made, they can be viewed in the output of the management client’s `SHOW` command.

The default value for `NoOfReplicas` is 2. This is the recommended value for most production environments, and prior to NDB 8.0.18, it was the maximum value supported. Beginning with NDB 8.0.19, setting this parameter’s value to 3 or 4 is fully tested and supported in production.

**Warning**

Setting `NoOfReplicas` to 1 means that there is only a single copy of all Cluster data; in this case, the loss of a single data node causes the cluster to fail because there are no additional copies of the data stored by that node.

The value for this parameter must divide evenly into the number of data nodes in the cluster. For example, if there are two data nodes, then `NoOfReplicas` must be equal to either 1 or 2, since 2/3 and 2/4 both yield fractional values; if there are four data nodes, then `NoOfReplicas` must be equal to 1, 2, or 4.

- **DataDir**

  **Table 22.34** This table provides type and value information for the DataDir data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>path</td>
</tr>
<tr>
<td>Default</td>
<td>.</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td><strong>IN</strong></td>
</tr>
</tbody>
</table>

This parameter specifies the directory where trace files, log files, pid files and error logs are placed.

The default is the data node process working directory.
• **FileSystemPath**

Table 22.35 This table provides type and value information for the FileSystemPath data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>path</td>
</tr>
<tr>
<td>Default</td>
<td>DataDir</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>IN</td>
</tr>
</tbody>
</table>

This parameter specifies the directory where all files created for metadata, REDO logs, UNDO logs (for Disk Data tables), and data files are placed. The default is the directory specified by `DataDir`.

**Note**

This directory must exist before the `ndbd` process is initiated.

The recommended directory hierarchy for NDB Cluster includes `/var/lib/mysql-cluster`, under which a directory for the node's file system is created. The name of this subdirectory contains the node ID. For example, if the node ID is 2, this subdirectory is named `ndb_2_fs`.

• **BackupDataDir**

Table 22.36 This table provides type and value information for the BackupDataDir data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>path</td>
</tr>
<tr>
<td>Default</td>
<td>FileSystemPath</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>IN</td>
</tr>
</tbody>
</table>

This parameter specifies the directory in which backups are placed.

**Important**

The string `/BACKUP` is always appended to this value. For example, if you set the value of `BackupDataDir` to `/var/lib/cluster-data`, then all backups are stored under `/var/lib/cluster-data/BACKUP`. This also means that the effective default backup location is the directory named `BACKUP` under the location specified by the `FileSystemPath` parameter.

**Data Memory, Index Memory, and String Memory**

`DataMemory` and `IndexMemory` are `[ndbd]` parameters specifying the size of memory segments used to store the actual records and their indexes. In setting values for these, it is important to understand how `DataMemory` is used, as it usually needs to be updated to reflect actual usage by the cluster.

**Note**

`IndexMemory` is deprecated, and subject to removal in a future version of NDB Cluster. See the descriptions that follow for further information.
Table 22.37 This table provides type and value information for the DataMemory data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>

</tr>
<tr>
<td>Default</td>
<td>98M</td>
</tr>
<tr>
<td>Range</td>
<td>1M - 16T</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter defines the amount of space (in bytes) available for storing database records. The entire amount specified by this value is allocated in memory, so it is extremely important that the machine has sufficient physical memory to accommodate it.

The memory allocated by DataMemory is used to store both the actual records and indexes. There is a 16-byte overhead on each record; an additional amount for each record is incurred because it is stored in a 32KB page with 128 byte page overhead (see below). There is also a small amount wasted per page due to the fact that each record is stored in only one page.

For variable-size table attributes, the data is stored on separate data pages, allocated from DataMemory. Variable-length records use a fixed-size part with an extra overhead of 4 bytes to reference the variable-size part. The variable-size part has 2 bytes overhead plus 2 bytes per attribute.

As of NDB 8.0.18, the maximum record size is 30000 bytes. Previously, this was 14000 bytes.

Resources assigned to DataMemory are used for storing all data and indexes. (Any memory configured as IndexMemory is automatically added to that used by DataMemory to form a common resource pool.)

Currently, NDB Cluster can use a maximum of 512 MB for hash indexes per partition, which means in some cases it is possible to get Table is full errors in MySQL client applications even when ndb_mgm -e "ALL REPORT MEMORYUSAGE" shows significant free DataMemory. This can also pose a problem with data node restarts on nodes that are heavily loaded with data.

You can control the number of partitions per local data manager for a given table by setting the NDB_TABLE option PARTITION_BALANCE to one of the values FOR_RA_BY_LDM, FOR_RA_BY_LDM_X_2, FOR_RA_BY_LDM_X_3, or FOR_RA_BY_LDM_X_4, for 1, 2, 3, or 4 partitions per LDM, respectively, when creating the table (see Section 13.1.20.10, “Setting NDB_TABLE Options”).

Note

In previous versions of NDB Cluster it was possible to create extra partitions for NDB Cluster tables and thus have more memory available for hash indexes by using the MAX_ROWS option for CREATE TABLE. While still
supported for backward compatibility, using `MAX_ROWS` for this purpose is deprecated; you should use `PARTITION_BALANCE` instead.

You can also use the `MinFreePct` configuration parameter to help avoid problems with node restarts.

The memory space allocated by `DataMemory` consists of 32KB pages, which are allocated to table fragments. Each table is normally partitioned into the same number of fragments as there are data nodes in the cluster. Thus, for each node, there are the same number of fragments as are set in `NoOfReplicas`.

Once a page has been allocated, it is currently not possible to return it to the pool of free pages, except by deleting the table. (This also means that `DataMemory` pages, once allocated to a given table, cannot be used by other tables.) Performing a data node recovery also compresses the partition because all records are inserted into empty partitions from other live nodes.

The `DataMemory` memory space also contains UNDO information: For each update, a copy of the unaltered record is allocated in the `DataMemory`. There is also a reference to each copy in the ordered table indexes. Unique hash indexes are updated only when the unique index columns are updated, in which case a new entry in the index table is inserted and the old entry is deleted upon commit. For this reason, it is also necessary to allocate enough memory to handle the largest transactions performed by applications using the cluster. In any case, performing a few large transactions holds no advantage over using many smaller ones, for the following reasons:

- Large transactions are not any faster than smaller ones
- Large transactions increase the number of operations that are lost and must be repeated in event of transaction failure
- Large transactions use more memory

The default value for `DataMemory` in NDB 8.0 is 98MB. The minimum value is 1MB. There is no maximum size, but in reality the maximum size has to be adapted so that the process does not start swapping when the limit is reached. This limit is determined by the amount of physical RAM available on the machine and by the amount of memory that the operating system may commit to any one process. 32-bit operating systems are generally limited to 2−4GB per process; 64-bit operating systems can use more. For large databases, it may be preferable to use a 64-bit operating system for this reason.

- `IndexMemory`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>1M - 1T</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

The `IndexMemory` parameter is deprecated (and subject to future removal); any memory assigned to `IndexMemory` is allocated instead to the same pool as `DataMemory`, which is solely responsible for all resources needed for storing data and indexes in memory. In NDB 8.0, the use of `IndexMemory` in the cluster configuration file triggers a warning from the management server.

You can estimate the size of a hash index using this formula:

\[
\text{size} = (\text{fragments} \times 32K) + (\text{rows} \times 18)
\]
fragments is the number of fragments, replicas is the number of replicas (normally 2), and rows is the number of rows. If a table has one million rows, 8 fragments, and 2 replicas, the expected index memory usage is calculated as shown here:

\[
\text{expected index memory usage} = \left(\frac{8 \cdot 32K + (1000000 \cdot 18)}{2}\right) \cdot 2 = \left(\frac{262144 + 18000000}{2}\right)
\]

\[
= \frac{18262144}{2} = 36524288 \text{ bytes} = \sim 35\text{MB}
\]

Index statistics for ordered indexes (when these are enabled) are stored in the `mysql.ndb_index_stat_sample` table. Since this table has a hash index, this adds to index memory usage. An upper bound to the number of rows for a given ordered index can be calculated as follows:

\[
\text{sample size} = \text{key size} + ((\text{key attributes} + 1) \cdot 4)
\]

\[
\text{sample rows} = \frac{\text{IndexStatSaveSize} \cdot ((0.01 \cdot \text{IndexStatSaveScale} \cdot \log_2(\text{rows} \cdot \text{sample size})) + 1)}{\text{sample size}}
\]

In the preceding formula, key size is the size of the ordered index key in bytes, key attributes is the number of attributes in the ordered index key, and rows is the number of rows in the base table.

Assume that table `t1` has 1 million rows and an ordered index named `ix1` on two four-byte integers. Assume in addition that `IndexStatSaveSize` and `IndexStatSaveScale` are set to their default values (32K and 100, respectively). Using the previous 2 formulas, we can calculate as follows:

\[
\text{sample size} = 8 + ((1 + 2) \cdot 4) = 20 \text{ bytes}
\]

\[
\text{sample rows} = \frac{32K \cdot ((0.01 \cdot 100 \cdot \log_2(1000000 \cdot 20)) + 1)}{20}
\]

\[
= \frac{32768 \cdot (1 \cdot -16.811) + 1}{20}
\]

\[
= \frac{32768 \cdot -17.811}{20}
\]

\[
= -29182 \text{ rows}
\]

The expected index memory usage is thus \(2 \cdot 18 \cdot 29182 = \sim 1050550\) bytes.

In NDB 8.0, the minimum and default value for this parameter is 0 (zero).

- **StringMemory**

  Table 22.39 This table provides type and value information for the StringMemory data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>% or bytes</td>
</tr>
<tr>
<td>Default</td>
<td>25</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

This parameter determines how much memory is allocated for strings such as table names, and is specified in an `[ndbd]` or `[ndbd default]` section of the `config.ini` file. A value between 0 and 100 inclusive is interpreted as a percent of the maximum default value, which is calculated based on a number of factors including the number of tables, maximum table name size, maximum size of `.FRM` files, `MaxNoOfTriggers`, maximum column name size, and maximum default column value.

A value greater than 100 is interpreted as a number of bytes.
The default value is 25—that is, 25 percent of the default maximum.

Under most circumstances, the default value should be sufficient, but when you have a great many NDB tables (1000 or more), it is possible to get Error 773 Out of string memory, please modify StringMemory config parameter: Permanent error: Schema error, in which case you should increase this value. 25 (25 percent) is not excessive, and should prevent this error from recurring in all but the most extreme conditions.

The following example illustrates how memory is used for a table. Consider this table definition:

```sql
CREATE TABLE example (  
a INT NOT NULL,  
b INT NOT NULL,  
c INT NOT NULL,  
PRIMARY KEY(a),  
UNIQUE(b)  
) ENGINE=NDBCLUSTER;
```

For each record, there are 12 bytes of data plus 12 bytes overhead. Having no nullable columns saves 4 bytes of overhead. In addition, we have two ordered indexes on columns `a` and `b` consuming roughly 10 bytes each per record. There is a primary key hash index on the base table using roughly 29 bytes per record. The unique constraint is implemented by a separate table with `b` as primary key and `a` as a column. This other table consumes an additional 29 bytes of index memory per record in the `example` table as well 8 bytes of record data plus 12 bytes of overhead.

Thus, for one million records, we need 58MB for index memory to handle the hash indexes for the primary key and the unique constraint. We also need 64MB for the records of the base table and the unique index table, plus the two ordered index tables.

You can see that hash indexes takes up a fair amount of memory space; however, they provide very fast access to the data in return. They are also used in NDB Cluster to handle uniqueness constraints.

Currently, the only partitioning algorithm is hashing and ordered indexes are local to each node. Thus, ordered indexes cannot be used to handle uniqueness constraints in the general case.

An important point for both `IndexMemory` and `DataMemory` is that the total database size is the sum of all data memory and all index memory for each node group. Each node group is used to store replicated information, so if there are four nodes with two replicas, there will be two node groups. Thus, the total data memory available is $2 \times \text{DataMemory}$ for each data node.

It is highly recommended that `DataMemory` and `IndexMemory` be set to the same values for all nodes. Data distribution is even over all nodes in the cluster, so the maximum amount of space available for any node can be no greater than that of the smallest node in the cluster.

`DataMemory` can be changed, but decreasing it can be risky; doing so can easily lead to a node or even an entire NDB Cluster that is unable to restart due to there being insufficient memory space. Increasing these values should be acceptable, but it is recommended that such upgrades are performed in the same manner as a software upgrade, beginning with an update of the configuration file, and then restarting the management server followed by restarting each data node in turn.

**MinFreePct.** A proportion (5% by default) of data node resources including `DataMemory` is kept in reserve to insure that the data node does not exhaust its memory when performing a restart. This can be adjusted using the `MinFreePct` data node configuration parameter (default 5).

**Table 22.40** This table provides type and value information for the `MinFreePct` data node configuration parameter

</tbody>
</table>

Updates do not increase the amount of index memory used. Inserts take effect immediately; however, rows are not actually deleted until the transaction is committed.

**Transaction parameters.** The next few [ndbd] parameters that we discuss are important because they affect the number of parallel transactions and the sizes of transactions that can be handled by the system. `MaxNoOfConcurrentTransactions` sets the number of parallel transactions possible in a node. `MaxNoOfConcurrentOperations` sets the number of records that can be in update phase or locked simultaneously.

Both of these parameters (especially `MaxNoOfConcurrentOperations`) are likely targets for users setting specific values and not using the default value. The default value is set for systems using small transactions, to ensure that these do not use excessive memory.

`MaxDMLOperationsPerTransaction` sets the maximum number of DML operations that can be performed in a given transaction.

- `MaxNoOfConcurrentTransactions`

Table 22.41 This table provides type and value information for the `MaxNoOfConcurrentTransactions` data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td>Range</td>
<td>32 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Each cluster data node requires a transaction record for each active transaction in the cluster. The task of coordinating transactions is distributed among all of the data nodes. The total number of transaction records in the cluster is the number of transactions in any given node times the number of nodes in the cluster.

Transaction records are allocated to individual MySQL servers. Each connection to a MySQL server requires at least one transaction record, plus an additional transaction object per table accessed by that connection. This means that a reasonable minimum for the total number of transactions in the cluster can be expressed as

\[
\text{TotalNoOfConcurrentTransactions} = (\text{maximum number of tables accessed in any single transaction} + 1) \times \text{number of SQL nodes}
\]

Suppose that there are 10 SQL nodes using the cluster. A single join involving 10 tables requires 11 transaction records; if there are 10 such joins in a transaction, then 10 * 11 = 110 transaction records are required for this transaction, per MySQL server, or 110 * 10 = 1100 transaction records total. Each data node can be expected to handle `TotalNoOfConcurrentTransactions` / number of data nodes. For an NDB Cluster having 4 data nodes, this would mean setting `MaxNoOfConcurrentTransactions` on each data node to 1100 / 4 = 275. In addition, you should provide for failure recovery by ensuring that a single node group can accommodate all concurrent transactions; in other words, that each data node's `MaxNoOfConcurrentTransactions` is sufficient to cover a number of transactions equal to `TotalNoOfConcurrentTransactions` / number of node groups. If this cluster has a single node group, then `MaxNoOfConcurrentTransactions` should be set to 1100 (the same as the total number of concurrent transactions for the entire cluster).
In addition, each transaction involves at least one operation; for this reason, the value set for `MaxNoOfConcurrentTransactions` should always be no more than the value of `MaxNoOfConcurrentOperations`.

This parameter must be set to the same value for all cluster data nodes. This is due to the fact that, when a data node fails, the oldest surviving node re-creates the transaction state of all transactions that were ongoing in the failed node.

It is possible to change this value using a rolling restart, but the amount of traffic on the cluster must be such that no more transactions occur than the lower of the old and new levels while this is taking place.

The default value is 4096.

- `MaxNoOfConcurrentOperations`

Table 22.42 This table provides type and value information for the `MaxNoOfConcurrentOperations` data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>32K</td>
</tr>
<tr>
<td>Range</td>
<td>32 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

It is a good idea to adjust the value of this parameter according to the size and number of transactions. When performing transactions which involve only a few operations and records, the default value for this parameter is usually sufficient. Performing large transactions involving many records usually requires that you increase its value.

Records are kept for each transaction updating cluster data, both in the transaction coordinator and in the nodes where the actual updates are performed. These records contain state information needed to find UNDO records for rollback, lock queues, and other purposes.

This parameter should be set at a minimum to the number of records to be updated simultaneously in transactions, divided by the number of cluster data nodes. For example, in a cluster which has four data nodes and which is expected to handle one million concurrent updates using transactions, you should set this value to 1000000 / 4 = 250000. To help provide resiliency against failures, it is suggested that you set this parameter to a value that is high enough to permit an individual data node to handle the load for its node group. In other words, you should set the value equal to \( \frac{\text{total number of concurrent operations}}{\text{number of node groups}} \). (In the case where there
is a single node group, this is the same as the total number of concurrent operations for the entire cluster.)

Because each transaction always involves at least one operation, the value of MaxNoOfConcurrentOperations should always be greater than or equal to the value of MaxNoOfConcurrentTransactions.

Read queries which set locks also cause operation records to be created. Some extra space is allocated within individual nodes to accommodate cases where the distribution is not perfect over the nodes.

When queries make use of the unique hash index, there are actually two operation records used per record in the transaction. The first record represents the read in the index table and the second handles the operation on the base table.

The default value is 32768.

This parameter actually handles two values that can be configured separately. The first of these specifies how many operation records are to be placed with the transaction coordinator. The second part specifies how many operation records are to be local to the database.

A very large transaction performed on an eight-node cluster requires as many operation records in the transaction coordinator as there are reads, updates, and deletes involved in the transaction. However, the operation records of the are spread over all eight nodes. Thus, if it is necessary to configure the system for one very large transaction, it is a good idea to configure the two parts separately. MaxNoOfConcurrentOperations will always be used to calculate the number of operation records in the transaction coordinator portion of the node.

It is also important to have an idea of the memory requirements for operation records. These consume about 1KB per record.

- **MaxNoOfLocalOperations**

Table 22.43 This table provides type and value information for the MaxNoOfLocalOperations data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>UNDEFINED</td>
</tr>
<tr>
<td>Range</td>
<td>32 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

By default, this parameter is calculated as 1.1 × MaxNoOfConcurrentOperations. This fits systems with many simultaneous transactions, none of them being very large. If there is a need to handle one very large transaction at a time and there are many nodes, it is a good idea to override the default value by explicitly specifying this parameter.

This parameter is deprecated as of NDB 8.0.19, and is subject to removal in a future NDB Cluster release. In addition, this parameter is incompatible with the TransactionMemory parameter; if you try to set values for both parameters in the cluster configuration file (config.ini), the management server refuses to start.
NDB Cluster Configuration Files

- **MaxDMLOperationsPerTransaction**

  Table 22.44 This table provides type and value information for the MaxDMLOperationsPerTransaction data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>operations (DML)</td>
</tr>
<tr>
<td>Default</td>
<td>4294967295</td>
</tr>
<tr>
<td>Range</td>
<td>32 - 4294967295</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

  This parameter limits the size of a transaction. The transaction is aborted if it requires more than this many DML operations. The minimum number of operations per transaction is 32; however, you can set `MaxDMLOperationsPerTransaction` to 0 to disable any limitation on the number of DML operations per transaction. The maximum (and default) is 4294967295.

  The value of this parameter cannot exceed that set for `MaxNoOfConcurrentOperations`.

  **Transaction temporary storage.** The next set of `[ndbd]` parameters is used to determine temporary storage when executing a statement that is part of a Cluster transaction. All records are released when the statement is completed and the cluster is waiting for the commit or rollback.

  The default values for these parameters are adequate for most situations. However, users with a need to support transactions involving large numbers of rows or operations may need to increase these values to enable better parallelism in the system, whereas users whose applications require relatively small transactions can decrease the values to save memory.

- **MaxNoOfConcurrentIndexOperations**

  Table 22.45 This table provides type and value information for the MaxNoOfConcurrentIndexOperations data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>8K</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

  For queries using a unique hash index, another temporary set of operation records is used during a query's execution phase. This parameter sets the size of that pool of records. Thus, this record is allocated only while executing a part of a query. As soon as this part has been executed, the record is released. The state needed to handle aborts and commits is handled by the normal operation records, where the pool size is set by the parameter `MaxNoOfConcurrentOperations`.

  The default value of this parameter is 8192. Only in rare cases of extremely high parallelism using unique hash indexes should it be necessary to increase this value. Using a smaller value is possible and can save memory if the DBA is certain that a high degree of parallelism is not required for the cluster.

  This parameter is deprecated as of NDB 8.0.19, and is subject to removal in a future NDB Cluster release. In addition, this parameter is incompatible with the `TransactionMemory` parameter; if you try to set values for both parameters in the cluster configuration file (`config.ini`), the management server refuses to start.

- **MaxNoOfFiredTriggers**
Table 22.46 This table provides type and value information for the MaxNoOfFiredTriggers data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>4000</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

The default value of MaxNoOfFiredTriggers is 4000, which is sufficient for most situations. In some cases it can even be decreased if the DBA feels certain the need for parallelism in the cluster is not high.

A record is created when an operation is performed that affects a unique hash index. Inserting or deleting a record in a table with unique hash indexes or updating a column that is part of a unique hash index fires an insert or a delete in the index table. The resulting record is used to represent this index table operation while waiting for the original operation that fired it to complete. This operation is short-lived but can still require a large number of records in its pool for situations with many parallel write operations on a base table containing a set of unique hash indexes.

This parameter is deprecated as of NDB 8.0.19, and is subject to removal in a future NDB Cluster release. In addition, this parameter is incompatible with the TransactionMemory parameter; if you try to set values for both parameters in the cluster configuration file (config.ini), the management server refuses to start.

- TransactionBufferMemory

Table 22.47 This table provides type and value information for the TransactionBufferMemory data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>1M</td>
</tr>
<tr>
<td>Range</td>
<td>1K - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

The memory affected by this parameter is used for tracking operations fired when updating index tables and reading unique indexes. This memory is used to store the key and column information for these operations. It is only very rarely that the value for this parameter needs to be altered from the default.

The default value for TransactionBufferMemory is 1MB.

Normal read and write operations use a similar buffer, whose usage is even more short-lived. The compile-time parameter ZATTRBUF_FILESIZE (found in ndb/src/kernel/blocks/Dbtc/Dbtc.hpp) set to 4000 × 128 bytes (500KB). A similar buffer for key information, ZDATABUF_FILESIZE (also in Dbtc.hpp) contains 4000 × 16 = 62.5KB of buffer space. Dbtc is the module that handles transaction coordination.

Transaction resource allocation parameters. The parameters in the following list are used to allocate transaction resources in the transaction coordinator (DBTC). Leaving any one of these set to the default (0) dedicates transaction memory for 25% of estimated total data node usage for the corresponding resource. The actual maximum possible values for
these parameters are typically limited by the amount of memory available to the data node; setting them has no impact on the total amount of memory allocated to the data node. In addition, you should keep in mind that they control numbers of reserved internal records for the data node independent of any settings for MaxDMLOperationsPerTransaction, MaxNoOfConcurrentIndexOperations, MaxNoOfConcurrentOperations, MaxNoOfConcurrentScans, MaxNoOfConcurrentTransactions, MaxNoOfFiredTriggers, MaxNoOfLocalScans, or TransactionBufferMemory (see Transaction parameters and Transaction temporary storage).

</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.19</td>
</tr>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 16384G</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter determines the memory (in bytes) allocated for transactions on each data node. Setting of transaction memory can be handled in any one of the three ways listed here:

- A number of configuration parameters are incompatible with TransactionMemory. If any of these are set, transaction memory is calculated as it was previous to NDB 8.0.19. You should be aware that it is not possible to set any of these parameters concurrently with TransactionMemory; if you attempt to do so, the management server is unable to start (see Parameters incompatible with TransactionMemory).

- If TransactionMemory is set, this value is used for determining transaction memory.

- If neither any incompatible parameters are set nor TransactionMemory is set, transaction memory is set by NDB to 10% of the value of the DataMemory configuration parameter.

**Parameters incompatible with TransactionMemory.** The following parameters cannot be used concurrently with TransactionMemory and are deprecated as of NDB 8.0.19:

- MaxNoOfConcurrentIndexOperations
- MaxNoOfFiredTriggers
- MaxNoOfLocalOperations
- MaxNoOfLocalScans

Explicitly setting any of the parameters just listed when TransactionMemory has also been set in the cluster configuration file (config.ini) keeps the management node from starting.

For more information regarding resource allocation in NDB Cluster data nodes, see Section 22.3.3.13, “Data Node Memory Management”.

**Scans and buffering.** There are additional [ndbd] parameters in the Dblqh module (in ndb/src/kernel/blocks/Dblqh/Dblqh.hpp) that affect reads and updates. These include ZATTRINBUF_FILESIZE, set by default to 10000 × 128 bytes (1250KB) and ZDATABUF_FILE_SIZE, set by default to 10000*16 bytes (roughly 156KB) of buffer space. To date, there have been neither any reports from users nor any results from our own extensive tests suggesting that either of these compile-time limits should be increased.

- BatchSizePerLocalScan
**Table 22.56** This table provides type and value information for the BatchSizePerLocalScan data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>256</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 992</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter is used to calculate the number of lock records used to handle concurrent scan operations.

BatchSizePerLocalScan has a strong connection to the BatchSize defined in the SQL nodes.

Deprecated as of NDB 8.0.19.

- **LongMessageBuffer**

**Table 22.57** This table provides type and value information for the LongMessageBuffer data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>64M</td>
</tr>
<tr>
<td>Range</td>
<td>512K - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>N</td>
</tr>
</tbody>
</table>

This is an internal buffer used for passing messages within individual nodes and between nodes. The default is 64MB.

This parameter seldom needs to be changed from the default.

- **MaxFKBuildBatchSize**

**Table 22.58** This table provides type and value information for the MaxFKBuildBatchSize data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>

<td>Default</td>
<td>256</td>
</tr>
<tr>
<td>Range</td>
<td>2 - 500</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter is used to control the number of parallel scans that can be performed in the cluster. Each transaction coordinator can handle the number of parallel scans defined for this parameter. Each scan query is performed by scanning all partitions in parallel. Each partition scan uses a scan record in the node where the partition is located, the number of records being the value of this parameter times the number of nodes. The cluster should be able to sustain MaxNoOfConcurrentScans scans concurrently from all nodes in the cluster.

Scans are actually performed in two cases. The first of these cases occurs when no hash or ordered indexes exists to handle the query, in which case the query is executed by performing a full table scan. The second case is encountered when there is no hash index to support the query but there is an ordered index. Using the ordered index means executing a parallel range scan. The order is kept on the local partitions only, so it is necessary to perform the index scan on all partitions.

The default value of MaxNoOfConcurrentScans is 256. The maximum value is 500.

• **MaxNoOfLocalScans**

Table 22.60 This table provides type and value information for the MaxNoOfLocalScans data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td>Range</td>
<td>32 - 4294967039 (0xFFFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Specifies the number of local scan records if many scans are not fully parallelized. When the number of local scan records is not provided, it is calculated as shown here:

\[4 \times \text{MaxNoOfConcurrentScans} \times \# \text{of data nodes} + 2\]

This parameter is deprecated as of NDB 8.0.19, and is subject to removal in a future NDB Cluster release. In addition, this parameter is incompatible with the TransactionMemory parameter; if you try to set values for both parameters in the cluster configuration file (config.ini), the management server refuses to start.
• **MaxParallelCopyInstances**

Table 22.61 This table provides type and value information for the MaxParallelCopyInstances data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>

<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 64</td>
</tr>
<tr>
<td>Restart Type</td>
<td>S</td>
</tr>
</tbody>
</table>

This parameter sets the parallelization used in the copy phase of a node restart or system restart, when a node that is currently just starting is synchronised with a node that already has current data by copying over any changed records from the node that is up to date. Because full parallelism in such cases can lead to overload situations, **MaxParallelCopyInstances** provides a means to decrease it. This parameter's default value 0. This value means that the effective parallelism is equal to the number of LDM instances in the node just starting as well as the node updating it.

• **MaxParallelScansPerFragment**

Table 22.62 This table provides type and value information for the MaxParallelScansPerFragment data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>

<td>64</td>
</tr>
<tr>
<td>Range</td>
<td>16 - 512</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>S</td>
</tr>
</tbody>
</table>

Maximum scan batch size used for building unique keys. Increasing the value set for this parameter may speed up such builds at the expense of greater impact to ongoing traffic.

**Memory Allocation**

**MaxAllocate**

Table 22.65 This table provides type and value information for the MaxAllocate data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>32M</td>
</tr>
<tr>
<td>Range</td>
<td>1M - 1G</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>N</td>
</tr>
</tbody>
</table>

This is the maximum size of the memory unit to use when allocating memory for tables. In cases where *NDB* gives Out of memory errors, but it is evident by examining the cluster logs or the output of `DUMP 1000` that all available memory has not yet been used, you can increase the value of this parameter (or **MaxNoOfTables**, or both) to cause *NDB* to make sufficient memory available.

**Multiple Transporters**

Beginning with version 8.0.20, *NDB* allocates multiple transporters for communication between pairs of data nodes. The number of transporters so allocated can be influenced by setting an appropriate value for the **NodeGroupTransporters** parameter introduced in that release.

**NodeGroupTransporters**

Table 22.66 This table provides type and value information for the NodeGroupTransporters data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.20</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 32</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter determines the number of transporters used between nodes in the same node group. The default value (0) means that the number of transporters used is the same as the number of LDMs in the node. This should be sufficient for most use cases; thus it should seldom be necessary to change this value from its default.
Setting `NodeGroupTransporters` to a number greater than the number of LDM threads or the number of TC threads, whichever is higher, causes NDB to use the maximum of these two numbers of threads. This means that a value greater than this is effectively ignored.

**Hash Map Size**

`DefaultHashMapSize`

Table 22.67 This table provides type and value information for the `DefaultHashMapSize` data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>LDM threads</td>
</tr>
<tr>
<td>Default</td>
<td>240</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 3840</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td><strong>N</strong></td>
</tr>
</tbody>
</table>

The original intended use for this parameter was to facilitate upgrades and especially downgrades to and from very old releases with differing default hash map sizes. This is not an issue when upgrading from NDB Cluster 7.3 (or later) to later versions.

Decreasing this parameter online after any tables have been created or modified with `DefaultHashMapSize` equal to 3840 is not currently supported.

**Logging and checkpointing.** The following [ndbd] parameters control log and checkpoint behavior.

- `FragmentLogFileSize`

Table 22.68 This table provides type and value information for the `FragmentLogFileSize` data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>16M</td>
</tr>
<tr>
<td>Range</td>
<td>4M - 1G</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td><strong>IN</strong></td>
</tr>
</tbody>
</table>

Setting this parameter enables you to control directly the size of redo log files. This can be useful in situations when NDB Cluster is operating under a high load and it is unable to close fragment log files quickly enough before attempting to open new ones (only 2 fragment log files can be open at one time); increasing the size of the fragment log files gives the cluster more time before having to open each new fragment log file. The default value for this parameter is 16M.

For more information about fragment log files, see the description for `NoOfFragmentLogFiles`.

- `InitialNoOfOpenFiles`

Table 22.69 This table provides type and value information for the `InitialNoOfOpenFiles` data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>files</td>
</tr>
<tr>
<td>Default</td>
<td>27</td>
</tr>
</tbody>
</table>
This parameter sets the initial number of internal threads to allocate for open files.

The default value is 27.

- **InitFragmentLogFiles**

  Table 22.70 This table provides type and value information for the InitFragmentLogFiles data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>[see values]</td>
</tr>
<tr>
<td>Default</td>
<td>SPARSE</td>
</tr>
<tr>
<td>Range</td>
<td>SPARSE, FULL</td>
</tr>
<tr>
<td>Restart Type</td>
<td>IN</td>
</tr>
</tbody>
</table>

By default, fragment log files are created sparsely when performing an initial start of a data node—that is, depending on the operating system and file system in use, not all bytes are necessarily written to disk. However, it is possible to override this behavior and force all bytes to be written, regardless of the platform and file system type being used, by means of this parameter. **InitFragmentLogFiles** takes either of two values:

- **SPARSE**. Fragment log files are created sparsely. This is the default value.
- **FULL**. Force all bytes of the fragment log file to be written to disk.

Depending on your operating system and file system, setting **InitFragmentLogFiles=FULL** may help eliminate I/O errors on writes to the REDO log.

- **EnablePartialLcp**

  Table 22.71 This table provides type and value information for the EnablePartialLcp data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>true</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

When **true**, enable partial local checkpoints: This means that each LCP records only part of the full database, plus any records containing rows changed since the last LCP; if no rows have changed, the LCP updates only the LCP control file and does not update any data files.

If **EnablePartialLcp** is disabled (**false**), each LCP uses only a single file and writes a full checkpoint; this requires the least amount of disk space for LCPs, but increases the write load for each LCP. The default value is enabled (**true**). The proportion of space used by partial LCPS can be modified by the setting for the **RecoveryWork** configuration parameter.

For more information about files and directories used for full and partial LCPs, see [NDB Cluster Data Node File System Directory](#).
Setting this parameter to `false` also disables the calculation of disk write speed used by the adaptive LCP control mechanism.

- **LcpScanProgressTimeout**

  Table 22.72 This table provides type and value information for the LcpScanProgressTimeout data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>

<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

A local checkpoint fragment scan watchdog checks periodically for no progress in each fragment scan performed as part of a local checkpoint, and shuts down the node if there is no progress after a given amount of time has elapsed. This interval can be set using the `LcpScanProgressTimeout` data node configuration parameter, which sets the maximum time for which the local checkpoint can be stalled before the LCP fragment scan watchdog shuts down the node.

The default value is 60 seconds (providing compatibility with previous releases). Setting this parameter to 0 disables the LCP fragment scan watchdog altogether.

- **MaxNoOfOpenFiles**

  Table 22.73 This table provides type and value information for the MaxNoOfOpenFiles data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td>Range</td>
<td>20 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter sets a ceiling on how many internal threads to allocate for open files. *Any situation requiring a change in this parameter should be reported as a bug.*

The default value is 0. However, the minimum value to which this parameter can be set is 20.

- **MaxNoOfSavedMessages**

  Table 22.74 This table provides type and value information for the MaxNoOfSavedMessages data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
</tbody>
</table>
This parameter sets the maximum number of errors written in the error log as well as the maximum number of trace files that are kept before overwriting the existing ones. Trace files are generated when, for whatever reason, the node crashes.

The default is 25, which sets these maximums to 25 error messages and 25 trace files.

- **MaxLCPStartDelay**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>seconds</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 600</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

In parallel data node recovery, only table data is actually copied and synchronized in parallel; synchronization of metadata such as dictionary and checkpoint information is done in a serial fashion. In addition, recovery of dictionary and checkpoint information cannot be executed in parallel with performing of local checkpoints. This means that, when starting or restarting many data nodes concurrently, data nodes may be forced to wait while a local checkpoint is performed, which can result in longer node recovery times.

It is possible to force a delay in the local checkpoint to permit more (and possibly all) data nodes to complete metadata synchronization; once each data node’s metadata synchronization is complete, all of the data nodes can recover table data in parallel, even while the local checkpoint is being executed. To force such a delay, set **MaxLCPStartDelay**, which determines the number of seconds the cluster can wait to begin a local checkpoint while data nodes continue to synchronize metadata. This parameter should be set in the `[ndbd default]` section of the `config.ini` file, so that it is the same for all data nodes. The maximum value is 600; the default is 0.

- **NoOfFragmentLogFiles**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>

<td>16</td>
</tr>
<tr>
<td>Range</td>
<td>3 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>IN</td>
</tr>
</tbody>
</table>

This parameter sets the number of REDO log files for the node, and thus the amount of space allocated to REDO logging. Because the REDO log files are organized in a ring, it is extremely important that the first and last log files in the set (sometimes referred to as the “head” and “tail” log
files, respectively) do not meet. When these approach one another too closely, the node begins aborting all transactions encompassing updates due to a lack of room for new log records.

A REDO log record is not removed until both required local checkpoints have been completed since that log record was inserted. Checkpointing frequency is determined by its own set of configuration parameters discussed elsewhere in this chapter.

The default parameter value is 16, which by default means 16 sets of 4 16MB files for a total of 1024MB. The size of the individual log files is configurable using the FragmentLogFileSize parameter. In scenarios requiring a great many updates, the value for NoOfFragmentLogFiles may need to be set as high as 300 or even higher to provide sufficient space for REDO logs.

If the checkpointing is slow and there are so many writes to the database that the log files are full and the log tail cannot be cut without jeopardizing recovery, all updating transactions are aborted with internal error code 410 (Out of log file space temporarily). This condition prevails until a checkpoint has completed and the log tail can be moved forward.

**Important**

This parameter cannot be changed “on the fly”; you must restart the node using --initial. If you wish to change this value for all data nodes in a running cluster, you can do so using a rolling node restart (using --initial when starting each data node).

• **RecoveryWork**

**Table 22.77 This table provides type and value information for the RecoveryWork data node configuration parameter**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>60</td>
</tr>
<tr>
<td>Range</td>
<td>25 - 100</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>N</td>
</tr>
</tbody>
</table>

Percentage of storage overhead for LCP files. This parameter has an effect only when EnablePartialLcp is true, that is, only when partial local checkpoints are enabled. A higher value means:

• Fewer records are written for each LCP, LCPs use more space

• More work is needed during restarts

A lower value for RecoveryWork means:

• More records are written during each LCP, but LCPs require less space on disk.

• Less work during restart and thus faster restarts, at the expense of more work during normal operations

For example, setting RecoveryWork to 60 means that the total size of an LCP is roughly 1 + 0.6 = 1.6 times the size of the data to be checkpointed. This means that 60% more work is required during the restore phase of a restart compared to the work done during a restart that uses full checkpoints. (This is more than compensated for during other phases of the restart such that the restart as a whole is still faster when using partial LCPs than when using full LCPs.) In order not to fill up the redo log, it is necessary to write at 1 + (1 / RecoveryWork) times the rate of data changes during checkpoints—thus, when RecoveryWork = 60, it is necessary to write at approximately 1 + (1 / 0.6)
NDB Cluster Configuration Files

= 2.67 times the change rate. In other words, if changes are being written at 10 MByte per second, the checkpoint needs to be written at roughly 26.7 MByte per second.

Setting `RecoveryWork` = 40 means that only 1.4 times the total LCP size is needed (and thus the restore phase takes 10 to 15 percent less time. In this case, the checkpoint write rate is 3.5 times the rate of change.

The NDB source distribution includes a test program for simulating LCPs. `lcp_simulator.cc` can be found in `storage/ndb/src/kernel/blocks/backup/`. To compile and run it on Unix platforms, execute the commands shown here:

```
shell> gcc lcp_simulator.cc
shell> ./a.out
```

This program has no dependencies other than `stdio.h`, and does not require a connection to an NDB cluster or a MySQL server. By default, it simulates 300 LCPs (three sets of 100 LCPs, each consisting of inserts, updates, and deletes, in turn), reporting the size of the LCP after each one. You can alter the simulation by changing the values of `recovery_work`, `insert_work`, and `delete_work` in the source and recompiling. For more information, see the source of the program.

- **InsertRecoveryWork**

  Table 22.78 This table provides type and value information for the `InsertRecoveryWork` data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>40</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 70</td>
</tr>
</tbody>
</table>

  Percentage of `RecoveryWork` used for inserted rows. A higher value increases the number of writes during a local checkpoint, and decreases the total size of the LCP. A lower value decreases the number of writes during an LCP, but results in more space being used for the LCP, which means that recovery takes longer. This parameter has an effect only when `EnablePartialLcp` is true, that is, only when partial local checkpoints are enabled.

- **EnableRedoControl**

  Table 22.79 This table provides type and value information for the `EnableRedoControl` data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
</tbody>
</table>

  Enable adaptive checkpointing speed for controlling redo log usage. Set to `false` to disable (the default). Setting `EnablePartialLcp` to `false` also disables the adaptive calculation.

  When enabled, `EnableRedoControl` allows the data nodes greater flexibility with regard to the rate at which they write LCPs to disk. More specifically, enabling this parameter means that higher write rates can be employed, so that LCPs can complete and Redo logs be trimmed more quickly, thereby reducing recovery time and disk space requirements. This functionality allows data nodes
to make better use of the higher rate of I/O and greater bandwidth available from modern solid-
state storage devices and protocols, such as solid-state drives (SSDs) using Non-Volatile Memory
Express (NVMe).

The parameter currently defaults to false (disabled) due to the fact that NDB is still deployed
widely on systems whose I/O or bandwidth is constrained relative to those employing solid-state
technology, such as those using conventional hard disks (HDDs). In settings such as these, the
EnableRedoControl mechanism can easily cause the I/O subsystem to become saturated,
increasing wait times for data node input and output. In particular, this can cause issues with NDB
Disk Data tables which have tablespaces or log file groups sharing a constrained IO subsystem with
data node LCP and redo log files; such problems potentially include node or cluster failure due to
GCP stop errors.

Metadata objects. The next set of [ndbd] parameters defines pool sizes for metadata objects,
used to define the maximum number of attributes, tables, indexes, and trigger objects used by indexes,
events, and replication between clusters.

Note

These act merely as “suggestions” to the cluster, and any that are not specified
revert to the default values shown.

• MaxNoOfAttributes

Table 22.80 This table provides type and value information for the MaxNoOfAttributes data
node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>1000</td>
</tr>
<tr>
<td>Range</td>
<td>32 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter sets a suggested maximum number of attributes that can be defined in the cluster;
like MaxNoOfTables, it is not intended to function as a hard upper limit.

(In older NDB Cluster releases, this parameter was sometimes treated as a hard limit for certain
operations. This caused problems with NDB Cluster Replication, when it was possible to create
more tables than could be replicated, and sometimes led to confusion when it was possible [or not
possible, depending on the circumstances] to create more than MaxNoOfAttributes attributes.)

The default value is 1000, with the minimum possible value being 32. The maximum is 4294967039.
Each attribute consumes around 200 bytes of storage per node due to the fact that all metadata is
fully replicated on the servers.

When setting MaxNoOfAttributes, it is important to prepare in advance for any ALTER
TABLE statements that you might want to perform in the future. This is due to the fact, during the
execution of ALTER TABLE on a Cluster table, 3 times the number of attributes as in the original
table are used, and a good practice is to permit double this amount. For example, if the NDB
Cluster table having the greatest number of attributes (greatest_number_of_attributes) has 100 attributes, a good starting point for the value of MaxNoOfAttributes would be 6 *
greatest_number_of_attributes = 600.

You should also estimate the average number of attributes per table and multiply this by
MaxNoOfTables. If this value is larger than the value obtained in the previous paragraph, you
should use the larger value instead.
Assuming that you can create all desired tables without any problems, you should also verify that this number is sufficient by trying an actual ALTER TABLE after configuring the parameter. If this is not successful, increase MaxNoOfAttributes by another multiple of MaxNoOfTables and test it again.

• **MaxNoOfTables**

  **Table 22.81** This table provides type and value information for the MaxNoOfTables data node configuration parameter

<table>

</tbody>
</table>

A table object is allocated for each table and for each unique hash index in the cluster. This parameter sets a suggested maximum number of table objects for the cluster as a whole; like MaxNoOfAttributes, it is not intended to function as a hard upper limit.

(In older NDB Cluster releases, this parameter was sometimes treated as a hard limit for certain operations. This caused problems with NDB Cluster Replication, when it was possible to create more tables than could be replicated, and sometimes led to confusion when it was possible [or not possible, depending on the circumstances] to create more than MaxNoOfTables tables.)

For each attribute that has a BLOB data type an extra table is used to store most of the BLOB data. These tables also must be taken into account when defining the total number of tables.

The default value of this parameter is 128. The minimum is 8 and the maximum is 20320. Each table object consumes approximately 20KB per node.

**Note**

The sum of MaxNoOfTables, MaxNoOfOrderedIndexes, and MaxNoOfUniqueHashIndexes must not exceed $2^{32} - 2$ (4294967294).

• **MaxNoOfOrderedIndexes**

  **Table 22.82** This table provides type and value information for the MaxNoOfOrderedIndexes data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>128</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>N</td>
</tr>
</tbody>
</table>

For each ordered index in the cluster, an object is allocated describing what is being indexed and its storage segments. By default, each index so defined also defines an ordered index. Each unique index and primary key has both an ordered index and a hash index. MaxNoOfOrderedIndexes sets the total number of ordered indexes that can be in use in the system at any one time.

The default value of this parameter is 128. Each index object consumes approximately 10KB of data per node.
Note

The sum of MaxNoOfTables, MaxNoOfOrderedIndexes, and MaxNoOfUniqueHashIndexes must not exceed $2^{32} - 2$ (4294967294).

- MaxNoOfUniqueHashIndexes

Table 22.83 This table provides type and value information for the MaxNoOfUniqueHashIndexes data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>64</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

For each unique index that is not a primary key, a special table is allocated that maps the unique key to the primary key of the indexed table. By default, an ordered index is also defined for each unique index. To prevent this, you must specify the USING HASH option when defining the unique index.

The default value is 64. Each index consumes approximately 15KB per node.

Note

The sum of MaxNoOfTables, MaxNoOfOrderedIndexes, and MaxNoOfUniqueHashIndexes must not exceed $2^{32} - 2$ (4294967294).

- MaxNoOfTriggers

Table 22.84 This table provides type and value information for the MaxNoOfTriggers data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>768</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Internal update, insert, and delete triggers are allocated for each unique hash index. (This means that three triggers are created for each unique hash index.) However, an ordered index requires only a single trigger object. Backups also use three trigger objects for each normal table in the cluster.

Replication between clusters also makes use of internal triggers.

This parameter sets the maximum number of trigger objects in the cluster.

The default value is 768.
### MaxNoOfSubscriptions

Table 22.85 This table provides type and value information for the MaxNoOfSubscriptions data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Each **NDB** table in an NDB Cluster requires a subscription in the NDB kernel. For some NDB API applications, it may be necessary or desirable to change this parameter. However, for normal usage with MySQL servers acting as SQL nodes, there is not any need to do so.

The default value for `MaxNoOfSubscriptions` is 0, which is treated as equal to `MaxNoOfTables`. Each subscription consumes 108 bytes.

### MaxNoOfSubscribers

Table 22.86 This table provides type and value information for the MaxNoOfSubscribers data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter is of interest only when using NDB Cluster Replication. The default value is 0, which is treated as `2 * MaxNoOfTables`; that is, there is one subscription per **NDB** table for each of two MySQL servers (one acting as the replication master and the other as the slave). Each subscriber uses 16 bytes of memory.

When using circular replication, multi-master replication, and other replication setups involving more than 2 MySQL servers, you should increase this parameter to the number of **mysqld** processes included in replication (this is often, but not always, the same as the number of clusters). For example, if you have a circular replication setup using three NDB Cluster s, with one **mysqld** attached to each cluster, and each of these **mysqld** processes acts as a master and as a slave, you should set `MaxNoOfSubscribers` equal to `3 * MaxNoOfTables`.

For more information, see Section 22.6, “NDB Cluster Replication”.

### MaxNoOfConcurrentSubOperations

Table 22.87 This table provides type and value information for the MaxNoOfConcurrentSubOperations data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>256</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>
This parameter sets a ceiling on the number of operations that can be performed by all API nodes in the cluster at one time. The default value (256) is sufficient for normal operations, and might need to be adjusted only in scenarios where there are a great many API nodes each performing a high volume of operations concurrently.

**Boolean parameters.** The behavior of data nodes is also affected by a set of [ndbd] parameters taking on boolean values. These parameters can each be specified as TRUE by setting them equal to 1 or Y, and as FALSE by setting them equal to 0 or N.

- **CompressedBackup**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Enabling this parameter causes backup files to be compressed. The compression used is equivalent to `gzip --fast`, and can save 50% or more of the space required on the data node to store uncompressed backup files. Compressed backups can be enabled for individual data nodes, or for all data nodes (by setting this parameter in the [ndbd default] section of the `config.ini` file).

**Important**

You cannot restore a compressed backup to a cluster running a MySQL version that does not support this feature.

The default value is 0 (disabled).

- **CompressedLCP**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Setting this parameter to 1 causes local checkpoint files to be compressed. The compression used is equivalent to `gzip --fast`, and can save 50% or more of the space required on the data node to store uncompressed checkpoint files. Compressed LCPs can be enabled for individual data nodes, or for all data nodes (by setting this parameter in the [ndbd default] section of the `config.ini` file).
Important

You cannot restore a compressed local checkpoint to a cluster running a MySQL version that does not support this feature.

The default value is 0 (disabled).

• CrashOnCorruptedTuple

Table 22.90 This table provides type and value information for the CrashOnCorruptedTuple data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>true</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td>Restart Type</td>
<td>S</td>
</tr>
</tbody>
</table>

When this parameter is enabled (the default), it forces a data node to shut down whenever it encounters a corrupted tuple.

• Diskless

Table 22.91 This table provides type and value information for the Diskless data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>true</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td>Restart Type</td>
<td>IS</td>
</tr>
</tbody>
</table>

It is possible to specify NDB Cluster tables as *diskless*, meaning that tables are not checkpointed to disk and that no logging occurs. Such tables exist only in main memory. A consequence of using diskless tables is that neither the tables nor the records in those tables survive a crash. However, when operating in diskless mode, it is possible to run *ndbd* on a diskless computer.

Important

This feature causes the *entire* cluster to operate in diskless mode.

When this feature is enabled, Cluster online backup is disabled. In addition, a partial start of the cluster is not possible.

**Diskless** is disabled by default.

• LateAlloc

Table 22.92 This table provides type and value information for the LateAlloc data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
</tbody>
</table>
Allocate memory for this data node after a connection to the management server has been established. Enabled by default.

- **LockPagesInMainMemory**

Table 22.93 This table provides type and value information for the LockPagesInMainMemory data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 2</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

For a number of operating systems, including Solaris and Linux, it is possible to lock a process into memory and so avoid any swapping to disk. This can be used to help guarantee the cluster's real-time characteristics.

This parameter takes one of the integer values 0, 1, or 2, which act as shown in the following list:

- **0**: Disables locking. This is the default value.
- **1**: Performs the lock after allocating memory for the process.
- **2**: Performs the lock before memory for the process is allocated.

If the operating system is not configured to permit unprivileged users to lock pages, then the data node process making use of this parameter may have to be run as system root. ([LockPagesInMainMemory](#) uses the `mlockall` function. From Linux kernel 2.6.9, unprivileged users can lock memory as limited by `max locked memory`. For more information, see `ulimit -l` and [http://linux.die.net/man/2/mlock](#).

### Note

In older NDB Cluster releases, this parameter was a Boolean. 0 or `false` was the default setting, and disabled locking. 1 or `true` enabled locking of the process after its memory was allocated. NDB Cluster 8.0 treats `true` or `false` for the value of this parameter as an error.

### Important

Beginning with `glibc` 2.10, `glibc` uses per-thread arenas to reduce lock contention on a shared pool, which consumes real memory. In general, a data node process does not need per-thread arenas, since it does not perform any memory allocation after startup. (This difference in allocators does not appear to affect performance significantly.)

The `glibc` behavior is intended to be configurable via the `MALLOC_ARENA_MAX` environment variable, but a bug in this mechanism prior to `glibc` 2.16 meant that this variable could not be set to less than 8, so
that the wasted memory could not be reclaimed. (Bug #15907219; see also http://sourceware.org/bugzilla/show_bug.cgi?id=13137 for more information concerning this issue.)

One possible workaround for this problem is to use the `LD_PRELOAD` environment variable to preload a `jemalloc` memory allocation library to take the place of that supplied with `glibc`.

- **ODirect**

  Table 22.94 This table provides type and value information for the ODirect data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Enabling this parameter causes NDB to attempt using `O_DIRECT` writes for LCP, backups, and redo logs, often lowering `kswapd` and CPU usage. When using NDB Cluster on Linux, enable `ODirect` if you are using a 2.6 or later kernel.

`ODirect` is disabled by default.

- **ODirectSyncFlag**

  Table 22.95 This table provides type and value information for the ODirectSyncFlag data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

When this parameter is enabled, redo log writes are performed such that each completed file system write is handled as a call to `fsync`. The setting for this parameter is ignored if at least one of the following conditions is true:

- **ODirect** is not enabled.

- **InitFragmentLogFiles** is set to `SPARSE`.

Disabled by default.

- **RestartOnErrorInsert**

  Table 22.96 This table provides type and value information for the RestartOnErrorInsert data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>error code</td>
</tr>
</tbody>
</table>
### NDB Cluster Configuration Files

**Property** | **Value**
--- | ---
Default | 2
Range | 0 - 4

**Restart Type** | N

This feature is accessible only when building the debug version where it is possible to insert errors in the execution of individual blocks of code as part of testing.

This feature is disabled by default.

- **StopOnError**

  **Table 22.97** This table provides type and value information for the StopOnError data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>1</td>
</tr>
<tr>
<td>Range</td>
<td>0, 1</td>
</tr>
</tbody>
</table>

**Restart Type** | N

This parameter specifies whether a data node process should exit or perform an automatic restart when an error condition is encountered.

This parameter's default value is 1; this means that, by default, an error causes the data node process to halt.

When an error is encountered and **StopOnError** is 0, the data node process is restarted.

Users of MySQL Cluster Manager should note that, when **StopOnError** equals 1, this prevents the MySQL Cluster Manager agent from restarting any data nodes after it has performed its own restart and recovery. See [Starting and Stopping the Agent on Linux](#), for more information.

- **UseShm**

  **Table 22.98** This table provides type and value information for the UseShm data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
</tbody>
</table>

**Restart Type** | S

Enable a shared memory connection between this data node and the API node also running on this host. Set to 1 to enable.

### Controlling Timeouts, Intervals, and Disk Paging

There are a number of `[ndbd]` parameters specifying timeouts and intervals between various actions in Cluster data nodes. Most of the timeout values are specified in milliseconds. Any exceptions to this are mentioned where applicable.

- **TimeBetweenWatchDogCheck**
To prevent the main thread from getting stuck in an endless loop at some point, a “watchdog” thread checks the main thread. This parameter specifies the number of milliseconds between checks. If the process remains in the same state after three checks, the watchdog thread terminates it.

This parameter can easily be changed for purposes of experimentation or to adapt to local conditions. It can be specified on a per-node basis although there seems to be little reason for doing so.

The default timeout is 6000 milliseconds (6 seconds).

- **TimeBetweenWatchDogCheckInitial**

This is similar to the **TimeBetweenWatchDogCheck** parameter, except that **TimeBetweenWatchDogCheckInitial** controls the amount of time that passes between execution checks inside a storage node in the early start phases during which memory is allocated.

The default timeout is 6000 milliseconds (6 seconds).

- **StartPartialTimeout**

This table provides type and value information for the **StartPartialTimeout** data node configuration parameter.
**NDB Cluster Configuration Files**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Restart Type</strong></td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter specifies how long the Cluster waits for all data nodes to come up before the cluster initialization routine is invoked. This timeout is used to avoid a partial Cluster startup whenever possible.

This parameter is overridden when performing an initial start or initial restart of the cluster.

The default value is 30000 milliseconds (30 seconds). 0 disables the timeout, in which case the cluster may start only if all nodes are available.

- **StartPartitionedTimeout**

  **Table 22.102** This table provides type and value information for the StartPartitionedTimeout data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>N</td>
</tr>
</tbody>
</table>

If the cluster is ready to start after waiting for StartPartialTimeout milliseconds but is still possibly in a partitioned state, the cluster waits until this timeout has also passed. If StartPartitionedTimeout is set to 0, the cluster waits indefinitely (\(2^{32} - 1\) ms, or approximately 49.71 days).

This parameter is overridden when performing an initial start or initial restart of the cluster.

- **StartFailureTimeout**

  **Table 22.103** This table provides type and value information for the StartFailureTimeout data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>N</td>
</tr>
</tbody>
</table>

If a data node has not completed its startup sequence within the time specified by this parameter, the node startup fails. Setting this parameter to 0 (the default value) means that no data node timeout is applied.

For nonzero values, this parameter is measured in milliseconds. For data nodes containing extremely large amounts of data, this parameter should be increased. For example, in the case of a data node containing several gigabytes of data, a period as long as 10–15 minutes (that is, 600000 to 1000000 milliseconds) might be required to perform a node restart.
• **StartNoNodeGroupTimeout**

Table 22.104 This table provides type and value information for the StartNoNodeGroupTimeout data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>15000</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

When a data node is configured with `Nodegroup = 65536`, is regarded as not being assigned to any node group. When that is done, the cluster waits `StartNoNodeGroupTimeout` milliseconds, then treats such nodes as though they had been added to the list passed to the `--nowait-nodes` option, and starts. The default value is **15000** (that is, the management server waits 15 seconds). Setting this parameter equal to **0** means that the cluster waits indefinitely.

`StartNoNodeGroupTimeout` must be the same for all data nodes in the cluster; for this reason, you should always set it in the `[ndbd default]` section of the `config.ini` file, rather than for individual data nodes.

See Section 22.5.15, “Adding NDB Cluster Data Nodes Online”, for more information.

• **HeartbeatIntervalDbDb**

Table 22.105 This table provides type and value information for the HeartbeatIntervalDbDb data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>5000</td>
</tr>
<tr>
<td>Range</td>
<td>10 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

One of the primary methods of discovering failed nodes is by the use of heartbeats. This parameter states how often heartbeat signals are sent and how often to expect to receive them. Heartbeats cannot be disabled.

After missing four heartbeat intervals in a row, the node is declared dead. Thus, the maximum time for discovering a failure through the heartbeat mechanism is five times the heartbeat interval.

The default heartbeat interval is 5000 milliseconds (5 seconds). This parameter must not be changed drastically and should not vary widely between nodes. If one node uses 5000 milliseconds and the node watching it uses 1000 milliseconds, obviously the node will be declared dead very quickly. This parameter can be changed during an online software upgrade, but only in small increments.

See also Network communication and latency, as well as the description of the `ConnectCheckIntervalDelay` configuration parameter.
• **HeartbeatIntervalDbApi**

Table 22.106 This table provides type and value information for the HeartbeatIntervalDbApi data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>1500</td>
</tr>
<tr>
<td>Range</td>
<td>100 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Each data node sends heartbeat signals to each MySQL server (SQL node) to ensure that it remains in contact. If a MySQL server fails to send a heartbeat in time it is declared “dead,” in which case all ongoing transactions are completed and all resources released. The SQL node cannot reconnect until all activities initiated by the previous MySQL instance have been completed. The three-heartbeat criteria for this determination are the same as described for HeartbeatIntervalDbDb.

The default interval is 1500 milliseconds (1.5 seconds). This interval can vary between individual data nodes because each data node watches the MySQL servers connected to it, independently of all other data nodes.

For more information, see Network communication and latency.

• **HeartbeatOrder**

Table 22.107 This table provides type and value information for the HeartbeatOrder data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 65535</td>
</tr>
<tr>
<td>Restart Type</td>
<td>S</td>
</tr>
</tbody>
</table>

Data nodes send heartbeats to one another in a circular fashion whereby each data node monitors the previous one. If a heartbeat is not detected by a given data node, this node declares the previous data node in the circle “dead” (that is, no longer accessible by the cluster). The determination that a data node is dead is done globally; in other words; once a data node is declared dead, it is regarded as such by all nodes in the cluster.

It is possible for heartbeats between data nodes residing on different hosts to be too slow compared to heartbeats between other pairs of nodes (for example, due to a very low heartbeat interval or temporary connection problem), such that a data node is declared dead, even though the node can still function as part of the cluster.

In this type of situation, it may be that the order in which heartbeats are transmitted between data nodes makes a difference as to whether or not a particular data node is declared dead. If this
declaration occurs unnecessarily, this can in turn lead to the unnecessary loss of a node group and as thus to a failure of the cluster.

Consider a setup where there are 4 data nodes A, B, C, and D running on 2 host computers host1 and host2, and that these data nodes make up 2 node groups, as shown in the following table:

Table 22.108 Four data nodes A, B, C, D running on two host computers host1, host2; each data node belongs to one of two node groups.

<table>
<thead>
<tr>
<th>Node Group</th>
<th>Nodes Running on host1</th>
<th>Nodes Running on host2</th>
</tr>
</thead>
<tbody>
<tr>
<td>Node Group 0:</td>
<td>Node A</td>
<td>Node B</td>
</tr>
<tr>
<td>Node Group 1:</td>
<td>Node C</td>
<td>Node D</td>
</tr>
</tbody>
</table>

Suppose the heartbeats are transmitted in the order A->B->C->D->A. In this case, the loss of the heartbeat between the hosts causes node B to declare node A dead and node C to declare node B dead. This results in loss of Node Group 0, and so the cluster fails. On the other hand, if the order of transmission is A->B->D->C->A (and all other conditions remain as previously stated), the loss of the heartbeat causes nodes A and D to be declared dead; in this case, each node group has one surviving node, and the cluster survives.

The **HeartbeatOrder** configuration parameter makes the order of heartbeat transmission user-configurable. The default value for **HeartbeatOrder** is zero; allowing the default value to be used on all data nodes causes the order of heartbeat transmission to be determined by **NDB**. If this parameter is used, it must be set to a nonzero value (maximum 65535) for every data node in the cluster, and this value must be unique for each data node; this causes the heartbeat transmission to proceed from data node to data node in the order of their **HeartbeatOrder** values from lowest to highest (and then directly from the data node having the highest **HeartbeatOrder** to the data node having the lowest value, to complete the circle). The values need not be consecutive. For example, to force the heartbeat transmission order A->B->D->C->A in the scenario outlined previously, you could set the **HeartbeatOrder** values as shown here:

Table 22.109 HeartbeatOrder values to force a heartbeat transition order of A->B->D->C->A.

<table>
<thead>
<tr>
<th>Node</th>
<th>HeartbeatOrder Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>10</td>
</tr>
<tr>
<td>B</td>
<td>20</td>
</tr>
<tr>
<td>C</td>
<td>30</td>
</tr>
<tr>
<td>D</td>
<td>25</td>
</tr>
</tbody>
</table>

To use this parameter to change the heartbeat transmission order in a running NDB Cluster, you must first set **HeartbeatOrder** for each data node in the cluster in the global configuration (config.ini) file (or files). To cause the change to take effect, you must perform either of the following:

- A complete shutdown and restart of the entire cluster.
- 2 rolling restarts of the cluster in succession. *All nodes must be restarted in the same order in both rolling restarts.*

You can use **DUMP 908** to observe the effect of this parameter in the data node logs.
• ConnectCheckIntervalDelay

Table 22.110 This table provides type and value information for the ConnectCheckIntervalDelay data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter enables connection checking between data nodes after one of them has failed heartbeat checks for 5 intervals of up to \(\text{HeartbeatIntervalDbDb}\) milliseconds.

Such a data node that further fails to respond within an interval of \(\text{ConnectCheckIntervalDelay}\) milliseconds is considered suspect, and is considered dead after two such intervals. This can be useful in setups with known latency issues.

The default value for this parameter is 0 (disabled).

• TimeBetweenLocalCheckpoints

Table 22.111 This table provides type and value information for the TimeBetweenLocalCheckpoints data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>number of 4-byte words, as a base-2 logarithm</td>
</tr>
<tr>
<td>Default</td>
<td>20</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 31</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter is an exception in that it does not specify a time to wait before starting a new local checkpoint; rather, it is used to ensure that local checkpoints are not performed in a cluster where relatively few updates are taking place. In most clusters with high update rates, it is likely that a new local checkpoint is started immediately after the previous one has been completed.

The size of all write operations executed since the start of the previous local checkpoints is added. This parameter is also exceptional in that it is specified as the base-2 logarithm of the number of 4-byte words, so that the default value 20 means 4MB (\(4 \times 2^{20}\)) of write operations, 21 would mean 8MB, and so on up to a maximum value of 31, which equates to 8GB of write operations.

All the write operations in the cluster are added together. Setting \(\text{TimeBetweenLocalCheckpoints}\) to 6 or less means that local checkpoints will be executed continuously without pause, independent of the cluster's workload.

• TimeBetweenGlobalCheckpoints

Table 22.112 This table provides type and value information for the TimeBetweenGlobalCheckpoints data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td></td>
<td>3673</td>
</tr>
</tbody>
</table>
When a transaction is committed, it is committed in main memory in all nodes on which the data is mirrored. However, transaction log records are not flushed to disk as part of the commit. The reasoning behind this behavior is that having the transaction safely committed on at least two autonomous host machines should meet reasonable standards for durability.

It is also important to ensure that even the worst of cases—a complete crash of the cluster—is handled properly. To guarantee that this happens, all transactions taking place within a given interval are put into a global checkpoint, which can be thought of as a set of committed transactions that has been flushed to disk. In other words, as part of the commit process, a transaction is placed in a global checkpoint group. Later, this group's log records are flushed to disk, and then the entire group of transactions is safely committed to disk on all computers in the cluster.

In NDB 8.0.19 and later, it recommended when using solid-state disks (especially those employing NVMe) with Disk Data tables that you reduce this value. In such cases, you should also ensure that MaxDiskDataLatency is set to a proper level.

This parameter defines the interval between global checkpoints. The default is 2000 milliseconds.

- **TimeBetweenGlobalCheckpointsTimeout**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>120000</td>
</tr>
<tr>
<td>Range</td>
<td>10 - 4294967039 (0xFFFFFFFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter defines the minimum timeout between global checkpoints. The default is 120000 milliseconds.

- **TimeBetweenEpochs**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>100</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 32000</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter defines the interval between synchronization epochs for NDB Cluster Replication. The default value is 100 milliseconds.

**TimeBetweenEpochs** is part of the implementation of “micro-GCPs”, which can be used to improve the performance of NDB Cluster Replication.
• **TimeBetweenEpochsTimeout**

Table 22.115 This table provides type and value information for the TimeBetweenEpochsTimeout data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 256000</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter defines a timeout for synchronization epochs for NDB Cluster Replication. If a node fails to participate in a global checkpoint within the time determined by this parameter, the node is shut down. The default value is 0; in other words, the timeout is disabled.

**TimeBetweenEpochsTimeout** is part of the implementation of “micro-GCPs”, which can be used to improve the performance of NDB Cluster Replication.

The current value of this parameter and a warning are written to the cluster log whenever a GCP save takes longer than 1 minute or a GCP commit takes longer than 10 seconds.

Setting this parameter to zero has the effect of disabling GCP stops caused by save timeouts, commit timeouts, or both. The maximum possible value for this parameter is 256000 milliseconds.

• **MaxBufferedEpochs**

Table 22.116 This table provides type and value information for the MaxBufferedEpochs data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>epochs</td>
</tr>
<tr>
<td>Default</td>
<td>100</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 100000</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

The number of unprocessed epochs by which a subscribing node can lag behind. Exceeding this number causes a lagging subscriber to be disconnected.

The default value of 100 is sufficient for most normal operations. If a subscribing node does lag enough to cause disconnections, it is usually due to network or scheduling issues with regard to processes or threads. (In rare circumstances, the problem may be due to a bug in the NDB client.) It may be desirable to set the value lower than the default when epochs are longer.

Disconnection prevents client issues from affecting the data node service, running out of memory to buffer data, and eventually shutting down. Instead, only the client is affected as a result of the disconnect (by, for example gap events in the binary log), forcing the client to reconnect or restart the process.
- **MaxBufferedEpochBytes**

Table 22.117 This table provides type and value information for the MaxBufferedEpochBytes data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>26214400</td>
</tr>
<tr>
<td>Range</td>
<td>26214400 (0x01900000) - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

**Restart Type** | N

The total number of bytes allocated for buffering epochs by this node.

- **TimeBetweenInactiveTransactionAbortCheck**

Table 22.118 This table provides type and value information for the TimeBetweenInactiveTransactionAbortCheck data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>1000</td>
</tr>
<tr>
<td>Range</td>
<td>1000 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

**Restart Type** | N

Timeout handling is performed by checking a timer on each transaction once for every interval specified by this parameter. Thus, if this parameter is set to 1000 milliseconds, every transaction will be checked for timing out once per second.

The default value is 1000 milliseconds (1 second).

- **TransactionInactiveTimeout**

Table 22.119 This table provides type and value information for the TransactionInactiveTimeout data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

**Restart Type** | N

This parameter states the maximum time that is permitted to lapse between operations in the same transaction before the transaction is aborted.

The default for this parameter is 4G (also the maximum). For a real-time database that needs to ensure that no transaction keeps locks for too long, this parameter should be set to a relatively small value. Setting it to 0 means that the application never times out. The unit is milliseconds.
**TransactionDeadlockDetectionTimeout**

Table 22.120 This table provides type and value information for the TransactionDeadlockDetectionTimeout data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>1200</td>
</tr>
<tr>
<td>Range</td>
<td>50 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

When a node executes a query involving a transaction, the node waits for the other nodes in the cluster to respond before continuing. This parameter sets the amount of time that the transaction can spend executing within a data node, that is, the time that the transaction coordinator waits for each data node participating in the transaction to execute a request.

A failure to respond can occur for any of the following reasons:

- The node is “dead”
- The operation has entered a lock queue
- The node requested to perform the action could be heavily overloaded.

This timeout parameter states how long the transaction coordinator waits for query execution by another node before aborting the transaction, and is important for both node failure handling and deadlock detection.

The default timeout value is 1200 milliseconds (1.2 seconds).

The minimum for this parameter is 50 milliseconds.

**DiskSyncSize**

Table 22.121 This table provides type and value information for the DiskSyncSize data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>4M</td>
</tr>
<tr>
<td>Range</td>
<td>32K - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This is the maximum number of bytes to store before flushing data to a local checkpoint file. This is done to prevent write buffering, which can impede performance significantly. This parameter is not intended to take the place of `TimeBetweenLocalCheckpoints`.

**Note**

When `ODirect` is enabled, it is not necessary to set `DiskSyncSize`; in fact, in such cases its value is simply ignored.

The default value is 4M (4 megabytes).
• MaxDiskWriteSpeed

Table 22.122 This table provides type and value information for the MaxDiskWriteSpeed data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>20M</td>
</tr>
<tr>
<td>Range</td>
<td>1M - 1024G</td>
</tr>
<tr>
<td>Restart Type</td>
<td>S</td>
</tr>
</tbody>
</table>

Set the maximum rate for writing to disk, in bytes per second, by local checkpoints and backup operations when no restarts (by this data node or any other data node) are taking place in this NDB Cluster.

For setting the maximum rate of disk writes allowed while this data node is restarting, use MaxDiskWriteSpeedOwnRestart. For setting the maximum rate of disk writes allowed while other data nodes are restarting, use MaxDiskWriteSpeedOtherNodeRestart. The minimum speed for disk writes by all LCPs and backup operations can be adjusted by setting MinDiskWriteSpeed.

• MaxDiskWriteSpeedOtherNodeRestart

Table 22.123 This table provides type and value information for the MaxDiskWriteSpeedOtherNodeRestart data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>50M</td>
</tr>
<tr>
<td>Range</td>
<td>1M - 1024G</td>
</tr>
<tr>
<td>Restart Type</td>
<td>S</td>
</tr>
</tbody>
</table>

Set the maximum rate for writing to disk, in bytes per second, by local checkpoints and backup operations when one or more data nodes in this NDB Cluster are restarting, other than this node.

For setting the maximum rate of disk writes allowed while this data node is restarting, use MaxDiskWriteSpeedOwnRestart. For setting the maximum rate of disk writes allowed when no data nodes are restarting anywhere in the cluster, use MaxDiskWriteSpeed. The minimum speed for disk writes by all LCPs and backup operations can be adjusted by setting MinDiskWriteSpeed.

• MaxDiskWriteSpeedOwnRestart

Table 22.124 This table provides type and value information for the MaxDiskWriteSpeedOwnRestart data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>200M</td>
</tr>
<tr>
<td>Range</td>
<td>1M - 1024G</td>
</tr>
</tbody>
</table>
Set the maximum rate for writing to disk, in bytes per second, by local checkpoints and backup operations while this data node is restarting.

For setting the maximum rate of disk writes allowed while other data nodes are restarting, use `MaxDiskWriteSpeedOtherNodeRestart`. For setting the maximum rate of disk writes allowed when no data nodes are restarting anywhere in the cluster, use `MaxDiskWriteSpeed`. The minimum speed for disk writes by all LCPs and backup operations can be adjusted by setting `MinDiskWriteSpeed`.

- **MinDiskWriteSpeed**

  **Table 22.125** This table provides type and value information for the `MinDiskWriteSpeed` data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Version (or later)</strong></td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td><strong>Type or units</strong></td>
<td>numeric</td>
</tr>
<tr>
<td><strong>Default</strong></td>
<td>10M</td>
</tr>
<tr>
<td><strong>Range</strong></td>
<td>1M - 1024G</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>S</td>
</tr>
</tbody>
</table>

Set the minimum rate for writing to disk, in bytes per second, by local checkpoints and backup operations.

The maximum rates of disk writes allowed for LCPs and backups under various conditions are adjustable using the parameters `MaxDiskWriteSpeed`, `MaxDiskWriteSpeedOwnRestart`, and `MaxDiskWriteSpeedOtherNodeRestart`. See the descriptions of these parameters for more information.

- **ArbitrationTimeout**

  **Table 22.126** This table provides type and value information for the `ArbitrationTimeout` data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Version (or later)</strong></td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td><strong>Type or units</strong></td>
<td>milliseconds</td>
</tr>
<tr>
<td><strong>Default</strong></td>
<td>7500</td>
</tr>
<tr>
<td><strong>Range</strong></td>
<td>10 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter specifies how long data nodes wait for a response from the arbitrator to an arbitration message. If this is exceeded, the network is assumed to have split.

The default value is 7500 milliseconds (7.5 seconds).

- **Arbitration**

  **Table 22.127** This table provides type and value information for the `Arbitration` data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Version (or later)</strong></td>
<td>NDB 8.0.13</td>
</tr>
</tbody>
</table>
The `Arbitration` parameter enables a choice of arbitration schemes, corresponding to one of 3 possible values for this parameter:

- **Default.** This enables arbitration to proceed normally, as determined by the `ArbitrationRank` settings for the management and API nodes. This is the default value.

- **Disabled.** Setting `Arbitration = Disabled` in the `[ndbd default]` section of the `config.ini` file to accomplish the same task as setting `ArbitrationRank` to 0 on all management and API nodes. When `Arbitration` is set in this way, any `ArbitrationRank` settings are ignored.

- **WaitExternal.** The `Arbitration` parameter also makes it possible to configure arbitration in such a way that the cluster waits until after the time determined by `ArbitrationTimeout` has passed for an external cluster manager application to perform arbitration instead of handling arbitration internally. This can be done by setting `Arbitration = WaitExternal` in the `[ndbd default]` section of the `config.ini` file. For best results with the `WaitExternal` setting, it is recommended that `ArbitrationTimeout` be 2 times as long as the interval required by the external cluster manager to perform arbitration.

### Important

This parameter should be used only in the `[ndbd default]` section of the cluster configuration file. The behavior of the cluster is unspecified when `Arbitration` is set to different values for individual data nodes.

- **RestartSubscriberConnectTimeout**

This parameter determines the time that a data node waits for subscribing API nodes to connect. Once this timeout expires, any “missing” API nodes are disconnected from the cluster. To disable this timeout, set `RestartSubscriberConnectTimeout` to 0.

While this parameter is specified in milliseconds, the timeout itself is resolved to the next-greatest whole second.

### Buffering and logging

Several `[ndbd]` configuration parameters enable the advanced user to have more control over the resources used by node processes and to adjust various buffer sizes at need.

These buffers are used as front ends to the file system when writing log records to disk. If the node is running in diskless mode, these parameters can be set to their minimum values without penalty due to the fact that disk writes are “faked” by the NDB storage engine’s file system abstraction layer.
• **UndoIndexBuffer**

Table 22.129 This table provides type and value information for the UndoIndexBuffer data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>2M</td>
</tr>
<tr>
<td>Range</td>
<td>1M - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

The UNDO index buffer, whose size is set by this parameter, is used during local checkpoints. The NDB storage engine uses a recovery scheme based on checkpoint consistency in conjunction with an operational REDO log. To produce a consistent checkpoint without blocking the entire system for writes, UNDO logging is done while performing the local checkpoint. UNDO logging is activated on a single table fragment at a time. This optimization is possible because tables are stored entirely in main memory.

The UNDO index buffer is used for the updates on the primary key hash index. Inserts and deletes rearrange the hash index; the NDB storage engine writes UNDO log records that map all physical changes to an index page so that they can be undone at system restart. It also logs all active insert operations for each fragment at the start of a local checkpoint.

Reads and updates set lock bits and update a header in the hash index entry. These changes are handled by the page-writing algorithm to ensure that these operations need no UNDO logging.

This buffer is 2MB by default. The minimum value is 1MB, which is sufficient for most applications. For applications doing extremely large or numerous inserts and deletes together with large transactions and large primary keys, it may be necessary to increase the size of this buffer. If this buffer is too small, the NDB storage engine issues internal error code 677 (Index UNDO buffers overloaded).

**Important**

It is not safe to decrease the value of this parameter during a rolling restart.

• **UndoDataBuffer**

Table 22.130 This table provides type and value information for the UndoDataBuffer data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>16M</td>
</tr>
<tr>
<td>Range</td>
<td>1M - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter sets the size of the UNDO data buffer, which performs a function similar to that of the UNDO index buffer, except the UNDO data buffer is used with regard to data memory rather than index memory. This buffer is used during the local checkpoint phase of a fragment for inserts, deletes, and updates.

Because UNDO log entries tend to grow larger as more operations are logged, this buffer is also larger than its index memory counterpart, with a default value of 16MB.
This amount of memory may be unnecessarily large for some applications. In such cases, it is possible to decrease this size to a minimum of 1MB.

It is rarely necessary to increase the size of this buffer. If there is such a need, it is a good idea to check whether the disks can actually handle the load caused by database update activity. A lack of sufficient disk space cannot be overcome by increasing the size of this buffer.

If this buffer is too small and gets congested, the NDB storage engine issues internal error code 891 (Data UNDO buffers overloaded).

Important
It is not safe to decrease the value of this parameter during a rolling restart.

- **RedoBuffer**

Table 22.131 This table provides type and value information for the RedoBuffer data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>32M</td>
</tr>
<tr>
<td>Range</td>
<td>1M - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>N</td>
</tr>
</tbody>
</table>

All update activities also need to be logged. The REDO log makes it possible to replay these updates whenever the system is restarted. The NDB recovery algorithm uses a “fuzzy” checkpoint of the data together with the UNDO log, and then applies the REDO log to play back all changes up to the restoration point.

RedoBuffer sets the size of the buffer in which the REDO log is written. The default value is 32MB; the minimum value is 1MB.

If this buffer is too small, the NDB storage engine issues error code 1221 (REDO log buffers overloaded). For this reason, you should exercise care if you attempt to decrease the value of RedoBuffer as part of an online change in the cluster’s configuration.

ndbmtd allocates a separate buffer for each LDM thread (see ThreadConfig). For example, with 4 LDM threads, an ndbmtd data node actually has 4 buffers and allocates RedoBuffer bytes to each one, for a total of 4 * RedoBuffer bytes.

- **EventLogBufferSize**

Table 22.132 This table provides type and value information for the EventLogBufferSize data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>

</tr>
<tr>
<td>Range</td>
<td>0 - 64K</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>S</td>
</tr>
</tbody>
</table>

Controls the size of the circular buffer used for NDB log events within data nodes.
Controlling log messages. In managing the cluster, it is very important to be able to control the number of log messages sent for various event types to stdout. For each event category, there are 16 possible event levels (numbered 0 through 15). Setting event reporting for a given event category to level 15 means all event reports in that category are sent to stdout; setting it to 0 means that there will be no event reports made in that category.

By default, only the startup message is sent to stdout, with the remaining event reporting level defaults being set to 0. The reason for this is that these messages are also sent to the management server’s cluster log.

An analogous set of levels can be set for the management client to determine which event levels to record in the cluster log.

- **LogLevelStartup**

  Table 22.133 This table provides type and value information for the LogLevelStartup data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>

<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 15</td>
</tr>
</tbody>
</table>
The reporting level for events generated for information about the general state of the cluster.

The default level is 0.

- **MemReportFrequency**

Table 22.142 This table provides type and value information for the MemReportFrequency data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter controls how often data node memory usage reports are recorded in the cluster log; it is an integer value representing the number of seconds between reports.

Each data node's data memory and index memory usage is logged as both a percentage and a number of 32 KB pages of DataMemory, as set in the config.ini file. For example, if DataMemory is equal to 100 MB, and a given data node is using 50 MB for data memory storage, the corresponding line in the cluster log might look like this:

```
2006-12-24 01:18:16 [MgmSrvr] INFO -- Node 2: Data usage is 50%(1280 32K pages of total 2560)
```

MemReportFrequency is not a required parameter. If used, it can be set for all cluster data nodes in the [ndbd default] section of config.ini, and can also be set or overridden for individual data nodes in the corresponding [ndbd] sections of the configuration file. The minimum value—which is also the default value—is 0, in which case memory reports are logged only when memory usage reaches certain percentages (80%, 90%, and 100%), as mentioned in the discussion of statistics events in Section 22.5.6.2, "NDB Cluster Log Events".

- **StartupStatusReportFrequency**

Table 22.143 This table provides type and value information for the StartupStatusReportFrequency data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>seconds</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

When a data node is started with the --initial, it initializes the redo log file during Start Phase 4 (see Section 22.5.1, "Summary of NDB Cluster Start Phases"). When very large values are set for NoOfFragmentLogFiles, FragmentLogFileSize, or both, this initialization can take a long time. You can force reports on the progress of this process to be logged periodically, by means of the StartupStatusReportFrequency configuration parameter. In this case, progress is reported
in the cluster log, in terms of both the number of files and the amount of space that have been
initialized, as shown here:

<table>
<thead>
<tr>
<th>Date/Time</th>
<th>Log Message</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>#Total files: 80, Completed: 60</td>
</tr>
<tr>
<td></td>
<td>#Total MBytes: 20480, Completed: 15557</td>
</tr>
<tr>
<td></td>
<td>#Total files: 80, Completed: 60</td>
</tr>
<tr>
<td></td>
<td>#Total MBytes: 20480, Completed: 15570</td>
</tr>
</tbody>
</table>

These reports are logged each `StartupStatusReportFrequency` seconds during Start Phase 4. If `StartupStatusReportFrequency` is 0 (the default), then reports are written to the cluster log only when at the beginning and at the completion of the redo log file initialization process.

**Data Node Debugging Parameters**

The following parameters are intended for use during testing or debugging of data nodes, and not for use in production.

- **DictTrace**

  **Table 22.144 This table provides type and value information for the DictTrace data node configuration parameter**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>undefined</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 100</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td><strong>N</strong></td>
</tr>
</tbody>
</table>

  It is possible to cause logging of traces for events generated by creating and dropping tables using `DictTrace`. This parameter is useful only in debugging NDB kernel code. `DictTrace` takes an integer value. 0 is the default, and means no logging is performed; 1 enables trace logging, and 2 enables logging of additional `DBDICT` debugging output.

- **WatchdogImmediateKill**

  **Table 22.145 This table provides type and value information for the WatchDogImmediateKill data node configuration parameter**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td><strong>S</strong></td>
</tr>
</tbody>
</table>

  You can cause threads to be killed immediately whenever watchdog issues occur by enabling the `WatchdogImmediateKill` data node configuration parameter. This parameter should be used only when debugging or troubleshooting, to obtain trace files reporting exactly what was occurring the instant that execution ceased.

**Backup parameters.** The `[ndbd]` parameters discussed in this section define memory buffers set aside for execution of online backups.

- **BackupDataBufferSize**
In creating a backup, there are two buffers used for sending data to the disk. The backup data buffer is used to fill in data recorded by scanning a node’s tables. Once this buffer has been filled to the level specified as `BackupWriteSize`, the pages are sent to disk. While flushing data to disk, the backup process can continue filling this buffer until it runs out of space. When this happens, the backup process pauses the scan and waits until some disk writes have completed freeing up memory so that scanning may continue.

The default value for this parameter is 16MB. The minimum is 512K.

- **BackupDiskWriteSpeedPct**

This problem can be addressed by using the `BackupDiskWriteSpeedPct` configuration parameter, which takes a value in the range 0-90 (inclusive) which is interpreted as the percentage of the node’s maximum write rate budget that is reserved prior to sharing out the remainder of the budget among LDM threads for LCPs. The LDM thread running the backup receives the whole write rate budget for the backup, plus its (reduced) share of the write rate budget for local checkpoints.

The default value for this parameter is 50 (interpreted as 50%).

- **BackupLogBufferSize**

During normal operation, data nodes attempt to maximize the disk write speed used for local checkpoints and backups while remaining within the bounds set by `MinDiskWriteSpeed` and `MaxDiskWriteSpeed`. Disk write throttling gives each LDM thread an equal share of the total budget. This allows parallel LCPs to take place without exceeding the disk I/O budget. Because a backup is executed by only one LDM thread, this effectively caused a budget cut, resulting in longer backup completion times, and—if the rate of change is sufficiently high—in failure to complete the backup when the backup log buffer fill rate is higher than the achievable write rate.

This problem can be addressed by using the `BackupLogBufferSize` configuration parameter, which takes a value in the range 0-90 (inclusive) which is interpreted as the percentage of the node’s maximum write rate budget that is reserved prior to sharing out the remainder of the budget among LDM threads for LCPs. The LDM thread running the backup receives the whole write rate budget for the backup, plus its (reduced) share of the write rate budget for local checkpoints.

The default value for this parameter is 16M. The minimum is 512K.
The backup log buffer fulfills a role similar to that played by the backup data buffer, except that it is used for generating a log of all table writes made during execution of the backup. The same principles apply for writing these pages as with the backup data buffer, except that when there is no more space in the backup log buffer, the backup fails. For that reason, the size of the backup log buffer must be large enough to handle the load caused by write activities while the backup is being made. See Section 22.5.3.3, “Configuration for NDB Cluster Backups”.

The default value for this parameter should be sufficient for most applications. In fact, it is more likely for a backup failure to be caused by insufficient disk write speed than it is for the backup log buffer to become full. If the disk subsystem is not configured for the write load caused by applications, the cluster is unlikely to be able to perform the desired operations.

It is preferable to configure cluster nodes in such a manner that the processor becomes the bottleneck rather than the disks or the network connections.

The default value for this parameter is 16MB.

- **BackupMemory**

Table 22.149 This table provides type and value information for the BackupMemory data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>32M</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter is deprecated, and subject to removal in a future version of NDB Cluster. Any setting made for it is ignored.

- **BackupReportFrequency**

Table 22.150 This table provides type and value information for the BackupReportFrequency data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>seconds</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter controls how often backup status reports are issued in the management client during a backup, as well as how often such reports are written to the cluster log (provided cluster event logging is configured to permit it—see Logging and checkpointing). **BackupReportFrequency** represents the time in seconds between backup status reports.

The default value is 0.
• **BackupWriteSize**

  Table 22.151 This table provides type and value information for the BackupWriteSize data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>256K</td>
</tr>
<tr>
<td>Range</td>
<td>32K - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

  This parameter specifies the default size of messages written to disk by the backup log and backup data buffers.

  The default value for this parameter is 256KB.

• **BackupMaxWriteSize**

  Table 22.152 This table provides type and value information for the BackupMaxWriteSize data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>1M</td>
</tr>
<tr>
<td>Range</td>
<td>256K - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

  This parameter specifies the maximum size of messages written to disk by the backup log and backup data buffers.

  The default value for this parameter is 1MB.

  **Note**

  The location of the backup files is determined by the `BackupDataDir` data node configuration parameter.

  **Additional requirements.** When specifying these parameters, the following relationships must hold true. Otherwise, the data node will be unable to start.

  • `BackupDataBufferSize >= BackupWriteSize + 188KB`
  • `BackupLogBufferSize >= BackupWriteSize + 16KB`
  • `BackupMaxWriteSize >= BackupWriteSize`

### NDB Cluster Realtime Performance Parameters

The `[ndbd]` parameters discussed in this section are used in scheduling and locking of threads to specific CPUs on multiprocessor data node hosts.

  **Note**

  To make use of these parameters, the data node process must be run as system root.

• **BuildIndexThreads**
Table 22.153 This table provides type and value information for the BuildIndexThreads data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>128</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 128</td>
</tr>
<tr>
<td>Restart Type</td>
<td>S</td>
</tr>
</tbody>
</table>

This parameter determines the number of threads to create when rebuilding ordered indexes during a system or node start, as well as when running \texttt{ndb_restore \(\text{-rebuild-indexes}\). It is supported only when there is more than one fragment for the table per data node (for example, when \texttt{COMMENT=\"NDB\_TABLE=PARTITION\_BALANCE=FOR\_RA\_BY\_LDM\_X\_2\" is used with \texttt{CREATE TABLE}).

Setting this parameter to 0 (the default) disables multithreaded building of ordered indexes.

This parameter is supported when using \texttt{ndbd} or \texttt{ndbmtd}.

You can enable multithreaded builds during data node initial restarts by setting the \texttt{TwoPassInitialNodeRestartCopy} data node configuration parameter to \texttt{TRUE}.

- \texttt{LockExecuteThreadToCPU}

Table 22.154 This table provides type and value information for the LockExecuteThreadToCPU data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>set of CPU IDs</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

When used with \texttt{ndbd}, this parameter (now a string) specifies the ID of the CPU assigned to handle the \texttt{NDBCLUSTER} execution thread. When used with \texttt{ndbmtd}, the value of this parameter is a comma-separated list of CPU IDs assigned to handle execution threads. Each CPU ID in the list should be an integer in the range 0 to 65535 (inclusive).

The number of IDs specified should match the number of execution threads determined by \texttt{MaxNoOfExecutionThreads}. However, there is no guarantee that threads are assigned to CPUs in any given order when using this parameter. You can obtain more finely-grained control of this type using \texttt{ThreadConfig}.

\texttt{LockExecuteThreadToCPU} has no default value.

- \texttt{LockMaintThreadsToCPU}

Table 22.155 This table provides type and value information for the LockMaintThreadsToCPU data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>CPU ID</td>
</tr>
</tbody>
</table>
This parameter specifies the ID of the CPU assigned to handle NDBCLUSTER maintenance threads.

The value of this parameter is an integer in the range 0 to 65535 (inclusive). There is no default value.

- **Numa**

Table 22.156 This table provides type and value information for the Numa data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>1</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter determines whether Non-Uniform Memory Access (NUMA) is controlled by the operating system or by the data node process, whether the data node uses ndbd or ndbmd. By default, NDB attempts to use an interleaved NUMA memory allocation policy on any data node where the host operating system provides NUMA support.

Setting `Numa = 0` means that the datanode process does not itself attempt to set a policy for memory allocation, and permits this behavior to be determined by the operating system, which may be further guided by the separate `numactl` tool. That is, `Numa = 0` yields the system default behavior, which can be customised by `numactl`. For many Linux systems, the system default behavior is to allocate socket-local memory to any given process at allocation time. This can be problematic when using `ndbmd`; this is because `ndbmd` allocates all memory at startup, leading to an imbalance, giving different access speeds for different sockets, especially when locking pages in main memory.

Setting `Numa = 1` means that the data node process uses `libnuma` to request interleaved memory allocation. (This can also be accomplished manually, on the operating system level, using `numactl`.) Using interleaved allocation in effect tells the data node process to ignore non-uniform memory access but does not attempt to take any advantage of fast local memory; instead, the data node process tries to avoid imbalances due to slow remote memory. If interleaved allocation is not desired, set `Numa` to 0 so that the desired behavior can be determined on the operating system level.

The `Numa` configuration parameter is supported only on Linux systems where `libnuma.so` is available.

- **RealtimeScheduler**

Table 22.157 This table provides type and value information for the RealtimeScheduler data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
</tbody>
</table>
NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Setting this parameter to 1 enables real-time scheduling of data node threads.

The default is 0 (scheduling disabled).

- **SchedulerExecutionTimer**

  Table 22.158 This table provides type and value information for the SchedulerExecutionTimer data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>µs</td>
</tr>
<tr>
<td>Default</td>
<td>50</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 11000</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter specifies the time in microseconds for threads to be executed in the scheduler before being sent. Setting it to 0 minimizes the response time; to achieve higher throughput, you can increase the value at the expense of longer response times.

The default is 50 µsec, which our testing shows to increase throughput slightly in high-load cases without materially delaying requests.

- **SchedulerResponsiveness**

  Table 22.159 This table provides type and value information for the SchedulerResponsiveness data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>5</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 10</td>
</tr>
<tr>
<td>Restart Type</td>
<td>S</td>
</tr>
</tbody>
</table>

Set the balance in the NDB scheduler between speed and throughput. This parameter takes an integer whose value is in the range 0-10 inclusive, with 5 as the default. Higher values provide better response times relative to throughput. Lower values provide increased throughput at the expense of longer response times.

- **SchedulerSpinTimer**

  Table 22.160 This table provides type and value information for the SchedulerSpinTimer data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>

<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 500</td>
</tr>
</tbody>
</table>
NDB Cluster Configuration Files

**Property** | **Value**
---|---
**Restart Type** | N

This parameter specifies the time in microseconds for threads to be executed in the scheduler before sleeping.

Starting with NDB 8.0.20, if SpinMethod is set, any setting for this parameter is ignored.

- SpinMethod

**Table 22.161 This table provides type and value information for the SpinMethod data node configuration parameter**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Version (or later)</strong></td>
<td>NDB 8.0.20</td>
</tr>
<tr>
<td><strong>Type or units</strong></td>
<td>enumeration</td>
</tr>
<tr>
<td><strong>Default</strong></td>
<td>StaticSpinning</td>
</tr>
<tr>
<td><strong>Range</strong></td>
<td>CostBasedSpinning, LatencyOptimisedSpinning, DatabaseMachineSpinning, StaticSpinning</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter provides a simple interface to control adaptive spinning on data nodes, with four possible values furnishing presets for spin parameter values, as shown in the following list:

1. **StaticSpinning** (default): Sets EnableAdaptiveSpinning to false and SchedulerSpinTimer to 0. (SetAllowedSpinOverhead is not relevant in this case.)

2. **CostBasedSpinning**: Sets EnableAdaptiveSpinning to true, SchedulerSpinTimer to 100, and SetAllowedSpinOverhead to 200.

3. **LatencyOptimisedSpinning**: Sets EnableAdaptiveSpinning to true, SchedulerSpinTimer to 200, and SetAllowedSpinOverhead to 1000.

4. **DatabaseMachineSpinning**: Sets EnableAdaptiveSpinning to true, SchedulerSpinTimer to 500, and SetAllowedSpinOverhead to 10000. This is intended for use in cases where threads own their own CPUs.

The spin parameters modified by SpinMethod are described in the following list:

- **SchedulerSpinTimer**: This is the same as the data node configuration parameter of that name. The setting applied to this parameter by SpinMethod overrides any value set in the config.ini file.

- **EnableAdaptiveSpinning**: Enables or disables adaptive spinning. Disabling it causes spinning to be performed without making any checks for CPU resources. This parameter cannot be set directly in the cluster configuration file, and under most circumstances should not need to be, but can be enabled directly using DUMP 104004 1 or disabled with DUMP 104004 0 in the ndb_mgm management client.

- **SetAllowedSpinOverhead**: Sets the amount of CPU time to allow for gaining latency. This parameter cannot be set directly in the config.ini file. In most cases, the setting applied by SpinMethod should be satisfactory, but if it is necessary to change it directly, you can use DUMP 104002 overhead to do so, where overhead is a value ranging from 0 to 10000, inclusive; see the description of the indicated DUMP command for details.

On platforms lacking usable spin instructions, such as PowerPC and some SPARC platforms,spin time is set to 0 in all situations, and values for SpinMethod other than StaticSpinning are ignored.
• TwoPassInitialNodeRestartCopy

Table 22.162 This table provides type and value information for the TwoPassInitialNodeRestartCopy data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>

<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>true</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Multithreaded building of ordered indexes can be enabled for initial restarts of data nodes by setting this configuration parameter to true (the default value), which enables two-pass copying of data during initial node restarts.

You must also set BuildIndexThreads to a nonzero value.

Multi-Threading Configuration Parameters (ndbmt). ndbmt runs by default as a single-threaded process and must be configured to use multiple threads, using either of two methods, both of which require setting configuration parameters in the config.ini file. The first method is simply to set an appropriate value for the MaxNoOfExecutionThreads configuration parameter. A second method, makes it possible to set up more complex rules for ndbmt multithreading using ThreadConfig. The next few paragraphs provide information about these parameters and their use with multithreaded data nodes.

Note

A backup using parallelism on the data nodes requires that multiple LDMs are in use on all data nodes in the cluster prior to taking the backup. For more information, see Section 22.5.3.5, “Taking an NDB Backup with Parallel Data Nodes”, as well as Section 22.4.23.2, “Restoring from a backup taken in parallel”.

• MaxNoOfExecutionThreads

This parameter directly controls the number of execution threads used by ndbmt, up to a maximum of 72. Although this parameter is set in [ndbd] or [ndbd default] sections of the config.ini file, it is exclusive to ndbmt and does not apply to ndbd.

Setting MaxNoOfExecutionThreads sets the number of threads for each type as determined by a matrix in the file storage/ndb/src/kernel/vm/mt_thr_config.cpp. This table shows these numbers of threads for possible values of MaxNoOfExecutionThreads.
Table 22.164 MaxNoOfExecutionThreads values and the corresponding number of threads by thread type (LQH, TC, Send, Receive).

</table>

There is always one SUMA (replication) thread.

NoOfFragmentLogParts should be set equal to the number of LDM threads used by ndbmttd, as determined by the setting for this parameter. This ratio should not be any greater than 4:1; a configuration in which this is the case is specifically disallowed.

The number of LDM threads also determines the number of partitions used by an NDB table that is not explicitly partitioned; this is the number of LDM threads times the number of data nodes in the cluster. (If ndbd is used on the data nodes rather than ndbmttd, then there is always a single LDM thread; in this case, the number of partitions created automatically is simply equal to the number of...

Adding large tablespaces for Disk Data tables when using more than the default number of LDM threads may cause issues with resource and CPU usage if the disk page buffer is insufficiently large; see the description of the DiskPageBufferMemory configuration parameter, for more information.

The thread types are described later in this section (see ThreadConfig).

Setting this parameter outside the permitted range of values causes the management server to abort on startup with the error:

```
Error line number: Illegal value value for parameter MaxNoOfExecutionThreads.
```

For MaxNoOfExecutionThreads, a value of 0 or 1 is rounded up internally by NDB to 2, so that 2 is considered this parameter’s default and minimum value.

MaxNoOfExecutionThreads is generally intended to be set equal to the number of CPU threads available, and to allocate a number of threads of each type suitable to typical workloads. It does not assign particular threads to specified CPUs. For cases where it is desirable to vary from the settings provided, or to bind threads to CPUs, you should use ThreadConfig instead, which allows you to allocate each thread directly to a desired type, CPU, or both.

The multithreaded data node process always spawns, at a minimum, the threads listed here:

- 1 local query handler (LDM) thread
- 1 receive thread
- 1 subscription manager (SUMA or replication) thread

For a MaxNoOfExecutionThreads value of 8 or less, no TC threads are created, and TC handling is instead performed by the main thread.

Changing the number of LDM threads normally requires a system restart, whether it is changed using this parameter or ThreadConfig, but it is possible to effect the change using a node initial restart (NI) provided the following two conditions are met:

- Each LDM thread handles a maximum of 8 fragments, and
- The total number of table fragments is an integer multiple of the number of LDM threads.

In NDB 8.0, an initial restart is not required to effect a change in this parameter, as it was in some older versions of NDB Cluster.

- NoOfFragmentLogParts

<table>
<thead>
<tr>

<td>IN</td>
</tr>
</tbody>
</table>

Set the number of log file groups for redo logs belonging to this ndbmtd. The value of this parameter should be set equal to the number of LDM threads used by ndbmtd as determined by the setting...
for MaxNoOfExecutionThreads. A configuration using more than 4 redo log parts per LDM is disallowed.

See the description of MaxNoOfExecutionThreads for more information.

- **ThreadConfig**

**Table 22.166** This table provides type and value information for the ThreadConfig multi-threaded data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>string</td>
</tr>
<tr>
<td>Default</td>
<td>&quot;</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>IS</td>
</tr>
</tbody>
</table>

This parameter is used with ndbmtd to assign threads of different types to different CPUs. Its value is a string whose format has the following syntax:

```
ThreadConfig := entry[,entry[,...]]

entry := type=[param[,param[,...]]]

type := ldm | main | recv | send | rep | io | tc | watchdog | idxbld

param := count=number |
        cpubind=cpu_list |
        cpuset=cpu_list |
        spintime=number |
        realtime={0|1} |
        nosend={0|1} |
        thread_prio={0..10} |
        cpubind_exclusive=cpu_list |
        cpuset_exclusive=cpu_list
```

The curly braces ( {...} ) surrounding the list of parameters are required, even if there is only one parameter in the list.

A **param** (parameter) specifies any or all of the following information:

- The number of threads of the given type (**count**).

- The set of CPUs to which the threads of the given type are to be nonexclusively bound. This is determined by either one of **cpubind** or **cpuset**. **cpubind** causes each thread to be bound (nonexclusively) to a CPU in the set; **cpuset** means that each thread is bound (nonexclusively) to the set of CPUs specified.

On Solaris, you can instead specify a set of CPUs to which the threads of the given type are to be bound exclusively. **cpubind_exclusive** causes each thread to be bound exclusively to a CPU in the set; **cpuset_exclusive** means that each thread is bound exclusively to the set of CPUs specified.

Only one of **cpubind**, **cpuset**, **cpubind_exclusive**, or **cpuset_exclusive** can be provided in a single configuration.
• **spintime** determines the wait time in microseconds the thread spins before going to sleep.

  The default value for **spintime** is the value of the **SchedulerSpinTimer** data node configuration parameter.

  **spintime** does not apply to I/O threads, watchdog, or offline index build threads, and so cannot be set for these thread types.

• **realtime** can be set to 0 or 1. If it is set to 1, the threads run with real-time priority. This also means that **thread_prio** cannot be set.

  The **realtime** parameter is set by default to the value of the **RealtimeScheduler** data node configuration parameter.

  **realtime** cannot be set for offline index build threads.

• By setting **nosend** to 1, you can prevent a **main**, **ldm**, **rep**, or **tc** thread from assisting the send threads. This parameter is 0 by default, and cannot be used with other types of threads.

• **thread_prio** is a thread priority level that can be set from 0 to 10, with 10 representing the greatest priority. The default is 5. The precise effects of this parameter are platform-specific, and are described later in this section.

  The thread priority level cannot be set for offline index build threads.

**thread_prio settings and effects by platform.** The implementation of **thread_prio** differs between Linux/FreeBSD, Solaris, and Windows. In the following list, we discuss its effects on each of these platforms in turn:

• **Linux and FreeBSD:** We map **thread_prio** to a value to be supplied to the **nice** system call. Since a lower niceness value for a process indicates a higher process priority, increasing **thread_prio** has the effect of lowering the **nice** value.

  Table 22.167 Mapping of **thread_prio** to **nice** values on Linux and FreeBSD

<table>
<thead>
<tr>
<th><strong>thread_prio</strong> value</th>
<th><strong>nice</strong> value</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>19</td>
</tr>
<tr>
<td>1</td>
<td>16</td>
</tr>
<tr>
<td>2</td>
<td>12</td>
</tr>
<tr>
<td>3</td>
<td>8</td>
</tr>
<tr>
<td>4</td>
<td>4</td>
</tr>
<tr>
<td>5</td>
<td>0</td>
</tr>
<tr>
<td>6</td>
<td>-4</td>
</tr>
<tr>
<td>7</td>
<td>-8</td>
</tr>
<tr>
<td>8</td>
<td>-12</td>
</tr>
<tr>
<td>9</td>
<td>-16</td>
</tr>
<tr>
<td>10</td>
<td>-20</td>
</tr>
</tbody>
</table>

Some operating systems may provide for a maximum process niceness level of 20, but this is not supported by all targeted versions; for this reason, we choose 19 as the maximum **nice** value that can be set.
• **Solaris**: Setting `thread_prio` on Solaris sets the Solaris FX priority, with mappings as shown in the following table:

Table 22.168 Mapping of `thread_prio` to FX priority on Solaris

<table>
<thead>
<tr>
<th><code>thread_prio</code> value</th>
<th>Solaris FX priority</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>15</td>
</tr>
<tr>
<td>1</td>
<td>20</td>
</tr>
<tr>
<td>2</td>
<td>25</td>
</tr>
<tr>
<td>3</td>
<td>30</td>
</tr>
<tr>
<td>4</td>
<td>35</td>
</tr>
<tr>
<td>5</td>
<td>40</td>
</tr>
<tr>
<td>6</td>
<td>45</td>
</tr>
<tr>
<td>7</td>
<td>50</td>
</tr>
<tr>
<td>8</td>
<td>55</td>
</tr>
<tr>
<td>9</td>
<td>59</td>
</tr>
<tr>
<td>10</td>
<td>60</td>
</tr>
</tbody>
</table>

A `thread_prio` setting of 9 is mapped on Solaris to the special FX priority value 59, which means that the operating system also attempts to force the thread to run alone on its own CPU core.

• **Windows**: We map `thread_prio` to a Windows thread priority value passed to the Windows API `SetThreadPriority()` function. This mapping is shown in the following table:

Table 22.169 Mapping of `thread_prio` to Windows thread priority

<table>
<thead>
<tr>
<th><code>thread_prio</code> value</th>
<th>Windows thread priority</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 - 1</td>
<td>THREAD_PRIORITY_LOWEST</td>
</tr>
<tr>
<td>2 - 3</td>
<td>THREAD_PRIORITY_BELOW_NORMAL</td>
</tr>
<tr>
<td>4 - 5</td>
<td>THREAD_PRIORITY_NORMAL</td>
</tr>
<tr>
<td>6 - 7</td>
<td>THREAD_PRIORITY ABOVE_NORMAL</td>
</tr>
<tr>
<td>8 - 10</td>
<td>THREAD_PRIORITY_HIGHEST</td>
</tr>
</tbody>
</table>

The `type` attribute represents an NDB thread type. The thread types supported, and the range of permitted `count` values for each, are provided in the following list:

• **ldm**: Local query handler (DBLQH kernel block) that handles data. The more LDM threads that are used, the more highly partitioned the data becomes. Each LDM thread maintains its own sets of data and index partitions, as well as its own redo log. The value set for `ldm` must be one of the values 1, 2, 4, 6, 8, 12, 16, 24, or 32.

Changing the number of LDM threads normally requires a system restart to be effective and safe for cluster operations, this requirement is relaxed in certain cases, as explained later in this section. This is also true when this is done using `MaxNoOfExecutionThreads`.

Adding large tablespaces (hundreds of gigabytes or more) for Disk Data tables when using more than the default number of LDMs may cause issues with resource and CPU usage if `DiskPageBufferMemory` is not sufficiently large.
**NDB Cluster Configuration Files**

- **tc**: Transaction coordinator thread (DBTC kernel block) containing the state of an ongoing transaction. The maximum number of TC threads is 32.

  Optimally, every new transaction can be assigned to a new TC thread. In most cases 1 TC thread per 2 LDM threads is sufficient to guarantee that this can happen. In cases where the number of writes is relatively small when compared to the number of reads, it is possible that only 1 TC thread per 4 LQH threads is required to maintain transaction states. Conversely, in applications that perform a great many updates, it may be necessary for the ratio of TC threads to LDM threads to approach 1 (for example, 3 TC threads to 4 LDM threads).

  Setting **tc** to 0 causes TC handling to be done by the main thread. In most cases, this is effectively the same as setting it to 1.

  Range: 0 - 32

- **main**: Data dictionary and transaction coordinator (DBDIH and DBTC kernel blocks), providing schema management. This is always handled by a single dedicated thread.

  Range: 1 only.

- **recv**: Receive thread (CMVMI kernel block). Each receive thread handles one or more sockets for communicating with other nodes in an NDB Cluster, with one socket per node. NDB Cluster supports multiple receive threads; the maximum is 16 such threads.

  Range: 1 - 16

- **send**: Send thread (CMVMI kernel block). To increase throughput, it is possible to perform sends from one or more separate, dedicated threads (maximum 8).

  In NDB 8.0.20 and later, due to changes in the multithreading implementation, using many send threads can have an adverse effect on scalability.

  Previously, all threads handled their own sending directly; this can still be made to happen by setting the number of send threads to 0 (this also happens when MaxNoOfExecutionThreads is set less than 10). While doing so can have an adverse impact on throughput, it can also in some cases provide decreased latency.

  Range: 0 - 16

- **rep**: Replication thread (SUMA kernel block). Asynchronous replication operations are always handled by a single, dedicated thread.

  Range: 1 only.

- **io**: File system and other miscellaneous operations. These are not demanding tasks, and are always handled as a group by a single, dedicated I/O thread.

  Range: 1 only.

- **watchdog**: Parameters settings associated with this type are actually applied to several threads, each having a specific use. These threads include the SocketServer thread, which receives connection setups from other nodes; the SocketClient thread, which attempts to set up connections to other nodes; and the thread watchdog thread that checks that threads are progressing.

  Range: 1 only.

- **idxbld**: Offline index build threads. Unlike the other thread types listed previously, which are permanent, these are temporary threads which are created and used only during node or system
restarts, or when running `ndb_restore --rebuild-indexes`. They may be bound to CPU sets which overlap with CPU sets bound to permanent thread types.

`thread_prio`, `realtime`, and `spintime` values cannot be set for offline index build threads. In addition, `count` is ignored for this type of thread.

If `idxbld` is not specified, the default behavior is as follows:

- Offline index build threads are not bound if the I/O thread is also not bound, and these threads use any available cores.
- If the I/O thread is bound, then the offline index build threads are bound to the entire set of bound threads, due to the fact that there should be no other tasks for these threads to perform.

Range: 0 - 1.

Changing `ThreadConfig` normally requires a system initial restart, but this requirement can be relaxed under certain circumstances:

- If, following the change, the number of LDM threads remains the same as before, nothing more than a simple node restart (rolling restart, or `N`) is required to implement the change.
- Otherwise (that is, if the number of LDM threads changes), it is still possible to effect the change using a node initial restart (`NI`) provided the following two conditions are met:
  a. Each LDM thread handles a maximum of 8 fragments, and
  b. The total number of table fragments is an integer multiple of the number of LDM threads.

In any other case, a system initial restart is needed to change this parameter.

**ND**B can distinguish between thread types by both of the following criteria:

- Whether the thread is an execution thread. Threads of type `main`, `ldm`, `recv`, `rep`, `tc`, and `send` are execution threads; `io`, `watchdog`, and `idxbld` threads are not considered execution threads.
- Whether the allocation of threads to a given task is permanent or temporary. Currently all thread types except `idxbld` are considered permanent; `idxbld` threads are regarded as temporary threads.

Simple examples:

```
# Example 1.
ThreadConfig=ldm={count=2, cpubind=1,2},main={cpubind=12},rep={cpubind=11}

# Example 2.
Threadconfig=main={cpubind=0},ldm={count=4, cpubind=1,2,5,6},io={cpubind=3}
```

It is usually desirable when configuring thread usage for a data node host to reserve one or more number of CPUs for operating system and other tasks. Thus, for a host machine with 24 CPUs, you might want to use 20 CPU threads (leaving 4 for other uses), with 8 LDM threads, 4 TC threads (half the number of LDM threads), 3 send threads, 3 receive threads, and 1 thread each for schema management, asynchronous replication, and I/O operations. (This is almost the same distribution of threads used when `MaxNoOfExecutionThreads` is set equal to 20.) The following `ThreadConfig` setting performs these assignments, additionally binding all of these threads to specific CPUs:

```
ThreadConfig=ldm{count=8, cpubind=1,2,3,4,5,6,7,8},main={cpubind=9},io={cpubind=9},
rep={cpubind=10},tc{count=4, cpubind=11,12,13,14},recv={count=3, cpubind=15,16,17},
send{count=3, cpubind=18,19,20}
```

It should be possible in most cases to bind the main (schema management) thread and the I/O thread to the same CPU, as we have done in the example just shown.
The following example incorporates groups of CPUs defined using both `cpuset` and `cpubind`, as well as use of thread prioritization.

```plaintext
ThreadConfig=ldm={count=4,cpuset=0-3,thread_prio=8,spintime=200}, 
    ldm={count=4,cpubind=4-7,thread_prio=8,spintime=200}, 
    tc={count=4,cpuset=8-9,thread_prio=6},send={count=2,thread_prio=10,cpubind=10-11}, 
    main={count=1,cpubind=10},rep={count=1,cpubind=11}
```

In this case we create two LDM groups; the first uses `cpubind` and the second uses `cpuset`. `thread_prio` and `spintime` are set to the same values for each group. This means there are eight LDM threads in total. (You should ensure that `NoOfFragmentLogParts` is also set to 8.) The four TC threads use only two CPUs; it is possible when using `cpuset` to specify fewer CPUs than threads in the group. (This is not true for `cpubind`.) The send threads use two threads using `cpubind` to bind these threads to CPUs 10 and 11. The main and rep threads can reuse these CPUs.

This example shows how `ThreadConfig` and `NoOfFragmentLogParts` might be set up for a 24-CPU host with hyperthreading, leaving CPUs 10, 11, 22, and 23 available for operating system functions and interrupts:

```plaintext
NoOfFragmentLogParts=10
ThreadConfig=main,ldm={count=10,cpubind=0-4,12-16,thread_prio=9,spintime=200}, 
    tc={count=4,cpuset=5,6,7,18-19,thread_prio=8},send={count=1,cpubind=8}, 
    recv={count=1,cpubind=20},main={count=1,cpubind=9},rep={count=1,cpubind=9}, 
    io={count=1,cpubind=9,thread_prio=8},watchdog={count=1,cpubind=9,thread_prio=9}
```

The next few examples include settings for `idxbld`. The first two of these demonstrate how a CPU set defined for `idxbld` can overlap those specified for other (permanent) thread types, the first using `cpuset` and the second using `cpubind`:

```plaintext
ThreadConfig=main,ldm={count=4,cpuset=1-4},tc={count=4,cpubind=5,6,7}, 
    io={cpubind=8},idxbld={count=1,cpubind=1}
ThreadConfig=main,ldm={count=1,cpubind=1},idxbld={count=1,cpubind=1}
```

The next example specifies a CPU for the I/O thread, but not for the index build threads:

```plaintext
ThreadConfig=main,ldm={count=4,cpuset=1-4},tc={count=4,cpubind=5,6,7}, 
    io={cpubind=8}
```

Since the `ThreadConfig` setting just shown locks threads to eight cores numbered 1 through 8, it is equivalent to the setting shown here:

```plaintext
ThreadConfig=main,ldm={count=4,cpuset=1-4},tc={count=4,cpubind=5,6,7}, 
    io={cpubind=8},idxbld={count=4,cpubind=1,2,3,4,5,6,7,8}
```

In order to take advantage of the enhanced stability that the use of `ThreadConfig` offers, it is necessary to insure that CPUs are isolated, and that they not subject to interrupts, or to being scheduled for other tasks by the operating system. On many Linux systems, you can do this by setting `IRQBALANCE_BANNED_CPUS` in `/etc/sysconfig/irqbalance` to `0xFFFFF0`, and by using the `isolcpus` boot option in `grub.conf`. For specific information, see your operating system or platform documentation.

**Disk Data Configuration Parameters.** Configuration parameters affecting Disk Data behavior include the following:

- **DiskPageBufferEntries**

  **Table 22.170** This table provides type and value information for the `DiskPageBufferEntries` data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>32K pages</td>
</tr>
<tr>
<td>Default</td>
<td>10</td>
</tr>
</tbody>
</table>
This is the number of page entries (page references) to allocate. It is specified as a number of 32K pages in DiskPageBufferMemory. The default is sufficient for most cases but you may need to increase the value of this parameter if you encounter problems with very large transactions on Disk Data tables. Each page entry requires approximately 100 bytes.

- **DiskPageBufferMemory**

Table 22.171 This table provides type and value information for the DiskPageBufferMemory data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.19</td>
</tr>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>64MB</td>
</tr>
<tr>
<td>Range</td>
<td>4M - 16TB</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This determines the amount of space used for caching pages on disk, and is set in the [ndbd] or [ndbd default] section of the config.ini file.

**Note**

Previously, this parameter was specified as a number of 32 KB pages. Beginning with NDB 8.0.19, it is specified as a number of bytes.

If the value for DiskPageBufferMemory is set too low in conjunction with using more than the default number of LDM threads in ThreadConfig (for example {ldm=6...}), problems can arise when trying to add a large (for example 500G) data file to a disk-based NDB table, wherein the process takes indefinitely long while occupying one of the CPU cores.

This is due to the fact that, as part of adding a data file to a tablespace, extent pages are locked into memory in an extra PGMAN worker thread, for quick metadata access. When adding a large file, this worker has insufficient memory for all of the data file metadata. In such cases, you should either increase DiskPageBufferMemory, or add smaller tablespace files. You may also need to adjust DiskPageBufferEntries.

You can query the ndbinfo.diskpagebuffer table to help determine whether the value for this parameter should be increased to minimize unnecessary disk seeks. See Section 22.5.10.20, “The ndbinfo diskpagebuffer Table”, for more information.
NDB Cluster Configuration Files

- **SharedGlobalMemory**

  Table 22.172 This table provides type and value information for the SharedGlobalMemory data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>128M</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 64T</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter determines the amount of memory that is used for log buffers, disk operations (such as page requests and wait queues), and metadata for tablespaces, log file groups, UNDO files, and data files. The shared global memory pool also provides memory used for satisfying the memory requirements of the UNDO_BUFFER_SIZE option used with CREATE LOGFILE GROUP and ALTER LOGFILE_GROUP statements, including any default value implied for this options by the setting of the InitialLogFileGroup data node configuration parameter. SharedGlobalMemory can be set in the [ndbd] or [ndbd default] section of the config.ini configuration file, and is measured in bytes.

The default value is **128M**.

- **DiskIOThreadPool**

  Table 22.173 This table provides type and value information for the DiskIOThreadPool data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>threads</td>
</tr>
<tr>
<td>Default</td>
<td>2</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter determines the number of unbound threads used for Disk Data file access. Before DiskIOThreadPool was introduced, exactly one thread was spawned for each Disk Data file, which could lead to performance issues, particularly when using very large data files. With DiskIOThreadPool, you can—for example—access a single large data file using several threads working in parallel.

This parameter applies to Disk Data I/O threads only.

The optimum value for this parameter depends on your hardware and configuration, and includes these factors:

- **Physical distribution of Disk Data files.** You can obtain better performance by placing data files, undo log files, and the data node file system on separate physical disks. If you do this with some or all of these sets of files, then you can (and should) set DiskIOThreadPool higher to enable separate threads to handle the files on each disk.

  In NDB 8.0.19 and later, you should also disable DiskDataUsingSameDisk when using a separate disk or disks for Disk Data files; this increases the rate at which checkpoints of Disk Data tablespaces can be performed.
• **Disk performance and types.** The number of threads that can be accommodated for Disk Data file handling is also dependent on the speed and throughput of the disks. Faster disks and higher throughput allow for more disk I/O threads. Our test results indicate that solid-state disk drives can handle many more disk I/O threads than conventional disks, and thus higher values for `DiskIOThreadPool`.

Decreasing `TimeBetweenGlobalCheckpoints` is also recommended when using solid-state disk drives, in particular those using NVMe. See also Disk Data latency parameters.

The default value for this parameter is 2.

• **Disk Data file system parameters.** The parameters in the following list make it possible to place NDB Cluster Disk Data files in specific directories without the need for using symbolic links.

  • `FileSystemPathDD`  

  **Table 22.174 This table provides type and value information for the `FileSystemPathDD` data node configuration parameter**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>filename</td>
</tr>
<tr>
<td>Default</td>
<td>FileSystemPath</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>IN</td>
</tr>
</tbody>
</table>

If this parameter is specified, then NDB Cluster Disk Data data files and undo log files are placed in the indicated directory. This can be overridden for data files, undo log files, or both, by specifying values for `FileSystemPathDataFiles`, `FileSystemPathUndoFiles`, or both, as explained for these parameters. It can also be overridden for data files by specifying a path in the `ADD DATAFILE` clause of a `CREATE TABLESPACE` or `ALTER TABLESPACE` statement, and for undo log files by specifying a path in the `ADD UNDOFILE` clause of a `CREATE LOGFILE GROUP` or `ALTER LOGFILE GROUP` statement. If `FileSystemPathDD` is not specified, then `FileSystemPath` is used.

If a `FileSystemPathDD` directory is specified for a given data node (including the case where the parameter is specified in the `[ndbd default]` section of the `config.ini` file), then starting that data node with `--initial` causes all files in the directory to be deleted.

• `FileSystemPathDataFiles`  

  **Table 22.175 This table provides type and value information for the `FileSystemPathDataFiles` data node configuration parameter**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>filename</td>
</tr>
<tr>
<td>Default</td>
<td>FileSystemPathDD</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>IN</td>
</tr>
</tbody>
</table>

If this parameter is specified, then NDB Cluster Disk Data data files are placed in the indicated directory. This overrides any value set for `FileSystemPathDataFiles`. This parameter can be overridden for a given data file by specifying a path in the `ADD DATAFILE` clause of a `CREATE TABLESPACE` or `ALTER TABLESPACE` statement used to create that data file. If `FileSystemPathDataFiles`
is not specified, then FileSystemPathDD is used (or FileSystemPath, if FileSystemPathDD has also not been set).

If a FileSystemPathDataFiles directory is specified for a given data node (including the case where the parameter is specified in the [ndbd default] section of the config.ini file), then starting that data node with --initial causes all files in the directory to be deleted.

• FileSystemPathUndoFiles

Table 22.176 This table provides type and value information for the FileSystemPathUndoFiles data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>filename</td>
</tr>
<tr>
<td>Default</td>
<td>FileSystemPathDD</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>IN</td>
</tr>
</tbody>
</table>

If this parameter is specified, then NDB Cluster Disk Data undo log files are placed in the indicated directory. This overrides any value set for FileSystemPathDD. This parameter can be overridden for a given data file by specifying a path in the ADD UNDO clause of a CREATE LOGFILE GROUP or ALTER LOGFILE GROUP statement used to create that data file. If FileSystemPathUndoFiles is not specified, then FileSystemPathDD is used (or FileSystemPath, if FileSystemPathDD has also not been set).

If a FileSystemPathUndoFiles directory is specified for a given data node (including the case where the parameter is specified in the [ndbd default] section of the config.ini file), then starting that data node with --initial causes all files in the directory to be deleted.

For more information, see Section 22.5.13.1, “NDB Cluster Disk Data Objects”.

• Disk Data object creation parameters. The next two parameters enable you—when starting the cluster for the first time—to cause a Disk Data log file group, tablespace, or both, to be created without the use of SQL statements.

• InitialLogFileGroup

Table 22.177 This table provides type and value information for the InitialLogFileGroup data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>string</td>
</tr>
<tr>
<td>Default</td>
<td>[see documentation]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>S</td>
</tr>
</tbody>
</table>

This parameter can be used to specify a log file group that is created when performing an initial start of the cluster. InitialLogFileGroup is specified as shown here:

InitialLogFileGroup = [name=name;] [undo_buffer_size=size;] file-specification-list

file-specification-list:  
  file-specification[; file-specification[; ...]]

file-specification:  
  filename:size
The name of the log file group is optional and defaults to DEFAULT-LG. The undo_buffer_size is also optional; if omitted, it defaults to 64M. Each file-specification corresponds to an undo log file, and at least one must be specified in the file-specification-list. Undo log files are placed according to any values that have been set for FileSystemPath, FileSystemPathDD, and FileSystemPathUndoFiles, just as if they had been created as the result of a CREATE LOGFILE GROUP or ALTER LOGFILE GROUP statement.

Consider the following:

```
InitialLogFileGroup = name=LG1; undo_buffer_size=128M; undo1.log:250M; undo2.log:150M
```

This is equivalent to the following SQL statements:

```
CREATE LOGFILE GROUP LG1
   ADD UNDOFILE 'undo1.log'
   INITIAL_SIZE 250M
   UNDO_BUFFER_SIZE 128M
   ENGINE NDBCLUSTER;

ALTER LOGFILE GROUP LG1
   ADD UNDOFILE 'undo2.log'
   INITIAL_SIZE 150M
   ENGINE NDBCLUSTER;
```

This logfile group is created when the data nodes are started with --initial.

Resources for the initial log file group are added to the global memory pool along with those indicated by the value of SharedGlobalMemory.

This parameter, if used, should always be set in the [ndbd default] section of the config.ini file. The behavior of an NDB Cluster when different values are set on different data nodes is not defined.

- InitialTablespace

Table 22.178 This table provides type and value information for the InitialTablespace data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>string</td>
</tr>
<tr>
<td>Default</td>
<td>[see documentation]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>S</td>
</tr>
</tbody>
</table>

This parameter can be used to specify an NDB Cluster Disk Data tablespace that is created when performing an initial start of the cluster. InitialTablespace is specified as shown here:

```
InitialTablespace = [name=name;] [extent_size=size;] file-specification-list
```

The name of the tablespace is optional and defaults to DEFAULT-TS. The extent_size is also optional; it defaults to 1M. The file-specification-list uses the same syntax as shown with the InitialLogfileGroup parameter, the only difference being that each file-specification used with InitialTablespace corresponds to a data file. At least one must be specified in the file-specification-list. Data files are placed according to any values that have been set for FileSystemPath, FileSystemPathDD, and
FileStreamPathDataFiles, just as if they had been created as the result of a CREATE TABLESPACE or ALTER TABLESPACE statement.

For example, consider the following line specifying InitialTablespace in the [ndbd default] section of the config.ini file (as with InitialLogfileGroup, this parameter should always be set in the [ndbd default] section, as the behavior of an NDB Cluster when different values are set on different data nodes is not defined):

```
InitialTablespace = name=TS1; extent_size=8M; data1.dat:2G; data2.dat:4G
```

This is equivalent to the following SQL statements:

```
CREATE TABLESPACE TS1
  ADD DATAFILE 'data1.dat'
  EXTENT_SIZE 8M
  INITIAL_SIZE 2G
  ENGINE NDBCLUSTER;

ALTER TABLESPACE TS1
  ADD DATAFILE 'data2.dat'
  INITIAL_SIZE 4G
  ENGINE NDBCLUSTER;
```

This tablespace is created when the data nodes are started with --initial, and can be used whenever creating NDB Cluster Disk Data tables thereafter.

- **Disk Data latency parameters.** The two parameters listed here can be used to improve handling of latency issues with NDB Cluster Disk Data tables.

  - **MaxDiskDataLatency**

  Table 22.179 This table provides type and value information for the MaxDiskDataLatency data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.19</td>
</tr>
<tr>
<td>Type or units</td>
<td>ms</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 8000</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter controls the maximum allowed mean latency for disk access (maximum 8000 milliseconds). When this limit is reached, NDB begins to abort transactions in order to decrease pressure on the Disk Data I/O subsystem. Use 0 to disable the latency check.

- **DiskDataUsingSameDisk**

  Table 22.180 This table provides type and value information for the DiskDataUsingSameDisk data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.19</td>
</tr>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>true</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
</tbody>
</table>
NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Set this parameter to false if your Disk Data tablespaces use one or more separate disks. Doing so allows checkpoints to tablespaces to be executed at a higher rate than normally used for when disks are shared.

When `DiskDataUsingSameDisk` is true, NDB decreases the rate of Disk Data checkpointing whenever an in-memory checkpoint is in progress to help ensure that disk load remains constant.

**Disk Data and GCP Stop errors.** Errors encountered when using Disk Data tables such as Node nodeid killed this node because GCP stop was detected (error 2303) are often referred to as “GCP stop errors”. Such errors occur when the redo log is not flushed to disk quickly enough; this is usually due to slow disks and insufficient disk throughput.

You can help prevent these errors from occurring by using faster disks, and by placing Disk Data files on a separate disk from the data node file system. Reducing the value of `TimeBetweenGlobalCheckpoints` tends to decrease the amount of data to be written for each global checkpoint, and so may provide some protection against redo log buffer overflows when trying to write a global checkpoint; however, reducing this value also permits less time in which to write the GCP, so this must be done with caution.

In addition to the considerations given for `DiskPageBufferMemory` as explained previously, it is also very important that the `DiskIOThreadPool` configuration parameter be set correctly; having `DiskIOThreadPool` set too high is very likely to cause GCP stop errors (Bug #37227).

GCP stops can be caused by save or commit timeouts; the `TimeBetweenEpochsTimeout` data node configuration parameter determines the timeout for commits. However, it is possible to disable both types of timeouts by setting this parameter to 0.

**Parameters for configuring send buffer memory allocation.** Send buffer memory is allocated dynamically from a memory pool shared between all transporters, which means that the size of the send buffer can be adjusted as necessary. (Previously, the NDB kernel used a fixed-size send buffer for every node in the cluster, which was allocated when the node started and could not be changed while the node was running.) The `TotalSendBufferMemory` and `OverLoadLimit` data node configuration parameters permit the setting of limits on this memory allocation. For more information about the use of these parameters (as well as `SendBufferMemory`), see Section 22.3.3.14, “Configuring NDB Cluster Send Buffer Parameters”.

- **ExtraSendBufferMemory**
  This parameter specifies the amount of transporter send buffer memory to allocate in addition to any set using `TotalSendBufferMemory`, `SendBufferMemory`, or both.

- **TotalSendBufferMemory**
  This parameter is used to determine the total amount of memory to allocate on this node for shared send buffer memory among all configured transporters.

  If this parameter is set, its minimum permitted value is 256KB; 0 indicates that the parameter has not been set. For more detailed information, see Section 22.3.3.14, “Configuring NDB Cluster Send Buffer Parameters”.

See also Section 22.5.15, “Adding NDB Cluster Data Nodes Online”.

**Redo log over-commit handling.** It is possible to control a data node’s handling of operations when too much time is taken flushing redo logs to disk. This occurs when a given redo log flush takes longer than `RedoOverCommitLimit` seconds, more than `RedoOverCommitCounter` times, causing any pending transactions to be aborted. When this happens, the API node that sent the transaction can handle the operations that should have been committed either by queuing the operations and re-trying
them, or by aborting them, as determined by `DefaultOperationRedoProblemAction`. The data node configuration parameters for setting the timeout and number of times it may be exceeded before the API node takes this action are described in the following list:

- **RedoOverCommitCounter**

  Table 22.181 This table provides type and value information for the RedoOverCommitCounter data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>3</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

  **Restart Type**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.19</td>
</tr>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>3</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

When RedoOverCommitLimit is exceeded when trying to write a given redo log to disk this many times or more, any transactions that were not committed as a result are aborted, and an API node where any of these transactions originated handles the operations making up those transactions according to its value for `DefaultOperationRedoProblemAction` (by either queuing the operations to be re-tried, or aborting them).

- **RedoOverCommitLimit**

  Table 22.182 This table provides type and value information for the RedoOverCommitLimit data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>seconds</td>
</tr>
<tr>
<td>Default</td>
<td>20</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

  **Restart Type**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.19</td>
</tr>
<tr>
<td>Type or units</td>
<td>seconds</td>
</tr>
<tr>
<td>Default</td>
<td>20</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

This parameter sets an upper limit in seconds for trying to write a given redo log to disk before timing out. The number of times the data node tries to flush this redo log, but takes longer than RedoOverCommitLimit, is kept and compared with RedoOverCommitCounter, and when flushing takes too long more times than the value of that parameter, any transactions that were not committed as a result of the flush timeout are aborted. When this occurs, the API node where any of these transactions originated handles the operations making up those transactions according to its `DefaultOperationRedoProblemAction` setting (it either queues the operations to be re-tried, or aborts them).
Controlling restart attempts. It is possible to exercise finely-grained control over restart attempts by data nodes when they fail to start using the `MaxStartFailRetries` and `StartFailRetryDelay` data node configuration parameters.

`MaxStartFailRetries` limits the total number of retries made before giving up on starting the data node, `StartFailRetryDelay` sets the number of seconds between retry attempts. These parameters are listed here:

- **StartFailRetryDelay**

  Table 22.183 This table provides type and value information for the `StartFailRetryDelay` data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

  Use this parameter to set the number of seconds between restart attempts by the data node in the event on failure on startup. The default is 0 (no delay).

  Both this parameter and `MaxStartFailRetries` are ignored unless `StopOnError` is equal to 0.

- **MaxStartFailRetries**

  Table 22.184 This table provides type and value information for the `MaxStartFailRetries` data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>3</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

  Use this parameter to limit the number restart attempts made by the data node in the event that it fails on startup. The default is 3 attempts.

  Both this parameter and `StartFailRetryDelay` are ignored unless `StopOnError` is equal to 0.

NDB index statistics parameters. The parameters in the following list relate to NDB index statistics generation.

- **IndexStatAutoCreate**

  Table 22.185 This table provides type and value information for the `IndexStatAutoCreate` data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>

<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0, 1</td>
</tr>
</tbody>
</table>
### NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Restart Type</strong></td>
<td>S</td>
</tr>
</tbody>
</table>

Enable (set equal to 1) or disable (set equal to 0) automatic statistics collection when indexes are created. Disabled by default.

- **IndexStatAutoUpdate**

Table 22.186 This table provides type and value information for the IndexStatAutoUpdate data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Version (or later)</strong></td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td><strong>Type or units</strong></td>
<td>integer</td>
</tr>
<tr>
<td><strong>Default</strong></td>
<td>0</td>
</tr>
<tr>
<td><strong>Range</strong></td>
<td>0, 1</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>S</td>
</tr>
</tbody>
</table>

Enable (set equal to 1) or disable (set equal to 0) monitoring of indexes for changes and trigger automatic statistics updates these are detected. The amount and degree of change needed to trigger the updates are determined by the settings for the `IndexStatTriggerPct` and `IndexStatTriggerScale` options.

- **IndexStatSaveSize**

Table 22.187 This table provides type and value information for the IndexStatSaveSize data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Version (or later)</strong></td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td><strong>Type or units</strong></td>
<td>bytes</td>
</tr>
<tr>
<td><strong>Default</strong></td>
<td>32768</td>
</tr>
<tr>
<td><strong>Range</strong></td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>IN</td>
</tr>
</tbody>
</table>

Maximum space in bytes allowed for the saved statistics of any given index in the NDB system tables and in the `mysqld` memory cache.

At least one sample is always produced, regardless of any size limit. This size is scaled by `IndexStatSaveScale`.

The size specified by `IndexStatSaveSize` is scaled by the value of `IndexStatTriggerPct` for a large index, times 0.01. This is further multiplied by the logarithm to the base 2 of the index size. Setting `IndexStatTriggerPct` equal to 0 disables the scaling effect.

- **IndexStatSaveScale**

Table 22.188 This table provides type and value information for the IndexStatSaveScale data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Version (or later)</strong></td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td><strong>Type or units</strong></td>
<td>percentage</td>
</tr>
<tr>
<td><strong>Default</strong></td>
<td>100</td>
</tr>
</tbody>
</table>
The size specified by `IndexStatSaveSize` is scaled by the value of `IndexStatTriggerPct` for a large index, times 0.01. This is further multiplied by the logarithm to the base 2 of the index size. Setting `IndexStatTriggerPct` equal to 0 disables the scaling effect.

- **IndexStatTriggerPct**

Table 22.189 This table provides type and value information for the `IndexStatTriggerPct` data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>percentage</td>
</tr>
<tr>
<td>Default</td>
<td>100</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>IN</td>
</tr>
</tbody>
</table>

Percentage change in updates that triggers an index statistics update. The value is scaled by `IndexStatTriggerScale`. You can disable this trigger altogether by setting `IndexStatTriggerPct` to 0.

- **IndexStatTriggerScale**

Table 22.190 This table provides type and value information for the `IndexStatTriggerScale` data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>percentage</td>
</tr>
<tr>
<td>Default</td>
<td>100</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>IN</td>
</tr>
</tbody>
</table>

Scale `IndexStatTriggerPct` by this amount times 0.01 for a large index. A value of 0 disables scaling.

- **IndexStatUpdateDelay**

Table 22.191 This table provides type and value information for the `IndexStatUpdateDelay` data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>seconds</td>
</tr>
<tr>
<td>Default</td>
<td>60</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>IN</td>
</tr>
</tbody>
</table>

Minimum delay in seconds between automatic index statistics updates for a given index. Setting this variable to 0 disables any delay. The default is 60 seconds.
**Restart types.** Information about the restart types used by the parameter descriptions in this section is shown in the following table:

Table 22.192 NDB Cluster restart types

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Restart Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>N</td>
<td>Node</td>
<td>The parameter can be updated using a rolling restart (see Section 22.5.5, “Performing a Rolling Restart of an NDB Cluster”)</td>
</tr>
<tr>
<td>S</td>
<td>System</td>
<td>All cluster nodes must be shut down completely, then restarted, to effect a change in this parameter</td>
</tr>
<tr>
<td>I</td>
<td>Initial</td>
<td>Data nodes must be restarted using the <code>--initial</code> option</td>
</tr>
</tbody>
</table>

22.3.3.7 Defining SQL and Other API Nodes in an NDB Cluster

The `[mysqlld]` and `[api]` sections in the `config.ini` file define the behavior of the MySQL servers (SQL nodes) and other applications (API nodes) used to access cluster data. None of the parameters shown is required. If no computer or host name is provided, any host can use this SQL or API node.

Generally speaking, a `[mysqlld]` section is used to indicate a MySQL server providing an SQL interface to the cluster, and an `[api]` section is used for applications other than `mysqlld` processes accessing cluster data, but the two designations are actually synonymous; you can, for instance, list parameters for a MySQL server acting as an SQL node in an `[api]` section.

**Note**

For a discussion of MySQL server options for NDB Cluster, see MySQL Server Options for NDB Cluster. For information about MySQL server system variables relating to NDB Cluster, see NDB Cluster System Variables.

• **Id**

Table 22.193 This table provides type and value information for the Id API node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 255</td>
</tr>
<tr>
<td>Restart Type</td>
<td>IS</td>
</tr>
</tbody>
</table>

The **Id** is an integer value used to identify the node in all cluster internal messages. The permitted range of values is 1 to 255 inclusive. This value must be unique for each node in the cluster, regardless of the type of node.

**Note**

In NDB 8.0.18 and later, data node IDs must be less than 145. If you plan to deploy a large number of data nodes, it is a good idea to limit the node IDs for API nodes (and management nodes) to values greater than 144. (Previous to NDB 8.0.18, the maximum supported value for a data node ID was 48.)

**NodeId** is the preferred parameter name to use when identifying API nodes. (**Id** continues to be supported for backward compatibility, but is now deprecated and generates a warning when used. It is also subject to future removal.)

• **ConnectionMap**
Table 22.194 This table provides type and value information for the ConnectionMap API node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>string</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Specifies which data nodes to connect.

- **NodeId**

Table 22.195 This table provides type and value information for the NodeId API node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 255</td>
</tr>
<tr>
<td>Restart Type</td>
<td>IS</td>
</tr>
</tbody>
</table>

The **NodeId** is an integer value used to identify the node in all cluster internal messages. The permitted range of values is 1 to 255 inclusive. This value must be unique for each node in the cluster, regardless of the type of node.

**Note**

In NDB 8.0.18 and later, data node IDs must be less than 145. If you plan to deploy a large number of data nodes, it is a good idea to limit the node IDs for API nodes (and management nodes) to values greater than 144. (Previous to NDB 8.0.18, the maximum supported value for a data node ID was 48.)

**NodeId** is the preferred parameter name to use when identifying management nodes. An alias, **Id**, was used for this purpose in very old versions of NDB Cluster, and continues to be supported for backward compatibility; it is now deprecated and generates a warning when used, and is subject to removal in a future release of NDB Cluster.

- **ExecuteOnComputer**

Table 22.196 This table provides type and value information for the ExecuteOnComputer API node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>name</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>S</td>
</tr>
</tbody>
</table>

This refers to the **Id** set for one of the computers (hosts) defined in a [computer] section of the configuration file.
Important

This parameter is deprecated, and is subject to removal in a future release. Use the `HostName` parameter instead.

- **HostName**

Table 22.197 This table provides type and value information for the `HostName` API node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>name or IP address</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Specifying this parameter defines the hostname of the computer on which the SQL node (API node) is to reside. To specify a hostname, either this parameter or `ExecuteOnComputer` is required.

If no `HostName` or `ExecuteOnComputer` is specified in a given `[mysql]` or `[api]` section of the `config.ini` file, then an SQL or API node may connect using the corresponding “slot” from any host which can establish a network connection to the management server host machine. *This differs from the default behavior for data nodes, where `localhost` is assumed for `HostName` unless otherwise specified.*

- **LocationDomainId**

Table 22.198 This table provides type and value information for the `LocationDomainId` API node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 16</td>
</tr>
<tr>
<td>Restart Type</td>
<td>S</td>
</tr>
</tbody>
</table>

Assigns an SQL or other API node to a specific availability domain (also known as an availability zone) within a cloud. By informing NDB which nodes are in which availability domains, performance can be improved in a cloud environment in the following ways:

- If requested data is not found on the same node, reads can be directed to another node in the same availability domain.

- Communication between nodes in different availability domains are guaranteed to use NDB transporters' WAN support without any further manual intervention.

- The transporter’s group number can be based on which availability domain is used, such that also SQL and other API nodes communicate with local data nodes in the same availability domain whenever possible.
• The arbitrator can be selected from an availability domain in which no data nodes are present, or, if no such availability domain can be found, from a third availability domain.

LocationDomainId takes an integer value between 0 and 16 inclusive, with 0 being the default; using 0 is the same as leaving the parameter unset.

• ArbitrationRank

Table 22.199 This table provides type and value information for the ArbitrationRank API node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>0-2</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 2</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter defines which nodes can act as arbitrators. Both management nodes and SQL nodes can be arbitrators. A value of 0 means that the given node is never used as an arbitrator, a value of 1 gives the node high priority as an arbitrator, and a value of 2 gives it low priority. A normal configuration uses the management server as arbitrator, setting its ArbitrationRank to 1 (the default for management nodes) and those for all SQL nodes to 0 (the default for SQL nodes).

By setting ArbitrationRank to 0 on all management and SQL nodes, you can disable arbitration completely. You can also control arbitration by overriding this parameter; to do so, set the Arbitration parameter in the [ndbd default] section of the config.ini global configuration file.

• ArbitrationDelay

Table 22.200 This table provides type and value information for the ArbitrationDelay API node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Setting this parameter to any other value than 0 (the default) means that responses by the arbitrator to arbitration requests will be delayed by the stated number of milliseconds. It is usually not necessary to change this value.

• BatchByteSize

Table 22.201 This table provides type and value information for the BatchByteSize API node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>16K</td>
</tr>
</tbody>
</table>
For queries that are translated into full table scans or range scans on indexes, it is important for best performance to fetch records in properly sized batches. It is possible to set the proper size both in terms of number of records (BatchSize) and in terms of bytes (BatchByteSize). The actual batch size is limited by both parameters.

The speed at which queries are performed can vary by more than 40% depending upon how this parameter is set.

This parameter is measured in bytes. The default value is 16K.

- **BatchSize**

  Table 22.202 This table provides type and value information for the BatchSize API node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>records</td>
</tr>
<tr>
<td>Default</td>
<td>256</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 992</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter is measured in number of records and is by default set to 256. The maximum size is 992.

- **ExtraSendBufferMemory**

  Table 22.203 This table provides type and value information for the ExtraSendBufferMemory API node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter specifies the amount of transporter send buffer memory to allocate in addition to any that has been set using TotalSendBufferMemory, SendBufferMemory, or both.

- **HeartbeatThreadPriority**

  Table 22.204 This table provides type and value information for the HeartbeatThreadPriority API node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>string</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
</tbody>
</table>
Use this parameter to set the scheduling policy and priority of heartbeat threads for management and API nodes. The syntax for setting this parameter is shown here:

\[
\text{HeartbeatThreadPriority} = \text{policy}[, \text{priority}]
\]

\[
\begin{align*}
\text{policy}: & \quad \{\text{FIFO} | \text{RR}\}
\end{align*}
\]

When setting this parameter, you must specify a policy. This is one of FIFO (first in, first in) or RR (round robin). This followed optionally by the priority (an integer).

### MaxScanBatchSize

Table 22.205 This table provides type and value information for the `MaxScanBatchSize` API node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>256K</td>
</tr>
<tr>
<td>Range</td>
<td>32K - 16M</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

The batch size is the size of each batch sent from each data node. Most scans are performed in parallel to protect the MySQL Server from receiving too much data from many nodes in parallel; this parameter sets a limit to the total batch size over all nodes.

The default value of this parameter is set to 256KB. Its maximum size is 16MB.

### TotalSendBufferMemory

Table 22.206 This table provides type and value information for the `TotalSendBufferMemory` API node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>256K - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter is used to determine the total amount of memory to allocate on this node for shared send buffer memory among all configured transporters.

If this parameter is set, its minimum permitted value is 256KB; 0 indicates that the parameter has not been set. For more detailed information, see Section 22.3.3.14, "Configuring NDB Cluster Send Buffer Parameters".
• AutoReconnect

Table 22.207 This table provides type and value information for the AutoReconnect API node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter is `false` by default. This forces disconnected API nodes (including MySQL Servers acting as SQL nodes) to use a new connection to the cluster rather than attempting to re-use an existing one, as re-use of connections can cause problems when using dynamically-allocated node IDs. (Bug #45921)

**Note**

This parameter can be overridden using the NDB API. For more information, see `Ndb_cluster_connection::set_auto_reconnect()`, and `Ndb_cluster_connection::get_auto_reconnect()`.

• DefaultOperationRedoProblemAction

Table 22.208 This table provides type and value information for the DefaultOperationRedoProblemAction API node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>enumeration</td>
</tr>
<tr>
<td>Default</td>
<td>QUEUE</td>
</tr>
<tr>
<td>Range</td>
<td>ABORT, QUEUE</td>
</tr>
<tr>
<td>Restart Type</td>
<td>S</td>
</tr>
</tbody>
</table>

This parameter (along with `RedoOverCommitLimit` and `RedoOverCommitCounter`) controls the data node’s handling of operations when too much time is taken flushing redo logs to disk. This occurs when a given redo log flush takes longer than `RedoOverCommitLimit` seconds, more than `RedoOverCommitCounter` times, causing any pending transactions to be aborted.

When this happens, the node can respond in either of two ways, according to the value of `DefaultOperationRedoProblemAction`, listed here:

- **ABORT**: Any pending operations from aborted transactions are also aborted.
- **QUEUE**: Pending operations from transactions that were aborted are queued up to be re-tried. This the default. Pending operations are still aborted when the redo log runs out of space—that is, when `P_TAIL_PROBLEM` errors occur.

• DefaultHashMapSize

Table 22.209 This table provides type and value information for the DefaultHashMapSize API node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
</tbody>
</table>
The size of the table hash maps used by NDB is configurable using this parameter. DefaultHashMapSize can take any of three possible values (0, 240, 3840). These values and their effects are described in the following table.

Table 22.210 DefaultHashMapSize parameter values

<table>
<thead>
<tr>
<th>Value</th>
<th>Description / Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Use the lowest value set, if any, for this parameter among all data nodes and API nodes in the cluster; if it is not set on any data or API node, use the default value.</td>
</tr>
<tr>
<td>240</td>
<td>Old default hash map size</td>
</tr>
<tr>
<td>3840</td>
<td>Hash map size used by default in NDB 8.0</td>
</tr>
</tbody>
</table>

The original intended use for this parameter was to facilitate upgrades and downgrades to and from older NDB Cluster versions, in which the hash map size differed, due to the fact that this change was not otherwise backward compatible. This is not an issue when upgrading to or downgrading from NDB Cluster 8.0.

- **Wan**

Table 22.211 This table provides type and value information for the wan API node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Use WAN TCP setting as default.

- **ConnectBackoffMaxTime**

Table 22.212 This table provides type and value information for the ConnectBackoffMaxTime API node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

In an NDB Cluster with many unstarted data nodes, the value of this parameter can be raised to circumvent connection attempts to data nodes which have not yet begun to function in the cluster, as well as moderate high traffic to management nodes. As long as the API node is not connected.
to any new data nodes, the value of the `StartConnectBackoffMaxTime` parameter is applied; otherwise, `ConnectBackoffMaxTime` is used to determine the length of time in milliseconds to wait between connection attempts.

Time elapsed during node connection attempts is not taken into account when calculating elapsed time for this parameter. The timeout is applied with approximately 100 ms resolution, starting with a 100 ms delay; for each subsequent attempt, the length of this period is doubled until it reaches `ConnectBackoffMaxTime` milliseconds, up to a maximum of 100000 ms (100s).

Once the API node is connected to a data node and that node reports (in a heartbeat message) that it has connected to other data nodes, connection attempts to those data nodes are no longer affected by this parameter, and are made every 100 ms thereafter until connected. Once a data node has started, it can take up `HeartbeatIntervalDbApi` for the API node to be notified that this has occurred.

- `StartConnectBackoffMaxTime`

Table 22.213 This table provides type and value information for the `StartConnectBackoffMaxTime` API node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

In an NDB Cluster with many unstarted data nodes, the value of this parameter can be raised to circumvent connection attempts to data nodes which have not yet begun to function in the cluster, as well as moderate high traffic to management nodes. As long as the API node is not connected to any new data nodes, the value of the `StartConnectBackoffMaxTime` parameter is applied; otherwise, `ConnectBackoffMaxTime` is used to determine the length of time in milliseconds to wait between connection attempts.

Time elapsed during node connection attempts is not taken into account when calculating elapsed time for this parameter. The timeout is applied with approximately 100 ms resolution, starting with a 100 ms delay; for each subsequent attempt, the length of this period is doubled until it reaches `StartConnectBackoffMaxTime` milliseconds, up to a maximum of 100000 ms (100s).

Once the API node is connected to a data node and that node reports (in a heartbeat message) that it has connected to other data nodes, connection attempts to those data nodes are no longer affected by this parameter, and are made every 100 ms thereafter until connected. Once a data node has started, it can take up `HeartbeatIntervalDbApi` for the API node to be notified that this has occurred.

**API Node Debugging Parameters.** You can use the `ApiVerbose` configuration parameter to enable debugging output from a given API node. This parameter takes an integer value. 0 is the default, and disables such debugging; 1 enables debugging output to the cluster log; 2 adds `DBDICT` debugging output as well. (Bug #20638450) See also DUMP 1229.

You can also obtain information from a MySQL server running as an NDB Cluster SQL node using `SHOW STATUS` in the `mysql` client, as shown here:

```
mysql> SHOW STATUS LIKE 'ndb\%';
+-----------------------------+----------------+
| Variable_name               | Value          |
+-----------------------------+----------------+
| Ndb_cluster_node_id         | 5              |
| Ndb_config_from_host        | 198.51.100.112 |
```
NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>Ndb_config_from_port</th>
<th>1186</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ndb_number_of_storage_nodes</td>
<td>4</td>
</tr>
</tbody>
</table>

4 rows in set (0.02 sec)

For information about the status variables appearing in the output from this statement, see NDB Cluster Status Variables.

**Note**

To add new SQL or API nodes to the configuration of a running NDB Cluster, it is necessary to perform a rolling restart of all cluster nodes after adding new [mysqld] or [api] sections to the config.ini file (or files, if you are using more than one management server). This must be done before the new SQL or API nodes can connect to the cluster.

It is *not* necessary to perform any restart of the cluster if new SQL or API nodes can employ previously unused API slots in the cluster configuration to connect to the cluster.

**Restart types.** Information about the restart types used by the parameter descriptions in this section is shown in the following table:

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Restart Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>N</td>
<td>Node</td>
<td>The parameter can be updated using a rolling restart (see Section 22.5.5, “Performing a Rolling Restart of an NDB Cluster”)</td>
</tr>
<tr>
<td>S</td>
<td>System</td>
<td>All cluster nodes must be shut down completely, then restarted, to effect a change in this parameter</td>
</tr>
<tr>
<td>I</td>
<td>Initial</td>
<td>Data nodes must be restarted using the --initial option</td>
</tr>
</tbody>
</table>

### 22.3.3.8 Defining the System

The [system] section is used for parameters applying to the cluster as a whole. The Name system parameter is used with MySQL Enterprise Monitor; ConfigGenerationNumber and PrimaryMGMNode are not used in production environments. Except when using NDB Cluster with MySQL Enterprise Monitor, is not necessary to have a [system] section in the config.ini file.

More information about these parameters can be found in the following list:

- **ConfigGenerationNumber**

#### Table 22.215 This table provides type and value information for the ConfigGenerationNumber system configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>N</td>
</tr>
</tbody>
</table>

Configuration generation number. This parameter is currently unused.

- **Name**
NDB Cluster Configuration Files

Table 22.216 This table provides type and value information for the Name system configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>string</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Set a name for the cluster. This parameter is required for deployments with MySQL Enterprise Monitor; it is otherwise unused.

You can obtain the value of this parameter by checking the `Ndb_system_name` status variable. In NDB API applications, you can also retrieve it using `get_system_name()`.

- PrimaryMGMNode

Table 22.217 This table provides type and value information for the PrimaryMGMNode system configuration parameter

| Property         | Value
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Node ID of the primary management node. This parameter is currently unused.

Restart types. Information about the restart types used by the parameter descriptions in this section is shown in the following table:

Table 22.218 NDB Cluster restart types

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Restart Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>N</td>
<td>Node</td>
<td>The parameter can be updated using a rolling restart (see Section 22.5.5, “Performing a Rolling Restart of an NDB Cluster”)</td>
</tr>
<tr>
<td>S</td>
<td>System</td>
<td>All cluster nodes must be shut down completely, then restarted, to effect a change in this parameter</td>
</tr>
<tr>
<td>I</td>
<td>Initial</td>
<td>Data nodes must be restarted using the <code>--initial</code> option</td>
</tr>
</tbody>
</table>

22.3.3.9 MySQL Server Options and Variables for NDB Cluster

This section provides information about MySQL server options, server and status variables that are specific to NDB Cluster. For general information on using these, and for other options and variables not specific to NDB Cluster, see Section 5.1, “The MySQL Server”.

For NDB Cluster configuration parameters used in the cluster configuration file (usually named `config.ini`), see Section 22.3, “Configuration of NDB Cluster.”

MySQL Server Options for NDB Cluster
This section provides descriptions of `mysqld` server options relating to NDB Cluster. For information about `mysqld` options not specific to NDB Cluster, and for general information about the use of options with `mysqld`, see Section 5.1.7, “Server Command Options”.

For information about command-line options used with other NDB Cluster processes (`ndbd`, `ndb_mgmd`, and `ndb_mgm`), see Section 22.4.31, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”. For information about command-line options used with NDB utility programs (such as `ndb_desc`, `ndb_size.pl`, and `ndb_show_tables`), see Section 22.4, “NDB Cluster Programs”.

- `--ndbcluster`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--ndbcluster[=value]</code></td>
</tr>
<tr>
<td>Disabled by</td>
<td><code>skip-ndbcluster</code></td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>ON</td>
</tr>
<tr>
<td>Valid Values</td>
<td>OFF, FORCE</td>
</tr>
</tbody>
</table>

The `NDBCLUSTER` storage engine is necessary for using NDB Cluster. If a `mysqld` binary includes support for the `NDBCLUSTER` storage engine, the engine is disabled by default. Use the `--ndbcluster` option to enable it. Use `--skip-ndbcluster` to explicitly disable the engine.

The `--ndbcluster` option is ignored (and the `NDB` storage engine is not enabled) if `--initialize` is also used. (It is neither necessary nor desirable to use this option together with `--initialize`.)

- `--ndb-allow-copying-alter-table=[ON|OFF]`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--ndb-allow-copying-alter-table[={OFF</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>ndb_allow_copying_alter_table</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>ON</td>
</tr>
</tbody>
</table>

Let `ALTER TABLE` and other DDL statements use copying operations on `NDB` tables. Set to `OFF` to keep this from happening; doing so may improve performance of critical applications.

- `--ndb-batch-size=#`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--ndb-batch-size</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>ndb_batch_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
</tbody>
</table>
### NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>32768</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>31536000</td>
</tr>
</tbody>
</table>

This sets the size in bytes that is used for NDB transaction batches.

- `--ndb-cluster-connection-pool=#`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--ndb-cluster-connection-pool</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>ndb_cluster_connection_pool</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>ndb_cluster_connection_pool</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>63</td>
</tr>
</tbody>
</table>

By setting this option to a value greater than 1 (the default), a `mysqld` process can use multiple connections to the cluster, effectively mimicking several SQL nodes. Each connection requires its own [api] or [mysqld] section in the cluster configuration (`config.ini`) file, and counts against the maximum number of API connections supported by the cluster.

Suppose that you have 2 cluster host computers, each running an SQL node whose `mysqld` process was started with `--ndb-cluster-connection-pool=4`; this means that the cluster must have 8 API slots available for these connections (instead of 2). All of these connections are set up when the SQL node connects to the cluster, and are allocated to threads in a round-robin fashion.

This option is useful only when running `mysqld` on host machines having multiple CPUs, multiple cores, or both. For best results, the value should be smaller than the total number of cores available on the host machine. Setting it to a value greater than this is likely to degrade performance severely.

---

**Important**

Because each SQL node using connection pooling occupies multiple API node slots—each slot having its own node ID in the cluster—you must not use a node ID as part of the cluster connection string when starting any `mysqld` process that employs connection pooling.

Setting a node ID in the connection string when using the `--ndb-cluster-connection-pool` option causes node ID allocation errors when the SQL node attempts to connect to the cluster.
### NDB Cluster Configuration Files

**--ndb-cluster-connection-pool-nodeids=list**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--ndb-cluster-connection-pool-nodeids</td>
</tr>
<tr>
<td>System Variable</td>
<td>ndb_cluster_connection_pool_nodeids</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Set</td>
</tr>
<tr>
<td>Default Value</td>
<td></td>
</tr>
</tbody>
</table>

Specifies a comma-separated list of node IDs for connections to the cluster used by an SQL node. The number of nodes in this list must be the same as the value set for the `--ndb-cluster-connection-pool` option.

**--ndb-blob-read-batch-bytes=bytes**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--ndb-blob-read-batch-bytes</td>
</tr>
<tr>
<td>System Variable</td>
<td>ndb_blob_read_batch_bytes</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>65536</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

This option can be used to set the size (in bytes) for batching of BLOB data reads in NDB Cluster applications. When this batch size is exceeded by the amount of BLOB data to be read within the current transaction, any pending BLOB read operations are immediately executed.

The maximum value for this option is 4294967295; the default is 65536. Setting it to 0 has the effect of disabling BLOB read batching.

**Note**

In NDB API applications, you can control BLOB write batching with the `setMaxPendingBlobReadBytes()` and `getMaxPendingBlobReadBytes()` methods.

**--ndb-blob-write-batch-bytes=bytes**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--ndb-blob-write-batch-bytes</td>
</tr>
<tr>
<td>System Variable</td>
<td>ndb_blob_write_batch_bytes</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
</tbody>
</table>
This option can be used to set the size (in bytes) for batching of BLOB data writes in NDB Cluster applications. When this batch size is exceeded by the amount of BLOB data to be written within the current transaction, any pending BLOB write operations are immediately executed.

The maximum value for this option is 4294967295; the default is 65536. Setting it to 0 has the effect of disabling BLOB write batching.

**Note**

In NDB API applications, you can control BLOB write batching with the `setMaxPendingBlobWriteBytes()` and `getMaxPendingBlobWriteBytes()` methods.

- **--ndb-connectstring=connection_string**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--ndb-connectstring</code></td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

When using the NDBCLUSTER storage engine, this option specifies the management server that distributes cluster configuration data. See Section 22.3.3.3, “NDB Cluster Connection Strings”, for syntax.

- **--ndb-default-column-format={FIXED|DYNAMIC}**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--ndb-default-column-format={FIXED</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>ndb_default_column_format</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>FIXED</td>
</tr>
<tr>
<td>Valid Values</td>
<td>FIXED, DYNAMIC</td>
</tr>
</tbody>
</table>

Sets the default COLUMN_FORMAT and ROW_FORMAT for new tables (see Section 13.1.20, “CREATE TABLE Statement”). The default is FIXED.

- **--ndb-deferred-constraints={0|1}**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--ndb-deferred-constraints</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>ndb_deferred_constraints</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
</tbody>
</table>
NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1</td>
</tr>
</tbody>
</table>

Controls whether or not constraint checks on unique indexes are deferred until commit time, where such checks are supported. 0 is the default.

This option is not normally needed for operation of NDB Cluster or NDB Cluster Replication, and is intended primarily for use in testing.

• `--ndb-schema-dist-timeout=#`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--ndb-schema-dist-timeout=#</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.17-ndb-8.0.17</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>ndb_schema_dist_timeout</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>120</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>5</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1200</td>
</tr>
</tbody>
</table>

Specifies the maximum time in seconds that this `mysqld` waits for a schema operation to complete before marking it as having timed out.

• `--ndb-distribution=[KEYHASH|LINHASH]`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--ndb-distribution=(KEYHASH</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>ndb_distribution</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>KEYHASH</code></td>
</tr>
<tr>
<td>Valid Values</td>
<td><code>LINHASH</code></td>
</tr>
<tr>
<td></td>
<td><code>KEYHASH</code></td>
</tr>
</tbody>
</table>

Controls the default distribution method for NDB tables. Can be set to either of `KEYHASH` (key hashing) or `LINHASH` (linear hashing). `KEYHASH` is the default.
### --ndb-log-apply-status

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--ndb-log-apply-status[={OFF</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>ndb_log_apply_status</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Causes a slave `mysqld` to log any updates received from its immediate master to the `mysql.ndb_apply_status` table in its own binary log using its own server ID rather than the server ID of the master. In a circular or chain replication setting, this allows such updates to propagate to the `mysql.ndb_apply_status` tables of any MySQL servers configured as slaves of the current `mysqld`.

In a chain replication setup, using this option allows downstream (slave) clusters to be aware of their positions relative to all of their upstream contributors (masters).

In a circular replication setup, this option causes changes to `ndb_apply_status` tables to complete the entire circuit, eventually propagating back to the originating NDB Cluster. This also allows a cluster acting as a master to see when its changes (epochs) have been applied to the other clusters in the circle.

This option has no effect unless the MySQL server is started with the `--ndbcluster` option.

### --ndb-log-empty-epochs=[ON|OFF]

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--ndb-log-empty-epochs[={OFF</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>ndb_log_empty_epochs</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Causes epochs during which there were no changes to be written to the `ndb_apply_status` and `ndb_binlog_index` tables, even when `log_slave_updates` is enabled.

By default this option is disabled. Disabling `--ndb-log-empty-epochs` causes epoch transactions with no changes not to be written to the binary log, although a row is still written even for an empty epoch in `ndb_binlog_index`.

Because `--ndb-log-empty-epochs=1` causes the size of the `ndb_binlog_index` table to increase independently of the size of the binary log, users should be prepared to manage the growth of this table, even if they expect the cluster to be idle a large part of the time.

### --ndb-log-empty-update=[ON|OFF]

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--ndb-log-empty-update[={OFF</td>
</tr>
</tbody>
</table>
### NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>ndb_log_empty_update</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Causes updates that produced no changes to be written to the `ndb_apply_status` and `ndb_binlog_index` tables, when when `log_slave_updates` is enabled.

By default this option is disabled (OFF). Disabling `--ndb-log-empty-update` causes updates with no changes not to be written to the binary log.

- `--ndb-log-exclusive-reads=[0|1]`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--ndb-log-exclusive-reads=[OFF</td>
</tr>
<tr>
<td>System Variable</td>
<td>ndb_log_exclusive_reads</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
</tbody>
</table>

Starting the server with this option causes primary key reads to be logged with exclusive locks, which allows for NDB Cluster Replication conflict detection and resolution based on read conflicts. You can also enable and disable these locks at runtime by setting the value of the `ndb_log_exclusive_reads` system variable to 1 or 0, respectively. 0 (disable locking) is the default.

For more information, see Read conflict detection and resolution.

- `--ndb-log-orig`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--ndb-log-orig=[OFF</td>
</tr>
<tr>
<td>System Variable</td>
<td>ndb_log_orig</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
</tbody>
</table>
NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Log the originating server ID and epoch in the `ndb_binlog_index` table.

**Note**

This makes it possible for a given epoch to have multiple rows in `ndb_binlog_index`, one for each originating epoch.

For more information, see Section 22.6.4, “NDB Cluster Replication Schema and Tables”.

- **--ndb-log-transaction-id**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--ndb-log-transaction-id[={OFF</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>ndb_log_transaction_id</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Causes a slave `mysqld` to write the NDB transaction ID in each row of the binary log. The default value is `FALSE`.

This option is not supported in mainline MySQL Server 8.0. It is required to enable NDB Cluster Replication conflict detection and resolution using the `NDB$EPOCH_TRANS()` function (see `NDB$EPOCH_TRANS()`). For more information, see Section 22.6.11, “NDB Cluster Replication Conflict Resolution”.

The deprecated `log_bin_use_v1_row_events` system variable, which defaults to `OFF`, must not be set to `ON` when you use `--ndb-log-transaction-id`.

- **--ndb-log-update-minimal**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--ndb-log-update-minimal[={OFF</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>ndb_log_update_minimal</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Log updates in a minimal fashion, by writing only the primary key values in the before image, and only the changed columns in the after image. This may cause compatibility problems if replicating to storage engines other than NDB.

- **--ndb-mgmd-host=host[:port]**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--ndb-mgmd-host=host_name[:port_num]</code></td>
</tr>
</tbody>
</table>
NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>localhost:1186</code></td>
</tr>
</tbody>
</table>

Can be used to set the host and port number of a single management server for the program to connect to. If the program requires node IDs or references to multiple management servers (or both) in its connection information, use the `--ndb-connectstring` option instead.

- `--ndb-nodeid=##`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--ndb-nodeid=##</code></td>
</tr>
<tr>
<td>Status Variable</td>
<td><code>Ndb_cluster_node_id</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>255</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>63</td>
</tr>
</tbody>
</table>

Set this MySQL server's node ID in an NDB Cluster.

The `--ndb-nodeid` option overrides any node ID set with `--ndb-connectstring`, regardless of the order in which the two options are used.

In addition, if `--ndb-nodeid` is used, then either a matching node ID must be found in a `[mysqld]` or `[api]` section of `config.ini`, or there must be an “open” `[mysqld]` or `[api]` section in the file (that is, a section without a `NodeId` or `Id` parameter specified). This is also true if the node ID is specified as part of the connection string.

Regardless of how the node ID is determined, its is shown as the value of the global status variable `Ndb_cluster_node_id` in the output of `SHOW STATUS`, and as `cluster_node_id` in the `connection` row of the output of `SHOW ENGINE NDBCLUSTER STATUS`.

For more information about node IDs for NDB Cluster SQL nodes, see Section 22.3.3.7, “Defining SQL and Other API Nodes in an NDB Cluster”.

- `--ndbinfo={ON|OFF|FORCE}`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--ndbinfo=value</code> (<code>≥ 8.0.13-ndb-8.0.13</code>)</td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.13-ndb-8.0.13</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>ON</td>
</tr>
<tr>
<td>Valid Values</td>
<td>OFF, FORCE</td>
</tr>
</tbody>
</table>

Enables the plugin for the `ndbinfo` information database. By default this is ON whenever `NDBCLUSTER` is enabled.
NDB Cluster Configuration Files

- **--ndb-optimization-delay=milliseconds**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--ndb-optimization-delay=#</td>
</tr>
<tr>
<td>System Variable</td>
<td>ndb_optimization_delay</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>10</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>100000</td>
</tr>
</tbody>
</table>

Set the number of milliseconds to wait between sets of rows by `OPTIMIZE TABLE` statements on NDB tables. The default is 10.

- **ndb-transid-mysql-connection-map=state**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--ndb-transid-mysql-connection-map=[=state]</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>ON</td>
</tr>
<tr>
<td>Valid Values</td>
<td>ON, OFF, FORCE</td>
</tr>
</tbody>
</table>

Enables or disables the plugin that handles the `ndb_transid_mysql_connection_map` table in the `INFORMATION_SCHEMA` database. Takes one of the values ON, OFF, or FORCE. ON (the default) enables the plugin. OFF disables the plugin, which makes `ndb_transid_mysql_connection_map` inaccessible. FORCE keeps the MySQL Server from starting if the plugin fails to load and start.

You can see whether the `ndb_transid_mysql_connection_map` table plugin is running by checking the output of `SHOW PLUGINS`.

- **--ndb-wait-connected=seconds**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--ndb-wait-connected=#</td>
</tr>
<tr>
<td>System Variable</td>
<td>ndb_wait_connected</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>30</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
</tbody>
</table>
### NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum Value</td>
<td>31536000</td>
</tr>
</tbody>
</table>

This option sets the period of time that the MySQL server waits for connections to NDB Cluster management and data nodes to be established before accepting MySQL client connections. The time is specified in seconds. The default value is **30**.

- **--ndb-wait-setup=seconds**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--ndb-wait-setup=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>ndb_wait_setup</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>30</td>
</tr>
<tr>
<td>Default Value</td>
<td>30</td>
</tr>
<tr>
<td>Default Value</td>
<td>15</td>
</tr>
<tr>
<td>Default Value</td>
<td>15</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>31536000</td>
</tr>
</tbody>
</table>

This variable shows the period of time that the MySQL server waits for the NDB storage engine to complete setup before timing out and treating NDB as unavailable. The time is specified in seconds. The default value is **30**.

- **--skip-ndbcluster**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--skip-ndbcluster</code></td>
</tr>
</tbody>
</table>

Disable the NDBCLUSTER storage engine. This is the default for binaries that were built with NDBCLUSTER storage engine support; the server allocates memory and other resources for this storage engine only if the `--ndbcluster` option is given explicitly. See Section 22.3.1, “Quick Test Setup of NDB Cluster”, for an example.

### NDB Cluster System Variables

This section provides detailed information about MySQL server system variables that are specific to NDB Cluster and the NDB storage engine. For system variables not specific to NDB Cluster, see Section 5.1.8, “Server System Variables”. For general information on using system variables, see Section 5.1.9, “Using System Variables”.

- **ndb_autoincrement_prefetch_sz**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--ndb-autoincrement-prefetch-sz=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>ndb_autoincrement_prefetch_sz</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
</tbody>
</table>
Determines the probability of gaps in an autoincremented column. Set it to 1 to minimize this. Setting it to a high value for optimization makes inserts faster, but decreases the likelihood of consecutive autoincrement numbers being used in a batch of inserts.

This variable affects only the number of AUTO_INCREMENT IDs that are fetched between statements; within a given statement, at least 32 IDs are obtained at a time.

**Important**

This variable does not affect inserts performed using `INSERT ... SELECT`.

- **ndb_cache_check_time**

The number of milliseconds that elapse between checks of NDB Cluster SQL nodes by the MySQL query cache. Setting this to 0 (the default and minimum value) means that the query cache checks for validation on every query.

The recommended maximum value for this variable is 1000, which means that the check is performed once per second. A larger value means that the check is performed and possibly invalidated due to updates on different SQL nodes less often. It is generally not desirable to set this to a value greater than 2000.

**Note**

The query cache `ndb_cache_check_time` are deprecated in MySQL 5.7; the query cache was removed in MySQL 8.0.

- **ndb_clear_apply_status**

NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>ON</td>
</tr>
</tbody>
</table>

By the default, executing `RESET SLAVE` causes an NDB Cluster replication slave to purge all rows from its `ndb_apply_status` table. You can disable this by setting `ndb_clear_apply_status=OFF`.

- **ndb_data_node_neighbour**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--ndb-data-node-neighbour=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>ndb_data_node_neighbour</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>255</td>
</tr>
</tbody>
</table>

Sets the ID of a “nearest” data node—that is, a preferred nonlocal data node is chosen to execute the transaction, rather than one running on the same host as the SQL or API node. This used to ensure that when a fully replicated table is accessed, we access it on this data node, to ensure that the local copy of the table is always used whenever possible. This can also be used for providing hints for transactions.

This can improve data access times in the case of a node that is physically closer than and thus has higher network throughput than others on the same host.

![Note](image)

An equivalent method `set_data_node_neighbour()` is provided for use in NDB API applications.

- **ndb DBG Check Shares**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--ndb-dbg-check-shares=#</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.13-ndb-8.0.13</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>ndb DBG check shares</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
</tbody>
</table>
When set to 1, check that no shares are lingering. Available in debug builds only.

Added in NDB 8.0.13.

- **ndb_default_column_format**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--ndb-default-column-format={FIXED</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>ndb_default_column_format</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>FIXED</td>
</tr>
<tr>
<td>Valid Values</td>
<td>FIXED, DYNAMIC</td>
</tr>
</tbody>
</table>

Sets the default `COLUMN_FORMAT` and `ROW_FORMAT` for new tables (see Section 13.1.20, "CREATE TABLE Statement"). The default is FIXED.

- **ndb_deferred_constraints**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--ndb-deferred-constraints=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>ndb_deferred_constraints</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1</td>
</tr>
</tbody>
</table>

Controls whether or not constraint checks are deferred, where these are supported. 0 is the default.

This variable is not normally needed for operation of NDB Cluster or NDB Cluster Replication, and is intended primarily for use in testing.

- **ndb_distribution**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--ndb-distribution={KEYHASH</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>ndb_distribution</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
</tbody>
</table>
### NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>KEYHASH</td>
</tr>
<tr>
<td>Valid Values</td>
<td>LINHASH, KEYHASH</td>
</tr>
</tbody>
</table>

Controls the default distribution method for **NDB** tables. Can be set to either of **KEYHASH** (key hashing) or **LINHASH** (linear hashing). **KEYHASH** is the default.

- **ndb_eventbuffer_free_percent**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--ndb-eventbuffer-free-percent=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>ndb_eventbuffer_free_percent</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>20</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>99</td>
</tr>
</tbody>
</table>

Sets the percentage of the maximum memory allocated to the event buffer (`ndb_eventbuffer_max_alloc`) that should be available in event buffer after reaching the maximum, before starting to buffer again.

- **ndb_eventbuffer_max_alloc**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--ndb-eventbuffer-max-alloc=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>ndb_eventbuffer_max_alloc</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

Sets the maximum amount memory (in bytes) that can be allocated for buffering events by the **NDB** API. 0 means that no limit is imposed, and is the default.

- **ndb_extra_logging**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>ndb_extra_logging=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>ndb_extra_logging</code></td>
</tr>
</tbody>
</table>
This variable enables recording in the MySQL error log of information specific to the NDB storage engine.

When this variable is set to 0, the only information specific to NDB that is written to the MySQL error log relates to transaction handling. If it set to a value greater than 0 but less than 10, NDB table schema and connection events are also logged, as well as whether or not conflict resolution is in use, and other NDB errors and information. If the value is set to 10 or more, information about NDB internals, such as the progress of data distribution among cluster nodes, is also written to the MySQL error log. The default is 1.

- **ndb_force_send**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--ndb-force-send=[{OFF</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>ndb_force_send</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>ON</td>
</tr>
</tbody>
</table>

Forces sending of buffers to NDB immediately, without waiting for other threads. Defaults to ON.

- **ndb_fully_replicated**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--ndb-fully-replicated=[{OFF</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>ndb_fully_replicated</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Determines whether new NDB tables are fully replicated. This setting can be overridden for an individual table using `COMMENT="NDB_TABLE=FULLY_REPLICATED=..."` in a CREATE TABLE or ALTER TABLE statement; see Section 13.1.20.10, “Setting NDB_TABLE Options”, for syntax and other information.

- **ndb_index_stat_enable**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--ndb-index-stat-enable=[{OFF</td>
</tr>
</tbody>
</table>
Use NDB index statistics in query optimization. The default is ON.

- `ndb_index_stat_option`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--ndb-index-stat-option=value</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>ndb_index_stat_option</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>loop_checkon=1000ms,loop_idle=1000ms,loop_busy=100ms,update_batch=1,read_batch=4,idle_batch=32,check_batch=32,check_delay=1m,delete_batch=8,clean_delay=0,error_batch=4,error_delay=1m,evict_batch=8,evict_delay=1m,cache_limit=32M,cache_lowpct=90</code></td>
</tr>
</tbody>
</table>

This variable is used for providing tuning options for NDB index statistics generation. The list consist of comma-separated name-value pairs of option names and values, and this list must not contain any space characters.

Options not used when setting `ndb_index_stat_option` are not changed from their default values. For example, you can set `ndb_index_stat_option = 'loop_idle=1000ms,cache_limit=32M'`.

Time values can be optionally suffixed with h (hours), m (minutes), or s (seconds). Millisecond values can optionally be specified using ms; millisecond values cannot be specified using h, m, or s.) Integer values can be suffixed with K, M, or G.

The names of the options that can be set using this variable are shown in the table that follows. The table also provides brief descriptions of the options, their default values, and (where applicable) their minimum and maximum values.

### Table 22.219 ndb_index_stat_option options and values

<table>
<thead>
<tr>

<tr>
<td>zero_total</td>
<td>Setting this to 1 resets all accumulating counters in ndb_index_stat_status to 0. This option value is also reset to 0 when this is done.</td>
<td>0</td>
<td>0/1</td>
</tr>
</tbody>
</table>

- ndb_log_apply_status

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--ndb-log-apply-status=[OFF</td>
</tr>
<tr>
<td>System Variable</td>
<td>ndb_log_apply_status</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

A read-only variable which shows whether the server was started with the --ndb-log-apply-status option.

- ndb_log_bin

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--ndb-log-bin=[OFF</td>
</tr>
<tr>
<td>System Variable</td>
<td>ndb_log_bin</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
</tbody>
</table>
### NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value (≥ 8.0.16-ndb-8.0.16)</td>
<td>OFF</td>
</tr>
<tr>
<td>Default Value (≤ 8.0.15-ndb-8.0.15)</td>
<td>ON</td>
</tr>
</tbody>
</table>

Causes updates to NDB tables to be written to the binary log. The setting for this variable has no effect if binary logging is not already enabled on the server using `log_bin`. In NDB 8.0.16 and later, `ndb_log_bin` defaults to 0 (FALSE).

#### ndb_log_binlog_index

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--ndb-log-binlog-index=[{OFF</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>ndb_log_binlog_index</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>ON</td>
</tr>
</tbody>
</table>

Causes a mapping of epochs to positions in the binary log to be inserted into the `ndb_binlog_index` table. Setting this variable has no effect if binary logging is not already enabled for the server using `log_bin`. (In addition, `ndb_log_bin` must not be disabled.)

`ndb_log_binlog_index` defaults to 1 (ON); normally, there is never any need to change this value in a production environment.

#### ndb_log_empty_epochs

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--ndb-log-empty-epochs=[{OFF</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>ndb_log_empty_epochs</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

When this variable is set to 0, epoch transactions with no changes are not written to the binary log, although a row is still written even for an empty epoch in `ndb_binlog_index`.

#### ndb_log_empty_update

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--ndb-log-empty-update=[{OFF</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>ndb_log_empty_update</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
</tbody>
</table>
NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

When this variable is set to ON (1), update transactions with no changes are written to the binary log, even when `log_slave_updates` is enabled.

- **ndb_log_exclusive_reads**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--ndb-log-exclusive-reads={OFF</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>ndb_log_exclusive_reads</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
</tbody>
</table>

This variable determines whether primary key reads are logged with exclusive locks, which allows for NDB Cluster Replication conflict detection and resolution based on read conflicts. To enable these locks, set the value of `ndb_log_exclusive_reads` to 1. 0, which disables such locking, is the default.

For more information, see Read conflict detection and resolution.

- **ndb_log_orig**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--ndb-log-orig={OFF</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>ndb_log_orig</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Shows whether the originating server ID and epoch are logged in the `ndb_binlog_index` table. Set using the `--ndb-log-orig` server option.

- **ndb_log_transaction_id**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>ndb_log_transaction_id</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
</tbody>
</table>
This read-only, Boolean system variable shows whether a slave `mysqld` writes NDB transaction IDs in the binary log (required to use “active-active” NDB Cluster Replication with `NDB$EPOCH_TRANS()` conflict detection). To change the setting, use the `--ndb-log-transaction-id` option.

`ndb_log_transaction_id` is not supported in mainline MySQL Server 8.0.

For more information, see Section 22.6.11, “NDB Cluster Replication Conflict Resolution”.

**ndb_metadata_check**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--ndb-metadata-check={OFF</td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.16-ndb-8.0.16</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>ndb_metadata_check</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>ON</td>
</tr>
</tbody>
</table>

Beginning with NDB 8.0.16, NDB uses a background thread to check for metadata changes each `ndb_metadata_check_interval` seconds as compared with the MySQL data dictionary. This metadata change detection thread can be disabled by setting `ndb_metadata_check` to `OFF`. The thread is enabled by default.

**ndb_metadata_check_interval**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--ndb-metadata-check-interval=#</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.16-ndb-8.0.16</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>ndb_metadata_check_interval</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>60</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>31536000</td>
</tr>
</tbody>
</table>

In NDB 8.0.16 and later, NDB runs a metadata change detection thread in the background to determine when the NDB dictionary has changed with respect to the MySQL data dictionary. By default, the interval between such checks is 60 seconds; this can be adjusted by setting the value of `ndb_metadata_check_interval`. To enable or disable the thread, use `ndb_metadata_check`.

**ndb_metadata_sync**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.19-ndb-8.0.19</td>
</tr>
</tbody>
</table>
NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>ndb_metadata_sync</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>false</td>
</tr>
</tbody>
</table>

Setting this variable causes the change monitor thread to override any values set for `ndb_metadata_check` or `ndb_metadata_check_interval`, and to enter a period of continuous change detection. When the thread ascertains that there are no more changes to be detected, it stalls until the binary logging thread has finished synchronization of all detected objects. `ndb_metadata_sync` is then set to `false`, and the change monitor thread reverts to the behavior determined by the settings for `ndb_metadata_check` and `ndb_metadata_check_interval`.

- **ndb_optimized_node_selection**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--ndb-optimized-node-selection=</code>#</td>
</tr>
<tr>
<td>System Variable</td>
<td>ndb_optimized_node_selection</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>3</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>3</td>
</tr>
</tbody>
</table>

There are two forms of optimized node selection, described here:

1. The SQL node uses **proximity** to determine the transaction coordinator; that is, the “closest” data node to the SQL node is chosen as the transaction coordinator. For this purpose, a data node having a shared memory connection with the SQL node is considered to be “closest” to the SQL node; the next closest (in order of decreasing proximity) are: TCP connection to `localhost`, followed by TCP connection from a host other than `localhost`.

2. The SQL thread uses **distribution awareness** to select the data node. That is, the data node housing the cluster partition accessed by the first statement of a given transaction is used as the transaction coordinator for the entire transaction. (This is effective only if the first statement of the transaction accesses no more than one cluster partition.)

This option takes one of the integer values 0, 1, 2, or 3. 3 is the default. These values affect node selection as follows:

- **0**: Node selection is not optimized. Each data node is employed as the transaction coordinator 8 times before the SQL thread proceeds to the next data node.

- **1**: Proximity to the SQL node is used to determine the transaction coordinator.

- **2**: Distribution awareness is used to select the transaction coordinator. However, if the first statement of the transaction accesses more than one cluster partition, the SQL node reverts to the round-robin behavior seen when this option is set to 0.
• **3:** If distribution awareness can be employed to determine the transaction coordinator, then it is used; otherwise proximity is used to select the transaction coordinator. (This is the default behavior.)

Proximity is determined as follows:

1. Start with the value set for the `Group` parameter (default 55).

2. For an API node sharing the same host with other API nodes, decrement the value by 1. Assuming the default value for `Group`, the effective value for data nodes on same host as the API node is 54, and for remote data nodes 55.

3. Setting `ndb_data_node_neighbour` further decreases the effective `Group` value by 50, causing this node to be regarded as the nearest node. This is needed only when all data nodes are on hosts other than that hosts the API node and it is desirable to dedicate one of them to the API node. In normal cases, the default adjustment described previously is sufficient.

Frequent changes in `ndb_data_node_neighbour` are not advisable, since this changes the state of the cluster connection and thus may disrupt the selection algorithm for new transactions from each thread until it stabilizes.

• **ndb_read_backup**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--ndb-read-backup[={OFF</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>ndb_read_backup</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value (≥ 8.0.19-ndb-8.0.19)</td>
<td><strong>ON</strong></td>
</tr>
<tr>
<td>Default Value (≤ 8.0.18-ndb-8.0.18)</td>
<td><strong>OFF</strong></td>
</tr>
</tbody>
</table>

Enable read from any replica for any NDB table subsequently created; doing so greatly improves the table read performance at a relatively small cost to writes.

To enable or disable read from any replica for an individual table, you can set the `NDB_TABLE` option `READ_BACKUP` for the table accordingly, in a `CREATE TABLE` or `ALTER TABLE` statement; see Section 13.1.20.10, “Setting NDB_TABLE Options”, for more information.

• **ndb_recv_thread_activation_threshold**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--ndb-recv-thread-activation-threshold=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>ndb_recv_thread_activation_threshold</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>8</td>
</tr>
</tbody>
</table>
NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Minimum Value</td>
<td>0 (MIN_ACTIVATION_THRESHOLD)</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>16 (MAX_ACTIVATION_THRESHOLD)</td>
</tr>
</tbody>
</table>

When this number of concurrently active threads is reached, the receive thread takes over polling of the cluster connection.

This variable is global in scope. It can also be set at startup.

- \texttt{ndb_recv_thread_cpu_mask}

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--ndb_recv_thread_cpu-mask=mask</td>
</tr>
<tr>
<td>System Variable</td>
<td>ndb_recv_thread_cpu_mask</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>\texttt{SET_VAR} Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Bitmap</td>
</tr>
<tr>
<td>Default Value</td>
<td>[empty]</td>
</tr>
</tbody>
</table>

CPU mask for locking receiver threads to specific CPUs. This is specified as a hexadecimal bitmask. For example, \texttt{0x33} means that one CPU is used per receiver thread. An empty string is the default; setting \texttt{ndb_recv_thread_cpu_mask} to this value removes any receiver thread locks previously set.

This variable is global in scope. It can also be set at startup.

- \texttt{ndb_report_thresh_binlog_epoch_slip}

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--ndb-report-thresh-binlog-epoch-slip=#</td>
</tr>
<tr>
<td>System Variable</td>
<td>ndb_report_thresh_binlog_epoch_slip</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>\texttt{SET_VAR} Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>10</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>256</td>
</tr>
</tbody>
</table>

This represents the threshold for the number of epochs completely buffered in the event buffer, but not yet consumed by the binlog injector thread. When this degree of slippage (lag) is exceeded, an event buffer status message is reported, with \texttt{BUFFERED_EPOCHS_OVER_THRESHOLD} supplied as the reason (see Section \ref{sec:cluster-replication}, “Event Buffer Reporting in the Cluster Log”). Slip is increased when an epoch is received from data nodes and buffered completely in the event buffer; it is decreased when an epoch is consumed by the binlog injector thread, it is reduced. Empty epochs are buffered and queued, and so included in this calculation only when this is enabled using the \texttt{Ndb::setEventBufferQueueEmptyEpoch()} method from the NDB API.
• ndb_report_thresh_binlog_mem_usage

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--ndb-report-thresh-binlog-mem-usage=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>ndb_report_thresh_binlog_mem_usage</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>10</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>10</td>
</tr>
</tbody>
</table>

This is a threshold on the percentage of free memory remaining before reporting binary log status. For example, a value of 10 (the default) means that if the amount of available memory for receiving binary log data from the data nodes falls below 10%, a status message is sent to the cluster log.

• ndb_row_checksum

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>ndb_row_checksum</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1</td>
</tr>
</tbody>
</table>

Traditionally, NDB has created tables with row checksums, which checks for hardware issues at the expense of performance. Setting `ndb_row_checksum` to 0 means that row checksums are not used for new or altered tables, which has a significant impact on performance for all types of queries. This variable is set to 1 by default, to provide backward-compatible behavior.

• ndb_schema_dist_lock_wait_timeout

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--ndb-schema-dist-lock-wait-timeout=value</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.18-ndb-8.0.18</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>ndb_schema_dist_lock_wait_timeout</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>30</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
</tbody>
</table>
NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum Value</td>
<td>1200</td>
</tr>
</tbody>
</table>

Number of seconds to wait during schema distribution for the metadata lock taken on each SQL node in order to change its local data dictionary to reflect the DDL statement change. After this time has elapsed, a warning is returned to the effect that a given SQL node's data dictionary was not updated with the change. This avoids having the binary logging thread wait an excessive length of time while handling schema operations.

- **ndb_schema_dist_timeout**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--ndb-schema-dist-timeout=value</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.16-ndb-8.0.16</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>ndb_schema_dist_timeout</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>120</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>5</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1200</td>
</tr>
</tbody>
</table>

Number of seconds to wait before detecting a timeout during schema distribution. This can indicate that other SQL nodes are experiencing excessive activity, or that they are somehow being prevented from acquiring necessary resources at this time.

- **ndb_schema_dist_upgrade_allowed**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--ndb-schema-dist-upgrade-allowed=value</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.17-ndb-8.0.17</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>ndb_schema_dist_upgrade_allowed</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>true</td>
</tr>
</tbody>
</table>

Allow upgrading of the schema distribution table when connecting to NDB. When true (the default), this change is deferred until all SQL nodes have been upgraded to the same version of the NDB Cluster software.

**Note**

The performance of the schema distribution may be somewhat degraded until the upgrade has been performed.
NDB Cluster Configuration Files

- **ndb_show_foreign_key_mock_tables**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--ndb-show-foreign-key-mock-tables=[{OFF</td>
</tr>
<tr>
<td>System Variable</td>
<td>ndb_show_foreign_key_mock_tables</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Show the mock tables used by NDB to support `foreign_key_checks=0`. When this is enabled, extra warnings are shown when creating and dropping the tables. The real (internal) name of the table can be seen in the output of `SHOW CREATE TABLE`.

- **ndb_slave_conflict_role**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--ndb-slave-conflict-role=value</td>
</tr>
<tr>
<td>System Variable</td>
<td>ndb_slave_conflict_role</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>NONE</td>
</tr>
<tr>
<td>Valid Values</td>
<td>NONE, PRIMARY, SECONDARY, PASS</td>
</tr>
</tbody>
</table>

Determine the role of this SQL node (and NDB Cluster) in a circular ("active-active") replication setup. `ndb_slave_conflict_role` can take any one of the values PRIMARY, SECONDARY, PASS, or NULL (the default). The slave SQL thread must be stopped before you can change `ndb_slave_conflict_role`. In addition, it is not possible to change directly between PASS and either of PRIMARY or SECONDARY directly; in such cases, you must ensure that the SQL thread is stopped, then execute `SET @@GLOBAL.ndb_slave_conflict_role = 'NONE'` first.

For more information, see Section 22.6.11, “NDB Cluster Replication Conflict Resolution”.

- **ndb_table_no_logging**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>ndb_table_no_logging</td>
</tr>
<tr>
<td>Scope</td>
<td>Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>
When this variable is set to ON or 1, it causes NDB tables not to be checkpointed to disk. More specifically, this setting applies to tables which are created or altered using ENGINE NDB when ndb_table_no_logging is enabled, and continues to apply for the lifetime of the table, even if ndb_table_no_logging is later changed. Suppose that A, B, C, and D are tables that we create (and perhaps also alter), and that we also change the setting for ndb_table_no_logging as shown here:

```
SET @@ndb_table_no_logging = 1;
CREATE TABLE A ... ENGINE NDB;
CREATE TABLE B ... ENGINE MYISAM;
CREATE TABLE C ... ENGINE MYISAM;
ALTER TABLE B ENGINE NDB;
SET @@ndb_table_no_logging = 0;
CREATE TABLE D ... ENGINE NDB;
ALTER TABLE C ENGINE NDB;
SET @@ndb_table_no_logging = 1;
```

After the previous sequence of events, tables A and B are not checkpointed; A was created with ENGINE NDB and B was altered to use NDB, both while ndb_table_no_logging was enabled. However, tables C and D are logged; C was altered to use NDB and D was created using ENGINE NDB, both while ndb_table_no_logging was disabled. Setting ndb_table_no_logging back to 1 or ON does not cause table C or D to be checkpointed.

Note

ndb_table_no_logging has no effect on the creation of NDB table schema files; to suppress these, use ndb_table_temporary instead.

- ndb_table_temporary

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>ndb_table_temporary</td>
</tr>
<tr>
<td>Scope</td>
<td>Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

When set to ON or 1, this variable causes NDB tables not to be written to disk: This means that no table schema files are created, and that the tables are not logged.

Note

Setting this variable currently has no effect. This is a known issue; see Bug #34036.

- ndb_use_copying_alter_table

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>ndb_use_copying_alter_table</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
</tbody>
</table>
NDB Cluster Configuration Files

### SET_VAR: Hint Applies

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>SET_VAR</td>
<td>Hint Applies</td>
</tr>
</tbody>
</table>

Forces NDB to use copying of tables in the event of problems with online ALTER TABLE operations. The default value is OFF.

#### ndb_use_exact_count

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>ndb_use_exact_count</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR</td>
<td>Hint Applies</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Forces NDB to use a count of records during SELECT COUNT(*) query planning to speed up this type of query. The default value is OFF, which allows for faster queries overall.

#### ndb_use_transactions

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--ndb-use-transactions=[OFF</td>
</tr>
<tr>
<td>System Variable</td>
<td>ndb_use_transactions</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR</td>
<td>Hint Applies</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>ON</td>
</tr>
</tbody>
</table>

You can disable NDB transaction support by setting this variable's values to OFF (not recommended). The default is ON.

#### ndb_version

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>ndb_version</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR</td>
<td>Hint Applies</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td></td>
</tr>
</tbody>
</table>

NDB engine version, as a composite integer.

#### ndb_version_string

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>ndb_version_string</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
</tbody>
</table>

3755
### NDB Cluster Configuration Files

**Property** | **Value**
--- | ---
Dynamic | No
**SET_VAR** Hint Applies | No
Type | String
Default Value | NDB engine version in `ndb-x.y.z` format.

- **server_id_bits**

  **Property** | **Value**
  --- | ---
  Command-Line Format | `--server-id-bits=#`
  System Variable | `server_id_bits`
  Scope | Global
  Dynamic | No
  **SET_VAR** Hint Applies | No
  Type | Integer
  Default Value | 32
  Minimum Value | 7
  Maximum Value | 32

This variable indicates the number of least significant bits within the 32-bit `server_id` which actually identify the server. Indicating that the server is actually identified by fewer than 32 bits makes it possible for some of the remaining bits to be used for other purposes, such as storing user data generated by applications using the NDB API's Event API within the `AnyValue` of an `OperationOptions` structure (NDB Cluster uses the `AnyValue` to store the server ID).

When extracting the effective server ID from `server_id` for purposes such as detection of replication loops, the server ignores the remaining bits. The `server_id_bits` variable is used to mask out any irrelevant bits of `server_id` in the IO and SQL threads when deciding whether an event should be ignored based on the server ID.

This data can be read from the binary log by `mysqlbinlog`, provided that it is run with its own `server_id_bits` variable set to 32 (the default).

If the value of `server_id` greater than or equal to 2 to the power of `server_id_bits`; otherwise, `mysqld` refuses to start.

This system variable is supported only by NDB Cluster. It is not supported in the standard MySQL 8.0 Server.

- **slave_allow_batching**

  **Property** | **Value**
  --- | ---
  Command-Line Format | `--slave-allow-batching[={OFF|ON}]`
  System Variable | `slave_allow_batching`
  Scope | Global
  Dynamic | Yes
  **SET_VAR** Hint Applies | No
  Type | Boolean
Whether or not batched updates are enabled on NDB Cluster replication slaves.

Setting this variable has an effect only when using replication with the NDB storage engine; in MySQL Server 8.0, it is present but does nothing. For more information, see Section 22.6.6, “Starting NDB Cluster Replication (Single Replication Channel)”.

- `transaction_allow_batching`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Default Value</strong></td>
<td>OFF</td>
</tr>
</tbody>
</table>

When set to 1 or ON, this variable enables batching of statements within the same transaction. To use this variable, `autocommit` must first be disabled by setting it to 0 or OFF; otherwise, setting `transaction_allow_batching` has no effect.

It is safe to use this variable with transactions that performs writes only, as having it enabled can lead to reads from the “before” image. You should ensure that any pending transactions are committed (using an explicit `COMMIT` if desired) before issuing a `SELECT`.

**Important**

`transaction_allow_batching` should not be used whenever there is the possibility that the effects of a given statement depend on the outcome of a previous statement within the same transaction.

This variable is currently supported for NDB Cluster only.

The system variables in the following list all relate to the `ndbinfo` information database.

- `ndbinfo_database`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>System Variable</strong></td>
<td><code>ndbinfo_database</code></td>
</tr>
<tr>
<td><strong>Scope</strong></td>
<td>Global</td>
</tr>
<tr>
<td><strong>Dynamic</strong></td>
<td>No</td>
</tr>
<tr>
<td><strong>SET_VAR Hint Applies</strong></td>
<td>No</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>String</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td><code>ndbinfo</code></td>
</tr>
</tbody>
</table>

Shows the name used for the NDB information database; the default is `ndbinfo`. This is a read-only variable whose value is determined at compile time; you can set it by starting the server using `--ndbinfo-database=name`, which sets the value shown for this variable but does not actually change the name used for the NDB information database.

- `ndbinfo_max_bytes`
### NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td><code>--ndbinfo-max-bytes=#</code></td>
</tr>
<tr>
<td><strong>System Variable</strong></td>
<td><code>ndbinfo_max_bytes</code></td>
</tr>
<tr>
<td><strong>Scope</strong></td>
<td>Global, Session</td>
</tr>
<tr>
<td><strong>Dynamic</strong></td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR Hint Applies</strong></td>
<td>No</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Integer</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>0</td>
</tr>
</tbody>
</table>

Used in testing and debugging only.

- `ndbinfo_max_rows`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td><code>--ndbinfo-max-rows=#</code></td>
</tr>
<tr>
<td><strong>System Variable</strong></td>
<td><code>ndbinfo_max_rows</code></td>
</tr>
<tr>
<td><strong>Scope</strong></td>
<td>Global, Session</td>
</tr>
<tr>
<td><strong>Dynamic</strong></td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR Hint Applies</strong></td>
<td>No</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Integer</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>10</td>
</tr>
</tbody>
</table>

Used in testing and debugging only.

- `ndbinfo_offline`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>System Variable</strong></td>
<td><code>ndbinfo_offline</code></td>
</tr>
<tr>
<td><strong>Scope</strong></td>
<td>Global</td>
</tr>
<tr>
<td><strong>Dynamic</strong></td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR Hint Applies</strong></td>
<td>No</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Boolean</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>OFF</td>
</tr>
</tbody>
</table>

Place the `ndbinfo` database into offline mode, in which tables and views can be opened even when they do not actually exist, or when they exist but have different definitions in NDB. No rows are returned from such tables (or views).

- `ndbinfo_show_hidden`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td>`--ndbinfo-show-hidden=[OFF</td>
</tr>
<tr>
<td><strong>System Variable</strong></td>
<td><code>ndbinfo_show_hidden</code></td>
</tr>
<tr>
<td><strong>Scope</strong></td>
<td>Global, Session</td>
</tr>
<tr>
<td><strong>Dynamic</strong></td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR Hint Applies</strong></td>
<td>No</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Boolean</td>
</tr>
</tbody>
</table>
NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Whether or not the `ndbinfo` database's underlying internal tables are shown in the `mysql` client. The default is `OFF`.

- **ndbinfo_table_prefix**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--ndbinfo-table-prefix=name</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>ndbinfo_table_prefix</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>ndb$</code></td>
</tr>
</tbody>
</table>

The prefix used in naming the `ndbinfo` database's base tables (normally hidden, unless exposed by setting `ndbinfo_show_hidden`). This is a read-only variable whose default value is `ndb$`. You can start the server with the `--ndbinfo-table-prefix` option, but this merely sets the variable and does not change the actual prefix used to name the hidden base tables; the prefix itself is determined at compile time.

- **ndbinfo_version**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>ndbinfo_version</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td></td>
</tr>
</tbody>
</table>

Shows the version of the `ndbinfo` engine in use; read-only.

**NDB Cluster Status Variables**

This section provides detailed information about MySQL server status variables that relate to NDB Cluster and the NDB storage engine. For status variables not specific to NDB Cluster, and for general information on using status variables, see Section 5.1.10, "Server Status Variables".

- **Handler_discover**

  The MySQL server can ask the `NDBCLUSTER` storage engine if it knows about a table with a given name. This is called discovery. `Handler_discover` indicates the number of times that tables have been discovered using this mechanism.

- **Ndb_api_bytes_sent_count_session**

  Amount of data (in bytes) sent to the data nodes in this client session.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 22.5.17, "NDB API Statistics Counters and Variables".
• **Ndb_api_bytes_sent_count_slave**

Amount of data (in bytes) sent to the data nodes by this slave.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

• **Ndb_api_bytes_sent_count**

Amount of data (in bytes) sent to the data nodes by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

• **Ndb_api_bytes_received_count_session**

Amount of data (in bytes) received from the data nodes in this client session.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

• **Ndb_api_bytes_received_count_slave**

Amount of data (in bytes) received from the data nodes by this slave.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

• **Ndb_api_bytes_received_count**

Amount of data (in bytes) received from the data nodes by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

• **Ndb_api_event_data_count_injector**

The number of row change events received by the NDB binlog injector thread.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

---

3760
• **Ndb_api_event_data_count**

The number of row change events received by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

• **Ndb_api_event_nondata_count_injector**

The number of events received, other than row change events, by the NDB binary log injector thread.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

• **Ndb_api_event_nondata_count**

The number of events received, other than row change events, by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

• **Ndb_api_event_bytes_count_injector**

The number of bytes of events received by the NDB binlog injector thread.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

• **Ndb_api_event_bytes_count**

The number of bytes of events received by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

• **Ndb_api_pk_op_count_session**

The number of operations in this client session based on or using primary keys. This includes operations on blob tables, implicit unlock operations, and auto-increment operations, as well as user-visible primary key operations.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.
NDB Cluster Configuration Files

- **Ndb_api_pk_op_count_slave**
  The number of operations by this slave based on or using primary keys. This includes operations on blob tables, implicit unlock operations, and auto-increment operations, as well as user-visible primary key operations.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- **Ndb_api_pk_op_count**
  The number of operations by this MySQL Server (SQL node) based on or using primary keys. This includes operations on blob tables, implicit unlock operations, and auto-increment operations, as well as user-visible primary key operations.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- **Ndb_api_pruned_scan_count_session**
  The number of scans in this client session that have been pruned to a single partition.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- **Ndb_api_pruned_scan_count_slave**
  The number of scans by this slave that have been pruned to a single partition.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- **Ndb_api_pruned_scan_count**
  The number of scans by this MySQL Server (SQL node) that have been pruned to a single partition.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- **Ndb_api_range_scan_count_session**
  The number of range scans that have been started in this client session.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- **Ndb_api_range_scan_count_slave**
  The number of range scans that have been started by this slave.

- **Ndb_api_range_scan_count**
  The number of range scans by this MySQL Server (SQL node) that have been started.
Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- **Ndb_api_range_scan_count**

  The number of range scans that have been started by this MySQL Server (SQL node).

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- **Ndb_api_read_row_count_session**

  The total number of rows that have been read in this client session. This includes all rows read by any primary key, unique key, or scan operation made in this client session.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- **Ndb_api_read_row_count_slave**

  The total number of rows that have been read by this slave. This includes all rows read by any primary key, unique key, or scan operation made by this slave.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- **Ndb_api_read_row_count**

  The total number of rows that have been read by this MySQL Server (SQL node). This includes all rows read by any primary key, unique key, or scan operation made by this MySQL Server (SQL node).

  You should be aware that this value may not be completely accurate with regard to rows read by `SELECT COUNT(*)` queries, due to the fact that, in this case, the MySQL server actually reads pseudo-rows in the form `[table fragment ID]:[number of rows in fragment]` and sums the rows per fragment for all fragments in the table to derive an estimated count for all rows. `Ndb_api_read_row_count` uses this estimate and not the actual number of rows in the table.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

3763
• **Ndb_api_scan_batch_count_session**

  The number of batches of rows received in this client session. 1 batch is defined as 1 set of scan results from a single fragment.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

• **Ndb_api_scan_batch_count_slave**

  The number of batches of rows received by this slave. 1 batch is defined as 1 set of scan results from a single fragment.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

• **Ndb_api_scan_batch_count**

  The number of batches of rows received by this MySQL Server (SQL node). 1 batch is defined as 1 set of scan results from a single fragment.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

• **Ndb_api_table_scan_count_session**

  The number of table scans that have been started in this client session, including scans of internal tables..

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

• **Ndb_api_table_scan_count_slave**

  The number of table scans that have been started by this slave, including scans of internal tables..

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

• **Ndb_api_table_scan_count**

  The number of table scans that have been started by this MySQL Server (SQL node), including scans of internal tables..

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.
• **Ndb_api_trans_abort_count_session**

The number of transactions aborted in this client session.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 22.5.17, “NDB API Statistics Counters and Variables”](#).

• **Ndb_api_trans_abort_count_slave**

The number of transactions aborted by this slave.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

For more information, see [Section 22.5.17, “NDB API Statistics Counters and Variables”](#).

• **Ndb_api_trans_abort_count**

The number of transactions aborted by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 22.5.17, “NDB API Statistics Counters and Variables”](#).

• **Ndb_api_trans_close_count_session**

The number of transactions closed in this client session. This value may be greater than the sum of `Ndb_api_trans_commit_count_session` and `Ndb_api_trans_abort_count_session`, since some transactions may have been rolled back.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 22.5.17, “NDB API Statistics Counters and Variables”](#).

• **Ndb_api_trans_close_count_slave**

The number of transactions closed by this slave. This value may be greater than the sum of `Ndb_api_trans_commit_count_slave` and `Ndb_api_trans_abort_count_slave`, since some transactions may have been rolled back.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

For more information, see [Section 22.5.17, “NDB API Statistics Counters and Variables”](#).

• **Ndb_api_trans_close_count**

The number of transactions closed by this MySQL Server (SQL node). This value may be greater than the sum of `Ndb_api_trans_commit_count` and `Ndb_api_trans_abort_count`, since some transactions may have been rolled back.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 22.5.17, “NDB API Statistics Counters and Variables”](#).

• **Ndb_api_trans_commit_count_session**

The number of transactions committed in this client session. This value may be greater than the sum of `Ndb_api_trans_commit_count_session` and `Ndb_api_trans_abort_count_session`, since some transactions may have been rolled back.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 22.5.17, “NDB API Statistics Counters and Variables”](#).
The number of transactions committed in this client session.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

• **Ndb_api_trans_commit_count_slave**

The number of transactions committed by this slave.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

• **Ndb_api_trans_commit_count**

The number of transactions committed by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

• **Ndb_api_trans_local_read_row_count_session**

The total number of rows that have been read in this client session. This includes all rows read by any primary key, unique key, or scan operation made in this client session.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

• **Ndb_api_trans_local_read_row_count_slave**

The total number of rows that have been read by this slave. This includes all rows read by any primary key, unique key, or scan operation made by this slave.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

• **Ndb_api_trans_local_read_row_count**

The total number of rows that have been read by this MySQL Server (SQL node). This includes all rows read by any primary key, unique key, or scan operation made by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.
• **Ndb_api_trans_start_count_session**

The number of transactions started in this client session.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`

For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

• **Ndb_api_trans_start_count_slave**

The number of transactions started by this slave.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

• **Ndb_api_trans_start_count**

The number of transactions started by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

• **Ndb_api_uk_op_count_session**

The number of operations in this client session based on or using unique keys.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`

For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

• **Ndb_api_uk_op_count_slave**

The number of operations by this slave based on or using unique keys.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

• **Ndb_api_uk_op_count**

The number of operations by this MySQL Server (SQL node) based on or using unique keys.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

NDB Cluster Configuration Files

• **Ndb_api_wait_exec_complete_count_session**

  The number of times a thread has been blocked in this client session while waiting for execution of an operation to complete. This includes all \texttt{execute()} calls as well as implicit executes for blob and auto-increment operations not visible to clients.

  Although this variable can be read using either \texttt{SHOW GLOBAL STATUS} or \texttt{SHOW SESSION STATUS}, it relates to the current session only, and is not affected by any other clients of this \texttt{mysqld}.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

• **Ndb_api_wait_exec_complete_count_slave**

  The number of times a thread has been blocked by this slave while waiting for execution of an operation to complete. This includes all \texttt{execute()} calls as well as implicit executes for blob and auto-increment operations not visible to clients.

  Although this variable can be read using either \texttt{SHOW GLOBAL STATUS} or \texttt{SHOW SESSION STATUS}, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

• **Ndb_api_wait_exec_complete_count**

  The number of times a thread has been blocked by this MySQL Server (SQL node) while waiting for execution of an operation to complete. This includes all \texttt{execute()} calls as well as implicit executes for blob and auto-increment operations not visible to clients.

  Although this variable can be read using either \texttt{SHOW GLOBAL STATUS} or \texttt{SHOW SESSION STATUS}, it is effectively global in scope.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

• **Ndb_api_wait_meta_request_count_session**

  The number of times a thread has been blocked in this client session waiting for a metadata-based signal, such as is expected for DDL requests, new epochs, and seizure of transaction records.

  Although this variable can be read using either \texttt{SHOW GLOBAL STATUS} or \texttt{SHOW SESSION STATUS}, it relates to the current session only, and is not affected by any other clients of this \texttt{mysqld}.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

• **Ndb_api_wait_meta_request_count_slave**

  The number of times a thread has been blocked by this slave waiting for a metadata-based signal, such as is expected for DDL requests, new epochs, and seizure of transaction records.

  Although this variable can be read using either \texttt{SHOW GLOBAL STATUS} or \texttt{SHOW SESSION STATUS}, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.
• **Ndb_api_wait_meta_request_count**

The number of times a thread has been blocked by this MySQL Server (SQL node) waiting for a metadata-based signal, such as is expected for DDL requests, new epochs, and seizure of transaction records.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

• **Ndb_api_wait_nanos_count_session**

Total time (in nanoseconds) spent in this client session waiting for any type of signal from the data nodes.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

• **Ndb_api_wait_nanos_count_slave**

Total time (in nanoseconds) spent by this slave waiting for any type of signal from the data nodes.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

• **Ndb_api_wait_nanos_count**

Total time (in nanoseconds) spent by this MySQL Server (SQL node) waiting for any type of signal from the data nodes.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

• **Ndb_api_wait_scan_result_count_session**

The number of times a thread has been blocked in this client session while waiting for a scan-based signal, such as when waiting for more results from a scan, or when waiting for a scan to close.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

• **Ndb_api_wait_scan_result_count_slave**

The number of times a thread has been blocked by this slave while waiting for a scan-based signal, such as when waiting for more results from a scan, or when waiting for a scan to close.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

• **Ndb_api_wait_scan_result_count**
The number of times a thread has been blocked by this MySQL Server (SQL node) while waiting for a scan-based signal, such as when waiting for more results from a scan, or when waiting for a scan to close.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- **Ndb_cluster_node_id**

  If the server is acting as an NDB Cluster node, then the value of this variable is its node ID in the cluster.

  If the server is not part of an NDB Cluster, then the value of this variable is 0.

- **Ndb_config_from_host**

  If the server is part of an NDB Cluster, the value of this variable is the host name or IP address of the Cluster management server from which it gets its configuration data.

  If the server is not part of an NDB Cluster, then the value of this variable is an empty string.

- **Ndb_config_from_port**

  If the server is part of an NDB Cluster, the value of this variable is the number of the port through which it is connected to the Cluster management server from which it gets its configuration data.

  If the server is not part of an NDB Cluster, then the value of this variable is 0.

- **Ndb_conflict_fn_max_del_win**

  Shows the number of times that a row was rejected on the current SQL node due to NDB Cluster Replication conflict resolution using `NDB$MAX_DELETE_WIN()`, since the last time that this `mysqld` was started.

  For more information, see Section 22.6.11, “NDB Cluster Replication Conflict Resolution”.

- **Ndb_conflict_fn_max**

  Used in NDB Cluster Replication conflict resolution, this variable shows the number of times that a row was not applied on the current SQL node due to “greatest timestamp wins” conflict resolution since the last time that this `mysqld` was started.

  For more information, see Section 22.6.11, “NDB Cluster Replication Conflict Resolution”.

- **Ndb_conflict_fn_old**

  Used in NDB Cluster Replication conflict resolution, this variable shows the number of times that a row was not applied as the result of “same timestamp wins” conflict resolution on a given `mysqld` since the last time it was restarted.

  For more information, see Section 22.6.11, “NDB Cluster Replication Conflict Resolution”.

- **Ndb_conflict_fn_epoch**

  Used in NDB Cluster Replication conflict resolution, this variable shows the number of rows found to be in conflict using `NDB$EPOCH()` conflict resolution on a given `mysqld` since the last time it was restarted.

  For more information, see Section 22.6.11, “NDB Cluster Replication Conflict Resolution”.

3770
• **Ndb_conflict_fn_epoch2**

  Shows the number of rows found to be in conflict in NDB Cluster Replication conflict resolution, when using `NDB$EPOCH2()`, on the master designated as the primary since the last time it was restarted.

For more information, see `NDB$EPOCH2()`.

• **Ndb_conflict_fn_epoch_trans**

  Used in NDB Cluster Replication conflict resolution, this variable shows the number of rows found to be in conflict using `NDB$EPOCH_TRANS()` conflict resolution on a given `mysqld` since the last time it was restarted.

For more information, see Section 22.6.11, “NDB Cluster Replication Conflict Resolution”.

• **Ndb_conflict_fn_epoch2_trans**

  Used in NDB Cluster Replication conflict resolution, this variable shows the number of rows found to be in conflict using `NDB$EPOCH_TRANS2()` conflict resolution on a given `mysqld` since the last time it was restarted.

For more information, see `NDB$EPOCH2_TRANS()`.

• **Ndb_conflict_last_conflict_epoch**

  The most recent epoch in which a conflict was detected on this slave. You can compare this value with `Ndb_slave_max_replicated_epoch`; if `Ndb_slave_max_replicated_epoch` is greater than `Ndb_conflict_last_conflict_epoch`, no conflicts have yet been detected.

See Section 22.6.11, “NDB Cluster Replication Conflict Resolution”, for more information.

• **Ndb_conflict_reflected_op_discard_count**

  When using NDB Cluster Replication conflict resolution, this is the number of reflected operations that were not applied on the secondary, due to encountering an error during execution.

See Section 22.6.11, “NDB Cluster Replication Conflict Resolution”, for more information.

• **Ndb_conflict_reflected_op_prepare_count**

  When using conflict resolution with NDB Cluster Replication, this status variable contains the number of reflected operations that have been defined (that is, prepared for execution on the secondary).

See Section 22.6.11, “NDB Cluster Replication Conflict Resolution”.

• **Ndb_conflict_refresh_op_count**

  When using conflict resolution with NDB Cluster Replication, this gives the number of refresh operations that have been prepared for execution on the secondary.

See Section 22.6.11, “NDB Cluster Replication Conflict Resolution”, for more information.

• **Ndb_conflict_last_stable_epoch**

  Number of rows found to be in conflict by a transactional conflict function

See Section 22.6.11, “NDB Cluster Replication Conflict Resolution”, for more information.

• **Ndb_conflict_trans_row_conflict_count**

  Used in NDB Cluster Replication conflict resolution, this status variable shows the number of rows found to be directly in-conflict by a transactional conflict function on a given `mysqld` since the last time it was restarted.
Currently, the only transactional conflict detection function supported by NDB Cluster is NDB$EPOCH_TRANS(), so this status variable is effectively the same as Ndb_conflict_fn_epoch_trans.

For more information, see Section 22.6.11, “NDB Cluster Replication Conflict Resolution”.

• Ndb_conflict_trans_row_reject_count

Used in NDB Cluster Replication conflict resolution, this status variable shows the total number of rows realigned due to being determined as conflicting by a transactional conflict detection function. This includes not only Ndb_conflict_trans_row_conflict_count, but any rows in or dependent on conflicting transactions.

For more information, see Section 22.6.11, “NDB Cluster Replication Conflict Resolution”.

• Ndb_conflict_trans_reject_count

Used in NDB Cluster Replication conflict resolution, this status variable shows the number of transactions found to be in conflict by a transactional conflict detection function.

For more information, see Section 22.6.11, “NDB Cluster Replication Conflict Resolution”.

• Ndb_conflict_trans_detect_iter_count

Used in NDB Cluster Replication conflict resolution, this shows the number of internal iterations required to commit an epoch transaction. Should be (slightly) greater than or equal to Ndb_conflict_trans_conflict_commit_count.

For more information, see Section 22.6.11, “NDB Cluster Replication Conflict Resolution”.

• Ndb_conflict_trans_conflict_commit_count

Used in NDB Cluster Replication conflict resolution, this shows the number of epoch transactions committed after they required transactional conflict handling.

For more information, see Section 22.6.11, “NDB Cluster Replication Conflict Resolution”.

• Ndb_epoch_delete_delete_count

When using delete-delete conflict detection, this is the number of delete-delete conflicts detected, where a delete operation is applied, but the indicated row does not exist.

• Ndb_execute_count

Provides the number of round trips to the NDB kernel made by operations.

• Ndb_last_commit_epoch_server

The epoch most recently committed by NDB.

• Ndb_last_commit_epoch_session

The epoch most recently committed by this NDB client.

• Ndb_metadata_blacklist_size

The number of metadata objects that the NDB binlog thread has been unable to synchronize on this SQL node since it was last restarted.

Should an object be blacklisted, it is not again considered for automatic synchronization until the user corrects the mismatch manually. This can be done by attempting to use the table with a statement
such as `SHOW CREATE TABLE table`, `SELECT * FROM table`, or any other statement that would trigger table discovery.

Added in NDB 8.0.18.

- **Ndb_metadata_detected_count**

  The number of times since this server was last started that the NDB metadata change detection thread has discovered changes with respect to the MySQL data dictionary.

  Added in NDB 8.0.16.

- **Ndb_metadata_synced_count**

  The number of NDB metadata objects which have been synchronized on this SQL node since it was last restarted.

  Added in NDB 8.0.18.

- **Ndb_number_of_data_nodes**

  If the server is part of an NDB Cluster, the value of this variable is the number of data nodes in the cluster.

  If the server is not part of an NDB Cluster, then the value of this variable is 0.

- **Ndb_pushed_queries_defined**

  The total number of joins pushed down to the NDB kernel for distributed handling on the data nodes.

  **Note**

  Joins tested using `EXPLAIN` that can be pushed down contribute to this number.

- **Ndb_pushed_queries_dropped**

  The number of joins that were pushed down to the NDB kernel but that could not be handled there.

- **Ndb_pushed_queries_executed**

  The number of joins successfully pushed down to NDB and executed there.

- **Ndb_pushed_reads**

  The number of rows returned to `mysqld` from the NDB kernel by joins that were pushed down.

  **Note**

  Executing `EXPLAIN` on joins that can be pushed down to NDB does not add to this number.

- **Ndb_pruned_scan_count**

  This variable holds a count of the number of scans executed by NDBCLUSTER since the NDB Cluster was last started where NDBCLUSTER was able to use partition pruning.

  Using this variable together with `Ndb_scan_count` can be helpful in schema design to maximize the ability of the server to prune scans to a single table partition, thereby involving only a single data node.
NDB Cluster Configuration Files

- **Ndb\_scan\_count**

  This variable holds a count of the total number of scans executed by NDBCLUSTER since the NDB Cluster was last started.

- **Ndb\_slave\_max\_replicated\_epoch**

  The most recently committed epoch on this slave. You can compare this value with Ndb\_conflict\_last\_conflict\_epoch; if Ndb\_slave\_max\_replicated\_epoch is the greater of the two, no conflicts have yet been detected.

  For more information, see Section 22.6.11, “NDB Cluster Replication Conflict Resolution”.

- **Ndb\_system\_name**

  If this MySQL Server is connected to an NDB cluster, this read-only variable shows the cluster system name. Otherwise, the value is an empty string.

- **Ndb\_trans\_hint\_count\_session**

  The number of transactions using hints that have been started in the current session. Compare with Ndb\_api\_trans\_start\_count\_session to obtain the proportion of all NDB transactions able to use hints. Added in NDB 8.0.17.

### 22.3.3.10 NDB Cluster TCP/IP Connections

TCP/IP is the default transport mechanism for all connections between nodes in an NDB Cluster. Normally it is not necessary to define TCP/IP connections; NDB Cluster automatically sets up such connections for all data nodes, management nodes, and SQL or API nodes.

**Note**

For an exception to this rule, see Section 22.3.3.11, “NDB Cluster TCP/IP Connections Using Direct Connections”.

To override the default connection parameters, it is necessary to define a connection using one or more [tcp] sections in the config.ini file. Each [tcp] section explicitly defines a TCP/IP connection between two NDB Cluster nodes, and must contain at a minimum the parameters NodeId1 and NodeId2, as well as any connection parameters to override.

It is also possible to change the default values for these parameters by setting them in the [tcp default] section.

**Important**

Any [tcp] sections in the config.ini file should be listed last, following all other sections in the file. However, this is not required for a [tcp default] section. This requirement is a known issue with the way in which the config.ini file is read by the NDB Cluster management server.

Connection parameters which can be set in [tcp] and [tcp default] sections of the config.ini file are listed here:

- **Checksum**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
</tbody>
</table>
NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter is a boolean parameter (enabled by setting it to Y or 1, disabled by setting it to N or 0). It is disabled by default. When it is enabled, checksums for all messages are calculated before they placed in the send buffer. This feature ensures that messages are not corrupted while waiting in the send buffer, or by the transport mechanism.

- **Group**

  When `ndb_optimized_node_selection` is enabled, node proximity is used in some cases to select which node to connect to. This parameter can be used to influence proximity by setting it to a lower value, which is interpreted as “closer”. See the description of the system variable for more information.

- **HostName1**

  Table 22.221 This table provides type and value information for the HostName1 TCP configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>name or IP address</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

The HostName1 and HostName2 parameters can be used to specify specific network interfaces to be used for a given TCP connection between two nodes. The values used for these parameters can be host names or IP addresses.

- **HostName2**

  Table 22.222 This table provides type and value information for the HostName1 TCP configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>name or IP address</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

The HostName1 and HostName2 parameters can be used to specify specific network interfaces to be used for a given TCP connection between two nodes. The values used for these parameters can be host names or IP addresses.
NDB Cluster Configuration Files

- **NodeId1**

  Table 22.223 This table provides type and value information for the NodeId1 TCP configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 255</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

To identify a connection between two nodes it is necessary to provide their node IDs in the `[tcp]` section of the configuration file as the values of `NodeId1` and `NodeId2`. These are the same unique `Id` values for each of these nodes as described in Section 22.3.3.7, “Defining SQL and Other API Nodes in an NDB Cluster”.

- **NodeId2**

  Table 22.224 This table provides type and value information for the NodeId2 TCP configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 255</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

To identify a connection between two nodes it is necessary to provide their node IDs in the `[tcp]` section of the configuration file as the values of `NodeId1` and `NodeId2`. These are the same unique `Id` values for each of these nodes as described in Section 22.3.3.7, “Defining SQL and Other API Nodes in an NDB Cluster”.

- **OverloadLimit**

  Table 22.225 This table provides type and value information for the OverloadLimit TCP configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

When more than this many unsent bytes are in the send buffer, the connection is considered overloaded.

This parameter can be used to determine the amount of unsent data that must be present in the send buffer before the connection is considered overloaded. See Section 22.3.3.14, “Configuring NDB Cluster Send Buffer Parameters”, for more information.
• **PreSendChecksum**

Table 22.226 This table provides type and value information for the PreSendChecksum TCP configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>S</td>
</tr>
</tbody>
</table>

If this parameter and **Checksum** are both enabled, perform pre-send checksum checks, and check all TCP signals between nodes for errors. Has no effect if **Checksum** is not also enabled.

• **ReceiveBufferMemory**

Table 22.227 This table provides type and value information for the ReceiveBufferMemory TCP configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>2M</td>
</tr>
<tr>
<td>Range</td>
<td>16K - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>N</td>
</tr>
</tbody>
</table>

Specifies the size of the buffer used when receiving data from the TCP/IP socket.

The default value of this parameter is 2MB. The minimum possible value is 16KB; the theoretical maximum is 4GB.

• **SendBufferMemory**

Table 22.228 This table provides type and value information for the SendBufferMemory TCP configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>2M</td>
</tr>
<tr>
<td>Range</td>
<td>256K - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>N</td>
</tr>
</tbody>
</table>

TCP transporters use a buffer to store all messages before performing the send call to the operating system. When this buffer reaches 64KB its contents are sent; these are also sent when a round of messages have been executed. To handle temporary overload situations it is also possible to define a bigger send buffer.

If this parameter is set explicitly, then the memory is not dedicated to each transporter; instead, the value used denotes the hard limit for how much memory (out of the total available memory—that is, **TotalSendBufferMemory**) that may be used by a single transporter. For more
information about configuring dynamic transporter send buffer memory allocation in NDB Cluster, see Section 22.3.3.14, “Configuring NDB Cluster Send Buffer Parameters”.

The default size of the send buffer is 2MB, which is the size recommended in most situations. The minimum size is 64 KB; the theoretical maximum is 4 GB.

• **SendSignalId**

  **Table 22.229** This table provides type and value information for the SendSignalId TCP configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false (debug builds: true)</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

To be able to retrace a distributed message datagram, it is necessary to identify each message. When this parameter is set to Y, message IDs are transported over the network. This feature is disabled by default in production builds, and enabled in -debug builds.

• **TcpBind_INADDR_ANY**

  Setting this parameter to TRUE or 1 binds IP_ADDR_ANY so that connections can be made from anywhere (for autogenerated connections). The default is FALSE (0).

• **TcpSpinTime**

  **Table 22.230** This table provides type and value information for the TcpSpinTime TCP configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.20</td>
</tr>
<tr>
<td>Type or units</td>
<td>μsec</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 2000</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Controls spin for a TCP transporter; no enable, set to a nonzero value. This works for both the data node and management or SQL node side of the connection.

• **TCP_MAXSEG_SIZE**

  **Table 22.231** This table provides type and value information for the TCP_MAXSEG_SIZE TCP configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 2G</td>
</tr>
</tbody>
</table>
Property | Value
---|---
Restart Type | N

Determines the size of the memory set during TCP transporter initialization. The default is recommended for most common usage cases.

- **TCP_RCV_BUF_SIZE**

Table 22.232 This table provides type and value information for the TCP_RCV_BUF_SIZE TCP configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 2G</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Determines the size of the receive buffer set during TCP transporter initialization. The default and minimum value is 0, which allows the operating system or platform to set this value. The default is recommended for most common usage cases.

- **TCP_SND_BUF_SIZE**

Table 22.233 This table provides type and value information for the TCP_SND_BUF_SIZE TCP configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 2G</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Determines the size of the send buffer set during TCP transporter initialization. The default and minimum value is 0, which allows the operating system or platform to set this value. The default is recommended for most common usage cases.

**Restart types.** Information about the restart types used by the parameter descriptions in this section is shown in the following table:

Table 22.234 NDB Cluster restart types

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Restart Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>N</td>
<td>Node</td>
<td>The parameter can be updated using a rolling restart (see Section 22.5.5, “Performing a Rolling Restart of an NDB Cluster”)</td>
</tr>
<tr>
<td>S</td>
<td>System</td>
<td>All cluster nodes must be shut down completely, then restarted, to effect a change in this parameter</td>
</tr>
<tr>
<td>I</td>
<td>Initial</td>
<td>Data nodes must be restarted using the <code>--initial</code> option</td>
</tr>
</tbody>
</table>

22.3.3.11 NDB Cluster TCP/IP Connections Using Direct Connections
Setting up a cluster using direct connections between data nodes requires specifying explicitly the crossover IP addresses of the data nodes so connected in the [tcp] section of the cluster config.ini file.

In the following example, we envision a cluster with at least four hosts, one each for a management server, an SQL node, and two data nodes. The cluster as a whole resides on the 172.23.72.* subnet of a LAN. In addition to the usual network connections, the two data nodes are connected directly using a standard crossover cable, and communicate with one another directly using IP addresses in the 1.1.0.* address range as shown:

```ini
# Management Server
[ndb_mgmd]
Id=1
HostName=172.23.72.20

# SQL Node
[mysqld]
Id=2
HostName=172.23.72.21

# Data Nodes
[ndbd]
Id=3
HostName=172.23.72.22

[ndbd]
Id=4
HostName=172.23.72.23

# TCP/IP Connections
[tcp]
NodeId1=3
NodeId2=4
HostName1=1.1.0.1
HostName2=1.1.0.2
```

The HostName1 and HostName2 parameters are used only when specifying direct connections.

The use of direct TCP connections between data nodes can improve the cluster's overall efficiency by enabling the data nodes to bypass an Ethernet device such as a switch, hub, or router, thus cutting down on the cluster's latency.

**Note**

To take the best advantage of direct connections in this fashion with more than two data nodes, you must have a direct connection between each data node and every other data node in the same node group.

### 22.3.3.12 NDB Cluster Shared-Memory Connections

Communications between NDB cluster nodes are normally handled using TCP/IP. The shared memory (SHM) transporter is distinguished by the fact that signals are transmitted by writing in memory rather than on a socket. The shared-memory transporter (SHM) can improve performance by negating up to 20% of the overhead required by a TCP connection when running an API node (usually an SQL node) and a data node together on the same host. You can enable a shared memory connection in either of the two ways listed here:

- By setting the UseShm data node configuration parameter to 1, and setting HostName for the data node and HostName for the API node to the same value.

- By using [shm] sections in the cluster configuration file, each containing settings for NodeId1 and NodeId2. This method is described in more detail later in this section.

Suppose a cluster is running a data node which has node ID 1 and an SQL node having node ID 51 on the same host computer at 10.0.0.1. To enable an SHM connection between these two nodes, all that is necessary is to insure that the following entries are included in the cluster configuration file:
Important

The two entries just shown are in addition to any other entries and parameter settings needed by the cluster. A more complete example is shown later in this section.

Before starting data nodes that use SHM connections, it is also necessary to make sure that the operating system on each computer hosting such a data node has sufficient memory allocated to shared memory segments. See the documentation for your operating platform for information regarding this. In setups where multiple hosts are each running a data node and an API node, it is possible to enable shared memory on all such hosts by setting `UseShm` in the `[ndbd default]` section of the configuration file. This is shown in the example later in this section.

While not strictly required, tuning for all SHM connections in the cluster can be done by setting one or more of the following parameters in the `[shm default]` section of the cluster configuration (config.ini) file:

- **ShmSize**: Shared memory size
- **ShmSpinTime**: Time in µs to spin before sleeping
- **SendBufferMemory**: Size of buffer for signals sent from this node, in bytes.
- **SendSignalId**: Indicates that a signal ID is included in each signal sent through the transporter.
- **Checksum**: Indicates that a checksum is included in each signal sent through the transporter.
- **PreSendChecksum**: Checks of the checksum are made prior to sending the signal; Checksum must also be enabled for this to work.

This example shows a simple setup with SHM connections defined on multiple hosts, in an NDB Cluster using 3 computers listed here by host name, hosting the node types shown:

1. **10.0.0.0**: The management server
2. **10.0.0.1**: A data node and an SQL node
3. **10.0.0.2**: A data node and an SQL node

In this scenario, each data node communicates with both the management server and the other data node using TCP transporters; each SQL node uses a shared memory transporter to communicate with the data nodes that is local to it, and a TCP transporter to communicate with the remote data node. A basic configuration reflecting this setup is enabled by the config.ini file whose contents are shown here:

```
[ndbd default]
DataDir=/path/to/datadir
UseShm=1

[shm default]
ShmSize=8M
ShmSpinTime=200
SendBufferMemory=4M

[tcp default]
SendBufferMemory=8M
```
Parameters affecting all shared memory transporters are set in the [shm default] section; these can be overridden on a per-connection basis in one or more [shm] sections. Each such section must be associated with a given SHM connection using NodeId1 and NodeId2; the values required for these parameters are the node IDs of the two nodes connected by the transporter. You can also identify the nodes by host name using HostName1 and HostName2, but these parameters are not required.

The API nodes for which no host names are set use the TCP transporter to communicate with data nodes independent of the hosts on which they are started; the parameters and values set in the [tcp default] section of the configuration file apply to all TCP transporters in the cluster.

For optimum performance, you can define a spin time for the SHM transporter (ShmSpinTime parameter); this affects both the data node receiver thread and the poll owner (receive thread or user thread) in NDB.

• Checksum

Table 22.235 This table provides type and value information for the Checksum shared memory configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>true</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter is a boolean (Y/N) parameter which is disabled by default. When it is enabled, checksums for all messages are calculated before being placed in the send buffer.

This feature prevents messages from being corrupted while waiting in the send buffer. It also serves as a check against data being corrupted during transport.

• Group
Table 22.236 This table provides type and value information for the Group shared memory configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>35</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 200</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Determines the group proximity; a smaller value is interpreted as being closer. The default value is sufficient for most conditions.

- **HostName1**

Table 22.237 This table provides type and value information for the HostName1 shared memory configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>name or IP address</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

The HostName1 and HostName2 parameters can be used to specify specific network interfaces to be used for a given SHM connection between two nodes. The values used for these parameters can be host names or IP addresses.

- **HostName2**

Table 22.238 This table provides type and value information for the HostName1 shared memory configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>name or IP address</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

The HostName1 and HostName2 parameters can be used to specify specific network interfaces to be used for a given SHM connection between two nodes. The values used for these parameters can be host names or IP addresses.

- **NodeId1**

Table 22.239 This table provides type and value information for the NodeId1 shared memory configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
</tbody>
</table>
To identify a connection between two nodes it is necessary to provide node identifiers for each of them, as NodeId1 and NodeId2.

- **NodeId2**

Table 22.240 This table provides type and value information for the NodeId2 shared memory configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 255</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

To identify a connection between two nodes it is necessary to provide node identifiers for each of them, as NodeId1 and NodeId2.

- **NodeIdServer**

Table 22.241 This table provides type and value information for the NodeIdServer shared memory configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 63</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Identify the server end of a shared memory connection. By default, this is the node ID of the data node.

- **OverloadLimit**

Table 22.242 This table provides type and value information for the OverloadLimit shared memory configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

When more than this many unsent bytes are in the send buffer, the connection is considered overloaded. See Section 22.3.3.14, “Configuring NDB Cluster Send Buffer Parameters”, and Section 22.5.10.47, “The ndbinfo transporters Table”, for more information.
### PreSendChecksum

Table 22.243 This table provides type and value information for the PreSendChecksum shared memory configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>S</td>
</tr>
</tbody>
</table>

If this parameter and Checksum are both enabled, perform pre-send checksum checks, and check all SHM signals between nodes for errors. Has no effect if Checksum is not also enabled.

### SendBufferMemory

Table 22.244 This table provides type and value information for the SendBufferMemory shared memory configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>

<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>2M</td>
</tr>
<tr>
<td>Range</td>
<td>256K - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>N</td>
</tr>
</tbody>
</table>

Size (in bytes) of the shared memory buffer for signals sent from this node using a shared memory connection.

### SendSignalId

Table 22.245 This table provides type and value information for the SendSignalId shared memory configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>N</td>
</tr>
</tbody>
</table>

To retrace the path of a distributed message, it is necessary to provide each message with a unique identifier. Setting this parameter to Y causes these message IDs to be transported over the network as well. This feature is disabled by default in production builds, and enabled in -debug builds.

### ShmKey

Table 22.246 This table provides type and value information for the ShmKey shared memory configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
</tbody>
</table>
When setting up shared memory segments, a node ID, expressed as an integer, is used to identify uniquely the shared memory segment to use for the communication. There is no default value. If UseShm is enabled, the shared memory key is calculated automatically by NDB.

• **ShmSize**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td><strong>N</strong></td>
</tr>
</tbody>
</table>

Each SHM connection has a shared memory segment where messages between nodes are placed by the sender and read by the reader. The size of this segment is defined by ShmSize. The default value is 4MB.

• **ShmSpinTime**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 2000</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td><strong>S</strong></td>
</tr>
</tbody>
</table>

When receiving, the time to wait before sleeping, in microseconds.

• **SigNum**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td><strong>N</strong></td>
</tr>
</tbody>
</table>

This parameter was used formerly to override operating system signal numbers; in NDB 8.0, it is no longer used, and any setting for it is ignored.
**Restart types.** Information about the restart types used by the parameter descriptions in this section is shown in the following table:

<table>
<thead>
<tr>

<td>Data nodes must be restarted using the --initial option</td>
</tr>
</tbody>
</table>

### 22.3.3.13 Data Node Memory Management

All memory allocation for a data node is performed when the node is started. This ensures that the data node can run in a stable manner without using swap memory, so that NDB can be used for latency-sensitive (realtime) applications. The following types of memory are allocated on data node startup:

- Data memory
- Shared global memory
- Redo log buffers
- Job buffers
- Send buffers
- Page cache for disk data records
- Schema transaction memory
- Transaction memory
- Undo log buffer
- Query memory
- Block objects
- Schema memory
- Block data structures
- Long signal memory
- Shared memory communication buffers

The NDB memory manager, which regulates most data node memory, handles the following memory resources:

- Data Memory (DataMemory)
- Redo log buffers (RedoBuffer)
- Job buffers
- Send buffers (SendBufferMemory, TotalSendBufferMemory, ExtraSendBufferMemory, ReservedSendBufferMemory)
- Disk Data record page cache (DiskPageBufferMemory, DiskPageBufferEntries)
- Transaction memory \((\text{TransactionMemory})\)
- Query memory
- Disk access records
- File buffers

Each of these resources is set up with a reserved memory area and a maximum memory area. The reserved memory area can be used only by the resource for which it is reserved and cannot be shared with other resources; a given resource can never allocate more than the maximum memory allowed for the resource. A resource that has no maximum memory can expand to use all the shared memory in the memory manager.

The size of the global shared memory for these resources is controlled by the \(\text{SharedGlobalMemory}\) configuration parameter (default: 128 MB).

Data memory is always reserved and never acquires any memory from shared memory. It is controlled using the \(\text{DataMemory}\) configuration parameter, whose maximum is 16384 GB. \(\text{DataMemory}\) is where records are stored, including hash indexes (approximately 15 bytes per row), ordered indexes (10-12 bytes per row per index), and row headers (16-32 bytes per row).

Redo log buffers also use reserved memory only; this is controlled by the \(\text{RedoBuffer}\) configuration parameter, which sets the size of the redo log buffer per LDM thread. This means that the actual amount of memory used is the value of this parameter multiplied by the number of LDM threads in the data node.

Job buffers use reserved memory only; the size of this memory is calculated by \(\text{NDB}\), based on the numbers of threads of various types.

Send buffers have a reserved part but can also allocate an additional 25% of shared global memory. The send buffer reserved size is calculated in two steps:

1. Use the value of the \(\text{TotalSendBufferMemory}\) configuration parameter (no default value) or the sum of the individual send buffers used by all individual connections to the data node. A data node is connected to all other data nodes, to all API nodes, and to all management nodes. This means that, in a cluster with 2 data nodes, 2 management nodes, and 10 API nodes each data node has 13 node connections. Since the default value for \(\text{SendBufferMemory}\) for a data node connection is 2 MByte, this works out to 26 MB total.

2. To obtain the total reserved size for the send buffer, the value of the \(\text{ExtraSendBufferMemory}\) configuration parameter, if any (default value 0), is added to the value obtained in the previous step.

In other words, if \(\text{TotalSendBufferMemory}\) has been set, the send buffer size is \(\text{TotalSendBufferMemory} + \text{ExtraSendBufferMemory}\); otherwise, the size of the send buffer is equal to \((\text{number of node connections} \times \text{SendBufferMemory}) + \text{ExtraSendBufferMemory}\).

The page cache for disk data records uses a reserved resource only; the size of this resource is controlled by the \(\text{DiskPageBufferMemory}\) configuration parameter (default 64 MB). Memory for 32 KB disk page entries is also allocated; the number of these is determined by the \(\text{DiskPageBufferEntries}\) configuration parameter (default 10).

Transaction memory has a reserved part that either is calculated by \(\text{NDB}\), or is set explicitly using the \(\text{TransactionMemory}\) configuration parameter introduced in NDB 8.0.19 (in previous releases, this value was always calculated by \(\text{NDB}\)); transaction memory can also use an unlimited amount of shared global memory. Transaction memory is used for all operational resources handling transactions, scans, locks, scan buffers, and trigger operations. It also holds table rows as they are updated, before the next commit writes them to data memory.

In NDB 8.0.16 and earlier, operational records used dedicated resources whose sizes were controlled by a number of configuration parameters. Beginning with NDB 8.0.17, these are all allocated from a
common transaction memory resource and can also use resources from global shared memory. In NDB 8.0.19 and later, the size of this resource can be controlled using a single `TransactionMemory` configuration parameter.

Reserved memory for undo log buffers can be set using the `InitialLogFileGroup` configuration parameter. If an undo log buffer is created as part of a `CREATE LOGFILE GROUP` SQL statement, the memory is taken from the transaction memory.

A number of resources relating to metadata for Disk Data resources also have no reserved part, and use shared global memory only. Shared global shared memory is thus shared between send buffers, transaction memory, and Disk Data metadata.

If `TransactionMemory` is not set, it is calculated based on the following parameters:

- `MaxNoOfConcurrentOperations`
- `MaxNoOfConcurrentTransactions`
- `MaxNoOfFiredTriggers`
- `MaxNoOfLocalOperations`
- `MaxNoOfConcurrentIndexOperations`
- `MaxNoOfConcurrentScans`
- `MaxNoOfLocalScans`
- `BatchSizePerLocalScan`
- `TransactionBufferMemory`

When `TransactionMemory` is set explicitly, none of the configuration parameters just listed are used to calculate memory size. In addition, the parameters `MaxNoOfConcurrentIndexOperations`, `MaxNoOfFiredTriggers`, `MaxNoOfLocalOperations`, and `MaxNoOfLocalScans` are incompatible with `TransactionMemory` and cannot be set concurrently with it; if `TransactionMemory` is set and any of these four parameters are also set in the `config.ini` configuration file, the management server cannot start. These four parameters are deprecated in NDB 8.0.19, and will be removed from a future release of MySQL NDB Cluster.

The transaction memory resource contains a large number of memory pools. Each memory pool represents an object type and contains a set of objects; each pool includes a reserved part allocated to the pool at startup; this reserved memory is never returned to shared global memory. Reserved records are found using a data structure having only a single level for fast retrieval, which means that a number of records in each pool should be reserved. The number of reserved records in each pool has some impact on performance and reserved memory allocation, but is generally necessary only in certain very advanced use cases to set the reserved sizes explicitly.

The size of the reserved part of the pool can be controlled by setting the following configuration parameters:

- `ReservedConcurrentIndexOperations`
- `ReservedFiredTriggers`
- `ReservedConcurrentOperations`
- `ReservedLocalScans`
- `ReservedConcurrentTransactions`
- `ReservedConcurrentScans`
NDB Cluster Configuration Files

• **ReservedTransactionBufferMemory**

If the parameters just listed are not set, the reserved setting is 25% of transaction memory. The number of reserved records is per data node; these records are split among the threads handling them (LDM and TC threads) on each node. In most cases, it is sufficient to set **TransactionMemory** alone, and to allow the number of records in pools to be governed by its value.

**MaxNoOfConcurrentScans** limits the number of concurrent scans that can be active in each TC thread. This is important in guarding against cluster overload.

**MaxNoOfConcurrentOperations** limits the number of operations that can be active at any one time in updating transactions. (Simple reads are not affected by this parameter.) This number needs to be limited because it is necessary to preallocate memory for node failure handling, and a resource must be available for handling the maximum number of active operations in one TC thread when contending with node failures. It is imperative that **MaxNoOfConcurrentOperations** be set to the same number on all nodes (this can be done most easily by setting a value for it once, in the [ndbd default] section of the config.ini global configuration file). While its value can be increased using a rolling restart (see Section 22.5.5, “Performing a Rolling Restart of an NDB Cluster”), decreasing it in this way is not considered safe due to the possibility of a node failure occurring during the rolling restart.

It is possible to limit the size of a single transaction in NDB Cluster through the **MaxDMLOperationsPerTransaction** parameter. If this is not set, the size of one transaction is limited by **MaxNoOfConcurrentOperations** since this parameter limits the total number of concurrent operations per TC thread.

Schema memory size is controlled by the following set of configuration parameters:

• **MaxNoOfSubscriptions**
• **MaxNoOfSubscribers**
• **MaxNoOfConcurrentSubOperations**
• **MaxNoOfAttributes**
• **MaxNoOfTables**
• **MaxNoOfOrderedIndexes**
• **MaxNoOfUniqueHashIndexes**
• **MaxNoOfTriggers**

The number of nodes and the number of LDM threads also have a major impact on the size of schema memory since the number of partitions in each table and each partition (and its replicas) have to be represented in schema memory.

In addition, a number of other records are allocated during startup. These are relatively small. Each block in each thread contains block objects that use memory. This memory size is also normally quite small compared to the other data node memory structures.

22.3.3.14 Configuring NDB Cluster Send Buffer Parameters

The **NDB** kernel employs a unified send buffer whose memory is allocated dynamically from a pool shared by all transporters. This means that the size of the send buffer can be adjusted as necessary. Configuration of the unified send buffer can accomplished by setting the following parameters:

• **TotalSendBufferMemory**. This parameter can be set for all types of NDB Cluster nodes—that is, it can be set in the [ndbd], [mgm], and [api] (or [mysql]) sections of the config.ini file. It represents the total amount of memory (in bytes) to be allocated by each node for which it is set for use among all configured transporters. If set, its minimum is 256KB; the maximum is 4294967039.
To be backward-compatible with existing configurations, this parameter takes as its default value the sum of the maximum send buffer sizes of all configured transporters, plus an additional 32KB (one page) per transporter. The maximum depends on the type of transporter, as shown in the following table:

Table 22.251 Transporter types with maximum send buffer sizes

<table>
<thead>
<tr>
<th>Transporter</th>
<th>Maximum Send Buffer Size (bytes)</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCP</td>
<td>SendBufferMemory (default = 2M)</td>
</tr>
<tr>
<td>SHM</td>
<td>20K</td>
</tr>
</tbody>
</table>

This enables existing configurations to function in close to the same way as they did with NDB Cluster 6.3 and earlier, with the same amount of memory and send buffer space available to each transporter. However, memory that is unused by one transporter is not available to other transporters.

- **OverloadLimit.** This parameter is used in the `config.ini` file `[tcp]` section, and denotes the amount of unsent data (in bytes) that must be present in the send buffer before the connection is considered overloaded. When such an overload condition occurs, transactions that affect the overloaded connection fail with NDB API Error 1218 (*Send Buffers overloaded in NDB kernel*) until the overload status passes. The default value is 0, in which case the effective overload limit is calculated as `SendBufferMemory * 0.8` for a given connection. The maximum value for this parameter is 4G.

- **SendBufferMemory.** This value denotes a hard limit for the amount of memory that may be used by a single transporter out of the entire pool specified by `TotalSendBufferMemory`. However, the sum of `SendBufferMemory` for all configured transporters may be greater than the `TotalSendBufferMemory` that is set for a given node. This is a way to save memory when many nodes are in use, as long as the maximum amount of memory is never required by all transporters at the same time.

You can use the `ndbinfo.transporters` table to monitor send buffer memory usage, and to detect slowdown and overload conditions that can adversely affect performance.

### 22.3.4 Using High-Speed Interconnects with NDB Cluster

Even before design of NDBCLUSTER began in 1996, it was evident that one of the major problems to be encountered in building parallel databases would be communication between the nodes in the network. For this reason, NDBCLUSTER was designed from the very beginning to permit the use of a number of different data transport mechanisms. In this Manual, we use the term `transporter` for these.

The NDB Cluster codebase provides for four different transporters:

- **TCP/IP using 100 Mbps or gigabit Ethernet**, as discussed in Section 22.3.3.10, “NDB Cluster TCP/IP Connections”.

- **Direct (machine-to-machine) TCP/IP**: although this transporter uses the same TCP/IP protocol as mentioned in the previous item, it requires setting up the hardware differently and is configured differently as well. For this reason, it is considered a separate transport mechanism for NDB Cluster. See Section 22.3.3.11, “NDB Cluster TCP/IP Connections Using Direct Connections”, for details.

- **Shared memory (SHM)**. For more information about SHM, see Section 22.3.3.12, “NDB Cluster Shared-Memory Connections”.

- **Scalable Coherent Interface (SCI)**.

**Note**

Using SCI transporters in NDB Cluster requires specialized hardware, software, and MySQL binaries not available with NDB 8.0.
Most users today employ TCP/IP over Ethernet because it is ubiquitous. TCP/IP is also by far the best-tested transporter for use with NDB Cluster.

Regardless of the transporter used, NDB attempts to make sure that communication with data node processes is done using chunks that are as large as possible since this benefits all types of data transmission.

22.4 NDB Cluster Programs

Using and managing an NDB Cluster requires several specialized programs, which we describe in this chapter. We discuss the purposes of these programs in an NDB Cluster, how to use the programs, and what startup options are available for each of them.

These programs include the NDB Cluster data, management, and SQL node processes (ndbd, ndbmtd, ndb_mgmd, and mysqld) and the management client (ndb_mgm).

Information about the program ndb_setup.py, used to start the NDB Cluster Auto-Installer, is also included in this section. You should be aware that Section 22.4.26, "ndb_setup.py — Start browser-based Auto-Installer for NDB Cluster", contains information about the command-line client only; for information about using the GUI installer spawned by this program to configure and deploy an NDB Cluster, see The NDB Cluster Auto-Installer (NDB 7.5).

For information about using mysqld as an NDB Cluster process, see Section 22.5.4, “MySQL Server Usage for NDB Cluster”.

Other NDB utility, diagnostic, and example programs are included with the NDB Cluster distribution. These include ndb_restore, ndb_show_tables, and ndb_config. These programs are also covered in this section.

The final portion of this section contains tables of options that are common to all the various NDB Cluster programs.

22.4.1 ndbd — The NDB Cluster Data Node Daemon

ndbd is the process that is used to handle all the data in tables using the NDB Cluster storage engine. This is the process that empowers a data node to accomplish distributed transaction handling, node recovery, checkpointing to disk, online backup, and related tasks.

In an NDB Cluster, a set of ndbd processes cooperate in handling data. These processes can execute on the same computer (host) or on different computers. The correspondences between data nodes and Cluster hosts is completely configurable.

The following table includes command options specific to the NDB Cluster data node program ndbd. Additional descriptions follow the table. For options common to most NDB Cluster programs (including ndbd), see Section 22.4.31, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

Table 22.252 Command-line options for the ndbd program

<tr>
<td>--nodaemon</td>
<td>Do not start ndbd as daemon; provided for testing purposes</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--nostart, -n</td>
<td>Do not start ndbd immediately; ndbd waits for command to start from ndb_mgmd</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--nowait-nodes=list</td>
<td>Do not wait for these data nodes to start (takes comma-separated list of node IDs). Also requires --ndb-nodeid to be used</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--remove[=name]</td>
<td>Used to remove a data node process that was previously installed as a Windows service. Does not apply on non-Windows platforms</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--verbose, -v</td>
<td>Causes the data log to write extra debugging information to the node log</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
</tbody>
</table>

### Note

All of these options also apply to the multithreaded version of this program (ndbmtd) and you may substitute “ndbmtd” for “ndbd” wherever the latter occurs in this section.

- --bind-address
ndbd — The NDB Cluster Data Node Daemon

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--bind-address=name</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td></td>
</tr>
</tbody>
</table>

Causes ndbd to bind to a specific network interface (host name or IP address). This option has no default value.

- **--connect-delay=#**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--connect-delay=#</td>
</tr>
<tr>
<td>Deprecated</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>5</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>3600</td>
</tr>
</tbody>
</table>

Determines the time to wait between attempts to contact a management server when starting (the number of attempts is controlled by the **--connect-retries** option). The default is 5 seconds.

This option is deprecated, and is subject to removal in a future release of NDB Cluster. Use **--connect-retry-delay** instead.

- **--connect-retries=#**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--connect-retries=#</td>
</tr>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>12</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>65535</td>
</tr>
</tbody>
</table>

Set the number of times to retry a connection before giving up; 0 means 1 attempt only (and no retries). The default is 12 attempts. The time to wait between attempts is controlled by the **--connect-retry-delay** option.

- **--connect-retry-delay=#**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--connect-retry-delay=#</td>
</tr>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>5</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

Determines the time to wait between attempts to contact a management server when starting (the time between attempts is controlled by the **--connect-retries** option). The default is 5 seconds.

This option takes the place of the **--connect-delay** option, which is now deprecated and subject to removal in a future release of NDB Cluster.
**--daemon, -d**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--daemon</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>TRUE</td>
</tr>
</tbody>
</table>

Instructs `ndbd` or `ndbmtd` to execute as a daemon process. This is the default behavior. `--nodaemon` can be used to prevent the process from running as a daemon.

This option has no effect when running `ndbd` or `ndbmtd` on Windows platforms.

**--foreground**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--foreground</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Causes `ndbd` or `ndbmtd` to execute as a foreground process, primarily for debugging purposes. This option implies the `--nodaemon` option.

This option has no effect when running `ndbd` or `ndbmtd` on Windows platforms.

**--initial**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--initial</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Instructs `ndbd` to perform an initial start. An initial start erases any files created for recovery purposes by earlier instances of `ndbd`. It also re-creates recovery log files. On some operating systems, this process can take a substantial amount of time.

An `--initial` start is to be used only when starting the `ndbd` process under very special circumstances; this is because this option causes all files to be removed from the NDB Cluster file system and all redo log files to be re-created. These circumstances are listed here:

- When performing a software upgrade which has changed the contents of any files.
- When restarting the node with a new version of `ndbd`.
- As a measure of last resort when for some reason the node restart or system restart repeatedly fails. In this case, be aware that this node can no longer be used to restore data due to the destruction of the data files.

**Warning**

To avoid the possibility of eventual data loss, it is recommended that you not use the `--initial` option together with `StopOnError = 0`. Instead, set `StopOnError` to 0 in `config.ini` only after the cluster has been started, then restart the data nodes normally—that is, without the `--initial` option.
See the description of the `StopOnError` parameter for a detailed explanation of this issue. (Bug #24945638)

Use of this option prevents the `StartPartialTimeout` and `StartPartitionedTimeout` configuration parameters from having any effect.

**Important**

This option does *not* affect either of the following types of files:

- Backup files that have already been created by the affected node
- NDB Cluster Disk Data files (see Section 22.5.13, “NDB Cluster Disk Data Tables”).

This option also has no effect on recovery of data by a data node that is just starting (or restarting) from data nodes that are already running. This recovery of data occurs automatically, and requires no user intervention in an NDB Cluster that is running normally.

It is permissible to use this option when starting the cluster for the very first time (that is, before any data node files have been created); however, it is *not* necessary to do so.

- **--initial-start**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--initial-start</code></td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

This option is used when performing a partial initial start of the cluster. Each node should be started with this option, as well as `--nowait-nodes`.

Suppose that you have a 4-node cluster whose data nodes have the IDs 2, 3, 4, and 5, and you wish to perform a partial initial start using only nodes 2, 4, and 5—that is, omitting node 3:

```
shell> ndbd --ndb-nodeid=2 --nowait-nodes=3 --initial-start
shell> ndbd --ndb-nodeid=4 --nowait-nodes=3 --initial-start
shell> ndbd --ndb-nodeid=5 --nowait-nodes=3 --initial-start
```

When using this option, you must also specify the node ID for the data node being started with the `--ndb-nodeid` option.

**Important**

Do not confuse this option with the `--nowait-nodes` option for `ndb_mgmd`, which can be used to enable a cluster configured with multiple management servers to be started without all management servers being online.

- **--install=[name]**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--install=[name]</code></td>
</tr>
<tr>
<td>Platform Specific</td>
<td>Windows</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>
ndbd — The NDB Cluster Data Node Daemon

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>ndbd</td>
</tr>
</tbody>
</table>

Causes ndbd to be installed as a Windows service. Optionally, you can specify a name for the service; if not set, the service name defaults to ndbd. Although it is preferable to specify other ndbd program options in a my.ini or my.cnf configuration file, it is possible to use together with --install. However, in such cases, the --install option must be specified first, before any other options are given, for the Windows service installation to succeed.

It is generally not advisable to use this option together with the --initial option, since this causes the data node file system to be wiped and rebuilt every time the service is stopped and started. Extreme care should also be taken if you intend to use any of the other ndbd options that affect the starting of data nodes—including --initial-start, --nostart, and --nowait-nodes— together with --install, and you should make absolutely certain you fully understand and allow for any possible consequences of doing so.

The --install option has no effect on non-Windows platforms.

- **--logbuffer-size=#**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--logbuffer-size=#</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>32768</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>2048</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

Sets the size of the data node log buffer. When debugging with high amounts of extra logging, it is possible for the log buffer to run out of space if there are too many log messages, in which case some log messages can be lost. This should not occur during normal operations.

- **--nodaemon**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--nodaemon</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Prevents ndbd or ndbmtd from executing as a daemon process. This option overrides the --daemon option. This is useful for redirecting output to the screen when debugging the binary.

The default behavior for ndbd and ndbmtd on Windows is to run in the foreground, making this option unnecessary on Windows platforms, where it has no effect.

- **--nostart, -n**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--nostart</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Instructs ndbd not to start automatically. When this option is used, ndbd connects to the management server, obtains configuration data from it, and initializes communication objects. However, it does not actually start the execution engine until specifically requested to do so by
the management server. This can be accomplished by issuing the proper `START` command in the management client (see Section 22.5.2, "Commands in the NDB Cluster Management Client").

- `--nowait-nodes=node_id_1[, node_id_2[, ...]]`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--nowait-nodes=list</code></td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>
| Default Value     | This option takes a list of data nodes which for which the cluster will not wait for before starting. This can be used to start the cluster in a partitioned state. For example, to start the cluster with only half of the data nodes (nodes 2, 3, 4, and 5) running in a 4-node cluster, you can start each `ndbd` process with `--nowait-nodes=3,5`. In this case, the cluster starts as soon as nodes 2 and 4 connect, and does not wait `StartPartitionedTimeout` milliseconds for nodes 3 and 5 to connect as it would otherwise.

If you wanted to start up the same cluster as in the previous example without one `ndbd` (say, for example, that the host machine for node 3 has suffered a hardware failure) then start nodes 2, 4, and 5 with `--nowait-nodes=3`. Then the cluster will start as soon as nodes 2, 4, and 5 connect and will not wait for node 3 to start.

- `--remove[=name]`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--remove[=name]</code></td>
</tr>
<tr>
<td>Platform Specific</td>
<td>Windows</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>ndbd</code></td>
</tr>
</tbody>
</table>

Causes an `ndbd` process that was previously installed as a Windows service to be removed. Optionally, you can specify a name for the service to be uninstalled; if not set, the service name defaults to `ndbd`.

The `--remove` option has no effect on non-Windows platforms.

- `--verbose, -v`

Causes extra debug output to be written to the node log.

You can also use `NODELOG_DEBUG ON` and `NODELOG_DEBUG OFF` to enable and disable this extra logging while the data node is running.

`ndbd` generates a set of log files which are placed in the directory specified by `DataDir` in the `config.ini` configuration file.

These log files are listed below. `node_id` is and represents the node's unique identifier. For example, `ndb_2_error.log` is the error log generated by the data node whose node ID is `2`.

- `ndb_node_id_error.log` is a file containing records of all crashes which the referenced `ndbd` process has encountered. Each record in this file contains a brief error string and a reference to a trace file for this crash. A typical entry in this file might appear as shown here:

```
Date/Time: Saturday 30 July 2004 - 00:20:01
Type of error: error
Message: Internal program error (failed ndbrequire)
Fault ID: 2341
```
Important

The last entry in the error log file is not necessarily the newest one (nor is it likely to be). Entries in the error log are not listed in chronological order; rather, they correspond to the order of the trace files as determined in the ndb_node_id_trace.log.next file (see below). Error log entries are thus overwritten in a cyclical and not sequential fashion.

• ndb_node_id_trace.log.trace_id is a trace file describing exactly what happened just before the error occurred. This information is useful for analysis by the NDB Cluster development team.

It is possible to configure the number of these trace files that will be created before old files are overwritten. trace_id is a number which is incremented for each successive trace file.

• ndb_node_id_trace.log.next is the file that keeps track of the next trace file number to be assigned.

• ndb_node_id_out.log is a file containing any data output by the ndbd process. This file is created only if ndbd is started as a daemon, which is the default behavior.

• ndb_node_id.pid is a file containing the process ID of the ndbd process when started as a daemon. It also functions as a lock file to avoid the starting of nodes with the same identifier.

• ndb_node_id_signal.log is a file used only in debug versions of ndbd, where it is possible to trace all incoming, outgoing, and internal messages with their data in the ndbd process.

It is recommended not to use a directory mounted through NFS because in some environments this can cause problems whereby the lock on the .pid file remains in effect even after the process has terminated.

To start ndbd, it may also be necessary to specify the host name of the management server and the port on which it is listening. Optionally, one may also specify the node ID that the process is to use.

shell> ndbd --connect-string="nodeid=2;host=ndb_mgmd.mysql.com:1186"

See Section 22.3.3.3, “NDB Cluster Connection Strings”, for additional information about this issue. Section 22.4.31, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”, describes other command-line options which can be used with ndbd. For information about data node configuration parameters, see Section 22.3.3.6, “Defining NDB Cluster Data Nodes”.

When ndbd starts, it actually initiates two processes. The first of these is called the “angel process”; its only job is to discover when the execution process has been completed, and then to restart the ndbd process if it is configured to do so. Thus, if you attempt to kill ndbd using the Unix kill command, it is necessary to kill both processes, beginning with the angel process. The preferred method of terminating an ndbd process is to use the management client and stop the process from there.

The execution process uses one thread for reading, writing, and scanning data, as well as all other activities. This thread is implemented asynchronously so that it can easily handle thousands of concurrent actions. In addition, a watch-dog thread supervises the execution thread to make sure that it does not hang in an endless loop. A pool of threads handles file I/O, with each thread able to handle one open file. Threads can also be used for transporter connections by the transporters in the ndbd.
process. In a multi-processor system performing a large number of operations (including updates), the \texttt{ndbd} process can consume up to 2 CPUs if permitted to do so.

For a machine with many CPUs it is possible to use several \texttt{ndbd} processes which belong to different node groups; however, such a configuration is still considered experimental and is not supported for MySQL 8.0 in a production setting. See Section 22.1.7, “Known Limitations of NDB Cluster”.

### 22.4.2 \texttt{ndbinfo_select_all} — Select From \texttt{ndbinfo} Tables

\texttt{ndbinfo_select_all} is a client program that selects all rows and columns from one or more tables in the \texttt{ndbinfo} database.

Not all \texttt{ndbinfo} tables available in the \texttt{mysql} client can be read by this program. In addition, \texttt{ndbinfo_select_all} can show information about some tables internal to \texttt{ndbinfo} which cannot be accessed using SQL, including the tables and columns metadata tables.

To select from one or more \texttt{ndbinfo} tables using \texttt{ndbinfo_select_all}, it is necessary to supply the names of the tables when invoking the program as shown here:

```
shell> ndbinfo_select_all table_name1 [table_name2] [...]
```

For example:

```
shell> ndbinfo_select_all logbuffers logspaces
== logbuffers ==
node_id log_type        log_id  log_part        total   used    high
5       0       0       0       33554432        262144  0
6       0       0       0       33554432        262144  0
7       0       0       0       33554432        262144  0
8       0       0       0       33554432        262144  0
== logspaces ==
node_id log_type        log_id  log_part        total   used    high
5       0       0       0       268435456       0       0
5       0       0       1       268435456       0       0
5       0       0       2       268435456       0       0
5       0       0       3       268435456       0       0
6       0       0       0       268435456       0       0
6       0       0       1       268435456       0       0
6       0       0       2       268435456       0       0
7       0       0       0       268435456       0       0
7       0       0       1       268435456       0       0
7       0       0       2       268435456       0       0
7       0       0       3       268435456       0       0
8       0       0       0       268435456       0       0
8       0       0       1       268435456       0       0
8       0       0       2       268435456       0       0
8       0       0       3       268435456       0       0
shell>
```

The following table includes options that are specific to \texttt{ndbinfo_select_all}. Additional descriptions follow the table. For options common to most NDB Cluster programs (including \texttt{ndbinfo_select_all}), see Section 22.4.31, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

**Table 22.253 Command-line options for the \texttt{ndbinfo_select_all} program**

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{--delay=#}</td>
<td>Set the delay in seconds between loops. Default is 5</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>\texttt{--loops=#, -l}</td>
<td>Set the number of times to perform the select. Default is 1</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
</tbody>
</table>
ndbmtd — The NDB Cluster Data Node Daemon (Multi-Threaded)

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--database=db_name, -d --parallelism=#, -p</td>
<td>Name of the database where the table located</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td></td>
<td>Set the degree of parallelism</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
</tbody>
</table>

**--delay=seconds**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--delay=#</td>
</tr>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>5</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>MAX_INT</td>
</tr>
</tbody>
</table>

This option sets the number of seconds to wait between executing loops. Has no effect if --loops is set to 0 or 1.

**--loops=number, -l number**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--loops=#</td>
</tr>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>MAX_INT</td>
</tr>
</tbody>
</table>

This option sets the number of times to execute the select. Use --delay to set the time between loops.

**22.4.3 ndbmtd — The NDB Cluster Data Node Daemon (Multi-Threaded)**

ndbmtd is a multithreaded version of ndbd, the process that is used to handle all the data in tables using the NDBCLUSTER storage engine. ndbmtd is intended for use on host computers having multiple CPU cores. Except where otherwise noted, ndbmtd functions in the same way as ndbd; therefore, in this section, we concentrate on the ways in which ndbmtd differs from ndbd, and you should consult Section 22.4.1, “ndbd — The NDB Cluster Data Node Daemon”, for additional information about running NDB Cluster data nodes that apply to both the single-threaded and multithreaded versions of the data node process.

Command-line options and configuration parameters used with ndbd also apply to ndbmtd. For more information about these options and parameters, see Section 22.4.1, “ndbd — The NDB Cluster Data Node Daemon”, and Section 22.3.3.6, “Defining NDB Cluster Data Nodes”, respectively.

ndbmtd is also file system-compatible with ndbd. In other words, a data node running ndbd can be stopped, the binary replaced with ndbmtd, and then restarted without any loss of data. (However, when doing this, you must make sure that MaxNoOfExecutionThreads is set to an appropriate value before restarting the node if you wish for ndbmtd to run in multithreaded fashion.) Similarly, an ndbmtd binary can be replaced with ndbd simply by stopping the node and then starting ndbd in place of the multithreaded binary. It is not necessary when switching between the two to start the data node binary using --initial.
Using `ndbmd` differs from using `ndbd` in two key respects:

1. Because `ndbmd` runs by default in single-threaded mode (that is, it behaves like `ndbd`), you must configure it to use multiple threads. This can be done by setting an appropriate value in the `config.ini` file for the `MaxNoOfExecutionThreads` configuration parameter or the `ThreadConfig` configuration parameter. Using `MaxNoOfExecutionThreads` is simpler, but `ThreadConfig` offers more flexibility. For more information about these configuration parameters and their use, see Multi-Threading Configuration Parameters (ndbmd).

2. Trace files are generated by critical errors in `ndbmd` processes in a somewhat different fashion from how these are generated by `ndbd` failures. These differences are discussed in more detail in the next few paragraphs.

Like `ndbd`, `ndbmd` generates a set of log files which are placed in the directory specified by `DataDir` in the `config.ini` configuration file. Except for trace files, these are generated in the same way and have the same names as those generated by `ndbd`.

In the event of a critical error, `ndbmd` generates trace files describing what happened just prior to the error occurrence. These files, which can be found in the data node's `DataDir`, are useful for analysis of problems by the NDB Cluster Development and Support teams. One trace file is generated for each `ndbmd` thread. The names of these files have the following pattern:

```
ndb_node_id_trace.log.trace_id_tthread_id,
```

In this pattern, `node_id` stands for the data node's unique node ID in the cluster, `trace_id` is a trace sequence number, and `thread_id` is the thread ID. For example, in the event of the failure of an `ndbmd` process running as an NDB Cluster data node having the node ID 3 and with `MaxNoOfExecutionThreads` equal to 4, four trace files are generated in the data node's data directory. If this is the first time this node has failed, then these files are named `ndb_3_trace.log.1_t1`, `ndb_3_trace.log.1_t2`, `ndb_3_trace.log.1_t3`, and `ndb_3_trace.log.1_t4`. Internally, these trace files follow the same format as `ndbd` trace files.

The `ndbd` exit codes and messages that are generated when a data node process shuts down prematurely are also used by `ndbmd`. See Data Node Error Messages, for a listing of these.

**Note**

It is possible to use `ndbd` and `ndbmd` concurrently on different data nodes in the same NDB Cluster. However, such configurations have not been tested extensively; thus, we cannot recommend doing so in a production setting at this time.

## 22.4.4 `ndb_mgmd` — The NDB Cluster Management Server Daemon

The management server is the process that reads the cluster configuration file and distributes this information to all nodes in the cluster that request it. It also maintains a log of cluster activities. Management clients can connect to the management server and check the cluster's status.

The following table includes options that are specific to the NDB Cluster management server program `ndb_mgmd`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndb_mgmd`), see Section 22.4.31, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

**Table 22.254 Command-line options for the `ndb_mgmd` program**

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--bind-address=host</code></td>
<td>Local bind address</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>Format</td>
<td>Description</td>
<td>Added, Deprecated, or Removed</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>-------------------------------------------------------------------</td>
</tr>
<tr>
<td>--config-cache[=TRUE</td>
<td>FALSE]</td>
<td>Enable the management server configuration cache; TRUE by default</td>
</tr>
<tr>
<td>--config-file=file, -f</td>
<td>Specify the cluster configuration file; in NDB-6.4.0 and later, needs --reload or --initial to override configuration cache if present</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--configdir=directory, --config-dir=directory</td>
<td>Specify the cluster management server's configuration cache directory</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--daemon, -d</td>
<td>Run ndb_mgmd in daemon mode (default)</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--initial</td>
<td>Causes the management server reload its configuration data from the configuration file, bypassing the configuration cache</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--install[=name]</td>
<td>Used to install the management server process as a Windows service. Does not apply on non-Windows platforms</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--interactive</td>
<td>Run ndb_mgmd in interactive mode (not officially supported in production; for testing purposes only)</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--log-name=name</td>
<td>A name to use when writing messages applying to this node in the cluster log</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--mycnf</td>
<td>Read cluster configuration data from the my.cnf file</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--no-nodeid-checks</td>
<td>Do not provide any node id checks</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--nodaemon</td>
<td>Do not run ndb_mgmd as a daemon</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--nowait-nodes=list</td>
<td>Do not wait for these management nodes when starting this management server. Also requires --ndb-nodeid to be used</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--print-full-config, -P</td>
<td>Print full configuration and exit</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--reload</td>
<td>Causes the management server to compare the configuration file with its configuration cache</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--remove[=name]</td>
<td>Used to remove a management server process that was previously installed as a Windows service, optionally specifying the name of the service to be removed. Does not apply on non-Windows platforms</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
</tbody>
</table>
--verbose, -v

Write additional information to the log
(Supported in all MySQL 8.0 based releases)

• --bind-address=host

Causes the management server to bind to a specific network interface (host name or IP address). This option has no default value.

• --config-cache

This option, whose default value is 1 (or TRUE, or ON), can be used to disable the management server’s configuration cache, so that it reads its configuration from config.ini every time it starts (see Section 22.3.3, "NDB Cluster Configuration Files"). You can do this by starting the ndb_mgmd process with any one of the following options:

• --config-cache=0

• --config-cache=FALSE

• --config-cache=OFF

• --skip-config-cache

Using one of the options just listed is effective only if the management server has no stored configuration at the time it is started. If the management server finds any configuration cache files, then the --config-cache option or the --skip-config-cache option is ignored. Therefore, to disable configuration caching, the option should be used the first time that the management server is started. Otherwise—that is, if you wish to disable configuration caching for a management server that has already created a configuration cache—you must stop the management server, delete any existing configuration cache files manually, then restart the management server with --skip-config-cache (or with --config-cache set equal to 0, OFF, or FALSE).

Configuration cache files are normally created in a directory named mysql-cluster under the installation directory (unless this location has been overridden using the --configdir option). Each time the management server updates its configuration data, it writes a new cache file. The files are named sequentially in order of creation using the following format:

```
ndb_node-id_config.bin.seq-number
```

`node-id` is the management server’s node ID; `seq-number` is a sequence number, beginning with 1. For example, if the management server’s node ID is 5, then the first three configuration cache files would be:

```
ndb_node-5_config.bin.000
ndb_node-5_config.bin.001
ndb_node-5_config.bin.002
```
would, when they are created, be named ndb_5_config.bin.1, ndb_5_config.bin.2, and ndb_5_config.bin.3.

If your intent is to purge or reload the configuration cache without actually disabling caching, you should start ndb_mgmd with one of the options --reload or --initial instead of --skip-config-cache.

To re-enable the configuration cache, simply restart the management server, but without the --config-cache or --skip-config-cache option that was used previously to disable the configuration cache.

ndb_mgmd does not check for the configuration directory (--configdir) or attempts to create one when --skip-config-cache is used. (Bug #13428853)

• --config-file=filename, -f filename

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--config-file=file</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Instructs the management server as to which file it should use for its configuration file. By default, the management server looks for a file named config.ini in the same directory as the ndb_mgmd executable; otherwise the file name and location must be specified explicitly.

This option has no default value, and is ignored unless the management server is forced to read the configuration file, either because ndb_mgmd was started with the --reload or --initial option, or because the management server could not find any configuration cache. This option is also read if ndb_mgmd was started with --config-cache=OFF. See Section 22.3.3, "NDB Cluster Configuration Files", for more information.

• --configdir=dir_name

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--configdir=directory</td>
</tr>
<tr>
<td></td>
<td>--config-dir=directory</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td>$INSTALLDIR/mysql-cluster</td>
</tr>
</tbody>
</table>

Specifies the cluster management server's configuration cache directory. --config-dir is an alias for this option.

• --daemon, -d

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--daemon</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>TRUE</td>
</tr>
</tbody>
</table>

Instructs ndb_mgmd to start as a daemon process. This is the default behavior.

This option has no effect when running ndb_mgmd on Windows platforms.
• **--initial**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--initial</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Configuration data is cached internally, rather than being read from the cluster global configuration file each time the management server is started (see Section 22.3.3, “NDB Cluster Configuration Files”). Using the **--initial** option overrides this behavior, by forcing the management server to delete any existing cache files, and then to re-read the configuration data from the cluster configuration file and to build a new cache.

This differs in two ways from the **--reload** option. First, **--reload** forces the server to check the configuration file against the cache and reload its data only if the contents of the file are different from the cache. Second, **--reload** does not delete any existing cache files.

If ndb_mgmd is invoked with **--initial** but cannot find a global configuration file, the management server cannot start.

When a management server starts, it checks for another management server in the same NDB Cluster and tries to use the other management server's configuration data. This behavior has implications when performing a rolling restart of an NDB Cluster with multiple management nodes. See Section 22.5.5, “Performing a Rolling Restart of an NDB Cluster”, for more information.

When used together with the **--config-file** option, the cache is cleared only if the configuration file is actually found.

• **--install[=name]**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--install[=name]</td>
</tr>
<tr>
<td>Platform Specific</td>
<td>Windows</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>ndb_mgmd</td>
</tr>
</tbody>
</table>

Causes ndb_mgmd to be installed as a Windows service. Optionally, you can specify a name for the service; if not set, the service name defaults to ndb_mgmd. Although it is preferable to specify other ndb_mgmd program options in a my.ini or my.cnf configuration file, it is possible to use them together with **--install**. However, in such cases, the **--install** option must be specified first, before any other options are given, for the Windows service installation to succeed.

It is generally not advisable to use this option together with the **--initial** option, since this causes the configuration cache to be wiped and rebuilt every time the service is stopped and started. Care should also be taken if you intend to use any other ndb_mgmd options that affect the starting of the management server, and you should make absolutely certain you fully understand and allow for any possible consequences of doing so.

The **--install** option has no effect on non-Windows platforms.

• **--interactive**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--interactive</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
</tbody>
</table>
**ndb_mgmd** — The NDB Cluster Management Server Daemon

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Starts `ndb_mgmd` in interactive mode; that is, an `ndb_mgm` client session is started as soon as the management server is running. This option does not start any other NDB Cluster nodes.

- **--log-name=name**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--log-name=name</code></td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>MgmtSrvr</code></td>
</tr>
</tbody>
</table>

Provides a name to be used for this node in the cluster log.

- **--mycnf**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--mycnf</code></td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Read configuration data from the `my.cnf` file.

- **--no-nodeid-checks**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--no-nodeid-checks</code></td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Do not perform any checks of node IDs.

- **--nodaemon**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--nodaemon</code></td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Instructs `ndb_mgmd` not to start as a daemon process.

The default behavior for `ndb_mgmd` on Windows is to run in the foreground, making this option unnecessary on Windows platforms.

- **--nowait-nodes**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--nowait-nodes=list</code></td>
</tr>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>3807</td>
</tr>
</tbody>
</table>

Minimum Value | 1 |
When starting an NDB Cluster is configured with two management nodes, each management server normally checks to see whether the other \texttt{ndb\_mgmd} is also operational and whether the other management server's configuration is identical to its own. However, it is sometimes desirable to start the cluster with only one management node (and perhaps to allow the other \texttt{ndb\_mgmd} to be started later). This option causes the management node to bypass any checks for any other management nodes whose node IDs are passed to this option, permitting the cluster to start as though configured to use only the management node that was started.

For purposes of illustration, consider the following portion of a \texttt{config.ini} file (where we have omitted most of the configuration parameters that are not relevant to this example):

```ini
[nxdbd]
NodeId = 1
HostName = 198.51.100.101

[nxdbd]
NodeId = 2
HostName = 198.51.100.102

[nxdbd]
NodeId = 3
HostName = 198.51.100.103

[nxdbd]
NodeId = 4
HostName = 198.51.100.104

[ndb\_mgmd]
NodeId = 10
HostName = 198.51.100.150

[ndb\_mgmd]
NodeId = 11
HostName = 198.51.100.151

[api]
NodeId = 20
HostName = 198.51.100.200

[api]
NodeId = 21
HostName = 198.51.100.201
```

Assume that you wish to start this cluster using only the management server having node ID 10 and running on the host having the IP address 198.51.100.150. (Suppose, for example, that the host computer on which you intend to the other management server is temporarily unavailable due to a hardware failure, and you are waiting for it to be repaired.) To start the cluster in this way, use a command line on the machine at 198.51.100.150 to enter the following command:

```
shell> ndb\_mgmd --ndb\-nodeid=10 --nowait-nodes=11
```

As shown in the preceding example, when using \texttt{--nowait-nodes}, you must also use the \texttt{--ndb\_nodeid} option to specify the node ID of this \texttt{ndb\_mgmd} process.

You can then start each of the cluster's data nodes in the usual way. If you wish to start and use the second management server in addition to the first management server at a later time without
restarting the data nodes, you must start each data node with a connection string that references both management servers, like this:

```
shell> ndbd -c 198.51.100.150,198.51.100.151
```

The same is true with regard to the connection string used with any `mysqld` processes that you wish to start as NDB Cluster SQL nodes connected to this cluster. See Section 22.3.3.3, “NDB Cluster Connection Strings”, for more information.

When used with `ndb_mgmd`, this option affects the behavior of the management node with regard to other management nodes only. Do not confuse it with the `--nowait-nodes` option used with `ndbd` or `ndbmtd` to permit a cluster to start with fewer than its full complement of data nodes; when used with data nodes, this option affects their behavior only with regard to other data nodes.

Multiple management node IDs may be passed to this option as a comma-separated list. Each node ID must be no less than 1 and no greater than 255. In practice, it is quite rare to use more than two management servers for the same NDB Cluster (or to have any need for doing so); in most cases you need to pass to this option only the single node ID for the one management server that you do not wish to use when starting the cluster.

![Note]

When you later start the “missing” management server, its configuration must match that of the management server that is already in use by the cluster. Otherwise, it fails the configuration check performed by the existing management server, and does not start.

- **--print-full-config, -P**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--print-full-config</code></td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>FALSE</code></td>
</tr>
</tbody>
</table>

Shows extended information regarding the configuration of the cluster. With this option on the command line the `ndb_mgmd` process prints information about the cluster setup including an extensive list of the cluster configuration sections as well as parameters and their values. Normally used together with the `--config-file (-f)` option.

- **--reload**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--reload</code></td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>FALSE</code></td>
</tr>
</tbody>
</table>

NDB Cluster configuration data is stored internally rather than being read from the cluster global configuration file each time the management server is started (see Section 22.3.3, “NDB Cluster Configuration Files”). Using this option forces the management server to check its internal data store against the cluster configuration file and to reload the configuration if it finds that the configuration file does not match the cache. Existing configuration cache files are preserved, but not used.

This differs in two ways from the `--initial` option. First, `--initial` causes all cache files to be deleted. Second, `--initial` forces the management server to re-read the global configuration file and construct a new cache.

If the management server cannot find a global configuration file, then the `--reload` option is ignored.
When `--reload` is used, the management server must be able to communicate with data nodes and any other management servers in the cluster before it attempts to read the global configuration file; otherwise, the management server fails to start. This can happen due to changes in the networking environment, such as new IP addresses for nodes or an altered firewall configuration. In such cases, you must use `--initial` instead to force the existing cached configuration to be discarded and reloaded from the file. See Section 22.5.5, “Performing a Rolling Restart of an NDB Cluster”, for additional information.

### --remove{=name}

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--remove{=name}</code></td>
</tr>
<tr>
<td>Platform Specific</td>
<td>Windows</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>ndb_mgmd</td>
</tr>
</tbody>
</table>

Remove a management server process that has been installed as a Windows service, optionally specifying the name of the service to be removed. Applies only to Windows platforms.

### --verbose, -v

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--verbose</code></td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Remove a management server process that has been installed as a Windows service, optionally specifying the name of the service to be removed. Applies only to Windows platforms.

It is not strictly necessary to specify a connection string when starting the management server. However, if you are using more than one management server, a connection string should be provided and each node in the cluster should specify its node ID explicitly.

See Section 22.3.3.3, “NDB Cluster Connection Strings”, for information about using connection strings. Section 22.4.4, “ndb_mgmd — The NDB Cluster Management Server Daemon”, describes other options for `ndb_mgmd`.

The following files are created or used by `ndb_mgmd` in its starting directory, and are placed in the `DataDir` as specified in the `config.ini` configuration file. In the list that follows, `node_id` is the unique node identifier.

- `config.ini` is the configuration file for the cluster as a whole. This file is created by the user and read by the management server. Section 22.3, “Configuration of NDB Cluster”, discusses how to set up this file.
- `ndb_node_id_cluster.log` is the cluster events log file. Examples of such events include checkpoint startup and completion, node startup events, node failures, and levels of memory usage. A complete listing of cluster events with descriptions may be found in Section 22.5, “Management of NDB Cluster”.

By default, when the size of the cluster log reaches one million bytes, the file is renamed to `ndb_node_id_cluster.log.seq_id`, where `seq_id` is the sequence number of the cluster log file. (For example: If files with the sequence numbers 1, 2, and 3 already exist, the next log file is named using the number 4.) You can change the size and number of files, and other characteristics of the cluster log, using the `LogDestination` configuration parameter.
• `ndb_node_id_out.log` is the file used for stdout and stderr when running the management server as a daemon.

• `ndb_node_id.pid` is the process ID file used when running the management server as a daemon.

### 22.4.5 `ndb_mgm` — The NDB Cluster Management Client

The `ndb_mgm` management client process is actually not needed to run the cluster. Its value lies in providing a set of commands for checking the cluster’s status, starting backups, and performing other administrative functions. The management client accesses the management server using a C API. Advanced users can also employ this API for programming dedicated management processes to perform tasks similar to those performed by `ndb_mgm`.

To start the management client, it is necessary to supply the host name and port number of the management server:

```shell
shell> ndb_mgm [host_name [port_num]]
```

For example:

```shell
shell> ndb_mgm ndb_mgmd.mysql.com 1186
```

The default host name and port number are `localhost` and 1186, respectively.

The following table includes options that are specific to the NDB Cluster management client program `ndb_mgm`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndb_mgm`), see Section 22.4.31, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

#### Table 22.255 Command-line options for the `ndb_mgm` program

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--connect-retries=#</td>
<td>Set the number of times to retry a connection before giving up; 0 means 1 attempt only (and no retries)</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--try-reconnect=#, -t</td>
<td>Set the number of times to retry a connection before giving up; synonym for --connect-retries</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--execute=name, -e</td>
<td>Execute command and exit</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
</tbody>
</table>

- `--connect-retries=#`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--connect-retries=#</code></td>
</tr>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>3</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

This option specifies the number of times following the first attempt to retry a connection before giving up (the client always tries the connection at least once). The length of time to wait per attempt is set using `--connect-retry-delay`.

This option is synonymous with the `--try-reconnect` option, which is now deprecated.
The default for this option differs from its default when used with other NDB programs. See Section 22.4.31, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”, for more information.

- **--execute=command**, **-e command**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--execute=name</td>
</tr>
</tbody>
</table>

This option can be used to send a command to the NDB Cluster management client from the system shell. For example, either of the following is equivalent to executing `SHOW` in the management client:

```
shell> ndb_mgm -e "SHOW"
shell> ndb_mgm --execute="SHOW"
```

This is analogous to how the `--execute` or `-e` option works with the `mysql` command-line client. See Section 4.2.2.1, “Using Options on the Command Line”.

**Note**

If the management client command to be passed using this option contains any space characters, then the command must be enclosed in quotation marks. Either single or double quotation marks may be used. If the management client command contains no space characters, the quotation marks are optional.

- **--try-reconnect=number**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--try-reconnect=#</td>
</tr>
<tr>
<td>Deprecated</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>12</td>
</tr>
<tr>
<td>Default Value</td>
<td>3</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

If the connection to the management server is broken, the node tries to reconnect to it every 5 seconds until it succeeds. By using this option, it is possible to limit the number of attempts to `number` before giving up and reporting an error instead.

This option is deprecated and subject to removal in a future release. Use `--connect-retries`, instead.

Additional information about using `ndb_mgm` can be found in Section 22.5.2, “Commands in the NDB Cluster Management Client”.

### 22.4.6 ndb_blob_tool — Check and Repair BLOB and TEXT columns of NDB Cluster Tables

This tool can be used to check for and remove orphaned BLOB column parts from NDB tables, as well as to generate a file listing any orphaned parts. It is sometimes useful in diagnosing and repairing corrupted or damaged NDB tables containing BLOB or TEXT columns.
The basic syntax for ndb_blob_tool is shown here:

```
ndb_blob_tool [options] table [column, ...]
```

Unless you use the `--help` option, you must specify an action to be performed by including one or more of the options `--check-orphans`, `--delete-orphans`, or `--dump-file`. These options cause ndb_blob_tool to check for orphaned BLOB parts, remove any orphaned BLOB parts, and generate a dump file listing orphaned BLOB parts, respectively, and are described in more detail later in this section.

You must also specify the name of a table when invoking ndb_blob_tool. In addition, you can optionally follow the table name with the (comma-separated) names of one or more BLOB or TEXT columns from that table. If no columns are listed, the tool works on all of the table's BLOB and TEXT columns. If you need to specify a database, use the `--database (-d)` option.

The `--verbose` option provides additional information in the output about the tool's progress.

The following table includes options that are specific to ndb_blob_tool. Additional descriptions follow the table. For options common to most NDB Cluster programs (including ndb_blob_tool), see Section 22.4.31, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

### Table 22.256 Command-line options for the ndb_blob_tool program

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--add-missing</code></td>
<td>Write dummy blob parts to take place of those which are missing</td>
<td>ADDED: NDB 8.0.20</td>
</tr>
<tr>
<td><code>--check-missing</code></td>
<td>Check for blobs having inline parts but missing one or more parts from parts table</td>
<td>ADDED: NDB 8.0.20</td>
</tr>
<tr>
<td><code>--check-orphans</code></td>
<td>Check for blob parts having no corresponding inline parts</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--database=db_name, -d</code></td>
<td>Database to find the table in</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--delete-orphans</code></td>
<td>Delete blob parts having no corresponding inline parts</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--dump-file=file</code></td>
<td>Write orphan keys to specified file</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--verbose, -v</code></td>
<td>Verbose output</td>
<td></td>
</tr>
</tbody>
</table>

### --add-missing

For each inline part in NDB Cluster tables which has no corresponding BLOB part, write a dummy BLOB part of the required length, consisting of spaces.

### --check-missing

3813
**ndb_blob_tool** — Check and Repair BLOB and TEXT columns of NDB Cluster Tables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td><code>--check-missing</code></td>
</tr>
<tr>
<td><strong>Introduced</strong></td>
<td>8.0.20-ndb-8.0.20</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Boolean</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Check for inline parts in NDB Cluster tables which have no corresponding BLOB parts.

- **--check-orphans**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td><code>--check-orphans</code></td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Boolean</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Check for BLOB parts in NDB Cluster tables which have no corresponding inline parts.

- **--database=db_name,** -$d$

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td><code>--database=db_name</code></td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>String</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>[none]</td>
</tr>
</tbody>
</table>

Specify the database to find the table in.

- **--delete-orphans**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td><code>--delete-orphans</code></td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Boolean</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Remove BLOB parts from NDB Cluster tables which have no corresponding inline parts.

- **--dump-file=file**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td><code>--dump-file=file</code></td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>File name</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>[none]</td>
</tr>
</tbody>
</table>

Writes a list of orphaned BLOB column parts to `file`. The information written to the file includes the table key and BLOB part number for each orphaned BLOB part.

- **--verbose**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td><code>--verbose</code></td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Boolean</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>FALSE</td>
</tr>
</tbody>
</table>
Example

First we create an NDB table in the test database, using the CREATE TABLE statement shown here:

```sql
USE test;
CREATE TABLE btest (
  c0 BIGINT UNSIGNED NOT NULL AUTO_INCREMENT PRIMARY KEY,
  c1 TEXT,
  c2 BLOB
) ENGINE=NDB;
```

Then we insert a few rows into this table, using a series of statements similar to this one:

```sql
INSERT INTO btest VALUES (NULL, 'x', REPEAT('x', 1000));
```

When run with --check-orphans against this table, ndb_blob_tool generates the following output:

```
shell> ndb_blob_tool --check-orphans --verbose --d test btest
connected
processing 2 blobs
processing blob #0 c1 NDB$BLOB_19_1
NDB$BLOB_19_1: nextResult: res=1
  total parts: 0
  orphan parts: 0
processing blob #1 c2 NDB$BLOB_19_2
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=1
  total parts: 10
  orphan parts: 0
disconnected
NDBT_ProgramExit: 0 - OK
```

The tool reports that there are no NDB BLOB column parts associated with column c1, even though c1 is a TEXT column. This is due to the fact that, in an NDB table, only the first 256 bytes of a BLOB or TEXT column value are stored inline, and only the excess, if any, is stored separately; thus, if there are no values using more than 256 bytes in a given column of one of these types, no BLOB column parts are created by NDB for this column. See Section 11.7, “Data Type Storage Requirements”, for more information.

### 22.4.7 ndb_config — Extract NDB Cluster Configuration Information

This tool extracts current configuration information for data nodes, SQL nodes, and API nodes from one of a number of sources: an NDB Cluster management node, or its config.ini or my.cnf file. By default, the management node is the source for the configuration data; to override the default, execute ndb_config with the --config-file or --mycnf option. It is also possible to use a data node as the source by specifying its node ID with --config_from_node=node_id.

ndb_config can also provide an offline dump of all configuration parameters which can be used, along with their default, maximum, and minimum values and other information. The dump can be produced in either text or XML format; for more information, see the discussion of the --configinfo and --xml options later in this section).

You can filter the results by section (DB, SYSTEM, or CONNECTIONS) using one of the options --nodes, --system, or --connections.
The following table includes options that are specific to `ndb_config`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndb_config`), see Section 22.4.31, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

**Table 22.257 Command-line options for the ndb_config program**

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--config-file=file_name</code></td>
<td>Set the path to config.ini file</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--config-from-node=#</code></td>
<td>Obtain configuration data from the node having this ID (must be a data node)</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--configinfo</code></td>
<td>Dumps information about all NDB configuration parameters in text format with default, maximum, and minimum values. Use with <code>--xml</code> to obtain XML output</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--connections</code></td>
<td>Print connections information ([tcp], [tcp default], [sci], [sci default], [shm], or [shm default] sections of cluster configuration file) only. Cannot be used with <code>--system</code> or <code>--nodes</code></td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--diff-default</code></td>
<td>Print only configuration parameters that have non-default values</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--fields=string, -f</code></td>
<td>Field separator</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--host=name</code></td>
<td>Specify host</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--mycnf</code></td>
<td>Read configuration data from my.cnf file</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--nodeid</code></td>
<td>Get configuration of node with this ID</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--nodes</code></td>
<td>Print node information ([ndbd] or [ndbd default] section of cluster configuration file) only. Cannot be used with <code>--system</code> or <code>--connections</code></td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>-c</code></td>
<td>Short form for <code>--ndb-connectstring</code></td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--query=string, -q</code></td>
<td>One or more query options (attributes)</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--query-all, -a</code></td>
<td>Dumps all parameters and values to a single comma-delimited string</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--rows=string, -r</code></td>
<td>Row separator</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
</tbody>
</table>
### ndb_config — Extract NDB Cluster Configuration Information

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--system</code></td>
<td>Print SYSTEM section information only (see ndb_config --configinfo output). Cannot be used with --nodes or --connections</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--type=name</code></td>
<td>Specify node type</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--configinfo --xml</code></td>
<td>Use --xml with --configinfo to obtain a dump of all NDB configuration parameters in XML format with default, maximum, and minimum values</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
</tbody>
</table>

- **--configinfo**

The **--configinfo** option causes `ndb_config` to dump a list of each NDB Cluster configuration parameter supported by the NDB Cluster distribution of which `ndb_config` is a part, including the following information:

- A brief description of each parameter's purpose, effects, and usage
- The section of the config.ini file where the parameter may be used
- The parameter's data type or unit of measurement
- Where applicable, the parameter's default, minimum, and maximum values
- NDB Cluster release version and build information

By default, this output is in text format. Part of this output is shown here:

```shell
shell> ndb_config --configinfo

****** SYSTEM ******
Name (String)
Name of system (NDB Cluster)
MANDATORY

PrimaryMGMNode (Non-negative Integer)
Node ID of Primary ndb_mgmd (MGM) node
Default: 0 (Min: 0, Max: 4294967039)

ConfigGenerationNumber (Non-negative Integer)
Configuration generation number
Default: 0 (Min: 0, Max: 4294967039)

****** DB ******
MaxNoOfSubscriptions (Non-negative Integer)
Max no of subscriptions (default 0 == MaxNoOfTables)
Default: 0 (Min: 0, Max: 4294967039)

MaxNoOfSubscribers (Non-negative Integer)
Max no of subscribers (default 0 == 2 * MaxNoOfTables)
Default: 0 (Min: 0, Max: 4294967039)
```

Use this option together with the **--xml** option to obtain output in XML format.

- **--config-file=path-to-file**
ndb_config — Extract NDB Cluster Configuration Information

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--config-file=file_name</code></td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td></td>
</tr>
</tbody>
</table>

Gives the path to the management server’s configuration file (config.ini). This may be a relative or absolute path. If the management node resides on a different host from the one on which ndb_config is invoked, then an absolute path must be used.

- **`--config_from_node=#`**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--config-from-node=#</code></td>
</tr>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>none</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>48</td>
</tr>
</tbody>
</table>

Obtain the cluster’s configuration data from the data node that has this ID.

If the node having this ID is not a data node, ndb_config fails with an error. (To obtain configuration data from the management node instead, simply omit this option.)

- **`--connections`**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--connections</code></td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Tells ndb_config to print CONNECTIONS information only—that is, information about parameters found in the [tcp], [tcp default], [shm], or [shm default] sections of the cluster configuration file (see Section 22.3.3.10, “NDB Cluster TCP/IP Connections”, and Section 22.3.3.12, “NDB Cluster Shared-Memory Connections”, for more information).

This option is mutually exclusive with --nodes and --system; only one of these 3 options can be used.

- **`--diff-default`**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--diff-default</code></td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Print only configuration parameters that have non-default values.

- **`--fields=delimiter,-f delimiter`**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--fields=string</code></td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>
### ndb_config — Extract NDB Cluster Configuration Information

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td></td>
</tr>
</tbody>
</table>

Specifies a `delimiter` string used to separate the fields in the result. The default is `,` (the comma character).

**Note**

If the delimiter contains spaces or escapes (such as `\n` for the linefeed character), then it must be quoted.

- **--host=hostname**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--host=name</code></td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td></td>
</tr>
</tbody>
</table>

Specifies the host name of the node for which configuration information is to be obtained.

**Note**

While the hostname `localhost` usually resolves to the IP address `127.0.0.1`, this may not necessarily be true for all operating platforms and configurations. This means that it is possible, when `localhost` is used in `config.ini`, for `ndb_config --host=localhost` to fail if `ndb_config` is run on a different host where `localhost` resolves to a different address (for example, on some versions of SUSE Linux, this is `127.0.0.2`). In general, for best results, you should use numeric IP addresses for all NDB Cluster configuration values relating to hosts, or verify that all NDB Cluster hosts handle `localhost` in the same fashion.

- **--mycnf**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--mycnf</code></td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Read configuration data from the `my.cnf` file.

- **--ndb-connectstring=connection_string, `-c connection_string`**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--ndb-connectstring=connectstring</code></td>
</tr>
<tr>
<td></td>
<td><code>--connect-string=connectstring</code></td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>localhost:1186</code></td>
</tr>
</tbody>
</table>

Specifies the connection string to use in connecting to the management server. The format for the connection string is the same as described in Section 22.3.3.3, “NDB Cluster Connection Strings”, and defaults to `localhost:1186`. 

3819
• **--nodeid=node_id**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--ndb-nodeid=#</td>
</tr>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
</tbody>
</table>

Specify the node ID of the node for which configuration information is to be obtained.

• **--nodes**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--nodes</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Tells *ndb_config* to print information relating only to parameters defined in an [ndbd] or [ndbd default] section of the cluster configuration file (see Section 22.3.3.6, "Defining NDB Cluster Data Nodes").

This option is mutually exclusive with **--connections** and **--system**; only one of these 3 options can be used.

• **--query=query-options,-q query-options**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--query=string</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td></td>
</tr>
</tbody>
</table>

This is a comma-delimited list of *query options*—that is, a list of one or more node attributes to be returned. These include *nodeid* (node ID), *type* (node type—that is, *ndbd*, *mysqld*, or *ndb_mgmd*), and any configuration parameters whose values are to be obtained.

For example, **--query=nodeid,type,datamemory,datadir** returns the node ID, node type, DataMemory, and DataDir for each node.

**Note**

If a given parameter is not applicable to a certain type of node, than an empty string is returned for the corresponding value. See the examples later in this section for more information.

• **--query-all,-a**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--query-all</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td></td>
</tr>
</tbody>
</table>

Returns a comma-delimited list of all query options (node attributes; note that this list is a single string.)
**--rows=separator, -r separator**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--rows=string</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td></td>
</tr>
</tbody>
</table>

Specifies a *separator* string used to separate the rows in the result. The default is a space character.

**Note**

If the *separator* contains spaces or escapes (such as \n for the linefeed character), then it must be quoted.

**--system**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--system</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Tells `ndb_config` to print **SYSTEM** information only. This consists of system variables that cannot be changed at run time; thus, there is no corresponding section of the cluster configuration file for them. They can be seen (prefixed with ****** SYSTEM ******) in the output of `ndb_config --configinfo`.

This option is mutually exclusive with `--nodes` and `--connections`; only one of these 3 options can be used.

**--type=node_type**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--type=name</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
<tr>
<td>Valid Values</td>
<td>ndbd</td>
</tr>
<tr>
<td></td>
<td>mysqld</td>
</tr>
<tr>
<td></td>
<td>ndb_mgmd</td>
</tr>
</tbody>
</table>

Filters results so that only configuration values applying to nodes of the specified *node_type* (ndbd, mysqld, or ndb_mgmd) are returned.

**--usage, --help, or -?**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--help</td>
</tr>
<tr>
<td></td>
<td>--usage</td>
</tr>
</tbody>
</table>

Causes `ndb_config` to print a list of available options, and then exit.
ndb_config — Extract NDB Cluster Configuration Information

- **--version, -V**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--version</td>
</tr>
</tbody>
</table>

Causes `ndb_config` to print a version information string, and then exit.

- **--configinfo --xml**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--configinfo --xml</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>false</td>
</tr>
</tbody>
</table>

Cause `ndb_config --configinfo` to provide output as XML by adding this option. A portion of such output is shown in this example:

```shell
shell> ndb_config --configinfo --xml
<configvariables protocolversion="1" ndbversionstring="5.7.29-ndb-7.5.17"
    ndbversion="460032" ndbversionmajor="7" ndbversionminor="5"
    ndbversionbuild="0">
    <section name="SYSTEM">
        <param name="Name" comment="Name of system (NDB Cluster)" type="string"
            mandatory="true"/>
        <param name="PrimaryMGMNode" comment="Node id of Primary ndb_mgmd (MGM) node"
            type="unsigned" default="0" min="0" max="4294967039"/>
        <param name="ConfigGenerationNumber" comment="Configuration generation number"
            type="unsigned" default="0" min="0" max="4294967039"/>
    </section>
    <section name="MYSQLD" primarykeys="NodeId">
        <param name="wan" comment="Use WAN TCP setting as default" type="bool"
            default="false"/>
        <param name="HostName" comment="Name of computer for this node"
            type="string" default=""/>
        <param name="Id" comment="NodeId" type="unsigned" mandatory="true"
            min="1" max="255" deprecated="true"/>
        <param name="NodeId" comment="Number identifying application node (mysqld(API))"
            type="unsigned" mandatory="true" min="1" max="255"/>
        <param name="ExecuteOnComputer" comment="HostName" type="string"
            deprecated="true"/>
        ...
    </section>
    ...
</configvariables>
```

**Note**

Normally, the XML output produced by `ndb_config --configinfo --xml` is formatted using one line per element; we have added extra whitespace in the previous example, as well as the next one, for reasons of legibility. This should not make any difference to applications using this output, since most XML processors either ignore nonessential whitespace as a matter of course, or can be instructed to do so.

The XML output also indicates when changing a given parameter requires that data nodes be restarted using the `--initial` option. This is shown by the presence of an `initial="true"` attribute in the corresponding `<param>` element. In addition, the restart type (`system` or `node`) is also shown; if a given parameter requires a system restart, this is indicated by the presence of
a `restart="system"` attribute in the corresponding `<param>` element. For example, changing the value set for the Diskless parameter requires a system initial restart, as shown here (with the `restart` and `initial` attributes highlighted for visibility):

```
[param name="Diskless" comment="Run wo/ disk" type="bool" default="false"
  restart="system" initial="true" />
```

Currently, no `initial` attribute is included in the XML output for `<param>` elements corresponding to parameters which do not require initial restarts; in other words, `initial="false"` is the default, and the value `false` should be assumed if the attribute is not present. Similarly, the default restart type is `node` (that is, an online or “rolling” restart of the cluster), but the `restart` attribute is included only if the restart type is `system` (meaning that all cluster nodes must be shut down at the same time, then restarted).

Deprecated parameters are indicated in the XML output by the `deprecated` attribute, as shown here:

```
[param name="NoOfDiskPagesToDiskAfterRestartACC" comment="DiskCheckpointSpeed"
  type="unsigned" default="20" min="1" max="4294967039"
  deprecated="true" />
```

In such cases, the `comment` refers to one or more parameters that supersede the deprecated parameter. Similarly to `initial`, the `deprecated` attribute is indicated only when the parameter is deprecated, with `deprecated="true"`, and does not appear at all for parameters which are not deprecated. (Bug #21127135)

Beginning with NDB 7.5.0, parameters that are required are indicated with `mandatory="true"`, as shown here:

```
[param name="NodeId"
  comment="Number identifying application node (mysqld(API))"
  type="unsigned" mandatory="true" min="1" max="255" />
```

In much the same way that the `initial` or `deprecated` attribute is displayed only for a parameter that requires an initial restart or that is deprecated, the `mandatory` attribute is included only if the given parameter is actually required.

**Important**

The `--xml` option can be used only with the `--configinfo` option. Using `--xml` without `--configinfo` fails with an error.

Unlike the options used with this program to obtain current configuration data, `--configinfo` and `--xml` use information obtained from the NDB Cluster sources when `ndb_config` was compiled. For this reason, no connection to a running NDB Cluster or access to a `config.ini` or `my.cnf` file is required for these two options.

Combining other `ndb_config` options (such as `--query` or `--type`) with `--configinfo` (with or without the `--xml` option is not supported. Currently, if you attempt to do so, the usual result is that all other options besides `--configinfo` or `--xml` are simply ignored. However, this behavior is not guaranteed and is subject to change at any time. In addition, since `ndb_config`, when used with the `--configinfo` option, does not access the NDB Cluster or read any files, trying to specify additional options such as `--ndb-connectstring` or `--config-file` with `--configinfo` serves no purpose.

**Examples**

1. To obtain the node ID and type of each node in the cluster:

```
shell> ./ndb_config --query=nodeid,type --fields=':\' --rows='\n'
1:ndbd
2:ndbd
3:ndbd
4:ndbd
```
5: ndb_mgmd
6: mysql
7: mysql
8: mysql
9: mysql

In this example, we used the --fields options to separate the ID and type of each node with a colon character (:), and the --rows options to place the values for each node on a new line in the output.

2. To produce a connection string that can be used by data, SQL, and API nodes to connect to the management server:

shell> ./ndb_config --config-file=/usr/local/mysql/cluster-data/config.ini \ --query=hostname,portnumber --fields= --rows=, --type=ndb_mgmd
198.51.100.179:1186

3. This invocation of ndb_config checks only data nodes (using the --type option), and shows the values for each node’s ID and host name, as well as the values set for its DataMemory and DataDir parameters:

shell> ./ndb_config --type=ndbd --query=nodeid,host,datamemory,datadir -f ' : ' -r '
' 1 : 198.51.100.193 : 83886080 : /usr/local/mysql/cluster-data
2 : 198.51.100.112 : 83886080 : /usr/local/mysql/cluster-data
3 : 198.51.100.176 : 83886080 : /usr/local/mysql/cluster-data
4 : 198.51.100.119 : 83886080 : /usr/local/mysql/cluster-data

In this example, we used the short options -f and -r for setting the field delimiter and row separator, respectively, as well as the short option -q to pass a list of parameters to be obtained.

4. To exclude results from any host except one in particular, use the --host option:

shell> ./ndb_config --host=198.51.100.176 -f : -r '
' -q id,type
3: ndbd
5: ndb_mgmd

In this example, we also used the short form -q to determine the attributes to be queried.

Similarly, you can limit results to a node with a specific ID using the --nodeid option.

22.4.8 ndb_delete_all — Delete All Rows from an NDB Table

ndb_delete_all deletes all rows from the given NDB table. In some cases, this can be much faster than DELETE or even TRUNCATE TABLE.

Usage

dadb_delete_all -c connection_string tbl_name -d db_name

This deletes all rows from the table named tbl_name in the database named db_name. It is exactly equivalent to executing TRUNCATE db_name.tbl_name in MySQL.

The following table includes options that are specific to ndb_delete_all. Additional descriptions follow the table. For options common to most NDB Cluster programs (including ndb_delete_all), see Section 22.4.31, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

Table 22.258 Command-line options for the ndb_delete_all program

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--database=dbname,</td>
<td>Name of the database in which the table is found</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
</tbody>
</table>
**ndb_desc** — Describe NDB Tables

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>-d</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--transactional, -t</td>
<td>Perform the delete in a single transaction (may run out of operations)</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>-t</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--tupscan</td>
<td>Run tup scan</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--diskscan</td>
<td>Run disk scan</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
</tbody>
</table>

- **--transactional, -t**

Use of this option causes the delete operation to be performed as a single transaction.

**Warning**

With very large tables, using this option may cause the number of operations available to the cluster to be exceeded.

Prior to NDB 8.0.18, this program printed `NDBT_ProgramExit - status` upon completion of its run, due to an unnecessary dependency on the NDBT testing library. This dependency has been removed, eliminating the extraneous output.

### 22.4.9 ndb_desc — Describe NDB Tables

**ndb_desc** provides a detailed description of one or more NDB tables.

**Usage**

```
ndb_desc -c connection_string tbl_name -d db_name [options]
ndb_desc -c connection_string index_name -d db_name -t tbl_name
```

Additional options that can be used with **ndb_desc** are listed later in this section.

**Sample Output**

MySQL table creation and population statements:

```sql
USE test;
CREATE TABLE fish (
    id INT(11) NOT NULL AUTO_INCREMENT,
    name VARCHAR(20) NOT NULL,
    length_mm INT(11) NOT NULL,
    weight_gm INT(11) NOT NULL,
    PRIMARY KEY pk (id),
    UNIQUE KEY uk (name)
) ENGINE=NDB;
```

```
INSERT INTO fish VALUES
    (NULL, 'guppy', 35, 2), (NULL, 'tuna', 2500, 150000),
    (NULL, 'shark', 3000, 110000), (NULL, 'manta ray', 1500, 50000),
    (NULL, 'grouper', 900, 125000), (NULL, 'puffer', 250, 2500);
```

Output from **ndb_desc**:

```
shell> ./ndb_desc -c localhost fish -d test -p
-- fish --
Version: 2
```
ndb_desc — Describe NDB Tables

NDBT_ProgramExit: 0 - OK

Information about multiple tables can be obtained in a single invocation of ndb_desc by using their names, separated by spaces. All of the tables must be in the same database.

You can obtain additional information about a specific index using the --table (short form: -t) option and supplying the name of the index as the first argument to ndb_desc, as shown here:

shell> ./ndb_desc uk -d test -t fish
-- uk --
Version: 2
Base table: fish
Number of attributes: 1
Logging: 0
Index type: OrderedIndex
Index status: Retrieved
-- Attributes --
  name Varchar(20;latin1_swedish_ci) NOT NULL AT=SHORT_VAR ST=MEMORY
-- IndexTable 10/uk --
Version: 2
Fragment type: FragUndefined
K Value: 6
Min load factor: 78
Max load factor: 80
Temporary table: yes
Number of attributes: 2
Number of primary keys: 1
Length of frm data: 0
Max Rows: 0
Row Checksum: 1
Row GCI: 1
SingleUserMode: 2
ForceVarPart: 0
FragmentCount: 2

FragmentCountType: ONE_PER_LDM_PER_NODE
ExtraRowGciBits: 0
ExtraRowAuthorBits: 0
TableStatus: Retrieved
Table options:
-- Attributes --
name Varchar(20;latin1_swedish_ci) NOT NULL AT=SHORT_VAR ST=MEMORY
NDB$TNODE Unsigned [64] PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY
-- Indexes --
PRIMARY KEY(NDB$TNODE) - UniqueHashIndex

NDBT_ProgramExit: 0 - OK

When an index is specified in this way, the --extra-partition-info and --extra-node-info options have no effect.

The Version column in the output contains the table's schema object version. For information about interpreting this value, see NDB Schema Object Versions.

Three of the table properties that can be set using NDB_TABLE comments embedded in CREATE TABLE and ALTER TABLE statements are also visible in ndb_desc output. The table's FRAGMENT_COUNT_TYPE is always shown in the FragmentCountType column. READ_ONLY and FULLY_REPLICATED, if set to 1, are shown in the Table options column. You can see this after executing the following ALTER TABLE statement in the mysql client:

```
mysql> ALTER TABLE fish COMMENT='NDB_TABLE=READ_ONLY=1,FULLY_REPLICATED=1';
1 row in set, 1 warning (0.00 sec)
```

The warning is issued because READ_ONLY=1 requires that the table's fragment count type is (or be set to) ONE_PER_LDM_PER_NODE_GROUP; NDB sets this automatically in such cases. You can check that the ALTER TABLE statement has the desired effect using SHOW CREATE TABLE:

```
mysql> SHOW CREATE TABLE fish\G
*************************** 1. row ***************************
Table: fish
Create Table: CREATE TABLE `fish` (  `id` int(11) NOT NULL AUTO_INCREMENT,  `name` varchar(20) NOT NULL,  `length_mm` int(11) NOT NULL,  `weight_gm` int(11) NOT NULL,  PRIMARY KEY (`id`),  UNIQUE KEY `uk` (`name`)) ENGINE=ndbcluster DEFAULT CHARSET=latin1
COMMENT='NDB_TABLE=READ_BACKUP=1,FULLY_REPLICATED=1'
1 row in set (0.01 sec)
```

Because FRAGMENT_COUNT_TYPE was not set explicitly, its value is not shown in the comment text printed by SHOW CREATE TABLE. ndb_desc, however, displays the updated value for this attribute. The Table options column shows the binary properties just enabled. You can see this in the output shown here (emphasized text):

```
shell> ./ndb_desc -- localhost fish --p
-- fish --
Version: 4
Fragment type: HashMapPartition
K Value: 6
Min load factor: 78
Max load factor: 80
Temporary table: no
Number of attributes: 4
```
For more information about these table properties, see Section 13.1.20.10, “Setting NDB_TABLE Options”.

The **Extent_space** and **Free extent_space** columns are applicable only to **NDB** tables having columns on disk; for tables having only in-memory columns, these columns always contain the value 0.

To illustrate their use, we modify the previous example. First, we must create the necessary Disk Data objects, as shown here:

```sql
CREATE LOGFILE GROUP lg_1
  ADD UNDOFILE 'undo_1.log'
  INITIAL_SIZE 16M
  UNDO_BUFFER_SIZE 2M
  ENGINE NDB;

ALTER LOGFILE GROUP lg_1
  ADD UNDOFILE 'undo_2.log'
  INITIAL_SIZE 12M
  ENGINE NDB;

CREATE TABLESPACE ts_1
  ADD DATAFILE 'data_1.dat'
  USE LOGFILE GROUP lg_1
  INITIAL_SIZE 32M
  ENGINE NDB;

ALTER TABLESPACE ts_1
  ADD DATAFILE 'data_2.dat'
  INITIAL_SIZE 48M
  ENGINE NDB;

(For more information on the statements just shown and the objects created by them, see Section 22.5.13.1, “NDB Cluster Disk Data Objects”, as well as Section 13.1.16, “CREATE LOGFILE GROUP Statement”, and Section 13.1.21, “CREATE TABLESPACE Statement”.)

Now we can create and populate a version of the **fish** table that stores 2 of its columns on disk (deleting the previous version of the table first, if it already exists):

```sql
CREATE TABLE fish (
When run against this version of the table, `ndb_desc` displays the following output:

```plaintext
shell> ./ndb_desc -c localhost fish -d test -p
-- fish --
Version: 1
Fragment type: HashMapPartition
K Value: 6
Min load factor: 78
Max load factor: 80
Temporary table: no
Number of attributes: 4
Number of primary keys: 1
Length of frm data: 346
Max Rows: 0
Row Checksum: 1
Row GCI: 1
SingleUserMode: 0
ForceVarPart: 1
PartitionCount: 2
FragmentCount: 2
FragmentCountType: ONE_PER_LDM_PER_NODE
ExtraRowGciBits: 0
ExtraRowAuthorBits: 0
TableStatus: Retrieved
Table options:
HashMap: DEFAULT-HASHMAP-3840-2
-- Attributes --
id Int PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY AUTO_INCR
name Varchar(20) latin1_swedish_ci NOT NULL AT=SHORT_VAR ST=MEMORY
length_mm Int NOT NULL AT=FIXED ST=DISK

0 2 2 32768 32768
1 4 4 32768 32768

NDBT_ProgramExit: 0 - OK
```

This means that 1048576 bytes are allocated from the tablespace for this table on each partition, of which 1044440 bytes remain free for additional storage. In other words, 1048576 - 1044440 = 4136 bytes per partition is currently being used to store the data from this table's disk-based columns. The number of bytes shown as `Free extent space` is available for storing on-disk column data from the `fish` table only; for this reason, it is not visible when selecting from the `INFORMATION_SCHEMA.FILES` table.

For fully replicated tables, `ndb_desc` shows only the nodes holding primary partition fragment replicas; nodes with copy fragment replicas (only) are ignored. Beginning with NDB 7.5.4, you can obtain such information, using the `mysql` client, from the `table_distribution_status`, `table_fragments`, `table_info`, and `table_replicas` tables in the `ndbinfo` database.
The following table includes options that are specific to `ndb_desc`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndb_desc`), see Section 22.4.31, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

Table 22.259 Command-line options for the `ndb_desc` program

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--auto-inc</code>, <code>-a</code></td>
<td>Show next value for AUTO_INCREMENT column if table has one</td>
<td>ADDED: NDB 8.0.21</td>
</tr>
<tr>
<td><code>--blob-info</code>, <code>-b</code></td>
<td>Include partition information for BLOB tables in output. Requires that the <code>-p</code> option also be used</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--context</code>, <code>-x</code></td>
<td>Show extra information for table such as database, schema, name, internal ID</td>
<td>ADDED: NDB 8.0.21</td>
</tr>
<tr>
<td><code>--database=dbname</code>, <code>-d</code></td>
<td>Name of database containing table</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--extra-node-info</code>, <code>-n</code></td>
<td>Include partition-to-data-node mappings in output. Requires that the <code>-p</code> option also be used</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--extra-partition-info</code>, <code>-p</code></td>
<td>Display information about partitions</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--retries=#</code>, <code>-r</code></td>
<td>Number of times to retry the connection (once per second)</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--table=tbl_name</code>, <code>-t</code></td>
<td>Specify the table in which to find an index. When this option is used, <code>-p</code> and <code>-n</code> have no effect and are ignored</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--unqualified</code>, <code>-u</code></td>
<td>Use unqualified table names</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
</tbody>
</table>

- `--auto-inc`, `-a`  
  Show the next value for a table's AUTO_INCREMENT column, if it has one.

- `--blob-info`, `-b`  
  Include information about subordinate BLOB and TEXT columns.  
  Use of this option also requires the use of the `--extra-partition-info` (`-p`) option.

- `--context`, `-x`  
  Show additional contextual information for the table such as schema, database name, table name, and the table's internal ID.

- `--database=dbname`, `-d`  
  Specify the database in which the table should be found.

- `--extra-node-info`, `-n`
Include information about the mappings between table partitions and the data nodes upon which
they reside. This information can be useful for verifying distribution awareness mechanisms and
supporting more efficient application access to the data stored in NDB Cluster.

Use of this option also requires the use of the --extra-partition-info (-p) option.

- **--extra-partition-info, -p**
  Print additional information about the table's partitions.

- **--retries=#, -r**
  Try to connect this many times before giving up. One connect attempt is made per second.

- **--table=tbl_name, -t**
  Specify the table in which to look for an index.

- **--unqualified, -u**
  Use unqualified table names.

In NDB 7.5.3 and later, table indexes listed in the output are ordered by ID. Previously, this was not
deterministic and could vary between platforms. (Bug #81763, Bug #23547742)

### 22.4.10 ndb_drop_index — Drop Index from an NDB Table

ndb_drop_index drops the specified index from an NDB table. It is recommended that you use this
utility only as an example for writing NDB API applications—see the Warning later in this section for
details.

#### Usage

```
ndb_drop_index -c connection_string table_name index -d db_name
```

The statement shown above drops the index named `index` from the `table` in the `database`.

The following table includes options that are specific to ndb_drop_index. Additional descriptions
follow the table. For options common to most NDB Cluster programs (including ndb_drop_index),
see Section 22.4.31, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster
Programs”.

#### Table 22.260 Command-line options for the ndb_drop_index program

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--database=dbname, -d</td>
<td>Name of the database in which the table is found</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
</tbody>
</table>

**Warning**

*Operations performed on Cluster table indexes using the NDB API are not visible to MySQL and make the table unusable by a MySQL server. If you use this program to drop an index, then try to access the table from an SQL node, an error results, as shown here:*  

```
shell> ./ndb_drop_index -c localhost dogs ix -d ctest1
Dropping index dogs/idx...OK
NDBT_ProgramExit: 0 - OK
shell> ./mysql -u jon -p ctest1
```

3831
Enter password: *******
You can turn off this feature to get a quicker startup with -A

Welcome to the MySQL monitor. Commands end with ; or \g.
Your MySQL connection id is 7 to server version: 5.7.29-ndb-7.5.17
Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

```sql
mysql> SHOW TABLES;
+------------------+
| Tables_in_ctest1 |
+------------------+
| a                |
| bt1              |
| bt2              |
| dogs             |
| employees        |
| fish             |
+------------------+
6 rows in set (0.00 sec)
```

```sql
mysql> SELECT * FROM dogs;
ERROR 1296 (HY000): Got error 4243 'Index not found' from NDBCLUSTER
```

In such a case, your only option for making the table available to MySQL again is to drop the table and re-create it. You can use either the SQL statement `DROP TABLE` or the `ndb_drop_table` utility (see Section 22.4.11, "ndb_drop_table — Drop an NDB Table") to drop the table.

### 22.4.11 ndb_drop_table — Drop an NDB Table

`ndb_drop_table` drops the specified NDB table. (If you try to use this on a table created with a storage engine other than NDB, the attempt fails with the error 723: No such table exists.) This operation is extremely fast; in some cases, it can be an order of magnitude faster than using a MySQL `DROP TABLE` statement on an NDB table.

#### Usage

```
ndb_drop_table -c connection_string tbl_name -d db_name
```

The following table includes options that are specific to `ndb_drop_table`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndb_drop_table`), see Section 22.4.31, "Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs".

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--database=dbname, -d</td>
<td>Name of the database in which the table is found</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
</tbody>
</table>

Prior to NDB 8.0.17, an NDB table dropped using this utility persisted in the MySQL data dictionary but could not be dropped using `DROP TABLE` in the `mysql` client. In NDB 8.0.17 and later, such “orphan” tables can be dropped using `DROP TABLE`. (Bug #29125206, Bug #93672)

### 22.4.12 ndb_error_reporter — NDB Error-Reporting Utility

`ndb_error_reporter` creates an archive from data node and management node log files that can be used to help diagnose bugs or other problems with a cluster. It is highly recommended that you make use of this utility when filing reports of bugs in NDB Cluster.

The following table includes command options specific to the NDB Cluster program `ndb_error_reporter`. Additional descriptions follow the table. For options common to most NDB
Cluster programs (including \texttt{ndb\_error\_reporter}), see Section \ref{common-ndb-cluster}, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

Table 22.262 Command-line options for the \texttt{ndb\_error\_reporter} program

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{--connection-timeout=timeout}</td>
<td>Number of seconds to wait when connecting to nodes before timing out</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>\texttt{--dry-scp}</td>
<td>Disable scp with remote hosts; used only for testing</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>\texttt{--fs}</td>
<td>Include file system data in error report; can use a large amount of disk space</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>\texttt{--skip-nodegroup=nodegroup_id}</td>
<td>Skip all nodes in the node group having this ID</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
</tbody>
</table>

Usage

\texttt{ndb\_error\_reporter \ path/to/config-file [username] [options]}

This utility is intended for use on a management node host, and requires the path to the management host configuration file (usually named \texttt{config.ini}). Optionally, you can supply the name of a user that is able to access the cluster's data nodes using SSH, to copy the data node log files. \texttt{ndb\_error\_reporter} then includes all of these files in archive that is created in the same directory in which it is run. The archive is named \texttt{ndb\_error\_report_YYYYMMDDhhmmss.tar.bz2}, where \texttt{YYYYMMDDhhmmss} is a datetime string.

\texttt{ndb\_error\_reporter} also accepts the options listed here:

- \texttt{--connection-timeout=timeout}

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>\texttt{--connection-timeout=timeout}</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
</tbody>
</table>

Wait this many seconds when trying to connect to nodes before timing out.

- \texttt{--dry-scp}

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>\texttt{--dry-scp}</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>TRUE</td>
</tr>
</tbody>
</table>

Run \texttt{ndb\_error\_reporter} without using scp from remote hosts. Used for testing only.

- \texttt{--fs}

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>\texttt{--fs}</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>
Copy the data node file systems to the management host and include them in the archive.

Because data node file systems can be extremely large, even after being compressed, we ask that you please do not send archives created using this option to Oracle unless you are specifically requested to do so.

- **--skip-nodegroup=nodegroup_id**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--connection-timeout=timeout</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
</tbody>
</table>

Skip all nodes belong to the node group having the supplied node group ID.

### 22.4.13 ndb_import — Import CSV Data Into NDB

`ndb_import` imports CSV-formatted data, such as that produced by `mysqldump --tab`, directly into NDB using the NDB API. `ndb_import` requires a connection to an NDB management server (`ndb_mgmd`) to function; it does not require a connection to a MySQL Server.

#### Usage

```
ndb_import db_name file_name options
```

`ndb_import` requires two arguments. `db_name` is the name of the database where the table into which to import the data is found; `file_name` is the name of the CSV file from which to read the data; this must include the path to this file if it is not in the current directory. The name of the file must match that of the table; the file’s extension, if any, is not taken into consideration. Options supported by `ndb_import` include those for specifying field separators, escapes, and line terminators, and are described later in this section. `ndb_import` must be able to connect to an NDB Cluster management server; for this reason, there must be an unused [api] slot in the cluster `config.ini` file.

To duplicate an existing table that uses a different storage engine, such as InnoDB, as an NDB table, use the `mysql` client to perform a `SELECT INTO OUTFILE` statement to export the existing table to a CSV file, then to execute a `CREATE TABLE LIKE` statement to create a new table having the same structure as the existing table, then perform `ALTER TABLE ... ENGINE=NDB` on the new table; after this, from the system shell, invoke `ndb_import` to load the data into the new NDB table. For example, an existing InnoDB table named `myinnodb_table` in a database named `myinnodb` can be exported into an NDB table named `myndb_table` in a database named `myndb` as shown here, assuming that you are already logged in as a MySQL user with the appropriate privileges:

1. In the `mysql` client:

   ```
   mysql> USE myinnodb;
   mysql> SELECT * INTO OUTFILE '/tmp/myndb_table.csv'
     > FIELDS TERMINATED BY ',' OPTIONALLY ENCLOSED BY '"' ESCAPED BY '\\'
     > LINES TERMINATED BY '\n'
     > FROM myinnodbtable;
   mysql> CREATE DATABASE myndb;
   mysql> USE myndb;
   mysql> CREATE TABLE myndb_table LIKE myinnodb.myinnodb_table;
   mysql> ALTER TABLE myndb_table ENGINE=NDB;
   mysql> EXIT;
   ```
Once the target database and table have been created, a running `mysqld` is no longer required. You can stop it using `mysqladmin shutdown` or another method before proceeding, if you wish.

2. In the system shell:

```bash
# if you are not already in the MySQL bin directory:
shell> cd path-to-mysql-bin-dir
shell> ndb_import myndb /tmp/myndb_table.csv --fields-optionally-enclosed-by='"' \ 
    --fields-terminated-by='","' --fields-escaped-by='\\'
```

The output should resemble what is shown here:

```bash
job-1 import myndb.myndb_table from /tmp/myndb_table.csv
job-1 [running] import myndb.myndb_table from /tmp/myndb_table.csv
job-1 [success] import myndb.myndb_table from /tmp/myndb_table.csv
job-1 imported 19984 rows in 0h0m9s at 2277 rows/s
jobs summary: defined: 1 run: 1 with success: 1 with failure: 0
shell>
```

The following table includes options that are specific to `ndb_import`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndb_import`), see Section 22.4.31, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

**Table 22.263 Command-line options for the ndb_import program**

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--abort-on-error</code></td>
<td>Dump core on any fatal error; used for debugging</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--ai-increment=#</code></td>
<td>For table with hidden PK, specify autoincrement increment. See <code>mysqld</code></td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--ai-offset=#</code></td>
<td>For table with hidden PK, specify autoincrement offset. See <code>mysqld</code></td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--ai-prefetch-sz=#</code></td>
<td>For table with hidden PK, specify number of autoincrement values that are prefetched. See <code>mysqld</code></td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--connections=#</code></td>
<td>Number of cluster connections to create</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--continue</code></td>
<td>When job fails, continue to next job</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--db-workers=#</code></td>
<td>Number of threads, per data node, executing database operations</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--errins-type=name</code></td>
<td>Error insert type, for testing purposes; use &quot;list&quot; to obtain all possible values</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--errins-delay=#</code></td>
<td>Error insert delay in milliseconds; random variation is added</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--fields-enclosed-by=char</code></td>
<td>Same as FIELDS ENCLOSED BY option for LOAD DATA statements. For CSV input this is same as using --fields-optionally-enclosed-by</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
</tbody>
</table>
## ndb_import — Import CSV Data Into NDB

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--fields-escaped-by=name</td>
<td>Same as FIELDS ESCAPED BY option for LOAD DATA statements</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--fields-optionally-enclosed-by=char</td>
<td>Same as FIELDS OPTIONALLY ENCLOSED BY option for LOAD DATA statements</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--fields-terminated-by=char</td>
<td>Same as FIELDS TERMINATED BY option for LOAD DATA statements</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--idlesleep=#</td>
<td>Number of milliseconds to sleep waiting for more to do</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--idlepin=#</td>
<td>Number of times to re-try before idlesleep</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--ignore-lines=#</td>
<td>Ignore first # lines in input file. Used to skip a non-data header</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--input-type=name</td>
<td>Input type: random or csv</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--input-workers=#</td>
<td>Number of threads processing input. Must be 2 or more if --input-type is csv</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--keep-state</td>
<td>State files (except non-empty *.rej files) are normally removed on job completion. Using this option causes all state files to be preserved instead</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--lines-terminated-by=name</td>
<td>Same as LINES TERMINATED BY option for LOAD DATA statements</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--max-rows=#</td>
<td>Import only this number of input data rows; default is 0, which imports all rows</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--monitor=#</td>
<td>Periodically print status of running job if something has changed (status, rejected rows, temporary errors). Value 0 disables. Value 1 prints any change seen. Higher values reduce status printing exponentially up to some pre-defined limit</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--no-asynch</td>
<td>Run database operations as batches, in single transactions</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--no-hint</td>
<td>Do not use distribution key hint to select data node (TC)</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--opbatch=#</td>
<td>A db execution batch is a set of transactions and operations sent to NDB kernel. This option limits NDB operations (including blob operations) in a db execution batch. Therefore it also limits</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
</tbody>
</table>
### ndb_import — Import CSV Data Into NDB

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--opbytes=#</td>
<td>Limit bytes in execution batch (default 0 = no limit)</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--output-type=name</td>
<td>Output type: ndb is default, null used for testing</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--output-workers=#</td>
<td>Number of threads processing output or relaying database operations</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--pagesize=#</td>
<td>Align I/O buffers to given size</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--pagecnt=#</td>
<td>Size of I/O buffers as multiple of page size. CSV input worker allocates a double-sized buffer</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--polltimeout=#</td>
<td>Timeout per poll for completed asynchronous transactions; polling continues until all polls are completed, or error occurs</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--rejects=#</td>
<td>Limit number of rejected rows (rows with permanent error) in data load. Default is 0 which means that any rejected row causes a fatal error. The row exceeding the limit is also added to *.rej</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--resume</td>
<td>If job aborted (temporary error, user interrupt), resume with rows not yet processed</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--rowbatch=#</td>
<td>Limit rows in row queues (default 0 = no limit); must be 1 or more if --input-type is random</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--rowbytes=#</td>
<td>Limit bytes in row queues (0 = no limit)</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--state-dir=name</td>
<td>Where to write state files; current directory is default</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--stats</td>
<td>Save performance related options and internal statistics in *.sto and *.stt files. These files are kept on successful completion even if --keep-state is not used</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--tempdelay=#</td>
<td>Number of milliseconds to sleep between temporary errors</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--temperrors=#</td>
<td>Number of times a transaction can fail due to a temporary error, per execution batch; 0 means any temporary error is fatal. Such errors do not cause any rows to be written to .rej file</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--verbose,</td>
<td>Enable verbose output</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
</tbody>
</table>
### ndb_import — Import CSV Data Into NDB

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>-v</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

- **--abort-on-error**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--abort-on-error</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Dump core on any fatal error; used for debugging only.

- **--ai-increment=#**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--ai-increment=#</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

For a table with a hidden primary key, specify the autoincrement increment, like the `auto_increment_increment` system variable does in the MySQL Server.

- **--ai-offset=#**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--ai-offset=#</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

For a table with hidden primary key, specify the autoincrement offset. Similar to the `auto_increment_offset` system variable.

- **--ai-prefetch-sz=#**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--ai-prefetch-sz=#</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1024</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

For a table with a hidden primary key, specify the number of autoincrement values that are prefetched. Behaves like the `ndb_autoincrement_prefetch_sz` system variable does in the MySQL Server.
### --connections=#

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--connections=#</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

Number of cluster connections to create.

### --continue

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--continue</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

When a job fails, continue to the next job.

### --db-workers=#

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--db-workers=#</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>4</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

Number of threads, per data node, executing database operations.

### --errins-type=name

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--errins-type=name</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
<tr>
<td>Valid Values</td>
<td>stopjob</td>
</tr>
<tr>
<td></td>
<td>stopall</td>
</tr>
<tr>
<td></td>
<td>sighup</td>
</tr>
<tr>
<td></td>
<td>sigint</td>
</tr>
<tr>
<td></td>
<td>list</td>
</tr>
</tbody>
</table>

Error insert type; use list as the name value to obtain all possible values. This option is used for testing purposes only.
• **--errins-delay=#**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--errins-delay=#</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1000</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

Error insert delay in milliseconds; random variation is added. This option is used for testing purposes only.

• **--fields-enclosed-by=char**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--fields-enclosed-by=char</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

This works in the same way as the `FIELDS ENCLOSED BY` option does for the `LOAD DATA` statement, specifying a character to be interpreted as quoting field values. For CSV input, this is the same as `--fields-optionally-enclosed-by`.

• **--fields-escaped-by=name**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--fields-escaped-by=name</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>\</td>
</tr>
</tbody>
</table>

Specify an escape character in the same way as the `FIELDS ESCAPED BY` option does for the SQL `LOAD DATA` statement.

• **--fields-optionally-enclosed-by=char**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--fields-optionally-enclosed-by=char</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

This works in the same way as the `FIELDS OPTIONALLY ENCLOSED BY` option does for the `LOAD DATA` statement, specifying a character to be interpreted as optionally quoting field values. For CSV input, this is the same as `--fields-enclosed-by`.

• **--fields-terminated-by=char**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--fields-terminated-by=char</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>
This works in the same way as the `FIELDS TERMINATED BY` option does for the `LOAD DATA` statement, specifying a character to be interpreted as the field separator.

- **--idlesleep=#**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
<th>Command-Line Format</th>
<th>Type</th>
<th>Default Value</th>
<th>Minimum Value</th>
<th>Maximum Value</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>--idlesleep=#</td>
<td>Integer</td>
<td>1</td>
<td>1</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

Number of milliseconds to sleep waiting for more work to perform.

- **--idlespin=#**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
<th>Command-Line Format</th>
<th>Type</th>
<th>Default Value</th>
<th>Minimum Value</th>
<th>Maximum Value</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>--idlespin=#</td>
<td>Integer</td>
<td>0</td>
<td>0</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

Number of times to retry before sleeping.

- **--ignore-lines=#**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
<th>Command-Line Format</th>
<th>Type</th>
<th>Default Value</th>
<th>Minimum Value</th>
<th>Maximum Value</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>--ignore-lines=#</td>
<td>Integer</td>
<td>0</td>
<td>0</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

Cause `ndb_import` to ignore the first `#` lines of the input file. This can be employed to skip a file header that does not contain any data.

- **--input-type=name**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
<th>Command-Line Format</th>
<th>Type</th>
<th>Default Value</th>
<th>Valid Values</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>--input-type=name</td>
<td>Enumeration</td>
<td>csv</td>
<td>random, csv</td>
</tr>
</tbody>
</table>

Set the type of input type. The default is `csv`; `random` is intended for testing purposes only.
**--input-workers=#**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--input-workers=#</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>4</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

Set the number of threads processing input.

**--keep-state**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--keep-state</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>false</td>
</tr>
</tbody>
</table>

By default, ndb_import removes all state files (except non-empty *.rej files) when it completes a job. Specify this option (nor argument is required) to force the program to retain all state files instead.

**--lines-terminated-by=name**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--lines-terminated-by=name</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>\n</td>
</tr>
</tbody>
</table>

This works in the same way as the LINES TERMINATED BY option does for the LOAD DATA statement, specifying a character to be interpreted as end-of-line.

**--log-level=#**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--log-level=#</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>2</td>
</tr>
</tbody>
</table>

Performs internal logging at the given level. This option is intended primarily for internal and development use.

In debug builds of NDB only, the logging level can be set using this option to a maximum of 4.

**--max-rows=#**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--max-rows=#</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
</tbody>
</table>
Import only this number of input data rows; the default is 0, which imports all rows.

- **--monitor=#**

Periodically print the status of a running job if something has changed (status, rejected rows, temporary errors). Set to 0 to disable this reporting. Setting to 1 prints any change that is seen. Higher values reduce the frequency of this status reporting.

- **--no-asynch**

Run database operations as batches, in single transactions.

- **--no-hint**

Do not use distribution key hinting to select a data node.

- **--opbatch=#**

Set a limit on the number of operations (including blob operations), and thus the number of asynchronous transactions, per execution batch.
• **--opbytes=#**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--opbytes=#</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

Set a limit on the number of bytes per execution batch. Use 0 for no limit.

• **--output-type=name**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--output-type=name</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>ndb</td>
</tr>
<tr>
<td>Valid Values</td>
<td>null</td>
</tr>
</tbody>
</table>

Set the output type. *ndb* is the default. *null* is used only for testing.

• **--output-workers=#**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--output-workers=#</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>2</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

Set the number of threads processing output or relaying database operations.

• **--pagesize=#**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--pagesize=#</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>4096</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

Align I/O buffers to the given size.

• **--pagecnt=#**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--pagecnt=#</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>64</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
</tbody>
</table>
Set the size of I/O buffers as multiple of page size. The CSV input worker allocates buffer that is doubled in size.

- **--polltimeout=#**

Set a timeout per poll for completed asynchronous transactions; polling continues until all polls are completed, or until an error occurs.

- **--rejects=#**

Limit the number of rejected rows (rows with permanent errors) in the data load. The default is 0, which means that any rejected row causes a fatal error. Any rows causing the limit to be exceeded are added to the .rej file.

The limit imposed by this option is effective for the duration of the current run. A run restarted using **--resume** is considered a "new" run for this purpose.

- **--resume**

If a job is aborted (due to a temporary db error or when interrupted by the user), resume with any rows not yet processed.

- **--rowbatch=#**
### ndb_import — Import CSV Data Into NDB

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

Set a limit on the number of rows per row queue. Use 0 for no limit.

- **--rowbytes=#**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--rowbytes=#</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>262144</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

Set a limit on the number of bytes per row queue. Use 0 for no limit.

- **--stats**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--stats</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>false</td>
</tr>
</tbody>
</table>

Save information about options related to performance and other internal statistics in files named 
*.sto and *.stt. These files are always kept on successful completion (even if **--keep-state** is not also specified).

- **--state-dir=name**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--state-dir=name</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>.</td>
</tr>
</tbody>
</table>

Where to write the state files (*tbl_name.map, tbl_name.rej, tbl_name.res, and tbl_name.stt*) produced by a run of the program; the default is the current directory.

- **--tempdelay=#**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--tempdelay=#</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>10</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

Number of milliseconds to sleep between temporary errors.

- **--temperrors=#**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--temperrors=#</td>
</tr>
</tbody>
</table>
### ndb_index_stat — NDB Index Statistics Utility

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

Number of times a transaction can fail due to a temporary error, per execution batch. The default is 0, which means that any temporary error is fatal. Temporary errors do not cause any rows to be added to the `.rej` file.

- `--verbose`, `-v`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--verbose</code></td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>false</td>
</tr>
</tbody>
</table>

Enable verbose output.

As with `LOAD DATA`, options for field and line formatting much match those used to create the CSV file, whether this was done using `SELECT INTO ... OUTFILE`, or by some other means. There is no equivalent to the `LOAD DATA` statement `STARTING WITH` option.

`ndb_import` was added in NDB 7.6.2.

**22.4.14 ndb_index_stat — NDB Index Statistics Utility**

`ndb_index_stat` provides per-fragment statistical information about indexes on NDB tables. This includes cache version and age, number of index entries per partition, and memory consumption by indexes.

**Usage**

To obtain basic index statistics about a given NDB table, invoke `ndb_index_stat` as shown here, with the name of the table as the first argument and the name of the database containing this table specified immediately following it, using the `--database (-d)` option:

```bash
ndb_index_stat table -d database
```

In this example, we use `ndb_index_stat` to obtain such information about an NDB table named `mytable` in the `test` database:

```
shell> ndb_index_stat -d test mytable
table:City index:PRIMARY fragCount:2
query cache: valid:1 sampleCount:1994 totalBytes:27916
times in ms: save: 7.133 sort: 1.974 sort per sample: 0.000
NDBT_ProgramExit: 0 - OK
```

`sampleVersion` is the version number of the cache from which the statistics data is taken. Running `ndb_index_stat` with the `--update` option causes `sampleVersion` to be incremented.

`loadTime` shows when the cache was last updated. This is expressed as seconds since the Unix Epoch.

`sampleCount` is the number of index entries found per partition. You can estimate the total number of entries by multiplying this by the number of fragments (shown as `fragCount`).

3847
sampleCount can be compared with the cardinality of SHOW INDEX or INFORMATION_SCHEMA.STATISTICS, although the latter two provide a view of the table as a whole, while ndb_index_stat provides a per-fragment average.

keyBytes is the number of bytes used by the index. In this example, the primary key is an integer, which requires four bytes for each index, so keyBytes can be calculated in this case as shown here:

\[
\text{keyBytes} = \text{sampleCount} \times (4 \text{ bytes per index}) = 1994 \times 4 = 7976
\]

This information can also be obtained using the corresponding column definitions from INFORMATION_SCHEMA.COLUMNS (this requires a MySQL Server and a MySQL client application).

totalBytes is the total memory consumed by all indexes on the table, in bytes.

Timings shown in the preceding examples are specific to each invocation of ndb_index_stat.

The --verbose option provides some additional output, as shown here:

```
shell> ndb_index_stat -d test mytable --verbose
random seed 1337010518
connected
loop 1 of 1
table:mytable index:PRIMARY fragCount:4
sampleVersion:2 loadTime:1336751773 sampleCount:0 keyBytes:0
read stats
query cache created
query cache: valid:1 sampleCount:0 totalBytes:0
times in ms: save: 20.766 sort: 0.001
disconnected
NDBT_ProgramExit: 0 - OK
shell>
```

If the only output from the program is NDBT_ProgramExit: 0 - OK, this may indicate that no statistics yet exist. To force them to be created (or updated if they already exist), invoke ndb_index_stat with the --update option, or execute ANALYZE TABLE on the table in the mysql client.

**Options**

The following table includes options that are specific to the NDB Cluster ndb_index_stat utility. Additional descriptions are listed following the table. For options common to most NDB Cluster programs (including ndb_index_stat), see Section 22.4.31, "Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs".

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>

</tbody>
</table>

**ndb_index_stat statistics options.** The following options are used to generate index statistics. They work with a given table and database. They cannot be mixed with system options (see ndb_index_stat system options).

- **--database=name, -d name**
  
<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--database=name</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
<tr>
<td>Minimum Value</td>
<td></td>
</tr>
<tr>
<td>Maximum Value</td>
<td></td>
</tr>
</tbody>
</table>

  The name of the database that contains the table being queried.

- **--delete**
  
<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--delete</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>false</td>
</tr>
</tbody>
</table>
Delete the index statistics for the given table, stopping any auto-update that was previously configured.

- **--update**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Minimum Value</td>
<td></td>
</tr>
<tr>
<td>Maximum Value</td>
<td></td>
</tr>
</tbody>
</table>

Update the index statistics for the given table, and restart any auto-update that was previously configured.

- **--dump**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Minimum Value</td>
<td></td>
</tr>
<tr>
<td>Maximum Value</td>
<td></td>
</tr>
</tbody>
</table>

Dump the contents of the query cache.

- **--query=#**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>MAX_INT</td>
</tr>
</tbody>
</table>

Perform random range queries on first key attribute (must be int unsigned).

**ndb_index_stat system options.** The following options are used to generate and update the statistics tables in the NDB kernel. None of these options can be mixed with statistics options (see [ndb_index_stat statistics options](#)).

- **--sys-drop**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Minimum Value</td>
<td></td>
</tr>
<tr>
<td>Maximum Value</td>
<td></td>
</tr>
</tbody>
</table>
ndb_index_stat — NDB Index Statistics Utility

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Minimum Value</td>
<td></td>
</tr>
<tr>
<td>Maximum Value</td>
<td></td>
</tr>
</tbody>
</table>

Drop all statistics tables and events in the NDB kernel. *This causes all statistics to be lost.*

• *--sys-create*

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--sys-create</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>false</td>
</tr>
<tr>
<td>Minimum Value</td>
<td></td>
</tr>
<tr>
<td>Maximum Value</td>
<td></td>
</tr>
</tbody>
</table>

Create all statistics tables and events in the NDB kernel. This works only if none of them exist previously.

• *sys-create-if-not-exist*

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--sys-create-if-not-exist</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>false</td>
</tr>
<tr>
<td>Minimum Value</td>
<td></td>
</tr>
<tr>
<td>Maximum Value</td>
<td></td>
</tr>
</tbody>
</table>

Create any NDB system statistics tables or events (or both) that do not already exist when the program is invoked.

• *--sys-create-if-not-valid*

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--sys-create-if-not-valid</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>false</td>
</tr>
<tr>
<td>Minimum Value</td>
<td></td>
</tr>
<tr>
<td>Maximum Value</td>
<td></td>
</tr>
</tbody>
</table>

Create any NDB system statistics tables or events that do not already exist, after dropping any that are invalid.

• *--sys-check*

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--sys-check</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>false</td>
</tr>
<tr>
<td>Minimum Value</td>
<td></td>
</tr>
</tbody>
</table>
Verify that all required system statistics tables and events exist in the NDB kernel.

- **--sys-skip-tables**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--sys-skip-tables</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>false</td>
</tr>
<tr>
<td>Minimum Value</td>
<td></td>
</tr>
<tr>
<td>Maximum Value</td>
<td></td>
</tr>
</tbody>
</table>

Do not apply any **--sys-* options to any statistics tables.

- **--sys-skip-events**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--sys-skip-events</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>false</td>
</tr>
<tr>
<td>Minimum Value</td>
<td></td>
</tr>
<tr>
<td>Maximum Value</td>
<td></td>
</tr>
</tbody>
</table>

Do not apply any **--sys-* options to any events.

- **--verbose**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--verbose</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>false</td>
</tr>
<tr>
<td>Minimum Value</td>
<td></td>
</tr>
<tr>
<td>Maximum Value</td>
<td></td>
</tr>
</tbody>
</table>

Turn on verbose output.

- **--loops=#**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--loops=#</td>
</tr>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>MAX_INT</td>
</tr>
</tbody>
</table>

Repeat commands this number of times (for use in testing).
ndb_move_data copies data from one NDB table to another.

Usage

The program is invoked with the names of the source and target tables; either or both of these may be qualified optionally with the database name. Both tables must use the NDB storage engine.

```
ndb_move_data options source target
```

The following table includes options that are specific to ndb_move_data. Additional descriptions follow the table. For options common to most NDB Cluster programs (including ndb_move_data), see Section 22.4.31, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

Table 22.265 Command-line options for the ndb_move_data program

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--abort-on-error</td>
<td>Dump core on permanent error (debug option)</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--character-sets-dir=name</td>
<td>Directory where character sets are</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--database=dbname, -d</td>
<td>Name of the database in which the table is found</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--drop-source</td>
<td>Drop source table after all rows have been moved</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--error-insert</td>
<td>Insert random temporary errors (testing option)</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--exclude-missing-columns</td>
<td>Ignore extra columns in source or target table</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--lossy-conversions, -l</td>
<td>Allow attribute data to be truncated when converted to a smaller type</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--promote-attributes, -A</td>
<td>Allow attribute data to be converted to a larger type</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--staging-tries=x[,y[,z]]</td>
<td>Specify tries on temporary errors. Format is x,y,z where x=max tries (0=no limit), y=min delay (ms), z=max delay (ms)</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--verbose</td>
<td>Enable verbose messages</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
</tbody>
</table>

- **--abort-on-error**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--abort-on-error</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

  Dump core on permanent error (debug option).

- **--character-sets-dir=name**
<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--character-sets-dir=\textit{name}</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Directory where character sets are.

- **--database=\textit{dbname}, -d**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--database=\textit{dbname}</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>TEST_DB</td>
</tr>
</tbody>
</table>

Name of the database in which the table is found.

- **--drop-source**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--drop-source</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Drop source table after all rows have been moved.

- **--error-insert**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--error-insert</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Insert random temporary errors (testing option).

- **--exclude-missing-columns**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--exclude-missing-columns</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Ignore extra columns in source or target table.

- **--lossy-conversions, -l**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--lossy-conversions</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Allow attribute data to be truncated when converted to a smaller type.
• **--promote-attributes, -A**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--promote-attributes</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Allow attribute data to be converted to a larger type.

• **--staging-tries=x[,y[,z]]**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--staging-tries=x[,y[,z]]</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>0,1000,60000</td>
</tr>
</tbody>
</table>

Specify tries on temporary errors. Format is x,y,z] where x=max tries (0=no limit), y=min delay (ms), z=max delay (ms).

• **--verbose**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--verbose</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Enable verbose messages.

### 22.4.16 ndb_perror — Obtain NDB Error Message Information

`ndb_perror` shows information about an NDB error, given its error code. This includes the error message, the type of error, and whether the error is permanent or temporary. Added to the MySQL NDB Cluster distribution in NDB 7.6.4, it is intended as a drop-in replacement for `perror --ndb`.

**Usage**

```
ndb_perror [options] error_code
```

`ndb_perror` does not need to access a running NDB Cluster, or any nodes (including SQL nodes). To view information about a given NDB error, invoke the program, using the error code as an argument, like this:

```
shell> ndb_perror 323
NDB error code 323: Invalid nodegroup id, nodegroup already existing: Permanent error: Application error
```

To display only the error message, invoke `ndb_perror` with the `--silent` option (short form `-s`), as shown here:

```
shell> ndb_perror --s 323
Invalid nodegroup id, nodegroup already existing: Permanent error: Application error
```

Like `perror`, `ndb_perror` accepts multiple error codes:

```
shell> ndb_perror 321 1001
NDB error code 321: Invalid nodegroup id: Permanent error: Application error
NDB error code 1001: Illegal connect string
```

Additional program options for `ndb_perror` are described later in this section.
ndb_perror replaces perror --ndb, which is deprecated as of NDB 7.6.4 and subject to removal in a future release of MySQL NDB Cluster. To make substitution easier in scripts and other applications that might depend on perror for obtaining NDB error information, ndb_perror supports its own “dummy” --ndb option, which does nothing.

The following table includes all options that are specific to the NDB Cluster program ndb_perror. Additional descriptions follow the table.

Table 22.266 Command-line options for the ndb_perror program

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--help, -?</td>
<td>Display help text</td>
<td></td>
</tr>
<tr>
<td>--ndb</td>
<td>For compatibility with applications depending on old versions of perror; does nothing</td>
<td></td>
</tr>
<tr>
<td>--silent, -s</td>
<td>Show error message only</td>
<td></td>
</tr>
<tr>
<td>--version, -v</td>
<td>Print program version information and exit</td>
<td></td>
</tr>
<tr>
<td>--verbose, -v</td>
<td>Verbose output; disable with --silent</td>
<td></td>
</tr>
</tbody>
</table>

Additional Options

- **--help, --?**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--help</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>TRUE</td>
</tr>
</tbody>
</table>

Display program help text and exit.

- **--ndb**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--ndb</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>TRUE</td>
</tr>
</tbody>
</table>

For compatibility with applications depending on old versions of perror that use that program's --ndb option. The option when used with ndb_perror does nothing, and is ignored by it.

- **--silent, -s**

<table>
<thead>
<tr>
<th>Property</th>

Verbose output; disable with **--silent**.

22.4.17 ndb_print_backup_file — Print NDB Backup File Contents

ndb_print_backup_file obtains diagnostic information from a cluster backup file.

**Usage**

```
ndb_print_backup_file file_name
```

*file_name* is the name of a cluster backup file. This can be any of the files (.Data, .ctl, or .log file) found in a cluster backup directory. These files are found in the data node's backup directory under the subdirectory `BACKUP-#`, where # is the sequence number for the backup. For more information about cluster backup files and their contents, see Section 22.5.3.1, “NDB Cluster Backup Concepts”.

Like *ndb_print_schema_file* and *ndb_print_sys_file* (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a management server) *ndb_print_backup_file* must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

In NDB 8.0.17 and later, this program can also be used to read undo log files.

**Additional Options**

None.

22.4.18 ndb_print_file — Print NDB Disk Data File Contents

ndb_print_file obtains information from an NDB Cluster Disk Data file.

**Usage**

```
ndb_print_file [-v] [-q] file_name
```

*file_name* is the name of an NDB Cluster Disk Data file. Multiple filenames are accepted, separated by spaces.

Like *ndb_print_schema_file* and *ndb_print_sys_file* (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a management server) *ndb_print_file* must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

In NDB 8.0.17 and later, this program can also be used to read undo log files.
server) `ndb_print_file` must be run on an NDB Cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

Additional Options

`ndb_print_file` supports the following options:

• `-v`: Make output verbose.
• `-q`: Suppress output (quiet mode).
• `--help`, `-h`, `-?`: Print help message.

For more information, see Section 22.5.13, “NDB Cluster Disk Data Tables”.

22.4.19 `ndb_print_frag_file` — Print NDB Fragment List File Contents

`ndb_print_frag_file` obtains information from a cluster fragment list file. It is intended for use in helping to diagnose issues with data node restarts.

Usage

```
ndb_print_frag_file file_name
```

`file_name` is the name of a cluster fragment list file, which matches the pattern `SX.FragList`, where `X` is a digit in the range 2-9 inclusive, and are found in the data node file system of the data node having the node ID `nodeid`, in directories named `ndb_nodeid_fs/DN/DBDIH/`, where `N` is 1 or 2. Each fragment file contains records of the fragments belonging to each NDB table. For more information about cluster fragment files, see NDB Cluster Data Node File System Directory.

Like `ndb_print_backup_file`, `ndb_print_sys_file`, and `ndb_print_schema_file` (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a management server), `ndb_print_frag_file` must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

Additional Options

None.

Sample Output

```
shell> ndb_print_frag_file /usr/local/mysqld/data/ndb_3_fs/D1/DBDIH/S2.FragList
Filename: /usr/local/mysqld/data/ndb_3_fs/D1/DBDIH/S2.FragList with size 8192
noOfPages = 1 noOfWords = 182

```

3858
22.4.20 **ndb_print_schema_file** — Print NDB Schema File Contents

`ndb_print_schema_file` obtains diagnostic information from a cluster schema file.

**Usage**

```
ndb_print_schema_file  file_name
```

`file_name` is the name of a cluster schema file. For more information about cluster schema files, see *NDB Cluster Data Node File System Directory*.

Like `ndb_print_backup_file` and `ndb_print_sys_file` (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a management server) `ndb_print_schema_file` must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

**Additional Options**

None.

22.4.21 **ndb_print_sys_file** — Print NDB System File Contents

`ndb_print_sys_file` obtains diagnostic information from an NDB Cluster system file.

**Usage**

```
ndb_print_sys_file  file_name
```

`file_name` is the name of a cluster system file (sysfile). Cluster system files are located in a data node's data directory (`DataDir`); the path under this directory to system files matches the pattern `ndb_#_fs/D/#/DBDIH/P/#.sysfile`. In each case, the `#` represents a number (not necessarily the same number). For more information, see *NDB Cluster Data Node File System Directory*.

Like `ndb_print_backup_file` and `ndb_print_schema_file` (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a management server) `ndb_print_backup_file` must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

**Additional Options**

None.

22.4.22 **ndb_redo_log_reader** — Check and Print Content of Cluster Redo Log

Reads a redo log file, checking it for errors, printing its contents in a human-readable format, or both. `ndb_redo_log_reader` is intended for use primarily by NDB Cluster developers and Support personnel in debugging and diagnosing problems.

This utility remains under development, and its syntax and behavior are subject to change in future NDB Cluster releases.
The C++ source files for `ndb_redo_log_reader` can be found in the directory `/storage/ndb/src/kernel/blocks/dblqh/redoLogReader`.

The following table includes options that are specific to the NDB Cluster program `ndb_redo_log_reader`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndb_redo_log_reader`), see Section 22.4.31, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

**Table 22.267 Command-line options for the ndb_redo_log_reader program**

</tr>
</tbody>
</table>

**Usage**

```
ndb_redo_log_reader file_name [options]
```

`file_name` is the name of a cluster redo log file. Redo log files are located in the numbered directories under the data node's data directory (`DataDir`); the path under this directory to the redo log files matches the pattern `ndb_nodeid_fs/D/#/DBLQH/S/#.FragLog.nodeid` is the data node's node ID. The two instances of `#` each represent a number (not necessarily the same number); the number following `D` is in the range 8-39 inclusive; the range of the number following `S` varies according to the value of the `NoOfFragmentLogFiles` configuration parameter, whose default value is 16; thus, the default range of the number in the file name is 0-15 inclusive. For more information, see NDB Cluster Data Node File System Directory.

The name of the file to be read may be followed by one or more of the options listed here:

- `-dump`
### ndb_redo_log_reader — Check and Print Content of Cluster Redo Log

<table>
<thead>
<tr>

<td>FALSE</td>
</tr>
</tbody>
</table>

  Provide lap info, with max GCI started and completed.

- **Property**
  - **Value**
  - **Command-Line Format** `-mbyte #`
  - **Type** Numeric
  - **Default Value** 0
  - **Minimum Value** 0
  - **Maximum Value** 15

  `-mbyte #`: Starting megabyte.

  # is an integer in the range 0 to 15, inclusive.

- **Property**
  - **Value**
  - **Command-Line Format** `-mbyteheaders`
  - **Type** Boolean
  - **Default Value** FALSE

  `-mbyteheaders`: Show only the first page header of every megabyte in the file.

- **Property**
  - **Value**
  - **Command-Line Format** `-noprint`
  - **Type** Boolean
  - **Default Value** FALSE

  `-noprint`: Do not print the contents of the log file.
**ndb_restore** — Restore an NDB Cluster Backup

- **-nocheck**: Do not check the log file for errors.

- **-page #**: Start at this page.
  
  
  # is an integer in the range 0 to 31, inclusive.

- **-pageheaders**: Show page headers only.

- **-pageindex #**: Start at this page index.
  
  
  # is an integer between 12 and 8191, inclusive.

- **-twiddle**

  Bit-shifted dump.

Like `ndb_print_backup_file` and `ndb_print_schema_file` (and unlike most of the NDB utilities that are intended to be run on a management server host or to connect to a management server) `ndb_redo_log_reader` must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.
The NDB Cluster restoration program is implemented as a separate command-line utility `ndb_restore`, which can normally be found in the MySQL bin directory. This program reads the files created as a result of the backup and inserts the stored information into the database.

**Note**

Beginning with NDB 8.0.17, this program no longer prints `NDBT_ProgramExit: ...` when it finishes its run. Applications depending on this behavior should be modified accordingly when upgrading from NDB 8.0.16 or earlier to a NDB 8.0 later release.

`ndb_restore` must be executed once for each of the backup files that were created by the `START BACKUP` command used to create the backup (see Section 22.5.3.2, “Using The NDB Cluster Management Client to Create a Backup”). This is equal to the number of data nodes in the cluster at the time that the backup was created.

**Note**

Before using `ndb_restore`, it is recommended that the cluster be running in single user mode, unless you are restoring multiple data nodes in parallel. See Section 22.5.8, “NDB Cluster Single User Mode”, for more information.

The following table includes options that are specific to the NDB Cluster native backup restoration program `ndb_restore`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndb_restore`), see Section 22.4.31, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

</tbody>
</table>

Typical options for this utility are shown here:

```bash
ndb_restore [-c connection_string] -n node_id -b backup_id \
[-m] -r --backup-path=/path/to/backup/files
```

Normally, when restoring from an NDB Cluster backup, *ndb_restore* requires at a minimum the **--nodeid** (short form: **-n**), **--backupid** (short form: **-b**), and **--backup-path** options.

Prior to NDB 8.0.19, when *ndb_restore* was used to restore any tables containing unique indexes, it was necessary to include **--disable-indexes** or **--rebuild-indexes**. Beginning with NDB 8.0.19, when automatic metadata synchronization is enabled, this is no longer necessary.

The **-c** option is used to specify a connection string which tells *ndb_restore* where to locate the cluster management server (see Section 22.3.3.3, “NDB Cluster Connection Strings”). If this option is not used, then *ndb_restore* attempts to connect to a management server on localhost:1186. This utility acts as a cluster API node, and so requires a free connection “slot” to connect to the cluster management server. This means that there must be at least one [api] or [mysqld] section that can be used by it in the cluster config.ini file. It is a good idea to keep at least one empty [api] or [mysqld] section in config.ini that is not being used for a MySQL server or other application for this reason (see Section 22.3.3.7, “Defining SQL and Other API Nodes in an NDB Cluster”).

You can verify that *ndb_restore* is connected to the cluster by using the **SHOW** command in the ndb_mgm management client. You can also accomplish this from a system shell, as shown here:

```bash
shell> ndb_mgm -e "SHOW"
```

More detailed information about all options used by *ndb_restore* can be found in the following list:

- **--allow-pk-changes**
**ndb_restore** — Restore an NDB Cluster Backup

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--allow-pk-changes[=0</td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.21-ndb-8.0.21</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1</td>
</tr>
</tbody>
</table>

When this option is set to 1, `ndb_restore` allows the primary keys in a table definition to differ from that of the same table in the backup. This may be desirable when backing up and restoring between different schema versions with primary key changes on one or more tables, and it appears that performing the restore operation using `ndb_restore` is simpler or more efficient than issuing many `ALTER TABLE` statements after restoring table schemas and data.

The following changes in primary key definitions are supported by `--allow-pk-changes`:

- **Extending the primary key**: A non-nullable column that exists in the table schema in the backup becomes part of the table's primary key in the database.

  **Important**
  
  When extending a table's primary key, any columns which become part of primary key must not be updated while the backup is being taken; any such updates discovered by `ndb_restore` cause the restore operation to fail, even when no change in value takes place. In some cases, it may be possible to override this behavior using the `--ignore-extended-pk-updates` option; see the description of this option for more information.

- **Contracting the primary key (1)**: A column that is already part of the table's primary key in the backup schema is no longer part of the primary key, but remains in the table.

- **Contracting the primary key (2)**: A column that is already part of the table's primary key in the backup schema is removed from the table entirely.

These differences can be combined with other schema differences supported by `ndb_restore`, including changes to blob and text columns requiring the use of staging tables.

Basic steps in a typical scenario using primary key schema changes are listed here:

1. Restore table schemas using `ndb_restore --restore-meta`
2. Alter schema to that desired, or create it
3. Back up the desired schema
4. Run `ndb_restore --disable-indexes` using the backup from the previous step, to drop indexes and constraints
5. Run `ndb_restore --allow-pk-changes` (possibly along with `--ignore-extended-pk-updates`, `--disable-indexes`, and possibly other options as needed) to restore all data
6. Run `ndb_restore --rebuild-indexes` using the backup made with the desired schema, to rebuild indexes and constraints

When extending the primary key, it may be necessary for `ndb_restore` to use a temporary secondary unique index during the restore operation to map from the old primary key to the new one. Such an index is created only when necessary to apply events from the backup log to a table which
has an extended primary key. This index is named `NDB$RESTORE_PK_MAPPING`, and is created on each table requiring it; it can be shared, if necessary, by multiple instances of `ndb_restore` instances running in parallel. (Running `ndb_restore --rebuild-indexes` at the end of the restore process causes this index to be dropped.)

- **--append**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
<th>Command-Line Format</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>--append</td>
</tr>
</tbody>
</table>

When used with the `--tab` and `--print-data` options, this causes the data to be appended to any existing files having the same names.

- **--backup-path=dir_name**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
<th>Command-Line Format</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>--backup-path=dir_name</td>
</tr>
</tbody>
</table>

The path to the backup directory is required; this is supplied to `ndb_restore` using the `--backup-path` option, and must include the subdirectory corresponding to the ID backup of the backup to be restored. For example, if the data node’s `DataDir` is `/var/lib/mysql-cluster`, then the backup directory is `/var/lib/mysql-cluster/BACKUP`, and the backup files for the backup with the ID 3 can be found in `/var/lib/mysql-cluster/BACKUP/BACKUP-3`. The path may be absolute or relative to the directory in which the `ndb_restore` executable is located, and may be optionally prefixed with `backup-path=.`.

It is possible to restore a backup to a database with a different configuration than it was created from. For example, suppose that a backup with backup ID 12, created in a cluster with two storage nodes having the node IDs 2 and 3, is to be restored to a cluster with four nodes. Then `ndb_restore` must be run twice—once for each storage node in the cluster where the backup was taken. However, `ndb_restore` cannot always restore backups made from a cluster running one version of MySQL to a cluster running a different MySQL version.

---

**Important**

It is not possible to restore a backup made from a newer version of NDB Cluster using an older version of `ndb_restore`. You can restore a backup made from a newer version of MySQL to an older cluster, but you must use a copy of `ndb_restore` from the newer NDB Cluster version to do so.

For example, to restore a cluster backup taken from a cluster running NDB Cluster 7.5.17 to a cluster running NDB Cluster 7.4.27, you must use the `ndb_restore` that comes with the NDB Cluster 7.5.17 distribution.

For more rapid restoration, the data may be restored in parallel, provided that there is a sufficient number of cluster connections available. That is, when restoring to multiple nodes in parallel, you must have an `[api]` or `[mysqld]` section in the cluster `config.ini` file available for each concurrent `ndb_restore` process. However, the data files must always be applied before the logs.

- **--backupid=#, -b**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
<th>Command-Line Format</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>--backupid=#</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>none</td>
</tr>
</tbody>
</table>
This option is used to specify the ID or sequence number of the backup, and is the same number shown by the management client in the `Backup backup_id completed` message displayed upon completion of a backup. (See Section 22.5.3.2, “Using The NDB Cluster Management Client to Create a Backup”.)

**Important**

When restoring cluster backups, you must be sure to restore all data nodes from backups having the same backup ID. Using files from different backups will at best result in restoring the cluster to an inconsistent state, and may fail altogether.

In NDB 8.0.15 and later, this option is required.

- `-connect, --connect`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
<th>Command-Line Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--connect</code></td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
<td></td>
</tr>
<tr>
<td>Default Value</td>
<td><code>localhost:1186</code></td>
<td></td>
</tr>
</tbody>
</table>

Alias for `--ndb-connectstring`.

- `--disable-indexes`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
<th>Command-Line Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--disable-indexes</code></td>
<td></td>
</tr>
</tbody>
</table>

Disable restoration of indexes during restoration of the data from a native NDB backup. Afterwards, you can restore indexes for all tables at once with multithreaded building of indexes using `--rebuild-indexes`, which should be faster than rebuilding indexes concurrently for very large tables.

- `--dont-ignore-systab-0, -f`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
<th>Command-Line Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--dont-ignore-systab-0</code></td>
<td></td>
</tr>
</tbody>
</table>

Normally, when restoring table data and metadata, `ndb_restore` ignores the copy of the NDB system table that is present in the backup. `--dont-ignore-systab-0` causes the system table to be restored. *This option is intended for experimental and development use only, and is not recommended in a production environment.*

- `--exclude-databases=db-list`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
<th>Command-Line Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--exclude-databases=db-list</code></td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
<td></td>
</tr>
<tr>
<td>Default Value</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Comma-delimited list of one or more databases which should not be restored.

This option is often used in combination with `--exclude-tables`; see that option's description for further information and examples.

- `--exclude-intermediate-sql-tables`
When performing copying `ALTER TABLE` operations, `mysqld` creates intermediate tables (whose names are prefixed with `#sql-`). When `TRUE`, the `--exclude-intermediate-sql-tables` option keeps `ndb_restore` from restoring such tables that may have been left over from these operations. This option is `TRUE` by default.

- **--exclude-missing-columns**

It is possible to restore only selected table columns using this option, which causes `ndb_restore` to ignore any columns missing from tables being restored as compared to the versions of those tables found in the backup. This option applies to all tables being restored. If you wish to apply this option only to selected tables or databases, you can use it in combination with one or more of the `--include-*` or `--exclude-*` options described elsewhere in this section to do so, then restore data to the remaining tables using a complementary set of these options.

- **--exclude-missing-tables**

It is possible to restore only selected tables using this option, which causes `ndb_restore` to ignore any tables from the backup that are not found in the target database.

- **--exclude-tables=table-list**

List of one or more tables to exclude; each table reference must include the database name. Often used together with `--exclude-databases`.

When `--exclude-databases` or `--exclude-tables` is used, only those databases or tables named by the option are excluded; all other databases and tables are restored by `ndb_restore`.

This table shows several invocations of `ndb_restore` using `--exclude-*` options (other options possibly required have been omitted for clarity), and the effects these options have on restoring from an NDB Cluster backup:

<table>
<thead>
<tr>
<th>Option</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--exclude-databases=db1</code></td>
<td>All tables in all databases except <code>db1</code> are restored; no tables in <code>db1</code> are restored</td>
</tr>
</tbody>
</table>
ndb_restore — Restore an NDB Cluster Backup

<table>
<thead>
<tr>
<th>Option</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>--exclude-databases=db1,db2 (or --exclude-databases=db1 --exclude-</td>
<td>All tables in all databases except db1 and db2 are restored; no tables in db1 or db2 are restored</td>
</tr>
<tr>
<td>databases=db2)</td>
<td></td>
</tr>
<tr>
<td>--exclude-tables=db1.t1</td>
<td>All tables except t1 in database db1 are restored; all other tables in db1 are restored; all tables in all other databases are restored</td>
</tr>
<tr>
<td>--exclude-tables=db1.t2,db2.t1 (or --exclude-tables=db1.t2 --exclude-</td>
<td>All tables in database db1 except for t2 and all tables in database db2 except for table t1 are restored; no other tables in db1 or db2 are restored; all tables in all other databases are restored</td>
</tr>
<tr>
<td>tables=db2.t1)</td>
<td></td>
</tr>
</tbody>
</table>

You can use these two options together. For example, the following causes all tables in all databases except for databases db1 and db2, and tables t1 and t2 in database db3, to be restored:

```
shell> ndb_restore [...] --exclude-databases=db1,db2 --exclude-tables=db3.t1,db3.t2
```

(Again, we have omitted other possibly necessary options in the interest of clarity and brevity from the example just shown.)

You can use --include-* and --exclude-* options together, subject to the following rules:

- The actions of all --include-* and --exclude-* options are cumulative.
- All --include-* and --exclude-* options are evaluated in the order passed to ndb_restore, from right to left.
- In the event of conflicting options, the first (rightmost) option takes precedence. In other words, the first option (going from right to left) that matches against a given database or table “wins”.

For example, the following set of options causes ndb_restore to restore all tables from database db1 except db1.t1, while restoring no other tables from any other databases:

```
--include-databases=db1 --exclude-tables=db1.t1
```

However, reversing the order of the options just given simply causes all tables from database db1 to be restored (including db1.t1, but no tables from any other database), because the --include-databases option, being farthest to the right, is the first match against database db1 and thus takes precedence over any other option that matches db1 or any tables in db1:

```
--exclude-tables=db1.t1 --include-databases=db1
```

- --fields-enclosed-by=char

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--fields-enclosed-by=char</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td></td>
</tr>
</tbody>
</table>

Each column value is enclosed by the string passed to this option (regardless of data type; see the description of --fields-optionally-enclosed-by).

- --fields-optionally-enclosed-by

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--fields-optionally-enclosed-by</td>
</tr>
</tbody>
</table>
The string passed to this option is used to enclose column values containing character data (such as `CHAR`, `VARCHAR`, `BINARY`, `TEXT`, or `ENUM`).

- **--fields-terminated-by=char**

The string passed to this option is used to separate column values. The default value is a tab character (`\t`).

- **--hex**

If this option is used, all binary values are output in hexadecimal format.

- **--ignore-extended-pk-updates**

When using `--allow-pk-changes`, columns which become part of a table's primary key must not be updated while the backup is being taken; such columns should keep the same values from the time values are inserted into them until the rows containing the values are deleted. If `ndb_restore` encounters updates to these columns when restoring a backup, the restore fails. Because some applications may set values for all columns when updating a row, even when some column values are not changed, the backup may include log events appearing to update columns which are not in fact modified. In such cases you can set `--ignore-extended-pk-updates` to 1, forcing `ndb_restore` to ignore such updates.

**Important**

When causing these updates to be ignored, the user is responsible for ensuring that there are no updates to the values of any columns that become part of the primary key.

For more information, see the description of `--allow-pk-changes`.
### ndb_restore — Restore an NDB Cluster Backup

- **--include-databases=db-list**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--include-databases=db-list</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td></td>
</tr>
</tbody>
</table>

  Comma-delimited list of one or more databases to restore. Often used together with **--include-tables**; see the description of that option for further information and examples.

- **--include-stored-grants**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--include-stored-grants</td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.19-ndb-8.0.19</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

  In NDB 8.0.19 and later, **ndb_restore** does not by default restore shared users and grants (see Section 22.5.16, “Distributed MySQL Privileges with NDB_STORED_USER”) to the `ndb_sql_metadata` table. Specifying this option causes it to do so.

- **--include-tables=table-list**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--include-tables=table-list</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td></td>
</tr>
</tbody>
</table>

  Comma-delimited list of tables to restore; each table reference must include the database name.

  When **--include-databases** or **--include-tables** is used, only those databases or tables named by the option are restored; all other databases and tables are excluded by **ndb_restore**, and are not restored.

  The following table shows several invocations of **ndb_restore** using **--include-*** options (other options possibly required have been omitted for clarity), and the effects these have on restoring from an NDB Cluster backup:

  **Table 22.270** Several invocations of **ndb_restore** using **--include-*** options, and their effects on restoring from an NDB Cluster backup.

<table>
<thead>
<tr>
<th>Option</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>--include-databases=db1</strong></td>
<td>Only tables in database <strong>db1</strong> are restored; all tables in all other databases are ignored</td>
</tr>
<tr>
<td><strong>--include-databases=db1,db2</strong> (or <strong>--include-databases=db1 --include-databases=db2</strong>)</td>
<td>Only tables in databases <strong>db1</strong> and <strong>db2</strong> are restored; all tables in all other databases are ignored</td>
</tr>
<tr>
<td><strong>--include-tables=db1.t1</strong></td>
<td>Only table <strong>t1</strong> in database <strong>db1</strong> is restored; no other tables in <strong>db1</strong> or in any other database are restored</td>
</tr>
<tr>
<td><strong>--include-tables=db1.t2,db2.t1</strong> (or <strong>--include-tables=db1.t2 --include-tables=db2.t1</strong>)</td>
<td>Only the table <strong>t2</strong> in database <strong>db1</strong> and the table <strong>t1</strong> in database <strong>db2</strong> are restored; no other tables in <strong>db1,db2</strong>, or any other database are restored</td>
</tr>
</tbody>
</table>
You can also use these two options together. For example, the following causes all tables in databases `db1` and `db2`, together with the tables `t1` and `t2` in database `db3`, to be restored (and no other databases or tables):

```shell
shell> ndb_restore [...] --include-databases=db1,db2 --include-tables=db3.t1,db3.t2
```

(Again we have omitted other, possibly required, options in the example just shown.)

It also possible to restore only selected databases, or selected tables from a single database, without any `--include-*` (or `--exclude-*`) options, using the syntax shown here:

```
ndb_restore other_options db_name,[db_name[,...] | tbl_name[,tbl_name][,...]]
```

In other words, you can specify either of the following to be restored:

- All tables from one or more databases
- One or more tables from a single database
- `--lines-terminated-by=char`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--lines-terminated-by=char</code></td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>\n (linebreak)</td>
</tr>
</tbody>
</table>

Specifies the string used to end each line of output. The default is a linefeed character (`\n`).

- `--lossy-conversions,-L`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--lossy-conversions</code></td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE (If option is not used)</td>
</tr>
</tbody>
</table>

This option is intended to complement the `--promote-attributes` option. Using `--lossy-conversions` allows lossy conversions of column values (type demotions or changes in sign) when restoring data from backup. With some exceptions, the rules governing demotion are the same as for MySQL replication; see Replication of Columns Having Different Data Types, for information about specific type conversions currently supported by attribute demotion.

`ndb_restore` reports any truncation of data that it performs during lossy conversions once per attribute and column.

- `--no-binlog`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--no-binlog</code></td>
</tr>
</tbody>
</table>

This option prevents any connected SQL nodes from writing data restored by `ndb_restore` to their binary logs.

- `--no-restore-disk-objects,-d`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--no-restore-disk-objects</code></td>
</tr>
</tbody>
</table>
This option stops \texttt{ndb\_restore} from restoring any NDB Cluster Disk Data objects, such as tablespaces and log file groups; see Section 22.5.13, "NDB Cluster Disk Data Tables", for more information about these.

* **--no-upgrade, -u**

This option can be used to restore a backup taken from one node group to a different node group. Its argument is a list of the form \texttt{source\_node\_group}, \texttt{target\_node\_group}.

* **--nodeid=\#, -n**

Specify the node ID of the data node on which the backup was taken.

When restoring to a cluster with different number of data nodes from that where the backup was taken, this information helps identify the correct set or sets of files to be restored to a given node. (In such cases, multiple files usually need to be restored to a single data node.) See Section 22.4.23.1, "Restoring to a different number of data nodes", for additional information and examples.

In NDB 8.0.15 and later, this option is required.

* **--num-slices=\#**

When restoring a backup by slices, this option sets the number of slices into which to divide the backup. This allows multiple instances of \texttt{ndb\_restore} to restore disjoint subsets in parallel, potentially reducing the amount of time required to perform the restore operation.
A *slice* is a subset of the data in a given backup; that is, it is a set of fragments having the same slice ID, specified using the `--slice-id` option. The two options must always be used together, and the value set by `--slice-id` must always be less than the number of slices.

`ndb_restore` encounters fragments and assigns each one a fragment counter. When restoring by slices, a slice ID is assigned to each fragment; this slice ID is in the range 0 to 1 less than the number of slices. For a table that is not a **BLOB** table, the slice to which a given fragment belongs is determined using the formula shown here:

\[
\text{slice}_{ID} = \frac{\text{fragment}_{counter}}{\text{number}_{of}_{slices}}
\]

For a **BLOB** table, a fragment counter is not used; the fragment number is used instead, along with the ID of the main table for the **BLOB** table (recall that NDB stores **BLOB** values in a separate table internally). In this case, the slice ID for a given fragment is calculated as shown here:

\[
\text{slice}_{ID} = \left(\frac{\text{main}_{table}_{ID} + \text{fragment}_{ID}}{\text{number}_{of}_{slices}}\right)
\]

Thus, restoring by \( N \) slices means running \( N \) instances of `ndb_restore`, all with `--num-slices=N` (along with any other necessary options) and one each with `--slice-id=1`, `--slice-id=2`, `--slice-id=3`, and so on through `slice-id=N-1`.

**Example.** Assume that you want to restore a backup named `BACKUP-1`, found in the default directory `/var/lib/mysql-cluster/BACKUP/BACKUP-3` on the node file system on each data node, to a cluster with four data nodes having the node IDs 1, 2, 3, and 4. To perform this operation using five slices, execute the sets of commands shown in the following list:

1. Restore the cluster metadata using `ndb_restore` as shown here:

   ```
   shell> ndb_restore -b 1 -n 1 -m --disable-indexes --backup-path=/home/ndbuser/backups
   ```

2. Restore the cluster data to the data nodes invoking `ndb_restore` as shown here:

   ```
   shell> ndb_restore -b 1 -n 1 -r --num-slices=5 --slice-id=0 --backup-path=/var/lib/mysql-cluster/BACKUP
   shell> ndb_restore -b 1 -n 1 -r --num-slices=5 --slice-id=1 --backup-path=/var/lib/mysql-cluster/BACKUP
   shell> ndb_restore -b 1 -n 1 -r --num-slices=5 --slice-id=2 --backup-path=/var/lib/mysql-cluster/BACKUP
   shell> ndb_restore -b 1 -n 1 -r --num-slices=5 --slice-id=3 --backup-path=/var/lib/mysql-cluster/BACKUP
   shell> ndb_restore -b 1 -n 1 -r --num-slices=5 --slice-id=4 --backup-path=/var/lib/mysql-cluster/BACKUP
   ```

   ```
   shell> ndb_restore -b 1 -n 2 -r --num-slices=5 --slice-id=0 --backup-path=/var/lib/mysql-cluster/BACKUP
   shell> ndb_restore -b 1 -n 2 -r --num-slices=5 --slice-id=1 --backup-path=/var/lib/mysql-cluster/BACKUP
   shell> ndb_restore -b 1 -n 2 -r --num-slices=5 --slice-id=2 --backup-path=/var/lib/mysql-cluster/BACKUP
   shell> ndb_restore -b 1 -n 2 -r --num-slices=5 --slice-id=3 --backup-path=/var/lib/mysql-cluster/BACKUP
   shell> ndb_restore -b 1 -n 2 -r --num-slices=5 --slice-id=4 --backup-path=/var/lib/mysql-cluster/BACKUP
   ```

   ```
   shell> ndb_restore -b 1 -n 3 -r --num-slices=5 --slice-id=0 --backup-path=/var/lib/mysql-cluster/BACKUP
   shell> ndb_restore -b 1 -n 3 -r --num-slices=5 --slice-id=1 --backup-path=/var/lib/mysql-cluster/BACKUP
   shell> ndb_restore -b 1 -n 3 -r --num-slices=5 --slice-id=2 --backup-path=/var/lib/mysql-cluster/BACKUP
   shell> ndb_restore -b 1 -n 3 -r --num-slices=5 --slice-id=3 --backup-path=/var/lib/mysql-cluster/BACKUP
   shell> ndb_restore -b 1 -n 3 -r --num-slices=5 --slice-id=4 --backup-path=/var/lib/mysql-cluster/BACKUP
   ```

   ```
   shell> ndb_restore -b 1 -n 4 -r --num-slices=5 --slice-id=0 --backup-path=/var/lib/mysql-cluster/BACKUP
   shell> ndb_restore -b 1 -n 4 -r --num-slices=5 --slice-id=1 --backup-path=/var/lib/mysql-cluster/BACKUP
   shell> ndb_restore -b 1 -n 4 -r --num-slices=5 --slice-id=2 --backup-path=/var/lib/mysql-cluster/BACKUP
   shell> ndb_restore -b 1 -n 4 -r --num-slices=5 --slice-id=3 --backup-path=/var/lib/mysql-cluster/BACKUP
   shell> ndb_restore -b 1 -n 4 -r --num-slices=5 --slice-id=4 --backup-path=/var/lib/mysql-cluster/BACKUP
   ```

   All of the commands just shown in this step can be executed in parallel, provided there are enough slots for connections to the cluster (see the description for the `--backup-path` option).

3. Restore indexes as usual, as shown here:

   ```
   shell> ndb_restore -b 1 -n 1 --rebuild-indexes --backup-path=/var/lib/mysql-cluster/BACKUP/BACKUP-1
   ```
4. Finally, restore the epoch, using the command shown here:

```
shell> ndb_restore --restore-epoch --backup-path=/var/lib/mysql-cluster/BACKUP/BACKUP-1
```

You should use slicing to restore the cluster data only; it is not necessary to employ `--num-slices` or `--slice-id` when restoring the metadata, indexes, or epoch information. If either or both of these options are used with the `ndb_restore` options controlling restoration of these, the program ignores them.

The effects of using the `--parallelism` option on the speed of restoration are independent of those produced by slicing or parallel restoration using multiple instances of `ndb_restore` (`--parallelism` specifies the number of parallel transactions executed by a single `ndb_restore` thread), but it can be used together with either or both of these. You should be aware that increasing `--parallelism` causes `ndb_restore` to impose a greater load on the cluster; if the system can handle this, restoration should complete even more quickly.

The value of `--num-slices` is not directly dependent on values relating to hardware such as number of CPUs or CPU cores, amount of RAM, and so forth, nor does it depend on the number of LDMs.

It is possible to employ different values for this option on different data nodes as part of the same restoration; doing so should not in and of itself produce any ill effects.

* `--parallelism=#, -p`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--parallelism=#</code></td>
</tr>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>128</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1024</td>
</tr>
</tbody>
</table>

`ndb_restore` uses single-row transactions to apply many rows concurrently. This parameter determines the number of parallel transactions (concurrent rows) that an instance of `ndb_restore` tries to use. By default, this is 128; the minimum is 1, and the maximum is 1024.

The work of performing the inserts is parallelized across the threads in the data nodes involved. This mechanism is employed for restoring bulk data from the `.Data` file—that is, the fuzzy snapshot of the data; it is not used for building or rebuilding indexes. The change log is applied serially; index drops and builds are DDL operations and handled separately. There is no thread-level parallelism on the client side of the restore.

* `--preserve-trailing-spaces, -P`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--preserve-trailing-spaces</code></td>
</tr>
</tbody>
</table>

Cause trailing spaces to be preserved when promoting a fixed-width character data type to its variable-width equivalent—that is, when promoting a `CHAR` column value to `VARCHAR`, or a `BINARY` column value to `VARBINARY`. Otherwise, any trailing spaces are dropped from such column values when they are inserted into the new columns.

**Note**

Although you can promote `CHAR` columns to `VARCHAR` and `BINARY` columns to `VARBINARY`, you cannot promote `VARCHAR` columns to `CHAR` or `VARBINARY` columns to `BINARY`. 3877
ndb_restore — Restore an NDB Cluster Backup

- **--print**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--print</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Causes `ndb_restore` to print all data, metadata, and logs to `stdout`. Equivalent to using the `--print-data`, `--print-meta`, and `--print-log` options together.

**Note**

Use of `--print` or any of the `--print_*` options is in effect performing a dry run. Including one or more of these options causes any output to be redirected to `stdout`; in such cases, `ndb_restore` makes no attempt to restore data or metadata to an NDB Cluster.

- **--print-data**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--print-data</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Causes `ndb_restore` to direct its output to `stdout`. Often used together with one or more of `--tab`, `--fields-enclosed-by`, `--fields-optionally-enclosed-by`, `--fields-terminated-by`, `--hex`, and `--append`. **TEXT** and **BLOB** column values are always truncated. Such values are truncated to the first 256 bytes in the output. This cannot currently be overridden when using `--print-data`.

- **--print-log**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--print-log</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Causes `ndb_restore` to output its log to `stdout`.

- **--print-meta**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--print-meta</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Print all metadata to `stdout`.

- **print-sql-log**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--print-sql-log</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
</tbody>
</table>
**ndb_restore** — Restore an NDB Cluster Backup

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Log SQL statements to *stdout*. Use the option to enable; normally this behavior is disabled. The option checks before attempting to log whether all the tables being restored have explicitly defined primary keys; queries on a table having only the hidden primary key implemented by NDB cannot be converted to valid SQL.

This option does not work with tables having BLOB columns.

- **--progress-frequency=N**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><strong>--progress-frequency=#</strong></td>
</tr>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>65535</td>
</tr>
</tbody>
</table>

Print a status report each *N* seconds while the backup is in progress. 0 (the default) causes no status reports to be printed. The maximum is 65535.

- **--promote-attributes, -A**

**ndb_restore** supports limited *attribute promotion* in much the same way that it is supported by MySQL replication; that is, data backed up from a column of a given type can generally be restored to a column using a “larger, similar” type. For example, data from a CHAR(20) column can be restored to a column declared as VARCHAR(20), VARCHAR(30), or CHAR(30); data from a MEDIUMINT column can be restored to a column of type INT or BIGINT. See *Replication of Columns Having Different Data Types*, for a table of type conversions currently supported by attribute promotion.

Attribute promotion by *ndb_restore* must be enabled explicitly, as follows:

1. Prepare the table to which the backup is to be restored. *ndb_restore* cannot be used to re-create the table with a different definition from the original; this means that you must either create the table manually, or alter the columns which you wish to promote using ALTER TABLE after restoring the table metadata but before restoring the data.

2. Invoke *ndb_restore* with the **--promote-attributes** option (short form **-A**) when restoring the table data. Attribute promotion does not occur if this option is not used; instead, the restore operation fails with an error.

When converting between character data types and TEXT or BLOB, only conversions between character types (CHAR and VARCHAR) and binary types (BINARY and VARBINARY) can be performed at the same time. For example, you cannot promote an INT column to BIGINT while promoting a VARCHAR column to TEXT in the same invocation of *ndb_restore*.

Converting between TEXT columns using different character sets is not supported, and is expressly disallowed.

When performing conversions of character or binary types to TEXT or BLOB with *ndb_restore*, you may notice that it creates and uses one or more staging tables named $table_name$STnode_id.
These tables are not needed afterwards, and are normally deleted by `ndb_restore` following a successful restoration.

- **--rebuild-indexes**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--rebuild-indexes</code></td>
</tr>
</tbody>
</table>

Enable multithreaded rebuilding of the ordered indexes while restoring a native NDB backup. The number of threads used for building ordered indexes by `ndb_restore` with this option is controlled by the `BuildIndexThreads` data node configuration parameter and the number of LDMs.

It is necessary to use this option only for the first run of `ndb_restore`; this causes all ordered indexes to be rebuilt without using `--rebuild-indexes` again when restoring subsequent nodes. You should use this option prior to inserting new rows into the database; otherwise, it is possible for a row to be inserted that later causes a unique constraint violation when trying to rebuild the indexes.

Building of ordered indexes is parallelized with the number of LDMs by default. Offline index builds performed during node and system restarts can be made faster using the `BuildIndexThreads` data node configuration parameter; this parameter has no effect on dropping and rebuilding of indexes by `ndb_restore`, which is performed online.

Rebuilding of unique indexes uses disk write bandwidth for redo logging and local checkpointing. An insufficient amount of this bandwidth can lead to redo buffer overload or log overload errors. In such cases you can run `ndb_restore --rebuild-indexes` again; the process resumes at the point where the error occurred. You can also do this when you have encountered temporary errors. You can repeat execution of `ndb_restore --rebuild-indexes` indefinitely; you may be able to stop such errors by reducing the value of `--parallelism`. If the problem is insufficient space, you can increase the size of the redo log (``FragmentLogFileSize`` node configuration parameter), or you can increase the speed at which LCPs are performed (``MaxDiskWriteSpeed`` and related parameters), in order to free space more quickly.

- **--remap-column=``db.tbl.col:fn:args``**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--remap-column=[db].[tbl].[col]:[fn]:[args]</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.21-ndb-8.0.21</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

When used together with `--restore-data`, this option applies a function to the value of the indicated column. Values in the argument string are listed here:

- **db**: Database name, following any renames performed by `--rewrite-database`.
- **tbl**: Table name.
- **col**: Name of the column to be updated. This column must be of one of the integer types `TINYINT`, `SMALLINT`, `MEDIUMINT`, `BIGINT`, or `INT` (``INTEGER``).
- **fn**: Function name; currently, the only supported name is `offset`.
- **args**: Arguments supplied to the function. Currently, only a single argument, the size of the offset to be added by the `offset` function, is supported. Negative values are supported. The size of the argument cannot exceed that of the signed variant of the column's type; for example, if `col` is a `MEDIUMINT` column, then the allowed range of the argument passed to the `offset` function is `-8388608` to `-8388607` (see Section 11.1.2, “Integer Types (Exact Value) - INTEGER, INT, SMALLINT, TINYINT, MEDIUMINT, BIGINT”).
If applying the offset value to the column would cause an overflow or underflow, the restore operation fails. This could happen, for example, if the column is a TINYINT, and the option attempts to apply an offset value of 8 on a row in which the column value is 125, since \(125 + 8 = 133 > 127\).

This option can be useful when you wish to merge data stored in multiple source instances of NDB Cluster (all using the same schema) into a single destination NDB Cluster, using NDB native backup (see Section 22.5.3.2, “Using The NDB Cluster Management Client to Create a Backup”) and ndb_restore to merge the data, where primary and unique key values are overlapping between source clusters, and it is necessary as part of the process to remap these values to ranges that do not overlap. It may also be necessary to preserve other relationships between tables. To fulfill such requirements, it is possible to use the option multiple times in the same invocation of ndb_restore to remap columns of different tables, as shown here:

```shell
shell> ndb_restore --restore-data --remap-column=hr.employee.id:offset:1000 \
                --remap-column=hr.manager.id:offset:1000 --remap-column=hr.firstaiders.id:offset:1000
```

(Other options not shown here may also be used.)

--remap-column can also be used to update multiple columns of the same table. Combinations of multiple tables and columns are possible. Different offset values can also be used for different columns of the same table, like this:

```shell
shell> ndb_restore --restore-data --remap-column=hr.employee.salary:offset:10000 \
                --remap-column=hr.employee.hours:offset:-10
```

When source backups contain duplicate tables which should not be merged, you can handle this by using --exclude-tables, --exclude-databases, or by some other means in your application.

Information about the structure and other characteristics of tables to be merged can obtained using SHOW CREATE TABLE; the ndb_desc tool; and MAX(), MIN(), LAST_INSERT_ID(), and other MySQL functions.

Replication of changes from merged to unmerged tables, or from unmerged to merged tables, in separate instances of NDB Cluster is not supported.

### Command-Line Format

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--restore-data</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Output NDB table data and logs.

### Command-Line Format

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--restore-epoch</td>
</tr>
</tbody>
</table>

Add (or restore) epoch information to the cluster replication status table. This is useful for starting replication on an NDB Cluster replication slave. When this option is used, the row in the `mysql.ndb_apply_status` having 0 in the `id` column is updated if it already exists; such a row is inserted if it does not already exist. (See Section 22.6.9, “NDB Cluster Backups With NDB Cluster Replication”.)
**--restore-meta, -m**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--restore-meta</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

This option causes `ndb_restore` to print NDB table metadata.

The first time you run the `ndb_restore` restoration program, you also need to restore the metadata. In other words, you must re-create the database tables—this can be done by running it with the `--restore-meta (-m)` option. Restoring the metadata need be done only on a single data node; this is sufficient to restore it to the entire cluster.

In older versions of NDB Cluster, tables whose schemas were restored using this option used the same number of partitions as they did on the original cluster, even if it had a differing number of data nodes from the new cluster. In NDB 8.0, when restoring metadata, this is no longer an issue; `ndb_restore` now uses the default number of partitions for the target cluster, unless the number of local data manager threads is also changed from what it was for data nodes in the original cluster.

When using this option in NDB 8.0.16 or later, it is recommended that auto synchronization be disabled by setting `ndb_metadata_check=OFF` until `ndb_restore` has completed restoring the metadata, after which it can turn on again to synchronize objects newly created in the NDB dictionary.

**Note**

The cluster should have an empty database when starting to restore a backup. (In other words, you should start the data nodes with `--initial` prior to performing the restore.)

**--restore-privilege-tables**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--restore-privilege-tables</td>
</tr>
<tr>
<td>Deprecated</td>
<td>8.0.16-ndb-8.0.16</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE (If option is not used)</td>
</tr>
</tbody>
</table>

`ndb_restore` does not by default restore distributed MySQL privilege tables created in releases of NDB Cluster prior to version 8.0, which does not support distributed privileges as implemented in NDB 7.6 and earlier. This option causes `ndb_restore` to restore them.

In NDB 8.0.16 and later, such tables are not used for access control; as part of the MySQL server's upgrade process, the server creates InnoDB copies of these tables local to itself. For more information, see Section 22.2.8, “Upgrading and Downgrading NDB Cluster”, as well as Section 6.2.3, “Grant Tables”.

**--rewrite-database=olddb,newdb**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--rewrite-database=olddb,newdb</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>
This option makes it possible to restore to a database having a different name from that used in the backup. For example, if a backup is made of a database named `products`, you can restore the data it contains to a database named `inventory`, use this option as shown here (omitting any other options that might be required):

```shell
shell> ndb_restore --rewrite-database=product,inventory
```

The option can be employed multiple times in a single invocation of `ndb_restore`. Thus it is possible to restore simultaneously from a database named `db1` to a database named `db2` and from a database named `db3` to one named `db4` using `--rewrite-database=db1,db2 --rewrite-database=db3,db4`. Other `ndb_restore` options may be used between multiple occurrences of `--rewrite-database`.

In the event of conflicts between multiple `--rewrite-database` options, the last `--rewrite-database` option used, reading from left to right, is the one that takes effect. For example, if `--rewrite-database=db1,db2 --rewrite-database=db1,db3` is used, only `--rewrite-database=db1,db3` is honored, and `--rewrite-database=db1,db2` is ignored.

It is also possible to restore from multiple databases to a single database, so that `--rewrite-database=db1,db3 --rewrite-database=db2,db3` restores all tables and data from databases `db1` and `db2` into database `db3`.

**Important**

When restoring from multiple backup databases into a single target database using `--rewrite-database`, no check is made for collisions between table or other object names, and the order in which rows are restored is not guaranteed. This means that it is possible in such cases for rows to be overwritten and updates to be lost.

- `--skip-broken-objects`

This option causes `ndb_restore` to ignore corrupt tables while reading a native NDB backup, and to continue restoring any remaining tables (that are not also corrupted). Currently, the `--skip-broken-objects` option works only in the case of missing blob parts tables.

- `--skip-table-check, -s`

It is possible to restore data without restoring table metadata. By default when doing this, `ndb_restore` fails with an error if a mismatch is found between the table data and the table schema; this option overrides that behavior.

Some of the restrictions on mismatches in column definitions when restoring data using `ndb_restore` are relaxed; when one of these types of mismatches is encountered, `ndb_restore` does not stop with an error as it did previously, but rather accepts the data and inserts it into the target table while issuing a warning to the user that this is being done. This behavior occurs whether

---

**Table:**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>none</td>
</tr>
</tbody>
</table>

---
or not either of the options `--skip-table-check` or `--promote-attributes` is in use. These differences in column definitions are of the following types:

- Different `COLUMN_FORMAT` settings (`FIXED`, `DYNAMIC`, `DEFAULT`)
- Different `STORAGE` settings (`MEMORY`, `DISK`)
- Different default values
- Different distribution key settings

- `--skip-unknown-objects`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--skip-unknown-objects</code></td>
</tr>
</tbody>
</table>

This option causes `ndb_restore` to ignore any schema objects it does not recognize while reading a native NDB backup. This can be used for restoring a backup made from a cluster running (for example) NDB 7.6 to a cluster running NDB Cluster 7.5.

- `--slice-id=#`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--slice-id=#</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.20-ndb-8.0.20</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1023</td>
</tr>
</tbody>
</table>

When restoring by slices, this is the ID of the slice to restore. This option is always used together with `--num-slices`, and its value must be always less than that of `--num-slices`.

For more information, see the description of the `--num-slices` elsewhere in this section.

- `--tab=dir_name, -T dir_name`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--tab=dir_name</code></td>
</tr>
<tr>
<td>Type</td>
<td>Directory name</td>
</tr>
</tbody>
</table>

Causes `--print-data` to create dump files, one per table, each named `tbl_name.txt`. It requires as its argument the path to the directory where the files should be saved; use . for the current directory.

- `--verbose=#`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--verbose=#</code></td>
</tr>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Property</td>
<td>Value</td>
</tr>
<tr>
<td>----------------</td>
<td>-------</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>255</td>
</tr>
</tbody>
</table>

Sets the level for the verbosity of the output. The minimum is 0; the maximum is 255. The default value is 1.

**Error reporting.**

`ndb_restore` reports both temporary and permanent errors. In the case of temporary errors, it may be able to recover from them, and reports *Restore successful, but encountered temporary error, please look at configuration* in such cases.

**Important**

After using `ndb_restore` to initialize an NDB Cluster for use in circular replication, binary logs on the SQL node acting as the replication slave are not automatically created, and you must cause them to be created manually. To cause the binary logs to be created, issue a `SHOW TABLES` statement on that SQL node before running `START SLAVE`. This is a known issue in NDB Cluster.

Restoring a backup to a previous version of NDB Cluster. You may encounter issues when restoring a backup taken from a later version of NDB Cluster to a previous one, due to the use of features which do not exist in the earlier version. For example, tables created in NDB 8.0 by default use the `utf8mb4_ai_ci` character set, which is not available in NDB 7.6 and earlier, and so cannot be read by an `ndb_restore` binary from one of these earlier versions.

### 22.4.23.1 Restoring to a different number of data nodes

It is possible to restore from an NDB backup to a cluster having a different number of data nodes than the original from which the backup was taken. The following two sections discuss, respectively, the cases where the target cluster has a lesser or greater number of data nodes than the source of the backup.

#### Restoring to Fewer Nodes Than the Original

You can restore to a cluster having fewer data nodes than the original provided that the larger number of nodes is an even multiple of the smaller number. In the following example, we use a backup taken on a cluster having four data nodes to a cluster having two data nodes.

1. The management server for the original cluster is on host `host10`. The original cluster has four data nodes, with the node IDs and host names shown in the following extract from the management server’s `config.ini` file:

   ```ini
   [ndbd]
   NodeId=2
   HostName=host2

   [ndbd]
   NodeId=4
   HostName=host4

   [ndbd]
   NodeId=6
   HostName=host6

   [ndbd]
   NodeId=8
   HostName=host8
   ```

   We assume that each data node was originally started with `ndbmd --ndb-connectstring=host10` or the equivalent.

2. Perform a backup in the normal manner. See Section 22.5.3.2, “Using The NDB Cluster Management Client to Create a Backup”, for information about how to do this.
3. The files created by the backup on each data node are listed here, where $N$ is the node ID and $B$ is the backup ID.

- BACKUP-$B$-0.$N$.Data
- BACKUP-$B$.$N$.ctl
- BACKUP-$B$.$N$.log

These files are found under `BackupDataDir/BACKUP/BACKUP-$B` on each data node. For the rest of this example, we assume that the backup ID is 1.

Have all of these files available for later copying to the new data nodes (where they can be accessed on the data node's local file system by `ndb_restore`). It is simplest to copy them all to a single location; we assume that this is what you have done.

4. The management server for the target cluster is on host `host20`, and the target has two data nodes, with the node IDs and host names shown, from the management server `config.ini` file on `host20`:

```ini
[ndbd]
NodeId=3
hostname=host3
```

```ini
[ndbd]
NodeId=5
hostname=host5
```

Each of the data node processes on `host3` and `host5` should be started with `ndbmtd -c host20 --initial` or the equivalent, so that the new (target) cluster starts with clean data node file systems.
5. Copy two different sets of two backup files to each of the target data nodes. For this example, copy the backup files from nodes 2 and 4 from the original cluster to node 3 in the target cluster. These files are listed here:

- BACKUP-1-0.2.Data
- BACKUP-1.2.ctl
- BACKUP-1.2.log
- BACKUP-1-0.6.Data
- BACKUP-1.6.ctl
- BACKUP-1.6.log

Then copy the backup files from nodes 6 and 8 to node 5; these files are shown in the following list:

- BACKUP-1-0.4.Data
- BACKUP-1.4.ctl
- BACKUP-1.4.log
- BACKUP-1-0.8.Data
- BACKUP-1.8.ctl
- BACKUP-1.8.log

For the remainder of this example, we assume that the respective backup files have been saved to the directory `/BACKUP-1` on each of nodes 3 and 5.

6. On each of the two target data nodes, you must restore from both sets of backups. First, restore the backups from nodes 2 and 4 to node 3 by invoking `ndb_restore` on `host3` as shown here:

```shell
shell> ndb_restore -c host20 --nodeid=2 --backupid=1 --restore-data --backup-path=/BACKUP-1
shell> ndb_restore -c host20 --nodeid=4 --backupid=1 --restore-data --backup-path=/BACKUP-1
```

Then restore the backups from nodes 6 and 8 to node 5 by invoking `ndb_restore` on `host5`, like this:

```shell
shell> ndb_restore -c host20 --nodeid=6 --backupid=1 --restore-data --backup-path=/BACKUP-1
shell> ndb_restore -c host20 --nodeid=8 --backupid=1 --restore-data --backup-path=/BACKUP-1
```

**Restoring to More Nodes Than the Original**

The node ID specified for a given `ndb_restore` command is that of the node in the original backup and not that of the data node to restore it to. When performing a backup using the method described in this section, `ndb_restore` connects to the management server and obtains a list of data nodes in the cluster the backup is being restored to. The restored data is distributed accordingly, so that the number of nodes in the target cluster does not need to be to be known or calculated when performing the backup.

**Note**

When changing the total number of LCP threads or LOH threads per node group, you should recreate the schema from backup created using `mysqldump`.

1. **Create the backup of the data.** You can do this by invoking the `ndb_mgm` client `START_BACKUP` command from the system shell, like this:
### ndb_restore — Restore an NDB Cluster Backup

**1.** `ndb_mgm -e "START BACKUP 1"`

This assumes that the desired backup ID is 1.

**2.** Create a backup of the schema. This step is necessary only if the total number of LCP threads or LQH threads per node group is changed.

```
shell> mysqldump --no-data --routines --events --triggers --databases > myschema.sql
```

**Important**

Once you have created the NDB native backup using `ndb_mgm`, you must not make any schema changes before creating the backup of the schema, if you do so.

**3.** Copy the backup directory to the new cluster. For example if the backup you want to restore has ID 1 and `BackupDataDir=/backups/node_nodeid`, then the path to the backup on this node is `/backups/node_1/BACKUP/BACKUP-1`. Inside this directory there are three files, listed here:

- BACKUP-1-0.1.Data
- BACKUP-1.1.ctl
- BACKUP-1.1.log

You should copy the entire directory to the new node.

If you needed to create a schema file, copy this to a location on an SQL node where it can be read by `mysqld`.

There is no requirement for the backup to be restored from a specific node or nodes.

To restore from the backup just created, perform the following steps:

1. **Restore the schema.**

   - If you created a separate schema backup file using `mysqldump`, import this file using the `mysql` client, similar to what is shown here:

     ```
     shell> mysql < myschema.sql
     ```

     When importing the schema file, you may need to specify the `--user` and `--password` options (and possibly others) in addition to what is shown, in order for the `mysql` client to be able to connect to the MySQL server.

   - If you did **not** need to create a schema file, you can re-create the schema using `ndb_restore --restore-meta` (short form `-m`), similar to what is shown here:

     ```
     shell> ndb_restore --nodeid=1 --backupid=1 --restore-meta --backup-path=/backups/node_1/BACKUP/BACKUP-1
     ```

     `ndb_restore` must be able to contact the management server; add the `--ndb-connectstring` option if and as needed to make this possible.

2. **Restore the data.** This needs to be done once for each data node in the original cluster, each time using that data node's node ID. Assuming that there were 4 data nodes originally, the set of commands required would look something like this:

   ```
   ndb_restore --nodeid=1 --backupid=1 --restore-data --backup-path=/backups/node_1/BACKUP/BACKUP-1
   ndb_restore --nodeid=2 --backupid=1 --restore-data --backup-path=/backups/node_2/BACKUP/BACKUP-1
   ndb_restore --nodeid=3 --backupid=1 --restore-data --backup-path=/backups/node_3/BACKUP/BACKUP-1
   ndb_restore --nodeid=4 --backupid=1 --restore-data --backup-path=/backups/node_4/BACKUP/BACKUP-1
   ```

   These can be run in parallel.
Be sure to add the `--ndb-connectstring` option as needed.

3. **Rebuild the indexes.** These were disabled by the `--disable-indexes` option used in the commands just shown. Recreating the indexes avoids errors due to the restore not being consistent at all points. Rebuilding the indexes can also improve performance in some cases. To rebuild the indexes, execute the following command once, on a single node:

```
shell> ndb_restore --nodeid=1 --backupid=1 --backup-path=/backups/node_1/BACKUP/BACKUP-1 --rebuild-indexes
```

As mentioned previously, you may need to add the `--ndb-connectstring` option, so that `ndb_restore` can contact the management server.

### 22.4.23.2 Restoring from a backup taken in parallel

Beginning with NDB Cluster 8.0.16, it is possible to take parallel backups on each data node using `ndbmtd` with multiple LDMs (see Section 22.5.3.5, “Taking an NDB Backup with Parallel Data Nodes”). The next two sections describe how to restore backups that were taken in this fashion.

#### Restoring a parallel backup in parallel

Restoring a parallel backup in parallel requires an `ndb_restore` binary from an NDB Cluster distribution version 8.0.16 or later. The process is not substantially different from that outlined in the general usage section under the description of the `ndb_restore` program, and consists of executing `ndb_restore` twice, similarly to what is shown here:

```
shell> ndb_restore -n 1 -b 1 -m --backup-path=path/to/backup_dir/BACKUP/BACKUP-backup_id
shell> ndb_restore -n 1 -b 1 -r --backup-path=path/to/backup_dir/BACKUP/BACKUP-backup_id
```

`backup_id` is the ID of the backup to be restored. In the general case, no additional special arguments are required; `ndb_restore` always checks for the existence of parallel subdirectories under the directory indicated by the `--backup-path` option and restores the metadata (serially) and then the table data (in parallel).

#### Restoring a parallel backup serially

It is possible to restore a backup that was made using parallelism on the data nodes in serial fashion. To do this, invoke `ndb_restore` with `--backup-path` pointing to the subdirectories created by each LDM under the main backup directory, once to any one of the subdirectories to restore the metadata (it does not matter which one, since each subdirectory contains a complete copy of the metadata), then to each of the subdirectories in turn to restore the data. Suppose that we want to restore the backup having backup ID 100 that was taken with four LDMs, and that the `BackupDataDir` is `/opt`. To restore the metadata in this case, we can invoke `ndb_restore` like this:

```
shell> ndb_restore -n 1 -b 1 -m --backup-path=/opt/BACKUP/BACKUP-100/BACKUP-100-PART-1-OF-4
```

To restore the table data, execute `ndb_restore` four times, each time using one of the subdirectories in turn, as shown here:

```
shell> ndb_restore -n 1 -b 1 -r --backup-path=/opt/BACKUP/BACKUP-100/BACKUP-100-PART-1-OF-4
shell> ndb_restore -n 1 -b 1 -r --backup-path=/opt/BACKUP/BACKUP-100/BACKUP-100-PART-2-OF-4
shell> ndb_restore -n 1 -b 1 -r --backup-path=/opt/BACKUP/BACKUP-100/BACKUP-100-PART-3-OF-4
shell> ndb_restore -n 1 -b 1 -r --backup-path=/opt/BACKUP/BACKUP-100/BACKUP-100-PART-4-OF-4
```

You can employ the same technique to restore a parallel backup to an older version of NDB Cluster (prior to NDB 8.0.16) that does not support parallel backups, using the `ndb_restore` binary supplied with the older version of the NDB Cluster software.

### 22.4.24 ndb_select_all — Print Rows from an NDB Table

`ndb_select_all` prints all rows from an NDB table to stdout.
**Usage**

```
ndb_select_all -c connection_string tbl_name -d db_name [> file_name]
```

The following table includes options that are specific to the NDB Cluster native backup restoration program `ndb_select_all`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndb_select_all`), see Section 22.4.31, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--database=dbname, -d</td>
<td>Name of the database in which the table is found</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--parallelism=#, -p</td>
<td>Degree of parallelism</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--lock=#, -l</td>
<td>Lock type</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--order=index, -o</td>
<td>Sort resultset according to index whose name is supplied</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--descending, -z</td>
<td>Sort resultset in descending order (requires order flag)</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--header, -h</td>
<td>Print header (set to 0</td>
<td>FALSE to disable headers in output)</td>
</tr>
<tr>
<td>--useHexFormat, -x</td>
<td>Output numbers in hexadecimal format</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--delimiter=char, -D</td>
<td>Set a column delimiter</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--disk</td>
<td>Print disk references (useful only for Disk Data tables having nonindexed columns)</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--rowid</td>
<td>Print rowid</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--gci</td>
<td>Include GCI in output</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--gci64</td>
<td>Include GCI and row epoch in output</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--tupscan, -t</td>
<td>Scan in tup order</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--nodata</td>
<td>Do not print table column data</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
</tbody>
</table>

- **--database=dbname, -d dbname**
  
  Name of the database in which the table is found. The default value is `TEST_DB`.

- **parallelism=#, -p #**
ndb_select_all — Print Rows from an NDB Table

Specifies the degree of parallelism.

- **--lock=lock_type, -l lock_type**
  Employs a lock when reading the table. Possible values for lock_type are:
  - **0**: Read lock
  - **1**: Read lock with hold
  - **2**: Exclusive read lock
  There is no default value for this option.

- **--order=index_name, -o index_name**
  Orders the output according to the index named index_name.
  
  **Note**
  This is the name of an index, not of a column; the index must have been explicitly named when created.

- **--descending, -z**
  Sorts the output in descending order. This option can be used only in conjunction with the -o (--order) option.

- **--header=FALSE**
  Excludes column headers from the output.

- **--useHexFormat -x**
  Causes all numeric values to be displayed in hexadecimal format. This does not affect the output of numerals contained in strings or datetime values.

- **--delimiter=character, -D character**
  Causes the character to be used as a column delimiter. Only table data columns are separated by this delimiter.
  
  The default delimiter is the tab character.

- **--disk**
  Adds a disk reference column to the output. The column is nonempty only for Disk Data tables having nonindexed columns.

- **--rowid**
  Adds a ROWID column providing information about the fragments in which rows are stored.

- **--gci**
  Adds a GCI column to the output showing the global checkpoint at which each row was last updated. See Section 22.1, “NDB Cluster Overview”, and Section 22.5.6.2, “NDB Cluster Log Events”, for more information about checkpoints.

- **--gci64**
  Adds a ROW$GCI64 column to the output showing the global checkpoint at which each row was last updated, as well as the number of the epoch in which this update occurred.
**ndb_select_all** — Print Rows from an NDB Table

- **--tupscan, -t**
  
  Scan the table in the order of the tuples.

- **--nodata**
  
  Causes any table data to be omitted.

### Sample Output

#### Output from a MySQL `SELECT` statement:

```sql
mysql> SELECT * FROM ctest1.fish;
+----+-----------+
| id | name      |
+----+-----------+
|  3 | shark     |
|  6 | puffer    |
|  2 | tuna      |
|  4 | manta ray |
|  5 | grouper   |
|  1 | guppy     |
+----+-----------+
6 rows in set (0.04 sec)
```

#### Output from the equivalent invocation of `ndb_select_all`:

```sh
csh> ./ndb_select_all -c localhost fish -d ctest1
id      name
3       
6       
2       
4       
5       
1       
6 rows returned
```

**All string values are enclosed by square brackets ([...]) in the output of ndb_select_all.**

For another example, consider the table created and populated as shown here:

```sql
CREATE TABLE dogs (  
id INT(11) NOT NULL AUTO_INCREMENT,  
nname VARCHAR(25) NOT NULL,  
bbreed VARCHAR(50) NOT NULL,  
PRIMARY KEY pk (id),  
KEY ix (name)  
) TABLESPACE ts STORAGE DISK  
ENGINE=NDBCLUSTER;
```

```sql
INSERT INTO dogs VALUES  
("", 'Lassie', 'collie'),  
("", 'Scooby-Doo', 'Great Dane'),  
("", 'Rin-Tin-Tin', 'Alsatian'),  
("", 'Rosscoe', 'Mutt');
```

This demonstrates the use of several additional `ndb_select_all` options:

```sh
csh> ./ndb_select_all -d ctest1 dogs -o ix -z --gci --disk
GCI     id name          breed        DISK_REF
834461  2  
834463  3  
834878  4  
4 rows returned
```

**NDBT_ProgramExit: 0 - OK**
22.4.25 ndb_select_count — Print Row Counts for NDB Tables

`ndb_select_count` prints the number of rows in one or more NDB tables. With a single table, the result is equivalent to that obtained by using the MySQL statement `SELECT COUNT(*) FROM tbl_name`.

**Usage**

```
ndb_select_count [-c connection_string] -d db_name tbl_name[, tbl_name2[, ...]]
```

The following table includes options that are specific to the NDB Cluster native backup restoration program `ndb_select_count`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndb_select_count`), see Section 22.4.31, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

**Table 22.272 Command-line options for the ndb_select_count program**

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--database=dbname, -d</td>
<td>Name of the database in which the table is found</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--parallelism=#, -p</td>
<td>Degree of parallelism</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--lock=#, -l</td>
<td>Lock type</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
</tbody>
</table>

You can obtain row counts from multiple tables in the same database by listing the table names separated by spaces when invoking this command, as shown under Sample Output.

**Sample Output**

```
shell> ./ndb_select_count -c localhost -d ctest1 fish dogs
6 records in table fish
4 records in table dogs
NDBT_ProgramExit: 0 - OK
```

22.4.26 ndb_setup.py — Start browser-based Auto-Installer for NDB Cluster

`ndb_setup.py` starts the NDB Cluster Auto-Installer and opens the installer's Start page in the default Web browser.

⚠️ **Important**

This program is intended to be invoked as a normal user, and not with the `mysql`, system `root` or other administrative account.

This section describes usage of and program options for the command-line tool only. For information about using the Auto-Installer GUI that is spawned when `ndb_setup.py` is invoked, see The NDB Cluster Auto-Installer (NDB 7.5).

**Usage**

All platforms:

```
ndb_setup.py [options]
```

Additionally, on Windows platforms only:
The following table includes all options that are supported by the NDB Cluster installation and configuration program `ndb_setup.py`. Additional descriptions follow the table.

### Table 22.273 Command-line options for the `ndb_setup.py` program

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--browser-start-page=filename</code>, <code>-s</code></td>
<td>Page that the web browser opens when starting</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--ca-certs-file=filename</code>, <code>-a</code></td>
<td>File containing list of client certificates allowed to connect to the server</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--cert-file=filename</code>, <code>-c</code></td>
<td>File containing X509 certificate that identifies the server. (Default: mcc.cfg.pem in the installation share directory)</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--debug-level=level</code>, <code>-d</code></td>
<td>Python logging module debug level. One of DEBUG, INFO, WARNING (default), ERROR, or CRITICAL</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--help</code>, <code>-h</code></td>
<td>Print help message</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--key-file=file</code>, <code>-k</code></td>
<td>Specify file containing private key (if not included in --cert-file)</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--no-browser</code>, <code>-n</code></td>
<td>Do not open the start page in a browser, merely start the tool</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--port#=</code>, <code>-p</code></td>
<td>Specify the port used by the web server</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--server-log-file=file</code>, <code>-o</code></td>
<td>Log requests to this file. Use '-' to force logging to stderr instead</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--server-name=name</code>, <code>-N</code></td>
<td>The name of the server to connect with</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--use-http</code>, <code>-H</code></td>
<td>Use unencrypted (HTTP) client/server connection</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--use-https</code>, <code>-S</code></td>
<td>Use encrypted (HTTPS) client/server connection</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
</tbody>
</table>

• `--browser-start-page=filename`, `-s`
Specify the file to open in the browser as the installation and configuration Start page. The default is `index.html`.

- `--ca-certs-file=filename, -a`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--ca-certs-file=filename</code></td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>{none}</code></td>
</tr>
</tbody>
</table>

Specify a file containing a list of client certificates which are allowed to connect to the server. The default is an empty string, which means that no client authentication is used.

- `--cert-file=filename, -c`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--cert-file=filename</code></td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>/usr/share/mysql/mcc/cfg.pem</code></td>
</tr>
</tbody>
</table>

Specify a file containing an X509 certificate which identifies the server. It is possible for the certificate to be self-signed. The default is `cfg.pem`.

- `--debug-level=level, -d`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--debug-level=level</code></td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>WARNING</td>
</tr>
<tr>
<td>Valid Values</td>
<td>WARNING, DEBUG, INFO, ERROR, CRITICAL</td>
</tr>
</tbody>
</table>

Set the Python logging module debug level. This is one of DEBUG, INFO, WARNING, ERROR, or CRITICAL. WARNING is the default.

- `--help, -h`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--help</code></td>
</tr>
</tbody>
</table>

Print a help message.

- `--key-file=filename, -d`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--key-file=filename</code></td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
</tbody>
</table>
Specify a file containing the private key if this is not included in the X509 certificate file (`--cert-file`). The default is an empty string, which means that no such file is used.

- `--no-browser, -n`

Start the installation and configuration tool, but do not open the Start page in a browser.

- `--port=#, -p`

Set the port used by the web server. The default is 8081.

- `--server-log-file=file, -o`

Log requests to this file. The default is `ndb_setup.log`. To specify logging to `stderr`, rather than to a file, use a `−` (dash character) for the file name.

- `--server-name=host, -N`

Specify the host name or IP address for the browser to use when connecting. The default is `localhost`.
ndb_show_tables — Display List of NDB Tables

- **--use-http, -H**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
<th>Command-Line Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--use-http</td>
<td></td>
</tr>
</tbody>
</table>

Make the browser use HTTP to connect with the server. This means that the connection is unencrypted and not secured in any way.

- **--use-https, -S**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
<th>Command-Line Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--use-https</td>
<td></td>
</tr>
</tbody>
</table>

Make the browser use a secure (HTTPS) connection with the server.

### 22.4.27 ndb_show_tables — Display List of NDB Tables

`ndb_show_tables` displays a list of all NDB database objects in the cluster. By default, this includes not only both user-created tables and NDB system tables, but NDB-specific indexes, internal triggers, and NDB Cluster Disk Data objects as well.

The following table includes options that are specific to the NDB Cluster native backup restoration program `ndb_show_tables`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndb_show_tables`), see Section 22.4.31, "Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs".

**Table 22.274 Command-line options for the ndb_show_tables program**

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--database=string, -d</code></td>
<td>Specifies database in which table is found; database name must be followed by table name</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--loops=#, -l</code></td>
<td>Number of times to repeat output</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--parsable, -p</code></td>
<td>Return output suitable for MySQL LOAD DATA statement</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--show-temp-status</code></td>
<td>Show table temporary flag</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--type=#, -t</code></td>
<td>Limit output to objects of this type</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--unqualified, -u</code></td>
<td>Do not qualify table names</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
</tbody>
</table>

**Usage**

```
ndb_show_tables [-c connection_string]
```

- **--database, -d**

  Specifies the name of the database in which the desired table is found. If this option is given, the name of a table must follow the database name.
If this option has not been specified, and no tables are found in the TEST_DB database, ndb_show_tables issues a warning.

- --loops, -l

Specifies the number of times the utility should execute. This is 1 when this option is not specified, but if you do use the option, you must supply an integer argument for it.

- --parsable, -p

Using this option causes the output to be in a format suitable for use with LOAD DATA.

- --show-temp-status

If specified, this causes temporary tables to be displayed.

- --type, -t

Can be used to restrict the output to one type of object, specified by an integer type code as shown here:

- 1: System table
- 2: User-created table
- 3: Unique hash index

Any other value causes all NDB database objects to be listed (the default).

- --unqualified, -u

If specified, this causes unqualified object names to be displayed.

Only user-created NDB Cluster tables may be accessed from MySQL; system tables such as SYSTAB_0 are not visible to mysqld. However, you can examine the contents of system tables using NDB API applications such as ndb_select_all (see Section 22.4.24, “ndb_select_all — Print Rows from an NDB Table”).

Prior to NDB 8.0.20, this program printed NDBT_ProgramExit - status upon completion of its run, due to an unnecessary dependency on the NDBT testing library. This dependency has been removed, eliminating the extraneous output.

22.4.28 ndb_size.pl — NDBCLUSTER Size Requirement Estimator

This is a Perl script that can be used to estimate the amount of space that would be required by a MySQL database if it were converted to use the NDBCLUSTER storage engine. Unlike the other utilities discussed in this section, it does not require access to an NDB Cluster (in fact, there is no reason for it to do so). However, it does need to access the MySQL server on which the database to be tested resides.

Requirements

- A running MySQL server. The server instance does not have to provide support for NDB Cluster.
- A working installation of Perl.
- The DBI module, which can be obtained from CPAN if it is not already part of your Perl installation. (Many Linux and other operating system distributions provide their own packages for this library.)
A MySQL user account having the necessary privileges. If you do not wish to use an existing account, then creating one using `GRANT USAGE ON db_name.*`—where `db_name` is the name of the database to be examined—is sufficient for this purpose.

`ndb_size.pl` can also be found in the MySQL sources in `storage/ndb/tools`.

The following table includes options that are specific to the NDB Cluster program `ndb_size.pl`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndb_size.pl`), see Section 22.4.31, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

### Table 22.275 Command-line options for the `ndb_size.pl` program

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--database=dbname</code></td>
<td>The database or databases to examine; accepts a comma-delimited list; the default is ALL (use all databases found on the server)</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--hostname[:port]</code></td>
<td>Specify host and optional port as host[:port]</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--socket=file_name</code></td>
<td>Specify a socket to connect to</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--user=string</code></td>
<td>Specify a MySQL user name</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--password=string</code></td>
<td>Specify a MySQL user password</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--format=string</code></td>
<td>Set output format (text or HTML)</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--excludetables=tbl_list</code></td>
<td>Skip any tables in a comma-separated list of tables</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>

</tr>
</tbody>
</table>

#### Usage

```
perl ndb_size.pl [--database={db_name|ALL}] [--hostname=host[:port]] [--socket=socket] \[
  [--user=user] [--password=password] \[--help|-h] [--format={html|text}] \[
  --loadqueries=file \[--savequeries=file_name]
```

By default, this utility attempts to analyze all databases on the server. You can specify a single database using the `--database` option; the default behavior can be made explicit by using `ALL` for the name of the database. You can also exclude one or more databases by using the `--excludedbs` option with a comma-separated list of the names of the databases to be skipped. Similarly, you can cause specific tables to be skipped by listing their names, separated by commas, following the optional `--excludetables` option. A host name can be specified using `--hostname`; the default is
localhost. You can specify a port in addition to the host using host:port format for the value of --hostname. The default port number is 3306. If necessary, you can also specify a socket; the default is /var/lib/mysql.sock. A MySQL user name and password can be specified the corresponding options shown. It also possible to control the format of the output using the --format option; this can take either of the values html or text, with text being the default. An example of the text output is shown here:

shell> ndb_size.pl --database=test --socket=/tmp/mysql.sock
ndb_size.pl report for database: 'test' (1 tables)
Connected to: DBI:mysql:host=localhost;mysql_socket=/tmp/mysql.sock
Including information for versions: 4.1, 5.0, 5.1

For debugging purposes, the Perl arrays containing the queries run by this script can be read from the file specified using `--savequeries`; a file containing such arrays to be read during script execution can be specified using `--loadqueries`. Neither of these options has a default value.

To produce output in HTML format, use the `--format` option and redirect the output to a file, as shown here:

```
shell> ndb_size.pl --database=test --socket=/tmp/mysql.sock --format=html > ndb_size.html
```

(Without the redirection, the output is sent to `stdout`).

The output from this script includes the following information:

- Minimum values for the `DataMemory`, `IndexMemory`, `MaxNoOfTables`, `MaxNoOfAttributes`, `MaxNoOfOrderedIndexes`, and `MaxNoOfTriggers` configuration parameters required to accommodate the tables analyzed.
- Memory requirements for all of the tables, attributes, ordered indexes, and unique hash indexes defined in the database.
- The `IndexMemory` and `DataMemory` required per table and table row.

22.4.29 **ndb_top** — View CPU usage information for NDB threads

`ndb_top` displays running information in the terminal about CPU usage by NDB threads on an NDB Cluster data node. Each thread is represented by two rows in the output, the first showing system statistics, the second showing the measured statistics for the thread.

`ndb_top` is available beginning with MySQL NDB Cluster 7.6.3.

**Usage**

```
ndb_top [-h hostname] [-t port] [-u user] [-p pass] [-n node_id]
```

`ndb_top` connects to a MySQL Server running as an SQL node of the cluster. By default, it attempts to connect to a `mysqld` running on `localhost` and port 3306, as the MySQL `root` user with no password specified. You can override the default host and port using, respectively, `--host (-h)` and `--port (-t)`. To specify a MySQL user and password, use the `--user (-u)` and `--passwd (-p)` options. This user must be able to read tables in the `ndbinfo` database (`ndb_top` uses information from `ndbinfo.cpustat` and related tables).

For more information about MySQL user accounts and passwords, see Section 6.2, ”Access Control and Account Management”.

Output is available as plain text or an ASCII graph; you can specify this using the `--text (-x)` and `--graph (-g)` options, respectively. These two display modes provide the same information; they can be used concurrently. At least one display mode must be in use.

Color display of the graph is supported and enabled by default (`--color` or `-c` option). With color support enabled, the graph display shows OS user time in blue, OS system time in green, and idle time as blank. For measured load, blue is used for execution time, yellow for send time, red for time spent in send buffer full waits, and blank spaces for idle time. The percentage shown in the graph display is the sum of percentages for all threads which are not idle. Colors are not currently configurable; you can use grayscale instead by using `--skip-color`.

The sorted view (`--sort, -r`) is based on the maximum of the measured load and the load reported by the OS. Display of these can be enabled and disabled using the `--measured-load (-m)` and `--os-load (-c)` options. Display of at least one of these loads must be enabled.

The program tries to obtain statistics from a data node having the node ID given by the `--node-id (-n)` option; if unspecified, this is 1. `ndb_top` cannot provide information about other types of nodes.
The view adjusts itself to the height and width of the terminal window; the minimum supported width is 76 characters.

Once started, `ndb_top` runs continuously until forced to exit; you can quit the program using `Ctrl-C`. The display updates once per second; to set a different delay interval, use `--sleep-time (-s)`.

**Note**

`ndb_top` is available on macOS, Linux, and Solaris. It is not currently supported on Windows platforms.

The following table includes all options that are specific to the NDB Cluster program `ndb_top`. Additional descriptions follow the table.

**Table 22.276 Command-line options for the ndb_top program**

<table>

</tr>
<tr>
<td>Property</td>
<td>Value</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>----------------</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Show measured load by thread. This option or `--os-load` must be true; both options may be true.

- `--node-id[=#], -n`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--node-id[=#]</code></td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
</tbody>
</table>

Watch the data node having this node ID.

- `--os-load, -o`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--os-load</code></td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>TRUE</td>
</tr>
</tbody>
</table>

Show load measured by operating system. This option or `--measured-load` must be true; both options may be true.

- `--passwd[=password], -p`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--passwd[=password]</code></td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>NULL</td>
</tr>
</tbody>
</table>

Connect using this password.

This option is deprecated in NDB 7.6.4. It is removed in NDB 7.6.6, where it is replaced by the `--password` option. (Bug #26907833)

- `--password[=password], -p`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--password[=password]</code></td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>NULL</td>
</tr>
</tbody>
</table>

Connect using this password.

This option was added in NDB 7.6.6 as a replacement for the `--passwd` option used previously. (Bug #26907833)

- `--port[=#], -t` (NDB 7.6.6 and later: `-P`)

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--port[=#]</code></td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
</tbody>
</table>
**ndb_top** — View CPU usage information for NDB threads

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>3306</td>
</tr>
</tbody>
</table>

Port number to use when connecting to MySQL Server.

Beginning with NDB 7.6.6, the short form for this option is `-p`, and `-t` is repurposed as the short form for the `--text` option. (Bug #26907833)

- **`--sleep-time[=seconds], -s`**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--sleep-time[=seconds]</code></td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
</tbody>
</table>

Time to wait between display refreshes, in seconds.

- **`--socket=path/to/file, -S`**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--socket</code></td>
</tr>
<tr>
<td>Type</td>
<td>Path name</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Use the specified socket file for the connection.

Added in NDB 7.6.6. (Bug #86614, Bug #26236298)

- **`--sort, -r`**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--sort</code></td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>TRUE</td>
</tr>
</tbody>
</table>

Sort threads by usage; use `--skip-sort` to disable.

- **`--text, -x` (NDB 7.6.6 and later: `-t`)**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--text</code></td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Display data using text. This option or `--graph` must be true; both options may be true.

Beginning with NDB 7.6.6, the short form for this option is `-t` and support for `-x` is removed. (Bug #26907833)

- **`--user[=name], -u`**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--user[=name]</code></td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>
**ndb_waiter** — Wait for NDB Cluster to Reach a Given Status

### Sample Output

The next figure shows `ndb_top` running in a terminal window on a Linux system with an `ndbmd` data node under a moderate load. Here, the program has been invoked using `ndb_top -n8 -x` to provide both text and graph output:

![ndb_top Running in Terminal](image)

### 22.4.30 **ndb_waiter** — Wait for NDB Cluster to Reach a Given Status

`ndb_waiter` repeatedly (each 100 milliseconds) prints out the status of all cluster data nodes until either the cluster reaches a given status or the `--timeout` limit is exceeded, then exits. By default, it waits for the cluster to achieve **STARTED** status, in which all nodes have started and connected to the cluster. This can be overridden using the `--no-contact` and `--not-started` options.

The node states reported by this utility are as follows:

- **NO_CONTACT**: The node cannot be contacted.
- **UNKNOWN**: The node can be contacted, but its status is not yet known. Usually, this means that the node has received a **START** or **RESTART** command from the management server, but has not yet acted on it.
- **NOT_STARTED**: The node has stopped, but remains in contact with the cluster. This is seen when restarting the node using the management client's **RESTART** command.
- **STARTING**: The node’s `ndbd` process has started, but the node has not yet joined the cluster.
- **STARTED**: The node is operational, and has joined the cluster.
- **SHUTTING_DOWN**: The node is shutting down.
- **SINGLE USER MODE**: This is shown for all cluster data nodes when the cluster is in single user mode.

The following table includes options that are specific to the NDB Cluster native backup restoration program `ndb_waiter`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndb_waiter`), see Section 22.4.31, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

<table>

**ndb_waiter** — Wait for NDB Cluster to Reach a Given Status

---

**Table 22.277 Command-line options for the ndb_waiter program**

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--no-contact, -n</td>
<td>Wait for cluster to reach NO CONTACT state</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--not-started</td>
<td>Wait for cluster to reach NOT STARTED state</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--single-user</td>
<td>Wait for cluster to enter single user mode</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--timeout=#, -t</td>
<td>Wait this many seconds, then exit whether or not cluster has reached desired state; default is 2 minutes (120 seconds)</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--nowait-nodes=list</td>
<td>List of nodes not to be waited for</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--wait-nodes=list, -w</td>
<td>List of nodes to be waited for</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
</tbody>
</table>

**Usage**

```
ndb_waiter [-c connection_string]
```

**Additional Options**

- **--no-contact, -n**

  Instead of waiting for the STARTED state, *ndb_waiter* continues running until the cluster reaches NO_CONTACT status before exiting.

- **--not-started**

  Instead of waiting for the STARTED state, *ndb_waiter* continues running until the cluster reaches NOT_STARTED status before exiting.

- **--timeout=seconds, -t seconds**

  Time to wait. The program exits if the desired state is not achieved within this number of seconds. The default is 120 seconds (1200 reporting cycles).

- **--single-user**

  The program waits for the cluster to enter single user mode.

- **--nowait-nodes=list**

  When this option is used, *ndb_waiter* does not wait for the nodes whose IDs are listed. The list is comma-delimited; ranges can be indicated by dashes, as shown here:

  ```
  shell> ndb_waiter --nowait-nodes=1,3,7-9
  ```

  **Important**

  *Do not use this option together with the --wait-nodes option.*

- **--wait-nodes=list, -w list**
When this option is used, `ndb_waiter` waits only for the nodes whose IDs are listed. The list is comma-delimited; ranges can be indicated by dashes, as shown here:

```
shell> ndb_waiter --wait-nodes=2,4-6,10
```

**Important**

Do *not* use this option together with the `--nowait-nodes` option.

**Sample Output.** Shown here is the output from `ndb_waiter` when run against a 4-node cluster in which two nodes have been shut down and then started again manually. Duplicate reports (indicated by `...`) are omitted.

```

State node 3 STARTED
State node 4 STARTING
Waiting for cluster enter state STARTED
...
```
Note

If no connection string is specified, then `ndb_waiter` tries to connect to a management on `localhost`, and reports `Connecting to mgmsrv at (null)`.

Prior to NDB 8.0.20, this program printed `NDBT_ProgramExit - status` upon completion of its run, due to an unnecessary dependency on the `NDBT` testing library. This dependency has been removed, eliminating the extraneous output.

22.4.31 Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs

All NDB Cluster programs accept the options described in this section, with the following exceptions:

- `mysqld`
- `ndb_print_backup_file`
- `ndb_print_schema_file`
- `ndb_print_sys_file`

Note

Users of earlier NDB Cluster versions should note that some of these options have been changed to make them consistent with one another, and also with `mysqld`. You can use the `--help` option with any NDB Cluster program—with the exception of `ndb_print_backup_file`, `ndb_print_schema_file`, and `ndb_print_sys_file`—to view a list of the options which the program supports.

The options in the following table are common to all NDB Cluster executables (except those noted previously in this section).

Table 22.278 Command-line options common to all MySQL NDB Cluster programs

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--character-sets-dir=dir_name</code></td>
<td>Directory where character sets are installed</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--connect-retries=#</code></td>
<td>Set the number of times to retry a connection before giving up</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--connect-retry-delay=#</code></td>
<td>Time to wait between attempts to contact a management server, in seconds</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--core-file</code></td>
<td>Write core on errors (defaults to TRUE in debug builds)</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--debug=options</code></td>
<td>Enable output from debug calls. Can be used only for versions compiled with debugging enabled</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--defaults-extra-file=filename</code></td>
<td>Read this file after global option files are read</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--defaults-file=filename</code></td>
<td>Read default options from this file</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--defaults-group-suffix</code></td>
<td>Also read groups with names ending in this suffix</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
</tbody>
</table>
### Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--help, --usage, -?</code></td>
<td>Display help message and exit</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--login-path=path</code></td>
<td>Read this path from the login file</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--ndb-connectstring=connectstring, --connect-string=connectstring, -c</code></td>
<td>Set connection string for connecting to ndb_mgmd. Syntax: `[nodeid=&lt;id&gt;;;] [host=]&lt;hostname&gt;[:&lt;port&gt;]. Overrides entries specified in NDB_CONNECTSTRING or my.cnf</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--ndb-mgmd-host=host[:port]</code></td>
<td>Set the host (and port, if desired) for connecting to management server</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--ndb-nodeid=#</code></td>
<td>Set node id for this node</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--ndb-optimized-node-selection</code></td>
<td>Select nodes for transactions in a more optimal way</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--no-defaults</code></td>
<td>Do not read default options from any option file other than login file</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--print-defaults</code></td>
<td>Print the program argument list and exit</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--version, -V</code></td>
<td>Output version information and exit</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
</tbody>
</table>

For options specific to individual NDB Cluster programs, see Section 22.4, “NDB Cluster Programs”.

See MySQL Server Options for NDB Cluster, for `mysqld` options relating to NDB Cluster.

- `--character-sets-dir=dirname`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--character-sets-dir=dir_name</code></td>
</tr>
<tr>
<td>Type</td>
<td>Directory name</td>
</tr>
<tr>
<td>Default Value</td>
<td></td>
</tr>
</tbody>
</table>

Tells the program where to find character set information.

- `--connect-retries=#`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--connect-retries=#</code></td>
</tr>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>12</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>
This option specifies the number of times following the first attempt to retry a connection before giving up (the client always tries the connection at least once). The length of time to wait per attempt is set using `--connect-retry-delay`.

### Note

When used with `ndb_mgm`, this option has 3 as its default. See Section 22.4.5, "ndb_mgm — The NDB Cluster Management Client", for more information.

- **--connect-retry-delay=#**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--connect-retry-delay=#</td>
</tr>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>5</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

This option specifies the length of time to wait per attempt a connection before giving up. The number of times to try connecting is set by `--connect-retries`.

- **--core-file**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--core-file</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Write a core file if the program dies. The name and location of the core file are system-dependent. (For NDB Cluster programs nodes running on Linux, the default location is the program's working directory—for a data node, this is the node's `DataDir`.) For some systems, there may be restrictions or limitations. For example, it might be necessary to execute `ulimit -c unlimited` before starting the server. Consult your system documentation for detailed information.

If NDB Cluster was built using the `--debug` option for `configure`, then `--core-file` is enabled by default. For regular builds, `--core-file` is disabled by default.

- **--debug[=options]**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--debug=options</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>d:t:O,/tmp/ndb_restore.trace</code></td>
</tr>
</tbody>
</table>

This option can be used only for versions compiled with debugging enabled. It is used to enable output from debug calls in the same manner as for the `mysqld` process.

- **--defaults-extra-file=filename**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--defaults-extra-file=filename</td>
</tr>
</tbody>
</table>
## Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Type</strong></td>
<td>String</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>[none]</td>
</tr>
</tbody>
</table>

Read this file after global option files are read.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.  

- **--defaults-file=filename**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td>--defaults-file=filename</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>String</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>[none]</td>
</tr>
</tbody>
</table>

Read default options from this file.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.  

- **--defaults-group-suffix**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td>--defaults-group-suffix</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>String</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>[none]</td>
</tr>
</tbody>
</table>

Also read groups with names ending in this suffix.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.  

- **--help, --usage, -?**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td>--help</td>
</tr>
<tr>
<td></td>
<td>--usage</td>
</tr>
</tbody>
</table>

Prints a short list with descriptions of the available command options.

- **--login-path=path**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td>--login-path=path</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>String</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>[none]</td>
</tr>
</tbody>
</table>

Read this path from the login file.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.  

---

3912
Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs

- `--ndb-connectstring=connection_string,--connect-string=connection_string, -c connection_string`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--ndb-connectstring=connectstring</code></td>
</tr>
<tr>
<td></td>
<td><code>--connect-string=connectstring</code></td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>localhost:1186</code></td>
</tr>
</tbody>
</table>

This option takes an NDB Cluster connection string that specifies the management server for the application to connect to, as shown here:

```shell
ndbd --ndb-connectstring="nodeid=2;host=ndb_mgmd.mysql.com:1186"
```

For more information, see Section 22.3.3.3, "NDB Cluster Connection Strings".

- `--ndb-mgmd-host=host[:port]`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--ndb-mgmd-host=host[:port]</code></td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>localhost:1186</code></td>
</tr>
</tbody>
</table>

Can be used to set the host and port number of a single management server for the program to connect to. If the program requires node IDs or references to multiple management servers (or both) in its connection information, use the `--ndb-connectstring` option instead.

- `--ndb-nodeid=#`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--ndb-nodeid=#</code></td>
</tr>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
</tbody>
</table>

Sets this node's NDB Cluster node ID. The range of permitted values depends on the node's type (data, management, or API) and the NDB Cluster software version. See Section 22.1.7.2, "Limits and Differences of NDB Cluster from Standard MySQL Limits", for more information.

- `--no-defaults`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--no-defaults</code></td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>TRUE</td>
</tr>
</tbody>
</table>

Do not read default options from any option file other than login file.

For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- `--ndb-optimized-node-selection`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--ndb-optimized-node-selection</code></td>
</tr>
</tbody>
</table>
Management of NDB Cluster

---

**Property** | **Value**
---|---
**Type** | Boolean
**Default Value** | TRUE

Optimize selection of nodes for transactions. Enabled by default.

- **--print-defaults**

---

**Property** | **Value**
---|---
**Command-Line Format** | --print-defaults
**Type** | Boolean
**Default Value** | TRUE

Print the program argument list and exit.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- **--version, -V**

---

**Property** | **Value**
---|---
**Command-Line Format** | --version

Prints the NDB Cluster version number of the executable. The version number is relevant because not all versions can be used together, and the NDB Cluster startup process verifies that the versions of the binaries being used can co-exist in the same cluster. This is also important when performing an online (rolling) software upgrade or downgrade of NDB Cluster.

See Section 22.5.5, “Performing a Rolling Restart of an NDB Cluster”), for more information.

### 22.5 Management of NDB Cluster

Managing an NDB Cluster involves a number of tasks, the first of which is to configure and start NDB Cluster. This is covered in Section 22.3, “Configuration of NDB Cluster”, and Section 22.4, “NDB Cluster Programs”.

The next few sections cover the management of a running NDB Cluster.

For information about security issues relating to management and deployment of an NDB Cluster, see Section 22.5.12, “NDB Cluster Security Issues”.

There are essentially two methods of actively managing a running NDB Cluster. The first of these is through the use of commands entered into the management client whereby cluster status can be checked, log levels changed, backups started and stopped, and nodes stopped and started. The second method involves studying the contents of the cluster log ndb_node_id_cluster.log; this is usually found in the management server’s DataDir directory, but this location can be overridden using the LogDestination option. (Recall that node_id represents the unique identifier of the node whose activity is being logged.) The cluster log contains event reports generated by ndbd. It is also possible to send cluster log entries to a Unix system log.

Some aspects of the cluster's operation can be also be monitored from an SQL node using the SHOW ENGINE NDB STATUS statement.

More detailed information about NDB Cluster operations is available in real time through an SQL interface using the ndbinfo database. For more information, see Section 22.5.10, “ndbinfo: The NDB Cluster Information Database”.

---
NDB statistics counters provide improved monitoring using the *mysql* client. These counters, implemented in the NDB kernel, relate to operations performed by or affecting *Ndb* objects, such as starting, closing, and aborting transactions; primary key and unique key operations; table, range, and pruned scans; blocked threads waiting for various operations to complete; and data and events sent and received by NDB Cluster. The counters are incremented by the NDB kernel whenever NDB API calls are made or data is sent to or received by the data nodes.

*mysqld* exposes the NDB API statistics counters as system status variables, which can be identified from the prefix common to all of their names (Ndb_api_). The values of these variables can be read in the *mysql* client from the output of a `SHOW STATUS` statement, or by querying either the Performance Schema `session_status` or `global_status` table. By comparing the values of the status variables before and after the execution of an SQL statement that acts on *NDB* tables, you can observe the actions taken on the NDB API level that correspond to this statement, which can be beneficial for monitoring and performance tuning of NDB Cluster.

MySQL Cluster Manager provides an advanced command-line interface that simplifies many otherwise complex NDB Cluster management tasks, such as starting, stopping, or restarting an NDB Cluster with a large number of nodes. The MySQL Cluster Manager client also supports commands for getting and setting the values of most node configuration parameters as well as *mysqld* server options and variables relating to NDB Cluster. MySQL Cluster Manager version 1.4.8 provides experimental support for NDB 8.0. See *MySQL™ Cluster Manager 1.4.8 User Manual*, for more information.

### 22.5.1 Summary of NDB Cluster Start Phases

This section provides a simplified outline of the steps involved when NDB Cluster data nodes are started. More complete information can be found in [NDB Cluster Start Phases](https://mariadb.com/kb/en/ndb-cluster-start-phases/), in the *NDB Internals Guide*.

These phases are the same as those reported in the output from the `node_id STATUS` command in the management client (see [Section 22.5.2, "Commands in the NDB Cluster Management Client"](https://mariadb.com/kb/en/ndb-cluster-management-client/)). These start phases are also reported in the `start_phase` column of the `ndbinfo.nodes` table.

#### Start types

There are several different startup types and modes, as shown in the following list:

- **Initial start.** The cluster starts with a clean file system on all data nodes. This occurs either when the cluster started for the very first time, or when all data nodes are restarted using the `--initial` option.

  **Note**
  
  Disk Data files are not removed when restarting a node using `--initial`.

- **System restart.** The cluster starts and reads data stored in the data nodes. This occurs when the cluster has been shut down after having been in use, when it is desired for the cluster to resume operations from the point where it left off.

- **Node restart.** This is the online restart of a cluster node while the cluster itself is running.

- **Initial node restart.** This is the same as a node restart, except that the node is reinitialized and started with a clean file system.

#### Setup and initialization (phase -1).

Prior to startup, each data node (*ndbd* process) must be initialized. Initialization consists of the following steps:

1. Obtain a node ID
2. Fetch configuration data
3. Allocate ports to be used for inter-node communications
4. Allocate memory according to settings obtained from the configuration file

When a data node or SQL node first connects to the management node, it reserves a cluster node ID. To make sure that no other node allocates the same node ID, this ID is retained until the node has managed to connect to the cluster and at least one ndbd reports that this node is connected. This retention of the node ID is guarded by the connection between the node in question and ndb_mgmd.

After each data node has been initialized, the cluster startup process can proceed. The stages which the cluster goes through during this process are listed here:

- **Phase 0.** The NDBFS and NDBCNTR blocks start (see NDB Kernel Blocks). Data node file systems are cleared on those data nodes that were started with --initial option.

- **Phase 1.** In this stage, all remaining NDB kernel blocks are started. NDB Cluster connections are set up, inter-block communications are established, and heartbeats are started. In the case of a node restart, API node connections are also checked.

  **Note**
  
  When one or more nodes hang in Phase 1 while the remaining node or nodes hang in Phase 2, this often indicates network problems. One possible cause of such issues is one or more cluster hosts having multiple network interfaces. Another common source of problems causing this condition is the blocking of TCP/IP ports needed for communications between cluster nodes. In the latter case, this is often due to a misconfigured firewall.

- **Phase 2.** The NDBCNTR kernel block checks the states of all existing nodes. The master node is chosen, and the cluster schema file is initialized.

- **Phase 3.** The DBLQH and DBTC kernel blocks set up communications between them. The startup type is determined; if this is a restart, the DBDIH block obtains permission to perform the restart.

- **Phase 4.** For an initial start or initial node restart, the redo log files are created. The number of these files is equal to NoOfFragmentLogFiles.

For a system restart:

- Read schema or schemas.
- Read data from the local checkpoint.
- Apply all redo information until the latest restorable global checkpoint has been reached.

For a node restart, find the tail of the redo log.

- **Phase 5.** Most of the database-related portion of a data node start is performed during this phase. For an initial start or system restart, a local checkpoint is executed, followed by a global checkpoint. Periodic checks of memory usage begin during this phase, and any required node takeovers are performed.

- **Phase 6.** In this phase, node groups are defined and set up.

- **Phase 7.** The arbitrator node is selected and begins to function. The next backup ID is set, as is the backup disk write speed. Nodes reaching this start phase are marked as Started. It is now possible for API nodes (including SQL nodes) to connect to the cluster.

- **Phase 8.** If this is a system restart, all indexes are rebuilt (by DBDIH).

- **Phase 9.** The node internal startup variables are reset.

- **Phase 100 (OBSOLETE).** Formerly, it was at this point during a node restart or initial node restart that API nodes could connect to the node and begin to receive events. Currently, this phase is empty.
• **Phase 101.** At this point in a node restart or initial node restart, event delivery is handed over to the node joining the cluster. The newly-joined node takes over responsibility for delivering its primary data to subscribers. This phase is also referred to as *SUMA handover phase*.

After this process is completed for an initial start or system restart, transaction handling is enabled. For a node restart or initial node restart, completion of the startup process means that the node may now act as a transaction coordinator.

### 22.5.2 Commands in the NDB Cluster Management Client

In addition to the central configuration file, a cluster may also be controlled through a command-line interface available through the management client `ndb_mgm`. This is the primary administrative interface to a running cluster.

Commands for the event logs are given in Section 22.5.6, “Event Reports Generated in NDB Cluster”; commands for creating backups and restoring from them are provided in Section 22.5.3, “Online Backup of NDB Cluster”.

**Using ndb_mgm with MySQL Cluster Manager.** MySQL Cluster Manager 1.4.8 provides experimental support for NDB 8.0. MySQL Cluster Manager handles starting and stopping processes and tracks their states internally, so it is not necessary to use `ndb_mgm` for these tasks for an NDB Cluster that is under MySQL Cluster Manager control. It is recommended not to use the `ndb_mgm` command-line client that comes with the NDB Cluster distribution to perform operations that involve starting or stopping nodes. These include but are not limited to the `START`, `STOP`, `RESTART`, and `SHUTDOWN` commands. For more information, see MySQL Cluster Manager Process Commands.

The management client has the following basic commands. In the listing that follows, `node_id` denotes either a data node ID or the keyword `ALL`, which indicates that the command should be applied to all of the cluster’s data nodes.

- **HELP**
  Displays information on all available commands.

- **CONNECT connection-string**
  Connects to the management server indicated by the connection string. If the client is already connected to this server, the client reconnects.

- **SHOW**
  Displays information on the cluster’s status. Possible node status values include `UNKNOWN`, `NO_CONTACT`, `NOT_STARTED`, `STARTING`, `STARTED`, `SHUTTING_DOWN`, and `RESTARTING`.

  The output from this command also indicates when the cluster is in single user mode (status `SINGLE USER MODE`). In NDB 8.0.17 and later, it also indicates which API or SQL node has exclusive access when this mode is in effect; this works only when all data nodes and management nodes connected to the cluster are version 8.0.17 or later.

- **node_id START**
  Brings online the data node identified by `node_id` (or all data nodes).

  `ALL START` works on all data nodes only, and does not affect management nodes.

  **Important**
  To use this command to bring a data node online, the data node must have been started using `--nostart` or `-n`.

- **node_id STOP [-a] [-f]**
Stops the data or management node identified by \textit{node\_id}.

\textbf{Note}

\texttt{ALL STOP} works to stop all data nodes only, and does not affect management nodes.

A node affected by this command disconnects from the cluster, and its associated \texttt{ndbd} or \texttt{ndb\_mgmd} process terminates.

The \texttt{-a} option causes the node to be stopped immediately, without waiting for the completion of any pending transactions.

Normally, \texttt{STOP} fails if the result would cause an incomplete cluster. The \texttt{-f} option forces the node to shut down without checking for this. If this option is used and the result is an incomplete cluster, the cluster immediately shuts down.

\textbf{Warning}

Use of the \texttt{-a} option also disables the safety check otherwise performed when \texttt{STOP} is invoked to insure that stopping the node does not cause an incomplete cluster. In other words, you should exercise extreme care when using the \texttt{-a} option with the \texttt{STOP} command, due to the fact that this option makes it possible for the cluster to undergo a forced shutdown because it no longer has a complete copy of all data stored in NDB.

\begin{itemize}
\item \texttt{node\_id RESTART [-n] [-i] [-a] [-f]}
\end{itemize}

Restarts the data node identified by \textit{node\_id} (or all data nodes).

Using the \texttt{-i} option with \texttt{RESTART} causes the data node to perform an initial restart; that is, the node's file system is deleted and recreated. The effect is the same as that obtained from stopping the data node process and then starting it again using \texttt{ndbd --initial} from the system shell.

\textbf{Note}

Backup files and Disk Data files are not removed when this option is used.

Using the \texttt{-n} option causes the data node process to be restarted, but the data node is not actually brought online until the appropriate \texttt{START} command is issued. The effect of this option is the same as that obtained from stopping the data node and then starting it again using \texttt{ndbd --nostart} or \texttt{ndbd -n} from the system shell.

Using the \texttt{-a} causes all current transactions relying on this node to be aborted. No GCP check is done when the node rejoins the cluster.

Normally, \texttt{RESTART} fails if taking the node offline would result in an incomplete cluster. The \texttt{-f} option forces the node to restart without checking for this. If this option is used and the result is an incomplete cluster, the entire cluster is restarted.

\begin{itemize}
\item \texttt{node\_id STATUS}
\end{itemize}

Displays status information for the data node identified by \textit{node\_id} (or for all data nodes).

The output from this command also indicates when the cluster is in single user mode.
• **node_id REPORT report-type**

Displays a report of type `report-type` for the data node identified by `node_id`, or for all data nodes using `ALL`.

Currently, there are three accepted values for `report-type`:

• **BackupStatus** provides a status report on a cluster backup in progress

• **MemoryUsage** displays how much data memory and index memory is being used by each data node as shown in this example:

```plaintext
ndb_mgm> ALL REPORT MEMORY

Node 1: Data usage is 5%(177 32K pages of total 3200)
Node 1: Index usage is 0%(108 8K pages of total 12832)
Node 2: Data usage is 5%(177 32K pages of total 3200)
Node 2: Index usage is 0%(108 8K pages of total 12832)
```

This information is also available from the `ndbinfo.memoryusage` table.

• **EventLog** reports events from the event log buffers of one or more data nodes.

`report-type` is case-insensitive and “fuzzy”; for `MemoryUsage`, you can use `MEMORY` (as shown in the prior example), `memory`, or even simply `MEM` (or `mem`). You can abbreviate `BackupStatus` in a similar fashion.

• **ENTER SINGLE USER MODE node_id**

Enters single user mode, whereby only the MySQL server identified by the node ID `node_id` is permitted to access the database.

Beginning with NDB 8.0.17, the `ndb_mgm` client provides a clear acknowledgement that this command has been issued and has taken effect, as shown here:

```plaintext
ndb_mgm> ENTER SINGLE USER MODE 100
Single user mode entered
Access is granted for API node 100 only.
```

Also in NDB 8.0.17 and later, the API or SQL node having exclusive access when in single user mode is indicated in the output of the `SHOW` command, like this:

```plaintext
ndb_mgm> SHOW
Cluster Configuration
----------------------
[ndbd(NDB)]     2 node(s)
  id=5 @127.0.0.1 (mysql-8.0.17 ndb-8.0.17, single user mode, Nodegroup: 0, *)
  id=6 @127.0.0.1 (mysql-8.0.17 ndb-8.0.17, single user mode, Nodegroup: 0)

[ndb_mgmd(MGM)] 1 node(s)
  id=50 @127.0.0.1 (mysql-8.0.17 ndb-8.0.17)

[mysqld(API)]    2 node(s)
  id=100 @127.0.0.1 (mysql-8.0.17 ndb-8.0.17, allowed single user)
  id=101 (not connected, accepting connect from any host)
```

---

**Note**

All data and management nodes must be running version 8.0.17 of the NDB Cluster software for this feature to be enabled.
• **EXIT SINGLE USER MODE**

Exits single user mode, enabling all SQL nodes (that is, all running `mysqld` processes) to access the database.

**Note**

It is possible to use **EXIT SINGLE USER MODE** even when not in single user mode, although the command has no effect in this case.

• **QUIT, EXIT**

Terminates the management client.

This command does not affect any nodes connected to the cluster.

• **SHUTDOWN**

Shuts down all cluster data nodes and management nodes. To exit the management client after this has been done, use **EXIT** or **QUIT**.

This command does not shut down any SQL nodes or API nodes that are connected to the cluster.

• **CREATE NODEGROUP nodeid[, nodeid, ...]**

Creates a new NDB Cluster node group and causes data nodes to join it.

This command is used after adding new data nodes online to an NDB Cluster, and causes them to join a new node group and thus to begin participating fully in the cluster. The command takes as its sole parameter a comma-separated list of node IDs—these are the IDs of the nodes just added and started that are to join the new node group. The number of nodes must be the same as the number of nodes in each node group that is already part of the cluster (each NDB Cluster node group must have the same number of nodes). In other words, if the NDB Cluster has 2 node groups of 2 data nodes each, then the new node group must also have 2 data nodes.

The node group ID of the new node group created by this command is determined automatically, and always the next highest unused node group ID in the cluster; it is not possible to set it manually.

For more information, see Section 22.5.15, “Adding NDB Cluster Data Nodes Online”.

• **DROP NODEGROUP nodegroup_id**

Drops the NDB Cluster node group with the given `nodegroup_id`.

This command can be used to drop a node group from an NDB Cluster. **DROP NODEGROUP** takes as its sole argument the node group ID of the node group to be dropped.

**DROP NODEGROUP** acts only to remove the data nodes in the effected node group from that node group. It does not stop data nodes, assign them to a different node group, or remove them from the cluster’s configuration. A data node that does not belong to a node group is indicated in the output of the management client **SHOW** command with *no nodegroup* in place of the node group ID, like this (indicated using bold text):

```
id=3  80.100.2.67  (8.0.20-ndb-8.0.20, no nodegroup)
```

**DROP NODEGROUP** works only when all data nodes in the node group to be dropped are completely empty of any table data and table definitions. Since there is currently no way using `ndb_mgm` or the `mysql` client to remove all data from a specific data node or node group, this means that the command succeeds only in the two following cases:

1. After issuing **CREATE NODEGROUP** in the `ndb_mgm` client, but before issuing any **ALTER TABLE ... REORGANIZE PARTITION** statements in the `mysql` client.
Online Backup of NDB Cluster

2. After dropping all NDBCLUSTER tables using DROP TABLE.

   TRUNCATE TABLE does not work for this purpose because this removes only the table data; the
data nodes continue to store an NDBCLUSTER table’s definition until a DROP TABLE statement is
issued that causes the table metadata to be dropped.

   For more information about DROP NODEGROUP, see Section 22.5.15, “Adding NDB Cluster Data
Nodes Online”.

   • PROMPT [prompt]

   Changes the prompt shown by ndb_mgm to the string literal prompt.

   prompt should not be quoted (unless you want the prompt to include the quotation marks). Unlike
the case with the mysql client, special character sequences and escapes are not recognized. If
called without an argument, the command resets the prompt to the default value (ndb_mgm>).

   Some examples are shown here:

   ndb_mgm> PROMPT mgm#1:
   mgm#1: SHOW
   Cluster Configuration
   ...
   mgm#1: PROMPT mymgm >
   mymgm > PROMPT 'mymgm: '
   "mymgm:" PROMPT mymgm:
   mymgm: PROMPT
   ndb_mgm> EXIT
   jon@valhaj:/bin>

   Note that leading spaces and spaces within the prompt string are not trimmed. Trailing spaces are
removed.

   • node_id NODELOG DEBUG {ON|OFF}

   Toggles debug logging in the node log, as though the effected data node or nodes had been started
with the --verbose option. NODELOG DEBUG ON starts debug logging; NODELOG DEBUG OFF
switches debug logging off.

   Additional commands. A number of other commands available in the ndb_mgm client are
described elsewhere, as shown in the following list:

   • START BACKUP is used to perform an online backup in the ndb_mgm client; the ABORT BACKUP
command is used to cancel a backup already in progress. For more information, see Section 22.5.3,
“Online Backup of NDB Cluster”.

   • The CLUSTERLOG command is used to perform various logging functions. See Section 22.5.6, “Event
Reports Generated in NDB Cluster”, for more information and examples. NODELOG DEBUG activates
or deactivates debug printouts in node logs, as described previously in this section.

   • For testing and diagnostics work, the client supports a DUMP command which can be used to execute
internal commands on the cluster. It should never be used in a production setting unless directed to
do so by MySQL Support. For more information, see MySQL NDB Cluster Internals Manual.

22.5.3 Online Backup of NDB Cluster

The next few sections describe how to prepare for and then to create an NDB Cluster backup using
the functionality for this purpose found in the ndb_mgm management client. To distinguish this type
of backup from a backup made using mysqlDump, we sometimes refer to it as a “native” NDB
Cluster backup. (For information about the creation of backups with mysqlDump, see Section 4.5.4,
“mysqlDump — A Database Backup Program”.) Restoration of NDB Cluster backups is done using the
ndb_restore utility provided with the NDB Cluster distribution; for information about ndb_restore
Online Backup of NDB Cluster and its use in restoring NDB Cluster backups, see Section 22.4.23, “ndb_restore — Restore an NDB Cluster Backup”.

Starting with NDB 8.0.16, it is possible to create backups using multiple LDMs to achieve parallelism on the data nodes. See Section 22.5.3.5, “Taking an NDB Backup with Parallel Data Nodes”.

### 22.5.3.1 NDB Cluster Backup Concepts

A backup is a snapshot of the database at a given time. The backup consists of three main parts:

- **Metadata.** The names and definitions of all database tables
- **Table records.** The data actually stored in the database tables at the time that the backup was made
- **Transaction log.** A sequential record telling how and when data was stored in the database

Each of these parts is saved on all nodes participating in the backup. During backup, each node saves these three parts into three files on disk:

- **BACKUP-backup_id.node_id.ctl**
  
  A control file containing control information and metadata. Each node saves the same table definitions (for all tables in the cluster) to its own version of this file.

- **BACKUP-backup_id-0.node_id.data**
  
  A data file containing the table records, which are saved on a per-fragment basis. That is, different nodes save different fragments during the backup. The file saved by each node starts with a header that states the tables to which the records belong. Following the list of records there is a footer containing a checksum for all records.

- **BACKUP-backup_id.node_id.log**
  
  A log file containing records of committed transactions. Only transactions on tables stored in the backup are stored in the log. Nodes involved in the backup save different records because different nodes host different database fragments.

In the listing just shown, `backup_id` stands for the backup identifier and `node_id` is the unique identifier for the node creating the file.

The location of the backup files is determined by the `BackupDataDir` parameter.

### 22.5.3.2 Using The NDB Cluster Management Client to Create a Backup

Before starting a backup, make sure that the cluster is properly configured for performing one. (See Section 22.5.3.3, “Configuration for NDB Cluster Backups”.)

The `START BACKUP` command is used to create a backup:

```sql
START BACKUP [backup_id] [wait_option] [snapshot_option]
```

- **wait_option:**
  
  `WAIT {STARTED | COMPLETED} | NOWAIT`

- **snapshot_option:**
  
  `SNAPSHOTSTART | SNAPSHOTEND`

Successive backups are automatically identified sequentially, so the `backup_id`, an integer greater than or equal to 1, is optional; if it is omitted, the next available value is used. If an existing `backup_id` value is used, the backup fails with the error `Backup failed: file already exists`. If used, the `backup_id` must follow `START BACKUP` immediately, before any other options are used.

The `wait_option` can be used to determine when control is returned to the management client after a `START BACKUP` command is issued, as shown in the following list:
Online Backup of NDB Cluster

- If **NOWAIT** is specified, the management client displays a prompt immediately, as seen here:

  ```
  ndb_mgm> START BACKUP NOWAIT
  ndb_mgm>
  ```

  In this case, the management client can be used even while it prints progress information from the backup process.

- With **WAIT STARTED** the management client waits until the backup has started before returning control to the user, as shown here:

  ```
  ndb_mgm> START BACKUP WAIT STARTED
  Waiting for started, this may take several minutes
  Node 2: Backup 3 started from node 1
  ndb_mgm>
  ```

- **WAIT COMPLETED** causes the management client to wait until the backup process is complete before returning control to the user. **WAIT COMPLETED** is the default.

  A **snapshot_option** can be used to determine whether the backup matches the state of the cluster when **START BACKUP** was issued, or when it was completed. **SNAPSHOTSTART** causes the backup to match the state of the cluster when the backup began; **SNAPSHOTEND** causes the backup to reflect the state of the cluster when the backup was finished. **SNAPSHOTEND** is the default, and matches the behavior found in previous NDB Cluster releases.

  **Note**
  
  If you use the **SNAPSHOTSTART** option with **START BACKUP**, and the **CompressedBackup** parameter is enabled, only the data and control files are compressed—the log file is not compressed.

  If both a **wait_option** and a **snapshot_option** are used, they may be specified in either order. For example, all of the following commands are valid, assuming that there is no existing backup having 4 as its ID:

  ```
  START BACKUP WAIT STARTED SNAPSHOTSTART
  START BACKUP SNAPSHOTSTART WAIT STARTED
  START BACKUP 4 WAIT COMPLETED SNAPSHOTSTART
  START BACKUP SNAPSHOTEND WAIT COMPLETED
  START BACKUP 4 NOWAIT SNAPSHOTSTART
  ```

  The procedure for creating a backup consists of the following steps:

  1. Start the management client (**ndb_mgm**), if it not running already.

  2. Execute the **START BACKUP** command. This produces several lines of output indicating the progress of the backup, as shown here:

     ```
     ndb_mgm> START BACKUP
     Waiting for completed, this may take several minutes
     Node 2: Backup 1 started from node 1
     Node 2: Backup 1 started from node 1 completed
     StartGCP: 177 StopGCP: 180
     #Records: 7362 #LogRecords: 0
     Data: 453648 bytes Log: 0 bytes
     ndb_mgm>
     ```

  3. When the backup has started the management client displays this message:

     ```
     Backup backup_id started from node node_id
     ```

     **backup_id** is the unique identifier for this particular backup. This identifier is saved in the cluster log, if it has not been configured otherwise. **node_id** is the identifier of the management server that is coordinating the backup with the data nodes. At this point in the backup process the cluster
Online Backup of NDB Cluster

has received and processed the backup request. It does not mean that the backup has finished. An example of this statement is shown here:

Node 2: Backup 1 started from node 1

4. The management client indicates with a message like this one that the backup has started:

```
Backup backup_id started from node node_id completed
```

As is the case for the notification that the backup has started, `backup_id` is the unique identifier for this particular backup, and `node_id` is the node ID of the management server that is coordinating the backup with the data nodes. This output is accompanied by additional information including relevant global checkpoints, the number of records backed up, and the size of the data, as shown here:

```
Node 2: Backup 1 started from node 1 completed
StartGCP: 177 StopGCP: 180
#Records: 7362 #LogRecords: 0
Data: 453648 bytes Log: 0 bytes
```

It is also possible to perform a backup from the system shell by invoking `ndb_mgm` with the `-e` or `--execute` option, as shown in this example:

```
shell> ndb_mgm -e "START BACKUP 6 WAIT COMPLETED SNAPSHOTSTART"
```

When using `START BACKUP` in this way, you must specify the backup ID.

Cluster backups are created by default in the `BACKUP` subdirectory of the `DataDir` on each data node. This can be overridden for one or more data nodes individually, or for all cluster data nodes in the `config.ini` file using the `BackupDataDir` configuration parameter. The backup files created for a backup with a given `backup_id` are stored in a subdirectory named `BACKUP-backup_id` in the backup directory.

** Cancelling backups. ** To cancel or abort a backup that is already in progress, perform the following steps:

1. Start the management client.
2. Execute this command:

```
ndb_mgm> ABORT BACKUP backup_id
```

The number `backup_id` is the identifier of the backup that was included in the response of the management client when the backup was started (in the message `Backup backup_id started from node management_node_id`).

3. The management client will acknowledge the abort request with `Abort of backup backup_id ordered`.

Note

At this point, the management client has not yet received a response from the cluster data nodes to this request, and the backup has not yet actually been aborted.

4. After the backup has been aborted, the management client will report this fact in a manner similar to what is shown here:

```
Node 1: Backup 3 started from 5 has been aborted.
   Error: 1321 - Backup aborted by user request: Permanent error: User defined error
Node 3: Backup 3 started from 5 has been aborted.
   Error: 1321 - 1323: Permanent error: Internal error
Node 2: Backup 3 started from 5 has been aborted.
   Error: 1323 - 1323: Permanent error: Internal error
Node 4: Backup 3 started from 5 has been aborted.
```
In this example, we have shown sample output for a cluster with 4 data nodes, where the sequence number of the backup to be aborted is 3, and the management node to which the cluster management client is connected has the node ID 5. The first node to complete its part in aborting the backup reports that the reason for the abort was due to a request by the user. (The remaining nodes report that the backup was aborted due to an unspecified internal error.)

Note
There is no guarantee that the cluster nodes respond to an ABORT BACKUP command in any particular order.

The Backup backup_id started from node management_node_id has been aborted messages mean that the backup has been terminated and that all files relating to this backup have been removed from the cluster file system.

It is also possible to abort a backup in progress from a system shell using this command:

```
shell> ndb_mgm -e "ABORT BACKUP backup_id"
```

Note
If there is no backup having the ID backup_id running when an ABORT BACKUP is issued, the management client makes no response, nor is it indicated in the cluster log that an invalid abort command was sent.

### 22.5.3.3 Configuration for NDB Cluster Backups

Five configuration parameters are essential for backup:

- **BackupDataBufferSize**
  The amount of memory used to buffer data before it is written to disk.

- **BackupLogBufferSize**
  The amount of memory used to buffer log records before these are written to disk.

- **BackupMemory**
  The total memory allocated in a data node for backups. This should be the sum of the memory allocated for the backup data buffer and the backup log buffer.

- **BackupWriteSize**
  The default size of blocks written to disk. This applies for both the backup data buffer and the backup log buffer.

- **BackupMaxWriteSize**
  The maximum size of blocks written to disk. This applies for both the backup data buffer and the backup log buffer.

More detailed information about these parameters can be found in Backup Parameters.

You can also set a location for the backup files using the BackupDataDir configuration parameter. The default is FileSystemPath /BACKUP/BACKUP-backup_id.

### 22.5.3.4 NDB Cluster Backup Troubleshooting

If an error code is returned when issuing a backup request, the most likely cause is insufficient memory or disk space. You should check that there is enough memory allocated for the backup.
Important

If you have set `BackupDataBufferSize` and `BackupLogBufferSize` and their sum is greater than 4MB, then you must also set `BackupMemory` as well.

You should also make sure that there is sufficient space on the hard drive partition of the backup target.

**NDB** does not support repeatable reads, which can cause problems with the restoration process. Although the backup process is "hot", restoring an NDB Cluster from backup is not a 100% "hot" process. This is due to the fact that, for the duration of the restore process, running transactions get nonrepeatable reads from the restored data. This means that the state of the data is inconsistent while the restore is in progress.

### 22.5.3.5 Taking an NDB Backup with Parallel Data Nodes

Beginning with NDB 8.0.16, it is possible to take a backup with multiple local data managers (LDMs) acting in parallel on the data nodes. For this to work, all data nodes in the cluster must use multiple LDMs, and each data node must use the same number of LDMs. This means that all data nodes must run `ndbmd` (in single-threaded mode). You must use multiple LDMs if you want to use the appropriate setting for one of the multi-threaded data node configuration parameters `MaxNoOfExecutionThreads` or `ThreadConfig`. Keep in mind that changing these parameters requires a restart of the cluster; this can be a rolling restart.

Depending on the number of LDMs and other factors, you may also need to increase `NoOfFragmentLogParts`. If you are using large Disk Data tables, you may also need to increase `DiskPageBufferMemory`. As with single-threaded backups, you also want or need to make adjustments to settings for `BackupDataBufferSize`, `BackupMemory`, and other configuration parameters relating to backups (see **Backup parameters**).

Once all data nodes are using multiple LDMs, you can take the parallel backup using the `START BACKUP` command in the NDB management client just as you would if the data nodes were running `ndbd` (or `ndbmd` in single-threaded mode); no additional or special syntax is required, and you can specify a backup ID, wait option, or snapshot option in any combination as needed or desired.

Backups using multiple LDMs create subdirectories, one per LDM, under the directory `BACKUP/BACKUP-backup_id/` (which in turn resides under the `BackupDataDir`) on each data node; these subdirectories are named `BACKUP-backup_id-PART-1-OF-N/`, `BACKUP-backup_id-PART-2-OF-N/`, and so on, up to `BACKUP-backup_id-PART-N-OF-N/`, where `backup_id` is the backup ID used for this backup and `N` is the number of LDMs per data node. Each of these subdirectories contains the usual backup files `BACKUP-backup_id-0.node_id.Data`, `BACKUP-backup_id.node_id.ctl`, and `BACKUP-backup_id.node_id.log`, where `node_id` is the node ID of this data node.

In NDB 8.0.16 and later, `ndb_restore` automatically checks for the presence of the subdirectories just described; if it finds them, it attempts to restore the backup in parallel. For information about restoring backups taken with multiple LDMs, see Section 22.4.23.2, “Restoring from a backup taken in parallel”.

### 22.5.4 MySQL Server Usage for NDB Cluster

`mysqld` is the traditional MySQL server process. To be used with NDB Cluster, `mysqld` needs to be built with support for the **NDB** storage engine, as it is in the precompiled binaries available from [https://dev.mysql.com/downloads/](https://dev.mysql.com/downloads/). If you build MySQL from source, you must invoke `CMake` with the `-DBUILD_NDBCLUSTER=1` option to include support for NDB.

For more information about compiling NDB Cluster from source, see Section 22.2.2.4, “Building NDB Cluster from Source on Linux”, and Section 22.2.3.2, “Compiling and Installing NDB Cluster from Source on Windows”.
If the mysqld binary has been built with Cluster support, the NDBCLUSTER storage engine is still disabled by default. You can use either of two possible options to enable this engine:

- Use `--ndbcluster` as a startup option on the command line when starting mysqld.
- Insert a line containing `ndbcluster` in the `[mysqld]` section of your `my.cnf` file.

An easy way to verify that your server is running with the NDBCLUSTER storage engine enabled is to issue the `SHOW ENGINES` statement in the MySQL Monitor (mysql). You should see the value `YES` as the Support value in the row for NDBCLUSTER. If you see `NO` in this row or if there is no such row displayed in the output, you are not running an NDB-enabled version of MySQL. If you see `DISABLED` in this row, you need to enable it in either one of the two ways just described.

To read cluster configuration data, the MySQL server requires at a minimum three pieces of information:

- The MySQL server's own cluster node ID
- The host name or IP address for the management server (MGM node)
- The number of the TCP/IP port on which it can connect to the management server

Node IDs can be allocated dynamically, so it is not strictly necessary to specify them explicitly.

The `mysqld` parameter `ndb-connectstring` is used to specify the connection string either on the command line when starting `mysqld` or in `my.cnf`. The connection string contains the host name or IP address where the management server can be found, as well as the TCP/IP port it uses.

In the following example, `ndb_mgmd.mysql.com` is the host where the management server resides, and the management server listens for cluster messages on port 1186:

```
shell> mysqld --ndbcluster --ndb-connectstring=ndb_mgmd.mysql.com:1186
```

See Section 22.3.3.3, “NDB Cluster Connection Strings”, for more information on connection strings.

Given this information, the MySQL server will be a full participant in the cluster. (We often refer to a `mysqld` process running in this manner as an SQL node.) It will be fully aware of all cluster data nodes as well as their status, and will establish connections to all data nodes. In this case, it is able to use any data node as a transaction coordinator and to read and update node data.

You can see in the `mysql` client whether a MySQL server is connected to the cluster using `SHOW PROCESSLIST`. If the MySQL server is connected to the cluster, and you have the `PROCESS` privilege, then the first row of the output is as shown here:

```
mysql> SHOW PROCESSLIST \G
*************************** 1. row ***************************
  Id: 1
  User: system user
  Host: 
  Command: Daemon
  Time: 1
  State: Waiting for event from ndbcluster
  Info: NULL
```

**Important**

To participate in an NDB Cluster, the `mysqld` process must be started with *both* the options `--ndbcluster` and `--ndb-connectstring` (or their equivalents in `my.cnf`). If `mysqld` is started with only the `--ndbcluster` option, or if it is unable to contact the cluster, it is not possible to work with NDB tables, nor is it possible to create any new tables regardless of storage engine. The latter
Performing a Rolling Restart of an NDB Cluster

22.5.5 Performing a Rolling Restart of an NDB Cluster

This section discusses how to perform a rolling restart of an NDB Cluster installation, so called because it involves stopping and starting (or restarting) each node in turn, so that the cluster itself remains operational. This is often done as part of a rolling upgrade or rolling downgrade, where high availability of the cluster is mandatory and no downtime of the cluster as a whole is permissible. Where we refer to upgrades, the information provided here also generally applies to downgrades as well.

There are a number of reasons why a rolling restart might be desirable. These are described in the next few paragraphs.

**Configuration change.**
To make a change in the cluster's configuration, such as adding an SQL node to the cluster, or setting a configuration parameter to a new value.

**NDB Cluster software upgrade or downgrade.** To upgrade the cluster to a newer version of the NDB Cluster software (or to downgrade it to an older version). This is usually referred to as a “rolling upgrade” (or “rolling downgrade”, when reverting to an older version of NDB Cluster).

**Change on node host.** To make changes in the hardware or operating system on which one or more NDB Cluster node processes are running.

**System reset (cluster reset).**
To reset the cluster because it has reached an undesirable state. In such cases it is often desirable to reload the data and metadata of one or more data nodes. This can be done in any of three ways:

- Start each data node process (ndbd or possibly ndbmtd) with the --initial option, which forces the data node to clear its file system and to reload all NDB Cluster data and metadata from the other data nodes.

- Create a backup using the ndb_mgm client START BACKUP command prior to performing the restart. Following the upgrade, restore the node or nodes using ndb_restore.

  See Section 22.5.3, “Online Backup of NDB Cluster”, and Section 22.4.23, “ndb_restore — Restore an NDB Cluster Backup”, for more information.

- Use mysqldump to create a backup prior to the upgrade; afterward, restore the dump using LOAD DATA.

**Resource Recovery.**
To free memory previously allocated to a table by successive INSERT and DELETE operations, for reuse by other NDB Cluster tables.

The process for performing a rolling restart may be generalized as follows:

1. Stop all cluster management nodes (ndb_mgmd processes), reconfigure them, then restart them. (See Rolling restarts with multiple management servers.)

2. Stop, reconfigure, then restart each cluster data node (ndbd process) in turn.

Some node configuration parameters can be updated by issuing RESTART for each of the data nodes in the ndb_mgm client following the previous step. Other parameters require that the data node be stopped completely using the management client STOP command, then started again from a system shell by invoking the ndbd or ndbmtd executable as appropriate. (A shell command such as kill can also be used on most Unix systems to stop a data node process, but the STOP command is preferred and usually simpler.)
Event Reports Generated in NDB Cluster

Note

On Windows, you can also use `SC STOP` and `SC START` commands, `NET STOP` and `NET START` commands, or the Windows Service Manager to stop and start nodes which have been installed as Windows services (see Section 22.2.3.4, “Installing NDB Cluster Processes as Windows Services”).

The type of restart required is indicated in the documentation for each node configuration parameter. See Section 22.3.3, “NDB Cluster Configuration Files”.

3. Stop, reconfigure, then restart each cluster SQL node (`mysqld` process) in turn.

NDB Cluster supports a somewhat flexible order for upgrading nodes. When upgrading an NDB Cluster, you may upgrade API nodes (including SQL nodes) before upgrading the management nodes, data nodes, or both. In other words, you are permitted to upgrade the API and SQL nodes in any order. This is subject to the following provisions:

- This functionality is intended for use as part of an online upgrade only. A mix of node binaries from different NDB Cluster releases is neither intended nor supported for continuous, long-term use in a production setting.

- All management nodes must be upgraded before any data nodes are upgraded. This remains true regardless of the order in which you upgrade the cluster's API and SQL nodes.

- Features specific to the “new” version must not be used until all management nodes and data nodes have been upgraded.

This also applies to any MySQL Server version change that may apply, in addition to the NDB engine version change, so do not forget to take this into account when planning the upgrade. (This is true for online upgrades of NDB Cluster in general.)

It is not possible for any API node to perform schema operations (such as data definition statements) during a node restart. Due in part to this limitation, schema operations are also not supported during an online upgrade or downgrade.

**Rolling restarts with multiple management servers.** When performing a rolling restart of an NDB Cluster with multiple management nodes, you should keep in mind that `ndb_mgmd` checks to see if any other management node is running, and, if so, tries to use that node's configuration data. To keep this from occurring, and to force `ndb_mgmd` to reread its configuration file, perform the following steps:

1. Stop all NDB Cluster `ndb_mgmd` processes.

2. Update all `config.ini` files.

3. Start a single `ndb_mgmd` with `--reload`, `--initial`, or both options as desired.

4. If you started the first `ndb_mgmd` with the `--initial` option, you must also start any remaining `ndb_mgmd` processes using `--initial`.

   Regardless of any other options used when starting the first `ndb_mgmd`, you should not start any remaining `ndb_mgmd` processes after the first one using `--reload`.

5. Complete the rolling restarts of the data nodes and API nodes as normal.

When performing a rolling restart to update the cluster's configuration, you can use the `config_generation` column of the `ndbinfo.nodes` table to keep track of which data nodes have been successfully restarted with the new configuration. See Section 22.5.10.30, “The ndbinfo nodes Table”.

**22.5.6 Event Reports Generated in NDB Cluster**
In this section, we discuss the types of event logs provided by NDB Cluster, and the types of events that are logged.

NDB Cluster provides two types of event log:

- The cluster log, which includes events generated by all cluster nodes. The cluster log is the log recommended for most uses because it provides logging information for an entire cluster in a single location.

  By default, the cluster log is saved to a file named ndb_node_id_cluster.log, where node_id is the node ID of the management server in the management server’s DataDir.

  Cluster logging information can also be sent to stdout or a syslog facility in addition to or instead of being saved to a file, as determined by the values set for the DataDir and LogDestination configuration parameters. See Section 22.3.3.5, “Defining an NDB Cluster Management Server”, for more information about these parameters.

- Node logs are local to each node.

  Output generated by node event logging is written to the file ndb_node_id_out.log, where node_id is the node's node ID in the node's DataDir. Node event logs are generated for both management nodes and data nodes.

  Node logs are intended to be used only during application development, or for debugging application code.

Both types of event logs can be set to log different subsets of events.

Each reportable event can be distinguished according to three different criteria:

- **Category:** This can be any one of the following values: STARTUP, SHUTDOWN, STATISTICS, CHECKPOINT, NODERESTART, CONNECTION, ERROR, or INFO.

- **Priority:** This is represented by one of the numbers from 0 to 15 inclusive, where 0 indicates “most important” and 15 “least important.”

- **Severity Level:** This can be any one of the following values: ALERT, CRITICAL, ERROR, WARNING, INFO, or DEBUG.

Both the cluster log and the node log can be filtered on these properties.

The format used in the cluster log is as shown here:

```
2007-01-26 19:35:55 [MgmSrvr] INFO     -- Node 1: Data usage is 2% (60 32K pages of total 2560)
2007-01-26 19:35:55 [MgmSrvr] INFO     -- Node 1: Index usage is 1% (24 8K pages of total 2336)
2007-01-26 19:35:55 [MgmSrvr] INFO     -- Node 2: Data usage is 2% (76 32K pages of total 2560)
2007-01-26 19:35:55 [MgmSrvr] INFO     -- Node 2: Index usage is 1% (24 8K pages of total 2336)
2007-01-26 19:35:55 [MgmSrvr] INFO     -- Node 3: Data usage is 2% (58 32K pages of total 2560)
2007-01-26 19:35:55 [MgmSrvr] INFO     -- Node 3: Index usage is 1% (25 8K pages of total 2336)
2007-01-26 19:35:55 [MgmSrvr] INFO     -- Node 4: Data usage is 2% (78 32K pages of total 2560)
2007-01-26 19:35:55 [MgmSrvr] INFO     -- Node 4: Index usage is 1% (25 8K pages of total 2336)
```
Each line in the cluster log contains the following information:

- A timestamp in `YYYY-MM-DD HH:MM:SS` format.
- The type of node which is performing the logging. In the cluster log, this is always `[MgmSrvr]`.
- The severity of the event.
- The ID of the node reporting the event.
- A description of the event. The most common types of events to appear in the log are connections and disconnections between different nodes in the cluster, and when checkpoints occur. In some cases, the description may contain status information.

### 22.5.6.1 NDB Cluster Logging Management Commands

`ndb_mgm` supports a number of management commands related to the cluster log and node logs. In the listing that follows, `node_id` denotes either a storage node ID or the keyword `ALL`, which indicates that the command should be applied to all of the cluster's data nodes.

- **CLUSTERLOG ON**
  
  Turns the cluster log on.

- **CLUSTERLOG OFF**
  
  Turns the cluster log off.

- **CLUSTERLOG INFO**
  
  Provides information about cluster log settings.

- **node_id CLUSTERLOG category=threshold**
  
  Logs `category` events with priority less than or equal to `threshold` in the cluster log.

- **CLUSTERLOG FILTER severity_level**
  
  Toggles cluster logging of events of the specified `severity_level`.

The following table describes the default setting (for all data nodes) of the cluster log category threshold. If an event has a priority with a value lower than or equal to the priority threshold, it is reported in the cluster log.

<table>
<thead>
<tr>
<th>Category</th>
<th>Default threshold (All data nodes)</th>
</tr>
</thead>
<tbody>
<tr>
<td>STARTUP</td>
<td>7</td>
</tr>
<tr>
<td>SHUTDOWN</td>
<td>7</td>
</tr>
<tr>
<td>STATISTICS</td>
<td>7</td>
</tr>
<tr>
<td>CHECKPOINT</td>
<td>7</td>
</tr>
<tr>
<td>NODERESTART</td>
<td>7</td>
</tr>
<tr>
<td>CONNECTION</td>
<td>7</td>
</tr>
<tr>
<td>ERROR</td>
<td>15</td>
</tr>
<tr>
<td>INFO</td>
<td>7</td>
</tr>
</tbody>
</table>

**Note**

Events are reported per data node, and that the threshold can be set to different values on different nodes.
The **STATISTICS** category can provide a great deal of useful data. See Section 22.5.6.3, “Using CLUSTERLOG STATISTICS in the NDB Cluster Management Client”, for more information.

Thresholds are used to filter events within each category. For example, a **STARTUP** event with a priority of 3 is not logged unless the threshold for **STARTUP** is set to 3 or higher. Only events with priority 3 or lower are sent if the threshold is 3.

The following table shows the event severity levels.

**Note**

These correspond to Unix **syslog** levels, except for **LOG_EMERG** and **LOG_NOTICE**, which are not used or mapped.

<table>
<thead>
<tr>
<th>Severity Level Value</th>
<th>Severity</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>ALERT</td>
<td>A condition that should be corrected immediately, such as a corrupted system database</td>
</tr>
<tr>
<td>2</td>
<td>CRITICAL</td>
<td>Critical conditions, such as device errors or insufficient resources</td>
</tr>
<tr>
<td>3</td>
<td>ERROR</td>
<td>Conditions that should be corrected, such as configuration errors</td>
</tr>
<tr>
<td>4</td>
<td>WARNING</td>
<td>Conditions that are not errors, but that might require special handling</td>
</tr>
<tr>
<td>5</td>
<td>INFO</td>
<td>Informational messages</td>
</tr>
<tr>
<td>6</td>
<td>DEBUG</td>
<td>Debugging messages used for NDBCLUSTER development</td>
</tr>
</tbody>
</table>

Event severity levels can be turned on or off (using **CLUSTERLOG FILTER**—see above). If a severity level is turned on, then all events with a priority less than or equal to the category thresholds are logged. If the severity level is turned off then no events belonging to that severity level are logged.

**Important**

Cluster log levels are set on a per **ndb_mgmd**, per subscriber basis. This means that, in an NDB Cluster with multiple management servers, using a **CLUSTERLOG** command in an instance of **ndb_mgm** connected to one management server affects only logs generated by that management server but not by any of the others. This also means that, should one of the management servers be restarted, only logs generated by that management server are affected by the resetting of log levels caused by the restart.

### 22.5.6.2 NDB Cluster Log Events

An event report reported in the event logs has the following format:

`datetime [string] severity -- message`

For example:

```
```

This section discusses all reportable events, ordered by category and severity level within each category.

In the event descriptions, **GCP and LCP** mean “Global Checkpoint” and “Local Checkpoint”, respectively.
### CONNECTION Events

These events are associated with connections between Cluster nodes.

**Table 22.281 Events associated with connections between cluster nodes**

<table>
<thead>
<tr>
<th>Event</th>
<th>Priority</th>
<th>Severity Level</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Connected</td>
<td>8</td>
<td>INFO</td>
<td>Data nodes connected</td>
</tr>
<tr>
<td>Disconnected</td>
<td>8</td>
<td>ALERT</td>
<td>Data nodes disconnected</td>
</tr>
<tr>
<td>CommunicationClosed</td>
<td>8</td>
<td>INFO</td>
<td>SQL node or data node connection closed</td>
</tr>
<tr>
<td>CommunicationOpened</td>
<td>8</td>
<td>INFO</td>
<td>SQL node or data node connection open</td>
</tr>
<tr>
<td>ConnectedApiVersion</td>
<td>8</td>
<td>INFO</td>
<td>Connection using API version</td>
</tr>
</tbody>
</table>

### CHECKPOINT Events

The logging messages shown here are associated with checkpoints.

**Table 22.282 Events associated with checkpoints**

<table>
<thead>
<tr>
<th>Event</th>
<th>Priority</th>
<th>Severity Level</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlobalCheckpointStarted</td>

<td>ALERT</td>
<td>LCP stopped</td>
</tr>
<tr>
<td>LCPFragmmentCompleted</td>
<td>11</td>
<td>INFO</td>
<td>LCP on a fragment has been completed</td>
</tr>
<tr>
<td>UndoLogBlocked</td>
<td>7</td>
<td>INFO</td>
<td>UNDO logging blocked; buffer near overflow</td>
</tr>
<tr>
<td>RedoStatus</td>
<td>7</td>
<td>INFO</td>
<td>Redo status</td>
</tr>
</tbody>
</table>

### STARTUP Events

The following events are generated in response to the startup of a node or of the cluster and of its success or failure. They also provide information relating to the progress of the startup process, including information concerning logging activities.

**Table 22.283 Events relating to the startup of a node or cluster**

<table>
<thead>
<tr>
<th>Event</th>
<th>Priority</th>
<th>Severity Level</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDBStartStarted</td>

22.5.6.3 Using CLUSTERLOG STATISTICS in the NDB Cluster Management Client

The NDB management client's CLUSTERLOG STATISTICS command can provide a number of useful statistics in its output. Counters providing information about the state of the cluster are updated at 5-second reporting intervals by the transaction coordinator (TC) and the local query handler (LQH), and written to the cluster log.

Transaction coordinator statistics. Each transaction has one transaction coordinator, which is chosen by one of the following methods:

• In a round-robin fashion
• By communication proximity
• By supplying a data placement hint when the transaction is started

Note
You can determine which TC selection method is used for transactions started from a given SQL node using the ndb_optimized_node_selection system variable.

All operations within the same transaction use the same transaction coordinator, which reports the following statistics:
• **Trans count.** This is the number transactions started in the last interval using this TC as the transaction coordinator. Any of these transactions may have committed, have been aborted, or remain uncommitted at the end of the reporting interval.

  [Note]
  Transactions do not migrate between TCs.

• **Commit count.** This is the number of transactions using this TC as the transaction coordinator that were committed in the last reporting interval. Because some transactions committed in this reporting interval may have started in a previous reporting interval, it is possible for Commit count to be greater than Trans count.

• **Read count.** This is the number of primary key read operations using this TC as the transaction coordinator that were started in the last reporting interval, including simple reads. This count also includes reads performed as part of unique index operations. A unique index read operation generates 2 primary key read operations—one for the hidden unique index table, and 1 for the table on which the read takes place.

• **Simple read count.** This is the number of simple read operations using this TC as the transaction coordinator that were started in the last reporting interval.

• **Write count.** This is the number of primary key write operations using this TC as the transaction coordinator that were started in the last reporting interval. This includes all inserts, updates, writes and deletes, as well as writes performed as part of unique index operations.

  [Note]
  A unique index update operation can generate multiple PK read and write operations on the index table and on the base table.

• **AttrInfoCount.** This is the number of 32-bit data words received in the last reporting interval for primary key operations using this TC as the transaction coordinator. For reads, this is proportional to the number of columns requested. For inserts and updates, this is proportional to the number of columns written, and the size of their data. For delete operations, this is usually zero.

  Unique index operations generate multiple PK operations and so increase this count. However, data words sent to describe the PK operation itself, and the key information sent, are not counted here. Attribute information sent to describe columns to read for scans, or to describe ScanFilters, is also not counted in AttrInfoCount.

• **Concurrent Operations.** This is the number of primary key or scan operations using this TC as the transaction coordinator that were started during the last reporting interval but that were not completed. Operations increment this counter when they are started and decrement it when they are completed; this occurs after the transaction commits. Dirty reads and writes—as well as failed operations—decrement this counter.

  The maximum value that Concurrent Operations can have is the maximum number of operations that a TC block can support; currently, this is $(2 \times \text{MaxNoOfConcurrentOperations}) + 16 + \text{MaxNoOfConcurrentTransactions}$. (For more information about these configuration parameters, see the Transaction Parameters section of Section 22.3.3.6, “Defining NDB Cluster Data Nodes”.)

• **Abort count.** This is the number of transactions using this TC as the transaction coordinator that were aborted during the last reporting interval. Because some transactions that were aborted in the last reporting interval may have started in a previous reporting interval, Abort count can sometimes be greater than Trans count.

• **Scans.** This is the number of table scans using this TC as the transaction coordinator that were started during the last reporting interval. This does not include range scans (that is, ordered index scans).
• **Range scans.** This is the number of ordered index scans using this TC as the transaction coordinator that were started in the last reporting interval.

• **Local reads.** This is the number of primary-key read operations performed using a transaction coordinator on a node that also holds the primary replica of the record. This count can also be obtained from the `LOCAL_READS` counter in the `ndbinfo.counters` table.

• **Local writes.** This contains the number of primary-key read operations that were performed using a transaction coordinator on a node that also holds the primary replica of the record. This count can also be obtained from the `LOCAL_WRITES` counter in the `ndbinfo.counters` table.

**Local query handler statistics (Operations).** There is 1 cluster event per local query handler block (that is, 1 per data node process). Operations are recorded in the LQH where the data they are operating on resides.

**Note**

A single transaction may operate on data stored in multiple LQH blocks.

The `Operations` statistic provides the number of local operations performed by this LQH block in the last reporting interval, and includes all types of read and write operations (insert, update, write, and delete operations). This also includes operations used to replicate writes. For example, in a 2-replica cluster, the write to the primary replica is recorded in the primary LQH, and the write to the backup will be recorded in the backup LQH. Unique key operations may result in multiple local operations; however, this does not include local operations generated as a result of a table scan or ordered index scan, which are not counted.

**Process scheduler statistics.** In addition to the statistics reported by the transaction coordinator and local query handler, each `ndbd` process has a scheduler which also provides useful metrics relating to the performance of an NDB Cluster. This scheduler runs in an infinite loop; during each loop the scheduler performs the following tasks:

1. Read any incoming messages from sockets into a job buffer.
2. Check whether there are any timed messages to be executed; if so, put these into the job buffer as well.
3. Execute (in a loop) any messages in the job buffer.
4. Send any distributed messages that were generated by executing the messages in the job buffer.
5. Wait for any new incoming messages.

Process scheduler statistics include the following:

• **Mean Loop Counter.** This is the number of loops executed in the third step from the preceding list. This statistic increases in size as the utilization of the TCP/IP buffer improves. You can use this to monitor changes in performance as you add new data node processes.

• **Mean send size and Mean receive size.** These statistics enable you to gauge the efficiency of, respectively writes and reads between nodes. The values are given in bytes. Higher values mean a lower cost per byte sent or received; the maximum value is 64K.

To cause all cluster log statistics to be logged, you can use the following command in the NDB management client:

```
ndb_mgm> ALL CLUSTERLOG STATISTICS=15
```

**Note**

Setting the threshold for `STATISTICS` to 15 causes the cluster log to become very verbose, and to grow quite rapidly in size, in direct proportion to the number of cluster nodes and the amount of activity in the NDB Cluster.
For more information about NDB Cluster management client commands relating to logging and reporting, see Section 22.5.6.1, “NDB Cluster Logging Management Commands”.

22.5.7 NDB Cluster Log Messages

This section contains information about the messages written to the cluster log in response to different cluster log events. It provides additional, more specific information on NDB transporter errors.

22.5.7.1 NDB Cluster: Messages in the Cluster Log

The following table lists the most common NDB cluster log messages. For information about the cluster log, log events, and event types, see Section 22.5.6, “Event Reports Generated in NDB Cluster”. These log messages also correspond to log event types in the MGM API; see The Ndb_logevent_type Type, for related information of interest to Cluster API developers.

Table 22.291 Common NDB cluster log messages

**22.5.7.2 NDB Cluster Log Startup Messages**

Possible startup messages with descriptions are provided in the following list:

- Initial start, waiting for %s to connect, nodes [ all: %s connected: %s no-wait: %s ]
- Waiting until nodes: %s connects, nodes [ all: %s connected: %s no-wait: %s ]
- Waiting %u sec for nodes %s to connect, nodes [ all: %s connected: %s no-wait: %s ]
- Waiting for non partitioned start, nodes [ all: %s connected: %s missing: %s no-wait: %s ]
- Waiting %u sec for non partitioned start, nodes [ all: %s connected: %s missing: %s no-wait: %s ]
- Initial start with nodes %s [ missing: %s no-wait: %s ]
- Start with all nodes %s
- Start with nodes %s [ missing: %s no-wait: %s ]
- Start potentially partitioned with nodes %s [ missing: %s no-wait: %s ]
- Unknown start report: 0x%x [ %s %s %s %s ]

**22.5.7.3 Event Buffer Reporting in the Cluster Log**

NDB uses one or more memory buffers for events received from the data nodes. There is one such buffer for each Ndb object subscribing to table events, which means that there are usually two buffers for each mysqld performing binary logging (one buffer for schema events, and one for data events). Each buffer contains epochs made up of events. These events consist of operation types (insert, update, delete) and row data (before and after images plus metadata).

NDB generates messages in the cluster log to describe the state of these buffers. Although these reports appear in the cluster log, they refer to buffers on API nodes (unlike most other cluster log messages, which are generated by data nodes).

Event buffer logging reports in the cluster log use the format shown here:

Node node_id: Event buffer status (object_id):
used=bytes_used (percent_used% of alloc)
alloc=bytes_allocated (percent_alloc% of max) max=bytes_available
latest_consumed_epoch=latest_consumed_epoch
latest_buffered_epoch=latest_buffered_epoch
report_reason=report_reason
The fields making up this report are listed here, with descriptions:

- **node_id**: ID of the node where the report originated.
- **object_id**: ID of the Ndb object where the report originated.
- **bytes_used**: Number of bytes used by the buffer.
- **percent_used**: Percentage of allocated bytes used.
- **bytes_allocated**: Number of bytes allocated to this buffer.
- **percent_alloc**: Percentage of available bytes used; not printed if `ndb_eventbuffer_max_alloc` is equal to 0 (unlimited).
- **bytes_available**: Number of bytes available; this is 0 if `ndb_eventbuffer_max_alloc` is 0 (unlimited).
- **latest_consumed_epoch**: The epoch most recently consumed to completion. (In NDB API applications, this is done by calling `nextEvent()`.)
- **latest_buffered_epoch**: The epoch most recently buffered (completely) in the event buffer.
- **report_reason**: The reason for making the report. Possible reasons are shown later in this section.

Possible reasons for reporting are described in the following list:

- **ENOUGH_FREE_EVENTBUFFER**: The event buffer has sufficient space.
- **LOW_FREE_EVENTBUFFER**: The event buffer is running low on free space.

The threshold free percentage level triggering these reports can be adjusted by setting the `ndb_report_thresh_binlog_mem_usage` server variable.

- **BUFFERED_EPOCHS_OVER_THRESHOLD**: Whether the number of buffered epochs has exceeded the configured threshold. This number is the difference between the latest epoch that has been received in its entirety and the epoch that has most recently been consumed (in NDB API applications, this is done by calling `nextEvent()` or `nextEvent2()`). The report is generated every second until the number of buffered epochs goes below the threshold, which can be adjusted by setting the `ndb_report_thresh_binlog_epoch_slip` server variable. You can also adjust the threshold in NDB API applications by calling `setEventBufferQueueEmptyEpoch()`.

- **PARTIALLY_DISCARDING**: Event buffer memory is exhausted—that is, 100% of `ndb_eventbuffer_max_alloc` has been used. Any partially buffered epoch is buffered to completion even if usage exceeds 100%, but any new epochs received are discarded. This means that a gap has occurred in the event stream.

- **COMPLETELY_DISCARDING**: No epochs are buffered.

- **PARTIALLY_BUFFERING**: The buffer free percentage following the gap has risen to the threshold, which can be set in the `mysql` client using the `ndb_eventbuffer_free_percent` server system variable or in NDB API applications by calling `set_eventbuffer_free_percent()`. New epochs are buffered. Epochs that could not be completed due to the gap are discarded.

- **COMPLETELY_BUFFERING**: All epochs received are being buffered, which means that there is sufficient event buffer memory. The gap in the event stream has been closed.

22.5.7.4 NDB Cluster: NDB Transporter Errors

This section lists error codes, names, and messages that are written to the cluster log in the event of transporter errors.
<table>
<thead>
<tr>
<th>Code</th>
<th>Error Message</th>

Note
Transporter error codes 0x17 through 0x20 and 0x22 are reserved for SCI connections, which are not supported in this version of NDB Cluster, and so are not included here.

22.5.8 NDB Cluster Single User Mode

Single user mode enables the database administrator to restrict access to the database system to a single API node, such as a MySQL server (SQL node) or an instance of ndb_restore. When entering single user mode, connections to all other API nodes are closed gracefully and all running transactions are aborted. No new transactions are permitted to start.

Once the cluster has entered single user mode, only the designated API node is granted access to the database.

You can use the ALL STATUS command in the ndb_mgm client to see when the cluster has entered single user mode. You can also check the status column of the ndbinfo.nodes table (see Section 22.5.10.30, “The ndbinfo nodes Table”, for more information).

Example:

```
ndb_mgm> ENTER SINGLE USER MODE 5
```

After this command has executed and the cluster has entered single user mode, the API node whose node ID is 5 becomes the cluster’s only permitted user.

The node specified in the preceding command must be an API node; attempting to specify any other type of node will be rejected.

Note
When the preceding command is invoked, all transactions running on the designated node are aborted, the connection is closed, and the server must be restarted.

The command EXIT SINGLE USER MODE changes the state of the cluster’s data nodes from single user mode to normal mode. API nodes—such as MySQL Servers—waiting for a connection (that is,
waiting for the cluster to become ready and available), are again permitted to connect. The API node
denoted as the single-user node continues to run (if still connected) during and after the state change.

Example:

```sql
ndb_mgm> EXIT SINGLE USER MODE
```

There are two recommended ways to handle a node failure when running in single user mode:

- **Method 1:**
  1. Finish all single user mode transactions
  2. Issue the `EXIT SINGLE USER MODE` command
  3. Restart the cluster's data nodes

- **Method 2:**
  Restart storage nodes prior to entering single user mode.

### 22.5.9 Quick Reference: NDB Cluster SQL Statements

This section discusses several SQL statements that can prove useful in managing and monitoring a
MySQL server that is connected to an NDB Cluster, and in some cases provide information about the
cluster itself.

- **SHOW ENGINE NDB STATUS, SHOW ENGINE NDBCLUSTER STATUS**

  The output of this statement contains information about the server's connection to the cluster,
  creation and usage of NDB Cluster objects, and binary logging for NDB Cluster replication.

  See Section 13.7.7.15, “SHOW ENGINE Statement”, for a usage example and more detailed
  information.

- **SHOW ENGINES**

  This statement can be used to determine whether or not clustering support is enabled in the MySQL
  server, and if so, whether it is active.

  See Section 13.7.7.16, “SHOW ENGINES Statement”, for more detailed information.

  **Note**

  This statement does not support a `LIKE` clause. However, you can use `LIKE` to filter queries against the `INFORMATION_SCHEMA.ENGINES` table, as discussed in the next item.

- **SELECT * FROM INFORMATION_SCHEMA.ENGINES [WHERE ENGINE LIKE 'NDB%']**

  This is the equivalent of `SHOW ENGINES`, but uses the `ENGINES` table of the
  `INFORMATION_SCHEMA` database. Unlike the case with the `SHOW ENGINES` statement, it is possible
to filter the results using a `LIKE` clause, and to select specific columns to obtain information that may
be of use in scripts. For example, the following query shows whether the server was built with NDB
support and, if so, whether it is enabled:

  ```sql
  mysql> SELECT SUPPORT FROM INFORMATION_SCHEMA.ENGINES
    WHERE ENGINE LIKE 'NDB%';
  +-----------+
  | support   |
  +-----------+
  | ENABLED    |
  +-----------+
  ```
See Section 25.12, “The INFORMATION_SCHEMA ENGINES Table”, for more information.

- **SHOW VARIABLES LIKE 'NDB%'**

This statement provides a list of most server system variables relating to the NDB storage engine, and their values, as shown here:

```sql
mysql> SHOW VARIABLES LIKE 'NDB%';
+--------------------------+-------------------+
| Variable_name             | Value             |
|--------------------------+-------------------+
| ndb_allow_copying_alter_table | ON               |
| ndb_autoincrement_prefetch_sz | 512              |

See Section 5.1.8, “Server System Variables”, for more information.

- **SELECT * FROM performance_schema.global_variables WHERE VARIABLE_NAME LIKE 'NDB%'**

This statement is the equivalent of the **SHOW VARIABLES** statement described in the previous item, and provides almost identical output, as shown here:

```sql
mysql> SELECT * FROM performance_schema.global_variables
    -> WHERE VARIABLE_NAME LIKE 'NDB%';
+--------------------------------------|---------------------------------------|
| VARIABLE_NAME                        | VARIABLE_VALUE                        |
+--------------------------------------|---------------------------------------|
| ndb_allow_copying_alter_table        | ON                                    |
| ndb_autoincrement_prefetch_sz        | 512                                   |
| ndb_batch_size                       | 32768                                 |
| ndb_blob_read_batch_bytes            | 65536                                 |

| ndb_log_exclusive_reads              | OFF                                   |
| ndb_log_orig                         | OFF                                   |
| ndb_log_transaction_id               | OFF                                   |
| ndb_log_update_as_write              | ON                                    |
| ndb_log_update_minimal               | OFF                                   |
| ndb_log_updated_only                 | ON                                    |
| ndb_metadata_check                   | ON                                    |
| ndb_metadata_check_interval          | 60                                    |
| ndb_metadata_sync                    | OFF                                   |
| ndb_mgmd_host                        | 127.0.0.1                             |
| ndbnodeid                            | 0                                     |
| ndb_optimization_delay               | 10                                    |
| ndb_optimized_node_selection         | 3                                     |
| ndb_read_backup                      | ON                                    |
| ndb_recv_thread_activation_threshold | 8                                     |
| ndb_recv_thread_cpu_mask             |                                       |
| ndb_report_thresh_binlog_epoch_slip  | 10                                    |
Unlike the case with the `SHOW VARIABLES` statement, it is possible to select individual columns. For example:

```sql
mysql> SELECT VARIABLE_VALUE
-> FROM performance_schema.global_variables
-> WHERE VARIABLE_NAME = 'ndb_force_send';
+----------------+
| VARIABLE_VALUE |
+----------------+
| ON             |
+----------------+
```

A more useful query is shown here:

```sql
mysql> SELECT VARIABLE_NAME AS Name, VARIABLE_VALUE AS Value
-> FROM performance_schema.global_variables
-> WHERE VARIABLE_NAME
-> IN ('version', 'ndb_version',
->     'ndb_version_string', 'ndbinfo_version');
```

For more information, see Section 26.12.15, “Performance Schema Status Variable Tables”, and Section 5.1.8, “Server System Variables”.

- **SHOW STATUS LIKE 'NDB%'**

This statement shows at a glance whether or not the MySQL server is acting as a cluster SQL node, and if so, provides the MySQL server’s cluster node ID, the host name and port for the cluster management server to which it is connected, and the number of data nodes in the cluster, as shown here:

```sql
mysql> SHOW STATUS LIKE 'NDB%';
```

If the MySQL server was built with clustering support, but it is not connected to a cluster, every row in the output of this statement contains a zero or an empty string for the Value column.

See also Section 13.7.7.35, “SHOW STATUS Statement”.

- SELECT * FROM performance_schema.global_status WHERE VARIABLE_NAME LIKE 'NDB%'

This statement provides similar output to the SHOW STATUS statement discussed in the previous item. Unlike the case with SHOW STATUS, it is possible using SELECT statements to extract values in SQL for use in scripts for monitoring and automation purposes.

For more information, see Section 26.12.15, “Performance Schema Status Variable Tables”.

- SELECT * FROM INFORMATION_SCHEMA.PLUGINS WHERE PLUGIN_NAME LIKE 'NDB%'

This statement displays information from the INFORMATION_SCHEMA.PLUGINS table about plugins associated with NDB Cluster, such as version, author, and license, as shown here:

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.PLUGINS
> WHERE PLUGIN_NAME LIKE 'NDB%'\G
3961
```
**ndbinfo: The NDB Cluster Information Database**

---

You can also use the `SHOW PLUGINS` statement to display this information, but the output from that statement cannot easily be filtered. See also Section 29.2, “The MySQL Plugin API”, which describes where and how the information in the `PLUGINS` table is obtained.

You can also query the tables in the `ndbinfo` information database for real-time data about many NDB Cluster operations. See Section 22.5.10, “ndbinfo: The NDB Cluster Information Database”.

## 22.5.10 ndbinfo: The NDB Cluster Information Database

`ndbinfo` is a database containing information specific to NDB Cluster.

This database contains a number of tables, each providing a different sort of data about NDB Cluster node status, resource usage, and operations. You can find more detailed information about each of these tables in the next several sections.

`ndbinfo` is included with NDB Cluster support in the MySQL Server; no special compilation or configuration steps are required; the tables are created by the MySQL Server when it connects to the cluster. You can verify that `ndbinfo` support is active in a given MySQL Server instance using `SHOW PLUGINS`; if `ndbinfo` support is enabled, you should see a row containing `ndbinfo` in the Name column and `ACTIVE` in the Status column, as shown here (emphasized text):

```
mysql> SHOW PLUGINS;
+----------------------------------+--------+--------------------+---------+---------+
| Name                             | Status | Type               | Library | License |
+----------------------------------+--------+--------------------+---------+---------+
| binlog                           | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| mysql_native_password            | ACTIVE | AUTHENTICATION     | NULL    | GPL     |
| sha256_password                  | ACTIVE | AUTHENTICATION     | NULL    | GPL     |
| MRG_MYISAM                       | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| MEMORY                           | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
+----------------------------------+--------+--------------------+---------+---------+
```
You can also do this by checking the output of `SHOW ENGINES` for a line including `ndbinfo` in the `Engine` column and `YES` in the `Support` column, as shown here (emphasized text):

```
mysql> SHOW ENGINES;
+----------------+--------------------+---------+---------+
| Name           | Storage Engine     | Support | Comment |
|----------------+--------------------+---------+---------+
| ndbinfo        | ACTION              | NULL    | GPL     |
| ndbCluster     | ACTION              | NULL    | GPL     |
| ndbinfo        | ACTION              | NULL    | GPL     |
| ndb_transid_mysql_connection_map | ACTION | NULL | GPL |
| BLACKHOLE      | ACTION              | NULL    | GPL     |
| ARCHIVE        | ACTION              | NULL    | GPL     |
| partition      | ACTION              | NULL    | GPL     |
| ngram          | ACTION              | FTPARSER | NULL |
+----------------+--------------------+---------+---------+
```

46 rows in set (0.00 sec)
**ndbinfo: The NDB Cluster Information Database**

<table>
<thead>
<tr>
<th>Engine</th>
<th>Support</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>

</tbody>
</table>

If **ndbinfo** support is enabled, then you can access **ndbinfo** using SQL statements in **mysql** or another MySQL client. For example, you can see **ndbinfo** listed in the output of **SHOW DATABASES**, as shown here (emphasized text):

```
mysql> SHOW DATABASES;
+--------------------+
| Database           |
+--------------------+
| information_schema |
| mysql              |
| ndbinfo            |
| performance_schema |
| sys                |
+--------------------+
5 rows in set (0.04 sec)
```

If the **mysqld** process was not started with the **--ndbcluster** option, **ndbinfo** is not available and is not displayed by **SHOW DATABASES**. If **mysqld** was formerly connected to an NDB Cluster but the cluster becomes unavailable (due to events such as cluster shutdown, loss of network connectivity, and so forth), **ndbinfo** and its tables remain visible, but an attempt to access any tables (other than **blocks** or **config_params**) fails with **Got error 157 'Connection to NDB failed' from NDBINFO**.
With the exception of the `blocks` and `config_params` tables, what we refer to as `ndbinfo` “tables” are actually views generated from internal NDB tables not normally visible to the MySQL Server.

All `ndbinfo` tables are read-only, and are generated on demand when queried. Because many of them are generated in parallel by the data nodes while other are specific to a given SQL node, they are not guaranteed to provide a consistent snapshot.

In addition, pushing down of joins is not supported on `ndbinfo` tables; so joining large `ndbinfo` tables can require transfer of a large amount of data to the requesting API node, even when the query makes use of a `WHERE` clause.

`ndbinfo` tables are not included in the query cache. (Bug #59831)

You can select the `ndbinfo` database with a `USE` statement, and then issue a `SHOW TABLES` statement to obtain a list of tables, just as for any other database, like this:

```
mysql> USE ndbinfo;
Database changed
mysql> SHOW TABLES;
+---------------------------------+
| Tables_in_ndbinfo               |
+---------------------------------+
<p>| arbitrator_validity_detail      |
| arbitrator_validity_summary     |

<table>
<thead>
<tr>
<th>transporters</th>
</tr>
</thead>
</table>
44 rows in set (0.00 sec)
```
In NDB 8.0, all ndbinfo tables use the NDB storage engine; however, an ndbinfo entry still appears in the output of `SHOW ENGINES` and `SHOW PLUGINS` as described previously.

You can execute `SELECT` statements against these tables, just as you would normally expect:

```
mysql> SELECT * FROM memoryusage;
+---------+---------------------+--------+------------+------------+-------------+
| node_id | memory_type         | used   | used_pages | total      | total_pages |
+---------+---------------------+--------+------------+------------+-------------+
|       5 | Data memory         | 753664 |         23 | 1073741824 |       32768 |
|       5 | Index memory        | 163840 |         20 | 1074003968 |      131104 |
|       5 | Long message buffer |   2304 |          9 |   67108864 |      262144 |
|       6 | Data memory         | 753664 |         23 | 1073741824 |       32768 |
|       6 | Index memory        | 163840 |         20 | 1074003968 |      131104 |
|       6 | Long message buffer |   2304 |          9 |   67108864 |      262144 |
+---------+---------------------+--------+------------+------------+-------------+
6 rows in set (0.02 sec)
```

More complex queries, such as the two following `SELECT` statements using the `memoryusage` table, are possible:

```
mysql> SELECT SUM(used) as 'Data Memory Used, All Nodes'
    -> FROM memoryusage
    -> WHERE memory_type = 'Data memory';
+-----------------------------+
| Data Memory Used, All Nodes |
+-----------------------------+
|                        6460 |
+-----------------------------+
1 row in set (0.37 sec)
```

```
mysql> SELECT SUM(max) as 'Total IndexMemory Available'
    -> FROM memoryusage
    -> WHERE memory_type = 'Index memory';
+-----------------------------+
| Total IndexMemory Available |
+-----------------------------+
|                     25664 |
+-----------------------------+
1 row in set (0.33 sec)
```

The `ndbinfo` table and column names are case sensitive (as is the name of the `ndbinfo` database itself). These identifiers are in lowercase. Trying to use the wrong lettercase results in an error, as shown in this example:

```
mysql> SELECT * FROM nodes;
+---------+--------+---------+-------------+
| node_id | uptime | status  | start_phase |
+---------+--------+---------+-------------+
|       1 |  13602 | STARTED |           0 |
|       2 |     16 | STARTED |           0 |
+---------+--------+---------+-------------+
2 rows in set (0.04 sec)
```

```
mysql> SELECT * FROM Nodes;
ERROR 1146 (42S02): Table 'ndbinfo.Nodes' doesn't exist
```

`mysqldump` ignores the `ndbinfo` database entirely, and excludes it from any output. This is true even when using the `--databases` or `--all-databases` option.

NDB Cluster also maintains tables in the `INFORMATION_SCHEMA` information database, including the `FILES` table which contains information about files used for NDB Cluster Disk Data storage, and the `ndb_transid_mysql_connection_map` table, which shows the relationships between transactions, transaction coordinators, and NDB Cluster API nodes. For more information, see the descriptions of the tables or Section 22.5.11, “INFORMATION_SCHEMA Tables for NDB Cluster”.

### 22.5.10.1 The ndbinfo arbitrator_validity_detail Table
The `arbitrator_validity_detail` table shows the view that each data node in the cluster has of the arbitrator. It is a subset of the `membership` table.

The following table provides information about the columns in the `arbitrator_validity_detail` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

**Table 22.292 Columns of the arbitrator_validity_detail table**

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>node_id</td>
<td>integer</td>
<td>This node's node ID</td>
</tr>
<tr>
<td>arbitrator</td>
<td>integer</td>
<td>Node ID of arbitrator</td>
</tr>
<tr>
<td>arb_ticket</td>
<td>string</td>
<td>Internal identifier used to track arbitration</td>
</tr>
<tr>
<td>arb_connected</td>
<td>Yes or No</td>
<td>Whether this node is connected to the arbitrator</td>
</tr>
<tr>
<td>arb_state</td>
<td>Enumeration (see text)</td>
<td>Arbitration state</td>
</tr>
</tbody>
</table>

The node ID is the same as that reported by `ndb_mgm -e "SHOW"`.

All nodes should show the same `arbitrator` and `arb_ticket` values as well as the same `arb_state` value. Possible `arb_state` values are `ARBIT_NULL`, `ARBIT_INIT`, `ARBIT_FIND`, `ARBIT_PREP1`, `ARBIT_PREP2`, `ARBIT_START`, `ARBIT_RUN`, `ARBIT_CHOOSE`, `ARBIT_CRASH`, and `UNKNOWN`.

`arb_connected` shows whether the current node is connected to the arbitrator.

22.5.10.2 The ndbinfo arbitrator_validity_summary Table

The `arbitrator_validity_summary` table provides a composite view of the arbitrator with regard to the cluster's data nodes.

The following table provides information about the columns in the `arbitrator_validity_summary` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

**Table 22.293 Columns of the arbitrator_validity_summary table**

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>arbitrator</td>
<td>integer</td>
<td>Node ID of arbitrator</td>
</tr>
<tr>
<td>arb_ticket</td>
<td>string</td>
<td>Internal identifier used to track arbitration</td>
</tr>
<tr>
<td>arb_connected</td>
<td>Yes or No</td>
<td>Whether this arbitrator is connected to the cluster</td>
</tr>
<tr>
<td>consensus_count</td>
<td>integer</td>
<td>Number of data nodes that see this node as arbitrator</td>
</tr>
</tbody>
</table>

In normal operations, this table should have only 1 row for any appreciable length of time. If it has more than 1 row for longer than a few moments, then either not all nodes are connected to the arbitrator, or all nodes are connected, but do not agree on the same arbitrator.

The `arbitrator` column shows the arbitrator's node ID.

`arb_ticket` is the internal identifier used by this arbitrator.

`arb_connected` shows whether this node is connected to the cluster as an arbitrator.

22.5.10.3 The ndbinfo blocks Table
The blocks table is a static table which simply contains the names and internal IDs of all NDB kernel blocks (see NDB Kernel Blocks). It is for use by the other ndbinfo tables (most of which are actually views) in mapping block numbers to block names for producing human-readable output.

The following table provides information about the columns in the blocks table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Table 22.294 Columns of the blocks table

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>block_number</td>
<td>integer</td>
<td>Block number</td>
</tr>
<tr>
<td>block_name</td>
<td>string</td>
<td>Block name</td>
</tr>
</tbody>
</table>

To obtain a list of all block names, simply execute SELECT block_name FROM ndbinfo.blocks. Although this is a static table, its content can vary between different NDB Cluster releases.

22.5.10.4 The ndbinfo cluster_locks Table

The cluster_locks table provides information about current lock requests holding and waiting for locks on NDB tables in an NDB Cluster, and is intended as a companion table to cluster_operations. Information obtain from the cluster_locks table may be useful in investigating stalls and deadlocks.

The following table provides information about the columns in the cluster_locks table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Table 22.295 Columns of the cluster_locks table

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>node_id</td>
<td>integer</td>
<td>ID of reporting node</td>
</tr>
<tr>
<td>block_instance</td>
<td>integer</td>
<td>ID of reporting LDM instance</td>
</tr>
<tr>
<td>tableid</td>
<td>integer</td>
<td>ID of table containing this row</td>
</tr>
<tr>
<td>fragmentid</td>
<td>integer</td>
<td>ID of fragment containing locked row</td>
</tr>
<tr>
<td>rowid</td>
<td>integer</td>
<td>ID of locked row</td>
</tr>
<tr>
<td>transid</td>
<td>integer</td>
<td>Transaction ID</td>
</tr>
<tr>
<td>mode</td>
<td>string</td>
<td>Lock request mode</td>
</tr>
<tr>
<td>state</td>
<td>string</td>
<td>Lock state</td>
</tr>
<tr>
<td>detail</td>
<td>string</td>
<td>Whether this is first holding lock in row lock queue</td>
</tr>
<tr>
<td>op</td>
<td>string</td>
<td>Operation type</td>
</tr>
<tr>
<td>duration_millis</td>
<td>integer</td>
<td>Milliseconds spent waiting or holding lock</td>
</tr>
<tr>
<td>lock_num</td>
<td>integer</td>
<td>ID of lock object</td>
</tr>
<tr>
<td>waiting_for</td>
<td>integer</td>
<td>Waiting for lock with this ID</td>
</tr>
</tbody>
</table>

The table ID (tableid column) is assigned internally, and is the same as that used in other ndbinfo tables. It is also shown in the output of ndb_show_tables.

The transaction ID (transid column) is the identifier generated by the NDB API for the transaction requesting or holding the current lock.

The mode column shows the lock mode; this is always one of S (indicating a shared lock) or X (an exclusive lock). If a transaction holds an exclusive lock on a given row, all other locks on that row have the same transaction ID.
The \textit{state} column shows the lock state. Its value is always one of \texttt{H} (holding) or \texttt{W} (waiting). A waiting lock request waits for a lock held by a different transaction.

When the \textit{detail} column contains a \texttt{*} (asterisk character), this means that this lock is the first holding lock in the affected row's lock queue; otherwise, this column is empty. This information can be used to help identify the unique entries in a list of lock requests.

The \textit{op} column shows the type of operation requesting the lock. This is always one of the values \texttt{READ}, \texttt{INSERT}, \texttt{UPDATE}, \texttt{DELETE}, \texttt{SCAN}, or \texttt{REFRESH}.

The \textit{duration_millis} column shows the number of milliseconds for which this lock request has been waiting or holding the lock. This is reset to 0 when a lock is granted for a waiting request.

The lock ID (\textit{lockid} column) is unique to this node and block instance.

The lock state is shown in the \textit{lock_state} column; if this is \texttt{W}, the lock is waiting to be granted, and the \textit{waiting_for} column shows the lock ID of the lock object this request is waiting for. Otherwise, the \textit{waiting_for} column is empty. \textit{waiting_for} can refer only to locks on the same row, as identified by \texttt{node_id}, \texttt{block_instance}, \texttt{tableid}, \texttt{fragmentid}, and \texttt{rowid}.

\subsection*{22.5.10.5 The ndbinfo cluster\_operations Table}

The \textit{cluster\_operations} table provides a per-operation (stateful primary key op) view of all activity in the NDB Cluster from the point of view of the local data management (LQH) blocks (see \textit{The DBLQH Block}).

The following table provides information about the columns in the \textit{cluster\_operations} table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

\begin{table}[h]
\centering
\begin{tabular}{|l|l|l|}
\hline
\textbf{Column Name} & \textbf{Type} & \textbf{Description} \\
\hline
\texttt{node\_id} & integer & Node ID of reporting LQH block \\
\hline
\texttt{block\_instance} & integer & LQH block instance \\
\hline
\texttt{transid} & integer & Transaction ID \\
\hline
\texttt{operation\_type} & string & Operation type (see text for possible values) \\
\hline
\texttt{state} & string & Operation state (see text for possible values) \\
\hline
\texttt{tableid} & integer & Table ID \\
\hline
\texttt{fragmentid} & integer & Fragment ID \\
\hline
\texttt{client\_node\_id} & integer & Client node ID \\
\hline
\texttt{client\_block\_ref} & integer & Client block reference \\
\hline
\texttt{tc\_node\_id} & integer & Transaction coordinator node ID \\
\hline
\texttt{tc\_block\_no} & integer & Transaction coordinator block number \\
\hline
\texttt{tc\_block\_instance} & integer & Transaction coordinator block instance \\
\hline
\end{tabular}
\end{table}

The transaction ID is a unique 64-bit number which can be obtained using the NDB API's \texttt{getTransactionId()} method. (Currently, the MySQL Server does not expose the NDB API transaction ID of an ongoing transaction.)

The \textit{operation\_type} column can take any one of the values \texttt{READ}, \texttt{READ-SH}, \texttt{READ-EX}, \texttt{INSERT}, \texttt{UPDATE}, \texttt{DELETE}, \texttt{WRITE}, \texttt{UNLOCK}, \texttt{REFRESH}, \texttt{SCAN}, \texttt{SCAN-SH}, \texttt{SCAN-EX}, or \texttt{<unknown>}.

The \textit{state} column can have any one of the values \texttt{ABORT\_QUEUED}, \texttt{ABORT\_STOPPED}, \texttt{COMMITTED}, \texttt{COMMIT\_QUEUED}, \texttt{COMMIT\_STOPPED}, \texttt{COPY\_CLOSE\_STOPPED}, \texttt{COPY\_FIRST\_STOPPED}, \texttt{COPY\_STOPPED}, \texttt{COPY\_TUPKEY}, \texttt{IDLE}, \texttt{LOG\_ABORT\_QUEUED}, \texttt{LOG\_REDO\_QUEUED}, \texttt{RECOVER\_HOLD\_ABORTED}, \texttt{RECOVER\_HOLD\_COMMITTED}, \texttt{RECONNECT}, \texttt{REJECT\_UNRESOLVED\_RETRY}, \texttt{REJECT\_UNRESOLVED\_RETRY\_ABORTED}, \texttt{REJECT\_UNRESOLVED\_RETRY\_COMMITTED}, \texttt{REJECT\_UNRESOLVED\_RETRY\_LOST}, \texttt{REJECT\_UNRESOLVED\_RETRY\_STOPPED}, \texttt{REJECT\_UNRESOLVED\_RETRY\_UNREACHABLE}, \texttt{REJECT\_UNRESOLVED\_RETRY\_UNREACHABLE\_STOPPED}, \texttt{RETRY}, \texttt{ROLLBACK\_ABORTED}, \texttt{ROLLBACK\_COMMITTED}, \texttt{ROLLBACK\_STOPPED}, \texttt{ROLLBACK\_UNRESOLVED\_RETRY}, \texttt{ROLLBACK\_UNRESOLVED\_RETRY\_ABORTED}, \texttt{ROLLBACK\_UNRESOLVED\_RETRY\_COMMITTED}, \texttt{ROLLBACK\_UNRESOLVED\_RETRY\_STOPPED}, \texttt{ROLLBACK\_UNRESOLVED\_RETRY\_UNREACHABLE}, \texttt{ROLLBACK\_UNRESOLVED\_RETRY\_UNREACHABLE\_STOPPED}, \texttt{ROLLBACK\_UNRESOLVED\_RETRY\_UNRESOLVED\_RETRY\_ABORTED}, \texttt{ROLLBACK\_UNRESOLVED\_RETRY\_UNRESOLVED\_RETRY\_COMMITTED}, \texttt{ROLLBACK\_UNRESOLVED\_RETRY\_UNRESOLVED\_RETRY\_STOPPED}, \texttt{ROLLBACK\_UNRESOLVED\_RETRY\_UNRESOLVED\_RETRY\_UNREACHABLE}, \texttt{ROLLBACK\_UNRESOLVED\_RETRY\_UNRESOLVED\_RETRY\_UNREACHABLE\_STOPPED}, \texttt{UNREACHABLE}, \texttt{UNREACHABLE\_STOPPED}, \texttt{VERIFY\_COMMITTED}, \texttt{VERIFY\_STOPPED}, or \texttt{<unknown>}.
LOG_COMMIT_QUEUE_WAIT_SIGNAL, LOG_COMMIT_WRITTEN/backend, LOG_QUEUE, PREPARED, PREPARED_RECEIVED_COMMIT, SCAN_CHECK_STOPPED, SCAN_CLOSE_STOPPED, SCAN_FIRST_STOPPED, SCAN_RELEASE_STOPPED, SCAN_STATE_USED, SCAN_STOPPED, SCAN_TUPKEY, STOPPED, TC_NOT_CONNECTED, WAIT_ACC, WAIT_ACC_ABORT, WAIT_AI_AFTER_ABORT, WAIT_ATTR, WAIT_SCAN_AI, WAIT_TUP, WAIT_TUPKEYINFO, WAIT_TUP_COMMIT, or WAIT_TUP_TO_ABORT. (If the MySQL Server is running with ndbinfo_show_hidden enabled, you can view this list of states by selecting from the ndb$dblqh_tccommit_to_state table, which is normally hidden.)

You can obtain the name of an NDB table from its table ID by checking the output of ndb_show_tables.

The fragid is the same as the partition number seen in the output of ndb_deac --extra-partition-info (short form -p).

In client_node_id and client_block_ref, client refers to an NDB Cluster API or SQL node (that is, an NDB API client or a MySQL Server attached to the cluster).

The block_instance and tc_block_instance column provide, respectively, the DBLQH and DBTC block instance numbers. You can use these along with the block names to obtain information about specific threads from the threadblocks table.

### 22.5.10.6 The ndbinfo cluster_transactions Table

The cluster_transactions table shows information about all ongoing transactions in an NDB Cluster.

The following table provides information about the columns in the cluster_transactions table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>node_id</td>
<td>integer</td>
<td>Node ID of transaction coordinator</td>
</tr>
<tr>
<td>block_instance</td>
<td>integer</td>
<td>TC block instance</td>
</tr>
<tr>
<td>transid</td>
<td>integer</td>
<td>Transaction ID</td>
</tr>
<tr>
<td>state</td>
<td>string</td>
<td>Operation state (see text for possible values)</td>
</tr>
<tr>
<td>count_operations</td>
<td>integer</td>
<td>Number of stateful primary key operations in transaction (includes reads with locks, as well as DML operations)</td>
</tr>
<tr>
<td>outstanding_operations</td>
<td>integer</td>
<td>Operations still being executed in local data management blocks</td>
</tr>
<tr>
<td>inactive_seconds</td>
<td>integer</td>
<td>Time spent waiting for API</td>
</tr>
<tr>
<td>client_node_id</td>
<td>integer</td>
<td>Client node ID</td>
</tr>
<tr>
<td>client_block_ref</td>
<td>integer</td>
<td>Client block reference</td>
</tr>
</tbody>
</table>

The transaction ID is a unique 64-bit number which can be obtained using the NDB API's getTransactionId() method. (Currently, the MySQL Server does not expose the NDB API transaction ID of an ongoing transaction.)

block_instance refers to an instance of a kernel block. Together with the block name, this number can be used to look up a given instance in the threadblocks table.

The state column can have any one of the values CS_ABORTING, CS_COMMITTING, CS_COMMIT_SENT, CS_COMPLETE_SENT, CS_COMPLETING, CS_CONNECTED, CS_DISCONNECTED, CS_NOT_CONNECTED.
CS_FAIL_ABORTED, CS_FAIL_ABORTING, CS_FAIL_COMMITTED, CS_FAIL_COMMITTING, CS_FAIL_COMPLETED, CS_FAIL_PREPARED, CS_PREPARE_TO_COMMIT, CS_RECEIVING, CS_RECOVERY_COMMITTING, CS_RESTART, CS_SEND_FIRE_TRIG_REQ, CS_STARTED, CS_START_COMMITTING, CS_START_SCAN, CS_WAIT_ABORT_CONF, CS_WAIT_COMMIT_CONF, CS_WAIT_COMPLETE_CONF, CS_WAIT_FIRE_TRIG_REQ. (If the MySQL Server is running with ndbinfo_show_hidden enabled, you can view this list of states by selecting from the ndb $dbtc_apiconnect_state table, which is normally hidden.)

In client_node_id and client_block_ref, client refers to an NDB Cluster API or SQL node (that is, an NDB API client or a MySQL Server attached to the cluster).

The tc_block_instance column provides the DBTC block instance number. You can use this along with the block name to obtain information about specific threads from the threadblocks table.

### 22.5.10.7 The ndbinfo config_nodes Table

The config_nodes table shows nodes configured in an NDB Cluster config.ini file. For each node, the table displays a row containing the node ID, the type of node (management node, data node, or API node), and the name or IP address of the host on which the node is configured to run.

This table does not indicate whether a given node is actually running, or whether it is currently connected to the cluster. Information about nodes connected to an NDB Cluster can be obtained from the nodes and processes table.

The following table provides information about the columns in the config_nodes table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>node_id</td>
<td>integer</td>
<td>The node's ID</td>
</tr>
<tr>
<td>node_type</td>
<td>string</td>
<td>The type of node</td>
</tr>
<tr>
<td>node_hostname</td>
<td>string</td>
<td>The name or IP address of the host on which the node resides</td>
</tr>
</tbody>
</table>

The node_id column shows the node ID used in the config.ini file for this node; if none is specified, the node ID that would be assigned automatically to this node is displayed.

The node_type column displays one of the following three values:

- **MGM**: Management node.
- **NDB**: Data node.
- **API**: API node; this includes SQL nodes.

The node_hostname column shows the node host as specified in the config.ini file. This can be empty for an API node, if HostName has not been set in the cluster configuration file. If HostName has not been set for a data node in the configuration file, localhost is used here. localhost is also used if HostName has not been specified for a management node.

### 22.5.10.8 The ndbinfo config_params Table

The config_params table is a static table which provides the names and internal ID numbers of and other information about NDB Cluster configuration parameters.

The following table provides information about the columns in the config_params table. For each column, the table shows the name, data type, and a brief description. Additional information
can be found in the notes following the table. This table can also be used in conjunction with the config_values table for obtaining realtime information about node configuration parameters.

### Table 22.299 Columns of the config_params table

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>param_number</td>
<td>integer</td>
<td>The parameter's internal ID number</td>
</tr>
<tr>
<td>param_name</td>
<td>string</td>
<td>The name of the parameter</td>
</tr>
<tr>
<td>param_description</td>
<td>string</td>
<td>A brief description of the parameter</td>
</tr>
<tr>
<td>param_type</td>
<td>string</td>
<td>The parameter's data type</td>
</tr>
<tr>
<td>param_default</td>
<td>string</td>
<td>The parameter's default value, if any</td>
</tr>
<tr>
<td>param_min</td>
<td>string</td>
<td>The parameter's maximum value, if any</td>
</tr>
<tr>
<td>param_max</td>
<td>string</td>
<td>The parameter's minimum value, if any</td>
</tr>
<tr>
<td>param_mandatory</td>
<td>integer</td>
<td>This is 1 if the parameter is required, otherwise 0</td>
</tr>
<tr>
<td>param_status</td>
<td>string</td>
<td>Currently unused</td>
</tr>
</tbody>
</table>

This table is read-only.

Although this is a static table, its content can vary between NDB Cluster installations, since supported parameters can vary due to differences between software releases, cluster hardware configurations, and other factors.

### 22.5.10.9 The ndbinfo config_values Table

The config_values table provides information about the current state of node configuration parameter values. Each row in the table corresponds to the current value of a parameter on a given node.

### Table 22.300 Columns of the config_params table

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>node_id</td>
<td>integer</td>
<td>ID of the node in the cluster</td>
</tr>
<tr>
<td>config_param</td>
<td>integer</td>
<td>The parameter's internal ID number</td>
</tr>
<tr>
<td>config_value</td>
<td>string</td>
<td>Current value of the parameter</td>
</tr>
</tbody>
</table>

This table's config_param column and the config_params table's param_number column use the same parameter identifiers. By joining the two tables on these columns, you can obtain detailed information about desired node configuration parameters. The query shown here provides the current values for all parameters on each data node in the cluster, ordered by node ID and parameter name:

```sql
SELECT v.node_id AS 'Node Id',
       p.param_name AS 'Parameter',
       v.config_value AS 'Value'
FROM config_values v
JOIN config_params p
ON v.config_param=p.param_number
WHERE p.param_name NOT LIKE '__\_%'
ORDER BY v.node_id, p.param_name;
```

Partial output from the previous query when run on a small example cluster used for simple testing:

<table>
<thead>
<tr>
<th>Node Id</th>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>Arbitration</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>ArbitrationTimeout</td>
<td>7500</td>
</tr>
</tbody>
</table>
ndbinfo: The NDB Cluster Information Database

| 2 | BackupDataBufferSize | 16777216 |
| 2 | BackupDataDir        | /home/jon/data |
| 2 | BackupDiskWriteSpeedPct | 50 |
| 2 | BackupLogBufferSize  | 16777216 |

...

| 3 | TotalSendBufferMemory | 0 |
| 3 | TransactionBufferSize | 1048576 |
| 3 | TransactionDeadlockDetectionTimeout | 1200 |
| 3 | TransactionInactiveTimeout | 4294967039 |
| 3 | TwoPassInitialNodeRestartCopy | 0 |
| 3 | UndoDataBuffer | 16777216 |
| 3 | UndoIndexBuffer | 2097152 |

+------------------------------------------+----------------+
248 rows in set (0.02 sec)

The WHERE clause filters out parameters whose names begin with a double underscore (__); these parameters are reserved for testing and other internal uses by the NDB developers, and are not intended for use in a production NDB Cluster.

You can obtain output that is more specific, more detailed, or both by issuing the proper queries. This example provides all types of available information about the NodeId, NoOfReplicas, HostName, DataMemory, IndexMemory, and TotalSendBufferMemory parameters as currently set for all data nodes in the cluster:

```
SELECT p.param_name AS Name, v.node_id AS Node, p.param_type AS Type, p.param_default AS 'Default', p.param_min AS Minimum, p.param_max AS Maximum, CASE p.param_mandatory WHEN 1 THEN 'Y' ELSE 'N' END AS 'Required', v.config_value AS Current
FROM    config_params p
JOIN    config_values v
ON      p.param_number = v.config_param
WHERE   p.param_name
        IN ('NodeId', 'NoOfReplicas', 'HostName', 'DataMemory', 'IndexMemory', 'TotalSendBufferMemory')
```

The output from this query when run on a small NDB Cluster with 2 data nodes used for simple testing is shown here (NDB 8.0.18 and later):

```
*************************** 1. row ****************************
Name: NodeId
Node: 2
Type: unsigned
Default: 
Minimum: 1
Maximum: 144
Required: Y
Current: 2

*************************** 2. row ****************************
Name: HostName
Node: 2
Type: string
Default: localhost
Minimum: 
Maximum: 
Required: N
Current: 127.0.0.1

*************************** 3. row ****************************
Name: TotalSendBufferMemory
Node: 2
Type: unsigned
Default: 0
Minimum: 262144
Maximum: 4294967039
Required: N
```

The WHERE clause filters out parameters whose names begin with a double underscore (__); these parameters are reserved for testing and other internal uses by the NDB developers, and are not intended for use in a production NDB Cluster.

You can obtain output that is more specific, more detailed, or both by issuing the proper queries. This example provides all types of available information about the NodeId, NoOfReplicas, HostName, DataMemory, IndexMemory, and TotalSendBufferMemory parameters as currently set for all data nodes in the cluster:

```
SELECT p.param_name AS Name, v.node_id AS Node, p.param_type AS Type, p.param_default AS 'Default', p.param_min AS Minimum, p.param_max AS Maximum, CASE p.param_mandatory WHEN 1 THEN 'Y' ELSE 'N' END AS 'Required', v.config_value AS Current
FROM    config_params p
JOIN    config_values v
ON      p.param_number = v.config_param
WHERE   p.param_name
        IN ('NodeId', 'NoOfReplicas', 'HostName', 'DataMemory', 'IndexMemory', 'TotalSendBufferMemory')
```

The output from this query when run on a small NDB Cluster with 2 data nodes used for simple testing is shown here (NDB 8.0.18 and later):

```

Maximum: 4294967039
Required: N
```
The counters table provides running totals of events such as reads and writes for specific kernel blocks and data nodes. Counts are kept from the most recent node start or restart; a node start or restart resets all counters on that node. Not all kernel blocks have all types of counters.
The following table provides information about the columns in the `counters` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

### Table 22.301 Columns of the counters table

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>node_id</td>
<td>integer</td>
<td>The data node ID</td>
</tr>
<tr>
<td>block_name</td>
<td>string</td>
<td>Name of the associated NDB kernel block (see NDB Kernel Blocks).</td>
</tr>
<tr>
<td>block_instance</td>
<td>integer</td>
<td>Block instance</td>
</tr>
<tr>
<td>counter_id</td>
<td>integer</td>
<td>The counter's internal ID number; normally an integer between 1 and 10, inclusive.</td>
</tr>
<tr>
<td>counter_name</td>
<td>string</td>
<td>The name of the counter. See text for names of individual counters and the NDB kernel block with which each counter is associated.</td>
</tr>
<tr>
<td>val</td>
<td>integer</td>
<td>The counter's value</td>
</tr>
</tbody>
</table>

Each counter is associated with a particular NDB kernel block.

- The `OPERATIONS` counter is associated with the `DBLQH` (local query handler) kernel block (see The DBLQH Block). A primary-key read counts as one operation, as does a primary-key update. For reads, there is one operation in `DBLQH` per operation in `DBTC`. For writes, there is one operation counted per replica.

- The `ATTRINFO`, `TRANSACTIONS`, `COMMITS`, `READS`, `LOCAL_READS`, `SIMPLE_READS`, `WRITES`, `LOCAL_WRITES`, `ABORTS`, `TABLE_SCANS`, and `RANGE_SCANS` counters are associated with the `DBTC` (transaction co-ordinator) kernel block (see The DBTC Block).

- `LOCAL_WRITES` and `LOCAL_READS` are primary-key operations using a transaction coordinator in a node that also holds the primary replica of the record.

- The `READS` counter includes all reads. `LOCAL_READS` includes only those reads of the primary replica on the same node as this transaction coordinator. `SIMPLE_READS` includes only those reads in which the read operation is the beginning and ending operation for a given transaction. Simple reads do not hold locks but are part of a transaction, in that they observe uncommitted changes made by the transaction containing them but not of any other uncommitted transactions. Such reads are “simple” from the point of view of the TC block; since they hold no locks they are not durable, and once `DBTC` has routed them to the relevant LQH block, it holds no state for them.

- `ATTRINFO` keeps a count of the number of times an interpreted program is sent to the data node. See NDB Protocol Messages, for more information about `ATTRINFO` messages in the NDB kernel.

- The `LOCAL_TABLE_SCANS_SENT`, `READS_RECEIVED`, `PRUNED_RANGE_SCANS_RECEIVED`, `RANGE_SCANS_RECEIVED`, `LOCAL_READS_SENT`, `CONST_PRUNED_RANGE_SCANS_RECEIVED`, `LOCAL_RANGE_SCANS_SENT`, `REMOTE_READS_SENT`, `REMOTE_RANGE_SCANS_SENT`, `READS_NOT_FOUND`, `SCAN_BATCHES_RETURNED`, `TABLE_SCANS_RECEIVED`, and `SCAN_ROWS_RETURNED` counters are associated with the `DBSPJ` (select push-down join) kernel block (see The DBSPJ Block).

- The `block_name` and `block_instance` columns provide, respectively, the applicable NDB kernel block name and instance number. You can use these to obtain information about specific threads from the threadblocks table.

A number of counters provide information about transporter overload and send buffer sizing when troubleshooting such issues. For each LQH instance, there is one instance of each counter in the following list.
• **LQHKEY_OVERLOAD**: Number of primary key requests rejected at the LQH block instance due to transporter overload

• **LQHKEY_OVERLOAD_TC**: Count of instances of **LQHKEY_OVERLOAD** where the TC node transporter was overloaded

• **LQHKEY_OVERLOAD_READER**: Count of instances of **LQHKEY_OVERLOAD** where the API reader (reads only) node was overloaded.

• **LQHKEY_OVERLOAD_NODE_PEER**: Count of instances of **LQHKEY_OVERLOAD** where the next backup data node (writes only) was overloaded.

• **LQHKEY_OVERLOAD_SUBSCRIBER**: Count of instances of **LQHKEY_OVERLOAD** where a event subscriber (writes only) was overloaded.

• **LQHSCAN_SLOWDOWNS**: Count of instances where a fragment scan batch size was reduced due to scanning API transporter overload.

### 22.5.10.11 The ndbinfo cpustat Table

The **cpustat** table provides per-thread CPU statistics gathered each second, for each thread running in the NDB kernel.

The following table provides information about the columns in the **cpustat** table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

#### Table 22.302 Columns of the cpustat table

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>node_id</td>
<td>integer</td>
<td>ID of the node where the thread is running</td>
</tr>

<td>Elapsed time</td>
</tr>
</tbody>
</table>

### 22.5.10.12 The ndbinfo cpustat_50ms Table

The **cpustat_50ms** table provides raw, per-thread CPU data obtained each 50 milliseconds for each thread running in the NDB kernel.

Like **cpustat_1sec** and **cpustat_20sec**, this table shows 20 measurement sets per thread, each referencing a period of the named duration. Thus, **cpustat_50ms** provides 1 second of history.

The following table provides information about the columns in the **cpustat_50ms** table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

#### Table 22.303 Columns of the cpustat_50ms table

<table>
<thead>
<tr>

<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>node_id</td>
<td>integer</td>
<td>ID of the node where the thread is running</td>
</tr>
</tbody>
</table>
The `ndbinfo cpustat_1sec` Table

The `cpustat-1sec` table provides raw, per-thread CPU data obtained each second for each thread running in the NDB kernel.

Like `cpustat_50ms` and `cpustat_20sec`, this table shows 20 measurement sets per thread, each referencing a period of the named duration. Thus, `cpustat_1sec` provides 20 seconds of history.

The following table provides information about the columns in the `cpustat_1sec` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>

<tr>
<td>elapsed_time</td>
<td>integer</td>
<td>Elapsed time</td>
</tr>
</tbody>
</table>

The `ndbinfo cpustat_20sec` Table

The `cpustat_20sec` table provides raw, per-thread CPU data obtained each 20 seconds, for each thread running in the NDB kernel.

Like `cpustat_50ms` and `cpustat_1sec`, this table shows 20 measurement sets per thread, each referencing a period of the named duration. Thus, `cpustat_20sec` provides 400 seconds of history.

The following table provides information about the columns in the `cpustat_20sec` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

<table>
<thead>
<tr>
<th>Column Name</th>

</tbody>
</table>

22.5.10.15 The ndbinfo dict_obj_info Table

The dict_obj_info table provides information about NDB data dictionary (DICT) objects such as tables and indexes. (The dict_obj_types table can be queried for a list of all the types.) This information includes the object's type, state, parent object (if any), and fully qualified name.

The following table provides information about the columns in the dict_obj_info table. For each column, the table shows the name, data type, and a brief description.

Table 22.306 Columns of the dict_obj_info table

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>integer</td>
<td>Type of DICT object; join on dict_obj_types to obtain the name</td>
</tr>
<tr>
<td>id</td>
<td>integer</td>
<td>Object identifier</td>
</tr>
<tr>
<td>version</td>
<td>integer</td>
<td>Object version</td>
</tr>
<tr>
<td>state</td>
<td>integer</td>
<td>Object state</td>
</tr>
<tr>
<td>parent_obj_type</td>
<td>integer</td>
<td>Parent object's type (a dict_obj_types type ID); 0 indicates that the object has no parent</td>
</tr>
<tr>
<td>parent_obj_id</td>
<td>integer</td>
<td>Parent object ID (such as a base table); 0 indicates that the object has no parent</td>
</tr>
<tr>
<td>fq_name</td>
<td>string</td>
<td>Fully qualified object name; for a table, this has the form database_name/def/table_name, for a primary key, the form is sys/def/table_id/PRIMARY, and for a unique key it is sys/def/table_id/uk_name$unique</td>
</tr>
</tbody>
</table>

22.5.10.16 The ndbinfo dict_obj_types Table

The dict_obj_types table is a static table listing possible dictionary object types used in the NDB kernel. These are the same types defined by Object::Type in the NDB API.

The following table provides information about the columns in the dict_obj_types table. For each column, the table shows the name, data type, and a brief description.
**22.5.10.17 The ndbinfo disk_write_speed_base Table**

The *disk_write_speed_base* table provides base information about the speed of disk writes during LCP, backup, and restore operations.

The following table provides information about the columns in the *disk_write_speed_base* table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

**Table 22.308 Columns of the disk_write_speed_base table**

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>node_id</td>
<td>integer</td>
<td>Node ID of this node</td>
</tr>
<tr>
<td>thr_no</td>
<td>integer</td>
<td>Thread ID of this LDM thread</td>
</tr>
<tr>
<td>millis_ago</td>
<td>integer</td>
<td>Milliseconds since this reporting period ended</td>
</tr>
<tr>
<td>millis_passed</td>
<td>integer</td>
<td>Milliseconds elapsed in this reporting period</td>
</tr>
<tr>
<td>backup_lcp_bytes_written</td>
<td>integer</td>
<td>Number of bytes written to disk by local checkpoints and backup processes during this period</td>
</tr>
<tr>
<td>redo_bytes_written</td>
<td>integer</td>
<td>Number of bytes written to REDO log during this period</td>
</tr>
<tr>
<td>target_disk_write_speed</td>
<td>integer</td>
<td>Actual speed of disk writes per LDM thread (base data)</td>
</tr>
</tbody>
</table>

**22.5.10.18 The ndbinfo disk_write_speed_aggregate Table**

The *disk_write_speed_aggregate* table provides aggregated information about the speed of disk writes during LCP, backup, and restore operations.

The following table provides information about the columns in the *disk_write_speed_aggregate* table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

**Table 22.309 Columns in the disk_write_speed_aggregate table**

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>node_id</td>
<td>integer</td>
<td>Node ID of this node</td>
</tr>
<tr>
<td>thr_no</td>
<td>integer</td>
<td>Thread ID of this LDM thread</td>
</tr>
<tr>
<td>backup_lcp_speed_last_sec</td>
<td>integer</td>
<td>Number of bytes written to disk by backup and LCP processes in the last second</td>
</tr>
<tr>
<td>redo_speed_last_sec</td>
<td>integer</td>
<td>Number of bytes written to REDO log in the last second</td>
</tr>
<tr>
<td>backup_lcp_speed_last_10sec</td>
<td>integer</td>
<td>Number of bytes written to disk by backup and LCP processes per second, averaged over the last 10 seconds</td>
</tr>
</tbody>
</table>
### Column Name | Type     | Description
--- | --- | ---
redo_speed_last_10sec | integer | Number of bytes written to REDO log per second, averaged over the last 10 seconds
std_dev_backup_lcp_speed_last_10sec | integer | Standard deviation in number of bytes written to disk by backup and LCP processes per second, averaged over the last 10 seconds
std_dev_redo_speed_last_10sec | integer | Standard deviation in number of bytes written to REDO log per second, averaged over the last 10 seconds
backup_lcp_speed_last_60sec | integer | Number of bytes written to disk by backup and LCP processes per second, averaged over the last 60 seconds
redo_speed_last_60sec | integer | Number of bytes written to REDO log per second, averaged over the last 60 seconds
std_dev_backup_lcp_speed_last_60sec | integer | Standard deviation in number of bytes written to disk by backup and LCP processes per second, averaged over the last 60 seconds
std_dev_redo_speed_last_60sec | integer | Standard deviation in number of bytes written to REDO log per second, averaged over the last 60 seconds
slowdowns_due_to_io_lag | integer | Number of seconds since last node start that disk writes were slowed due to REDO log I/O lag
slowdowns_due_to_high_cpu | integer | Number of seconds since last node start that disk writes were slowed due to high CPU usage
disk_write_speed_set_to_min | integer | Number of seconds since last node start that disk write speed was set to minimum
current_target_disk_write_speed | integer | Actual speed of disk writes per LDM thread (aggregated)

#### 22.5.10.19 The ndbinfo disk_write_speed_aggregate_node Table

The `disk_write_speed_aggregate_node` table provides aggregated information per node about the speed of disk writes during LCP, backup, and restore operations.

The following table provides information about the columns in the `disk_write_speed_aggregate_node` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

### Table 22.310 Columns of the `disk_write_speed_aggregate_node` table

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>node_id</td>
<td>integer</td>
<td>Node ID of this node</td>
</tr>
<tr>
<td>backup_lcp_speed_last_sec</td>
<td>integer</td>
<td>Number of bytes written to disk by backup and LCP processes in the last second</td>
</tr>
<tr>
<td>redo_speed_last_sec</td>
<td>integer</td>
<td>Number of bytes written to REDO log in the last second</td>
</tr>
<tr>
<td>backup_lcp_speed_last_10sec</td>
<td>integer</td>
<td>Number of bytes written to disk by backup and LCP processes per second, averaged over the last 10 seconds</td>
</tr>
<tr>
<td>redo_speed_last_10sec</td>
<td>integer</td>
<td>Number of bytes written to REDO log per second, averaged over the last 10 seconds</td>
</tr>
</tbody>
</table>
22.5.10.20 The ndbinfo diskpagebuffer Table

The diskpagebuffer table provides statistics about disk page buffer usage by NDB Cluster Disk Data tables.

The following table provides information about the columns in the diskpagebuffer table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>backup_lcp_speed_last_60sec</td>
<td>integer</td>
<td>Number of bytes written to disk by backup and LCP processes per second, averaged over the last 60 seconds</td>
</tr>
<tr>
<td>redo_speed_last_60sec</td>
<td>integer</td>
<td>Number of bytes written to disk by backup and LCP processes per second, averaged over the last 60 seconds</td>
</tr>
</tbody>
</table>

You can use this table with NDB Cluster Disk Data tables to determine whether DiskPageBufferMemory is sufficiently large to allow data to be read from the buffer rather from disk; minimizing disk seeks can help improve performance of such tables.

You can determine the proportion of reads from DiskPageBufferMemory to the total number of reads using a query such as this one, which obtains this ratio as a percentage:

```
SELECT
  node_id,
  100 * page_requests_direct_return / (page_requests_direct_return + page_requests_wait_io)
AS hit_ratio
FROM ndbinfo.diskpagebuffer;
```

The result from this query should be similar to what is shown here, with one row for each data node in the cluster (in this example, the cluster has 4 data nodes):

```
+---------+-----------+
<table>
<thead>
<tr>
<th>node_id</th>
<th>hit_ratio</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

3981
hit_ratio values approaching 100% indicate that only a very small number of reads are being made from disk rather than from the buffer, which means that Disk Data read performance is approaching an optimum level. If any of these values are less than 95%, this is a strong indicator that the setting for `DiskPageBufferMemory` needs to be increased in the `config.ini` file.

**Note**

A change in `DiskPageBufferMemory` requires a rolling restart of all of the cluster's data nodes before it takes effect.

block_instance refers to an instance of a kernel block. Together with the block name, this number can be used to look up a given instance in the threadblocks table. Using this information, you can obtain information about disk page buffer metrics relating to individual threads; an example query using `LIMIT 1` to limit the output to a single thread is shown here:

```
mysql> SELECT 
  > node_id, thr_no, block_name, thread_name, pages_written, 
  > pages_written_lcp, pages_read, log_waits, 
  > page_requests_direct_return, page_requests_wait_queue, 
  > page_requests_wait_io 
  > FROM ndbinfo.diskpagebuffer 
  > INNER JOIN ndbinfo.threadblocks USING (node_id, block_instance) 
  > INNER JOIN ndbinfo.threads USING (node_id, thr_no) 
  > WHERE block_name = 'PGMAN' LIMIT 1
```

```
<table>
<thead>
<tr>
<th>node_id</th>
<th>thr_no</th>
<th>block_name</th>
<th>thread_name</th>
<th>pages_written</th>
<th>pages_written_lcp</th>
<th>pages_read</th>
<th>log_waits</th>
<th>page_requests_direct_return</th>
<th>page_requests_wait_queue</th>
<th>page_requests_wait_io</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>PGMAN</td>
<td>rep</td>
<td>0</td>
<td>0</td>
<td>1</td>
<td>0</td>
<td>4</td>
<td>0</td>
<td>1</td>
</tr>
</tbody>
</table>
```

1 row in set (0.01 sec)

22.5.10.21 The ndbinfo diskstat Table

The `diskstat` table provides information about writes to Disk Data tablespaces during the past 1 second.

The following table provides information about the columns in the `diskstat` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

**Table 22.312 Columns of the diskstat table**

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>node_id</td>
<td>integer</td>
<td>Node ID of this node</td>
</tr>
<tr>
<td>block_instance</td>
<td>integer</td>
<td>ID of reporting instance of <code>PGMAN</code></td>
</tr>
<tr>
<td>pages_made_dirty</td>
<td>integer</td>
<td>Number of pages made dirty during the past second</td>
</tr>
<tr>
<td>reads_issued</td>
<td>integer</td>
<td>Reads issued during the past second</td>
</tr>
<tr>
<td>reads_completed</td>
<td>integer</td>
<td>Reads completed during the past second</td>
</tr>
</tbody>
</table>
The \texttt{diskstats_1sec} table provides information about writes to Disk Data tablespaces over the past 20 seconds. The following table provides information about the columns in the \texttt{diskstat} table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

\textbf{Table 22.313 Columns of the diskstat table}

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>node_id</td>
<td>integer</td>
<td>Node ID of this node</td>
</tr>
<tr>
<td>block_instance</td>
<td>integer</td>
<td>ID of reporting instance of \texttt{PGMAN}</td>
</tr>
<tr>
<td>pages_made_dirty</td>
<td>integer</td>
<td>Pages made dirty during the designated 1-second interval</td>
</tr>
<tr>
<td>reads_issued</td>
<td>integer</td>
<td>Reads issued during the designated 1-second interval</td>
</tr>
<tr>
<td>reads_completed</td>
<td>integer</td>
<td>Reads completed during the designated 1-second interval</td>
</tr>
<tr>
<td>writes_issued</td>
<td>integer</td>
<td>Writes issued during the designated 1-second interval</td>
</tr>
<tr>
<td>writes_completed</td>
<td>integer</td>
<td>Writes completed during the designated 1-second interval</td>
</tr>
<tr>
<td>log_writes_issued</td>
<td>integer</td>
<td>Number of times a page write has required a log write during the designated 1-second interval</td>
</tr>
<tr>
<td>log_writes_completed</td>
<td>integer</td>
<td>Number of log writes completed during the designated 1-second interval</td>
</tr>
<tr>
<td>get_page_calls_issued</td>
<td>integer</td>
<td>Number of \texttt{get_page()} calls issued during the designated 1-second interval</td>
</tr>
<tr>
<td>get_page_reqs_issued</td>
<td>integer</td>
<td>Number of times that a \texttt{get_page()} call has resulted in a wait for I/O or completion of I/O already begun during the past second</td>
</tr>
<tr>
<td>get_page_reqs_completed</td>
<td>integer</td>
<td>Number of \texttt{get_page()} calls waiting for I/O or I/O completion that have completed during the past second</td>
</tr>
</tbody>
</table>

Each row in this table corresponds to an instance of \texttt{PGMAN}; there is one such instance per LDM thread plus an additional instance for each data node.

The \texttt{diskstat} table was added in NDB 8.0.19.
<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>get_page_reqs_issued</td>
<td>integer</td>
<td>Number of times that a <code>get_page()</code> call has resulted in a wait for I/O or completion of I/O already begun during the designated 1-second interval</td>
</tr>
<tr>
<td>get_page_reqs_completed</td>
<td>integer</td>
<td>Number of <code>get_page()</code> calls waiting for I/O or I/O completion that have completed during the designated 1-second interval</td>
</tr>
<tr>
<td>seconds_ago</td>
<td>integer</td>
<td>Number of 1-second intervals in the past of the interval to which this row applies</td>
</tr>
</tbody>
</table>

Each row in this table corresponds to an instance of `PGMAN` during a 1-second interval occurring from 0 to 19 seconds ago; there is one such instance per LDM thread plus an additional instance for each data node.

The `diskstats_1sec` table was added in NDB 8.0.19.

### 22.5.10.23 The `ndbinfo error_messages` Table

The `error_messages` table provides information about

The following table provides information about the columns in the `error_messages` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>error_code</td>
<td>integer</td>
<td>Numeric error code</td>
</tr>
<tr>
<td>error_description</td>
<td>string</td>
<td>Description of error</td>
</tr>
<tr>
<td>error_status</td>
<td>string</td>
<td>Error status code</td>
</tr>
<tr>
<td>error_classification</td>
<td>integer</td>
<td>Error classification code</td>
</tr>
</tbody>
</table>

`error_code` is a numeric NDB error code. This is the same error code that can be supplied to `ndb_perror` or `perror --ndb`.

`error_description` provides a basic description of the condition causing the error.

The `error_status` column provides status information relating to the error. Possible values for this column are listed here:

- No error
- Illegal connect string
- Illegal server handle
- Illegal reply from server
- Illegal number of nodes
- Illegal node status
- Out of memory
- Management server not connected
- Could not connect to socket
• Start failed
• Stop failed
• Restart failed
• Could not start backup
• Could not abort backup
• Could not enter single user mode
• Could not exit single user mode
• Failed to complete configuration change
• Failed to get configuration
• Usage error
• Success
• Permanent error
• Temporary error
• Unknown result
• Temporary error, restart node
• Permanent error, external action needed
• Ndbd file system error, restart node initial
• Unknown

The error_classification column shows the error classification. See NDB Error Classifications, for information about classification codes and their meanings.

22.5.10.24 The ndbinfo locks_per_fragment Table

The locks_per_fragment table provides information about counts of lock claim requests, and the outcomes of these requests on a per-fragment basis, serving as a companion table to operations_per_fragment and memory_per_fragment. This table also shows the total time spent waiting for locks successfully and unsuccessfully since fragment or table creation, or since the most recent restart.

The following table provides information about the columns in the locks_per_fragment table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Table 22.315 Columns of the locks_per_fragment table

<table>
<thead>
<tr>

</tr>
<tr>
<td>sh_wait_ok</td>
<td>integer</td>
<td>Shared lock requests granted following wait</td>
</tr>
<tr>
<td>sh_wait_fail</td>
<td>integer</td>
<td>Shared lock requests not granted</td>
</tr>
<tr>
<td>wait_ok_millis</td>
<td>integer</td>
<td>Time spent waiting for lock requests that were granted, in milliseconds</td>
</tr>
<tr>
<td>wait_fail_millis</td>
<td>integer</td>
<td>Time spent waiting for lock requests that failed, in milliseconds</td>
</tr>
</tbody>
</table>

- **block_instance** refers to an instance of a kernel block. Together with the block name, this number can be used to look up a given instance in the `threadblocks` table.

- **fq_name** is a fully qualified database object name in `database/schema/name` format, such as `test/def/t1` or `sys/def/10/b$unique`.

- **parent_fq_name** is the fully qualified name of this object’s parent object (table).

- **table_id** is the table’s internal ID generated by NDB. This is the same internal table ID shown in other `ndbinfo` tables; it is also visible in the output of `ndb_show_tables`.

The **type** column shows the type of table. This is always one of **System table**, **User table**, **Unique hash index**, **Hash index**, **Unique ordered index**, **Ordered index**, **Hash index trigger**, **Subscription trigger**, **Read only constraint**, **Index trigger**, **Reorganize trigger**, **Tablespace**, **Log file group**, **Data file**, **Undo file**, **Hash map**, **Foreign key definition**, **Foreign key parent trigger**, **Foreign key child trigger**, or **Schema transaction**.

The values shown in all of the columns `ex_req, ex_req_imm_ok, ex_wait_ok, ex_wait_fail, sh_req, sh_req_imm_ok, sh_wait_ok, and sh_wait_fail` represent cumulative numbers of requests since the table or fragment was created, or since the last restart of this node, whichever of these occurred later. This is also true for the time values shown in the `wait_ok_millis` and `wait_fail_millis` columns.

Every lock request is considered either to be in progress, or to have completed in some way (that is, to have succeeded or failed). This means that the following relationships are true:

```
ex_req >= (ex_req_imm_ok + ex_wait_ok + ex_wait_fail)
sh_req >= (sh_req_imm_ok + sh_wait_ok + sh_wait_fail)
```

The number of requests currently in progress is the current number of incomplete requests, which can be found as shown here:

```
[exclusive lock requests in progress] =
ex_req - (ex_req_imm_ok + ex_wait_ok + ex_wait_fail)

[shared lock requests in progress] =
sh_req - (sh_req_imm_ok + sh_wait_ok + sh_wait_fail)
```
A failed wait indicates an aborted transaction, but the abort may or may not be caused by a lock wait timeout. You can obtain the total number of aborts while waiting for locks as shown here:

\[ \text{[aborts while waiting for locks]} = \text{ex\_wait\_fail} + \text{sh\_wait\_fail} \]

### 22.5.10.25 The ndbinfo logbuffers Table

The `logbuffer` table provides information on NDB Cluster log buffer usage.

The following table provides information about the columns in the `logbuffers` table. For each column, the table shows the name, data type, and a brief description.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>node_id</td>
<td>integer</td>
<td>The ID of this data node.</td>
</tr>
<tr>
<td>log_type</td>
<td>string</td>
<td>Type of log. One of: <code>REDO</code>, <code>DD-UNDO</code>, <code>BACKUP-DATA</code>, or <code>BACKUP-LOG</code>.</td>
</tr>
<tr>
<td>log_id</td>
<td>integer</td>
<td>The log ID.</td>
</tr>
<tr>
<td>log_part</td>
<td>integer</td>
<td>The log part number.</td>
</tr>
<tr>
<td>total</td>
<td>integer</td>
<td>Total space available for this log.</td>
</tr>
<tr>
<td>used</td>
<td>integer</td>
<td>Space used by this log.</td>
</tr>
</tbody>
</table>

`logbuffers` table rows reflecting two additional log types are available when performing an NDB backup. One of these rows has the log type `BACKUP-DATA`, which shows the amount of data buffer used during backup to copy fragments to backup files. The other row has the log type `BACKUP-LOG`, which displays the amount of log buffer used during the backup to record changes made after the backup has started. One each of these `log_type` rows is shown in the `logbuffers` table for each data node in the cluster. These rows are not present unless an NDB backup is currently being performed.

### 22.5.10.26 The ndbinfo logspaces Table

This table provides information about NDB Cluster log space usage.

The following table provides information about the columns in the `logspaces` table. For each column, the table shows the name, data type, and a brief description.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>node_id</td>
<td>integer</td>
<td>The ID of this data node.</td>
</tr>
<tr>
<td>log_type</td>
<td>string</td>
<td>Type of log; one of: <code>REDO</code> or <code>DD-UNDO</code>.</td>
</tr>
<tr>
<td>log_id</td>
<td>integer</td>
<td>The log ID.</td>
</tr>
<tr>
<td>log_part</td>
<td>integer</td>
<td>The log part number.</td>
</tr>
<tr>
<td>total</td>
<td>integer</td>
<td>Total space available for this log.</td>
</tr>
<tr>
<td>used</td>
<td>integer</td>
<td>Space used by this log.</td>
</tr>
</tbody>
</table>

### 22.5.10.27 The ndbinfo membership Table

The `membership` table describes the view that each data node has of all the others in the cluster, including node group membership, president node, arbitrator, arbitrator successor, arbitrator connection states, and other information.
The following table provides information about the columns in the membership table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Table 22.318 Columns of the membership table

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>node_id</td>
<td>integer</td>
<td>This node’s node ID</td>
</tr>
<tr>
<td>group_id</td>
<td>integer</td>
<td>Node group to which this node belongs</td>
</tr>
<tr>
<td>left_node</td>
<td>integer</td>
<td>Node ID of the previous node</td>
</tr>
<tr>
<td>right_node</td>
<td>integer</td>
<td>Node ID of the next node</td>
</tr>
<tr>
<td>president</td>
<td>integer</td>
<td>President’s node ID</td>
</tr>
<tr>
<td>successor</td>
<td>integer</td>
<td>Node ID of successor to president</td>
</tr>
<tr>
<td>succession_order</td>
<td>integer</td>
<td>Order in which this node succeeds to presidency</td>
</tr>
<tr>
<td>Conf_HB_order</td>
<td>integer</td>
<td>-</td>
</tr>
<tr>
<td>arbitrator</td>
<td>integer</td>
<td>Node ID of arbitrator</td>
</tr>
<tr>
<td>arb_ticket</td>
<td>string</td>
<td>Internal identifier used to track arbitration</td>
</tr>
<tr>
<td>arb_state</td>
<td>Enumeration (see text)</td>
<td>Arbitration state</td>
</tr>
<tr>
<td>arb_connected</td>
<td>Yes or No</td>
<td>Whether this node is connected to the arbitrator</td>
</tr>
<tr>
<td>connected_rank1_arbs</td>
<td>List of node IDs</td>
<td>Connected arbitrators of rank 1</td>
</tr>
<tr>
<td>connected_rank2_arbs</td>
<td>List of node IDs</td>
<td>Connected arbitrators of rank 1</td>
</tr>
</tbody>
</table>

The node ID and node group ID are the same as reported by ndb_mgm -e "SHOW".

left_node and right_node are defined in terms of a model that connects all data nodes in a circle, in order of their node IDs, similar to the ordering of the numbers on a clock dial, as shown here:

Figure 22.27 Circular Arrangement of NDB Cluster Nodes

In this example, we have 8 data nodes, numbered 5, 6, 7, 8, 12, 13, 14, and 15, ordered clockwise in a circle. We determine “left” and “right” from the interior of the circle. The node to the left of node 5 is node 15, and the node to the right of node 5 is node 6. You can see all these relationships by running the following query and observing the output:

```
mysql> SELECT node_id, left_node, right_node
         -> FROM ndbinfo.membership;
+---------+-----------+------------+
| node_id | left_node | right_node |
+---------+-----------+------------+
|       5 |        15 |          6 |
```
The designations “left” and “right” are used in the event log in the same way.

The president node is the node viewed by the current node as responsible for setting an arbitrator (see NDB Cluster Start Phases). If the president fails or becomes disconnected, the current node expects the node whose ID is shown in the successor column to become the new president. The succession_order column shows the place in the succession queue that the current node views itself as having.

In a normal NDB Cluster, all data nodes should see the same node as president, and the same node (other than the president) as its successor. In addition, the current president should see itself as 1 in the order of succession, the successor node should see itself as 2, and so on.

All nodes should show the same arb_ticket values as well as the same arb_state values. Possible arb_state values are ARBIT_NULL, ARBIT_INIT, ARBIT_FIND, ARBIT_PREP1, ARBIT_PREF2, ARBIT_START, ARBIT_RUN, ARBIT_CHOOSE, ARBIT_CRASH, and UNKNOWN.

arb_connected shows whether this node is connected to the node shown as this node’s arbitrator.

The connected_rank1_arbs and connected_rank2_arbs columns each display a list of 0 or more arbitrators having an ArbitrationRank equal to 1, or to 2, respectively.

Note
Both management nodes and API nodes are eligible to become arbitrators.

22.5.10.28 The ndbinfo memoryusage Table

Querying this table provides information similar to that provided by the ALL REPORT MemoryUsage command in the ndb_mgm client, or logged by ALL DUMP 1000.

The following table provides information about the columns in the memoryusage table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>node_id</td>
<td>integer</td>
<td>The node ID of this data node.</td>
</tr>
<tr>
<td>memory_type</td>
<td>string</td>
<td>One of Data memory, Index memory, or Long message buffer.</td>
</tr>
<tr>
<td>used</td>
<td>integer</td>
<td>Number of bytes currently used for data memory or index memory by this data node.</td>
</tr>
<tr>
<td>used_pages</td>
<td>integer</td>
<td>Number of pages currently used for data memory or index memory by this data node; see text.</td>
</tr>
<tr>
<td>total</td>
<td>integer</td>
<td>Total number of bytes of data memory or index memory available for this data node; see text.</td>
</tr>
</tbody>
</table>
### Table 22.320 Columns of the ndbinfo memoryusage table

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>total_pages</td>
<td>integer</td>
<td>Total number of memory pages available for data memory or index memory on this data node; see text.</td>
</tr>
</tbody>
</table>

The `total` column represents the total amount of memory in bytes available for the given resource (data memory or index memory) on a particular data node. This number should be approximately equal to the setting of the corresponding configuration parameter in the `config.ini` file.

Suppose that the cluster has 2 data nodes having node IDs 5 and 6, and the `config.ini` file contains the following:

```plaintext
[ndbd default]
DataMemory = 1G
IndexMemory = 1G
```

Suppose also that the value of the `LongMessageBuffer` configuration parameter is allowed to assume its default (64 MB).

The following query shows approximately the same values:

```sql
mysql> SELECT node_id, memory_type, total
> FROM ndbinfo.memoryusage;
+---------+---------------------+------------+
<table>
<thead>
<tr>
<th>node_id</th>
<th>memory_type</th>
<th>total</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>Data memory</td>
<td>1073741824</td>
</tr>
<tr>
<td>5</td>
<td>Index memory</td>
<td>1074003968</td>
</tr>
<tr>
<td>5</td>
<td>Long message buffer</td>
<td>67108864</td>
</tr>
<tr>
<td>6</td>
<td>Data memory</td>
<td>1073741824</td>
</tr>
<tr>
<td>6</td>
<td>Index memory</td>
<td>1074003968</td>
</tr>
<tr>
<td>6</td>
<td>Long message buffer</td>
<td>67108864</td>
</tr>
</tbody>
</table>
+---------+---------------------+------------+
6 rows in set (0.00 sec)
```

In this case, the `total` column values for index memory are slightly higher than the value set of `IndexMemory` due to internal rounding.

For the `used_pages` and `total_pages` columns, resources are measured in pages, which are 32K in size for `DataMemory` and 8K for `IndexMemory`. For long message buffer memory, the page size is 256 bytes.

### 22.5.10.29 The ndbinfo memory_per_fragment Table

The `memory_per_fragment` table provides information about the usage of memory by individual fragments.

The following table provides information about the columns in the `memory_per_fragment` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

### Table 22.320 Columns of the memory_per_fragment table

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fq_name</td>
<td>string</td>
<td>Name of this fragment</td>
</tr>
<tr>
<td>parent_fq_name</td>
<td>string</td>
<td>Name of this fragment's parent</td>
</tr>
<tr>
<td>type</td>
<td>string</td>
<td>Type of object; see text for possible values</td>
</tr>
<tr>
<td>table_id</td>
<td>integer</td>
<td>Table ID for this table</td>
</tr>
<tr>
<td>node_id</td>
<td>integer</td>
<td>Node ID for this node</td>
</tr>
<tr>
<td>block_instance</td>
<td>integer</td>
<td>Kernel block instance ID</td>
</tr>
<tr>
<td>Column Name</td>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>-----------</td>
<td>------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>fragment_num</td>
<td>integer</td>
<td>Fragment ID (number)</td>
</tr>
<tr>
<td>fixed_elem_alloc_bytes</td>
<td>integer</td>
<td>Number of bytes allocated for fixed-sized elements</td>
</tr>
<tr>
<td>fixed_elem_free_bytes</td>
<td>integer</td>
<td>Free bytes remaining in pages allocated to fixed-size elements</td>
</tr>
<tr>
<td>fixed_elem_size_bytes</td>
<td>integer</td>
<td>Length of each fixed-size element in bytes</td>
</tr>
<tr>
<td>fixed_elem_count</td>
<td>integer</td>
<td>Number of fixed-size elements</td>
</tr>
<tr>
<td>fixed_elem_free_count</td>
<td>decimal</td>
<td>Number of free rows for fixed-size elements</td>
</tr>
<tr>
<td>var_elem_alloc_bytes</td>
<td>integer</td>
<td>Number of bytes allocated for variable-size elements</td>
</tr>
<tr>
<td>var_elem_free_bytes</td>
<td>integer</td>
<td>Free bytes remaining in pages allocated to variable-size elements</td>
</tr>
<tr>
<td>var_elem_count</td>
<td>integer</td>
<td>Number of variable-size elements</td>
</tr>
<tr>
<td>hash_index_alloc_bytes</td>
<td>integer</td>
<td>Number of bytes allocated to hash indexes</td>
</tr>
</tbody>
</table>

The **type** column from this table shows the dictionary object type used for this fragment (**Object::Type**, in the NDB API), and can take any one of the values shown in the following list:

- System table
- User table
- Unique hash index
- Hash index
- Unique ordered index
- Ordered index
- Hash index trigger
- Subscription trigger
- Read only constraint
- Index trigger
- Reorganize trigger
- Tablespace
- Log file group
- Data file
- Undo file
- Hash map
- Foreign key definition
- Foreign key parent trigger
- Foreign key child trigger
- Schema transaction
You can also obtain this list by executing `SELECT * FROM ndbinfo.dict_obj_types` in the `mysql` client.

The `block_instance` column provides the NDB kernel block instance number. You can use this to obtain information about specific threads from the `threadblocks` table.

### 22.5.10.30 The ndbinfo nodes Table

This table contains information on the status of data nodes. For each data node that is running in the cluster, a corresponding row in this table provides the node’s node ID, status, and uptime. For nodes that are starting, it also shows the current start phase.

The following table provides information about the columns in the `nodes` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>node_id</td>
<td>integer</td>
<td>The data node’s unique node ID in the cluster.</td>
</tr>
<tr>
<td>uptime</td>
<td>integer</td>
<td>Time since the node was last started, in seconds.</td>
</tr>
<tr>
<td>status</td>
<td>string</td>
<td>Current status of the data node; see text for possible values.</td>
</tr>
<tr>
<td>start_phase</td>
<td>integer</td>
<td>If the data node is starting, the current start phase.</td>
</tr>
<tr>
<td>config_generation</td>
<td>integer</td>
<td>The version of the cluster configuration file in use on this data node.</td>
</tr>
</tbody>
</table>

The `uptime` column shows the time in seconds that this node has been running since it was last started or restarted. This is a `BIGINT` value. This figure includes the time actually needed to start the node; in other words, this counter starts running the moment that `ndbd` or `ndbmtd` is first invoked; thus, even for a node that has not yet finished starting, `uptime` may show a nonzero value.

The `status` column shows the node’s current status. This is one of: `NOTHING`, `CMVMI`, `STARTING`, `STARTED`, `SINGLEUSER`, `STOPPING_1`, `STOPPING_2`, `STOPPING_3`, or `STOPPING_4`. When the status is `STARTING`, you can see the current start phase in the `start_phase` column (see later in this section). `SINGLEUSER` is displayed in the `status` column for all data nodes when the cluster is in single user mode (see Section 22.5.8, “NDB Cluster Single User Mode”). Seeing one of the `STOPPING` states does not necessarily mean that the node is shutting down but can mean rather that it is entering a new state. For example, if you put the cluster in single user mode, you can sometimes see data nodes report their state briefly as `STOPPING_2` before the status changes to `SINGLEUSER`.

The `start_phase` column uses the same range of values as those used in the output of the `ndb_mgm` client `node_id STATUS` command (see Section 22.5.2, “Commands in the NDB Cluster Management Client”). If the node is not currently starting, then this column shows 0. For a listing of NDB Cluster start phases with descriptions, see Section 22.5.1, “Summary of NDB Cluster Start Phases”.

The `config_generation` column shows which version of the cluster configuration is in effect on each data node. This can be useful when performing a rolling restart of the cluster in order to make changes in configuration parameters. For example, from the output of the following `SELECT` statement, you can see that node 3 is not yet using the latest version of the cluster configuration (6) although nodes 1, 2, and 4 are doing so:

```sql
mysql> USE ndbinfo;
Database changed
mysql> SELECT * FROM nodes;
+---------+--------+---------+-------------+-------------------+
| node_id | uptime | status  | start_phase |
|---------|--------|---------|-------------|-------------------|
| 3992    | 3      | STOPPING_4 | 1           |
| 1       | 0      | SINGLEUSER | 0           |
| 2       | 0      | SINGLEUSER | 0           |
| 4       | 0      | SINGLEUSER | 0           |
```
Therefore, for the case just shown, you should restart node 3 to complete the rolling restart of the cluster.

Nodes that are stopped are not accounted for in this table. Suppose that you have an NDB Cluster with 4 data nodes (node IDs 1, 2, 3 and 4), and all nodes are running normally, then this table contains 4 rows, 1 for each data node:

```
mysql> USE ndbinfo;
Database changed
mysql> SELECT * FROM nodes;
+---------+--------+---------+-------------+-------------------+
| node_id | uptime | status  | start_phase | config_generation |
+---------+--------+---------+-------------+-------------------+
|       1 |  11776 | STARTED |           0 |                 6 |
|       2 |  11774 | STARTED |           0 |                 6 |
|       3 |  11771 | STARTED |           0 |                 6 |
|       4 |  11769 | STARTED |           0 |                 6 |
+---------+--------+---------+-------------+-------------------+
4 rows in set (0.04 sec)
```

If you shut down one of the nodes, only the nodes that are still running are represented in the output of this `SELECT` statement, as shown here:

```
ndb_mgm> 2 STOP
Node 2: Node shutdown initiated
Node 2: Node shutdown completed.
Node 2 has shutdown.
mysql> SELECT * FROM nodes;
+---------+--------+---------+-------------+-------------------+
| node_id | uptime | status  | start_phase | config_generation |
+---------+--------+---------+-------------+-------------------+
|       1 |  11807 | STARTED |           0 |                 6 |
|       3 |  11802 | STARTED |           0 |                 6 |
|       4 |  11800 | STARTED |           0 |                 6 |
+---------+--------+---------+-------------+-------------------+
3 rows in set (0.02 sec)
```

### 22.5.10.31 The ndbinfo `operations_per_fragment` Table

The `operations_per_fragment` table provides information about the operations performed on individual fragments and fragment replicas, as well as about some of the results from these operations.

The following table provides information about the columns in the `operations_per_fragment` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>fq_name</code></td>
<td>string</td>
<td>Name of this fragment</td>
</tr>
<tr>
<td><code>parent_fq_name</code></td>
<td>string</td>
<td>Name of this fragment's parent</td>
</tr>
<tr>
<td><code>type</code></td>
<td>string</td>
<td>Type of object; see text for possible values</td>
</tr>
<tr>
<td><code>table_id</code></td>
<td>integer</td>
<td>Table ID for this table</td>
</tr>
<tr>
<td><code>node_id</code></td>
<td>integer</td>
<td>Node ID for this node</td>
</tr>
<tr>
<td><code>block_instance</code></td>
<td>integer</td>
<td>Kernel block instance ID</td>
</tr>
<tr>
<td>Column Name</td>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------</td>
<td>----------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>fragment_num</td>
<td>integer</td>
<td>Fragment ID (number)</td>
</tr>
<tr>
<td>tot_key_reads</td>
<td>integer</td>
<td>Total number of key reads for this fragment replica</td>
</tr>
<tr>
<td>tot_key_inserts</td>
<td>integer</td>
<td>Total number of key inserts for this fragment replica</td>
</tr>
<tr>
<td>tot_key_updates</td>
<td>integer</td>
<td>Total number of key updates for this fragment replica</td>
</tr>
<tr>
<td>tot_key_writes</td>
<td>integer</td>
<td>Total number of key writes for this fragment replica</td>
</tr>
<tr>
<td>tot_key_deletes</td>
<td>integer</td>
<td>Total number of key deletes for this fragment replica</td>
</tr>
<tr>
<td>tot_key.refs</td>
<td>integer</td>
<td>Number of key operations refused</td>
</tr>
<tr>
<td>tot_key_attrinfo_bytes</td>
<td>integer</td>
<td>Total size of all attrinfo attributes</td>
</tr>
<tr>
<td>tot_key_keyinfo_bytes</td>
<td>integer</td>
<td>Total size of all keyinfo attributes</td>
</tr>
<tr>
<td>tot_key_prog_bytes</td>
<td>integer</td>
<td>Total size of all interpreted programs carried by attrinfo attributes</td>
</tr>
<tr>
<td>tot_key_inst_exec</td>
<td>integer</td>
<td>Total number of instructions executed by interpreted programs for key operations</td>
</tr>
<tr>
<td>tot_key_bytes_returned</td>
<td>integer</td>
<td>Total size of all data and metadata returned from key read operations</td>
</tr>
<tr>
<td>tot_frag_scans</td>
<td>integer</td>
<td>Total number of scans performed on this fragment replica</td>
</tr>
<tr>
<td>tot_scan_rows_examined</td>
<td>integer</td>
<td>Total number of rows examined by scans</td>
</tr>
<tr>
<td>tot_scan_rows_returned</td>
<td>integer</td>
<td>Total number of rows returned to client</td>
</tr>
<tr>
<td>tot_scan_bytes_returned</td>
<td>integer</td>
<td>Total size of data and metadata returned to the client</td>
</tr>
<tr>
<td>tot_scan_prog_bytes</td>
<td>integer</td>
<td>Total size of interpreted programs for scan operations</td>
</tr>
<tr>
<td>tot_scan_bound_bytes</td>
<td>integer</td>
<td>Total size of all bounds used in ordered index scans</td>
</tr>
<tr>
<td>tot_scan_inst_exec</td>
<td>integer</td>
<td>Total number of instructions executed for scans</td>
</tr>
<tr>
<td>tot_qd_frag_scans</td>
<td>integer</td>
<td>Number of times that scans of this fragment replica have been queued</td>
</tr>
<tr>
<td>conc_frag_scans</td>
<td>integer</td>
<td>Number of scans currently active on this fragment replica (excluding queued scans)</td>
</tr>
<tr>
<td>conc_qd_frag_scans</td>
<td>integer</td>
<td>Number of scans currently queued for this fragment replica</td>
</tr>
<tr>
<td>tot_commits</td>
<td>integer</td>
<td>Total number of row changes committed to this fragment replica</td>
</tr>
</tbody>
</table>

The `fq_name` contains the fully qualified name of the schema object to which this fragment replica belongs. This currently has the following formats:

- **Base table:** - `DbName/def/TblName`
- **BLOB table:** - `DbName/def/NDB$BLOB_BaseTblId_ColNo`
- **Ordered index:** - `sys/def/BaseTblId/IndexName`
The $unique suffix shown for unique indexes is added by mysqld; for an index created by a different
NDB API client application, this may differ, or not be present.

The syntax just shown for fully qualified object names is an internal interface which is subject to change
in future releases.

Consider a table $t1 created and modified by the following SQL statements:

```sql
CREATE DATABASE mydb;
USE mydb;
CREATE TABLE t1 (  
a INT NOT NULL,  
b INT NOT NULL,  
t TEXT NOT NULL,  
PRIMARY KEY (b)  
) ENGINE=ndbcluster;
CREATE UNIQUE INDEX ix1 ON t1(b) USING HASH;
```

If $t1 is assigned table ID 11, this yields the fq_name values shown here:

- **Base table**: mydb/def/t1
- **BLOB table**: mydb/def/NDB$BLOB_11_2
- **Ordered index (primary key)**: sys/def/11(PRIMARY
- **Unique index**: sys/def/11/ix1$unique

For indexes or BLOB tables, the parent_fq_name column contains the fq_name of the corresponding
base table. For base tables, this column is always NULL.

The type column shows the schema object type used for this fragment, which can take any one of the values
System table, User table, Unique hash index, or Ordered index. BLOB tables are
shown as User table.

The table_id column value is unique at any given time, but can be reused if the corresponding object
has been deleted. The same ID can be seen using the ndb_show_tables utility.

The block_instance column shows which LDM instance this fragment replica belongs to. You can
use this to obtain information about specific threads from the threadblocks table. The first such
instance is always numbered 0.

Since there are typically two replicas, and assuming that this is so, each fragment_num value should
appear twice in the table, on two different data nodes from the same node group.

Since NDB does not use single-key access for ordered indexes, the counts for tot_key_reads,
tot_key_inserts, tot_key_updates, tot_key_writes, and tot_key_deletes are not
incremented by ordered index operations.

**Note**

When using tot_key_writes, you should keep in mind that a write operation
in this context updates the row if the key exists, and inserts a new row
otherwise. (One use of this is in the NDB implementation of the REPLACE SQL
statement.)

The tot_key.refs column shows the number of key operations refused by the LDM. Generally, such
a refusal is due to duplicate keys (inserts), Key not found errors (updates, deletes, and reads), or
the operation was rejected by an interpreted program used as a predicate on the row matching the key.
The `attrinfo` and `keyinfo` attributes counted by the `tot_key_attrinfo_bytes` and `tot_key_keyinfo_bytes` columns are attributes of an LQHKEYREQ signal (see The NDB Communication Protocol) used to initiate a key operation by the LDM. An `attrinfo` typically contains tuple field values (inserts and updates) or projection specifications (for reads); `keyinfo` contains the primary or unique key needed to locate a given tuple in this schema object.

The value shown by `tot_frag_scans` includes both full scans (that examine every row) and scans of subsets. Unique indexes and BLOB tables are never scanned, so this value, like other scan-related counts, is 0 for fragment replicas of these.

`tot_scan_rows_examined` may display less than the total number of rows in a given fragment replica, since ordered index scans can limited by bounds. In addition, a client may choose to end a scan before all potentially matching rows have been examined; this occurs when using an SQL statement containing a LIMIT or EXISTS clause, for example. `tot_scan_rows_returned` is always less than or equal to `tot_scan_rows_examined`.

`tot_scan_bytes_returned` includes, in the case of pushed joins, projections returned to the DBSPJ block in the NDB kernel.

`tot_qd_frag_scans` can be effected by the setting for the MaxParallelScansPerFragment data node configuration parameter, which limits the number of scans that may execute concurrently on a single fragment replica.

### 22.5.10.32 The ndbinfo pgman_time_track_stats Table

This table provides information regarding the latency of disk operations for NDB Cluster Disk Data tablespaces.

The following table provides information about the columns in the `pgman_time_track_stats` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

#### Table 22.323 Columns of the pgman_time_track_stats table

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>node_id</td>
<td>integer</td>
<td>Unique node ID of this node in the cluster</td>
</tr>
<tr>
<td>block_number</td>
<td>integer</td>
<td>Block number (from blocks table)</td>
</tr>
<tr>
<td>block_instance</td>
<td>integer</td>
<td>Block instance number</td>
</tr>
<tr>
<td>upper_bound</td>
<td>integer</td>
<td>Upper bound</td>
</tr>
<tr>
<td>page_reads</td>
<td>integer</td>
<td>Page read latency (ms)</td>
</tr>
<tr>
<td>page_writes</td>
<td>integer</td>
<td>Page write latency (ms)</td>
</tr>
<tr>
<td>log_waits</td>
<td>integer</td>
<td>Log wait latency (ms)</td>
</tr>
<tr>
<td>get_page</td>
<td>integer</td>
<td>Latency of <code>get_page()</code> calls (ms)</td>
</tr>
</tbody>
</table>

The read latency (`page_reads` column) measures the time from when the read request is sent to the file system thread until the read is complete and has been reported back to the execution thread. The write latency (`page_writes`) is calculated in a similar fashion. The size of the page read to or written from a Disk Data tablespace is always 32 KB.

Log wait latency (`log_waits` column) is the length of time a page write must wait for the undo log to be flushed, which must be done prior to each page write.

The `pgman_time_track_stats` table was added in NDB 8.0.19.

### 22.5.10.33 The ndbinfo processes Table

This table contains information about NDB Cluster node processes; each node is represented by the row in the table. Only nodes that are connected to the cluster are shown in this table. You can obtain
information about nodes that are configured but not connected to the cluster from the `nodes` and `config_nodes` tables.

The following table provides information about the columns in the `processes` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

**Table 22.324 Columns of the nodes table**

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>node_id</td>
<td>integer</td>
<td>The node's unique node ID in the cluster</td>
</tr>
<tr>
<td>node_type</td>
<td>string</td>
<td>Type of node (management, data, or API node; see text)</td>
</tr>
<tr>
<td>node_version</td>
<td>string</td>
<td>Version of the NDB software program running on this node.</td>
</tr>
<tr>
<td>process_id</td>
<td>integer</td>
<td>This node's process ID</td>
</tr>
<tr>
<td>angel_process_id</td>
<td>integer</td>
<td>Process ID of this node's angel process</td>
</tr>
<tr>
<td>process_name</td>
<td>string</td>
<td>Name of the executable</td>
</tr>
<tr>
<td>service_URI</td>
<td>string</td>
<td>Service URI of this node (see text)</td>
</tr>
</tbody>
</table>

- **node_id** is the ID assigned to this node in the cluster.

- **node_type** column displays one of the following three values:
  - **MGM**: Management node.
  - **NDB**: Data node.
  - **API**: API or SQL node.

  For an executable shipped with the NDB Cluster distribution, **node_version** shows the software Cluster version string, such as `8.0.20-ndb-8.0.20`.

- **process_id** is the node executable's process ID as shown by the host operating system using a process display application such as `top` on Linux, or the Task Manager on Windows platforms.

- **angel_process_id** is the system process ID for the node's angel process, which ensures that a data node or SQL is automatically restarted in cases of failures. For management nodes and API nodes other than SQL nodes, the value of this column is **NULL**.

- **process_name** column shows the name of the running executable. For management nodes, this is **ndb_mgmd**. For data nodes, this is **ndbd** (single-threaded) or **ndbmtd** (multithreaded). For SQL nodes, this is **mysqld**. For other types of API nodes, it is the name of the executable program connected to the cluster; NDB API applications can set a custom value for this using `Ndb_cluster_connection::set_name()`.

- **service_URI** shows the service network address. For management nodes and data nodes, the scheme used is **ndb://**. For SQL nodes, this is **mysql://**. By default, API nodes other than SQL nodes use **ndb://** for the scheme; NDB API applications can set this to a custom value using `Ndb_cluster_connection::set_service_uri()`. Regardless of the node type, the scheme is followed by the IP address used by the NDB transporter for the node in question. For management nodes and SQL nodes, this address includes the port number (usually 1186 for management nodes and 3306 for SQL nodes). If the SQL node was started with the `bind_address` system variable set, this address is used instead of the transporter address, unless the bind address is set to `*,0.0.0.0`, or `::`.

- Additional path information may be included in the **service_URI** value for an SQL node reflecting various configuration options. For example, **mysql://198.51.100.3/tmp/mysql.sock**
ndbinfo: The NDB Cluster Information Database

indicates that the SQL node was started with the `skip_networking` system variable enabled, and `mysql://198.51.100.3:3306/?server-id=1` shows that replication is enabled for this SQL node.

### 22.5.10.34 The ndbinfo resources Table

This table provides information about data node resource availability and usage.

These resources are sometimes known as *super-pools*.

The following table provides information about the columns in the `resources` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

#### Table 22.325 Columns of the resources table

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>node_id</td>
<td>integer</td>
<td>The unique node ID of this data node.</td>
</tr>
<tr>
<td>resource_name</td>
<td>string</td>
<td>Name of the resource; see text.</td>
</tr>
<tr>
<td>reserved</td>
<td>integer</td>
<td>The amount reserved for this resource.</td>
</tr>
<tr>
<td>used</td>
<td>integer</td>
<td>The amount actually used by this resource.</td>
</tr>
<tr>
<td>max</td>
<td>integer</td>
<td>The maximum amount of this resource used, since the node was last started.</td>
</tr>
</tbody>
</table>

The `resource_name` can be one of the names shown in the following table:

#### Table 22.326 ndbinfo.resources table resource names and descriptions

<table>
<thead>
<tr>
<th>Resource name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>RESERVED</td>
<td>Reserved by the system; cannot be overridden.</td>
</tr>
<tr>
<td>DISK_OPERATIONS</td>
<td>If a log file group is allocated, the size of the undo log buffer is used to set the size of this resource. This resource is used only to allocate the undo log buffer for an undo log file group; there can only be one such group. Overallocation occurs as needed by <code>CREATE LOGFILE GROUP</code>.</td>
</tr>
<tr>
<td>DISK_RECORDS</td>
<td>Records allocated for Disk Data operations.</td>
</tr>
<tr>
<td>DATA_MEMORY</td>
<td>Used for main memory tuples, indexes, and hash indexes. Sum of DataMemory and IndexMemory, plus 8 pages of 32 KB each if IndexMemory has been set. Cannot be overallocated.</td>
</tr>
<tr>
<td>JOBBUFFER</td>
<td>Used for allocating job buffers by the NDB scheduler; cannot be overallocated. This is approximately 2 MB per thread plus a 1 MB buffer in both directions for all threads that can communicate. For large configurations this consume several GB.</td>
</tr>
<tr>
<td>FILE_BUFFERS</td>
<td>Used by the redo log handler in the DBLQH kernel block; cannot be overallocated. Size is $\text{NoOfFragmentLogParts} \times \text{RedoBuffer}$, plus 1 MB per log file part.</td>
</tr>
<tr>
<td>TRANSPORTER_BUFFERS</td>
<td>Used for send buffers by <code>ndbmd</code>; the sum of <code>TotalSendBufferMemory</code> and <code>ExtraSendBufferMemory</code>. This resource that can be overallocated by up to 25 percent. <code>TotalSendBufferMemory</code> is calculated by summing the send buffer memory per node, the default value of which is 2 MB. Thus, in a system having four data nodes and eight API nodes, the data nodes have 12 * 2 MB send buffer memory. <code>ExtraSendBufferMemory</code> is used by <code>ndbmd</code> and amounts to 2 MB extra memory per thread. Thus, with 4 LDM threads, 2 TC threads, 1 main thread, 1 replication thread, and 2 receive threads, <code>ExtraSendBufferMemory</code> is 10 * 2 MB. Overallocation of...</td>
</tr>
</tbody>
</table>
### Resource name | Description
---|---
**ndbinfo**: The NDB Cluster Information Database

<table>
<thead>
<tr>
<th>Resource name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DISK_PAGE_BUFFER</td>
<td>Used for the disk page buffer; determined by the DiskPageBufferMemory configuration parameter. Cannot be overallocated.</td>
</tr>
<tr>
<td>QUERY_MEMORY</td>
<td>Used by the DBSPJ kernel block.</td>
</tr>
<tr>
<td>SCHEMA_TRANS_MEMORY</td>
<td>Minimum is 2 MB; can be overallocated to use any remaining available memory.</td>
</tr>
</tbody>
</table>

### 22.5.10.35 The ndbinfo restart_info Table

The restart_info table contains information about node restart operations. Each entry in the table corresponds to a node restart status report in real time from a data node with the given node ID. Only the most recent report for any given node is shown.

The following table provides information about the columns in the restart_info table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

**Table 22.327 Columns of the restart_info table**

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>node_id</td>
<td>integer</td>
<td>Node ID in the cluster</td>
</tr>
<tr>
<td>node_restart_status</td>
<td>VARCHAR(256)</td>
<td>Node status; see text for values. Each of these corresponds to a possible value of node_restart_status_int.</td>
</tr>
<tr>
<td>node_restart_status_int</td>
<td>integer</td>
<td>Node status code; see text for values.</td>
</tr>
<tr>
<td>secs_to_complete_node_failure</td>
<td>integer</td>
<td>Time in seconds to complete node failure handling</td>
</tr>
<tr>
<td>secs_to_allocate_node_id</td>
<td>integer</td>
<td>Time in seconds from node failure completion to allocation of node ID</td>
</tr>
<tr>
<td>secs_to_include_in_heartbeat_protocol</td>
<td>integer</td>
<td>Time in seconds from allocation of node ID to inclusion in heartbeat protocol</td>
</tr>
<tr>
<td>secs_until_wait_for_ndbcntr_master</td>
<td>integer</td>
<td>Time in seconds from being included in heartbeat protocol until waiting for NDBCNTR master began</td>
</tr>
<tr>
<td>secs_wait_for_ndbcntr_master</td>
<td>integer</td>
<td>Time in seconds spent waiting to be accepted by NDBCNTR master for starting</td>
</tr>
<tr>
<td>secs_to_get_start_permission</td>
<td>integer</td>
<td>Time in seconds elapsed from receiving of permission for start from master until all nodes have accepted start of this node</td>
</tr>
<tr>
<td>secs_to_wait_for_lcp_for_copy_meta_data</td>
<td>integer</td>
<td>Time in seconds spent waiting for LCP completion before copying meta data</td>
</tr>
<tr>
<td>secs_to_copy_meta_data</td>
<td>integer</td>
<td>Time in seconds required to copy metadata from master to newly starting node</td>
</tr>
<tr>
<td>secs_to_include_node</td>
<td>integer</td>
<td>Time in seconds waited for GCP and inclusion of all nodes into protocols</td>
</tr>
<tr>
<td>secs_starting_node_to_request_local_recovery</td>
<td>integer</td>
<td>Time in seconds that the node just starting spent waiting to request local recovery</td>
</tr>
<tr>
<td>secs_for_local_recovery</td>
<td>integer</td>
<td>Time in seconds required for local recovery by node just starting</td>
</tr>
<tr>
<td>Column Name</td>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>---------------</td>
<td>-------------------------------------------------------</td>
</tr>
<tr>
<td>secs_restore_fragments</td>
<td>integer</td>
<td>Time in seconds required to restore fragments from LCP files</td>
</tr>
<tr>
<td>secs_undo_disk_data</td>
<td>integer</td>
<td>Time in seconds required to execute undo log on disk data part of records</td>
</tr>
<tr>
<td>secs_exec_redo_log</td>
<td>integer</td>
<td>Time in seconds required to execute redo log on all restored fragments</td>
</tr>
<tr>
<td>secs_index_rebuild</td>
<td>integer</td>
<td>Time in seconds required to rebuild indexes on restored fragments</td>
</tr>
<tr>
<td>secs_to_synchronize_starting_node</td>
<td>integer_node</td>
<td>Time in seconds required to synchronize starting node from live nodes</td>
</tr>
<tr>
<td>secs_wait_lcp_for_restart</td>
<td>integer</td>
<td>Time in seconds required for LCP start and completion before restart was completed</td>
</tr>
<tr>
<td>secs_wait_subscription</td>
<td>integer</td>
<td>Time in seconds spent waiting for handover of replication subscriptions</td>
</tr>
<tr>
<td>total_restart_secs</td>
<td>integer</td>
<td>Total number of seconds from node failure until node is started again</td>
</tr>
</tbody>
</table>

Defined values for `node_restart_status_int` and corresponding status names and messages (`node_restart_status`) are shown in the following table:

**Table 22.328 Status codes and messages used in the restart_info table**

<table>

<td>string</td>
<td>Whether this is first holding lock in row lock queue</td>
</tr>
<tr>
<td>op</td>
<td>string</td>
<td>Operation type</td>
</tr>
<tr>
<td>duration_millis</td>
<td>integer</td>
<td>Milliseconds spent waiting or holding lock</td>
</tr>
<tr>
<td>lock_num</td>
<td>integer</td>
<td>ID of lock object</td>
</tr>
<tr>
<td>waiting_for</td>
<td>integer</td>
<td>Waiting for lock with this ID</td>
</tr>
</tbody>
</table>

The mysql_connection_id column shows the MySQL connection or thread ID as shown by `SHOW PROCESSLIST`.

block_instance refers to an instance of a kernel block. Together with the block name, this number can be used to look up a given instance in the threadblocks table.
The `tableid` is assigned to the table by NDB; the same ID is used for this table in other ndbinfo tables, as well as in the output of `ndb_show_tables`.

The transaction ID shown in the `transid` column is the identifier generated by the NDB API for the transaction requesting or holding the current lock.

The `mode` column shows the lock mode, which is always one of `S` (shared lock) or `X` (exclusive lock). If a transaction has an exclusive lock on a given row, all other locks on that row have the same transaction ID.

The `state` column shows the lock state. Its value is always one of `H` (holding) or `W` (waiting). A waiting lock request waits for a lock held by a different transaction.

The `detail` column indicates whether this lock is the first holding lock in the affected row’s lock queue, in which case it contains a * (asterisk character); otherwise, this column is empty. This information can be used to help identify the unique entries in a list of lock requests.

The `op` column shows the type of operation requesting the lock. This is always one of the values `READ`, `INSERT`, `UPDATE`, `DELETE`, `SCAN`, or `REFRESH`.

The `duration_millis` column shows the number of milliseconds for which this lock request has been waiting or holding the lock. This is reset to 0 when a lock is granted for a waiting request.

The lock ID (lockid column) is unique to this node and block instance.

If the `lock_state` column’s value is `W`, this lock is waiting to be granted, and the `waiting_for` column shows the lock ID of the lock object this request is waiting for. Otherwise, `waiting_for` is empty. `waiting_for` can refer only to locks on the same row (as identified by `node_id`, `block_instance`, `tableid`, `fragmentid`, and `rowid`).

### 22.5.10.37 The ndbinfo server_operations Table

The `server_operations` table contains entries for all ongoing NDB operations that the current SQL node (MySQL Server) is currently involved in. It effectively is a subset of the `cluster_operations` table, in which operations for other SQL and API nodes are not shown.

The following table provides information about the columns in the `server_operations` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mysql_connection_id</td>
<td>integer</td>
<td>MySQL Server connection ID</td>
</tr>
<tr>
<td>node_id</td>
<td>integer</td>
<td>Node ID</td>
</tr>
<tr>
<td>block_instance</td>
<td>integer</td>
<td>Block instance</td>
</tr>
<tr>
<td>transid</td>
<td>integer</td>
<td>Transaction ID</td>
</tr>
<tr>
<td>operation_type</td>
<td>string</td>
<td>Operation type (see text for possible values)</td>
</tr>
<tr>
<td>state</td>
<td>string</td>
<td>Operation state (see text for possible values)</td>
</tr>
<tr>
<td>tableid</td>
<td>integer</td>
<td>Table ID</td>
</tr>
<tr>
<td>fragmentid</td>
<td>integer</td>
<td>Fragment ID</td>
</tr>
<tr>
<td>client_node_id</td>
<td>integer</td>
<td>Client node ID</td>
</tr>
<tr>
<td>client_block_ref</td>
<td>integer</td>
<td>Client block reference</td>
</tr>
<tr>
<td>tc_node_id</td>
<td>integer</td>
<td>Transaction coordinator node ID</td>
</tr>
<tr>
<td>tc_block_no</td>
<td>integer</td>
<td>Transaction coordinator block number</td>
</tr>
<tr>
<td>tc_block_instance</td>
<td>integer</td>
<td>Transaction coordinator block instance</td>
</tr>
</tbody>
</table>
The **mysql_connection_id** is the same as the connection or session ID shown in the output of **SHOW PROCESSLIST**. It is obtained from the **INFORMATION_SCHEMA** table **NDB_TRANSID_MYSQL_CONNECTION_MAP**.

**block_instance** refers to an instance of a kernel block. Together with the block name, this number can be used to look up a given instance in the **threadblocks** table.

The transaction ID (**transid**) is a unique 64-bit number which can be obtained using the NDB API's **getTransactionId()** method. (Currently, the MySQL Server does not expose the NDB API transaction ID of an ongoing transaction.)

The **operation_type** column can take any one of the values **READ**, **READ-SH**, **READ-EX**, **INSERT**, **UPDATE**, **DELETE**, **WRITE**, **UNLOCK**, **REFRESH**, **SCAN**, **SCAN-SH**, **SCAN-EX**, or **<unknown>**.

### ndbinfo: The NDB Cluster Information Database

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>outstanding_operations</td>
<td>integer</td>
<td>Operations still being executed by local data management layer (LQH blocks)</td>
</tr>
<tr>
<td>inactive_seconds</td>
<td>integer</td>
<td>Time spent waiting for API</td>
</tr>
<tr>
<td>client_node_id</td>
<td>integer</td>
<td>Client node ID</td>
</tr>
<tr>
<td>client_block_ref</td>
<td>integer</td>
<td>Client block reference</td>
</tr>
</tbody>
</table>

The `mysql_connection_id` is the same as the connection or session ID shown in the output of `SHOW PROCESSLIST`. It is obtained from the `INFORMATION_SCHEMA` table `NDB_TRANSID_MYSQL_CONNECTION_MAP`.

`block_instance` refers to an instance of a kernel block. Together with the block name, this number can be used to look up a given instance in the `threadblocks` table.

The transaction ID (`transid`) is a unique 64-bit number which can be obtained using the NDB API's `getTransactionId()` method. (Currently, the MySQL Server does not expose the NDB API transaction ID of an ongoing transaction.)

The `state` column can have any one of the values `CS_ABORTING, CS_COMMITTING, CS_COMMIT_SEND, CS_COMPLETE_SEND, CS_COMMITTING, CS_CONNECTED, CS_DISCONNECTED, CS_FAIL_ABORTED, CS_FAIL_ABORTING, CS_FAIL_COMMITTED, CS_FAIL_COMMITTING, CS_FAIL_PREPARED, CS_PREPARE_TO_COMMIT, CS_RECEIVING, CS_RECG_COMMITTING, CS_RESTART, CS_SEND_FIRE_TRIG_REQ, CS_STARTED, CS_START_COMMITTING, CS_START_SCAN, CS_WAIT_ABORT_CONF, CS_WAIT_COMMIT_CONF, CS_WAIT_COMPLETE_CONF, CS_WAIT_FIRE_TRIG_REQ`. (If the MySQL Server is running with `ndbinfo_show_hidden` enabled, you can view this list of states by selecting from the `ndb $dbtc_apiconnect_state` table, which is normally hidden.)

In `client_node_id` and `client_block_ref`, `client` refers to an NDB Cluster API or SQL node (that is, an NDB API client or a MySQL Server attached to the cluster).

The `block_instance` column provides the `DBTC` kernel block instance number. You can use this to obtain information about specific threads from the `threadblocks` table.

#### 22.5.10.39 The ndbinfo table_distribution_status Table

The `table_distribution_status` table provides information about the progress of table distribution for NDB tables.

The following table provides information about the columns in `table_distribution_status`. For each column, the table shows the name, data type, and a brief description.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>node_id</td>
<td>integer</td>
<td>Node id</td>
</tr>
<tr>
<td>table_id</td>
<td>integer</td>
<td>Table ID</td>
</tr>
<tr>
<td>tab_copy_status</td>
<td>string</td>
<td>Status of copying of table distribution data to disk; one of <code>IDLE, SR_PHASE1_READ_PAGES</code>, <code>SR_PHASE2_READ_TABLE</code>, <code>SR_PHASE3_COPY_TABLE</code>, <code>REMOVE_NODE</code>, <code>LCP_READ_TABLE</code>, <code>COPY_TAB_REQ</code>, <code>COPY_NODE_STATE</code>, <code>ADD_TABLE_MASTER</code>, <code>ADD_TABLE_SLAVE</code>, <code>INVALIDATE_NODE_LCP</code>, <code>ALTER_TABLE</code>, <code>COPY_TO_SAVE</code>, or <code>GET_TABINFO</code></td>
</tr>
</tbody>
</table>
22.5.10.40 The ndbinfo table_fragments Table

The table_fragments table provides information about the fragmentation, partitioning, distribution, and (internal) replication of NDB tables.

The following table provides information about the columns in table_fragments. For each column, the table shows the name, data type, and a brief description.

Table 22.333 Columns of the table_fragments table

<table>
<thead>
<tr>
<th>Column Name</th>

**current_third_backup** | integer | Current third backup node ID
**num_alive_replicas** | integer | Current number of live replicas
**num_dead_replicas** | integer | Current number of dead replicas
**num_lcp_replicas** | integer | Number of replicas remaining to be checkpointed

### 22.5.10.41 The ndbinfo table_info Table

The `table_info` table provides information about logging, checkpointing, distribution, and storage options in effect for individual NDB tables.

The following table provides information about the columns in `table_info`. For each column, the table shows the name, data type, and a brief description.

#### Table 22.334 Columns of the table_info table

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>table_id</td>
<td>integer</td>
<td>Table ID</td>
</tr>
<tr>
<td>logged_table</td>
<td>integer</td>
<td>Whether table is logged (1) or not (0)</td>
</tr>
<tr>
<td>row_contains_gci</td>
<td>integer</td>
<td>Whether table rows contain GCI (1 true, 0 false)</td>
</tr>
<tr>
<td>row_contains_checksum</td>
<td>integer</td>
<td>Whether table rows contain checksum (1 true, 0 false)</td>
</tr>
<tr>
<td>read_backup</td>
<td>integer</td>
<td>If backup replicas are read this is 1, otherwise 0</td>
</tr>
<tr>
<td>fully_replicated</td>
<td>integer</td>
<td>If table is fully replicated this is 1, otherwise 0</td>
</tr>
<tr>
<td>storage_type</td>
<td>string</td>
<td>Table storage type; one of MEMORY or DISK</td>
</tr>
<tr>
<td>hashmap_id</td>
<td>integer</td>
<td>Hashmap ID</td>
</tr>
<tr>

<td>Partition balance (fragment count type) used for table; one of FOR_RP_BY_NODE, FOR_RA_BY_NODE, FOR_RP_BY_LDM, or FOR_RA_BY_LDM</td>
</tr>
<tr>
<td>create_gci</td>
<td>integer</td>
<td>GCI in which table was created</td>
</tr>
</tbody>
</table>

### 22.5.10.42 The ndbinfo table_replicas Table

The `table_replicas` table provides information about the copying, distribution, and checkpointing of NDB table fragments and fragment replicas.

The following table provides information about the columns in `table_replicas`. For each column, the table shows the name, data type, and a brief description.

#### Table 22.335 Columns of the table_replicas table

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>node_id</td>
<td>integer</td>
<td>ID of the node from which data is fetched (DIH master)</td>
</tr>
</tbody>
</table>
The **ndbinfo** table provides time-tracking information obtained from the DBTC (TC) instances in the data nodes, through API nodes accessing NDB. Each TC instance tracks latencies for a set of activities it undertakes on behalf of API nodes or other data nodes; these activities include transactions, transaction errors, key reads, key writes, unique index operations, failed key operations of any type, scans, failed scans, fragment scans, and failed fragment scans.

A set of counters is maintained for each activity, each counter covering a range of latencies less than or equal to an upper bound. At the conclusion of each activity, its latency is determined and the appropriate counter incremented. **`tc_time_track_stats`** presents this information as rows, with a row for each instance of the following:

- Data node, using its ID
- TC block instance
- Other communicating data node or API node, using its ID
- Upper bound value

Each row contains a value for each activity type. This is the number of times that this activity occurred with a latency within the range specified by the row (that is, where the latency does not exceed the upper bound).

The following table provides information about the columns in **`tc_time_track_stats`**. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>

</tbody>
</table>

**22.5.10.43 The ndbinfo tc_time_track_stats Table**

The **tc_time_track_stats** table provides time-tracking information obtained from the DBTC block (TC) instances in the data nodes, through API nodes accessing NDB. Each TC instance tracks latencies for a set of activities it undertakes on behalf of API nodes or other data nodes; these activities include transactions, transaction errors, key reads, key writes, unique index operations, failed key operations of any type, scans, failed scans, fragment scans, and failed fragment scans.

A set of counters is maintained for each activity, each counter covering a range of latencies less than or equal to an upper bound. At the conclusion of each activity, its latency is determined and the appropriate counter incremented. **`tc_time_track_stats`** presents this information as rows, with a row for each instance of the following:

- Data node, using its ID
- TC block instance
- Other communicating data node or API node, using its ID
- Upper bound value

Each row contains a value for each activity type. This is the number of times that this activity occurred with a latency within the range specified by the row (that is, where the latency does not exceed the upper bound).

The following table provides information about the columns in **`tc_time_track_stats`**. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

**Table 22.336 Columns of the tc_time_track_stats table**

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>node_id</td>
<td>integer</td>
<td>Requesting node ID</td>
</tr>
</tbody>
</table>

4007
### Column Name | Type | Description
---|---|---
block_number | integer | TC block number
block_instance | integer | TC block instance number
comm_node_id | integer | Node ID of communicating API or data node
upper_bound | integer | Upper bound of interval (in microseconds)
scans | integer | Based on duration of successful scans from opening to closing, tracked against the API or data nodes requesting them.
scan_errors | integer | Based on duration of failed scans from opening to closing, tracked against the API or data nodes requesting them.
scan_fragment_errors | integer | Based on duration of failed fragment scans from opening to closing, tracked against the data nodes executing them
transactions | integer | Based on duration of successful transactions from beginning until sending of commit ACK, tracked against the API or data nodes requesting them. Stateless transactions are not included.
transaction_errors | integer | Based on duration of failing transactions from start to point of failure, tracked against the API or data nodes requesting them.
read_key_ops | integer | Based on duration of successful primary key reads with locks. Tracked against both the API or data node requesting them and the data node executing them.
write_key_ops | integer | Based on duration of successful primary key writes, tracked against both the API or data node requesting them and the data node executing them.
index_key_ops | integer | Based on duration of successful unique index key operations, tracked against both the API or data node requesting them and the data node executing reads of base tables.
key_op_errors | integer | Based on duration of all unsuccessful key read or write operations, tracked against both the API or data node requesting them and the data node executing them.

The block_instance column provides the DBTC kernel block instance number. You can use this together with the block name to obtain information about specific threads from the threadblocks table.

### 22.5.10.44 The ndbinfo threadblocks Table

The threadblocks table associates data nodes, threads, and instances of NDB kernel blocks.

The following table provides information about the columns in the threadblocks table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.
Table 22.337 Columns of the threadblocks table

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>node_id</td>
<td>integer</td>
<td>Node ID</td>
</tr>
<tr>
<td>thr_no</td>
<td>integer</td>
<td>Thread ID</td>
</tr>
<tr>
<td>block_name</td>
<td>string</td>
<td>Block name</td>
</tr>
<tr>
<td>block_instance</td>
<td>integer</td>
<td>Block instance number</td>
</tr>
</tbody>
</table>

The value of the block_name in this table is one of the values found in the block_name column when selecting from the ndbinfo.blocks table. Although the list of possible values is static for a given NDB Cluster release, the list may vary between releases.

The block_instance column provides the kernel block instance number.

22.5.10.45 The ndbinfo threads Table

The threads table provides information about threads running in the NDB kernel.

The following table provides information about the columns in the threads table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Table 22.338 Columns of the threads table

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>node_id</td>
<td>integer</td>
<td>ID of the node where the thread is running</td>
</tr>
<tr>
<td>thr_no</td>
<td>integer</td>
<td>Thread ID (specific to this node)</td>
</tr>
<tr>
<td>thread_name</td>
<td>string</td>
<td>Thread name (type of thread)</td>
</tr>
<tr>
<td>thread_description</td>
<td>string</td>
<td>Thread (type) description</td>
</tr>
</tbody>
</table>

Sample output from a 2-node example cluster, including thread descriptions, is shown here:

```
mysql> SELECT * FROM threads;
+---------+--------+-------------+------------------------------------------------------------------+
| node_id | thr_no | thread_name | thread_description                                               |
|---------|--------|-------------+------------------------------------------------------------------|
|       5 |      0 | main        | main thread, schema and distribution handling                    |
|       5 |      1 | rep         | rep thread, asynchronous replication and proxy block handling     |
|       5 |      2 | ldm         | ldm thread, handling a set of data partitions                    |
|       5 |      3 | recv        | receive thread, performing receive and polling for new receives  |
|       6 |      0 | main        | main thread, schema and distribution handling                    |
|       6 |      1 | rep         | rep thread, asynchronous replication and proxy block handling     |
|       6 |      2 | ldm         | ldm thread, handling a set of data partitions                    |
|       6 |      3 | recv        | receive thread, performing receive and polling for new receives  |
+---------+--------+-------------+------------------------------------------------------------------+
8 rows in set (0.01 sec)
```

22.5.10.46 The ndbinfo threadstat Table

The threadstat table provides a rough snapshot of statistics for threads running in the NDB kernel.

The following table provides information about the columns in the threadstat table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Table 22.339 Columns of the threadstat table

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>node_id</td>
<td>integer</td>
<td>Node ID</td>
</tr>
</tbody>
</table>
### ndbinfo: The NDB Cluster Information Database

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>thr_no</td>
<td>integer</td>
<td>Thread ID</td>
</tr>
<tr>
<td>thr_nm</td>
<td>string</td>
<td>Thread name</td>
</tr>
<tr>
<td>c_loop</td>
<td>string</td>
<td>Number of loops in main loop</td>
</tr>
<tr>
<td>c_exec</td>
<td>string</td>
<td>Number of signals executed</td>
</tr>
<tr>
<td>c_wait</td>
<td>string</td>
<td>Number of times waiting for additional input</td>
</tr>
<tr>
<td>c_l_sent_prioa</td>
<td>integer</td>
<td>Number of priority A signals sent to own node</td>
</tr>
<tr>
<td>c_l_sent_prib</td>
<td>integer</td>
<td>Number of priority B signals sent to own node</td>
</tr>
<tr>
<td>c_r_sent_prioa</td>
<td>integer</td>
<td>Number of priority A signals sent to remote node</td>
</tr>
<tr>
<td>c_r_sent_prib</td>
<td>integer</td>
<td>Number of priority B signals sent to remote node</td>
</tr>
<tr>
<td>os_tid</td>
<td>integer</td>
<td>OS thread ID</td>
</tr>
<tr>
<td>os_now</td>
<td>integer</td>
<td>OS time (ms)</td>
</tr>
<tr>
<td>os_ru_utime</td>
<td>integer</td>
<td>OS user CPU time (µs)</td>
</tr>
<tr>
<td>os_ru_stime</td>
<td>integer</td>
<td>OS system CPU time (µs)</td>
</tr>
<tr>
<td>os_ru_minflt</td>
<td>integer</td>
<td>OS page reclaims (soft page faults)</td>
</tr>
<tr>
<td>os_ru_majflt</td>
<td>integer</td>
<td>OS page faults (hard page faults)</td>
</tr>
<tr>
<td>os_ru_nvcs</td>
<td>integer</td>
<td>OS voluntary context switches</td>
</tr>
<tr>
<td>os_ru_nvcs</td>
<td>integer</td>
<td>OS involuntary context switches</td>
</tr>
</tbody>
</table>

**os_time** uses the system `gettimeofday()` call.

The values of the `os_ru_utime, os_ru_stime, os_ru_minflt, os_ru_majflt, os_ru_nvcs,` and `os_ru_nvcs` columns are obtained using the system `getrusage()` call, or the equivalent.

Since this table contains counts taken at a given point in time, for best results it is necessary to query this table periodically and store the results in an intermediate table or tables. The MySQL Server's Event Scheduler can be employed to automate such monitoring. For more information, see Section 24.4, "Using the Event Scheduler".

### 22.5.10.47 The ndbinfo transporters Table

This table contains information about NDB transporters.

The following table provides information about the columns in the `transporters` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

#### Table 22.340 Columns of the transporters table

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>node_id</td>
<td>integer</td>
<td>This data node's unique node ID in the cluster</td>
</tr>
<tr>
<td>remote_node_id</td>
<td>integer</td>
<td>The remote data node's node ID</td>
</tr>
<tr>
<td>status</td>
<td>string</td>
<td>Status of the connection</td>
</tr>
<tr>
<td>remote_address</td>
<td>string</td>
<td>Name or IP address of the remote host</td>
</tr>
<tr>
<td>bytes_sent</td>
<td>integer</td>
<td>Number of bytes sent using this connection</td>
</tr>
</tbody>
</table>
### Column Name | Type | Description
---|---|---
bytes_received | integer | Number of bytes received using this connection
connect_count | integer | Number of times connection established on this transporter
overloaded | boolean (0 or 1) | 1 if this transporter is currently overloaded, otherwise 0
overload_count | integer | Number of times this transporter has entered overload state since connecting
slowdown | boolean (0 or 1) | 1 if this transporter is in slowdown state, otherwise 0
slowdown_count | integer | Number of times this transporter has entered slowdown state since connecting

For each running data node in the cluster, the `transporters` table displays a row showing the status of each of that node’s connections with all nodes in the cluster, including itself. This information is shown in the table’s `status` column, which can have any one of the following values: CONNECTING, CONNECTED, DISCONNECTING, or DISCONNECTED.

Connections to API and management nodes which are configured but not currently connected to the cluster are shown with status DISCONNECTED. Rows where the `node_id` is that of a data node which is not currently connected are not shown in this table. (This is similar omission of disconnected nodes in the `ndbinfo.nodes` table.

The `remote_address` is the host name or address for the node whose ID is shown in the `remote_node_id` column. The `bytes_sent` from this node and `bytes_received` by this node are the numbers, respectively, of bytes sent and received by the node using this connection since it was established. For nodes whose status is CONNECTING or DISCONNECTED, these columns always display 0.

Assume you have a 5-node cluster consisting of 2 data nodes, 2 SQL nodes, and 1 management node, as shown in the output of the `SHOW` command in the `ndb_mgm` client:

```
ndb_mgm> SHOW
Connected to Management Server at: localhost:1186
Cluster Configuration
---------------------
[ndbd(NDB)] 2 node(s)
id=1    @10.100.10.1  (8.0.20-ndb-8.0.20, Nodegroup: 0, *)
id=2    @10.100.10.2  (8.0.20-ndb-8.0.20, Nodegroup: 0)

[ndb_mgmd(MGM)] 1 node(s)
id=10   @10.100.10.10  (8.0.20-ndb-8.0.20)

[mysqld(API)] 2 node(s)
id=20   @10.100.10.20  (8.0.20-ndb-8.0.20)
id=21   @10.100.10.21  (8.0.20-ndb-8.0.20)
```

There are 10 rows in the `transporters` table—5 for the first data node, and 5 for the second—assuming that all data nodes are running, as shown here:

```
mysql> SELECT node_id, remote_node_id, status
    -> FROM ndbinfo.transporters;
```

<table>
<thead>
<tr>
<th>node_id</th>
<th>remote_node_id</th>
<th>status</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>DISCONNECTED</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>CONNECTED</td>
</tr>
<tr>
<td>1</td>
<td>10</td>
<td>CONNECTED</td>
</tr>
<tr>
<td>1</td>
<td>20</td>
<td>CONNECTED</td>
</tr>
<tr>
<td>1</td>
<td>21</td>
<td>CONNECTED</td>
</tr>
</tbody>
</table>
If you shut down one of the data nodes in this cluster using the command `STOP` in the `ndb_mgm` client, then repeat the previous query (again using the `mysql` client), this table now shows only 5 rows—1 row for each connection from the remaining management node to another node, including both itself and the data node that is currently offline—and displays `CONNECTING` for the status of each remaining connection to the data node that is currently offline, as shown here:

```
mysql> SELECT node_id, remote_node_id, status
    -> FROM ndbinfo.transporters;
```

<table>
<thead>
<tr>
<th>node_id</th>
<th>remote_node_id</th>
<th>status</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>DISCONNECTED</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>CONNECTING</td>
</tr>
<tr>
<td>1</td>
<td>10</td>
<td>CONNECTED</td>
</tr>
<tr>
<td>1</td>
<td>20</td>
<td>CONNECTED</td>
</tr>
<tr>
<td>1</td>
<td>21</td>
<td>CONNECTED</td>
</tr>
</tbody>
</table>

5 rows in set (0.02 sec)

The `connect_count`, `overloaded`, `overload_count`, `slowdown`, and `slowdown_count` counters are reset on connection, and retain their values after the remote node disconnects. The `bytes_sent` and `bytes_received` counters are also reset on connection, and so retain their values following disconnection (until the next connection resets them).

The `overload` state referred to by the `overloaded` and `overload_count` columns occurs when this transporter's send buffer contains more than `OverloadLimit` bytes (default is 80% of `SendBufferMemory`, that is, 0.8 * 2097152 = 1677721 bytes). When a given transporter is in a state of overload, any new transaction that tries to use this transporter fails with Error 1218 (Send Buffers overloaded in NDB kernel). This affects both scans and primary key operations.

The `slowdown` state referenced by the `slowdown` and `slowdown_count` columns of this table occurs when the transporter's send buffer contains more than 60% of the overload limit (equal to 0.6 * 2097152 = 1258291 bytes by default). In this state, any new scan using this transporter has its batch size reduced to minimize the load on the transporter.

Common causes of send buffer slowdown or overloading include the following:

- Data size, in particular the quantity of data stored in `TEXT` columns or `BLOB` columns (or both types of columns)
- Having a data node (ndbd or ndbmtd) on the same host as an SQL node that is engaged in binary logging
- Large number of rows per transaction or transaction batch
- Configuration issues such as insufficient `SendBufferMemory`
- Hardware issues such as insufficient RAM or poor network connectivity

See also Section 22.3.3.14, “Configuring NDB Cluster Send Buffer Parameters”.

### 22.5.11 INFORMATION_SCHEMA Tables for NDB Cluster

Two `INFORMATION_SCHEMA` tables provide information that is of particular use when managing an NDB Cluster. The `FILES` table provides information about NDB Cluster Disk Data files. The
NDB Cluster Security Issues

`ndb_transid_mysql_connection_map` table provides a mapping between transactions, transaction coordinators, and API nodes.

Additional statistical and other data about NDB Cluster transactions, operations, threads, blocks, and other aspects of performance can be obtained from the tables in the `ndbinfo` database. For information about these tables, see Section 22.5.10, “ndbinfo: The NDB Cluster Information Database”.

### 22.5.12 NDB Cluster Security Issues

This section discusses security considerations to take into account when setting up and running NDB Cluster.

Topics covered in this section include the following:

- NDB Cluster and network security issues
- Configuration issues relating to running NDB Cluster securely
- NDB Cluster and the MySQL privilege system
- MySQL standard security procedures as applicable to NDB Cluster

### 22.5.12.1 NDB Cluster Security and Networking Issues

In this section, we discuss basic network security issues as they relate to NDB Cluster. It is extremely important to remember that NDB Cluster “out of the box” is not secure; you or your network administrator must take the proper steps to ensure that your cluster cannot be compromised over the network.

Cluster communication protocols are inherently insecure, and no encryption or similar security measures are used in communications between nodes in the cluster. Because network speed and latency have a direct impact on the cluster’s efficiency, it is also not advisable to employ SSL or other encryption to network connections between nodes, as such schemes will effectively slow communications.

It is also true that no authentication is used for controlling API node access to an NDB Cluster. As with encryption, the overhead of imposing authentication requirements would have an adverse impact on Cluster performance.

In addition, there is no checking of the source IP address for either of the following when accessing the cluster:

- SQL or API nodes using “free slots” created by empty `[mysqld]` or `[api]` sections in the `config.ini` file

This means that, if there are any empty `[mysqld]` or `[api]` sections in the `config.ini` file, then any API nodes (including SQL nodes) that know the management server’s host name (or IP address) and port can connect to the cluster and access its data without restriction. (See Section 22.5.12.2, “NDB Cluster and MySQL Privileges”, for more information about this and related issues.)

---

**Note**

You can exercise some control over SQL and API node access to the cluster by specifying a `HostName` parameter for all `[mysqld]` and `[api]` sections in the `config.ini` file. However, this also means that, should you wish to connect an API node to the cluster from a previously unused host, you need to add an `[api]` section containing its host name to the `config.ini` file.

More information is available elsewhere in this chapter about the `HostName` parameter. Also see Section 22.3.1, “Quick Test Setup of NDB Cluster”, for configuration examples using `HostName` with API nodes.
NDB Cluster Security Issues

- Any ndb_mgm client

This means that any cluster management client that is given the management server's host name (or IP address) and port (if not the standard port) can connect to the cluster and execute any management client command. This includes commands such as **ALL STOP** and **SHUTDOWN**.

For these reasons, it is necessary to protect the cluster on the network level. The safest network configuration for Cluster is one which isolates connections between Cluster nodes from any other network communications. This can be accomplished by any of the following methods:

1. Keeping Cluster nodes on a network that is physically separate from any public networks. This option is the most dependable; however, it is the most expensive to implement.

   We show an example of an NDB Cluster setup using such a physically segregated network here:

   **Figure 22.28 NDB Cluster with Hardware Firewall**

   This setup has two networks, one private (solid box) for the Cluster management servers and data nodes, and one public (dotted box) where the SQL nodes reside. (We show the management and data nodes connected using a gigabit switch since this provides the best performance.) Both networks are protected from the outside by a hardware firewall, sometimes also known as a network-based firewall.

   This network setup is safest because no packets can reach the cluster's management or data nodes from outside the network—and none of the cluster's internal communications can reach the outside—without going through the SQL nodes, as long as the SQL nodes do not permit any packets to be forwarded. This means, of course, that all SQL nodes must be secured against hacking attempts.

   **Important**

   With regard to potential security vulnerabilities, an SQL node is no different from any other MySQL server. See Section 6.1.3, "Making MySQL Secure Against Attackers", for a description of techniques you can use to secure MySQL servers.

2. Using one or more software firewalls (also known as host-based firewalls) to control which packets pass through to the cluster from portions of the network that do not require access to it. In this type of setup, a software firewall must be installed on every host in the cluster which might otherwise be accessible from outside the local network.

   The host-based option is the least expensive to implement, but relies purely on software to provide protection and so is the most difficult to keep secure.
This type of network setup for NDB Cluster is illustrated here:

**Figure 22.29 NDB Cluster with Software Firewalls**

Using this type of network setup means that there are two zones of NDB Cluster hosts. Each cluster host must be able to communicate with all of the other machines in the cluster, but only those hosting SQL nodes (dotted box) can be permitted to have any contact with the outside, while those in the zone containing the data nodes and management nodes (solid box) must be isolated from any machines that are not part of the cluster. Applications using the cluster and user of those applications must *not* be permitted to have direct access to the management and data node hosts.

To accomplish this, you must set up software firewalls that limit the traffic to the type or types shown in the following table, according to the type of node that is running on each cluster host computer:

**Table 22.341 Node types in a host-based firewall cluster configuration**

<table>
<thead>

| SQL or API node         | • It originates from the IP address of a management or data node (using any TCP or UDP port).  
                          | • It originates from within the network in which the cluster resides and is on the port that your application is using. |
| Data node or Management node | • It originates from the IP address of a management or data node (using any TCP or UDP port).  
                         | • It originates from the IP address of an SQL or API node.                                 |

Any traffic other than that shown in the table for a given node type should be denied.

The specifics of configuring a firewall vary from firewall application to firewall application, and are beyond the scope of this Manual. *iptables* is a very common and reliable firewall application, which is often used with *APF* as a front end to make configuration easier. You can (and should) consult the documentation for the software firewall that you employ, should you choose to
implement an NDB Cluster network setup of this type, or of a “mixed” type as discussed under the next item.

3. It is also possible to employ a combination of the first two methods, using both hardware and software to secure the cluster—that is, using both network-based and host-based firewalls. This is between the first two schemes in terms of both security level and cost. This type of network setup keeps the cluster behind the hardware firewall, but permits incoming packets to travel beyond the router connecting all cluster hosts to reach the SQL nodes.

One possible network deployment of an NDB Cluster using hardware and software firewalls in combination is shown here:

**Figure 22.30 NDB Cluster with a Combination of Hardware and Software Firewalls**

In this case, you can set the rules in the hardware firewall to deny any external traffic except to SQL nodes and API nodes, and then permit traffic to them only on the ports required by your application.

Whatever network configuration you use, remember that your objective from the viewpoint of keeping the cluster secure remains the same—to prevent any unessential traffic from reaching the cluster while ensuring the most efficient communication between the nodes in the cluster.

Because NDB Cluster requires large numbers of ports to be open for communications between nodes, the recommended option is to use a segregated network. This represents the simplest way to prevent unwanted traffic from reaching the cluster.

**Note**

If you wish to administer an NDB Cluster remotely (that is, from outside the local network), the recommended way to do this is to use `ssh` or another secure login shell to access an SQL node host. From this host, you can then run the management client to access the management server safely, from within the Cluster’s own local network.

Even though it is possible to do so in theory, it is *not* recommended to use `ndb_mgm` to manage a Cluster directly from outside the local network on which the Cluster is running. Since neither authentication nor encryption takes place between the management client and the management server, this represents an extremely insecure means of managing the cluster, and is almost certain to be compromised sooner or later.
22.5.12.2 NDB Cluster and MySQL Privileges

In this section, we discuss how the MySQL privilege system works in relation to NDB Cluster and the implications of this for keeping an NDB Cluster secure.

Standard MySQL privileges apply to NDB Cluster tables. This includes all MySQL privilege types (SELECT privilege, UPDATE privilege, DELETE privilege, and so on) granted on the database, table, and column level. As with any other MySQL Server, user and privilege information is stored in the mysql system database. The SQL statements used to grant and revoke privileges on NDB tables, databases containing such tables, and columns within such tables are identical in all respects with the GRANT and REVOKE statements used in connection with database objects involving any (other) MySQL storage engine. The same thing is true with respect to the CREATE USER and DROP USER statements.

It is important to keep in mind that, by default, the MySQL grant tables use the MyISAM storage engine. Because of this, those tables are not normally duplicated or shared among MySQL servers acting as SQL nodes in an NDB Cluster. In other words, changes in users and their privileges do not automatically propagate between SQL nodes by default. If you wish, you can enable automatic distribution of MySQL users and privileges across NDB Cluster SQL nodes; see Section 22.5.16, “Distributed MySQL Privileges with NDB_STORED_USER”, for details.

Conversely, because there is no way in MySQL to deny privileges (privileges can either be revoked or not granted in the first place, but not denied as such), there is no special protection for NDB tables on one SQL node from users that have privileges on another SQL node; (This is true even if you are not using automatic distribution of user privileges. The definitive example of this is the MySQL root account, which can perform any action on any database object. In combination with empty [mysql] or [api] sections of the config.ini file, this account can be especially dangerous. To understand why, consider the following scenario:

• The config.ini file contains at least one empty [mysql] or [api] section. This means that the NDB Cluster management server performs no checking of the host from which a MySQL Server (or other API node) accesses the NDB Cluster.

• There is no firewall, or the firewall fails to protect against access to the NDB Cluster from hosts external to the network.

• The host name or IP address of the NDB Cluster management server is known or can be determined from outside the network.

If these conditions are true, then anyone, anywhere can start a MySQL Server with --ndbcluster --ndb-connectstring=management_host and access this NDB Cluster. Using the MySQL root account, this person can then perform the following actions:

• Execute metadata statements such as SHOW DATABASES statement (to obtain a list of all NDB databases on the server) or SHOW TABLES FROM some_ndb_database statement to obtain a list of all NDB tables in a given database

• Run any legal MySQL statements on any of the discovered tables, such as:
  • SELECT * FROM some_table to read all the data from any table
  • DELETE FROM some_table to delete all the data from a table
  • DESCRIBE some_table or SHOW CREATE TABLE some_table to determine the table schema
  • UPDATE some_table SET column1 = some_value to fill a table column with “garbage” data; this could actually cause much greater damage than simply deleting all the data

More insidious variations might include statements like these:

```
UPDATE some_table SET an_int_column = an_int_column + 1
```

or
UPDATE some_table SET a_varchar_column = REVERSE(a_varchar_column)

Such malicious statements are limited only by the imagination of the attacker.

The only tables that would be safe from this sort of mayhem would be those tables that were created using storage engines other than NDB, and so not visible to a “rogue” SQL node.

A user who can log in as root can also access the INFORMATION_SCHEMA database and its tables, and so obtain information about databases, tables, stored routines, scheduled events, and any other database objects for which metadata is stored in INFORMATION_SCHEMA.

It is also a very good idea to use different passwords for the root accounts on different NDB Cluster SQL nodes unless you are using distributed privileges.

In sum, you cannot have a safe NDB Cluster if it is directly accessible from outside your local network.

Important

Never leave the MySQL root account password empty. This is just as true when running MySQL as an NDB Cluster SQL node as it is when running it as a standalone (non-Cluster) MySQL Server, and should be done as part of the MySQL installation process before configuring the MySQL Server as an SQL node in an NDB Cluster.

If you wish to employ NDB Cluster’s distributed privilege capabilities, you should not simply convert the system tables in the mysql database to use the NDB storage engine manually. Use the stored procedure provided for this purpose instead; see Section 22.5.16, “Distributed MySQL Privileges with NDB_STORED_USER”.

Otherwise, if you need to synchronize mysql system tables between SQL nodes, you can use standard MySQL replication to do so, or employ a script to copy table entries between the MySQL servers.

Summary. The most important points to remember regarding the MySQL privilege system with regard to NDB Cluster are listed here:

1. Users and privileges established on one SQL node do not automatically exist or take effect on other SQL nodes in the cluster. Conversely, removing a user or privilege on one SQL node in the cluster does not remove the user or privilege from any other SQL nodes.

2. You can distribute MySQL users and privileges among SQL nodes using the SQL script, and the stored procedures it contains, that are supplied for this purpose in the NDB Cluster distribution.

3. Once a MySQL user is granted privileges on an NDB table from one SQL node in an NDB Cluster, that user can “see” any data in that table regardless of the SQL node from which the data originated, even if you are not using privilege distribution.

22.5.12.3 NDB Cluster and MySQL Security Procedures

In this section, we discuss MySQL standard security procedures as they apply to running NDB Cluster.

In general, any standard procedure for running MySQL securely also applies to running a MySQL Server as part of an NDB Cluster. First and foremost, you should always run a MySQL Server as the mysql operating system user; this is no different from running MySQL in a standard (non-Cluster) environment. The mysql system account should be uniquely and clearly defined. Fortunately, this is the default behavior for a new MySQL installation. You can verify that the mysqld process is running as the mysql operating system user by using the system command such as the one shown here:

```
shell> ps aux | grep mysql
root  10467  0.0  0.1   3616  1380 pts/3    S    11:53   0:00 
```
If the `mysqld` process is running as any other user than `mysql`, you should immediately shut it down and restart it as the `mysql` user. If this user does not exist on the system, the `mysql` user account should be created, and this user should be part of the `mysql` user group; in this case, you should also make sure that the MySQL data directory on this system (as set using the `--datadir` option for `mysqld`) is owned by the `mysql` user, and that the SQL node's `my.cnf` file includes `user=mysql` in the `[mysqld]` section. Alternatively, you can start the MySQL server process with `--user=mysql` on the command line, but it is preferable to use the `my.cnf` option, since you might forget to use the command-line option and so have `mysqld` running as another user unintentionally. The `mysqld_safe` startup script forces MySQL to run as the `mysql` user.

**Important**

Never run `mysqld` as the system root user. Doing so means that potentially any file on the system can be read by MySQL, and thus—should MySQL be compromised—by an attacker.

As mentioned in the previous section (see Section 22.5.12.2, “NDB Cluster and MySQL Privileges”), you should always set a root password for the MySQL Server as soon as you have it running. You should also delete the anonymous user account that is installed by default. You can accomplish these tasks using the following statements:

```
shell> mysql -u root
mysql> UPDATE mysql.user
    -> SET Password=PASSWORD('secure_password')
    -> WHERE User='root';
mysql> DELETE FROM mysql.user
    -> WHERE User='';
mysql> FLUSH PRIVILEGES;
```

Be very careful when executing the `DELETE` statement not to omit the `WHERE` clause, or you risk deleting all MySQL users. Be sure to run the `FLUSH PRIVILEGES` statement as soon as you have modified the `mysql.user` table, so that the changes take immediate effect. Without `FLUSH PRIVILEGES`, the changes do not take effect until the next time that the server is restarted.

**Note**

Many of the NDB Cluster utilities such as `ndb_show_tables`, `ndb_desc`, and `ndb_select_all` also work without authentication and can reveal table names, schemas, and data. By default these are installed on Unix-style systems with the permissions `wxr-xr-x` (755), which means they can be executed by any user that can access the `mysql/bin` directory.

See Section 22.4, “NDB Cluster Programs”, for more information about these utilities.

### 22.5.13 NDB Cluster Disk Data Tables

NDB Cluster supports storing nonindexed columns of NDB tables on disk, rather than in RAM. Column data and logging metadata are kept in data files and undo log files, conceptualized as tablespaces and log file groups, as described in the next section—see Section 22.5.13.1, “NDB Cluster Disk Data Objects”.

---

```bash
/bin/sh ./mysqld_safe --ndbcluster --ndb-connectstring=localhost:1186
mysql    10512  0.2  2.5  58528 26636 pts/3    Sl   11:53   0:00 \
    /usr/local/mysql/libexec/mysqld --basedir=/usr/local/mysql \ --datadir=/usr/local/mysql/var --user=mysql --ndbcluster \ --ndb-connectstring=localhost:1186 --pid-file=/usr/local/mysql/var/mothra.pid \ --log-error=/usr/local/mysql/var/mothra.err
jon      10579  0.0  0.0   2736   688 pts/0    S+   11:54   0:00 grep mysql
```
NDB Cluster Disk Data Tables

NDB Cluster Disk Data performance can be influenced by a number of configuration parameters. For information about these parameters and their effects, see Disk Data Configuration Parameters, and Disk Data and GCP Stop errors.

Beginning with NDB 8.0.19, you should also set the DiskDataUsingSameDisk data node configuration parameter to false when using separate disks for Disk Data files.

See also Disk Data file system parameters.

NDB 8.0.19 (and later) provides improved support when using Disk Data tables with solid-state drives, in particular those using NVMe. See the following documentation for more information:

- Disk Data latency parameters
- Section 22.5.10.21, “The ndbinfo diskstat Table”
- Section 22.5.10.22, “The ndbinfo diskstats_1sec Table”
- Section 22.5.10.32, “The ndbinfo pgman_time_track_stats Table”

22.5.13.1 NDB Cluster Disk Data Objects

NDB Cluster Disk Data storage is implemented using the following objects:

- **Tablespace**: Acts as containers for other Disk Data objects. A tablespace contains one or more data files and one or more undo log file groups.
- **Data file**: Stores column data. A data file is assigned directly to a tablespace.
- **Undo log file**: Contains undo information required for rolling back transactions. Assigned to an undo log file group.
- **log file group**: Contains one or more undo log files. Assigned to a tablespace.

Undo log files and data files are actual files in the file system of each data node; by default they are placed in ndb_node_id_fs in the DataDir specified in the NDB Cluster config.ini file, and where node_id is the data node’s node ID. It is possible to place these elsewhere by specifying either an absolute or relative path as part of the filename when creating the undo log or data file. Statements that create these files are shown later in this section.

Undo log files are used only by Disk Data tables, and are not needed or used by NDB tables that are stored in memory only.

NDB Cluster tablespaces and log file groups are not implemented as files.

Although not all Disk Data objects are implemented as files, they all share the same namespace. This means that each Disk Data object must be uniquely named (and not merely each Disk Data object of a given type). For example, you cannot have a tablespace and a log file group both named dd1.

Assuming that you have already set up an NDB Cluster with all nodes (including management and SQL nodes), the basic steps for creating an NDB Cluster table on disk are as follows:

1. Create a log file group, and assign one or more undo log files to it (an undo log file is also sometimes referred to as an undofile).
2. Create a tablespace; assign the log file group, as well as one or more data files, to the tablespace.
3. Create a Disk Data table that uses this tablespace for data storage.

Each of these tasks can be accomplished using SQL statements in the mysql client or other MySQL client application, as shown in the example that follows.

1. We create a log file group named lg_1 using CREATE LOGFILE GROUP. This log file group is to be made up of two undo log files, which we name undo_1.log and undo_2.log, whose initial
sizes are 16 MB and 12 MB, respectively. (The default initial size for an undo log file is 128 MB.) Optionally, you can also specify a size for the log file group's undo buffer, or permit it to assume the default value of 8 MB. In this example, we set the UNDO buffer's size at 2 MB. A log file group must be created with an undo log file; so we add undo_1.log to lg_1 in this CREATE LOGFILE GROUP statement:

```
CREATE LOGFILE GROUP lg_1
  ADD UNDOFILE 'undo_1.log'
  INITIAL_SIZE 16M
  UNDO_BUFFER_SIZE 2M
  ENGINE NDBCLUSTER;
```

To add undo_2.log to the log file group, use the following ALTER LOGFILE GROUP statement:

```
ALTER LOGFILE GROUP lg_1
  ADD UNDOFILE 'undo_2.log'
  INITIAL_SIZE 12M
  ENGINE NDBCLUSTER;
```

Some items of note:

- The .log file extension used here is not required. We employ it merely to make the log files easily recognizable.

- Every CREATE LOGFILE GROUP and ALTER LOGFILE GROUP statement must include an ENGINE option. The only permitted values for this option are NDBCLUSTER and NDB.

Important

There can exist at most one log file group in the same NDB Cluster at any given time.

- When you add an undo log file to a log file group using ADD UNDOFILE 'filename', a file with the name filename is created in the ndb_node_id_fs directory within the DataDir of each data node in the cluster, where node_id is the node ID of the data node. Each undo log file is of the size specified in the SQL statement. For example, if an NDB Cluster has 4 data nodes, then the ALTER LOGFILE GROUP statement just shown creates 4 undo log files, 1 each on in the data directory of each of the 4 data nodes; each of these files is named undo_2.log and each file is 12 MB in size.

- UNDO_BUFFER_SIZE is limited by the amount of system memory available.

- See Section 13.1.16, “CREATE LOGFILE GROUP Statement”, and Section 13.1.6, “ALTER LOGFILE GROUP Statement”, for more information about these statements.

2. Now we can create a tablespace—an abstract container for files used by Disk Data tables to store data. A tablespace is associated with a particular log file group; when creating a new tablespace, you must specify the log file group it uses for undo logging. You must also specify at least one data file; you can add more data files to the tablespace after the tablespace is created. It is also possible to drop data files from a tablespace (see example later in this section).

Assume that we wish to create a tablespace named ts_1 which uses lg_1 as its log file group. We want the tablespace to contain two data files, named data_1.dat and data_2.dat, whose initial sizes are 32 MB and 48 MB, respectively. (The default value for INITIAL_SIZE is 128 MB.) We can do this using two SQL statements, as shown here:

```
CREATE TABLESPACE ts_1
  ADD DATAFILE 'data_1.dat'
  USE LOGFILE GROUP lg_1
  INITIAL_SIZE 32M
  ENGINE NDBCLUSTER;
```

```
ALTER TABLESPACE ts_1
  ADD DATAFILE 'data_2.dat'
```
The `CREATE TABLESPACE` statement creates a tablespace `ts_1` with the data file `data_1.dat`, and associates `ts_1` with log file group `lg_1`. The `ALTER TABLESPACE` adds the second data file (`data_2.dat`).

Some items of note:

- As is the case with the `.log` file extension used in this example for undo log files, there is no special significance for the `.dat` file extension; it is used merely for easy recognition.

- When you add a data file to a tablespace using `ADD DATAFILE 'filename'`, a file with the name `filename` is created in the `ndb_node_id_fs` directory within the DataDir of each data node in the cluster, where `node_id` is the node ID of the data node. Each data file is of the size specified in the SQL statement. For example, if an NDB Cluster has 4 data nodes, then the `ALTER TABLESPACE` statement just shown creates 4 data files, 1 each in the data directory of each of the 4 data nodes; each of these files is named `data_2.dat` and each file is 48 MB in size.

- NDB reserves 4% of each tablespace for use during data node restarts. This space is not available for storing data.

- `CREATE TABLESPACE` statements must contain an `ENGINE` clause; only tables using the same storage engine as the tablespace can be created in the tablespace. For `ALTER TABLESPACE`, an `ENGINE` clause is accepted but is deprecated and subject to removal in a future release. For NDB tablespaces, the only permitted values for this option are `NDBCLUSTER` and `NDB`.

- For more information about the `CREATE TABLESPACE` and `ALTER TABLESPACE` statements, see Section 13.1.21, "CREATE TABLESPACE Statement", and Section 13.1.10, "ALTER TABLESPACE Statement".

3. Now it is possible to create a table whose unindexed columns are stored on disk using files in tablespace `ts_1`:

```sql
CREATE TABLE dt_1 (
    member_id INT UNSIGNED NOT NULL AUTO_INCREMENT PRIMARY KEY,
    last_name VARCHAR(50) NOT NULL,
    first_name VARCHAR(50) NOT NULL,
    dob DATE NOT NULL,
    joined DATE NOT NULL,
    INDEX(last_name, first_name)
) TABLESPACE ts_1 STORAGE DISK
ENGINE NDBCLUSTER;
```

`TABLESPACE ts_1 STORAGE DISK` tells the NDB storage engine to use tablespace `ts_1` for data storage on disk.

Once table `ts_1` has been created as shown, you can perform `INSERT`, `SELECT`, `UPDATE`, and `DELETE` statements on it just as you would with any other MySQL table.

It is also possible to specify whether an individual column is stored on disk or in memory by using a `STORAGE` clause as part of the column's definition in a `CREATE TABLE` or `ALTER TABLE` statement. `STORAGE DISK` causes the column to be stored on disk, and `STORAGE MEMORY` causes in-memory storage to be used. See Section 13.1.20, "CREATE TABLE Statement", for more information.

You can obtain information about the NDB disk data files and undo log files just created by querying the `FILES` table in the `INFORMATION_SCHEMA` database, as shown here:

```sql
mysql> SELECT FILE_NAME AS File, FILE_TYPE AS Type,
                      TABLESPACE_NAME AS Tablespace, TABLE_NAME AS Name,
```
### NDB Cluster Disk Data Tables

- **LOGFILE_GROUP_NAME** as 'File group',
- **FREE_EXTENTS** as Free, **TOTAL_EXTENTS** as Total

FROM INFORMATION_SCHEMA.FILES
WHERE ENGINE='ndbcluster';

<table>
<thead>
<tr>
<th>File</th>
<th>Type</th>

<tr>
<td>./data_2.dat</td>
<td>DATAFILE</td>
<td>ts_1</td>
<td>NULL</td>
<td>lg_1</td>
<td>48</td>
<td>48</td>
</tr>
</tbody>
</table>

4 rows in set (0.00 sec)

For more information and examples, see Section 25.14, “The INFORMATION_SCHEMA FILES Table”.

**Indexing of columns implicitly stored on disk.**

For table `dt_1` as defined in the example just shown, only the `dob` and `joined` columns are stored on disk. This is because there are indexes on the `id`, `last_name`, and `first_name` columns, and so data belonging to these columns is stored in RAM. Only nonindexed columns can be held on disk; indexes and indexed column data continue to be stored in memory. This tradeoff between the use of indexes and conservation of RAM is something you must keep in mind as you design Disk Data tables.

You cannot add an index to a column that has been explicitly declared `STORAGE DISK`, without first changing its storage type to `MEMORY`; any attempt to do so fails with an error. A column which `implicitly` uses disk storage can be indexed; when this is done, the column's storage type is changed to `MEMORY` automatically. By "implicitly", we mean a column whose storage type is not declared, but which is which inherited from the parent table. In the following CREATE TABLE statement (using the tablespace `ts_1` defined previously), columns `c2` and `c3` use disk storage implicitly:

```sql
mysql> CREATE TABLE ti (
    ->   c1 INT PRIMARY KEY,
    ->   c2 INT,
    ->   c3 INT,
    ->   c4 INT
    -> )
    -> STORAGE DISK
    -> TABLESPACE ts_1
    -> ENGINE NDBCLUSTER;
Query OK, 0 rows affected (1.31 sec)
```

Because `c2`, `c3`, and `c4` are themselves not declared with `STORAGE DISK`, it is possible to index them. Here, we add indexes to `c2` and `c3`, using, respectively, `CREATE INDEX` and `ALTER TABLE`:

```sql
mysql> CREATE INDEX i1 ON ti(c2);
Query OK, 0 rows affected (2.72 sec)
Records: 0  Duplicates: 0  Warnings: 0

mysql> ALTER TABLE ti ADD INDEX i2(c3);
Query OK, 0 rows affected (0.92 sec)
Records: 0  Duplicates: 0  Warnings: 0
```

SHOW CREATE TABLE confirms that the indexes were added.

```sql
mysql> SHOW CREATE TABLE ti\G
*************************** 1. row ***************************
Table: ti
Create Table: CREATE TABLE `ti` (  `c1` int(11) NOT NULL,  `c2` int(11) DEFAULT NULL,  `c3` int(11) DEFAULT NULL,  `c4` int(11) DEFAULT NULL, PRIMARY KEY (`c1`),  KEY `i1` (`c2`),  KEY `i2` (`c3`) )/*!50100 TABLESPACE `ts_1` STORAGE DISK */ ENGINE=ndbcluster DEFAULT CHARSET=latin1
1 row in set (0.00 sec)
```
You can see using `ndb_desc` that the indexed columns (emphasized text) now use in-memory rather than on-disk storage:

```
shell> ./ndb_desc -d test t1
-- t1 --
Version: 33554433
Fragment type: HashMapPartition

-- Indexes --
  PRIMARY KEY(c1) - UniqueHashIndex
  i2(c3) - OrderedIndex
  PRIMARY(c1) - OrderedIndex
  i1(c2) - OrderedIndex
NDBT_ProgramExit: 0 - OK
```

**Performance note.** The performance of a cluster using Disk Data storage is greatly improved if Disk Data files are kept on a separate physical disk from the data node file system. This must be done for each data node in the cluster to derive any noticeable benefit.

You can use absolute and relative file system paths with `ADD UNDOFILE` and `ADD DATAFILE`; relative paths are calculated with respect to the data node's data directory.

A log file group, a tablespace, and any Disk Data tables using these must be created in a particular order. This is also true for dropping these objects, subject to the following constraints:

- A log file group cannot be dropped as long as any tablespaces use it.
- A tablespace cannot be dropped as long as it contains any data files.
- You cannot drop any data files from a tablespace as long as there remain any tables which are using the tablespace.
- It is not possible to drop files created in association with a different tablespace other than the one with which the files were created.

For example, to drop all the objects created so far in this section, you can use the following statements:

```
mysql> DROP TABLE dt_1;
mysql> ALTER TABLESPACE ts_1
  -> DROP DATAFILE 'data_2.dat'
  -> ENGINE NDBCLUSTER;
mysql> ALTER TABLESPACE ts_1
```
These statements must be performed in the order shown, except that the two ALTER TABLESPACE ... DROP DATAFILE statements may be executed in either order.

### 22.5.13.2 NDB Cluster Disk Data Storage Requirements

The following items apply to Disk Data storage requirements:

- Variable-length columns of Disk Data tables take up a fixed amount of space. For each row, this is equal to the space required to store the largest possible value for that column.

For general information about calculating these values, see Section 11.7, “Data Type Storage Requirements”.

You can obtain an estimate the amount of space available in data files and undo log files by querying the INFORMATION_SCHEMA.FILES table. For more information and examples, see Section 25.14, “The INFORMATION_SCHEMA FILES Table”.

**Note**

The OPTIMIZE TABLE statement does not have any effect on Disk Data tables.

- In a Disk Data table, the first 256 bytes of a TEXT or BLOB column are stored in memory; only the remainder is stored on disk.

- Each row in a Disk Data table uses 8 bytes in memory to point to the data stored on disk. This means that, in some cases, converting an in-memory column to the disk-based format can actually result in greater memory usage. For example, converting a CHAR(4) column from memory-based to disk-based format increases the amount of DataMemory used per row from 4 to 8 bytes.

**Important**

Starting the cluster with the --initial option does not remove Disk Data files. You must remove these manually prior to performing an initial restart of the cluster.

Performance of Disk Data tables can be improved by minimizing the number of disk seeks by making sure that DiskPageBufferMemory is of sufficient size. You can query the diskpagebuffer table to help determine whether the value for this parameter needs to be increased.

### 22.5.14 Online Operations with ALTER TABLE in NDB Cluster

MySQL NDB Cluster 8.0 supports online table schema changes using the standard ALTER TABLE syntax employed by the MySQL Server (ALGORITHM=DEFAULT|INPLACE|COPY), and described elsewhere.

**Note**

Some older releases of NDB Cluster used a syntax specific to NDB for online ALTER TABLE operations. That syntax has since been removed.

Operations that add and drop indexes on variable-width columns of NDB tables occur online. Online operations are noncopying; that is, they do not require that indexes be re-created. They do not lock
the table being altered from access by other API nodes in an NDB Cluster (but see Limitations of NDB online operations, later in this section). Such operations do not require single user mode for NDB table alterations made in an NDB cluster with multiple API nodes; transactions can continue uninterrupted during online DDL operations.

**ALGORITHM=INPLACE** can be used to perform online **ADD COLUMN**, **ADD INDEX** (including **CREATE INDEX** statements), and **DROP INDEX** operations on NDB tables. Online renaming of NDB tables is also supported.

Previously, columns of NDB tables could not be renamed online; this limitation is removed in NDB 8.0.18.

Currently you cannot add disk-based columns to NDB tables online. This means that, if you wish to add an in-memory column to an NDB table that uses a table-level **STORAGE DISK** option, you must declare the new column as using memory-based storage explicitly. For example—assuming that you have already created tablespace `ts1`—suppose that you create table `t1` as follows:

```mysql
mysql> CREATE TABLE t1 (  
  >    c1 INT NOT NULL PRIMARY KEY,  
  >    c2 VARCHAR(30)  
  > )  
  > TABLESPACE ts1 STORAGE DISK  
  > ENGINE NDB;  
Query OK, 0 rows affected (1.73 sec)  
Records: 0  Duplicates: 0  Warnings: 0
```

You can add a new in-memory column to this table online as shown here:

```mysql
mysql> ALTER TABLE t1  
  >    ADD COLUMN c3 INT COLUMN_FORMAT DYNAMIC STORAGE MEMORY,  
  >    ALGORITHM=INPLACE;  
Query OK, 0 rows affected (1.25 sec)  
Records: 0  Duplicates: 0  Warnings: 0
```

This statement fails if the **STORAGE MEMORY** option is omitted:

```mysql
mysql> ALTER TABLE t1  
  >    ADD COLUMN c4 INT COLUMN_FORMAT DYNAMIC,  
  >    ALGORITHM=INPLACE;  
ERROR 1846 (0A000): ALGORITHM=INPLACE is not supported. Reason:  
Adding column(s) or add/reorganize partition not supported online. Try  
ALGORITHM=COPY.
```

If you omit the **COLUMN_FORMAT DYNAMIC** option, the dynamic column format is employed automatically, but a warning is issued, as shown here:

```mysql
mysql> ALTER ONLINE TABLE t1 ADD COLUMN c4 INT STORAGE MEMORY;  
Query OK, 0 rows affected, 1 warning (1.17 sec)  
Records: 0  Duplicates: 0  Warnings: 0
```

```mysql
mysql> SHOW WARNINGS\G  
*************************** 1. row ***************************  
Level: Warning  
Code: 1478  
Message: DYNAMIC column c4 with STORAGE DISK is not supported, column will  
become FIXED
```

```mysql
mysql> SHOW CREATE TABLE t1\G  
*************************** 1. row ***************************  
Create Table: CREATE TABLE `t1` (  
  c1` INT(11) NOT NULL,  
  c2` VARCHAR(30) DEFAULT NULL,  
  `c3` INT(11) /*!50606 STORAGE MEMORY */ /*!50606 COLUMN_FORMAT DYNAMIC */ DEFAULT NULL,  
  `c4` INT(11) /*!50606 STORAGE MEMORY */ DEFAULT NULL,  
  PRIMARY KEY (`c1`)  
) /*!50606 TABLESPACE ts_1 STORAGE DISK */ ENGINE=ndbcluster DEFAULT CHARSET=latin1
```
Online Operations with ALTER TABLE in NDB Cluster

Note

The STORAGE and COLUMN_FORMAT keywords are supported only in NDB Cluster; in any other version of MySQL, attempting to use either of these keywords in a CREATE TABLE or ALTER TABLE statement results in an error.

It is also possible to use the statement ALTER TABLE ... REORGANIZE PARTITION, ALGORITHM=INPLACE with no partition_names INTO (partition_definitions) option on NDB tables. This can be used to redistribute NDB Cluster data among new data nodes that have been added to the cluster online. This does not perform any defragmentation, which requires an OPTIMIZE TABLE or null ALTER TABLE statement. For more information, see Section 22.5.15, “Adding NDB Cluster Data Nodes Online”.

Limitations of NDB online operations

Online DROP COLUMN operations are not supported.

Online ALTER TABLE, CREATE INDEX, or DROP INDEX statements that add columns or add or drop indexes are subject to the following limitations:

• A given online ALTER TABLE can use only one of ADD COLUMN, ADD INDEX, or DROP INDEX. One or more columns can be added online in a single statement; only one index may be created or dropped online in a single statement.

• The table being altered is not locked with respect to API nodes other than the one on which an online ALTER TABLE ADD COLUMN, ADD INDEX, or DROP INDEX operation (or CREATE INDEX or DROP INDEX statement) is run. However, the table is locked against any other operations originating on the same API node while the online operation is being executed.

• The table to be altered must have an explicit primary key; the hidden primary key created by the NDB storage engine is not sufficient for this purpose.

• The storage engine used by the table cannot be changed online.

• The tablespace used by the table cannot be changed online. Beginning with NDB 8.0.21, a statement such as ALTER TABLE ndb_table ... ALGORITHM=INPLACE, TABLESPACE=new_tablespace is specifically disallowed. (Bug #99269, Bug #31180526)

• When used with NDB Cluster Disk Data tables, it is not possible to change the storage type (DISK or MEMORY) of a column online. This means, that when you add or drop an index in such a way that the operation would be performed online, and you want the storage type of the column or columns to be changed, you must use ALGORITHM=COPY in the statement that adds or drops the index.

Columns to be added online cannot use the BLOB or TEXT type, and must meet the following criteria:

• The columns must be dynamic; that is, it must be possible to create them using COLUMN_FORMAT DYNAMIC. If you omit the COLUMN_FORMAT DYNAMIC option, the dynamic column format is employed automatically.

• The columns must permit NULL values and not have any explicit default value other than NULL. Columns added online are automatically created as DEFAULT NULL, as can be seen here:

```sql
mysql> CREATE TABLE t2 (  > c1 INT NOT NULL AUTO_INCREMENT PRIMARY KEY  > ) ENGINE=NDB;
Query OK, 0 rows affected (1.44 sec)

mysql> ALTER TABLE t2  > ADD COLUMN c2 INT,
> ADD COLUMN c3 INT,
```
Online Operations with ALTER TABLE in NDB Cluster

> ALGORITHM=INPLACE;
Query OK, 0 rows affected, 2 warnings (0.93 sec)

mysql> SHOW CREATE TABLE t1;
*************************** 1. row ***************************
Table: t1
Create Table: CREATE TABLE `t2` (
  `c1` int(11) NOT NULL AUTO_INCREMENT,
  `c2` int(11) DEFAULT NULL,
  `c3` int(11) DEFAULT NULL,
  PRIMARY KEY (`c1`)
) ENGINE=ndbcluster DEFAULT CHARSET=latin1
1 row in set (0.00 sec)

• The columns must be added following any existing columns. If you attempt to add a column online before any existing columns or using the FIRST keyword, the statement fails with an error.

• Existing table columns cannot be reordered online.

For online ALTER TABLE operations on NDB tables, fixed-format columns are converted to dynamic when they are added online, or when indexes are created or dropped online, as shown here (repeating the CREATE TABLE and ALTER TABLE statements just shown for the sake of clarity):

mysql> CREATE TABLE t2 (  
  > c1 INT NOT NULL AUTO_INCREMENT PRIMARY KEY  
  > ) ENGINE=NDB;
Query OK, 0 rows affected (1.44 sec)

mysql> ALTER TABLE t2  
  > ADD COLUMN c2 INT,  
  > ADD COLUMN c3 INT,  
  > ALGORITHM=INPLACE;
Query OK, 0 rows affected, 2 warnings (0.93 sec)

Only the column or columns to be added online must be dynamic. Existing columns need not be; this includes the table's primary key, which may also be FIXED, as shown here:

mysql> CREATE TABLE t3 (  
  > c1 INT NOT NULL AUTO_INCREMENT PRIMARY KEY COLUMN_FORMAT FIXED  
  > ) ENGINE=NDB;
Query OK, 0 rows affected (2.10 sec)

mysql> ALTER TABLE t3 ADD COLUMN c2 INT, ALGORITHM=INPLACE;
Query OK, 0 rows affected, 1 warning (0.78 sec)
Records: 0  Duplicates: 0  Warnings: 0

mysql> SHOW WARNINGS;
*************************** 1. row ***************************
Level: Warning
Code: 1478
Message: Converted FIXED field 'c2' to DYNAMIC to enable online ADD COLUMN

2 rows in set (0.00 sec)

Columns are not converted from FIXED to DYNAMIC column format by renaming operations. For more information about COLUMN_FORMAT, see Section 13.1.20, "CREATE TABLE Statement".

The KEY, CONSTRAINT, and IGNORE keywords are supported in ALTER TABLE statements using ALGORITHM=INPLACE.
Adding NDB Cluster Data Nodes Online

22.5.15 Adding NDB Cluster Data Nodes Online

This section describes how to add NDB Cluster data nodes “online”—that is, without needing to shut down the cluster completely and restart it as part of the process.

Important
Currently, you must add new data nodes to an NDB Cluster as part of a new node group. In addition, it is not possible to change the number of replicas (or the number of nodes per node group) online.

22.5.15.1 Adding NDB Cluster Data Nodes Online: General Issues

This section provides general information about the behavior of and current limitations in adding NDB Cluster nodes online.

Redistribution of Data. The ability to add new nodes online includes a means to reorganize NDBCLUSTER table data and indexes so that they are distributed across all data nodes, including the new ones, by means of the ALTER TABLE ... REORGANIZE PARTITION statement. Table reorganization of both in-memory and Disk Data tables is supported. This redistribution does not currently include unique indexes (only ordered indexes are redistributed).

The redistribution for NDBCLUSTER tables already existing before the new data nodes were added is not automatic, but can be accomplished using simple SQL statements in mysql or another MySQL client application. However, all data and indexes added to tables created after a new node group has been added are distributed automatically among all cluster data nodes, including those added as part of the new node group.

Partial starts. It is possible to add a new node group without all of the new data nodes being started. It is also possible to add a new node group to a degraded cluster—that is, a cluster that is only partially started, or where one or more data nodes are not running. In the latter case, the cluster must have enough nodes running to be viable before the new node group can be added.

Effects on ongoing operations. Normal DML operations using NDB Cluster data are not prevented by the creation or addition of a new node group, or by table reorganization. However, it is not possible to perform DDL concurrently with table reorganization—that is, no other DDL statements can be issued while an ALTER TABLE ... REORGANIZE PARTITION statement is executing. In addition, during the execution of ALTER TABLE ... REORGANIZE PARTITION (or the execution of any other DDL statement), it is not possible to restart cluster data nodes.

Failure handling. Failures of data nodes during node group creation and table reorganization are handled as shown in the following table:

<table>
<thead>
<tr>
<th>Failure during</th>
<th>Failure in “Old” data node</th>
<th>Failure in “New” data node</th>
<th>System Failure</th>
</tr>
</thead>
<tbody>
<tr>
<td>Node group creation</td>
<td>• If a node other than the master fails: The creation of the node group is always rolled forward.</td>
<td>• If a node other than the master fails: The creation of the node group is always rolled forward.</td>
<td>• If the execution of CREATE NODEGROUP has reached the internal commit point: When restarted, the cluster includes the new node group. Otherwise it without.</td>
</tr>
<tr>
<td></td>
<td>• If the master fails:</td>
<td>• If the master fails:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• If the internal commit point has been reached:</td>
<td>• If the internal commit point has been reached:</td>
<td></td>
</tr>
</tbody>
</table>
### Adding NDB Cluster Data Nodes Online

#### Failure during

<table>
<thead>
<tr>
<th>Failure in “Old” data node</th>
<th>Failure in “New” data node</th>
<th>System Failure</th>
</tr>
</thead>
<tbody>
<tr>
<td>The creation of the node group is rolled forward.</td>
<td>The creation of the node group is rolled forward.</td>
<td>• If the execution of CREATE NODEGROUP has not yet reached the internal commit point: When restarted, the cluster does not include the new node group.</td>
</tr>
<tr>
<td>• If the internal commit point has not yet been reached. The creation of the node group is rolled back.</td>
<td>• If the internal commit point has not yet been reached. The creation of the node group is rolled back.</td>
<td></td>
</tr>
</tbody>
</table>

#### Table reorganization

- If a node other than the master fails: The table reorganization is always rolled forward.
- If the master fails:
  - If the internal commit point has been reached: The table reorganization is rolled forward.
  - If the internal commit point has not yet been reached. The table reorganization is rolled back.
- If a node other than the master fails: The table reorganization is always rolled forward.
- If the master fails:
  - If the internal commit point has been reached: The table reorganization is rolled forward.
  - If the internal commit point has not yet been reached. The table reorganization is rolled back.
- If the execution of an ALTER TABLE ... REORGANIZE PARTITION statement has reached the internal commit point: When the cluster is restarted, the data and indexes belonging to `table` are distributed using the “new” data nodes.
- If the execution of an ALTER TABLE ... REORGANIZE PARTITION statement has not yet reached the internal commit point: When the cluster is restarted, the data and indexes belonging to `table` are distributed using only the “old” data nodes.

#### Dropping node groups.

The `ndb_mgm` client supports a `DROP NODEGROUP` command, but it is possible to drop a node group only when no data nodes in the node group contain any data. Since there is currently no way to “empty” a specific data node or node group, this command works only the following two cases:

1. After issuing `CREATE NODEGROUP` in the `ndb_mgm` client, but before issuing any `ALTER TABLE ... REORGANIZE PARTITION` statements in the `mysql` client.
2. After dropping all `NDBCLUSTER` tables using `DROP TABLE`.

`TRUNCATE TABLE` does not work for this purpose because the data nodes continue to store the table definitions.

#### 22.5.15.2 Adding NDB Cluster Data Nodes Online: Basic procedure

In this section, we list the basic steps required to add new data nodes to an NDB Cluster. This procedure applies whether you are using `ndbd` or `ndbms` binaries for the data node processes.
Adding NDB Cluster Data Nodes Online

a more detailed example, see Section 22.5.15.3, “Adding NDB Cluster Data Nodes Online: Detailed Example”.

Assuming that you already have a running NDB Cluster, adding data nodes online requires the following steps:

1. Edit the cluster configuration `config.ini` file, adding new `[ndbd]` sections corresponding to the nodes to be added. In the case where the cluster uses multiple management servers, these changes need to be made to all `config.ini` files used by the management servers.

   You must be careful that node IDs for any new data nodes added in the `config.ini` file do not overlap node IDs used by existing nodes. In the event that you have API nodes using dynamically allocated node IDs and these IDs match node IDs that you want to use for new data nodes, it is possible to force any such API nodes to “migrate”, as described later in this procedure.

2. Perform a rolling restart of all NDB Cluster management servers.

   ![Important](image)
   
   All management servers must be restarted with the `--reload` or `--initial` option to force the reading of the new configuration.

3. Perform a rolling restart of all existing NDB Cluster data nodes. It is not necessary (or usually even desirable) to use `--initial` when restarting the existing data nodes.

   If you are using API nodes with dynamically allocated IDs matching any node IDs that you wish to assign to new data nodes, you must restart all API nodes (including SQL nodes) before restarting any of the data nodes processes in this step. This causes any API nodes with node IDs that were previously not explicitly assigned to relinquish those node IDs and acquire new ones.

4. Perform a rolling restart of any SQL or API nodes connected to the NDB Cluster.

5. Start the new data nodes.

   The new data nodes may be started in any order. They can also be started concurrently, as long as they are started after the rolling restarts of all existing data nodes have been completed, and before proceeding to the next step.

6. Execute one or more `CREATE_NODEGROUP` commands in the NDB Cluster management client to create the new node group or node groups to which the new data nodes will belong.

7. Redistribute the cluster’s data among all data nodes, including the new ones. Normally this is done by issuing an `ALTER TABLE ... ALGORITHM=INPLACE, REORGANIZE PARTITION` statement in the `mysql` client for each `NDBCLUSTER` table.

   *Exception:* For tables created using the `MAX_ROWS` option, this statement does not work; instead, use `ALTER TABLE ... ALGORITHM=INPLACE MAX_ROWS=...` to reorganize such tables. You should also bear in mind that using `MAX_ROWS` to set the number of partitions in this fashion is deprecated, and you should use `PARTITION_BALANCE` instead; see Section 13.1.20.10, “Setting NDB_TABLE Options”, for more information.

   ![Note](image)
   
   This needs to be done only for tables already existing at the time the new node group is added. Data in tables created after the new node group is added is distributed automatically; however, data added to any given table `tbl` that existed before the new nodes were added is not distributed using the new nodes until that table has been reorganized.

8. `ALTER TABLE ... REORGANIZE PARTITION ALGORITHM=INPLACE` reorganizes partitions but does not reclaim the space freed on the “old” nodes. You can do this by issuing, for each `NDBCLUSTER` table, an `OPTIMIZE TABLE` statement in the `mysql` client.
Adding NDB Cluster Data Nodes Online

This works for space used by variable-width columns of in-memory NDB tables. OPTIMIZE TABLE is not supported for fixed-width columns of in-memory tables; it is also not supported for Disk Data tables.

You can add all the nodes desired, then issue several CREATE NODEGROUP commands in succession to add the new node groups to the cluster.

22.5.15.3 Adding NDB Cluster Data Nodes Online: Detailed Example

In this section we provide a detailed example illustrating how to add new NDB Cluster data nodes online, starting with an NDB Cluster having 2 data nodes in a single node group and concluding with a cluster having 4 data nodes in 2 node groups.

Starting configuration. For purposes of illustration, we assume a minimal configuration, and that the cluster uses a config.ini file containing only the following information:

```
[nbdb default]
DataMemory = 100M
IndexMemory = 100M
NoOfReplicas = 2
DataDir = /usr/local/mysql/var/mysql-cluster

[nbdb]
Id = 1
HostName = 198.51.100.1

[nbdb]
Id = 2
HostName = 198.51.100.2

[mgm]
HostName = 198.51.100.10
Id = 10

[api]
Id=20
HostName = 198.51.100.20

[api]
Id=21
HostName = 198.51.100.21
```

Note

We have left a gap in the sequence between data node IDs and other nodes. This make it easier later to assign node IDs that are not already in use to data nodes which are newly added.

We also assume that you have already started the cluster using the appropriate command line or my.cnf options, and that running SHOW in the management client produces output similar to what is shown here:

```
-- NDB Cluster -- Management Client --
ndb_mgm> SHOW
Connected to Management Server at: 198.51.100.10:1186
Cluster Configuration---------------------
[nbdb(NDB)] 2 node(s)
 id=1  @198.51.100.1 (8.0.20-ndb-8.0.20, Nodegroup: 0, *)
 id=2  @198.51.100.2 (8.0.20-ndb-8.0.20, Nodegroup: 0)

[nbdb_mgmd(MGM)] 1 node(s)
 id=10 @198.51.100.10 (8.0.20-ndb-8.0.20)

[mysqld(API)] 2 node(s)
 id=20 @198.51.100.20 (8.0.20-ndb-8.0.20)
```
Finally, we assume that the cluster contains a single `NDBCluster` table created as shown here:

```sql
USE n;
CREATE TABLE ips (  id BIGINT NOT NULL AUTO_INCREMENT PRIMARY KEY,  country_code CHAR(2) NOT NULL,  type CHAR(4) NOT NULL,  ip_address VARCHAR(15) NOT NULL,  addresses BIGINT UNSIGNED DEFAULT NULL,  date BIGINT UNSIGNED DEFAULT NULL) ENGINE NDBCLUSTER;
```

The memory usage and related information shown later in this section was generated after inserting approximately 50000 rows into this table.

Note

In this example, we show the single-threaded `ndbd` being used for the data node processes. You can also apply this example, if you are using the multithreaded `ndbmtd` by substituting `ndbmtd` for `ndbd` wherever it appears in the steps that follow.

**Step 1: Update configuration file.** Open the cluster global configuration file in a text editor and add `[ndbd]` sections corresponding to the 2 new data nodes. (We give these data nodes IDs 3 and 4, and assume that they are to be run on host machines at addresses 198.51.100.3 and 198.51.100.4, respectively.) After you have added the new sections, the contents of the `config.ini` file should look like what is shown here, where the additions to the file are shown in bold type:

```ini
[nbdb default]
DataMemory = 100M
IndexMemory = 100M
NoOfReplicas = 2
DataDir = /usr/local/mysql/var/mysql-cluster

[nbdb]
Id = 1
HostName = 198.51.100.1

[nbdb]
Id = 2
HostName = 198.51.100.2

[nbdb]
Id = 3
HostName = 198.51.100.3

[nbdb]
Id = 4
HostName = 198.51.100.4

[mgm]
HostName = 198.51.100.10
Id = 10

[api]
Id=20
HostName = 198.51.100.20

[api]
Id=21
HostName = 198.51.100.21
```

Once you have made the necessary changes, save the file.

**Step 2: Restart the management server.** Restarting the cluster management server requires that you issue separate commands to stop the management server and then to start it again, as follows:
1. Stop the management server using the management client `STOP` command, as shown here:

```
ndb_mgm> 10 STOP
Node 10 has shut down.
Disconnecting to allow Management Server to shutdown
```

2. Because shutting down the management server causes the management client to terminate, you must start the management server from the system shell. For simplicity, we assume that `config.ini` is in the same directory as the management server binary, but in practice, you must supply the correct path to the configuration file. You must also supply the `--reload` or `--initial` option so that the management server reads the new configuration from the file rather than its configuration cache. If your shell's current directory is also the same as the directory where the management server binary is located, then you can invoke the management server as shown here:

```
shell> ndb_mgmd -f config.ini --reload
```

If you check the output of `SHOW` in the management client after restarting the `ndb_mgm` process, you should now see something like this:

```
-- NDB Cluster -- Management Client --
ndb_mgm> SHOW
Connected to Management Server at: 198.51.100.10:1186
Cluster Configuration
---------------------
[ndbd(NDB)]  2 node(s)
id=1    @198.51.100.1  (8.0.20-ndb-8.0.20, Nodegroup: 0, *)
id=2    @198.51.100.2  (8.0.20-ndb-8.0.20, Nodegroup: 0)
id=3 (not connected, accepting connect from 198.51.100.3)
id=4 (not connected, accepting connect from 198.51.100.4)

[ndb_mgmd(MGM)]  1 node(s)
id=10   @198.51.100.10  (8.0.20-ndb-8.0.20)

[mysqld(API)]  2 node(s)
id=20   @198.51.100.20  (8.0.20-ndb-8.0.20)
id=21   @198.51.100.21  (8.0.20-ndb-8.0.20)
```

**Step 3: Perform a rolling restart of the existing data nodes.** This step can be accomplished entirely within the cluster management client using the `RESTART` command, as shown here:

```
ndb_mgm> 1 RESTART
Node 1: Node shutdown initiated
Node 1: Node shutdown completed, restarting, no start.
Node 1 is being restarted
```

```
ndb_mgm> Node 1: Start initiated (version 8.0.20)
Node 1: Started (version 8.0.20)
```

```
ndb_mgm> 2 RESTART
Node 2: Node shutdown initiated
Node 2: Node shutdown completed, restarting, no start.
Node 2 is being restarted
```

```
ndb_mgm> Node 2: Start initiated (version 8.0.20)
ndb_mgm> Node 2: Started (version 8.0.20)
```

**Important**

After issuing each `X RESTART` command, wait until the management client reports `Node X: Started (version ...)` before proceeding any further.

You can verify that all existing data nodes were restarted using the updated configuration by checking the `ndbinfo.nodes` table in the `mysql` client.
**Step 4: Perform a rolling restart of all cluster API nodes.** Shut down and restart each MySQL server acting as an SQL node in the cluster using `mysqladmin shutdown` followed by `mysqld_safe` (or another startup script). This should be similar to what is shown here, where `password` is the MySQL root password for a given MySQL server instance:

```shell
shell> mysqladmin -uroot -p password shutdown
081208 20:19:56 mysqld_safe mysqld from pid file
/usr/local/mysql/var/tonfisk.pid ended
shell> mysqld_safe --ndbcluster --ndb-connectstring=198.51.100.10 &
081208 20:20:06 mysqld_safe Starting mysqld daemon with databases
from /usr/local/mysql/var
```

Of course, the exact input and output depend on how and where MySQL is installed on the system, as well as which options you choose to start it (and whether or not some or all of these options are specified in a `my.cnf` file).

**Step 5: Perform an initial start of the new data nodes.** From a system shell on each of the hosts for the new data nodes, start the data nodes as shown here, using the `--initial` option:

```shell
shell> ndbd -c 198.51.100.10 --initial
```

**Note**

Unlike the case with restarting the existing data nodes, you can start the new data nodes concurrently; you do not need to wait for one to finish starting before starting the other.

**Wait until both of the new data nodes have started before proceeding with the next step.** Once the new data nodes have started, you can see in the output of the management client `SHOW` command that they do not yet belong to any node group (as indicated with bold type here):

```
ndb_mgm> SHOW
Connected to Management Server at: 198.51.100.10:1186
Cluster Configuration
---------------------
[ndbd(NDB)]  2 node(s)
id=1 @198.51.100.1 (8.0.20-ndb-8.0.20, Nodegroup: 0, *)
id=2 @198.51.100.2 (8.0.20-ndb-8.0.20, Nodegroup: 0)
id=3 @198.51.100.3 (8.0.20-ndb-8.0.20, no nodegroup)
id=4 @198.51.100.4 (8.0.20-ndb-8.0.20, no nodegroup)
[ndb_mgmd(MGM)]  1 node(s)
id=10 @198.51.100.10 (8.0.20-ndb-8.0.20)
[mysqld(API)]  2 node(s)
id=20 @198.51.100.20 (8.0.20-ndb-8.0.20)
id=21 @198.51.100.21 (8.0.20-ndb-8.0.20)
```

**Step 6: Create a new node group.** You can do this by issuing a `CREATE NODEGROUP` command in the cluster management client. This command takes as its argument a comma-separated list of the node IDs of the data nodes to be included in the new node group, as shown here:

```
ndb_mgm> CREATE NODEGROUP 3,4
Nodegroup 1 created
```

By issuing `SHOW` again, you can verify that data nodes 3 and 4 have joined the new node group (again indicated in bold type here):

```
ndb_mgm> SHOW
Connected to Management Server at: 198.51.100.10:1186
Cluster Configuration
---------------------
[ndbd(NDB)]  2 node(s)
id=1 @198.51.100.1 (8.0.20-ndb-8.0.20, Nodegroup: 0, *)
id=2 @198.51.100.2 (8.0.20-ndb-8.0.20, Nodegroup: 0)
id=3 @198.51.100.3 (8.0.20-ndb-8.0.20, Nodegroup: 1)
id=4 @198.51.100.4 (8.0.20-ndb-8.0.20, Nodegroup: 1)
```
Adding NDB Cluster Data Nodes Online

Step 7: Redistribute cluster data. When a node group is created, existing data and indexes are not automatically distributed to the new node group’s data nodes, as you can see by issuing the appropriate REPORT command in the management client:

```shell
ndb_mgm> ALL REPORT MEMORY
```

Node 1: Data usage is 5%(177 32K pages of total 3200)
Node 1: Index usage is 0%(108 8K pages of total 12832)
Node 2: Data usage is 5%(177 32K pages of total 3200)
Node 2: Index usage is 0%(108 8K pages of total 12832)
Node 3: Data usage is 0%(0 32K pages of total 3200)
Node 3: Index usage is 0%(0 8K pages of total 12832)
Node 4: Data usage is 0%(0 32K pages of total 3200)
Node 4: Index usage is 0%(0 8K pages of total 12832)

By using ndb_desc with the -p option, which causes the output to include partitioning information, you can see that the table still uses only 2 partitions (in the Per partition info section of the output, shown here in bold text):

```shell
shell> ndb_desc -c 198.51.100.10 -d n ips -p
```

You can cause the data to be redistributed among all of the data nodes by performing, for each NDB table, an ALTER TABLE ... ALGORITHM=INPLACE, REORGANIZE PARTITION statement in the mysql client.

**Important**

ALTER TABLE ... ALGORITHM=INPLACE, REORGANIZE PARTITION does not work on tables that were created with the MAX_ROWS option. Instead, use
Adding NDB Cluster Data Nodes Online

ALTER TABLE ... ALGORITHM=INPLACE, MAX_ROWS=... to reorganize such tables.

Keep in mind that using MAX_ROWS to set the number of partitions per table is deprecated, and you should use PARTITION_BALANCE instead; see Section 13.1.20.10, “Setting NDB_TABLE Options”, for more information.

After issuing the statement ALTER TABLE ips ALGORITHM=INPLACE, REORGANIZE PARTITION, you can see using ndb_desc that the data for this table is now stored using 4 partitions, as shown here (with the relevant portions of the output in bold type):

```shell
ndb_desc -c 198.51.100.10 -d n ips -p
```

<table>
<thead>
<tr>
<th>Partition</th>
<th>Row count</th>
<th>Commit count</th>
<th>Frag fixed memory</th>
<th>Frag varsized memory</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>12981</td>
<td>52296</td>
<td>1572864</td>
<td>557056</td>
</tr>
<tr>
<td>1</td>
<td>13236</td>
<td>52515</td>
<td>1605632</td>
<td>557056</td>
</tr>
<tr>
<td>2</td>
<td>13105</td>
<td>13105</td>
<td>819200</td>
<td>294912</td>
</tr>
<tr>
<td>3</td>
<td>13093</td>
<td>13093</td>
<td>819200</td>
<td>294912</td>
</tr>
</tbody>
</table>

NDBT_ProgramExit: 0 - OK

Note

Normally, ALTER TABLE table_name [ALGORITHM=INPLACE,] REORGANIZE PARTITION is used with a list of partition identifiers and a set of partition definitions to create a new partitioning scheme for a table that has already been explicitly partitioned. Its use here to redistribute data onto a new NDB Cluster node group is an exception in this regard; when used in this way, no other keywords or identifiers follow REORGANIZE PARTITION.

For more information, see Section 13.1.9, “ALTER TABLE Statement”.

In addition, for each table, the ALTER_TABLE statement should be followed by an OPTIMIZE TABLE to reclaim wasted space. You can obtain a list of all NDBCLUSTER tables using the following query against the INFORMATION_SCHEMA.TABLES table:

```
SELECT TABLE_SCHEMA, TABLE_NAME FROM INFORMATION_SCHEMA.TABLES WHERE ENGINE = 'NDBCLUSTER';
```
Adding NDB Cluster Data Nodes Online

Note

The `INFORMATION_SCHEMA.TABLES.ENGINE` value for an NDB Cluster table is always `NDBCLUSTER`, regardless of whether the `CREATE TABLE` statement used to create the table (or `ALTER TABLE` statement used to convert an existing table from a different storage engine) used `NDB` or `NDBCLUSTER` in its `ENGINE` option.

You can see after performing these statements in the output of `ALL REPORT MEMORY` that the data and indexes are now redistributed between all cluster data nodes, as shown here:

```
ndb_mgm> ALL REPORT MEMORY

Node 1: Data usage is 5%(176 32K pages of total 3200)
Node 1: Index usage is 0%(76 8K pages of total 12832)
Node 2: Data usage is 5%(176 32K pages of total 3200)
Node 2: Index usage is 0%(76 8K pages of total 12832)
Node 3: Data usage is 2%(80 32K pages of total 3200)
Node 3: Index usage is 0%(51 8K pages of total 12832)
Node 4: Data usage is 2%(80 32K pages of total 3200)
Node 4: Index usage is 0%(50 8K pages of total 12832)
```

Note

Since only one DDL operation on `NDBCLUSTER` tables can be executed at a time, you must wait for each `ALTER TABLE ... REORGANIZE PARTITION` statement to finish before issuing the next one.

It is not necessary to issue `ALTER TABLE ... REORGANIZE PARTITION` statements for `NDBCLUSTER` tables created after the new data nodes have been added; data added to such tables is distributed among all data nodes automatically. However, in `NDBCLUSTER` tables that existed prior to the addition of the new nodes, neither existing nor new data is distributed using the new nodes until these tables have been reorganized using `ALTER TABLE ... REORGANIZE PARTITION`.

Alternative procedure, without rolling restart.

It is possible to avoid the need for a rolling restart by configuring the extra data nodes, but not starting them, when first starting the cluster. We assume, as before, that you wish to start with two data nodes—nodes 1 and 2—in one node group and later to expand the cluster to four data nodes, by adding a second node group consisting of nodes 3 and 4:

```
[nbdb default]
DataMemory = 100M
IndexMemory = 100M
NoOfReplicas = 2
DataDir = /usr/local/mysql/var/mysql-cluster

[nbdb]
Id = 1
HostName = 198.51.100.1

[nbdb]
Id = 2
HostName = 198.51.100.2

[nbdb]
Id = 3
HostName = 198.51.100.3
Nodegroup = 65536

[nbdb]
Id = 4
HostName = 198.51.100.4
Nodegroup = 65536

[mgm]
HostName = 198.51.100.10
Id = 10
```

[api]
The data nodes to be brought online at a later time (nodes 3 and 4) can be configured with `NodeGroup = 65536`, in which case nodes 1 and 2 can each be started as shown here:

```
shell> ndbd -c 198.51.100.10 --initial
```

The data nodes configured with `NodeGroup = 65536` are treated by the management server as though you had started nodes 1 and 2 using `--nowait-nodes=3,4` after waiting for a period of time determined by the setting for the `StartNoNodeGroupTimeout` data node configuration parameter. By default, this is 15 seconds (15000 milliseconds).

**Note**

`StartNoNodeGroupTimeout` must be the same for all data nodes in the cluster; for this reason, you should always set it in the `[ndbd default]` section of the `config.ini` file, rather than for individual data nodes.

When you are ready to add the second node group, you need only perform the following additional steps:

1. Start data nodes 3 and 4, invoking the data node process once for each new node:
   
   ```
   shell> ndbd -c 198.51.100.10 --initial
   ```

2. Issue the appropriate `CREATE NODEGROUP` command in the management client:

   ```
   ndb_mgm> CREATE NODEGROUP 3,4
   ```

3. In the `mysql` client, issue `ALTER TABLE ... REORGANIZE PARTITION` and `OPTIMIZE TABLE` statements for each existing `NDBCLUSTER` table. (As noted elsewhere in this section, existing NDB Cluster tables cannot use the new nodes for data distribution until this has been done.)

### 22.5.16 Distributed MySQL Privileges with NDB_STORED_USER

NDB 8.0.18 introduces a new mechanism for sharing and synchronizing users, roles, and privileges between SQL nodes connected to an NDB Cluster. This can be enabled by granting the `NDB_STORED_USER` privilege. See the description of the privilege for usage information.

`NDB_STORED_USER` is printed in the output of `SHOW GRANTS` as with any other privilege. To verify that privileges are shared, use the `ndb_select_all` utility supplied with the NDB Cluster distribution, as shown here (some output wrapped to preserve formatting):

```
shell> ndb_select_all -d mysql ndb_sql_metadata
<table>
<thead>
<tr>
<th>type</th>
<th>name</th>
<th>seq</th>
<th>note</th>
<th>sql_ddl_text</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>&quot;jon&quot;@'localhost'</td>
<td>0</td>
<td>4</td>
<td>CREATE USER 'jon'@'localhost' IDENTIFIED WITH 'caching_sha2_password' AS &quot;$A0509056;3?c\t\n'.EFy\ZASKSDQHw1BvuRNYTIMeo0Yeq1Pp2ot.FRP\VTYzTA5b0' REQUIRE NONE PASSWORD EXPIRE DEFAULT ACCOUNT UNLOCK PASSWORD HISTORY DEFAULT PASSWORD REUSE INTERVAL DEFAULT PASSWORD REQUIRE CURRENT DEFAULT</td>
</tr>
<tr>
<td>12</td>
<td>&quot;jon&quot;@'localhost'</td>
<td>3</td>
<td>NULL</td>
<td>&quot;GRANT ALL PRIVILEGES ON <code>test</code>.* TO <code>jon</code>@localhost&quot;</td>
</tr>
<tr>
<td>12</td>
<td>&quot;jon&quot;@'localhost'</td>
<td>2</td>
<td>NULL</td>
<td>&quot;GRANT ALL PRIVILEGES ON <code>mydb</code>.* TO <code>jon</code>@localhost&quot;</td>
</tr>
<tr>
<td>12</td>
<td>&quot;jon&quot;@'localhost'</td>
<td>1</td>
<td>NULL</td>
<td>&quot;GRANT NDB_STORED_USER ON <code>test</code>.* TO <code>jon</code>@localhost&quot;</td>
</tr>
</tbody>
</table>
```

5 rows returned

`ndb_sql_metadata` is a special NDB table that is not visible using the `mysql` or other MySQL client.

A statement granting the `NDB_STORED_USER` privilege, such as `GRANT NDB_STORED_USER ON *.* TO 'cluster_app_user'@'localhost'`, works by directing NDB to create a snapshot using the queries `SHOW CREATE USER cluster_app_user@localhost` and `SHOW GRANTS FOR...`
cluster_app_user@localhost, then storing the results in ndb_sql_metadata. Any other SQL nodes are then requested to read and apply the snapshot. Whenever a MySQL server starts up and joins the cluster as an SQL node it executes these stored CREATE USER and GRANT statements as part of the cluster schema synchronization process.

Whenever an SQL statement is executed on an SQL node other than the one where it originated, the statement is run in a utility thread of the NDBCLUSTER storage engine; this is done within a security environment equivalent to that of the MySQL replication slave applier thread.

You should be aware that changes to users with NDB_STORED_USER are distributed asynchronously. Because distributed schema change operations are performed synchronously, the next distributed schema change following a change to any distributed user or users serves as a synchronization point. Any pending user changes run to completion before the schema change distribution can begin; after this the schema change itself runs synchronously. For example, if a DROP USER statement follows a DROP DATABASE statement, the drop of the database cannot take place until the drop of the user has completed on all SQL nodes.

In the event that multiple GRANT, REVOKE, or other user administration statements from multiple SQL nodes cause privileges for a given user to diverge on different SQL nodes, you can fix this problem by issuing GRANT NDB_STORED_USER for this user on an SQL node where the privileges are known to be correct; this causes a new snapshot of the privileges to be taken and synchronized to the other SQL nodes.

NDB Cluster 8.0 does not support distribution of MySQL users and privileges across SQL nodes in an NDB Cluster by converting the MySQL privilege tables to use the NDB storage engine, as implemented in NDB 7.6 and earlier releases (see Distributed Privileges Using Shared Grant Tables). For information about the impact of this change on upgrades to NDB 8.0 from a previous release, see Section 22.2.8, “Upgrading and Downgrading NDB Cluster”.

### 22.5.17 NDB API Statistics Counters and Variables

A number of types of statistical counters relating to actions performed by or affecting Ndb objects are available. Such actions include starting and closing (or aborting) transactions; primary key and unique key operations; table, range, and pruned scans; threads blocked while waiting for the completion of various operations; and data and events sent and received by NDBCLUSTER. The counters are incremented inside the NDB kernel whenever NDB API calls are made or data is sent to or received by the data nodes. mysqld exposes these counters as system status variables; their values can be read in the output of SHOW STATUS, or by querying the Performance Schema session_status or global_status table. By comparing the values before and after statements operating on NDB tables, you can observe the corresponding actions taken on the API level, and thus the cost of performing the statement.

You can list all of these status variables using the following SHOW STATUS statement:

```sql
mysql> SHOW STATUS LIKE 'ndb_api\%';
+--------------------------------------------+----------+
| Variable_name                              | Value    |
+--------------------------------------------+----------+
| Ndb_api_wait_exec_complete_count_session   | 0        |
| Ndb_api_wait_scan_result_count_session     | 0        |
| Ndb_api_wait_meta_request_count_session    | 0        |
| Ndb_api_wait_nanos_count_session           | 0        |
| Ndb_api_bytes_sent_count_session           | 0        |
| Ndb_api_bytes_received_count_session       | 0        |
| Ndb_api_trans_start_count_session          | 0        |
| Ndb_api_trans_commit_count_session         | 0        |
| Ndb_api_trans_abort_count_session          | 0        |
| Ndb_api_trans_close_count_session          | 0        |
| Ndb_api_pk_op_count_session                | 0        |
| Ndb_api_uk_op_count_session                | 0        |
| Ndb_api_table_scan_count_session           | 0        |
| Ndb_api_range_scan_count_session           | 0        |
| Ndb_api_pruned_scan_count_session          | 0        |
| Ndb_api_scan_batch_count_session           | 0        |
```
<table>
<thead>
<tr>
<th>VARIABLE_NAME</th>
<th>VARIABLE_VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB_API_WAIT_EXEC_COMPLETE_COUNT_SESSION</td>

60 rows in set (0.00 sec)

Each Ndb object has its own counters. NDB API applications can read the values of the counters for use in optimization or monitoring. For multithreaded clients which use more than one Ndb object concurrently, it is also possible to obtain a summed view of counters from all Ndb objects belonging to a given Ndb_cluster_connection.

Four sets of these counters are exposed. One set applies to the current session only; the other 3 are global. This is in spite of the fact that their values can be obtained as either session or global status variables in the mysql client. This means that specifying the SESSION or GLOBAL keyword with SHOW STATUS has no effect on the values reported for NDB API statistics status variables, and the value for each of these variables is the same whether the value is obtained from the equivalent column of the session_status or the global_status table.

- **Session counters (session specific)**
  
  Session counters relate to the Ndb objects in use by (only) the current session. Use of such objects by other MySQL clients does not influence these counts.

  In order to minimize confusion with standard MySQL session variables, we refer to the variables that correspond to these NDB API session counters as "_session variables", with a leading underscore.

- **Slave counters (global)**
  
  This set of counters relates to the Ndb objects used by the replication slave SQL thread, if any. If this mysqld does not act as a replication slave, or does not use NDB tables, then all of these counts are 0.
We refer to the related status variables as "_slave variables" (with a leading underscore).

• **Injector counters (global)**

  Injector counters relate to the Ndb object used to listen to cluster events by the binary log injector thread. Even when not writing a binary log, mysqld processes attached to an NDB Cluster continue to listen for some events, such as schema changes.

  We refer to the status variables that correspond to NDB API injector counters as "_injector variables" (with a leading underscore).

• **Server (Global) counters (global)**

  This set of counters relates to all Ndb objects currently used by this mysqld. This includes all MySQL client applications, the slave SQL thread (if any), the binlog injector, and the NDB utility thread.

  We refer to the status variables that correspond to these counters as "global variables" or "mysqld-level variables".

You can obtain values for a particular set of variables by additionally filtering for the substring `session`, `slave`, or `injector` in the variable name (along with the common prefix Ndb_api). For _session variables, this can be done as shown here:

```sql
mysql> SHOW STATUS LIKE 'ndb_api%session';
+--------------------------------------------+---------+
| Variable_name                              | Value   |
+--------------------------------------------+---------+
| Ndb_api_wait_exec_complete_count_session   | 2       |
| Ndb_api_wait_scan_result_count_session     | 0       |
| Ndb_api_wait_meta_request_count_session    | 1       |
| Ndb_api_wait_nanos_count_session           | 8144375 |
| Ndb_api_bytes_received_count_session       | 84      |
| Ndb_api_trans_start_count_session          | 1       |
| Ndb_api_trans_commit_count_session         | 1       |
| Ndb_api_trans_abort_count_session          | 0       |
| Ndb_api_trans_close_count_session          | 1       |
| Ndb_api_pk_op_count_session                | 1       |
| Ndb_api_uk_op_count_session                | 0       |
| Ndb_api_table_scan_count_session           | 0       |
| Ndb_api_range_scan_count_session           | 0       |
| Ndb_api_pruned_scan_count_session          | 0       |
| Ndb_api_scan_batch_count_session           | 0       |
| Ndb_api_read_row_count_session             | 1       |
| Ndb_api_trans_local_read_row_count_session | 1       |
+--------------------------------------------+---------+
18 rows in set (0.50 sec)
```

To obtain a listing of the NDB API mysqld-level status variables, filter for variable names beginning with ndb_api and ending in _count, like this:

```sql
mysql> SELECT * FROM performance_schema.session_status
> WHERE VARIABLE_NAME LIKE 'ndb_api%count';
+------------------------------------+----------------+
| VARIABLE_NAME                      | VARIABLE_VALUE |
+------------------------------------+----------------+
| NDB_API_WAIT_EXEC_COMPLETE_COUNT   | 4              |
| NDB_API_WAIT_SCAN_RESULT_COUNT     | 3              |
| NDB_API_WAIT_META_REQUEST_COUNT    | 28             |
| NDB_API_WAIT_NANOS_COUNT           | 53756398       |
| NDB_API_BYTES_SENT_COUNT           | 1060           |
| NDB_API_BYTES_RECEIVED_COUNT       | 9724           |
| NDB_API_TRANS_START_COUNT          | 3              |
| NDB_API_TRANS_COMMIT_COUNT         | 2              |
| NDB_API_TRANS_ABORT_COUNT          | 0              |
| NDB_API_TRANS_CLOSE_COUNT          | 3              |
| NDB_API_PK_OP_COUNT                | 2              |
```

4044
Not all counters are reflected in all 4 sets of status variables. For the event counters `DataEventsRecvdCount`, `NondataEventsRecvdCount`, and `EventBytesRecvdCount`, only _injector_ and `mysqld`-level NDB API status variables are available:

```
mysql> SHOW STATUS LIKE 'ndb_api%event%';
+--------------------------------------+-------+
<table>
<thead>
<tr>
<th>Variable_name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ndb_api_event_data_count_injector</td>
<td>0</td>
</tr>
<tr>
<td>Ndb_api_event_nondata_count_injector</td>
<td>0</td>
</tr>
<tr>
<td>Ndb_api_event_bytes_count_injector</td>
<td>0</td>
</tr>
<tr>
<td>Ndb_api_event_data_count</td>
<td>0</td>
</tr>
<tr>
<td>Ndb_api_event_nondata_count</td>
<td>0</td>
</tr>
<tr>
<td>Ndb_api_event_bytes_count</td>
<td>0</td>
</tr>
</tbody>
</table>
+--------------------------------------+-------+
```

_injector_ status variables are not implemented for any other NDB API counters, as shown here:

```
mysql> SHOW STATUS LIKE 'ndb_api%injector%';
+--------------------------------------+-------+
<table>
<thead>
<tr>
<th>Variable_name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ndb_api_event_data_count_injector</td>
<td>0</td>
</tr>
<tr>
<td>Ndb_api_event_nondata_count_injector</td>
<td>0</td>
</tr>
<tr>
<td>Ndb_api_event_bytes_count_injector</td>
<td>0</td>
</tr>
</tbody>
</table>
+--------------------------------------|-------+
```

The names of the status variables can easily be associated with the names of the corresponding counters. Each NDB API statistics counter is listed in the following table with a description as well as the names of any MySQL server status variables corresponding to this counter.

### Table 22.343 NDB API statistics counters

</tbody>
</table>

To see all counts of committed transactions—that is, all TransCommitCount counter status variables—you can filter the results of SHOW STATUS for the substring trans_commit_count, like this:

```
mysql> SHOW STATUS LIKE '%trans_commit_count%';
+------------------------------------+-------+
| Variable_name                      | Value |
+------------------------------------+-------+
| Ndb_api_trans_commit_count_session | 1     |
| Ndb_api_trans_commit_count_slave   | 0     |
| Ndb_api_trans_commit_count         | 2     |
+------------------------------------+-------+
3 rows in set (0.00 sec)
```
From this you can determine that 1 transaction has been committed in the current mysql client session, and 2 transactions have been committed on this mysqld since it was last restarted.

You can see how various NDB API counters are incremented by a given SQL statement by comparing the values of the corresponding _session status variables immediately before and after performing the statement. In this example, after getting the initial values from SHOW STATUS, we create in the test database an NDB table, named t, that has a single column:

```sql
SHOW STATUS LIKE 'ndb_api%session%';
```

```
+--------------------------------------------+--------+
| Variable_name                              | Value  |
|--------------------------------------------+--------+
| Ndb_api_wait_exec_complete_count_session   | 2      |
| Ndb_api_wait_scan_result_count_session     | 0      |
| Ndb_api_wait_meta_request_count_session    | 3      |
| Ndb_api_wait_nanos_count_session           | 820705 |
| Ndb_api_bytes_sent_count_session           | 132    |
| Ndb_api_bytes_received_count_session       | 372    |
| Ndb_api_trans_start_count_session          | 1      |
| Ndb_api_trans_commit_count_session         | 1      |
| Ndb_api_trans_abort_count_session          | 0      |
| Ndb_api_trans_close_count_session          | 1      |
| Ndb_api_pk_op_count_session                | 1      |
| Ndb_api_uk_op_count_session                | 0      |
| Ndb_api_table_scan_count_session           | 0      |
| Ndb_api_range_scan_count_session           | 0      |
| Ndb_api_pruned_scan_count_session          | 0      |
| Ndb_api_scan_batch_count_session           | 0      |
| Ndb_api_read_row_count_session             | 1      |
| Ndb_api_trans_local_read_row_count_session | 1      |
+--------------------------------------------+--------+
```

```
USE test;
```

```
CREATE TABLE t (c INT) ENGINE NDBCLUSTER;
```

Now you can execute a new SHOW STATUS statement and observe the changes, as shown here (with the changed rows highlighted in the output):

```sql
SHOW STATUS LIKE 'ndb_api%session%';
```

```
+--------------------------------------------+-----------+
| Variable_name                              | Value     |
|--------------------------------------------+-----------+
| Ndb_api_wait_exec_complete_count_session   | 8         |
| Ndb_api_wait_scan_result_count_session     | 0         |
| Ndb_api_wait_meta_request_count_session    | 17        |
| Ndb_api_wait_nanos_count_session           | 706871709 |
| Ndb_api_bytes_sent_count_session           | 2376      |
| Ndb_api_bytes_received_count_session       | 3844      |
| Ndb_api_trans_start_count_session          | 4         |
| Ndb_api_trans_commit_count_session         | 4         |
| Ndb_api_trans_abort_count_session          | 0         |
| Ndb_api_trans_close_count_session          | 4         |
| Ndb_api_pk_op_count_session                | 6         |
| Ndb_api_uk_op_count_session                | 0         |
| Ndb_api_table_scan_count_session           | 0         |
| Ndb_api_range_scan_count_session           | 0         |
| Ndb_api_pruned_scan_count_session          | 0         |
| Ndb_api_scan_batch_count_session           | 0         |
| Ndb_api_read_row_count_session             | 2         |
| Ndb_api_trans_local_read_row_count_session | 1         |
+--------------------------------------------+-----------+
```

Similarly, you can see the changes in the NDB API statistics counters caused by inserting a row into t: Insert the row, then run the same SHOW STATUS statement used in the previous example, as shown here:
We can make a number of observations from these results:

- Although we created t with no explicit primary key, 5 primary key operations were performed in doing so (the difference in the “before” and “after” values of Ndb_api_pk_op_count_session, or 6 minus 1). This reflects the creation of the hidden primary key that is a feature of all tables using the NDB storage engine.

- By comparing successive values for Ndb_api_wait_nanos_count_session, we can see that the NDB API operations implementing the CREATE TABLE statement waited much longer (706871709 - 820705 = 706051004 nanoseconds, or approximately 0.7 second) for responses from the data nodes than those executed by the INSERT (707370418 - 706871709 = 498709 ns or roughly .0005 second). The execution times reported for these statements in the mysql client correlate roughly with these figures.

On platforms without sufficient (nanosecond) time resolution, small changes in the value of the WaitNanosCount NDB API counter due to SQL statements that execute very quickly may not always be visible in the values of Ndb_api_wait_nanos_count_session, Ndb_api_wait_nanos_count_slave, or Ndb_api_wait_nanos_count.

- The INSERT statement incremented both the ReadRowCount and TransLocalReadRowCount NDB API statistics counters, as reflected by the increased values of Ndb_api_read_row_count_session and Ndb_api_trans_local_read_row_count_session.

### 22.6 NDB Cluster Replication

NDB Cluster supports asynchronous replication, more usually referred to simply as “replication”. This section explains how to set up and manage a configuration in which one group of computers operating as an NDB Cluster replicates to a second computer or group of computers. We assume some familiarity on the part of the reader with standard MySQL replication as discussed elsewhere in this Manual. (See Chapter 17, Replication).

**Note**

NDB Cluster does not support replication using GTIDs; semisynchronous replication is also not supported by the NDB storage engine.
Normal (non-clustered) replication involves a “master” server and a “slave” server, the master being the source of the operations and data to be replicated and the slave being the recipient of these. In NDB Cluster, replication is conceptually very similar but can be more complex in practice, as it may be extended to cover a number of different configurations including replicating between two complete clusters. Although an NDB Cluster itself depends on the NDB storage engine for clustering functionality, it is not necessary to use NDB as the storage engine for the slave’s copies of the replicated tables (see Replication from NDB to other storage engines). However, for maximum availability, it is possible (and preferable) to replicate from one NDB Cluster to another, and it is this scenario that we discuss, as shown in the following figure:

Figure 22.31 NDB Cluster-to-Cluster Replication Layout

In this scenario, the replication process is one in which successive states of a master cluster are logged and saved to a slave cluster. This process is accomplished by a special thread known as the NDB binary log injector thread, which runs on each MySQL server and produces a binary log (binlog). This thread ensures that all changes in the cluster producing the binary log—and not just those changes that are effected through the MySQL Server—are inserted into the binary log with the correct serialization order. We refer to the MySQL replication master and replication slave servers as replication servers or replication nodes, and the data flow or line of communication between them as a replication channel.

For information about performing point-in-time recovery with NDB Cluster and NDB Cluster Replication, see Section 22.6.9.2, “Point-In-Time Recovery Using NDB Cluster Replication”.

NDB API_slave status variables. NDB API counters can provide enhanced monitoring capabilities on NDB Cluster replication slaves. These are implemented as NDB statistics_slave status variables, as seen in the output of SHOW STATUS, or in the results of queries against the Performance Schema session_status or global_status table in a mysql client session connected to a MySQL Server that is acting as a slave in NDB Cluster Replication. By comparing the values of these status variables before and after the execution of statements affecting replicated NDB tables, you can observe the corresponding actions taken on the NDB API level by the slave, which can be useful when monitoring or troubleshooting NDB Cluster Replication. Section 22.5.17, “NDB API Statistics Counters and Variables”, provides additional information.

Replication from NDB to non-NDB tables. It is possible to replicate NDB tables from an NDB Cluster acting as the master to tables using other MySQL storage engines such as InnoDB or MyISAM on a slave mysql. This is subject to a number of conditions; see Replication from NDB to other storage engines, and Replication from NDB to a nontransactional storage engine, for more information.

22.6.1 NDB Cluster Replication: Abbreviations and Symbols
Throughout this section, we use the following abbreviations or symbols for referring to the master and slave clusters, and to processes and commands run on the clusters or cluster nodes:

Table 22.344 Abbreviations used throughout this section referring to master and slave clusters, and to processes and commands run on nodes

<table>
<thead>
<tr>
<th>Symbol or Abbreviation</th>
<th>Description (Refers to...)</th>
</tr>
</thead>
<tbody>
<tr>

</tbody>
</table>

22.6.2 General Requirements for NDB Cluster Replication

A replication channel requires two MySQL servers acting as replication servers (one each for the master and slave). For example, this means that in the case of a replication setup with two replication channels (to provide an extra channel for redundancy), there will be a total of four replication nodes, two per cluster.

Replication of an NDB Cluster as described in this section and those following is dependent on row-based replication. This means that the replication master MySQL server must be running with `--binlog-format=ROW` or `--binlog-format=MIXED`, as described in Section 22.6.6, "Starting NDB Cluster Replication (Single Replication Channel)". For general information about row-based replication, see Section 17.2.1, "Replication Formats".

![Important](https://via.placeholder.com/150)

**Important**

If you attempt to use NDB Cluster Replication with `--binlog-format=STATEMENT`, replication fails to work properly because the `ndb_binlog_index` table on the master and the `epoch` column of the `ndb_apply_status` table on the slave are not updated (see Section 22.6.4, "NDB Cluster Replication Schema and Tables"). Instead, only updates on the MySQL server acting as the replication master propagate to the slave, and no updates from any other SQL nodes on the master cluster are replicated.

The default value for the `--binlog-format` option in NDB 8.0 is `MIXED`.

Each MySQL server used for replication in either cluster must be uniquely identified among all the MySQL replication servers participating in either cluster (you cannot have replication servers on both the master and slave clusters sharing the same ID). This can be done by starting each SQL node using...
It is generally true in MySQL Replication that both MySQL servers (mysqld processes) involved must be compatible with one another with respect to both the version of the replication protocol used and the SQL feature sets which they support (see Section 17.5.2, “Replication Compatibility Between MySQL Versions”). It is due to such differences between the binaries in the NDB Cluster and MySQL Server 8.0 distributions that NDB Cluster Replication has the additional requirement that both mysqld binaries come from an NDB Cluster distribution. The simplest and easiest way to assure that the mysqld servers are compatible is to use the same NDB Cluster distribution for all master and slave mysqld binaries.

We assume that the slave server or cluster is dedicated to replication of the master, and that no other data is being stored on it.

All NDB tables being replicated must be created using a MySQL server and client. Tables and other database objects created using the NDB API (with, for example, `Dictionary::createTable()` are not visible to a MySQL server and so are not replicated. Updates by NDB API applications to existing tables that were created using a MySQL server can be replicated.

Note

It is possible to replicate an NDB Cluster using statement-based replication. However, in this case, the following restrictions apply:

- All updates to data rows on the cluster acting as the master must be directed to a single MySQL server.
- It is not possible to replicate a cluster using multiple simultaneous MySQL replication processes.
- Only changes made at the SQL level are replicated.

These are in addition to the other limitations of statement-based replication as opposed to row-based replication; see Section 17.2.1.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”, for more specific information concerning the differences between the two replication formats.

22.6.3 Known Issues in NDB Cluster Replication

This section discusses known problems or issues when using replication with NDB Cluster 8.0.

**Loss of master-slave connection.** A loss of connection can occur either between the replication master SQL node and the replication slave SQL node, or between the replication master SQL node and the data nodes in the master cluster. In the latter case, this can occur not only as a result of loss of physical connection (for example, a broken network cable), but due to the overflowing of node event buffers; if the SQL node is too slow to respond, it may be dropped by the cluster (this is controllable to some degree by adjusting the `MaxBufferedEpochs` and `TimeBetweenEpochs` configuration parameters). If this occurs, it is entirely possible for new data to be inserted into the master cluster without being recorded in the replication master’s binary log. For this reason, to guarantee high availability, it is extremely important to maintain a backup replication channel, to monitor the primary channel, and to fail over to the secondary replication channel when necessary to keep the slave cluster synchronized with the master. NDB Cluster is not designed to perform such monitoring on its own; for this, an external application is required.

The replication master issues a “gap” event when connecting or reconnecting to the master cluster. (A gap event is a type of “incident event,” which indicates an incident that occurs that affects the contents of the database but that cannot easily be represented as a set of changes. Examples of incidents are
Known Issues in NDB Cluster Replication

server crashes, database resynchronization, (some) software updates, and (some) hardware changes.) When the slave encounters a gap in the replication log, it stops with an error message. This message is available in the output of `SHOW SLAVE STATUS`, and indicates that the SQL thread has stopped due to an incident registered in the replication stream, and that manual intervention is required. See Section 22.6.8, “Implementing Failover with NDB Cluster Replication”, for more information about what to do in such circumstances.

**Important**

Because NDB Cluster is not designed on its own to monitor replication status or provide failover, if high availability is a requirement for the slave server or cluster, then you must set up multiple replication lines, monitor the master `mysql` on the primary replication line, and be prepared fail over to a secondary line if and as necessary. This must be done manually, or possibly by means of a third-party application. For information about implementing this type of setup, see Section 22.6.7, “Using Two Replication Channels for NDB Cluster Replication”, and Section 22.6.8, “Implementing Failover with NDB Cluster Replication”.

However, if you are replicating from a standalone MySQL server to an NDB Cluster, one channel is usually sufficient.

**Circular replication.** NDB Cluster Replication supports circular replication, as shown in the next example. The replication setup involves three NDB Clusters numbered 1, 2, and 3, in which Cluster 1 acts as the replication master for Cluster 2, Cluster 2 acts as the master for Cluster 3, and Cluster 3 acts as the master for Cluster 1, thus completing the circle. Each NDB Cluster has two SQL nodes, with SQL nodes A and B belonging to Cluster 1, SQL nodes C and D belonging to Cluster 2, and SQL nodes E and F belonging to Cluster 3.

Circular replication using these clusters is supported as long as the following conditions are met:

- The SQL nodes on all masters and slaves are the same.
- All SQL nodes acting as replication masters and slaves are started with the `log_slave_updates` system variable enabled.

This type of circular replication setup is shown in the following diagram:
In this scenario, SQL node A in Cluster 1 replicates to SQL node C in Cluster 2; SQL node C replicates to SQL node E in Cluster 3; SQL node E replicates to SQL node A. In other words, the replication line (indicated by the curved arrows in the diagram) directly connects all SQL nodes used as replication masters and slaves.

It should also be possible to set up circular replication in which not all master SQL nodes are also slaves, as shown here:
In this case, different SQL nodes in each cluster are used as replication masters and slaves. However, you must not start any of the SQL nodes with the `log_slave_updates` system variable enabled. This type of circular replication scheme for NDB Cluster, in which the line of replication (again indicated by the curved arrows in the diagram) is discontinuous, should be possible, but it should be noted that it has not yet been thoroughly tested and must therefore still be considered experimental.

**Note**

The NDB storage engine uses *idempotent execution mode*, which suppresses duplicate-key and other errors that otherwise break circular replication of NDB Cluster. This is equivalent to setting the global `slave_exec_mode` system variable to `IDEMPOTENT`, although this is not necessary in NDB Cluster replication, since NDB Cluster sets this variable automatically and ignores any attempts to set it explicitly.

**NDB Cluster replication and primary keys.** In the event of a node failure, errors in replication of NDB tables without primary keys can still occur, due to the possibility of duplicate rows being inserted in such cases. For this reason, it is highly recommended that all NDB tables being replicated have primary keys.

**NDB Cluster Replication and Unique Keys.** In older versions of NDB Cluster, operations that updated values of unique key columns of NDB tables could result in duplicate-key errors when replicated. This issue is solved for replication between NDB tables by deferring unique key checks until after all table row updates have been performed.
Deferring constraints in this way is currently supported only by NDB. Thus, updates of unique keys when replicating from NDB to a different storage engine such as MyISAM or InnoDB are still not supported.

The problem encountered when replicating without deferred checking of unique key updates can be illustrated using NDB table such as `t`, is created and populated on the master (and replicated to a slave that does not support deferred unique key updates) as shown here:

```sql
CREATE TABLE t (  
p INT PRIMARY KEY,  
c INT,  
UNIQUE KEY u (c) )  
ENGINE NDB;

INSERT INTO t  
VALUES (1,1), (2,2), (3,3), (4,4), (5,5);
```

The following `UPDATE` statement on `t` succeeded on the master, since the rows affected are processed in the order determined by the `ORDER BY` option, performed over the entire table:

```sql
UPDATE t SET c = c - 1 ORDER BY p;
```

However, the same statement failed with a duplicate key error or other constraint violation on the slave, because the ordering of the row updates was done for one partition at a time, rather than for the table as a whole.

**Note**

Every NDB table is implicitly partitioned by key when it is created. See Section 23.2.5, "KEY Partitioning", for more information.

GTIDs not supported. Replication using global transaction IDs is not compatible with the NDB storage engine, and is not supported. Enabling GTIDs is likely to cause NDB Cluster Replication to fail.

Multithreaded slaves not supported. NDB Cluster does not support multithreaded slaves, and setting related system variables such as `slave_parallel_workers`, `slave_checkpoint_group`, and `slave_checkpoint_group` (or the equivalent `mysqld` startup options) has no effect.

This is because the slave may not be able to separate transactions occurring in one database from those in another if they are written within the same epoch. In addition, every transaction handled by the NDB storage engine involves at least two databases—the target database and the `mysql` system database—due to the requirement for updating the `mysql.ndb_apply_status` table (see Section 22.6.4, "NDB Cluster Replication Schema and Tables"). This in turn breaks the requirement for multithreading that the transaction is specific to a given database.

Restarting with --initial. Restarting the cluster with the `--initial` option causes the sequence of GCI and epoch numbers to start over from 0. (This is generally true of NDB Cluster and not limited to replication scenarios involving Cluster.) The MySQL servers involved in replication should in this case be restarted. After this, you should use the `RESET MASTER` and `RESET SLAVE` statements to clear the invalid `ndb_binlog_index` and `ndb_apply_status` tables, respectively.

Replication from NDB to other storage engines. It is possible to replicate an NDB table on the master to a table using a different storage engine on the slave, taking into account the restrictions listed here:

- Multi-master and circular replication are not supported (tables on both the master and the slave must use the NDB storage engine for this to work).
- Using a storage engine which does not perform binary logging for slave tables requires special handling.
- Use of a nontransactional storage engine for slave tables also requires special handling.
- The master `mysqld` must be started with `--ndb-log-update-as-write=0` or `--ndb-log-update-as-write=OFF`. 
The next few paragraphs provide additional information about each of the issues just described.

**Multiple masters not supported when replicating NDB to other storage engines.**  For replication from NDB to a different storage engine, the relationship between the two databases must be a simple master-slave one. This means that circular or master-master replication is not supported between NDB Cluster and other storage engines.

In addition, it is not possible to configure more than one replication channel when replicating between NDB and a different storage engine. (However, an NDB Cluster database can simultaneously replicate to multiple slave NDB Cluster databases.) If the master uses NDB tables, it is still possible to have more than one MySQL Server maintain a binary log of all changes; however, for the slave to change masters (fail over), the new master-slave relationship must be explicitly defined on the slave.

**Replicating NDB to a slave storage engine that does not perform binary logging.**  If you attempt to replicate from an NDB Cluster to a slave that uses a storage engine that does not handle its own binary logging, the replication process aborts with the error Binary logging not possible ... Statement cannot be written atomically since more than one engine involved and at least one engine is self-logging (Error 1595). It is possible to work around this issue in one of the following ways:

- **Turn off binary logging on the slave.**  This can be accomplished by setting `sql_log_bin = 0`.

- **Change the storage engine used for the mysql.ndb_apply_status table.**  Causing this table to use an engine that does not handle its own binary logging can also eliminate the conflict. This can be done by issuing a statement such as `ALTER TABLE mysql.ndb_apply_status ENGINE=MyISAM` on the slave. It is safe to do this when using a non-NDB storage engine on the slave, since you do not then need to worry about keeping multiple slave SQL nodes synchronized.

- **Filter out changes to the mysql.ndb_apply_status table on the slave.**  This can be done by starting the slave SQL node with `--replicate-ignore-table=mysql.ndb_apply_status`. If you need for other tables to be ignored by replication, you might wish to use an appropriate `--replicate-wild-ignore-table` option instead.

> **Important**
> You should **not** disable replication or binary logging of `mysql.ndb_apply_status` or change the storage engine used for this table when replicating from one NDB Cluster to another. See [Replication and binary log filtering rules with replication between NDB Clusters](#), for details.

**Replication from NDB to a nontransactional storage engine.**  When replicating from NDB to a nontransactional storage engine such as MyISAM, you may encounter unnecessary duplicate key errors when replicating `INSERT ... ON DUPLICATE KEY UPDATE` statements. You can suppress these by using `--ndb-log-update-as-write=0`, which forces updates to be logged as writes (rather than as updates).

**Replication and binary log filtering rules with replication between NDB Clusters.**  If you are using any of the options `--replicate-do-*, --replicate-ignore-*, --binlog-do-db, or --binlog-ignore-db` to filter databases or tables being replicated, care must be taken not to block replication or binary logging of the `mysql.ndb_apply_status`, which is required for replication between NDB Clusters to operate properly. In particular, you must keep in mind the following:

1. Using `--replicate-do-db=db_name` (and no other `--replicate-do-*` or `--replicate-ignore-*` options) means that only tables in database `db_name` are replicated. In this case, you should also use `--replicate-do-db=mysql, --binlog-do-db=mysql, or --replicate-do-table=mysql.ndb_apply_status` to ensure that `mysql.ndb_apply_status` is populated on slaves.

Using `--binlog-do-db=db_name` (and no other `--binlog-do-db` options) means that changes only to tables in database `db_name` are written to the binary log. In this case, you should also use `--replicate-do-db=mysql, --binlog-do-db=mysql, or --replicate-do-
2. Using `--replicate-ignore-db=mysql` means that no tables in the `mysql` database are replicated. In this case, you should also use `--replicate-do-table=mysql.ndb_apply_status` to ensure that `mysql.ndb_apply_status` is replicated.

Using `--binlog-ignore-db=mysql` means that no changes to tables in the `mysql` database are written to the binary log. In this case, you should also use `--replicate-do-table=mysql.ndb_apply_status` to ensure that `mysql.ndb_apply_status` is replicated.

You should also remember that each replication rule requires the following:

1. Its own `--replicate-do-*` or `--replicate-ignore-*` option, and that multiple rules cannot be expressed in a single replication filtering option. For information about these rules, see Section 17.1.6, “Replication and Binary Logging Options and Variables”.

2. Its own `--binlog-do-db` or `--binlog-ignore-db` option, and that multiple rules cannot be expressed in a single binary log filtering option. For information about these rules, see Section 5.4.4, “The Binary Log”.

If you are replicating an NDB Cluster to a slave that uses a storage engine other than NDB, the considerations just given previously may not apply, as discussed elsewhere in this section.

**NDB Cluster Replication and IPv6.** Currently, the NDB API and MGM API do not support IPv6. However, MySQL Servers—including those acting as SQL nodes in an NDB Cluster—can use IPv6 to contact other MySQL Servers. This means that you can replicate between NDB Clusters using IPv6 to connect the master and slave SQL nodes as shown by the dotted arrow in the following diagram:

**Figure 22.34 Replication Between SQL Nodes Connected Using IPv6**

![Diagram of NDB Cluster Replication](image)

However, all connections originating within the NDB Cluster—represented in the preceding diagram by solid arrows—must use IPv4. In other words, all NDB Cluster data nodes, management servers, and management clients must be accessible from one another using IPv4. In addition, SQL nodes must use IPv4 to communicate with the cluster.

Since there is currently no support in the NDB and MGM APIs for IPv6, any applications written using these APIs must also make all connections using IPv4.

**Attribute promotion and demotion.** NDB Cluster Replication includes support for attribute promotion and demotion. The implementation of the latter distinguishes between lossy and
non-lossy type conversions, and their use on the slave can be controlled by setting the `slave_type_conversions` global server system variable.

For more information about attribute promotion and demotion in NDB Cluster, see Row-based replication: attribute promotion and demotion.

NDB, unlike InnoDB or MyISAM, does not write changes to virtual columns to the binary log; however, this has no detrimental effects on NDB Cluster Replication or replication between NDB and other storage engines. Changes to stored generated columns are logged.

22.6.4 NDB Cluster Replication Schema and Tables

Replication in NDB Cluster makes use of a number of dedicated tables in the `mysql` database on each MySQL Server instance acting as an SQL node in both the cluster being replicated and the replication slave (whether the slave is a single server or a cluster). These tables are created during the MySQL installation process, and include a table for storing the binary log's indexing data. Since the `ndb_binlog_index` table is local to each MySQL server and does not participate in clustering, it uses the InnoDB storage engine. This means that it must be created separately on each `mysqld` participating in the master cluster. (However, the binary log itself contains updates from all MySQL servers in the cluster to be replicated.) This table is defined as follows:

```sql
CREATE TABLE `ndb_binlog_index` (  `Position` BIGINT(20) UNSIGNED NOT NULL,  `File` VARCHAR(255) NOT NULL,  `epoch` BIGINT(20) UNSIGNED NOT NULL,  `inserts` INT(10) UNSIGNED NOT NULL,  `updates` INT(10) UNSIGNED NOT NULL,  `deletes` INT(10) UNSIGNED NOT NULL,  `schemapos` INT(10) UNSIGNED NOT NULL,  `orig_server_id` INT(10) UNSIGNED NOT NULL,  `orig_epoch` BIGINT(20) UNSIGNED NOT NULL,  `gci` INT(10) UNSIGNED NOT NULL,  `next_position` bigint(20) unsigned NOT NULL,  `next_file` varchar(255) NOT NULL,  PRIMARY KEY (`epoch`,`orig_server_id`,`orig_epoch`) ) ENGINE=InnoDB DEFAULT CHARSET=latin1;
```

Note

If you are upgrading from an old release (prior to NDB 7.5.2), perform the MySQL upgrade procedure and ensure that the system tables are upgraded. (As of MySQL 8.0.16, start the server with the `--upgrade=FORCE` option. Prior to MySQL 8.0.16, invoke `mysql_upgrade` with the `--force` and `--upgrade-system-tables` options after starting the server.) The system table upgrade causes an `ALTER TABLE ... ENGINE=INNODB` statement to be executed for this table. Use of the MyISAM storage engine for this table continues to be supported for backward compatibility.

`ndb_binlog_index` may require additional disk space after being converted to InnoDB. If this becomes an issue, you may be able to conserve space by using an InnoDB tablespace for this table, changing its `ROW_FORMAT` to `COMPRESSED`, or both. For more information, see Section 13.1.21, “CREATE TABLESPACE Statement”, and Section 13.1.20, “CREATE TABLE Statement”, as well as Section 15.6.3, “Tablespaces”.

The size of this table is dependent on the number of epochs per binary log file and the number of binary log files. The number of epochs per binary log file normally depends on the amount of binary log generated per epoch and the size of the binary log file, with smaller epochs resulting in more epochs per file. You should be aware that empty epochs produce inserts to the `ndb_binlog_index` table, even when the `--ndb-log-empty-epochs` option is `OFF`, meaning that the number of entries per file depends on the length of time that the file is in use; that is,

```
[number of epochs per file] = [time spent per file] / TimeBetweenEpochs
```
A busy NDB Cluster writes to the binary log regularly and presumably rotates binary log files more quickly than a quiet one. This means that a "quiet" NDB Cluster with `--ndb-log-empty-epochs=ON` can actually have a much higher number of `ndb_binlog_index` rows per file than one with a great deal of activity.

When `mysqld` is started with the `--ndb-log-orig` option, the `orig_server_id` and `orig_epoch` columns store, respectively, the ID of the server on which the event originated and the epoch in which the event took place on the originating server, which is useful in NDB Cluster replication setups employing multiple masters. The `SELECT` statement used to find the closest binary log position to the highest applied epoch on the slave in a multi-master setup (see Section 22.6.10, “NDB Cluster Replication: Multi-Master and Circular Replication”) employs these two columns, which are not indexed. This can lead to performance issues when trying to fail over, since the query must perform a table scan, especially when the master has been running with `--ndb-log-empty-epochs=ON`. You can improve multi-master failover times by adding an index to these columns, as shown here:

```
ALTER TABLE mysql.ndb_binlog_index
ADD INDEX orig_lookup USING BTREE (orig_server_id, orig_epoch);
```

Adding this index provides no benefit when replicating from a single master to a single slave, since the query used to get the binary log position in such cases makes no use of `orig_server_id` or `orig_epoch`.

See Section 22.6.8, “Implementing Failover with NDB Cluster Replication”, for more information about using the `next_position` and `next_file` columns.

The following figure shows the relationship of the NDB Cluster replication master server, its binary log injector thread, and the `mysql.ndb_binlog_index` table.

**Figure 22.35 The Replication Master Cluster**

MySQL Replication Between Clusters, Injecting into Binlog

An additional table, named `ndb_apply_status`, is used to keep a record of the operations that have been replicated from the master to the slave. Unlike the case with `ndb_binlog_index`, the data in this table is not specific to any one SQL node in the (slave) cluster, and so `ndb_apply_status` can use the `NDBCLUSTER` storage engine, as shown here:

```sql
CREATE TABLE `ndb_apply_status` (
  `server_id` INT(10) UNSIGNED NOT NULL,
  `...`)
```
Preparing the NDB Cluster for Replication

The `ndb_apply_status` table is populated only on slaves, which means that, on the master, this table never contains any rows; thus, there is no need to allow for `DataMemory` or `IndexMemory` to be allotted to `ndb_apply_status` there.

Because this table is populated from data originating on the master, it should be allowed to replicate; any replication filtering or binary log filtering rules that inadvertently prevent the slave from updating `ndb_apply_status` or the master from writing into the binary log may prevent replication between clusters from operating properly. For more information about potential problems arising from such filtering rules, see Replication and binary log filtering rules with replication between NDB Clusters.

The `ndb_binlog_index` and `ndb_apply_status` tables are created in the `mysql` database because they should not be explicitly replicated by the user. User intervention is normally not required to create or maintain either of these tables, since both `ndb_binlog_index` and the `ndb_apply_status` are maintained by the NDB binary log (binlog) injector thread. This keeps the master `mysqld` process updated to changes performed by the NDB storage engine. The NDB binlog injector thread receives events directly from the NDB storage engine. The NDB injector is responsible for capturing all the data events within the cluster, and ensures that all events which change, insert, or delete data are recorded in the `ndb_binlog_index` table. The slave I/O thread transfers the events from the master's binary log to the slave's relay log.

However, it is advisable to check for the existence and integrity of these tables as an initial step in preparing an NDB Cluster for replication. It is possible to view event data recorded in the binary log by querying the `mysql.ndb_binlog_index` table directly on the master. This can be also be accomplished using the `SHOW BINLOG EVENTS` statement on either the replication master or slave MySQL servers. (See Section 13.7.7.2, “SHOW BINLOG EVENTS Statement”.)

You can also obtain useful information from the output of `SHOW ENGINE NDB STATUS`.

Note

When performing schema changes on NDB tables, applications should wait until the `ALTER TABLE` statement has returned in the MySQL client connection that issued the statement before attempting to use the updated definition of the table.

If the `ndb_apply_status` table does not exist on the slave, `ndb_restore` re-creates it.

Conflict resolution for NDB Cluster Replication requires the presence of an additional `mysql.ndb_replication` table. Currently, this table must be created manually. For information about how to do this, see Section 22.6.11, “NDB Cluster Replication Conflict Resolution”.

22.6.5 Preparing the NDB Cluster for Replication

Preparing the NDB Cluster for replication consists of the following steps:

1. Check all MySQL servers for version compatibility (see Section 22.6.2, “General Requirements for NDB Cluster Replication”).

2. Create a slave account on the master Cluster with the appropriate privileges, using the following two SQL statements:

   ```sql
   mysql> CREATE USER 'slave_user'@'slave_host'
   -> IDENTIFIED BY 'slave_password';
   mysql> GRANT REPLICATION SLAVE ON *.*
   -> TO 'slave_user'@'slave_host';
   ```
Preparing the NDB Cluster for Replication

In the previous statement, \textit{slave\_user} is the slave account user name, \textit{slave\_host} is the host name or IP address of the replication slave, and \textit{slave\_password} is the password to assign to this account.

For example, to create a slave user account with the name \textit{myslave}, logging in from the host named \textit{rep-slave}, and using the password \textit{53cr37}, use the following CREATE USER and GRANT statements:

\begin{verbatim}
mysql> CREATE USER 'myslave'@'rep-slave'
    -> IDENTIFIED BY '53cr37';
mysql> GRANT REPLICATION SLAVE ON *.*
    -> TO '''myslave'@'rep-slave'';
\end{verbatim}

For security reasons, it is preferable to use a unique user account—not employed for any other purpose—for the replication slave account.

3. Configure the slave to use the master. Using the MySQL Monitor, this can be accomplished with the \texttt{CHANGE MASTER TO} statement:

\begin{verbatim}
mysql> CHANGE MASTER TO
    -> MASTER_HOST='master_host',
    -> MASTER_PORT=master_port,
    -> MASTER_USER='slave_user',
    -> MASTER_PASSWORD='slave_password';
\end{verbatim}

In the previous statement, \textit{master\_host} is the host name or IP address of the replication master, \textit{master\_port} is the port for the slave to use for connecting to the master, \textit{slave\_user} is the user name set up for the slave on the master, and \textit{slave\_password} is the password set for that user account in the previous step.

For example, to tell the slave to replicate from the MySQL server whose host name is \textit{rep-master}, using the replication slave account created in the previous step, use the following statement:

\begin{verbatim}
mysql> CHANGE MASTER TO
    -> MASTER_HOST='rep-master',
    -> MASTER_PORT=3306,
    -> MASTER_USER='myslave',
    -> MASTER_PASSWORD='53cr37';
\end{verbatim}

For a complete list of options that can be used with this statement, see Section 13.4.2.1, “CHANGE MASTER TO Statement”.

To provide replication backup capability, you also need to add an \texttt{--ndb-connectstring} option to the slave’s \texttt{my.cnf} file prior to starting the replication process. See Section 22.6.9, “NDB Cluster Backups With NDB Cluster Replication”, for details.

For additional options that can be set in \texttt{my.cnf} for replication slaves, see Section 17.1.6, “Replication and Binary Logging Options and Variables”.

4. If the master cluster is already in use, you can create a backup of the master and load this onto the slave to cut down on the amount of time required for the slave to synchronize itself with the master.
Starting NDB Cluster Replication (Single Replication Channel)

If the slave is also running NDB Cluster, this can be accomplished using the backup and restore procedure described in Section 22.6.9, “NDB Cluster Backups With NDB Cluster Replication”.

```
ndb-connectstring=management_host[:port]
```

In the event that you are not using NDB Cluster on the replication slave, you can create a backup with this command on the replication master:

```
shell> mysqldump --master-data=1
```

Then import the resulting data dump onto the slave by copying the dump file over to the slave. After this, you can use the `mysql` client to import the data from the dumpfile into the slave database as shown here, where `dump_file` is the name of the file that was generated using `mysqldump` on the master, and `db_name` is the name of the database to be replicated:

```
shell> mysql -u root -p db_name < dump_file
```

For a complete list of options to use with `mysqldump`, see Section 4.5.4, “`mysqldump` — A Database Backup Program”.

**Note**

If you copy the data to the slave in this fashion, you should make sure that the slave is started with the `--skip-slave-start` option on the command line, or else include `skip-slave-start` in the slave’s `my.cnf` file to keep it from trying to connect to the master to begin replicating before all the data has been loaded. Once the data loading has completed, follow the additional steps outlined in the next two sections.

5. Ensure that each MySQL server acting as a replication master is configured with a unique server ID, and with binary logging enabled, using the row format. (See Section 17.2.1, “Replication Formats”.) These options can be set either in the master server’s `my.cnf` file, or on the command line when starting the master `mysqld` process. See Section 22.6.6, “Starting NDB Cluster Replication (Single Replication Channel)”, for information regarding the latter option.

22.6.6 Starting NDB Cluster Replication (Single Replication Channel)

This section outlines the procedure for starting NDB Cluster replication using a single replication channel.

1. Start the MySQL replication master server by issuing this command:

```
shell> mysqld --ndbcluster --server-id=id \
    --log-bin --ndb-log-bin &
```

In the previous statement, `id` is this server’s unique ID (see Section 22.6.2, “General Requirements for NDB Cluster Replication”). This starts the server’s `mysqld` process with binary logging enabled using the proper logging format. It is also necessary to enable logging of updates to NDB tables explicitly, using the `--ndb-log-bin` option; this is a change from previous versions of NDB Cluster, in which this option was enabled by default.

**Note**

You can also start the master with `--binlog-format=MIXED`, in which case row-based replication is used automatically when replicating between clusters. `STATEMENT` based binary logging is not supported for NDB Cluster Replication (see Section 22.6.2, “General Requirements for NDB Cluster Replication”).

2. Start the MySQL replication slave server as shown here:

```
shell> mysqld --ndbcluster --server-id=id &
```
In the command just shown, \( id \) is the slave server's unique ID. It is not necessary to enable logging on the replication slave.

**Note**

You should use the `--skip-slave-start` option with this command or else you should include `skip-slave-start` in the slave server's `my.cnf` file, unless you want replication to begin immediately. With the use of this option, the start of replication is delayed until the appropriate `START SLAVE` statement has been issued, as explained in Step 4 below.

3. It is necessary to synchronize the slave server with the master server's replication binary log. If binary logging has not previously been running on the master, run the following statement on the slave:

```
mysql> CHANGE MASTER TO
    -> MASTER_LOG_FILE='',
    -> MASTER_LOG_POS=4;
```

This instructs the slave to begin reading the master's binary log from the log's starting point. Otherwise—that is, if you are loading data from the master using a backup—see Section 22.6.8, “Implementing Failover with NDB Cluster Replication”, for information on how to obtain the correct values to use for `MASTER_LOG_FILE` and `MASTER_LOG_POS` in such cases.

4. Finally, you must instruct the slave to begin applying replication by issuing this command from the `mysql` client on the replication slave:

```
mysql> START SLAVE;
```

This also initiates the transmission of replication data from the master to the slave.

It is also possible to use two replication channels, in a manner similar to the procedure described in the next section; the differences between this and using a single replication channel are covered in Section 22.6.7, “Using Two Replication Channels for NDB Cluster Replication”.

It is also possible to improve cluster replication performance by enabling *batched updates*. This can be accomplished by setting the `slave_allow_batching` system variable on the slave `mysqld` processes. Normally, updates are applied as soon as they are received. However, the use of batching causes updates to be applied in 32 KB batches, which can result in higher throughput and less CPU usage, particularly where individual updates are relatively small.

**Note**

Slave batching works on a per-epoch basis; updates belonging to more than one transaction can be sent as part of the same batch.

All outstanding updates are applied when the end of an epoch is reached, even if the updates total less than 32 KB.

Batching can be turned on and off at runtime. To activate it at runtime, you can use either of these two statements:

```
SET GLOBAL slave_allow_batching = 1;
SET GLOBAL slave_allow_batching = ON;
```

If a particular batch causes problems (such as a statement whose effects do not appear to be replicated correctly), slave batching can be deactivated using either of the following statements:

```
SET GLOBAL slave_allow_batching = 0;
SET GLOBAL slave_allow_batching = OFF;
```
You can check whether slave batching is currently being used by means of an appropriate `SHOW VARIABLES` statement, like this one:

```sql
mysql> SHOW VARIABLES LIKE 'slave%';
+---------------------------+-------+
| Variable_name             | Value |
+---------------------------+-------+
| slave_allow_batching      | ON    |
| slave_compressed_protocol | OFF   |
| slave_load_tmpdir         | /tmp  |
| slave_net_timeout         | 3600  |
| slave_skip_errors         | OFF   |
| slave_transaction_retries | 10    |
+---------------------------+-------+
6 rows in set (0.00 sec)
```

22.6.7 Using Two Replication Channels for NDB Cluster Replication

In a more complete example scenario, we envision two replication channels to provide redundancy and thereby guard against possible failure of a single replication channel. This requires a total of four replication servers, two masters for the master cluster and two slave servers for the slave cluster. For purposes of the discussion that follows, we assume that unique identifiers are assigned as shown here:

<table>
<thead>
<tr>
<th>Server ID</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Master - primary replication channel (M)</td>
</tr>
<tr>
<td>2</td>
<td>Master - secondary replication channel (M')</td>
</tr>
<tr>
<td>3</td>
<td>Slave - primary replication channel (S)</td>
</tr>
<tr>
<td>4</td>
<td>Slave - secondary replication channel (S')</td>
</tr>
</tbody>
</table>

Table 22.345 NDB Cluster replication servers described in the text

Setting up replication with two channels is not radically different from setting up a single replication channel. First, the `mysqld` processes for the primary and secondary replication masters must be started, followed by those for the primary and secondary slaves. Then the replication processes may be initiated by issuing the `START SLAVE` statement on each of the slaves. The commands and the order in which they need to be issued are shown here:

1. Start the primary replication master:

   ```bash
   shell> mysqld --ndbcluster --server-id=1 --log-bin &
   ```

2. Start the secondary replication master:

   ```bash
   shell> mysqld --ndbcluster --server-id=2 --log-bin &
   ```

3. Start the primary replication slave server:

   ```bash
   shell> mysqld --ndbcluster --server-id=3 --skip-slave-start &
   ```

4. Start the secondary replication slave:

   ```bash
   shell> mysqld --ndbcluster --server-id=4 --skip-slave-start &
   ```

5. Finally, initiate replication on the primary channel by executing the `START SLAVE` statement on the primary slave as shown here:

   ```sql
   mysql> START SLAVE;
   ```
Warning

Only the primary channel is to be started at this point. The secondary replication channel is to be started only in the event that the primary replication channel fails, as described in Section 22.6.8, “Implementing Failover with NDB Cluster Replication”. Running multiple replication channels simultaneously can result in unwanted duplicate records being created on the replication slaves.

As mentioned previously, it is not necessary to enable binary logging on replication slaves.

22.6.8 Implementing Failover with NDB Cluster Replication

In the event that the primary Cluster replication process fails, it is possible to switch over to the secondary replication channel. The following procedure describes the steps required to accomplish this.

1. Obtain the time of the most recent global checkpoint (GCP). That is, you need to determine the most recent epoch from the ndb_apply_status table on the slave cluster, which can be found using the following query:

```sql
mysql>
SELECT @latest:=MAX(epoch)
FROM mysql.ndb_apply_status;
```

In a circular replication topology, with a master and a slave running on each host, when you are using ndb_log_apply_status=1, NDB Cluster epochs are written in the slave binary logs. This means that the ndb_apply_status table contains information for the slave on this host as well as for any other host which acts as a slave of the master running on this host.

In this case, you need to determine the latest epoch on this slave to the exclusion of any epochs from any other slaves in this slave's binary log that were not listed in the IGNORE_SERVER_IDS options of the CHANGE MASTER TO statement used to set up this slave. The reason for excluding such epochs is that rows in the mysql.ndb_apply_status table whose server IDs have a match in the IGNORE_SERVER_IDS list used with the CHANGE MASTER TO statement used to prepare this slave's master are also considered to be from local servers, in addition to those having the slave's own server ID. You can retrieve this list as Replicate_Ignore_Server_Ids from the output of SHOW SLAVE STATUS. We assume that you have obtained this list and are substituting it for ignore_server_ids in the query shown here, which like the previous version of the query, selects the greatest epoch into a variable named @latest:

```sql
mysql>
SELECT @latest:=MAX(epoch)
FROM mysql.ndb_apply_status
WHERE server_id NOT IN (ignore_server_ids);
```

In some cases, it may be simpler or more efficient (or both) to use a list of the server IDs to be included and server_id IN server_id_list in the WHERE condition of the preceding query.

2. Using the information obtained from the query shown in Step 1, obtain the corresponding records from the ndb_binlog_index table on the master cluster.

You can use the following query to obtain the needed records from the master's ndb_binlog_index table:

```sql
mysql>
SELECT @file:=SUBSTRING_INDEX(next_file, '/', -1),
@pos:=next_position
FROM mysql.ndb_binlog_index
WHERE epoch >= @latest
ORDER BY epoch ASC LIMIT 1;
```

These are the records saved on the master since the failure of the primary replication channel. We have employed a user variable @latest here to represent the value obtained in Step 1. Of course,
it is not possible for one \texttt{mysqld} instance to access user variables set on another server instance directly. These values must be “plugged in” to the second query manually or in application code.

\begin{itemize}
  \item \textbf{Important}\hspace{5em}
  \begin{itemize}
    \item You must ensure that the slave \texttt{mysqld} is started with \texttt{--slave-skip-errors=ddl_exist_errors} before executing \texttt{START SLAVE}. Otherwise, replication may stop with duplicate DDL errors.
  \end{itemize}
\end{itemize}

\section*{3. Synchronizing the Secondary Channel}

Now it is possible to synchronize the secondary channel by running the following query on the secondary slave server:

\begin{verbatim}
mysql$> CHANGE MASTER TO
  -> MASTER_LOG_FILE='@file',
  -> MASTER_LOG_POS=@pos;
\end{verbatim}

Again we have employed user variables (in this case \texttt{@file} and \texttt{@pos}) to represent the values obtained in Step 2 and applied in Step 3; in practice these values must be inserted manually or using application code that can access both of the servers involved.

\begin{itemize}
  \item \textbf{Note}\hspace{5em}
    \begin{itemize}
      \item @file is a string value such as '/var/log/mysql/replication-master-bin.00001', and so must be quoted when used in SQL or application code. However, the value represented by \texttt{@pos} must \textit{not} be quoted. Although MySQL normally attempts to convert strings to numbers, this case is an exception.
    \end{itemize}
\end{itemize}

\section*{4. Initiating Replication on the Secondary Channel}

You can now initiate replication on the secondary channel by issuing the appropriate command on the secondary slave \texttt{mysqld}:

\begin{verbatim}
mysql$> START SLAVE;
\end{verbatim}

Once the secondary replication channel is active, you can investigate the failure of the primary and effect repairs. The precise actions required to do this will depend upon the reasons for which the primary channel failed.

\begin{itemize}
  \item \textbf{Warning}\hspace{5em}
    \begin{itemize}
      \item The secondary replication channel is to be started only if and when the primary replication channel has failed. Running multiple replication channels simultaneously can result in unwanted duplicate records being created on the replication slaves.
    \end{itemize}
\end{itemize}

If the failure is limited to a single server, it should (in theory) be possible to replicate from $M$ to $S'$, or from $M'$ to $S$; however, this has not yet been tested.

\section*{22.6.9 NDB Cluster Backups With NDB Cluster Replication}

This section discusses making backups and restoring from them using NDB Cluster replication. We assume that the replication servers have already been configured as covered previously (see Section 22.6.5, “Preparing the NDB Cluster for Replication”, and the sections immediately following). This having been done, the procedure for making a backup and then restoring from it is as follows:

\begin{itemize}
  \item \textbf{Method A}. This method requires that the cluster backup process was previously enabled on the master server, prior to starting the replication process. This can be done by including the following line in a \texttt{[mysql_cluster]} section in the \texttt{my.cnf} file, where \texttt{management_host} is the IP address or host name of the NDB management server for the master cluster, and \texttt{port} is the management server's port number:
\end{itemize}
NDB Cluster Backups With NDB Cluster Replication

```
ndb-connectstring=management_host[:port]
```

**Note**

The port number needs to be specified only if the default port (1186) is not being used. See Section 22.2.4, “Initial Configuration of NDB Cluster”, for more information about ports and port allocation in NDB Cluster.

In this case, the backup can be started by executing this statement on the replication master:

```
M> ndb_mgm -e "START BACKUP"
```

- **Method B.** If the my.cnf file does not specify where to find the management host, you can start the backup process by passing this information to the NDB management client as part of the `START BACKUP` command. This can be done as shown here, where `management_host` and `port` are the host name and port number of the management server:

```
M> ndb_mgm management_host:port -e "START BACKUP"
```

In our scenario as outlined earlier (see Section 22.6.5, “Preparing the NDB Cluster for Replication”), this would be executed as follows:

```
M> ndb_mgm rep-master:1186 -e "START BACKUP"
```

2. Copy the cluster backup files to the slave that is being brought on line. Each system running an `ndbd` process for the master cluster will have cluster backup files located on it, and *all* of these files must be copied to the slave to ensure a successful restore. The backup files can be copied into any directory on the computer where the slave management host resides, so long as the MySQL and NDB binaries have read permissions in that directory. In this case, we will assume that these files have been copied into the directory `/var/BACKUPS/BACKUP-1`.

   It is not necessary that the slave cluster have the same number of `ndbd` processes (data nodes) as the master; however, it is highly recommended this number be the same. It is necessary that the slave be started with the `--skip-slave-start` option, to prevent premature startup of the replication process.

3. Create any databases on the slave cluster that are present on the master cluster that are to be replicated to the slave.

   **Important**

   A `CREATE DATABASE` (or `CREATE SCHEMA`) statement corresponding to each database to be replicated must be executed on each SQL node in the slave cluster.

4. Reset the slave cluster using this statement in the MySQL Monitor:

```
mvsql> RESET SLAVE;
```

5. You can now start the cluster restoration process on the replication slave using the `ndb_restore` command for each backup file in turn. For the first of these, it is necessary to include the `-m` option to restore the cluster metadata:

```
shell> ndb_restore -c slave_host:port -n node-id -b backup-id -r dir
```

   `dir` is the path to the directory where the backup files have been placed on the replication slave. For the `ndb_restore` commands corresponding to the remaining backup files, the `-m` option should not be used.

   For restoring from a master cluster with four data nodes (as shown in the figure in Section 22.6, “NDB Cluster Replication”) where the backup files have been copied to the directory `/var/`
BACKUPS/BACKUP-1, the proper sequence of commands to be executed on the slave might look like this:

```
sHELL> ndb_restore -c rep-slave:1186 -n 2 -b 1 -m -r ./var/BACKUPS/BACKUP-1
```

```
sHELL> ndb_restore -c rep-slave:1186 -n 3 -b 1 -r ./var/BACKUPS/BACKUP-1
```

```
sHELL> ndb_restore -c rep-slave:1186 -n 4 -b 1 -r ./var/BACKUPS/BACKUP-1
```

```
sHELL> ndb_restore -c rep-slave:1186 -n 5 -b 1 -e -r ./var/BACKUPS/BACKUP-1
```

**Important**

The `--restore-epoch` option in the final invocation of `ndb_restore` in this example is required in order that the epoch is written to the slave `mysql.ndb_apply_status`. Without this information, the slave will not be able to synchronize properly with the master. (See Section 22.4.23, "ndb_restore — Restore an NDB Cluster Backup".)

6. Now you need to obtain the most recent epoch from the `ndb_apply_status` table on the slave (as discussed in Section 22.6.8, "Implementing Failover with NDB Cluster Replication"):

```
mysql> SELECT @latest:=MAX(epoch)
FROM mysql.ndb_apply_status;
```

7. Using `@latest` as the epoch value obtained in the previous step, you can obtain the correct starting position `@pos` in the correct binary log file `@file` from the master's `mysql.ndb_binlog_index` table using the query shown here:

```
mysql> SELECT @file:=SUBSTRING_INDEX(File, '/', -1),
       -> @pos:=Position,
       -> FROM mysql.ndb_binlog_index
       -> WHERE epoch >= @latest
       -> ORDER BY epoch ASC LIMIT 1;
```

In the event that there is currently no replication traffic, you can get this information by running `SHOW MASTER STATUS` on the master and using the value in the `Position` column for the file whose name has the suffix with the greatest value for all files shown in the `File` column. However, in this case, you must determine this and supply it in the next step manually or by parsing the output with a script.

8. Using the values obtained in the previous step, you can now issue the appropriate `CHANGE MASTER TO` statement in the slave’s `mysql` client:

```
mysql> CHANGE MASTER TO
       -> MASTER_LOG_FILE='@file',
       -> MASTER_LOG_POS=@pos;
```

9. Now that the slave “knows” from what point in which binary log file to start reading data from the master, you can cause the slave to begin replicating with this standard MySQL statement:

```
mysql> START SLAVE;
```

To perform a backup and restore on a second replication channel, it is necessary only to repeat these steps, substituting the host names and IDs of the secondary master and slave for those of the primary master and slave replication servers where appropriate, and running the preceding statements on them.

For additional information on performing Cluster backups and restoring Cluster from backups, see Section 22.5.3, “Online Backup of NDB Cluster”.

**22.6.9.1 NDB Cluster Replication: Automating Synchronization of the Replication Slave to the Master Binary Log**
It is possible to automate much of the process described in the previous section (see Section 22.6.9, “NDB Cluster Backups With NDB Cluster Replication”). The following Perl script `reset-slave.pl` serves as an example of how you can do this.

```perl
#!/user/bin/perl -w

# file: reset-slave.pl

### 22.6.9.2 Point-In-Time Recovery Using NDB Cluster Replication ###

**Point-in-time recovery**—that is, recovery of data changes made since a given point in time—is performed after restoring a full backup that returns the server to its state when the backup was made. Performing point-in-time recovery of NDB Cluster tables with NDB Cluster and NDB Cluster Replication can be accomplished using a native NDB data backup (taken by issuing `CREATE BACKUP` in the `ndb_mgm` client) and restoring the `ndb_binlog_index` table (from a dump made using `mysqldump`).

To perform point-in-time recovery of NDB Cluster, it is necessary to follow the steps shown here:

1. Back up all NDB databases in the cluster, using the `START BACKUP` command in the `ndb_mgm` client (see Section 22.5.3, “Online Backup of NDB Cluster”).

2. At some later point, prior to restoring the cluster, make a backup of the `mysql.ndb_binlog_index` table. It is probably simplest to use `mysqldump` for this task. Also back up the binary log files at this time.

   This backup should be updated regularly—perhaps even hourly—depending on your needs.

3. *(Catastrophic failure or error occurs.)*

4. Locate the last known good backup.

5. Clear the data node file systems (using `ndbd --initial` or `ndbmtd --initial`).
Note

NDB Cluster Disk Data tablespace and log files are not removed by --initial. You must delete these manually.

6. Use DROP TABLE or TRUNCATE TABLE with the mysql.ndb_binlog_index table.

7. Execute ndb_restore, restoring all data. You must include the --restore-epoch option when you run ndb_restore, so that the ndb_apply_status table is populated correctly. (See Section 22.4.23, "ndb_restore — Restore an NDB Cluster Backup", for more information.)

8. Restore the ndb_binlog_index table from the output of mysqldump and restore the binary log files from backup, if necessary.

9. Find the epoch applied most recently—that is, the maximum epoch column value in the ndb_apply_status table—as the user variable @LATEST_EPOCH (emphasized):

   ```sql
   SELECT @LATEST_EPOCH:=MAX(epoch)
   FROM mysql.ndb_apply_status;
   ```

10. Find the latest binary log file (@FIRST_FILE) and position (Position column value) within this file that correspond to @LATEST_EPOCH in the ndb_binlog_index table:

    ```sql
    SELECT Position, @FIRST_FILE:=File
    FROM mysql.ndb_binlog_index
    WHERE epoch > @LATEST_EPOCH ORDER BY epoch ASC LIMIT 1;
    ```

11. Using mysqlbinlog, replay the binary log events from the given file and position up to the point of the failure. (See Section 4.6.8, "mysqlbinlog — Utility for Processing Binary Log Files").

    See also Section 7.5, "Point-in-Time (Incremental) Recovery", for more information about the binary log, replication, and incremental recovery.

### 22.6.10 NDB Cluster Replication: Multi-Master and Circular Replication

It is possible to use NDB Cluster in multi-master replication, including circular replication between a number of NDB Clusters.

**Circular replication example.** In the next few paragraphs we consider the example of a replication setup involving three NDB Clusters numbered 1, 2, and 3, in which Cluster 1 acts as the replication master for Cluster 2, Cluster 2 acts as the master for Cluster 3, and Cluster 3 acts as the master for Cluster 1. Each cluster has two SQL nodes, with SQL nodes A and B belonging to Cluster 1, SQL nodes C and D belonging to Cluster 2, and SQL nodes E and F belonging to Cluster 3.

Circular replication using these clusters is supported as long as the following conditions are met:

- The SQL nodes on all masters and slaves are the same.
- All SQL nodes acting as replication masters and slaves are started with the log_slave_updates system variable enabled.

This type of circular replication setup is shown in the following diagram:
In this scenario, SQL node A in Cluster 1 replicates to SQL node C in Cluster 2; SQL node C replicates to SQL node E in Cluster 3; SQL node E replicates to SQL node A. In other words, the replication line (indicated by the curved arrows in the diagram) directly connects all SQL nodes used as replication masters and slaves.

It is also possible to set up circular replication in such a way that not all master SQL nodes are also slaves, as shown here:
In this case, different SQL nodes in each cluster are used as replication masters and slaves. However, you must not start any of the SQL nodes with the `log_slave_updates` system variable enabled. This type of circular replication scheme for NDB Cluster, in which the line of replication (again indicated by the curved arrows in the diagram) is discontinuous, should be possible, but it should be noted that it has not yet been thoroughly tested and must therefore still be considered experimental.

**Using NDB-native backup and restore to initialize a slave NDB Cluster.** When setting up circular replication, it is possible to initialize the slave cluster by using the management client `BACKUP` command on one NDB Cluster to create a backup and then applying this backup on another NDB Cluster using `ndb_restore`. However, this does not automatically create binary logs on the second NDB Cluster’s SQL node acting as the replication slave. In order to cause the binary logs to be created, you must issue a `SHOW TABLES` statement on that SQL node; this should be done prior to running `START SLAVE`.

This is a known issue which we intend to address in a future release.

**Multi-master failover example.** In this section, we discuss failover in a multi-master NDB Cluster replication setup with three NDB Clusters having server IDs 1, 2, and 3. In this scenario, Cluster 1 replicates to Clusters 2 and 3; Cluster 2 also replicates to Cluster 3. This relationship is shown here:
In other words, data replicates from Cluster 1 to Cluster 3 through 2 different routes: directly, and by way of Cluster 2.

Not all MySQL servers taking part in multi-master replication must act as both master and slave, and a given NDB Cluster might use different SQL nodes for different replication channels. Such a case is shown here:

MySQL servers acting as replication slaves must be run with the `log_slave_updates` system variable enabled. Which `mysqld` processes require this option is also shown in the preceding diagram.

**Note**

Using the `log_slave_updates` system variable has no effect on servers not being run as replication slaves.

The need for failover arises when one of the replicating clusters goes down. In this example, we consider the case where Cluster 1 is lost to service, and so Cluster 3 loses 2 sources of updates from Cluster 1. Because replication between NDB Clusters is asynchronous, there is no guarantee that Cluster 3’s updates originating directly from Cluster 1 are more recent than those received through Cluster 2. You can handle this by ensuring that Cluster 3 catches up to Cluster 2 with regard to updates from Cluster 1. In terms of MySQL servers, this means that you need to replicate any outstanding updates from MySQL server C to server F.
On server C, perform the following queries:

```sql
mysqlC> SELECT @latest:=MAX(epoch)
-> FROM mysql.ndb_apply_status
-> WHERE server_id=1;

mysqlC> SELECT
-> @file:=SUBSTRING_INDEX(File, '/', -1),
-> @pos:=Position
-> FROM mysql.ndb_binlog_index
-> WHERE orig_epoch >= @latest
-> AND orig_server_id = 1
-> ORDER BY epoch ASC LIMIT 1;
```

Note

You can improve the performance of this query, and thus likely speed up failover times significantly, by adding the appropriate index to the `ndb_binlog_index` table. See Section 22.6.4, “NDB Cluster Replication Schema and Tables”, for more information.

Copy over the values for `@file` and `@pos` manually from server C to server F (or have your application perform the equivalent). Then, on server F, execute the following `CHANGE MASTER TO` statement:

```sql
mysqlF> CHANGE MASTER TO
-> MASTER_HOST = 'serverC'
-> MASTER_LOG_FILE='@file',
-> MASTER_LOG_POS=@pos;
```

Once this has been done, you can issue a `START SLAVE` statement on MySQL server F, and any missing updates originating from server B will be replicated to server F.

The `CHANGE MASTER TO` statement also supports an `IGNORE_SERVER_IDS` option which takes a comma-separated list of server IDs and causes events originating from the corresponding servers to be ignored. For more information, see Section 13.4.2.1, “CHANGE MASTER TO Statement”, and Section 13.7.7.34, “SHOW SLAVE STATUS Statement”. For information about how this option interacts with the `ndb_log_apply_status` variable, see Section 22.6.8, “Implementing Failover with NDB Cluster Replication”.

### 22.6.11 NDB Cluster Replication Conflict Resolution

When using a replication setup involving multiple masters (including circular replication), it is possible that different masters may try to update the same row on the slave with different data. Conflict resolution in NDB Cluster Replication provides a means of resolving such conflicts by permitting a user-defined resolution column to be used to determine whether or not an update on a given master should be applied on the slave.

Some types of conflict resolution supported by NDB Cluster (`NDB$OLD()`, `NDB$MAX()`, `NDB$MAX_DELETE_WIN()`) implement this user-defined column as a "timestamp" column (although its type cannot be `TIMESTAMP`, as explained later in this section). These types of conflict resolution are always applied a row-by-row basis rather than a transactional basis. The epoch-based conflict resolution functions `NDB$EPOCH()` and `NDB$EPOCH_TRANS()` compare the order in which epochs are replicated (and thus these functions are transactional). Different methods can be used to compare resolution column values on the slave when conflicts occur, as explained later in this section; the method used can be set on a per-table basis.

You should also keep in mind that it is the application’s responsibility to ensure that the resolution column is correctly populated with relevant values, so that the resolution function can make the appropriate choice when determining whether to apply an update.

**Requirements.** Preparations for conflict resolution must be made on both the master and the slave. These tasks are described in the following list:
NDB Cluster Replication Conflict Resolution

- On the master writing the binary logs, you must determine which columns are sent (all columns or only those that have been updated). This is done for the MySQL Server as a whole by applying the `mysqld` startup option `--ndb-log-updated-only` (described later in this section) or on a per-table basis by entries in the `mysql.ndb_replication` table (see The ndb_replication system table).

  **Note**
  
  If you are replicating tables with very large columns (such as `TEXT` or `BLOB` columns), `--ndb-log-updated-only` can also be useful for reducing the size of the master and slave binary logs and avoiding possible replication failures due to exceeding `max_allowed_packet`.

  See Section 17.5.1.20, “Replication and max_allowed_packet”, for more information about this issue.

- On the slave, you must determine which type of conflict resolution to apply (“latest timestamp wins”, “same timestamp wins”, “primary wins”, “primary wins, complete transaction”, or none). This is done using the `mysql.ndb_replication` system table, on a per-table basis (see The ndb_replication system table).

- NDB Cluster also supports read conflict detection, that is, detecting conflicts between reads of a given row in one cluster and updates or deletes of the same row in another cluster. This requires exclusive read locks obtained by setting `ndb_log_exclusive_reads` equal to 1 on the slave. All rows read by a conflicting read are logged in the exceptions table. For more information, see Read conflict detection and resolution.

When using the functions `NDB$OLD()`, `NDB$MAX()`, and `NDB$MAX_DELETE_WIN()` for timestamp-based conflict resolution, we often refer to the column used for determining updates as a “timestamp” column. However, the data type of this column is never `TIMESTAMP`; instead, its data type should be `INT` (INTEGER) or `BIGINT`. The “timestamp” column should also be `UNSIGNED` and `NOT NULL`.

The `NDB$EPOCH()` and `NDB$EPOCH_TRANS()` functions discussed later in this section work by comparing the relative order of replication epochs applied on a primary and secondary NDB Cluster, and do not make use of timestamps.

**Master column control.** We can see update operations in terms of “before” and “after” images—that is, the states of the table before and after the update is applied. Normally, when updating a table with a primary key, the “before” image is not of great interest; however, when we need to determine on a per-update basis whether or not to use the updated values on a replication slave, we need to make sure that both images are written to the master's binary log. This is done with the `--ndb-log-update-as-write` option for `mysqld`, as described later in this section.

**Important**

Whether logging of complete rows or of updated columns only is done is decided when the MySQL server is started, and cannot be changed online; you must either restart `mysqld`, or start a new `mysqld` instance with different logging options.

### Logging Full or Partial Rows (`--ndb-log-updated-only` Option)

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--ndb-log-updated-only[={OFF</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>ndb_log_updated_only</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
</tbody>
</table>

For purposes of conflict resolution, there are two basic methods of logging rows, as determined by the setting of the `--ndb-log-updated-only` option for mysqld:

- Log complete rows
- Log only column data that has been updated—that is, column data whose value has been set, regardless of whether or not this value was actually changed. This is the default behavior.

It is usually sufficient—and more efficient—to log updated columns only; however, if you need to log full rows, you can do so by setting `--ndb-log-updated-only` to `0` or `OFF`.

---

**--ndb-log-update-as-write Option: Logging Changed Data as Updates**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--ndb-log-update-as-write[{=OFF</td>
</tr>
<tr>

</tr>
<tr>
<td>Default Value</td>
<td>ON</td>
</tr>
</tbody>
</table>

The setting of the MySQL Server's `--ndb-log-update-as-write` option determines whether logging is performed with or without the "before" image. Because conflict resolution is done in the MySQL Server's update handler, it is necessary to control logging on the master such that updates are updates and not writes; that is, such that updates are treated as changes in existing rows rather than the writing of new rows (even though these replace existing rows). This option is turned on by default; in other words, updates are treated as writes. (That is, updates are by default written as `write_row` events in the binary log, rather than as `update_row` events.)

To turn off the option, start the master `mysqld` with `--ndb-log-update-as-write=0` or `--ndb-log-update-as-write=OFF`. You must do this when replicating from NDB tables to tables using a different storage engine; see Replication from NDB to other storage engines, and Replication from NDB to a nontransactional storage engine, for more information.

**Conflict resolution control.** Conflict resolution is usually enabled on the server where conflicts can occur. Like logging method selection, it is enabled by entries in the `mysql.ndb_replication` table.

**The ndb_replication system table.** To enable conflict resolution, it is necessary to create an `ndb_replication` table in the `mysql` system database on the master, the slave, or both, depending on the conflict resolution type and method to be employed. This table is used to control logging and conflict resolution functions on a per-table basis, and has one row per table involved in replication. `ndb_replication` is created and filled with control information on the server where the conflict is to be resolved. In a simple master-slave setup where data can also be changed locally on the slave this will typically be the slave. In a more complex master-master (2-way) replication schema this will usually be all of the masters involved. Each row in `mysql.ndb_replication` corresponds to a table being replicated, and specifies how to log and resolve conflicts (that is, which conflict resolution function, if any, to use) for that table. The definition of the `mysql.ndb_replication` table is shown here:

```sql
CREATE TABLE mysql.ndb_replication (  
```
The columns in this table are described in the next few paragraphs.

**db.** The name of the database containing the table to be replicated. You may employ either or both of the wildcards _ and % as part of the database name. Matching is similar to what is implemented for the LIKE operator.

**table_name.** The name of the table to be replicated. The table name may include either or both of the wildcards _ and %. Matching is similar to what is implemented for the LIKE operator.

**server_id.** The unique server ID of the MySQL instance (SQL node) where the table resides.

**binlog_type.** The type of binary logging to be employed. This is determined as shown in the following table:

<table>
<thead>
<tr>
<th>Value</th>
<th>Internal Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>NBT_DEFAULT</td>
<td>Use server default</td>
</tr>
<tr>
<td>1</td>
<td>NBT_NO_LOGGING</td>
<td>Do not log this table in the binary log</td>
</tr>
<tr>
<td>2</td>
<td>NBT_UPDATED_ONLY</td>
<td>Only updated attributes are logged</td>
</tr>
<tr>
<td>3</td>
<td>NBT_FULL</td>
<td>Log full row, even if not updated (MySQL server default behavior)</td>
</tr>
<tr>
<td>4</td>
<td>NBT_USE_UPDATE</td>
<td>(For generating NBT_UPDATED_ONLY_USE_UPDATE and NBT_FULL_USE_UPDATE values only—not intended for separate use)</td>
</tr>
<tr>
<td>5</td>
<td>[Not used]</td>
<td>---</td>
</tr>
<tr>
<td>6</td>
<td>NBT_UPDATED_ONLY</td>
<td>Use updated attributes, even if values are unchanged (equal to NBT_UPDATED_ONLY</td>
</tr>
<tr>
<td>7</td>
<td>NBT_FULL_USE_UPDATE</td>
<td>Use full row, even if values are unchanged (equal to NBT_FULL</td>
</tr>
</tbody>
</table>

**conflict_fn.** The conflict resolution function to be applied. This function must be specified as one of those shown in the following list:

- NDB$OLD(column_name)
- NDB$MAX(column_name)
- NDB$MAX_DELETE_WIN()
- NDB$EPOCH() and NDB$EPOCH_TRANS()
- NDB$epoch TRANS()
- NDB$EPOCH2()
NDB Cluster Replication Conflict Resolution

• **NDB$EPOCH2_TRANS()**

• **NULL**: Indicates that conflict resolution is not to be used for the corresponding table.

These functions are described in the next few paragraphs.

**NDB$OLD(column_name).** If the value of `column_name` is the same on both the master and the slave, then the update is applied; otherwise, the update is not applied on the slave and an exception is written to the log. This is illustrated by the following pseudocode:

```plaintext
if (master_old_column_value == slave_current_column_value)
    apply_update();
else
    log_exception();
```

This function can be used for “same value wins” conflict resolution. This type of conflict resolution ensures that updates are not applied on the slave from the wrong master.

**Important**
The column value from the master’s “before” image is used by this function.

**NDB$MAX(column_name).** If the “timestamp” column value for a given row coming from the master is higher than that on the slave, it is applied; otherwise it is not applied on the slave. This is illustrated by the following pseudocode:

```plaintext
if (master_new_column_value > slave_current_column_value)
    apply_update();
```

This function can be used for “greatest timestamp wins” conflict resolution. This type of conflict resolution ensures that, in the event of a conflict, the version of the row that was most recently updated is the version that persists.

**Important**
The column value from the master’s “after” image is used by this function.

**NDB$MAX_DELETE_WIN().** This is a variation on **NDB$MAX()**. Due to the fact that no timestamp is available for a delete operation, a delete using **NDB$MAX()** is in fact processed as **NDB$OLD**. However, for some use cases, this is not optimal. For **NDB$MAX_DELETE_WIN()**, if the “timestamp” column value for a given row adding or updating an existing row coming from the master is higher than that on the slave, it is applied. However, delete operations are treated as always having the higher value. This is illustrated in the following pseudocode:

```plaintext
if ( (master_new_column_value > slave_current_column_value)
    ||
    operation.type == "delete")
    apply_update();
```

This function can be used for “greatest timestamp, delete wins” conflict resolution. This type of conflict resolution ensures that, in the event of a conflict, the version of the row that was deleted or (otherwise) most recently updated is the version that persists.

**Note**
As with **NDB$MAX()**, the column value from the master’s “after” image is the value used by this function.

**NDB$EPOCH() and NDB$EPOCH_TRANS().** The **NDB$EPOCH()** function tracks the order in which replicated epochs are applied on a slave NDB Cluster relative to changes originating on the slave. This relative ordering is used to determine whether changes originating on the slave are concurrent with any changes that originate locally, and are therefore potentially in conflict.
Most of what follows in the description of \texttt{NDB\$EPOCH()} also applies to \texttt{NDB\$EPOCH\_TRANS()}. Any exceptions are noted in the text.

\texttt{NDB\$EPOCH()} is asymmetric, operating on one NDB Cluster in a two-cluster circular replication configuration (sometimes referred to as “active-active” replication). We refer here to cluster on which it operates as the primary, and the other as the secondary. The slave on the primary is responsible for detecting and handling conflicts, while the slave on the secondary is not involved in any conflict detection or handling.

When the slave on the primary detects conflicts, it injects events into its own binary log to compensate for these; this ensures that the secondary NDB Cluster eventually realigns itself with the primary and so keeps the primary and secondary from diverging. This compensation and realignment mechanism requires that the primary NDB Cluster always wins any conflicts with the secondary—that is, that the primary's changes are always used rather than those from the secondary in event of a conflict. This “primary always wins” rule has the following implications:

\begin{itemize}
  \item Operations that change data, once committed on the primary, are fully persistent and will not be undone or rolled back by conflict detection and resolution.
  \item Data read from the primary is fully consistent. Any changes committed on the Primary (locally or from the slave) will not be reverted later.
  \item Operations that change data on the secondary may later be reverted if the primary determines that they are in conflict.
  \item Individual rows read on the secondary are self-consistent at all times, each row always reflecting either a state committed by the secondary, or one committed by the primary.
  \item Sets of rows read on the secondary may not necessarily be consistent at a given single point in time. For \texttt{NDB\$EPOCH\_TRANS()}, this is a transient state; for \texttt{NDB\$EPOCH()}, it can be a persistent state.
  \item Assuming a period of sufficient length without any conflicts, all data on the secondary NDB Cluster (eventually) becomes consistent with the primary's data.
\end{itemize}

\texttt{NDB\$EPOCH()} and \texttt{NDB\$EPOCH\_TRANS()} do not require any user schema modifications, or application changes to provide conflict detection. However, careful thought must be given to the schema used, and the access patterns used, to verify that the complete system behaves within specified limits.

Each of the \texttt{NDB\$EPOCH()} and \texttt{NDB\$EPOCH\_TRANS()} functions can take an optional parameter; this is the number of bits to use to represent the lower 32 bits of the epoch, and should be set to no less than

\[
\text{CEIL}( \log_2 \left( \frac{\text{TimeBetweenGlobalCheckpoints}}{\text{TimeBetweenEpochs}} \right), 1)
\]

For the default values of these configuration parameters (2000 and 100 milliseconds, respectively), this gives a value of 5 bits, so the default value (6) should be sufficient, unless other values are used for \texttt{TimeBetweenGlobalCheckpoints}, \texttt{TimeBetweenEpochs}, or both. A value that is too small can result in false positives, while one that is too large could lead to excessive wasted space in the database.

Both \texttt{NDB\$EPOCH()} and \texttt{NDB\$EPOCH\_TRANS()} insert entries for conflicting rows into the relevant exceptions tables, provided that these tables have been defined according to the same exceptions table schema rules as described elsewhere in this section (see \texttt{NDB\$OLD(column_name)}). You need to create any exceptions table before creating the table with which it is to be used.

As with the other conflict detection functions discussed in this section, \texttt{NDB\$EPOCH()} and \texttt{NDB\$EPOCH\_TRANS()} are activated by including relevant entries in the \texttt{mysql.ndb_replication} table (see The \texttt{ndb\_replication system table}). The roles of the primary and secondary NDB Clusters in this scenario are fully determined by \texttt{mysql.ndb_replication} table entries.
Because the conflict detection algorithms employed by \texttt{NDB\$EPOCH()} and \texttt{NDB\$EPOCH\_TRANS()} are asymmetric, you must use different values for the primary slave’s and secondary slave’s server\_id entries.

A conflict between \texttt{DELETE} operations alone is not sufficient to trigger a conflict using \texttt{NDB\$EPOCH()} or \texttt{NDB\$EPOCH\_TRANS()}, and the relative placement within epochs does not matter. (Bug \#18459944)

**Conflict detection status variables.** Several status variables can be used to monitor conflict detection. You can see how many rows have been found in conflict by \texttt{NDB\$EPOCH()} since this slave was last restarted from the current value of the \texttt{Ndb\_conflict\_fn\_epoch} system status variable.

\texttt{Ndb\_conflict\_fn\_epoch\_trans} provides the number of rows that have been found directly in conflict by \texttt{NDB\$EPOCH\_TRANS()}. \texttt{Ndb\_conflict\_fn\_epoch\_2} and \texttt{Ndb\_conflict\_fn\_epoch\_2\_trans} show the number of rows found in conflict by \texttt{NDB\$EPOCH\_2()} and \texttt{NDB\$EPOCH\_2\_TRANS()}, respectively. The number of rows actually realigned, including those affected due to their membership in or dependency on the same transactions as other conflicting rows, is given by \texttt{Ndb\_conflict\_trans\_row\_reject\_count}.

For more information, see \textit{NDB Cluster Status Variables}.

**Limitations on NDB\$EPOCH().** The following limitations currently apply when using \texttt{NDB\$EPOCH()} to perform conflict detection:

- Conflicts are detected using NDB Cluster epoch boundaries, with granularity proportional to \texttt{Time\_Between\_Epochs} (default: 100 milliseconds). The minimum conflict window is the minimum time during which concurrent updates to the same data on both clusters always report a conflict. This is always a nonzero length of time, and is roughly proportional to $2 \times (\text{latency} + \text{queueing} + \text{Time\_Between\_Epochs})$. This implies that—assuming the default for \texttt{Time\_Between\_Epochs} and ignoring any latency between clusters (as well as any queuing delays)—the minimum conflict window size is approximately 200 milliseconds. This minimum window should be considered when looking at expected application “race” patterns.

- Additional storage is required for tables using the \texttt{NDB\$EPOCH()} and \texttt{NDB\$EPOCH\_TRANS()} functions; from 1 to 32 bits extra space per row is required, depending on the value passed to the function.

- Conflicts between delete operations may result in divergence between the primary and secondary. When a row is deleted on both clusters concurrently, the conflict can be detected, but is not recorded, since the row is deleted. This means that further conflicts during the propagation of any subsequent realignment operations will not be detected, which can lead to divergence.

  Deletes should be externally serialized, or routed to one cluster only. Alternatively, a separate row should be updated transactionally with such deletes and any inserts that follow them, so that conflicts can be tracked across row deletes. This may require changes in applications.

- Only two NDB Clusters in a circular “active-active” configuration are currently supported when using \texttt{NDB\$EPOCH()} or \texttt{NDB\$EPOCH\_TRANS()} for conflict detection.

- Tables having \texttt{BLOB} or \texttt{TEXT} columns are not currently supported with \texttt{NDB\$EPOCH()} or \texttt{NDB\$EPOCH\_TRANS()}.

\texttt{NDB\$EPOCH\_TRANS().} \texttt{NDB\$EPOCH\_TRANS()} extends the \texttt{NDB\$EPOCH()} function. Conflicts are detected and handled in the same way using the “primary wins all” rule (see \texttt{NDB\$EPOCH()} and \texttt{NDB\$EPOCH\_TRANS()}), but with the extra condition that any other rows updated in the same transaction in which the conflict occurred are also regarded as being in conflict. In other words, where \texttt{NDB\$EPOCH()} realigns individual conflicting rows on the secondary, \texttt{NDB\$EPOCH\_TRANS()} realigns conflicting transactions.

In addition, any transactions which are detectably dependent on a conflicting transaction are also regarded as being in conflict, these dependencies being determined by the contents of the secondary cluster’s binary log. Since the binary log contains only data modification operations (inserts, updates,
and deletes), only overlapping data modifications are used to determine dependencies between transactions.

NDB$EPOCH_TRANS() is subject to the same conditions and limitations as NDB$EPOCH(), and in addition requires that all transaction IDs are recorded in the secondary's binary log (the --ndb-log-transaction-id option), which adds a variable overhead (up to 13 bytes per row). The deprecated log_bin_use_v1_row_events system variable, which defaults to OFF, must not be set to ON with NDB$EPOCH_TRANS().

See NDB$EPOCH() and NDB$EPOCH_TRANS().

**Status information.** A server status variable Ndb_conflict_fn_max provides a count of the number of times that a row was not applied on the current SQL node due to “greatest timestamp wins” conflict resolution since the last time that mysqld was started.

The number of times that a row was not applied as the result of “same timestamp wins” conflict resolution on a given mysqld since the last time it was restarted is given by the global status variable Ndb_conflict_fn_old. In addition to incrementing Ndb_conflict_fn_old, the primary key of the row that was not used is inserted into an exceptions table, as explained later in this section.

**NDB$EPOCH2().** The NDB$EPOCH2() function is similar to NDB$EPOCH(), except that NDB$EPOCH2() provides for delete-delete handling with a circular replication (“master-master”) topology. In this scenario, primary and secondary roles are assigned to the two masters by setting the ndb_slave_conflict_role system variable to the appropriate value on each master (usually one each of PRIMARY, SECONDARY). When this is done, modifications made by the secondary are reflected by the primary back to the secondary which then conditionally applies them.

**NDB$EPOCH2_TRANS().** NDB$EPOCH2_TRANS() extends the NDB$EPOCH2() function. Conflicts are detected and handled in the same way, and assigning primary and secondary roles to the replicating clusters, but with the extra condition that any other rows updated in the same transaction in which the conflict occurred are also regarded as being in conflict. That is, NDB$EPOCH2() realigns individual conflicting rows on the secondary, while NDB$EPOCH_TRANS() realigns conflicting transactions.

Where NDB$EPOCH() and NDB$EPOCH_TRANS() use metadata that is specified per row, per last modified epoch, to determine on the primary whether an incoming replicated row change from the secondary is concurrent with a locally committed change; concurrent changes are regarded as conflicting, with subsequent exceptions table updates and realignment of the secondary. A problem arises when a row is deleted on the primary so there is no longer any last-modified epoch available to determine whether any replicated operations conflict, which means that conflicting delete operations are not detected. This can result in divergence, an example being a delete on one cluster which is concurrent with a delete and insert on another; this why delete operations can be routed to only one cluster when using NDB$EPOCH() and NDB$EPOCH_TRANS().

NDB$EPOCH2() bypasses the issue just described—storing information about deleted rows on the PRIMARY—by ignoring any delete-delete conflict, and by avoiding any potential resultant divergence as well. This is accomplished by reflecting any operation successfully applied on and replicated from the secondary back to the secondary. On its return to the secondary, it can be used to reapply an operation on the secondary which was deleted by an operation originating from the primary.

When using NDB$EPOCH2(), you should keep in mind that the secondary applies the delete from the primary, removing the new row until it is restored by a reflected operation. In theory, the subsequent insert or update on the secondary conflicts with the delete from the primary, but in this case, we choose to ignore this and allow the secondary to “win”, in the interest of preventing divergence between the clusters. In other words, after a delete, the primary does not detect conflicts, and instead adopts the secondary’s following changes immediately. Because of this, the secondary’s state can revisit multiple previous committed states as it progresses to a final (stable) state, and some of these may be visible.

You should also be aware that reflecting all operations from the secondary back to the primary increases the size of the primary’s log binary log, as well as demands on bandwidth, CPU usage, and disk I/O.
Application of reflected operations on the secondary depends on the state of the target row on the secondary. Whether or not reflected changes are applied on the secondary can be tracked by checking the `Ndb_conflict_reflected_op_prepare_count` and `Ndb_conflict_reflected_op_discard_count` status variables. The number of changes applied is simply the difference between these two values (note that `Ndb_conflict_reflected_op_prepare_count` is always greater than or equal to `Ndb_conflict_reflected_op_discard_count`).

Events are applied if and only if both of the following conditions are true:

- The existence of the row—that is, whether or not it exists—is in accordance with the type of event. For delete and update operations, the row must already exist. For insert operations, the row must not exist.
- The row was last modified by the primary. It is possible that the modification was accomplished through the execution of a reflected operation.

If both of the conditions are not met, the reflected operation is discarded by the secondary.

**Conflict resolution exceptions table.** To use the `NDB$OLD()` conflict resolution function, it is also necessary to create an exceptions table corresponding to each `NDB` table for which this type of conflict resolution is to be employed. This is also true when using `NDB$EPOCH()` or `NDB$EPOCH_TRANS()`. The name of this table is that of the table for which conflict resolution is to be applied, with the string `$EX` appended. (For example, if the name of the original table is `mytable`, the name of the corresponding exceptions table name should be `mytable$EX`.) The syntax for creating the exceptions table is as shown here:

```sql
CREATE TABLE original_table$EX (  
[NDB$]server_id INT UNSIGNED,  
[NDB$]master_server_id INT UNSIGNED,  
[NDB$]master_epoch BIGINT UNSIGNED,  
[NDB$]count INT UNSIGNED,  
[NDB$OP_TYPE ENUM('WRITE_ROW','UPDATE_ROW', 'DELETE_ROW', 'REFRESH_ROW', 'READ_ROW') NOT NULL,]  
[NDB$CFT_CAUSE ENUM('ROW_DOES_NOT_EXIST', 'ROW_ALREADY_EXISTS', 'DATA_IN_CONFLICT', 'TRANS_IN_CONFLICT') NOT NULL,]  
[NDB$ORIG_TRANSID BIGINT UNSIGNED NOT NULL,]  
original_table_pk_columns,  
[orig_table_column|orig_table_column$OLD|orig_table_column$NEW],  
[additional_columns,]  
) ENGINE=NDB;
```

The first four columns are required. The names of the first four columns and the columns matching the original table's primary key columns are not critical; however, we suggest for reasons of clarity and consistency, that you use the names shown here for the `server_id, master_server_id, master_epoch,` and `count` columns, and that you use the same names as in the original table for the columns matching those in the original table's primary key.

If the exceptions table uses one or more of the optional columns `NDB$OP_TYPE, NDB$CFT_CAUSE,` or `NDB$ORIG_TRANSID` discussed later in this section, then each of the required columns must also be named using the prefix `NDB$.` If desired, you can use the `NDB$` prefix to name the required columns even if you do not define any optional columns, but in this case, all four of the required columns must be named using the prefix.

Following these columns, the columns making up the original table's primary key should be copied in the order in which they are used to define the primary key of the original table. The data types for the columns duplicating the primary key columns of the original table should be the same as (or larger than) those of the original columns. A subset of the primary key columns may be used.
Regardless of the NDB Cluster version employed, the exceptions table must use the NDB storage engine. (An example that uses NDB$OLD() with an exceptions table is shown later in this section.)

Additional columns may optionally be defined following the copied primary key columns, but not before any of them; any such extra columns cannot be NOT NULL. NDB Cluster supports three additional, predefined optional columns NDB$OP_TYPE, NDB$CFT_CAUSE, and NDB$ORIG_TRANSID, which are described in the next few paragraphs.

**NDB$OP_TYPE:** This column can be used to obtain the type of operation causing the conflict. If you use this column, define it as shown here:

```sql
NDB$OP_TYPE ENUM('WRITE_ROW', 'UPDATE_ROW', 'DELETE_ROW',
    'REFRESH_ROW', 'READ_ROW') NOT NULL
```

The WRITE_ROW, UPDATE_ROW, and DELETE_ROW operation types represent user-initiated operations. REFRESH_ROW operations are operations generated by conflict resolution in compensating transactions sent back to the originating cluster from the cluster that detected the conflict. READ_ROW operations are user-initiated read tracking operations defined with exclusive row locks.

**NDB$CFT_CAUSE:** You can define an optional column NDB$CFT_CAUSE which provides the cause of the registered conflict. This column, if used, is defined as shown here:

```sql
NDB$CFT_CAUSE ENUM('ROW_DOES_NOT_EXIST', 'ROW_ALREADY_EXISTS',
    'DATA_IN_CONFLICT', 'TRANS_IN_CONFLICT') NOT NULL
```

ROW_DOES_NOT_EXIST can be reported as the cause for UPDATE_ROW and WRITE_ROW operations; ROW_ALREADY_EXISTS can be reported for WRITE_ROW events. DATA_IN_CONFLICT is reported when a row-based conflict function detects a conflict; TRANS_IN_CONFLICT is reported when a transactional conflict function rejects all of the operations belonging to a complete transaction.

**NDB$ORIG_TRANSID:** The NDB$ORIG_TRANSID column, if used, contains the ID of the originating transaction. This column should be defined as follows:

```sql
NDB$ORIG_TRANSID BIGINT UNSIGNED NOT NULL
```

NDB$ORIG_TRANSID is a 64-bit value generated by NDB. This value can be used to correlate multiple exceptions table entries belonging to the same conflicting transaction from the same or different exceptions tables.

Additional reference columns which are not part of the original table's primary key can be named colname$OLD or colname$NEW. colname$OLD references old values in update and delete operations—that is, operations containing DELETE_ROW events. colname$NEW can be used to reference new values in insert and update operations—in other words, operations using WRITE_ROW events, UPDATE_ROW events, or both types of events. Where a conflicting operation does not supply a value for a given non-primary-key reference column, the exceptions table row contains either NULL, or a defined default value for that column.

**Important**

The mysql.ndb_replication table is read when a data table is set up for replication, so the row corresponding to a table to be replicated must be inserted into mysql.ndb_replication before the table to be replicated is created.

**Examples**

The following examples assume that you have already a working NDB Cluster replication setup, as described in Section 22.6.5, "Preparing the NDB Cluster for Replication", and Section 22.6.6, "Starting NDB Cluster Replication (Single Replication Channel)".

**NDB$MAX() example.** Suppose you wish to enable “greatest timestamp wins” conflict resolution on table test.t1, using column mycol as the “timestamp”. This can be done using the following steps:
1. Make sure that you have started the master `mysqld` with `--ndb-log-update-as-write=OFF`.

2. On the master, perform this `INSERT` statement:

   ```sql
   INSERT INTO mysql.ndb_replication
   VALUES ('test', 't1', 0, NULL, 'NDB$MAX(mycol)');
   ```

   Inserting a 0 into the `server_id` indicates that all SQL nodes accessing this table should use conflict resolution. If you want to use conflict resolution on a specific `mysqld` only, use the actual server ID.

   Inserting `NULL` into the `binlog_type` column has the same effect as inserting 0 (`NBT_DEFAULT`); the server default is used.

3. Create the `test.t1` table:

   ```sql
   CREATE TABLE test.t1 (
   columns
   mycol INT UNSIGNED,
   columns
   ) ENGINE=NDB;
   ```

   Now, when updates are done on this table, conflict resolution is applied, and the version of the row having the greatest value for `mycol` is written to the slave.

   **Note**

   Other `binlog_type` options—such as `NBT_UPDATED_ONLY_USE_UPDATE` should be used to control logging on the master using the `ndb_replication` table rather than by using command-line options.

   **NDB$OLD() example.** Suppose an NDB table such as the one defined here is being replicated, and you wish to enable "same timestamp wins" conflict resolution for updates to this table:

   ```sql
   CREATE TABLE test.t2  (
   a INT UNSIGNED NOT NULL,
   b CHAR(25) NOT NULL,
   columns,
   mycol INT UNSIGNED NOT NULL,
   columns,
   PRIMARY KEY pk (a, b)
   )   ENGINE=NDB;
   ```

   The following steps are required, in the order shown:

   1. First—and prior to creating `test.t2`—you must insert a row into the `mysql.ndb_replication` table, as shown here:

      ```sql
      INSERT INTO mysql.ndb_replication
      VALUES ('test', 't2', 0, NULL, 'NDB$OLD(mycol)');
      ```

      Possible values for the `binlog_type` column are shown earlier in this section. The value 'NDB$OLD(mycol)' should be inserted into the `conflict_fn` column.

   2. Create an appropriate exceptions table for `test.t2`. The table creation statement shown here includes all required columns; any additional columns must be declared following these columns, and before the definition of the table's primary key.

      ```sql
      CREATE TABLE test.t2$EX  (
      server_id INT UNSIGNED,
      master_server_id INT UNSIGNED,
      master_epoch BIGINT UNSIGNED,
      count INT UNSIGNED,
      a INT UNSIGNED NOT NULL,
      b CHAR(25) NOT NULL,
      ...)
We can include additional columns for information about the type, cause, and originating transaction ID for a given conflict. We are also not required to supply matching columns for all primary key columns in the original table. This means you can create the exceptions table like this:

```sql
CREATE TABLE test.t2$EX (  
    NDB$server_id INT UNSIGNED,
    NDB$master_server_id INT UNSIGNED,
    NDB$master_epoch BIGINT UNSIGNED,
    NDB$count INT UNSIGNED,
    a INT UNSIGNED NOT NULL,
    NDB$OP_TYPE ENUM('WRITE_ROW', 'UPDATE_ROW', 'DELETE_ROW', 'REFRESH_ROW', 'READ_ROW') NOT NULL,
    NDB$CFT_CAUSE ENUM('ROW_DOES_NOT_EXIST', 'ROW_ALREADY_EXISTS', 'DATA_IN_CONFLICT', 'TRANS_IN_CONFLICT') NOT NULL,
    NDB$ORIG_TRANSID BIGINT UNSIGNED NOT NULL,
) ENGINE=NDB;
```

**Note**

The `NDB$` prefix is required for the four required columns since we included at least one of the columns `NDB$OP_TYPE`, `NDB$CFT_CAUSE`, or `NDB$ORIG_TRANSID` in the table definition.

3. Create the table `test.t2` as shown previously.

These steps must be followed for every table for which you wish to perform conflict resolution using `NDB$OLD()`. For each such table, there must be a corresponding row in `mysql.ndb_replication`, and there must be an exceptions table in the same database as the table being replicated.

**Read conflict detection and resolution.** NDB Cluster also supports tracking of read operations, which makes it possible in circular replication setups to manage conflicts between reads of a given row in one cluster and updates or deletes of the same row in another. This example uses `employee` and `department` tables to model a scenario in which an employee is moved from one department to another on the master cluster (which we refer to hereafter as cluster A) while the slave cluster (hereafter B) updates the employee count of the employee's former department in an interleaved transaction.

The data tables have been created using the following SQL statements:

```sql
# Employee table
CREATE TABLE employee (  
    id INT PRIMARY KEY,
    name VARCHAR(2000),
    dept INT NOT NULL
) ENGINE=NDB;

# Department table
CREATE TABLE department (  
    id INT PRIMARY KEY,
    name VARCHAR(2000),
    members INT
) ENGINE=NDB;
```

The contents of the two tables include the rows shown in the (partial) output of the following `SELECT` statements:

```
mysql> SELECT id, name, dept FROM employee;
```

```sql
[additional_columns,]
PRIMARY KEY(server_id, master_server_id, master_epoch, count)
) ENGINE=NDB;
```
NDB Cluster Replication Conflict Resolution

NDB Cluster Replication Conflict Resolution

We assume that we are already using an exceptions table that includes the four required columns (and these are used for this table’s primary key), the optional columns for operation type and cause, and the original table’s primary key column, created using the SQL statement shown here:

```sql
CREATE TABLE employee$EX {
  NDB$server_id INT UNSIGNED,
  NDB$master_server_id INT UNSIGNED,
  NDB$master_epoch BIGINT UNSIGNED,
  NDB$count INT UNSIGNED,
  NDB$OP_TYPE ENUM( 'WRITE_ROW', 'UPDATE_ROW', 'DELETE_ROW', 'REFRESH_ROW', 'READ_ROW') NOT NULL,
  NDB$CFT_CAUSE ENUM( 'ROW_DOES_NOT_EXIST', 'ROW_ALREADY_EXISTS', 'DATA_IN_CONFLICT', 'TRANS_IN_CONFLICT') NOT NULL,
  id INT NOT NULL,
  PRIMARY KEY(NDB$server_id, NDB$master_server_id, NDB$master_epoch, NDB$count)
} ENGINE=NDB;
```

Suppose there occur the two simultaneous transactions on the two clusters. On cluster A, we create a new department, then move employee number 999 into that department, using the following SQL statements:

```sql
BEGIN;
  INSERT INTO department VALUES (4, "New project", 1);
  UPDATE employee SET dept = 4 WHERE id = 999;
COMMIT;
```

At the same time, on cluster B, another transaction reads from employee, as shown here:

```sql
BEGIN;
  SELECT name FROM employee WHERE id = 999;
  UPDATE department SET members = members - 1 WHERE id = 3;
commit;
```

The conflicting transactions are not normally detected by the conflict resolution mechanism, since the conflict is between a read (SELECT) and an update operation. You can circumvent this issue by executing `SET ndb_log_exclusive_reads = 1` on the slave cluster. Acquiring exclusive read locks in this way causes any rows read on the master to be flagged as needing conflict resolution on the slave cluster. If we enable exclusive reads in this way prior to the logging of these transactions, the read on cluster B is tracked and sent to cluster A for resolution; the conflict on the employee row will be detected and the transaction on cluster B is aborted.

The conflict is registered in the exceptions table (on cluster A) as a READ_ROW operation (see Conflict resolution exceptions table, for a description of operation types), as shown here:
Any existing rows found in the read operation are flagged. This means that multiple rows resulting from the same conflict may be logged in the exception table, as shown by examining the effects a conflict between an update on cluster A and a read of multiple rows on cluster B from the same table in simultaneous transactions. The transaction executed on cluster A is shown here:

```
BEGIN;
  INSERT INTO department VALUES (4, "New project", 0);
  UPDATE employee SET dept = 4 WHERE dept = 3;
  SELECT COUNT(*) INTO @count FROM employee WHERE dept = 4;
  UPDATE department SET members = @count WHERE id = 4;
COMMIT;
```

Concurrently a transaction containing the statements shown here runs on cluster B:

```
SET ndb_log_exclusive_reads = 1;  # Must be set if not already enabled
...
BEGIN;
  SELECT COUNT(*) INTO @count FROM employee WHERE dept = 3 FOR UPDATE;
  UPDATE department SET members = @count WHERE id = 3;
COMMIT;
```

In this case, all three rows matching the `WHERE` condition in the second transaction's `SELECT` are read, and are thus flagged in the exceptions table, as shown here:

```
mysql> SELECT id, NDB$OP_TYPE, NDB$CFT_CAUSE FROM employee$EX;
+-------+-------------+-------------------+
| id    | NDB$OP_TYPE | NDB$CFT_CAUSE     |
|-------+-------------+-------------------+
...    | READ_ROW    | TRANS_IN_CONFLICT |
| 998   | READ_ROW    | TRANS_IN_CONFLICT |
| 999   | READ_ROW    | TRANS_IN_CONFLICT |
| 1000  | READ_ROW    | TRANS_IN_CONFLICT |
...    +-------+-------------+-------------------+
```

Read tracking is performed on the basis of existing rows only. A read based on a given condition track conflicts only of any rows that are found and not of any rows that are inserted in an interleaved transaction. This is similar to how exclusive row locking is performed in a single instance of NDB Cluster.

## 22.7 NDB Cluster Release Notes

Changes in NDB Cluster releases are documented separately from this reference manual; you can find release notes for the changes in each NDB Cluster 8.0 release at [NDB 8.0 Release Notes](#). You can obtain release notes for older versions of NDB Cluster from [NDB Cluster Release Notes](#).

This chapter discusses user-defined partitioning.

Note
Table partitioning differs from partitioning as used by window functions. For information about window functions, see Section 12.21, “Window Functions”.

In MySQL 8.0, partitioning support is provided by the InnoDB and NDB storage engines.

MySQL 8.0 does not currently support partitioning of tables using any storage engine other than InnoDB or NDB, such as MyISAM. An attempt to create a partitioned tables using a storage engine that does not supply native partitioning support fails with ER_CHECK_NOT_IMPLEMENTED.

MySQL 8.0 Community binaries provided by Oracle include partitioning support provided by the InnoDB and NDB storage engines. For information about partitioning support offered in MySQL Enterprise Edition binaries, see Chapter 30, MySQL Enterprise Edition.

If you are compiling MySQL 8.0 from source, configuring the build with InnoDB support is sufficient to produce binaries with partition support for InnoDB tables. For more information, see Section 2.9, “Installing MySQL from Source”.

Nothing further needs to be done to enable partitioning support by InnoDB (for example, no special entries are required in the my.cnf file).

It is not possible to disable partitioning support by the InnoDB storage engine.

See Section 23.1, “Overview of Partitioning in MySQL”, for an introduction to partitioning and partitioning concepts.

Several types of partitioning are supported, as well as subpartitioning; see Section 23.2, “Partitioning Types”, and Section 23.2.6, “Subpartitioning”.

4093
Section 23.3, “Partition Management”, covers methods of adding, removing, and altering partitions in existing partitioned tables.

Section 23.3.4, “Maintenance of Partitions”, discusses table maintenance commands for use with partitioned tables.

The PARTITIONS table in the INFORMATION_SCHEMA database provides information about partitions and partitioned tables. See Section 25.20, “The INFORMATION_SCHEMA PARTITIONS Table”, for more information; for some examples of queries against this table, see Section 23.2.7, “How MySQL Partitioning Handles NULL”.

For known issues with partitioning in MySQL 8.0, see Section 23.6, “Restrictions and Limitations on Partitioning”.

You may also find the following resources to be useful when working with partitioned tables.

**Additional Resources.** Other sources of information about user-defined partitioning in MySQL include the following:

- **MySQL Partitioning Forum**
  This is the official discussion forum for those interested in or experimenting with MySQL Partitioning technology. It features announcements and updates from MySQL developers and others. It is monitored by members of the Partitioning Development and Documentation Teams.

- **Mikael Ronström’s Blog**
  MySQL Partitioning Architect and Lead Developer Mikael Ronström frequently posts articles here concerning his work with MySQL Partitioning and NDB Cluster.

- **PlanetMySQL**
  A MySQL news site featuring MySQL-related blogs, which should be of interest to anyone using my MySQL. We encourage you to check here for links to blogs kept by those working with MySQL Partitioning, or to have your own blog added to those covered.

### 23.1 Overview of Partitioning in MySQL

This section provides a conceptual overview of partitioning in MySQL 8.0.

For information on partitioning restrictions and feature limitations, see Section 23.6, “Restrictions and Limitations on Partitioning”.

The SQL standard does not provide much in the way of guidance regarding the physical aspects of data storage. The SQL language itself is intended to work independently of any data structures or media underlying the schemas, tables, rows, or columns with which it works. Nonetheless, most advanced database management systems have evolved some means of determining the physical location to be used for storing specific pieces of data in terms of the file system, hardware or even both. In MySQL, the InnoDB storage engine has long supported the notion of a tablespace (see Section 15.6.3, “Tablespaces”), and the MySQL Server, even prior to the introduction of partitioning, could be configured to employ different physical directories for storing different databases (see Section 8.12.2, “Using Symbolic Links”, for an explanation of how this is done).

Partitioning takes this notion a step further, by enabling you to distribute portions of individual tables across a file system according to rules which you can set largely as needed. In effect, different portions of a table are stored as separate tables in different locations. The user-selected rule by which the division of data is accomplished is known as a partitioning function, which in MySQL can be the modulus, simple matching against a set of ranges or value lists, an internal hashing function, or a linear hashing function. The function is selected according to the partitioning type specified by the user, and takes as its parameter the value of a user-supplied expression. This expression can be a column value,
Overview of Partitioning in MySQL

A function acting on one or more column values, or a set of one or more column values, depending on the type of partitioning that is used.

In the case of \texttt{RANGE}, \texttt{LIST}, and \texttt{LINEAR \& HASH} partitioning, the value of the partitioning column is passed to the partitioning function, which returns an integer value representing the number of the partition in which that particular record should be stored. This function must be nonconstant and nonrandom. It may not contain any queries, but may use an SQL expression that is valid in MySQL, as long as that expression returns either \texttt{NULL} or an integer \texttt{intval} such that

\[
-MAXVALUE <= intval <= MAXVALUE
\]

(\texttt{MAXVALUE} is used to represent the least upper bound for the type of integer in question. \texttt{-MAXVALUE} represents the greatest lower bound.)

For \texttt{LINEAR \& KEY}, \texttt{RANGE COLUMNS}, and \texttt{LIST COLUMNS} partitioning, the partitioning expression consists of a list of one or more columns.

For \texttt{LINEAR \& KEY} partitioning, the partitioning function is supplied by MySQL.

For more information about permitted partitioning column types and partitioning functions, see Section 23.2, “Partitioning Types”, as well as Section 13.1.20, “CREATE TABLE Statement”, which provides partitioning syntax descriptions and additional examples. For information about restrictions on partitioning functions, see Section 23.6.3, “Partitioning Limitations Relating to Functions”.

This is known as \textit{horizontal partitioning}—that is, different rows of a table may be assigned to different physical partitions. MySQL 8.0 does not support \textit{vertical partitioning}, in which different columns of a table are assigned to different physical partitions. There are no plans at this time to introduce vertical partitioning into MySQL.

For creating partitioned tables, you must use a storage engine that supports them. In MySQL 8.0, all partitions of the same partitioned table must use the same storage engine. However, there is nothing preventing you from using different storage engines for different partitioned tables on the same MySQL server or even in the same database.

In MySQL 8.0, the only storage engines that support partitioning are \texttt{InnoDB} and \texttt{NDB}. Partitioning cannot be used with storage engines that do not support it; these include the \texttt{MyISAM}, \texttt{MERGE}, \texttt{CSV}, and \texttt{FEDERATED} storage engines.

Partitioning by \texttt{KEY} or \texttt{LINEAR \& KEY} is possible with \texttt{NDB}, but other types of user-defined partitioning are not supported for tables using this storage engine. In addition, an \texttt{NDB} table that employs user-defined partitioning must have an explicit primary key, and any columns referenced in the table’s partitioning expression must be part of the primary key. However, if no columns are listed in the \texttt{PARTITION BY KEY} or \texttt{PARTITION BY LINEAR KEY} clause of the \texttt{CREATE TABLE} or \texttt{ALTER TABLE} statement used to create or modify a user-partitioned \texttt{NDB} table, then the table is not required to have an explicit primary key. For more information, see Section 22.1.7.1, “Noncompliance with SQL Syntax in NDB Cluster”.

When creating a partitioned table, the default storage engine is used just as when creating any other table; to override this behavior, it is necessary only to use the \texttt{[STORAGE\ ENGINE]} option just as you would for a table that is not partitioned. The target storage engine must provide native partitioning support, or the statement fails. You should keep in mind that \texttt{[STORAGE\ ENGINE]} (and other table options) need to be listed \textit{before} any partitioning options are used in a \texttt{CREATE TABLE} statement. This example shows how to create a table that is partitioned by hash into 6 partitions and which uses the \texttt{InnoDB} storage engine (regardless of the value of \texttt{default_storage_engine}):

\begin{verbatim}
CREATE TABLE ti (id INT, amount DECIMAL(7,2), tr_date DATE)
  ENGINE=INNODB
  PARTITION BY HASH( MONTH(tr_date) )
  PARTITIONS 6;
\end{verbatim}

Each \texttt{PARTITION} clause can include a \texttt{[STORAGE\ ENGINE]} option, but in MySQL 8.0 this has no effect.
Unless otherwise specified, the remaining examples in this discussion assume that `default_storage_engine` is `InnoDB`.

**Important**

Partitioning applies to all data and indexes of a table; you cannot partition only the data and not the indexes, or vice versa, nor can you partition only a portion of the table.

Data and indexes for each partition can be assigned to a specific directory using the `DATA DIRECTORY` and `INDEX DIRECTORY` options for the `PARTITION` clause of the `CREATE TABLE` statement used to create the partitioned table.

Only the `DATA DIRECTORY` option is supported for individual partitions and subpartitions of `InnoDB` tables.

All columns used in the table's partitioning expression must be part of every unique key that the table may have, including any primary key. This means that a table such as this one, created by the following SQL statement, cannot be partitioned:

```sql
CREATE TABLE tnp (
    id INT NOT NULL AUTO_INCREMENT,
    ref BIGINT NOT NULL,
    name VARCHAR(255),
    PRIMARY KEY pk (id),
    UNIQUE KEY uk (name)
);
```

Because the keys `pk` and `uk` have no columns in common, there are no columns available for use in a partitioning expression. Possible workarounds in this situation include adding the `name` column to the table's primary key, adding the `id` column to `uk`, or simply removing the unique key altogether. See Section 23.6.1, “Partitioning Keys, Primary Keys, and Unique Keys”, for more information.

In addition, `MAX_ROWS` and `MIN_ROWS` can be used to determine the maximum and minimum numbers of rows, respectively, that can be stored in each partition. See Section 23.3, “Partition Management”, for more information on these options.

The `MAX_ROWS` option can also be useful for creating NDB Cluster tables with extra partitions, thus allowing for greater storage of hash indexes. See the documentation for the `DataMemory` data node configuration parameter, as well as Section 22.1.2, “NDB Cluster Nodes, Node Groups, Replicas, and Partitions”, for more information.

Some advantages of partitioning are listed here:

- Partitioning makes it possible to store more data in one table than can be held on a single disk or file system partition.
- Data that loses its usefulness can often be easily removed from a partitioned table by dropping the partition (or partitions) containing only that data. Conversely, the process of adding new data can in some cases be greatly facilitated by adding one or more new partitions for storing specifically that data.
- Some queries can be greatly optimized in virtue of the fact that data satisfying a given `WHERE` clause can be stored only on one or more partitions, which automatically excludes any remaining partitions from the search. Because partitions can be altered after a partitioned table has been created, you can reorganize your data to enhance frequent queries that may not have been often used when the partitioning scheme was first set up. This ability to exclude non-matching partitions (and thus any rows they contain) is often referred to as *partition pruning*. For more information, see Section 23.4, “Partition Pruning”.

In addition, MySQL supports explicit partition selection for queries. For example, `SELECT * FROM t PARTITION (p0, p1) WHERE c < 5` selects only those rows in partitions `p0` and `p1` that
match the `WHERE` condition. In this case, MySQL does not check any other partitions of table \( t \); this can greatly speed up queries when you already know which partition or partitions you wish to examine. Partition selection is also supported for the data modification statements `DELETE`, `INSERT`, `REPLACE`, `UPDATE`, and `LOAD DATA`, `LOAD XML`. See the descriptions of these statements for more information and examples.

### 23.2 Partitioning Types

This section discusses the types of partitioning which are available in MySQL 8.0. These include the types listed here:

- **RANGE partitioning.** This type of partitioning assigns rows to partitions based on column values falling within a given range. See Section 23.2.1, “RANGE Partitioning”. For information about an extension to this type, `RANGE COLUMNS`, see Section 23.2.3.1, “RANGE COLUMNS partitioning”.

- **LIST partitioning.** Similar to partitioning by `RANGE`, except that the partition is selected based on columns matching one of a set of discrete values. See Section 23.2.2, “LIST Partitioning”. For information about an extension to this type, `LIST COLUMNS`, see Section 23.2.3.2, “LIST COLUMNS partitioning”.

- **HASH partitioning.** With this type of partitioning, a partition is selected based on the value returned by a user-defined expression that operates on column values in rows to be inserted into the table. The function may consist of any expression valid in MySQL that yields a nonnegative integer value. An extension to this type, `LINEAR HASH`, is also available. See Section 23.2.4, “HASH Partitioning”.

- **KEY partitioning.** This type of partitioning is similar to partitioning by `HASH`, except that only one or more columns to be evaluated are supplied, and the MySQL server provides its own hashing function. These columns can contain other than integer values, since the hashing function supplied by MySQL guarantees an integer result regardless of the column data type. An extension to this type, `LINEAR KEY`, is also available. See Section 23.2.5, “KEY Partitioning”.

A very common use of database partitioning is to segregate data by date. Some database systems support explicit date partitioning, which MySQL does not implement in 8.0. However, it is not difficult in MySQL to create partitioning schemes based on `DATE`, `TIME`, or `DATETIME` columns, or based on expressions making use of such columns.

When partitioning by `KEY` or `LINEAR KEY`, you can use a `DATE`, `TIME`, or `DATETIME` column as the partitioning column without performing any modification of the column value. For example, this table creation statement is perfectly valid in MySQL:

```sql
CREATE TABLE members (  
  firstname VARCHAR(25) NOT NULL,  
  lastname VARCHAR(25) NOT NULL,  
  username VARCHAR(16) NOT NULL,  
  email VARCHAR(35),  
  joined DATE NOT NULL  
)  
PARTITION BY KEY(joined)  
PARTITIONS 6;
```

In MySQL 8.0, it is also possible to use a `DATE` or `DATETIME` column as the partitioning column using `RANGE COLUMNS` and `LIST COLUMNS` partitioning.

Other partitioning types require a partitioning expression that yields an integer value or `NULL`. If you wish to use date-based partitioning by `RANGE`, `LIST`, `HASH`, or `LINEAR HASH`, you can simply employ a function that operates on a `DATE`, `TIME`, or `DATETIME` column and returns such a value, as shown here:

```sql
CREATE TABLE members (  
  firstname VARCHAR(25) NOT NULL,  
  lastname VARCHAR(25) NOT NULL,
```

---

4097
RANGE Partitioning

Additional examples of partitioning using dates may be found in the following sections of this chapter:

- Section 23.2.1, “RANGE Partitioning”
- Section 23.2.4, “HASH Partitioning”
- Section 23.2.4.1, “LINEAR HASH Partitioning”

For more complex examples of date-based partitioning, see the following sections:

- Section 23.4, “Partition Pruning”
- Section 23.2.6, “Subpartitioning”

MySQL partitioning is optimized for use with the `TO_DAYS()`, `YEAR()`, and `TO_SECONDS()` functions. However, you can use other date and time functions that return an integer or `NULL`, such as `WEEKDAY()`, `DAYOFYEAR()`, or `MONTH()`. See Section 12.6, “Date and Time Functions”, for more information about such functions.

It is important to remember—regardless of the type of partitioning that you use—that partitions are always numbered automatically and in sequence when created, starting with 0. When a new row is inserted into a partitioned table, it is these partition numbers that are used in identifying the correct partition. For example, if your table uses 4 partitions, these partitions are numbered 0, 1, 2, and 3. For the `RANGE` and `LIST` partitioning types, it is necessary to ensure that there is a partition defined for each partition number. For `HASH` partitioning, the user-supplied expression must evaluate to an integer value greater than 0. For `KEY` partitioning, this issue is taken care of automatically by the hashing function which the MySQL server employs internally.

Names of partitions generally follow the rules governing other MySQL identifiers, such as those for tables and databases. However, you should note that partition names are not case-sensitive. For example, the following `CREATE TABLE` statement fails as shown:

```sql
mysql> CREATE TABLE t2 (val INT)
    -> PARTITION BY LIST(val)(
    ->   PARTITION mypart VALUES IN (1,3,5),
    ->   PARTITION MyPart VALUES IN (2,4,6)
    -> );
ERROR 1488 (HY000): Duplicate partition name mypart
```

Failure occurs because MySQL sees no difference between the partition names `mypart` and `MyPart`.

When you specify the number of partitions for the table, this must be expressed as a positive, nonzero integer literal with no leading zeros, and may not be an expression such as `0.8E+01` or `6-2`, even if it evaluates to an integer value. Decimal fractions are not permitted.

In the sections that follow, we do not necessarily provide all possible forms for the syntax that can be used for creating each partition type; for this information, see Section 13.1.20, “CREATE TABLE Statement”.

### 23.2.1 RANGE Partitioning

A table that is partitioned by range is partitioned in such a way that each partition contains rows for which the partitioning expression value lies within a given range. Ranges should be contiguous but
not overlapping, and are defined using the \texttt{VALUES LESS THAN} operator. For the next few examples, suppose that you are creating a table such as the following to hold personnel records for a chain of 20 video stores, numbered 1 through 20:

\begin{verbatim}
CREATE TABLE employees (  
id INT NOT NULL,  
fname VARCHAR(30),  
lname VARCHAR(30),  
hired DATE NOT NULL DEFAULT '1970-01-01',  
separated DATE NOT NULL DEFAULT '9999-12-31',  
job_code INT NOT NULL,  
store_id INT NOT NULL  );
\end{verbatim}

\textbf{Note}

The \texttt{employees} table used here has no primary or unique keys. While the examples work as shown for purposes of the present discussion, you should keep in mind that tables are extremely likely in practice to have primary keys, unique keys, or both, and that allowable choices for partitioning columns depend on the columns used for these keys, if any are present. For a discussion of these issues, see Section 23.6.1, “Partitioning Keys, Primary Keys, and Unique Keys”.

This table can be partitioned by range in a number of ways, depending on your needs. One way would be to use the \texttt{store_id} column. For instance, you might decide to partition the table 4 ways by adding a \texttt{PARTITION BY RANGE} clause as shown here:

\begin{verbatim}
CREATE TABLE employees (  
id INT NOT NULL,  
fname VARCHAR(30),  
lname VARCHAR(30),  
hired DATE NOT NULL DEFAULT '1970-01-01',  
separated DATE NOT NULL DEFAULT '9999-12-31',  
job_code INT NOT NULL,  
store_id INT NOT NULL  )  
PARTITION BY RANGE (store_id) (  
PARTITION p0 VALUES LESS THAN (6),  
PARTITION p1 VALUES LESS THAN (11),  
PARTITION p2 VALUES LESS THAN (16),  
PARTITION p3 VALUES LESS THAN (21)  );
\end{verbatim}

In this partitioning scheme, all rows corresponding to employees working at stores 1 through 5 are stored in partition \texttt{p0}, to those employed at stores 6 through 10 are stored in partition \texttt{p1}, and so on. Each partition is defined in order, from lowest to highest. This is a requirement of the \texttt{PARTITION BY RANGE} syntax; you can think of it as being analogous to a series of \texttt{if ... elseif ...} statements in C or Java in this regard.

It is easy to determine that a new row containing the data (72, 'Mitchell', 'Wilson', '1998-06-25', NULL, 13) is inserted into partition \texttt{p2}, but what happens when your chain adds a 21st store? Under this scheme, there is no rule that covers a row whose \texttt{store_id} is greater than 20, so an error results because the server does not know where to place it. You can keep this from occurring by using a “catchall” \texttt{VALUES LESS THAN} clause in the \texttt{CREATE TABLE} statement that provides for all values greater than the highest value explicitly named:

\begin{verbatim}
CREATE TABLE employees (  
id INT NOT NULL,  
fname VARCHAR(30),  
lname VARCHAR(30),  
hired DATE NOT NULL DEFAULT '1970-01-01',  
separated DATE NOT NULL DEFAULT '9999-12-31',  
job_code INT NOT NULL,  
store_id INT NOT NULL  )  
PARTITION BY RANGE (store_id) (  
PARTITION p0 VALUES LESS THAN (6),  
PARTITION p1 VALUES LESS THAN (11),  
PARTITION p2 VALUES LESS THAN (16),  
PARTITION p3 VALUES LESS THAN (21),  
PARTITION DEFAULT VALUES LESS THAN (MAXVALUE)  );
\end{verbatim}
PARTITION BY RANGE (store_id) (
    PARTITION p0 VALUES LESS THAN (6),
    PARTITION p1 VALUES LESS THAN (11),
    PARTITION p2 VALUES LESS THAN (16),
    PARTITION p3 VALUES LESS THAN MAXVALUE
);

(As with the other examples in this chapter, we assume that the default storage engine is InnoDB.)

Note

Another way to avoid an error when no matching value is found is to use the IGNORE keyword as part of the INSERT statement. For an example, see Section 23.2.2, “LIST Partitioning”. Also see Section 13.2.6, “INSERT Statement”, for general information about IGNORE.

MAXVALUE represents an integer value that is always greater than the largest possible integer value (in mathematical language, it serves as a least upper bound). Now, any rows whose store_id column value is greater than or equal to 16 (the highest value defined) are stored in partition p3. At some point in the future—when the number of stores has increased to 25, 30, or more—you can use an ALTER TABLE statement to add new partitions for stores 21-25, 26-30, and so on (see Section 23.3, “Partition Management”, for details of how to do this).

In much the same fashion, you could partition the table based on employee job codes—that is, based on ranges of job_code column values. For example—assuming that two-digit job codes are used for regular (in-store) workers, three-digit codes are used for office and support personnel, and four-digit codes are used for management positions—you could create the partitioned table using the following statement:

CREATE TABLE employees (id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT NOT NULL,
    store_id INT NOT NULL
) PARTITION BY RANGE (job_code) (
    PARTITION p0 VALUES LESS THAN (100),
    PARTITION p1 VALUES LESS THAN (1000),
    PARTITION p2 VALUES LESS THAN (10000)
);

In this instance, all rows relating to in-store workers would be stored in partition p0, those relating to office and support staff in p1, and those relating to managers in partition p2.

It is also possible to use an expression in VALUES LESS THAN clauses. However, MySQL must be able to evaluate the expression's return value as part of a LESS THAN (<) comparison.

Rather than splitting up the table data according to store number, you can use an expression based on one of the two DATE columns instead. For example, let us suppose that you wish to partition based on the year that each employee left the company; that is, the value of YEAR(separated). An example of a CREATE TABLE statement that implements such a partitioning scheme is shown here:

CREATE TABLE employees (id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT,
    store_id INT
) PARTITION BY RANGE (YEAR(separated)) (
    PARTITION p0 VALUES LESS THAN (1991),
    PARTITION p1 VALUES LESS THAN (1996),
    PARTITION p2 VALUES LESS THAN (2000),
    PARTITION p3 VALUES LESS THAN (2005),
    PARTITION p4 VALUES LESS THAN (2010),
    PARTITION p5 VALUES LESS THAN (2015),
    PARTITION p6 VALUES LESS THAN (MAXVALUE)
);
RANGE Partitioning

```sql
PARTITION p2 VALUES LESS THAN (2001),
PARTITION p3 VALUES LESS THAN MAXVALUE
);
```

In this scheme, for all employees who left before 1991, the rows are stored in partition `p0`; for those who left in the years 1991 through 1995, in `p1`; for those who left in the years 1996 through 2000, in `p2`; and for any workers who left after the year 2000, in `p3`.

It is also possible to partition a table by `RANGE`, based on the value of a `TIMESTAMP` column, using the `UNIX_TIMESTAMP()` function, as shown in this example:

```sql
CREATE TABLE quarterly_report_status (
    report_id INT NOT NULL,
    report_status VARCHAR(20) NOT NULL,
    report_updated TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP
) PARTITION BY RANGE (UNIX_TIMESTAMP(report_updated)) (
    PARTITION p0 VALUES LESS THAN (UNIX_TIMESTAMP('2008-01-01 00:00:00')),
    PARTITION p1 VALUES LESS THAN (UNIX_TIMESTAMP('2008-04-01 00:00:00')),
    PARTITION p2 VALUES LESS THAN (UNIX_TIMESTAMP('2008-07-01 00:00:00')),
    PARTITION p3 VALUES LESS THAN (UNIX_TIMESTAMP('2008-10-01 00:00:00')),
    PARTITION p4 VALUES LESS THAN (UNIX_TIMESTAMP('2009-01-01 00:00:00')),
    PARTITION p5 VALUES LESS THAN (UNIX_TIMESTAMP('2009-04-01 00:00:00')),
    PARTITION p6 VALUES LESS THAN (UNIX_TIMESTAMP('2009-07-01 00:00:00')),
    PARTITION p7 VALUES LESS THAN (UNIX_TIMESTAMP('2009-10-01 00:00:00')),
    PARTITION p8 VALUES LESS THAN (UNIX_TIMESTAMP('2010-01-01 00:00:00')),
    PARTITION p9 VALUES LESS THAN (MAXVALUE)
);
```

Any other expressions involving `TIMESTAMP` values are not permitted. (See Bug #42849.)

Range partitioning is particularly useful when one or more of the following conditions is true:

- You want or need to delete “old” data. If you are using the partitioning scheme shown previously for the `employees` table, you can simply use `ALTER TABLE employees DROP PARTITION p0;` to delete all rows relating to employees who stopped working for the firm prior to 1991. (See Section 13.1.9, “ALTER TABLE Statement”, and Section 23.3, “Partition Management”, for more information.) For a table with a great many rows, this can be much more efficient than running a `DELETE` query such as `DELETE FROM employees WHERE YEAR(separated) <= 1990;`.

- You want to use a column containing date or time values, or containing values arising from some other series.

- You frequently run queries that depend directly on the column used for partitioning the table. For example, when executing a query such as `EXPLAIN SELECT COUNT(*) FROM employees WHERE separated BETWEEN '2000-01-01' AND '2000-12-31' GROUP BY store_id;`, MySQL can quickly determine that only partition `p2` needs to be scanned because the remaining partitions cannot contain any records satisfying the `WHERE` clause. See Section 23.4, “Partition Pruning”, for more information about how this is accomplished.

A variant on this type of partitioning is `RANGE COLUMNS` partitioning. Partitioning by `RANGE COLUMNS` makes it possible to employ multiple columns for defining partitioning ranges that apply both to placement of rows in partitions and for determining the inclusion or exclusion of specific partitions when performing partition pruning. See Section 23.2.3.1, “RANGE COLUMNS partitioning”, for more information.

**Partitioning schemes based on time intervals.** If you wish to implement a partitioning scheme based on ranges or intervals of time in MySQL 8.0, you have two options:

1. Partition the table by `RANGE`, and for the partitioning expression, employ a function operating on a `DATE`, `TIME`, or `DATETIME` column and returning an integer value, as shown here:

```sql
CREATE TABLE members (  
    firstname VARCHAR(25) NOT NULL,
    lastname VARCHAR(25) NOT NULL,
);
```
In MySQL 8.0, it is also possible to partition a table by RANGE based on the value of a TIMESTAMP column, using the UNIX_TIMESTAMP() function, as shown in this example:

```
CREATE TABLE quarterly_report_status (
    report_id INT NOT NULL,
    report_status VARCHAR(20) NOT NULL,
    report_updated TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP
) PARTITION BY RANGE ( UNIX_TIMESTAMP(report_updated) ) {
    PARTITION p0 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-01-01 00:00:00') ),
    PARTITION p1 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-04-01 00:00:00') ),
    PARTITION p2 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-07-01 00:00:00') ),
    PARTITION p3 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-01-01 00:00:00') ),
    PARTITION p4 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-04-01 00:00:00') ),
    PARTITION p5 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-07-01 00:00:00') ),
    PARTITION p6 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-10-01 00:00:00') ),
    PARTITION p7 VALUES LESS THAN ( UNIX_TIMESTAMP('2010-01-01 00:00:00') ),
    PARTITION p8 VALUES LESS THAN ( MAXVALUE )
};
```

In MySQL 8.0, any other expressions involving TIMESTAMP values are not permitted. (See Bug #42849.)

**Note**

It is also possible in MySQL 8.0 to use UNIX_TIMESTAMP(timestamp_column) as a partitioning expression for tables that are partitioned by LIST. However, it is usually not practical to do so.

2. Partition the table by RANGE_COLUMNS, using a DATE or DATETIME column as the partitioning column. For example, the members table could be defined using the joined column directly, as shown here:

```
CREATE TABLE members (
    firstname VARCHAR(25) NOT NULL,
    lastname VARCHAR(25) NOT NULL,
    username VARCHAR(16) NOT NULL,
    email VARCHAR(35),
    joined DATE NOT NULL
) PARTITION BY RANGE_COLUMNS(joined) {
    PARTITION p0 VALUES LESS THAN ('1960-01-01'),
    PARTITION p1 VALUES LESS THAN ('1970-01-01'),
    PARTITION p2 VALUES LESS THAN ('1980-01-01'),
    PARTITION p3 VALUES LESS THAN ('1990-01-01'),
    PARTITION p4 VALUES LESS THAN MAXVALUE
};
```

**Note**

The use of partitioning columns employing date or time types other than DATE or DATETIME is not supported with RANGE_COLUMNS.
List partitioning in MySQL is similar to range partitioning in many ways. As in partitioning by `RANGE`, each partition must be explicitly defined. The chief difference between the two types of partitioning is that, in list partitioning, each partition is defined and selected based on the membership of a column value in one of a set of value lists, rather than in one of a set of contiguous ranges of values. This is done by using `PARTITION BY LIST(expr)` where `expr` is a column value or an expression based on a column value and returning an integer value, and then defining each partition by means of a `VALUES IN (value_list)`, where `value_list` is a comma-separated list of integers.

**Note**

In MySQL 8.0, it is possible to match against only a list of integers (and possibly `NULL`—see Section 23.2.7, “How MySQL Partitioning Handles NULL”) when partitioning by `LIST`. However, other column types may be used in value lists when employing `LIST COLUMN` partitioning, which is described later in this section.

Unlike the case with partitions defined by range, list partitions do not need to be declared in any particular order. For more detailed syntactical information, see Section 13.1.20, “CREATE TABLE Statement”.

For the examples that follow, we assume that the basic definition of the table to be partitioned is provided by the `CREATE TABLE` statement shown here:

```sql
CREATE TABLE employees (  
id INT NOT NULL,
fname VARCHAR(30),
lname VARCHAR(30),
hired DATE NOT NULL DEFAULT '1970-01-01',
separated DATE NOT NULL DEFAULT '9999-12-31',
job_code INT,
store_id INT
);
```

(This is the same table used as a basis for the examples in Section 23.2.1, “RANGE Partitioning”. As with the other partitioning examples, we assume that the `default_storage_engine` is `InnoDB`.)

Suppose that there are 20 video stores distributed among 4 franchises as shown in the following table.

<table>
<thead>
<tr>
<th>Region</th>
<th>Store ID Numbers</th>
</tr>
</thead>
<tbody>
<tr>
<td>North</td>
<td>3, 5, 6, 9, 17</td>
</tr>
<tr>
<td>East</td>
<td>1, 2, 10, 11, 19, 20</td>
</tr>
<tr>
<td>West</td>
<td>4, 12, 13, 14, 18</td>
</tr>
<tr>
<td>Central</td>
<td>7, 8, 15, 16</td>
</tr>
</tbody>
</table>

To partition this table in such a way that rows for stores belonging to the same region are stored in the same partition, you could use the `CREATE TABLE` statement shown here:

```sql
CREATE TABLE employees (  
id INT NOT NULL,
fname VARCHAR(30),
lname VARCHAR(30),
hired DATE NOT NULL DEFAULT '1970-01-01',
separated DATE NOT NULL DEFAULT '9999-12-31',
job_code INT,
store_id INT
);
PARTITION BY LIST(store_id) (  
PARTITION pNorth VALUES IN (3,5,6,9,17),  
PARTITION pEast VALUES IN (1,2,10,11,19,20),  
PARTITION pWest VALUES IN (4,12,13,14,18),
```
LIST Partitioning

This makes it easy to add or drop employee records relating to specific regions to or from the table. For instance, suppose that all stores in the West region are sold to another company. In MySQL 8.0, all rows relating to employees working at stores in that region can be deleted with the query

```
ALTER TABLE employees TRUNCATE PARTITION pWest;
```

which can be executed much more efficiently than the equivalent `DELETE` statement `DELETE FROM employees WHERE store_id IN (4,12,13,14,18);` (Using `ALTER TABLE employees DROP PARTITION pWest` would also delete all of these rows, but would also remove the partition `pWest` from the definition of the table; you would need to use an `ALTER TABLE ... ADD PARTITION` statement to restore the table's original partitioning scheme.)

As with `RANGE` partitioning, it is possible to combine `LIST` partitioning with partitioning by hash or key to produce a composite partitioning (subpartitioning). See Section 23.2.6, “Subpartitioning”.

Unlike the case with `RANGE` partitioning, there is no “catch-all” such as `MAXVALUE`; all expected values for the partitioning expression should be covered in `PARTITION ... VALUES IN (...)` clauses. An `INSERT` statement containing an unmatched partitioning column value fails with an error, as shown in this example:

```
mysql> CREATE TABLE h2 (  
-> c1 INT,  
-> c2 INT  
-> )  
-> PARTITION BY LIST(c1) (  
-> PARTITION p0 VALUES IN (1, 4, 7),  
-> PARTITION p1 VALUES IN (2, 5, 8)  
-> );
Query OK, 0 rows affected (0.11 sec)

mysql> INSERT INTO h2 VALUES (3, 5);
ERROR 1525 (HY000): Table has no partition for value 3
```

When inserting multiple rows using a single `INSERT` statement into a single InnoDB table, InnoDB considers the statement a single transaction, so that the presence of any unmatched values causes the statement to fail completely, and so no rows are inserted.

You can cause this type of error to be ignored by using the `IGNORE` keyword. If you do so, rows containing unmatched partitioning column values are not inserted, but any rows with matching values are inserted, and no errors are reported:

```
mysql> TRUNCATE h2;
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM h2;
Empty set (0.00 sec)

mysql> INSERT IGNORE INTO h2 VALUES (2, 5), (6, 10), (7, 5), (3, 1), (1, 9);
Query OK, 3 rows affected (0.00 sec)
Records: 5  Duplicates: 2  Warnings: 0

mysql> SELECT * FROM h2;
++----+----+
<table>
<thead>
<tr>
<th>c1</th>
<th>c2</th>
</tr>
</thead>
<tbody>
<tr>
<td>7</td>
<td>5</td>
</tr>
<tr>
<td>1</td>
<td>9</td>
</tr>
<tr>
<td>2</td>
<td>5</td>
</tr>
</tbody>
</table>
++----+----+
3 rows in set (0.00 sec)
```

MySQL 8.0 also provides support for `LIST COLUMNS` partitioning, a variant of `LIST` partitioning that enables you to use columns of types other than integer types for partitioning columns, and to use multiple columns as partitioning keys. For more information, see Section 23.2.3.2, “LIST COLUMNS partitioning”.

4104
23.2.3 COLUMNS Partitioning

The next two sections discuss COLUMNS partitioning, which are variants on RANGE and LIST partitioning. COLUMNS partitioning enables the use of multiple columns in partitioning keys. All of these columns are taken into account both for the purpose of placing rows in partitions and for the determination of which partitions are to be checked for matching rows in partition pruning.

In addition, both RANGE COLUMNS partitioning and LIST COLUMNS partitioning support the use of non-integer columns for defining value ranges or list members. The permitted data types are shown in the following list:

- All integer types: TINYINT, SMALLINT, MEDIUMINT, INT (INTEGER), and BIGINT. (This is the same as with partitioning by RANGE and LIST.)
- DATE and DATETIME.
- Columns using other data types relating to dates or times are not supported as partitioning columns.
- The following string types: CHAR, VARCHAR, BINARY, and VARBINARY.
- TEXT and BLOB columns are not supported as partitioning columns.

The discussions of RANGE COLUMNS and LIST COLUMNS partitioning in the next two sections assume that you are already familiar with partitioning based on ranges and lists as supported in MySQL 5.1 and later; for more information about these, see Section 23.2.1, “RANGE Partitioning”, and Section 23.2.2, “LIST Partitioning”, respectively.

23.2.3.1 RANGE COLUMNS partitioning

Range columns partitioning is similar to range partitioning, but enables you to define partitions using ranges based on multiple column values. In addition, you can define the ranges using columns of types other than integer types.

RANGE COLUMNS partitioning differs significantly from RANGE partitioning in the following ways:

- RANGE COLUMNS does not accept expressions, only names of columns.
- RANGE COLUMNS accepts a list of one or more columns.

RANGE COLUMNS partitions are based on comparisons between tuples (lists of column values) rather than comparisons between scalar values. Placement of rows in RANGE COLUMNS partitions is also based on comparisons between tuples; this is discussed further later in this section.

- RANGE COLUMNS partitioning columns are not restricted to integer columns; string, DATE and DATETIME columns can also be used as partitioning columns. (See Section 23.2.3, “COLUMNS Partitioning”, for details.)

The basic syntax for creating a table partitioned by RANGE COLUMNS is shown here:

```
CREATE TABLE table_name
PARTITIONED BY RANGE COLUMNS(column_list) (
  PARTITION partition_name VALUES LESS THAN (value_list)[,]
  PARTITION partition_name VALUES LESS THAN (value_list)][,)

column_list: column_name[, column_name][, ...]

value_list: 4105
```
value[, value[, ...]]

<table>
<thead>
<tr>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>Not all CREATE TABLE options that can be used when creating partitioned tables are shown here. For complete information, see Section 13.1.20, “CREATE TABLE Statement”.</td>
</tr>
</tbody>
</table>

In the syntax just shown, \textit{column\_list} is a list of one or more columns (sometimes called a \textit{partitioning column list}), and \textit{value\_list} is a list of values (that is, it is a \textit{partition definition value list}). A \textit{value\_list} must be supplied for each partition definition, and each \textit{value\_list} must have the same number of values as the \textit{column\_list} has columns. Generally speaking, if you use \(N\) columns in the \textit{COLUMNS} clause, then each \textit{VALUES LESS THAN} clause must also be supplied with a list of \(N\) values.

The elements in the partitioning column list and in the value list defining each partition must occur in the same order. In addition, each element in the value list must be of the same data type as the corresponding element in the column list. However, the order of the column names in the partitioning column list and the value lists does not have to be the same as the order of the table column definitions in the main part of the CREATE TABLE statement. As with table partitioned by \textit{RANGE}, you can use \texttt{MAXVALUE} to represent a value such that any legal value inserted into a given column is always less than this value. Here is an example of a CREATE TABLE statement that helps to illustrate all of these points:

```sql
mysql> CREATE TABLE rcx (
    -> a INT,
    -> b INT,
    -> c CHAR(3),
    -> d INT
    -> )
    -> PARTITION BY RANGE COLUMNS(a,d,c) (
    -> PARTITION p0 VALUES LESS THAN (5,10,'ggg'),
    -> PARTITION p1 VALUES LESS THAN (10,20,'mmm'),
    -> PARTITION p2 VALUES LESS THAN (15,30,'sss'),
    -> PARTITION p3 VALUES LESS THAN (MAXVALUE,MAXVALUE,MAXVALUE)
    -> )
Query OK, 0 rows affected (0.15 sec)
```

Table \textit{rcx} contains the columns \texttt{a, b, c, d}. The partitioning column list supplied to the \textit{COLUMNS} clause uses 3 of these columns, in the order \texttt{a, d, c}. Each value list used to define a partition contains 3 values in the same order; that is, each value list tuple has the form \((\text{INT, INT, CHAR}(3))\), which corresponds to the data types used by columns \texttt{a, d, and c} (in that order).

Placement of rows into partitions is determined by comparing the tuple from a row to be inserted that matches the column list in the \textit{COLUMNS} clause with the tuples used in the \textit{VALUES LESS THAN} clauses to define partitions of the table. Because we are comparing tuples (that is, lists or sets of values) rather than scalar values, the semantics of \textit{VALUES LESS THAN} as used with \textit{RANGE COLUMNS} partitions differs somewhat from the case with simple \textit{RANGE} partitions. In \textit{RANGE} partitioning, a row generating an expression value that is equal to a limiting value in a \textit{VALUES LESS THAN} is never placed in the corresponding partition; however, when using \textit{RANGE COLUMNS} partitioning, it is sometimes possible for a row whose partitioning column list's first element is equal in value to the that of the first element in a \textit{VALUES LESS THAN} value list to be placed in the corresponding partition.

Consider the \textit{RANGE} partitioned table created by this statement:

```sql
CREATE TABLE r1 {
    a INT,
    b INT
} PARTITION BY RANGE (a) (
    PARTITION p0 VALUES LESS THAN (5),
    PARTITION p1 VALUES LESS THAN (MAXVALUE)
);```
If we insert 3 rows into this table such that the column value for \( a \) is 5 for each row, all 3 rows are stored in partition \( p1 \) because the \( a \) column value is in each case not less than 5, as we can see by executing the proper query against the `INFORMATION_SCHEMA.PARTITIONS` table:

```sql
mysql> INSERT INTO r1 VALUES (5,10), (5,11), (5,12);
Query OK, 3 rows affected (0.00 sec)
Records: 3  Duplicates: 0  Warnings: 0

mysql> SELECT PARTITION_NAME,TABLE_ROWS
    -> FROM INFORMATION_SCHEMA.PARTITIONS
    -> WHERE TABLE_NAME = 'r1';
+----------------+------------+
| PARTITION_NAME | TABLE_ROWS |
+----------------+------------+
| p0             |          2 |
| p1             |          1 |
+----------------+------------+
2 rows in set (0.00 sec)
```

Now consider a similar table \( rc1 \) that uses `RANGE COLUMNS` partitioning with both columns \( a \) and \( b \) referenced in the `COLUMNS` clause, created as shown here:

```sql
CREATE TABLE rc1 (
    a INT,
    b INT
) PARTITION BY RANGE COLUMNS(a, b) (
    PARTITION p0 VALUES LESS THAN (5, 12),
    PARTITION p3 VALUES LESS THAN (MAXVALUE, MAXVALUE)
);
```

If we insert exactly the same rows into \( rc1 \) as we just inserted into \( r1 \), the distribution of the rows is quite different:

```sql
mysql> INSERT INTO rc1 VALUES (5,10), (5,11), (5,12);
Query OK, 3 rows affected (0.00 sec)
Records: 3  Duplicates: 0  Warnings: 0

mysql> SELECT PARTITION_NAME,TABLE_ROWS
    -> FROM INFORMATION_SCHEMA.PARTITIONS
    -> WHERE TABLE_NAME = 'rc1';
+--------------+----------------+------------+
| TABLE_SCHEMA | PARTITION_NAME | TABLE_ROWS |
+--------------+----------------+------------+
| p            | p0             |          2 |
| p            | p1             |          1 |
+--------------+----------------+------------+
2 rows in set (0.00 sec)
```

This is because we are comparing rows rather than scalar values. We can compare the row values inserted with the limiting row value from the `VALUES THAN LESS THAN` clause used to define partition \( p0 \) in table \( rc1 \), like this:

```sql
mysql> SELECT (5,10) < (5,12), (5,11) < (5,12), (5,12) < (5,12);
+-----------------+-----------------+-----------------+
| (5,10) < (5,12) | (5,11) < (5,12) | (5,12) < (5,12) |
+-----------------+-----------------+-----------------+
|               1 |               1 |               0 |
+-----------------+-----------------+-----------------+
1 row in set (0.00 sec)
```

The 2 tuples \( (5,10) \) and \( (5,11) \) evaluate as less than \( (5,12) \), so they are stored in partition \( p0 \). Since 5 is not less than 5 and 12 is not less than 12, \( (5,12) \) is considered not less than \( (5,12) \), and is stored in partition \( p1 \).

The `SELECT` statement in the preceding example could also have been written using explicit row constructors, like this:

```sql
SELECT ROW(5,10) < ROW(5,12), ROW(5,11) < ROW(5,12), ROW(5,12) < ROW(5,12);
```
For more information about the use of row constructors in MySQL, see Section 13.2.11.5, “Row Subqueries”.

For a table partitioned by RANGE COLUMNS using only a single partitioning column, the storing of rows in partitions is the same as that of an equivalent table that is partitioned by RANGE. The following CREATE TABLE statement creates a table partitioned by RANGE COLUMNS using 1 partitioning column:

```sql
CREATE TABLE rx (  
a INT,  
b INT
)  
PARTITION BY RANGE COLUMNS (a) {  
    PARTITION p0 VALUES LESS THAN (5),  
    PARTITION p1 VALUES LESS THAN (MAXVALUE)
};
```

If we insert the rows (5,10), (5,11), and (5,12) into this table, we can see that their placement is the same as it is for the table r we created and populated earlier:

```sql
mysql> INSERT INTO rx VALUES (5,10), (5,11), (5,12);
Query OK, 3 rows affected (0.00 sec)
Records: 3  Duplicates: 0  Warnings: 0
mysql>
```

```sql
mysql> SELECT PARTITION_NAME,TABLE_ROWS  
-> FROM INFORMATION_SCHEMA.PARTITIONS  
-> WHERE TABLE_NAME = 'rx';
+--------------+----------------+------------+
| TABLE_SCHEMA | PARTITION_NAME | TABLE_ROWS |
+--------------+----------------+------------+
| p            | p0             |          0 |
| p            | p1             |          3 |
+--------------+----------------+------------+
```

It is also possible to create tables partitioned by RANGE COLUMNS where limiting values for one or more columns are repeated in successive partition definitions. You can do this as long as the tuples of column values used to define the partitions are strictly increasing. For example, each of the following CREATE TABLE statements is valid:

```sql
CREATE TABLE rc2 (  
a INT,  
b INT
)  
PARTITION BY RANGE COLUMNS(a,b) {  
PARTITION p0 VALUES LESS THAN (0,10),  
PARTITION p1 VALUES LESS THAN (10,20),  
PARTITION p2 VALUES LESS THAN (10,30),  
PARTITION p3 VALUES LESS THAN (10,35),  
PARTITION p4 VALUES LESS THAN (20,40),  
PARTITION p5 VALUES LESS THAN (MAXVALUE,MAXVALUE)
};
```

```sql
CREATE TABLE rc3 (  
a INT,  
b INT
)  
PARTITION BY RANGE COLUMNS(a,b) {  
PARTITION p0 VALUES LESS THAN (0,10),  
PARTITION p1 VALUES LESS THAN (10,20),  
PARTITION p2 VALUES LESS THAN (10,30),  
PARTITION p3 VALUES LESS THAN (10,35),  
PARTITION p4 VALUES LESS THAN (20,40),  
PARTITION p5 VALUES LESS THAN (MAXVALUE,MAXVALUE)
};
```

```sql
CREATE TABLE rc4 (  
a INT,  
b INT
)  
PARTITION BY RANGE COLUMNS(a,b) {  
PARTITION p0 VALUES LESS THAN (0,10),  
PARTITION p1 VALUES LESS THAN (10,20),  
PARTITION p2 VALUES LESS THAN (10,30),  
PARTITION p3 VALUES LESS THAN (10,35),  
PARTITION p4 VALUES LESS THAN (20,40),  
PARTITION p5 VALUES LESS THAN (MAXVALUE,MAXVALUE)
};
```

The following statement also succeeds, even though it might appear at first glance that it would not, since the limiting value of column b is 25 for partition p0 and 20 for partition p1, and the limiting value of column c is 100 for partition p1 and 50 for partition p2:

```sql
CREATE TABLE rc4 (  
a INT,
4108
```
When designing tables partitioned by `RANGE COLUMNS`, you can always test successive partition definitions by comparing the desired tuples using the `mysql` client, like this:

```sql
mysql> SELECT (0,25,50) < (10,20,100), (10,20,100) < (10,30,50);
+-------------------------+--------------------------+
| (0,25,50) < (10,20,100) | (10,20,100) < (10,30,50) |
+-------------------------+--------------------------+
|                       1 |                        1 |
+-------------------------+--------------------------+
1 row in set (0.00 sec)
```

If a `CREATE TABLE` statement contains partition definitions that are not in strictly increasing order, it fails with an error, as shown in this example:

```sql
mysql> CREATE TABLE rcf (a INT, b INT, c INT)
    -> PARTITION BY RANGE COLUMNS(a,b,c) (PARTITION p0 VALUES LESS THAN (0,25,50),
    -> PARTITION p1 VALUES LESS THAN (20,20,100),
    -> PARTITION p2 VALUES LESS THAN (10,30,50),
    -> PARTITION p3 VALUES LESS THAN (MAXVALUE,MAXVALUE,MAXVALUE)
    ->);
ERROR 1493 (HY000): VALUES LESS THAN value must be strictly increasing for each partition
```

When you get such an error, you can deduce which partition definitions are invalid by making “less than” comparisons between their column lists. In this case, the problem is with the definition of partition `p2` because the tuple used to define it is not less than the tuple used to define partition `p3`, as shown here:

```sql
mysql> SELECT (0,25,50) < (20,20,100), (20,20,100) < (10,30,50);
+-------------------------+--------------------------+
| (0,25,50) < (20,20,100) | (20,20,100) < (10,30,50) |
+-------------------------+--------------------------+
|                       1 |                        0 |
+-------------------------+--------------------------+
1 row in set (0.00 sec)
```

It is also possible for `MAXVALUE` to appear for the same column in more than one `VALUES LESS THAN` clause when using `RANGE COLUMNS`. However, the limiting values for individual columns in successive partition definitions should otherwise be increasing, there should be no more than one partition defined where `MAXVALUE` is used as the upper limit for all column values, and this partition definition should appear last in the list of `PARTITION ... VALUES LESS THAN` clauses. In addition, you cannot use `MAXVALUE` as the limiting value for the first column in more than one partition definition.

As stated previously, it is also possible with `RANGE COLUMNS` partitioning to use non-integer columns as partitioning columns. (See Section 23.2.3, “COLUMNS Partitioning”, for a complete listing of these.) Consider a table named `employees` (which is not partitioned), created using the following statement:

```sql
CREATE TABLE employees (id INT NOT NULL, fname VARCHAR(30), lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT NOT NULL,
);```
Using `RANGE COLUMNS` partitioning, you can create a version of this table that stores each row in one of four partitions based on the employee’s last name, like this:

```sql
CREATE TABLE employees_by_lname {
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT NOT NULL,
    store_id INT NOT NULL
} PARTITION BY RANGE COLUMNS (lname)  (
    PARTITION p0 VALUES LESS THAN ('g'),
    PARTITION p1 VALUES LESS THAN ('m'),
    PARTITION p2 VALUES LESS THAN ('t'),
    PARTITION p3 VALUES LESS THAN (MAXVALUE)
);```

Alternatively, you could cause the `employees` table as created previously to be partitioned using this scheme by executing the following `ALTER TABLE` statement:

```sql
ALTER TABLE employees PARTITION BY RANGE COLUMNS (lname)  (
    PARTITION p0 VALUES LESS THAN ('g'),
    PARTITION p1 VALUES LESS THAN ('m'),
    PARTITION p2 VALUES LESS THAN ('t'),
    PARTITION p3 VALUES LESS THAN (MAXVALUE)
);```

Note

Because different character sets and collations have different sort orders, the character sets and collations in use may affect which partition of a table partitioned by `RANGE COLUMNS` a given row is stored in when using string columns as partitioning columns. In addition, changing the character set or collation for a given database, table, or column after such a table is created may cause changes in how rows are distributed. For example, when using a case-sensitive collation, 'and' sorts before 'Andersen', but when using a collation that is case-insensitive, the reverse is true.

For information about how MySQL handles character sets and collations, see Chapter 10, Character Sets, Collations, Unicode.

Similarly, you can cause the `employees` table to be partitioned in such a way that each row is stored in one of several partitions based on the decade in which the corresponding employee was hired using the `ALTER TABLE` statement shown here:

```sql
ALTER TABLE employees PARTITION BY RANGE COLUMNS (hired)  (
    PARTITION p0 VALUES LESS THAN ('1970-01-01'),
    PARTITION p1 VALUES LESS THAN ('1980-01-01'),
    PARTITION p2 VALUES LESS THAN ('1990-01-01'),
    PARTITION p3 VALUES LESS THAN ('2000-01-01'),
    PARTITION p4 VALUES LESS THAN ('2010-01-01'),
    PARTITION p5 VALUES LESS THAN (MAXVALUE)
);```

See Section 13.1.20, “CREATE TABLE Statement”, for additional information about `PARTITION BY RANGE COLUMNS` syntax.

### 23.2.3.2 LIST COLUMNS partitioning

MySQL 8.0 provides support for `LIST COLUMNS` partitioning. This is a variant of `LIST` partitioning that enables the use of multiple columns as partition keys, and for columns of data types other than
integer types to be used as partitioning columns; you can use string types, DATE, and DATETIME columns. (For more information about permitted data types for COLUMNS partitioning columns, see Section 23.2.3, “COLUMNS Partitioning”.)

Suppose that you have a business that has customers in 12 cities which, for sales and marketing purposes, you organize into 4 regions of 3 cities each as shown in the following table:

<table>
<thead>
<tr>
<th>Region</th>
<th>Cities</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Oskarshamn, Högsby, Mönsterås</td>
</tr>
<tr>
<td>2</td>
<td>Vimmerby, Hultsfred, Västervik</td>
</tr>
<tr>
<td>3</td>
<td>Nässjö, Eksjö, Vetlanda</td>
</tr>
<tr>
<td>4</td>
<td>Uppvidinge, Alvesta, Växjo</td>
</tr>
</tbody>
</table>

With LIST COLUMNS partitioning, you can create a table for customer data that assigns a row to any of 4 partitions corresponding to these regions based on the name of the city where a customer resides, as shown here:

```sql
CREATE TABLE customers_1 (
  first_name VARCHAR(25),
  last_name VARCHAR(25),
  street_1 VARCHAR(30),
  street_2 VARCHAR(30),
  city VARCHAR(15),
  renewal DATE
)
PARTITION BY LIST COLUMNS(city) {
  PARTITION pRegion_1 VALUES IN('Oskarshamn', 'Högsby', 'Mönsterås'),
  PARTITION pRegion_2 VALUES IN('Vimmerby', 'Hultsfred', 'Västervik'),
  PARTITION pRegion_3 VALUES IN('Nässjö', 'Eksjö', 'Vetlanda'),
  PARTITION pRegion_4 VALUES IN('Uppvidinge', 'Alvesta', 'Växjo')
};
```

As with partitioning by RANGE COLUMNS, you do not need to use expressions in the COLUMNS() clause to convert column values into integers. (In fact, the use of expressions other than column names is not permitted with COLUMNS().)

It is also possible to use DATE and DATETIME columns, as shown in the following example that uses the same name and columns as the `customers_1` table shown previously, but employs LIST COLUMNS partitioning based on the renewal column to store rows in one of 4 partitions depending on the week in February 2010 the customer's account is scheduled to renew:

```sql
CREATE TABLE customers_2 (
  first_name VARCHAR(25),
  last_name VARCHAR(25),
  street_1 VARCHAR(30),
  street_2 VARCHAR(30),
  city VARCHAR(15),
  renewal DATE
)
PARTITION BY LIST COLUMNS(renewal) {
  PARTITION pWeek_1 VALUES IN('2010-02-01', '2010-02-02', '2010-02-03', '2010-02-04', '2010-02-05', '2010-02-06', '2010-02-07'),
  PARTITION pWeek_2 VALUES IN('2010-02-08', '2010-02-09', '2010-02-10', '2010-02-11', '2010-02-12', '2010-02-13', '2010-02-14'),
  PARTITION pWeek_3 VALUES IN('2010-02-15', '2010-02-16', '2010-02-17', '2010-02-18', '2010-02-19', '2010-02-20', '2010-02-21'),
  PARTITION pWeek_4 VALUES IN('2010-02-22', '2010-02-23', '2010-02-24', '2010-02-25', '2010-02-26', '2010-02-27', '2010-02-28')
};
```

This works, but becomes cumbersome to define and maintain if the number of dates involved grows very large; in such cases, it is usually more practical to employ RANGE or RANGE COLUMNS partitioning instead. In this case, since the column we wish to use as the partitioning key is a DATE column, we use RANGE COLUMNS partitioning, as shown here:
HASH Partitioning

CREATE TABLE customers_3 (
    first_name VARCHAR(25),
    last_name VARCHAR(25),
    street_1 VARCHAR(30),
    street_2 VARCHAR(30),
    city VARCHAR(15),
    renewal DATE
) PARTITION BY RANGE COLUMNS(renewal) (
    PARTITION pWeek_1 VALUES LESS THAN('2010-02-09'),
    PARTITION pWeek_2 VALUES LESS THAN('2010-02-15'),
    PARTITION pWeek_3 VALUES LESS THAN('2010-02-22'),
    PARTITION pWeek_4 VALUES LESS THAN('2010-03-01')
);

See Section 23.2.3.1, "RANGE COLUMNS partitioning", for more information.

In addition (as with RANGE COLUMNS partitioning), you can use multiple columns in the COLUMNS() clause.

See Section 13.1.20, "CREATE TABLE Statement", for additional information about PARTITION BY LIST COLUMNS() syntax.

23.2.4 HASH Partitioning

Partitioning by HASH is used primarily to ensure an even distribution of data among a predetermined number of partitions. With range or list partitioning, you must specify explicitly which partition a given column value or set of column values should be stored in; with hash partitioning, this decision is taken care of for you, and you need only specify a column value or expression based on a column value to be hashed and the number of partitions into which the partitioned table is to be divided.

To partition a table using HASH partitioning, it is necessary to append to the CREATE TABLE statement a PARTITION BY HASH (expr) clause, where expr is an expression that returns an integer. This can simply be the name of a column whose type is one of MySQL's integer types. In addition, you most likely want to follow this with PARTITIONS num, where num is a positive integer representing the number of partitions into which the table is to be divided.

Note

For simplicity, the tables in the examples that follow do not use any keys. You should be aware that, if a table has any unique keys, every column used in the partitioning expression for this table must be part of every unique key, including the primary key. See Section 23.6.1, "Partitioning Keys, Primary Keys, and Unique Keys", for more information.

The following statement creates a table that uses hashing on the store_id column and is divided into 4 partitions:

CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT,
    store_id INT
) PARTITION BY HASH(store_id)
PARTITIONS 4;

If you do not include a PARTITIONS clause, the number of partitions defaults to 1; using the PARTITIONS keyword without a number following it results in a syntax error.

You can also use an SQL expression that returns an integer for expr. For instance, you might want to partition based on the year in which an employee was hired. This can be done as shown here:
HASH Partitioning

CREATE TABLE employees (  
id INT NOT NULL,  
fname VARCHAR(30),  
lname VARCHAR(30),  
hired DATE NOT NULL DEFAULT '1970-01-01',  
separated DATE NOT NULL DEFAULT '9999-12-31',  
job_code INT,  
store_id INT  
)  
PARTITION BY HASH( YEAR(hired) )  
PARTITIONS 4;

expr must return a nonconstant, nonrandom integer value (in other words, it should be varying but deterministic), and must not contain any prohibited constructs as described in Section 23.6, “Restrictions and Limitations on Partitioning”. You should also keep in mind that this expression is evaluated each time a row is inserted or updated (or possibly deleted); this means that very complex expressions may give rise to performance issues, particularly when performing operations (such as batch inserts) that affect a great many rows at one time.

The most efficient hashing function is one which operates upon a single table column and whose value increases or decreases consistently with the column value, as this allows for “pruning” on ranges of partitions. That is, the more closely that the expression varies with the value of the column on which it is based, the more efficiently MySQL can use the expression for hash partitioning.

For example, where date_col is a column of type DATE, then the expression TO_DAYS(date_col) is said to vary directly with the value of date_col, because for every change in the value of date_col, the value of the expression changes in a consistent manner. The variance of the expression YEAR(date_col) with respect to date_col is not quite as direct as that of TO_DAYS(date_col), because not every possible change in date_col produces an equivalent change in YEAR(date_col). Even so, YEAR(date_col) is a good candidate for a hashing function, because it varies directly with a portion of date_col and there is no possible change in date_col that produces a disproportionate change in YEAR(date_col).

By way of contrast, suppose that you have a column named int_col whose type is INT. Now consider the expression POW(5-int_col,3) + 6. This would be a poor choice for a hashing function because a change in the value of int_col is not guaranteed to produce a proportional change in the value of the expression. Changing the value of int_col by a given amount can produce widely differing changes in the value of the expression. For example, changing int_col from 5 to 6 produces a change of −1 in the value of the expression, but changing the value of int_col from 6 to 7 produces a change of −1 in the expression value.

In other words, the more closely the graph of the column value versus the value of the expression follows a straight line as traced by the equation y=cx where c is some nonzero constant, the better the expression is suited to hashing. This has to do with the fact that the more nonlinear an expression is, the more uneven the distribution of data among the partitions it tends to produce.

In theory, pruning is also possible for expressions involving more than one column value, but determining which of such expressions are suitable can be quite difficult and time-consuming. For this reason, the use of hashing expressions involving multiple columns is not particularly recommended.

When PARTITION BY HASH is used, the storage engine determines which partition of num partitions to use based on the modulus of the result of the expression. In other words, for a given expression expr, the partition in which the record is stored is partition number N, where N = MOD(expr, num). Suppose that table t1 is defined as follows, so that it has 4 partitions:

CREATE TABLE t1 (col1 INT, col2 CHAR(5), col3 DATE)  
PARTITION BY HASH( YEAR(col3) )  
PARTITIONS 4;

If you insert a record into t1 whose col3 value is '2005-09-15', then the partition in which it is stored is determined as follows:

MOD(YEAR('2005-09-01'),4)
MySQL 8.0 also supports a variant of HASH partitioning known as linear hashing which employs a more complex algorithm for determining the placement of new rows inserted into the partitioned table. See Section 23.2.4.1, "LINEAR HASH Partitioning", for a description of this algorithm.

The user-supplied expression is evaluated each time a record is inserted or updated. It may also—depending on the circumstances—be evaluated when records are deleted.

### 23.2.4.1 LINEAR HASH Partitioning

MySQL also supports linear hashing, which differs from regular hashing in that linear hashing utilizes a linear powers-of-two algorithm whereas regular hashing employs the modulus of the hashing function’s value.

Syntactically, the only difference between linear-hash partitioning and regular hashing is the addition of the **LINEAR** keyword in the **PARTITION BY** clause, as shown here:

```sql
CREATE TABLE employees (  
id INT NOT NULL,  
fname VARCHAR(30),  
lname VARCHAR(30),  
hired DATE NOT NULL DEFAULT '1970-01-01',  
separated DATE NOT NULL DEFAULT '9999-12-31',  
job_code INT,  
store_id INT  
)  
PARTITION BY LINEAR HASH( YEAR(hired) )  
PARTITIONS 4;  
```

Given an expression $expr$, the partition in which the record is stored when linear hashing is used is partition number $N$ from among $num$ partitions, where $N$ is derived according to the following algorithm:

1. Find the next power of 2 greater than $num$. We call this value $V$; it can be calculated as:

   $$V = \text{POWER}(2, \text{CEILING}(\log(2, num)))$$

   (Suppose that $num$ is 13. Then $\log(2,13)$ is 3.7004397181411. $\text{CEILING}(3.7004397181411)$ is 4, and $V = \text{POWER}(2,4)$, which is 16.)

2. Set $N = F(column_list) \& (V - 1)$.

3. While $N >= num$:
   - Set $V = V / 2$
   - Set $N = N \& (V - 1)$

Suppose that the table $t1$, using linear hash partitioning and having 6 partitions, is created using this statement:

```sql
CREATE TABLE t1 (col1 INT, col2 CHAR(5), col3 DATE)  
PARTITION BY LINEAR HASH( YEAR(col3) )  
PARTITIONS 6;  
```

Now assume that you want to insert two records into $t1$ having the $col3$ column values '2003-04-14' and '1998-10-19'. The partition number for the first of these is determined as follows:

$$V = \text{POWER}(2, \text{CEILING}(\log(2,6))) = 8$$

$$N = \text{YEAR}(\text{'2003-04-14'}) \& (8 - 1)$$

$$= 2003 \& 7$$

$$= 3$$

($3 >= 6$ is FALSE: record stored in partition #3)
The number of the partition where the second record is stored is calculated as shown here:

\[
V = 8 \\
N = \text{YEAR('1998-10-19')} & (8 - 1) \\
= 1998 & 7 \\
= 6 \\
(6 \geq 6 \text{ is TRUE: additional step required}) \\
N = 6 & \left(\frac{8}{2}\right) - 1 \\
= 6 & 3 \\
= 2 \\
(2 \geq 6 \text{ is FALSE: record stored in partition #2})
\]

The advantage in partitioning by linear hash is that the adding, dropping, merging, and splitting of partitions is made much faster, which can be beneficial when dealing with tables containing extremely large amounts (terabytes) of data. The disadvantage is that data is less likely to be evenly distributed between partitions as compared with the distribution obtained using regular hash partitioning.

### 23.2.5 KEY Partitioning

Partitioning by key is similar to partitioning by hash, except that where hash partitioning employs a user-defined expression, the hashing function for key partitioning is supplied by the MySQL server. NDB Cluster uses \( \text{MD5()} \) for this purpose; for tables using other storage engines, the server employs its own internal hashing function.

The syntax rules for \texttt{CREATE TABLE ... PARTITION BY KEY} are similar to those for creating a table that is partitioned by hash. The major differences are listed here:

- \texttt{KEY} is used rather than \texttt{HASH}.
- \texttt{KEY} takes only a list of zero or more column names. Any columns used as the partitioning key must comprise part or all of the table’s primary key, if the table has one. Where no column name is specified as the partitioning key, the table’s primary key is used, if there is one. For example, the following \texttt{CREATE TABLE} statement is valid in MySQL 8.0:

```sql
CREATE TABLE k1 ( 
    id INT NOT NULL PRIMARY KEY, 
    name VARCHAR(20) 
) PARTITION BY KEY() 
PARTITIONS 2;
```

If there is no primary key but there is a unique key, then the unique key is used for the partitioning key:

```sql
CREATE TABLE k1 ( 
    id INT NOT NULL, 
    name VARCHAR(20), 
    UNIQUE KEY (id) 
) PARTITION BY KEY() 
PARTITIONS 2;
```

However, if the unique key column were not defined as \texttt{NOT NULL}, then the previous statement would fail.

In both of these cases, the partitioning key is the \texttt{id} column, even though it is not shown in the output of \texttt{SHOW CREATE TABLE} or in the \texttt{PARTITION_EXPRESSION} column of the \texttt{INFORMATION_SCHEMA.PARTITIONS} table.

Unlike the case with other partitioning types, columns used for partitioning by \texttt{KEY} are not restricted to integer or \texttt{NULL} values. For example, the following \texttt{CREATE TABLE} statement is valid:

```sql
CREATE TABLE tml ( 
```
The preceding statement would not be valid, were a different partitioning type to be specified. (In this case, simply using `PARTITION BY KEY()` would also be valid and have the same effect as `PARTITION BY KEY(s1)`, since `s1` is the table’s primary key.)

For additional information about this issue, see Section 23.6, “Restrictions and Limitations on Partitioning”.

Columns with index prefixes are not supported in partitioning keys. This means that `CHAR`, `VARCHAR`, `BINARY`, and `VARBINARY` columns can be used in a partitioning key, as long as they do not employ prefixes; because a prefix must be specified for `BLOB` and `TEXT` columns in index definitions, it is not possible to use columns of these two types in partitioning keys. Prior to MySQL 8.0.21, columns using prefixes were permitted when creating, altering, or upgrading a partitioned table, even though they were not included in the table's partitioning key; in MySQL 8.0.21 and later, this permissive behavior is deprecated, and the server displays appropriate warnings or errors when one or more such columns are used. See Column index prefixes not supported for key partitioning, for more information and examples.

See Section 23.6, “Restrictions and Limitations on Partitioning”.

Note

Tables using the NDB storage engine are implicitly partitioned by `KEY`, using the table’s primary key as the partitioning key (as with other MySQL storage engines). In the event that the NDB Cluster table has no explicit primary key, the “hidden” primary key generated by the NDB storage engine for each NDB Cluster table is used as the partitioning key.

If you define an explicit partitioning scheme for an NDB table, the table must have an explicit primary key, and any columns used in the partitioning expression must be part of this key. However, if the table uses an “empty” partitioning expression—that is, `PARTITION BY KEY()` with no column references—then no explicit primary key is required.

You can observe this partitioning using the `ndb_desc` utility (with the `-p` option).

Important

For a key-partitioned table, you cannot execute an `ALTER TABLE DROP PRIMARY KEY`, as doing so generates the error `ERROR 1466 (HY000): Field in list of fields for partition function not found in table`. This is not an issue for NDB Cluster tables which are partitioned by `KEY`; in such cases, the table is reorganized using the “hidden” primary key as the table’s new partitioning key. See Chapter 22, MySQL NDB Cluster 8.0.

It is also possible to partition a table by linear key. Here is a simple example:

```sql
CREATE TABLE tk (
    col1 INT NOT NULL,
    col2 CHAR(5),
    col3 DATE
) PARTITION BY LINEAR KEY (col1)
PARTITIONS 3;
```

The `LINEAR` keyword has the same effect on `KEY` partitioning as it does on `HASH` partitioning, with the partition number being derived using a powers-of-two algorithm rather than modulo arithmetic. See Section 23.2.4.1, “LINEAR HASH Partitioning”, for a description of this algorithm and its implications.
23.2.6 Subpartitioning

Subpartitioning—also known as *composite partitioning*—is the further division of each partition in a partitioned table. Consider the following `CREATE TABLE` statement:

```sql
CREATE TABLE ts (id INT, purchased DATE)
    PARTITION BY RANGE( YEAR(purchased) )
    SUBPARTITION BY HASH( TO_DAYS(purchased) )
    SUBPARTITIONS 2 {
        PARTITION p0 VALUES LESS THAN (1990),
        PARTITION p1 VALUES LESS THAN (2000),
        PARTITION p2 VALUES LESS THAN MAXVALUE
    };
```

Table `ts` has 3 `RANGE` partitions. Each of these partitions—`p0`, `p1`, and `p2`—is further divided into 2 subpartitions. In effect, the entire table is divided into $3 \times 2 = 6$ partitions. However, due to the action of the `PARTITION BY RANGE` clause, the first 2 of these store only those records with a value less than 1990 in the `purchased` column.

It is possible to subpartition tables that are partitioned by `RANGE` or `LIST`. Subpartitions may use either `HASH` or `KEY` partitioning. This is also known as *composite partitioning*.

**Note**

`SUBPARTITION BY HASH` and `SUBPARTITION BY KEY` generally follow the same syntax rules as `PARTITION BY HASH` and `PARTITION BY KEY`, respectively. An exception to this is that `SUBPARTITION BY KEY` (unlike `PARTITION BY KEY`) does not currently support a default column, so the column used for this purpose must be specified, even if the table has an explicit primary key. This is a known issue which we are working to address; see [Issues with subpartitions](#), for more information and an example.

It is also possible to define subpartitions explicitly using `SUBPARTITION` clauses to specify options for individual subpartitions. For example, a more verbose fashion of creating the same table `ts` as shown in the previous example would be:

```sql
CREATE TABLE ts (id INT, purchased DATE)
    PARTITION BY RANGE( YEAR(purchased) )
    SUBPARTITION BY HASH( TO_DAYS(purchased) )
        ( PARTITION p0 VALUES LESS THAN (1990) {
            SUBPARTITION s0,
            SUBPARTITION s1
        },
        PARTITION p1 VALUES LESS THAN (2000) {
            SUBPARTITION s2,
            SUBPARTITION s3
        },
        PARTITION p2 VALUES LESS THAN MAXVALUE {
            SUBPARTITION s4,
            SUBPARTITION s5
        } );
```

Some syntactical items of note are listed here:

- Each partition must have the same number of subpartitions.
- If you explicitly define any subpartitions using `SUBPARTITION` on any partition of a partitioned table, you must define them all. In other words, the following statement will fail:

```sql
CREATE TABLE ts (id INT, purchased DATE)
    PARTITION BY RANGE( YEAR(purchased) )
    SUBPARTITION BY HASH( TO_DAYS(purchased) )
        ( PARTITION p0 VALUES LESS THAN (1990) {
            SUBPARTITION s0,
            SUBPARTITION s1
        });
```
SUBPARTITION s0,
    SUBPARTITION s1
),
PARTITION p1 VALUES LESS THAN (2000),
PARTITION p2 VALUES LESS THAN MAXVALUE {
    SUBPARTITION s2,
    SUBPARTITION s3
};

This statement would still fail even if it used **SUBPARTITIONS 2**.

- Each **SUBPARTITION** clause must include (at a minimum) a name for the subpartition. Otherwise, you may set any desired option for the subpartition or allow it to assume its default setting for that option.

- Subpartition names must be unique across the entire table. For example, the following **CREATE TABLE** statement is valid:

```sql
CREATE TABLE ts (id INT, purchased DATE)
    PARTITION BY RANGE( YEAR(purchased) )
    SUBPARTITION BY HASH( TO_DAYS(purchased) ) {
        PARTITION p0 VALUES LESS THAN (1990) {
            SUBPARTITION s0, 
            SUBPARTITION s1
        },
        PARTITION p1 VALUES LESS THAN (2000) {
            SUBPARTITION s2, 
            SUBPARTITION s3
        },
        PARTITION p2 VALUES LESS THAN MAXVALUE {
            SUBPARTITION s4, 
            SUBPARTITION s5
        }
    };
```

### 23.2.7 How MySQL Partitioning Handles NULL

Partitioning in MySQL does nothing to disallow **NULL** as the value of a partitioning expression, whether it is a column value or the value of a user-supplied expression. Even though it is permitted to use **NULL** as the value of an expression that must otherwise yield an integer, it is important to keep in mind that **NULL** is not a number. MySQL’s partitioning implementation treats **NULL** as being less than any non-**NULL** value, just as **ORDER BY** does.

This means that treatment of **NULL** varies between partitioning of different types, and may produce behavior which you do not expect if you are not prepared for it. This being the case, we discuss in this section how each MySQL partitioning type handles **NULL** values when determining the partition in which a row should be stored, and provide examples for each.

**Handling of NULL with RANGE partitioning.** If you insert a row into a table partitioned by **RANGE** such that the column value used to determine the partition is **NULL**, the row is inserted into the lowest partition. Consider these two tables in a database named **p**, created as follows:

```sql
mysql> CREATE TABLE t1 (-> c1 INT, 
    -> c2 VARCHAR(20)
    )
    -> )
    -> PARTITION BY RANGE(c1) {
    -> PARTITION p0 VALUES LESS THAN (0),
    -> PARTITION p1 VALUES LESS THAN (10),
    -> PARTITION p2 VALUES LESS THAN MAXVALUE
    -> );
Query OK, 0 rows affected (0.09 sec)
```

```sql
mysql> CREATE TABLE t2 (-> c1 INT, 
    -> c2 VARCHAR(20)
    );
```
How MySQL Partitioning Handles NULL

You can see the partitions created by these two `CREATE TABLE` statements using the following query against the `PARTITIONS` table in the `INFORMATION_SCHEMA` database:

```
mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
    > FROM INFORMATION_SCHEMA.PARTITIONS
    > WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME LIKE 't_';
```

You can see which partitions are used to store the inserted rows by rerunning the previous query against `INFORMATION_SCHEMA.PARTITIONS` and inspecting the output:

```
mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
    > FROM INFORMATION_SCHEMA.PARTITIONS
    > WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME LIKE 't_';
```
You can also demonstrate that these rows were stored in the lowest-numbered partition of each table by dropping these partitions, and then re-running the `SELECT` statements:

```
mysql> ALTER TABLE t1 DROP PARTITION p0;
Query OK, 0 rows affected (0.16 sec)

mysql> ALTER TABLE t2 DROP PARTITION p0;
Query OK, 0 rows affected (0.16 sec)

mysql> SELECT * FROM t1;
Empty set (0.00 sec)

mysql> SELECT * FROM t2;
Empty set (0.00 sec)
```

(For more information on `ALTER TABLE ... DROP PARTITION`, see Section 13.1.9, “ALTER TABLE Statement”.)

**NULL** is also treated in this way for partitioning expressions that use SQL functions. Suppose that we define a table using a `CREATE TABLE` statement such as this one:

```
CREATE TABLE tndate (id INT, dt DATE)
PARTITION BY RANGE( YEAR(dt) ) (
  PARTITION p0 VALUES LESS THAN (1990),
  PARTITION p1 VALUES LESS THAN (2000),
  PARTITION p2 VALUES LESS THAN MAXVALUE);
```

As with other MySQL functions, `YEAR(NULL)` returns NULL. A row with a `dt` column value of NULL is treated as though the partitioning expression evaluated to a value less than any other value, and so is inserted into partition `p0`.

**Handling of NULL with LIST partitioning.** A table that is partitioned by **LIST** admits NULL values if and only if one of its partitions is defined using that value-list that contains NULL. The converse of this is that a table partitioned by **LIST** which does not explicitly use NULL in a value list rejects rows resulting in a NULL value for the partitioning expression, as shown in this example:

```
mysql> CREATE TABLE ts1 (->
  c1 INT,
  c2 VARCHAR(20)
  )
-> PARTITION BY LIST(c1) (
->  PARTITION p0 VALUES IN (0, 3, 6),
->  PARTITION p1 VALUES IN (1, 4, 7),
->  PARTITION p2 VALUES IN (2, 5, 8)
); Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO ts1 VALUES (9, 'mothra');
ERROR 1504 (HY000): Table has no partition for value 9

mysql> INSERT INTO ts1 VALUES (NULL, 'mothra');
ERROR 1504 (HY000): Table has no partition for value NULL
```

Only rows having a `c1` value between 0 and 8 inclusive can be inserted into `ts1`. NULL falls outside this range, just like the number 9. We can create tables `ts2` and `ts3` having value lists containing NULL, as shown here:

```
mysql> CREATE TABLE ts2 (->
  c1 INT,
  c2 VARCHAR(20)
  )
```
When defining value lists for partitioning, you can (and should) treat `NULL` just as you would any other value. For example, both `VALUES IN (NULL)` and `VALUES IN (1, 4, 7, NULL)` are valid, as are `VALUES IN (1, NULL, 4, 7)`, `VALUES IN (NULL, 1, 4, 7)`, and so on. You can insert a row having `NULL` for column `c1` into each of the tables `ts2` and `ts3`:

```
mysql> INSERT INTO ts2 VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)
```

```
mysql> INSERT INTO ts3 VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)
```

By issuing the appropriate query against `INFORMATION_SCHEMA.PARTITIONS`, you can determine which partitions were used for storing the rows just inserted (we assume, as in the previous examples, that the partitioned tables were created in the `p` database):

```
mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
    > FROM INFORMATION_SCHEMA.PARTITIONS
    > WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME LIKE 'ts_';
+------------+----------------+------------+----------------+-------------+
| TABLE_NAME | PARTITION_NAME | TABLE_ROWS | AVG_ROW_LENGTH | DATA_LENGTH |
+------------+----------------+------------+----------------+-------------+
| ts2        | p0             |          0 |              0 |           0 |
| ts2        | p1             |          0 |              0 |           0 |
| ts2        | p2             |          0 |              0 |           0 |
| ts2        | p3             |          1 |             20 |          20 |
| ts3        | p0             |          0 |              0 |           0 |
| ts3        | p1             |          1 |             20 |          20 |
| ts3        | p2             |          0 |              0 |           0 |
+------------+----------------+------------+----------------+-------------+
7 rows in set (0.01 sec)
```

As shown earlier in this section, you can also verify which partitions were used for storing the rows by deleting these partitions and then performing a `SELECT`.

Handling of `NULL` with `HASH` and `KEY` partitioning. `NULL` is handled somewhat differently for tables partitioned by `HASH` or `KEY`. In these cases, any partition expression that yields a `NULL` value is treated as though its return value were zero. We can verify this behavior by examining the effects on the file system of creating a table partitioned by `HASH` and populating it with a record containing appropriate values. Suppose that you have a table `th` (also in the `p` database) created using the following statement:

```
mysql> CREATE TABLE th (
    > c1 INT,
    > c2 VARCHAR(20)
    > )
    > PARTITION BY HASH(c1)
    > PARTITIONS 2;
Query OK, 0 rows affected (0.00 sec)
```
The partitions belonging to this table can be viewed using the query shown here:

```
mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
    > FROM INFORMATION_SCHEMA.PARTITIONS
    > WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME = 'th';
```

<table>
<thead>
<tr>
<th>TABLE_NAME</th>
<th>PARTITION_NAME</th>
<th>TABLE_ROWS</th>
<th>AVG_ROW_LENGTH</th>
<th>DATA_LENGTH</th>
</tr>
</thead>
<tbody>
<tr>
<td>th</td>
<td>p0</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>th</td>
<td>p1</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

2 rows in set (0.00 sec)

**TABLE_ROWS** for each partition is 0. Now insert two rows into **th** whose **c1** column values are **NULL** and 0, and verify that these rows were inserted, as shown here:

```
mysql> INSERT INTO th VALUES (NULL, 'mothra'), (0, 'gigan');
Query OK, 1 row affected (0.00 sec)
```

```
mysql> SELECT * FROM th;
+------+---------+
| c1   | c2      |
+------+---------+
| NULL | mothra  |
| 0    | gigan   |
+------+---------+
2 rows in set (0.01 sec)
```

Recall that for any integer **N**, the value of **NULL MOD N** is always **NULL**. For tables that are partitioned by **HASH** or **KEY**, this result is treated for determining the correct partition as 0. Checking the **INFORMATION_SCHEMA.PARTITIONS** table once again, we can see that both rows were inserted into partition **p0**:

```
mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
    > FROM INFORMATION_SCHEMA.PARTITIONS
    > WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME = 'th';
```

<table>
<thead>
<tr>
<th>TABLE_NAME</th>
<th>PARTITION_NAME</th>
<th>TABLE_ROWS</th>
<th>AVG_ROW_LENGTH</th>
<th>DATA_LENGTH</th>
</tr>
</thead>
<tbody>
<tr>
<td>th</td>
<td>p0</td>
<td>2</td>
<td>20</td>
<td>20</td>
</tr>
<tr>
<td>th</td>
<td>p1</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

2 rows in set (0.00 sec)

By repeating the last example using **PARTITION BY KEY** in place of **PARTITION BY HASH** in the definition of the table, you can verify that **NULL** is also treated like 0 for this type of partitioning.

### 23.3 Partition Management

There are a number of ways using SQL statements to modify partitioned tables; it is possible to add, drop, redefine, merge, or split existing partitions using the partitioning extensions to the **ALTER TABLE** statement. There are also ways to obtain information about partitioned tables and partitions. We discuss these topics in the sections that follow.

- For information about partition management in tables partitioned by **RANGE** or **LIST**, see Section 23.3.1, “Management of RANGE and LIST Partitions”.

- For a discussion of managing **HASH** and **KEY** partitions, see Section 23.3.2, “Management of HASH and KEY Partitions”.

- See Section 23.3.5, “Obtaining Information About Partitions”, for a discussion of mechanisms provided in MySQL 8.0 for obtaining information about partitioned tables and partitions.

- For a discussion of performing maintenance operations on partitions, see Section 23.3.4, “Maintenance of Partitions”.
Note
All partitions of a partitioned table must have the same number of subpartitions; it is not possible to change the subpartitioning once the table has been created.

To change a table’s partitioning scheme, it is necessary only to use the ALTER TABLE statement with a partition_options option, which has the same syntax as that as used with CREATE TABLE for creating a partitioned table; this option (also) always begins with the keywords PARTITION BY. Suppose that the following CREATE TABLE statement was used to create a table that is partitioned by range:

```sql
CREATE TABLE trb3 (id INT, name VARCHAR(50), purchased DATE)
PARTITION BY RANGE( YEAR(purchased) ) (
  PARTITION p0 VALUES LESS THAN (1990),
  PARTITION p1 VALUES LESS THAN (1995),
  PARTITION p2 VALUES LESS THAN (2000),
  PARTITION p3 VALUES LESS THAN (2005)
);
```

To repartition this table so that it is partitioned by key into two partitions using the id column value as the basis for the key, you can use this statement:

```sql
ALTER TABLE trb3 PARTITION BY KEY(id) PARTITIONS 2;
```

This has the same effect on the structure of the table as dropping the table and re-creating it using

```sql
CREATE TABLE trb3 PARTITION BY KEY(id) PARTITIONS 2;
```

`ALTER TABLE ... ENGINE = ...` changes only the storage engine used by the table, and leaves the table's partitioning scheme intact. The statement succeeds only if the target storage engine provides partitioning support. You can use `ALTER TABLE ... REMOVE PARTITIONING` to remove a table's partitioning; see Section 13.1.9, “ALTER TABLE Statement”.

Important
Only a single PARTITION BY, ADD PARTITION, DROP PARTITION, REORGANIZE PARTITION, or COALESCE PARTITION clause can be used in a given ALTER TABLE statement. If you (for example) wish to drop a partition and reorganize a table’s remaining partitions, you must do so in two separate ALTER TABLE statements (one using DROP PARTITION and then a second one using REORGANIZE PARTITION).

You can delete all rows from one or more selected partitions using `ALTER TABLE ... TRUNCATE PARTITION`.

23.3.1 Management of RANGE and LIST Partitions

Adding and dropping of range and list partitions are handled in a similar fashion, so we discuss the management of both sorts of partitioning in this section. For information about working with tables that are partitioned by hash or key, see Section 23.3.2, “Management of HASH and KEY Partitions”.

Dropping a partition from a table that is partitioned by either RANGE or by LIST can be accomplished using the ALTER TABLE statement with the DROP PARTITION option. Suppose that you have created a table that is partitioned by range and then populated with 10 records using the following CREATE TABLE and INSERT statements:

```sql
mysql> CREATE TABLE tr (id INT, name VARCHAR(50), purchased DATE)
     -> PARTITION BY RANGE( YEAR(purchased) ) (
     ->   PARTITION p0 VALUES LESS THAN (1990),
     ->   PARTITION p1 VALUES LESS THAN (1995),
     ->   PARTITION p2 VALUES LESS THAN (2000),
     ->   PARTITION p3 VALUES LESS THAN (2005),
     ->   PARTITION p4 VALUES LESS THAN (2010),
     ->   PARTITION p5 VALUES LESS THAN (2015)
```
You can see which items should have been inserted into partition p2 as shown here:

```
mysql> SELECT * FROM tr
WHERE purchased BETWEEN '1995-01-01' AND '1999-12-31';
+------+-------------+------------+
<table>
<thead>
<tr>
<th>id</th>
<th>name</th>
<th>purchased</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>alarm clock</td>
<td>1997-11-05</td>
</tr>
<tr>
<td>10</td>
<td>lava lamp</td>
<td>1998-12-25</td>
</tr>
</tbody>
</table>
+------+-------------+------------+
2 rows in set (0.00 sec)
```

You can also get this information using partition selection, as shown here:

```
mysql> SELECT * FROM tr PARTITION (p2);
+------+-------------+------------+
<table>
<thead>
<tr>
<th>id</th>
<th>name</th>
<th>purchased</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>alarm clock</td>
<td>1997-11-05</td>
</tr>
<tr>
<td>10</td>
<td>lava lamp</td>
<td>1998-12-25</td>
</tr>
</tbody>
</table>
+------+-------------+------------+
2 rows in set (0.00 sec)
```

See Section 23.5, “Partition Selection”, for more information.

To drop the partition named p2, execute the following command:

```
mysql> ALTER TABLE tr DROP PARTITION p2;
Query OK, 0 rows affected (0.03 sec)
```

Note

The NDBCLUSTER storage engine does not support ALTER TABLE ... DROP PARTITION. It does, however, support the other partitioning-related extensions to ALTER TABLE that are described in this chapter.

It is very important to remember that, when you drop a partition, you also delete all the data that was stored in that partition. You can see that this is the case by re-running the previous SELECT query:

```
mysql> SELECT * FROM tr WHERE purchased BETWEEN '1995-01-01' AND '1999-12-31';
Empty set (0.00 sec)
```

Note

DROP PARTITION is supported by native partitioning in-place APIs and may be used with ALGORITHM={COPY|INPLACE}. DROP PARTITION with ALGORITHM=INPLACE deletes data stored in the partition and drops the partition. However, DROP PARTITION with ALGORITHM=COPY or old_alter_table=ON rebuilds the partitioned table and attempts to
move data from the dropped partition to another partition with a compatible

**PARTITION . . . VALUES** definition. Data that cannot be moved to another

partition is deleted.

Because of this, you must have the **DROP** privilege for a table before you can execute **ALTER TABLE . . . DROP PARTITION** on that table.

If you wish to drop all data from all partitions while preserving the table definition and its partitioning

scheme, use the **TRUNCATE TABLE** statement. (See Section 13.1.37, “TRUNCATE TABLE

Statement”.)

If you intend to change the partitioning of a table **without** losing data, use **ALTER TABLE . . .

REORGANIZE PARTITION** instead. See below or in Section 13.1.9, “ALTER TABLE Statement”, for

information about **REORGANIZE PARTITION**.

If you now execute a **SHOW CREATE TABLE** statement, you can see how the partitioning makeup of

the table has been changed:

```sql
mysql> SHOW CREATE TABLE tr\G
*************************** 1. row ***************************
Table: tr
Create Table: CREATE TABLE `tr` (
  `id` int(11) DEFAULT NULL,
  `name` varchar(50) DEFAULT NULL,
  `purchased` date DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=latin1
  /*185100 PARTITION BY RANGE ( YEAR(purchased))
  (PARTITION p0 VALUES LESS THAN (1990) ENGINE = InnoDB,
  PARTITION p1 VALUES LESS THAN (1995) ENGINE = InnoDB,
  PARTITION p3 VALUES LESS THAN (2005) ENGINE = InnoDB,
  PARTITION p4 VALUES LESS THAN (2010) ENGINE = InnoDB,
  PARTITION p5 VALUES LESS THAN (2015) ENGINE = InnoDB) */
1 row in set (0.00 sec)
```

When you insert new rows into the changed table with **purchased** column values between

'1995-01-01' and '2004-12-31' inclusive, those rows will be stored in partition **p3**. You can verify

this as follows:

```sql
mysql> INSERT INTO tr VALUES (11, 'pencil holder', '1995-07-12');
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM tr WHERE purchased
    --> BETWEEN '1995-01-01' AND '2004-12-31';
+------+----------------+------------+
<table>
<thead>
<tr>
<th>id</th>
<th>name</th>
<th>purchased</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>desk organiser</td>
<td>2003-10-15</td>
</tr>
<tr>
<td>11</td>
<td>pencil holder</td>
<td>1995-07-12</td>
</tr>
</tbody>
</table>
+------+----------------+------------+
2 rows in set (0.00 sec)

mysql> ALTER TABLE tr DROP PARTITION p3;
Query OK, 0 rows affected (0.03 sec)

mysql> SELECT * FROM tr WHERE purchased
    --> BETWEEN '1995-01-01' AND '2004-12-31';
Empty set (0.00 sec)
```

The number of rows dropped from the table as a result of **ALTER TABLE . . . DROP PARTITION** is

not reported by the server as it would be by the equivalent **DELETE** query.

Dropping **LIST** partitions uses exactly the same **ALTER TABLE . . . DROP PARTITION** syntax as

used for dropping **RANGE** partitions. However, there is one important difference in the effect this has

on your use of the table afterward: You can no longer insert into the table any rows having any of the

values that were included in the value list defining the deleted partition. (See Section 23.2.2, “LIST

Partitioning”, for an example.)
Management of RANGE and LIST Partitions

To add a new range or list partition to a previously partitioned table, use the ALTER TABLE ... ADD PARTITION statement. For tables which are partitioned by RANGE, this can be used to add a new range to the end of the list of existing partitions. Suppose that you have a partitioned table containing membership data for your organization, which is defined as follows:

```sql
CREATE TABLE members {
  id INT,
  fname VARCHAR(25),
  lname VARCHAR(25),
  dob DATE
} PARTITION BY RANGE( YEAR(dob) ) {
  PARTITION p0 VALUES LESS THAN (1980),
  PARTITION p1 VALUES LESS THAN (1990),
  PARTITION p2 VALUES LESS THAN (2000)
};
```

Suppose further that the minimum age for members is 16. As the calendar approaches the end of 2015, you realize that you will soon be admitting members who were born in 2000 (and later). You can modify the `members` table to accommodate new members born in the years 2000 to 2010 as shown here:

```sql
ALTER TABLE members ADD PARTITION (PARTITION p3 VALUES LESS THAN (2010));
```

With tables that are partitioned by range, you can use ADD PARTITION to add new partitions to the high end of the partitions list only. Trying to add a new partition in this manner between or before existing partitions results in an error as shown here:

```sql
mysql> ALTER TABLE members
> ADD PARTITION {
>   PARTITION n VALUES LESS THAN (1970));
ERROR 1463 (HY000): VALUES LESS THAN value must be strictly increasing for each partition
```

You can work around this problem by reorganizing the first partition into two new ones that split the range between them, like this:

```sql
ALTER TABLE members
  REORGANIZE PARTITION p0 INTO {
    PARTITION n0 VALUES LESS THAN (1970),
    PARTITION n1 VALUES LESS THAN (1980)
};
```

Using SHOW CREATE TABLE you can see that the ALTER TABLE statement has had the desired effect:

```sql
mysql> SHOW CREATE TABLE members\G
*************************** 1. row ***************************
Table: members
Create Table: CREATE TABLE `members` (  `id` int(11) DEFAULT NULL,  `fname` varchar(25) DEFAULT NULL,  `lname` varchar(25) DEFAULT NULL,  `dob` date DEFAULT NULL) ENGINE=InnoDB DEFAULT CHARSET=latin1
1 row in set (0.00 sec)
```

See also Section 13.1.9.1, “ALTER TABLE Partition Operations”.

You can also use ALTER TABLE ... ADD PARTITION to add new partitions to a table that is partitioned by LIST. Suppose a table `tt` is defined using the following CREATE TABLE statement:
CREATE TABLE tt (id INT, data INT)
    PARTITION BY LIST(data) (
        PARTITION p0 VALUES IN (5, 10, 15),
        PARTITION p1 VALUES IN (6, 12, 18)
    );

You can add a new partition in which to store rows having the data column values 7, 14, and 21 as shown:

ALTER TABLE tt ADD PARTITION (PARTITION p2 VALUES IN (7, 14, 21));

Keep in mind that you cannot add a new LIST partition encompassing any values that are already included in the value list of an existing partition. If you attempt to do so, an error will result:

mysql> ALTER TABLE tt ADD PARTITION
    > (PARTITION np VALUES IN (4, 8, 12));
ERROR 1465 (HY000): Multiple definition of same constant »
in list partitioning

Because any rows with the data column value 12 have already been assigned to partition p1, you cannot create a new partition on table tt that includes 12 in its value list. To accomplish this, you could drop p1, and add np and then a new p1 with a modified definition. However, as discussed earlier, this would result in the loss of all data stored in p1—and it is often the case that this is not what you really want to do. Another solution might appear to be to make a copy of the table with the new partitioning and to copy the data into it using CREATE TABLE ... SELECT ..., then drop the old table and rename the new one, but this could be very time-consuming when dealing with a large amounts of data. This also might not be feasible in situations where high availability is a requirement.

You can add multiple partitions in a single ALTER TABLE ... ADD PARTITION statement as shown here:

CREATE TABLE employees (id INT NOT NULL, fname VARCHAR(50) NOT NULL, lname VARCHAR(50) NOT NULL, hired DATE NOT NULL)
    PARTITION BY RANGE( YEAR(hired) ) (
        PARTITION p1 VALUES LESS THAN (1991),
        PARTITION p2 VALUES LESS THAN (1996),
        PARTITION p3 VALUES LESS THAN (2001),
        PARTITION p4 VALUES LESS THAN (2005)
    );

ALTER TABLE employees ADD PARTITION (
    PARTITION p5 VALUES LESS THAN (2010),
    PARTITION p6 VALUES LESS THAN MAXVALUE
);

Fortunately, MySQL’s partitioning implementation provides ways to redefine partitions without losing data. Let us look first at a couple of simple examples involving RANGE partitioning. Recall the members table which is now defined as shown here:

mysql> SHOW CREATE TABLE members\G
*************************** 1. row ***************************
Table: members
Create Table: CREATE TABLE `members` (`id` int(11) DEFAULT NULL,`fname` varchar(25) DEFAULT NULL,`lname` varchar(25) DEFAULT NULL,`dob` date DEFAULT NULL)
    ENGINE=InnoDB DEFAULT CHARSET=latin1 /*150100 PARTITION BY RANGE ( YEAR(dob))
(PARTITION n0 VALUES LESS THAN (1970) ENGINE = InnoDB,"
Suppose that you would like to move all rows representing members born before 1960 into a separate partition. As we have already seen, this cannot be done using ALTER TABLE ... ADD PARTITION. However, you can use another partition-related extension to ALTER TABLE to accomplish this:

```
ALTER TABLE members REORGANIZE PARTITION n0 INTO (
    PARTITION s0 VALUES LESS THAN (1960),
    PARTITION s1 VALUES LESS THAN (1970)
);
```

In effect, this command splits partition p0 into two new partitions s0 and s1. It also moves the data that was stored in p0 into the new partitions according to the rules embodied in the two PARTITION ... VALUES ... clauses, so that s0 contains only those records for which YEAR(dob) is less than 1960 and s1 contains those rows in which YEAR(dob) is greater than or equal to 1960 but less than 1970.

A REORGANIZE PARTITION clause may also be used for merging adjacent partitions. You can reverse the effect of the previous statement on the members table as shown here:

```
ALTER TABLE members REORGANIZE PARTITION s0,s1 INTO (
    PARTITION p0 VALUES LESS THAN (1970)
);
```

No data is lost in splitting or merging partitions using REORGANIZE PARTITION. In executing the above statement, MySQL moves all of the records that were stored in partitions s0 and s1 into partition p0.

The general syntax for REORGANIZE PARTITION is shown here:

```
ALTER TABLE tbl_name REORGANIZE PARTITION partition_list INTO (partition_definitions);
```

Here, tbl_name is the name of the partitioned table, and partition_list is a comma-separated list of names of one or more existing partitions to be changed. partition_definitions is a comma-separated list of new partition definitions, which follow the same rules as for the partition_definitions list used in CREATE TABLE. You are not limited to merging several partitions into one, or to splitting one partition into many, when using REORGANIZE PARTITION. For example, you can reorganize all four partitions of the members table into two, like this:

```
ALTER TABLE members REORGANIZE PARTITION p0,p1,p2,p3 INTO (
    PARTITION m0 VALUES LESS THAN (1980),
    PARTITION m1 VALUES LESS THAN (2000)
);
```

You can also use REORGANIZE PARTITION with tables that are partitioned by LIST. Let us return to the problem of adding a new partition to the list-partitioned tt table and failing because the new partition had a value that was already present in the value-list of one of the existing partitions. We can handle this by adding a partition that contains only nonconflicting values, and then reorganizing the new partition and the existing one so that the value which was stored in the existing one is now moved to the new one:

```
ALTER TABLE tt ADD PARTITION (PARTITION np VALUES IN (4, 8));
ALTER TABLE tt REORGANIZE PARTITION p1,np INTO (
    PARTITION p1 VALUES IN (6, 18),
    PARTITION np VALUES IN (4, 8, 12)
);
```

Here are some key points to keep in mind when using ALTER TABLE ... REORGANIZE PARTITION to repartition tables that are partitioned by RANGE or LIST:
Management of HASH and KEY Partitions

- The **PARTITION** options used to determine the new partitioning scheme are subject to the same rules as those used with a **CREATE TABLE** statement.

A new **RANGE** partitioning scheme cannot have any overlapping ranges; a new **LIST** partitioning scheme cannot have any overlapping sets of values.

- The combination of partitions in the **partition_definitions** list should account for the same range or set of values overall as the combined partitions named in the **partition_list**.

For example, partitions **p1** and **p2** together cover the years 1980 through 1999 in the **members** table used as an example in this section. Any reorganization of these two partitions should cover the same range of years overall.

- For tables partitioned by **RANGE**, you can reorganize only adjacent partitions; you cannot skip range partitions.

For instance, you could not reorganize the example **members** table using a statement beginning with **ALTER TABLE members REORGANIZE PARTITION p0,p2 INTO ...** because **p0** covers the years prior to 1970 and **p2** the years from 1990 through 1999 inclusive, so these are not adjacent partitions. (You cannot skip partition **p1** in this case.)

- You cannot use **REORGANIZE PARTITION** to change the type of partitioning used by the table (for example, you cannot change **RANGE** partitions to **HASH** partitions or the reverse). You also cannot use this statement to change the partitioning expression or column. To accomplish either of these tasks without dropping and re-creating the table, you can use **ALTER TABLE ... PARTITION BY ...**, as shown here:

```sql
ALTER TABLE members
    PARTITION BY HASH( YEAR(dob) )
    PARTITIONS 8;
```

### 23.3.2 Management of HASH and KEY Partitions

Tables which are partitioned by hash or by key are very similar to one another with regard to making changes in a partitioning setup, and both differ in a number of ways from tables which have been partitioned by range or list. For that reason, this section addresses the modification of tables partitioned by hash or by key only. For a discussion of adding and dropping of partitions of tables that are partitioned by range or list, see Section 23.3.1, "Management of RANGE and LIST Partitions".

You cannot drop partitions from tables that are partitioned by **HASH** or **KEY** in the same way that you can from tables that are partitioned by **RANGE** or **LIST**. However, you can merge **HASH** or **KEY** partitions using **ALTER TABLE ... COALESCE PARTITION**. Suppose that a **clients** table containing data about clients is divided into 12 partitions, created as shown here:

```sql
CREATE TABLE clients (
    id INT,
    fname VARCHAR(30),
    lname VARCHAR(30),
    signed DATE
) PARTITION BY HASH( MONTH(signed) )
PARTITIONS 12;
```

To reduce the number of partitions from 12 to 8, execute the following **ALTER TABLE** statement:

```sql
mysql> ALTER TABLE clients COALESCE PARTITION 4;
Query OK, 0 rows affected (0.02 sec)
```

**COALESCE** works equally well with tables that are partitioned by **HASH**, **KEY**, **LINEAR HASH**, or **LINEAR KEY**. Here is an example similar to the previous one, differing only in that the table is partitioned by **LINEAR KEY**:

```sql
mysql> CREATE TABLE clients_lk (

```
23.3.3 Exchanging Partitions and Subpartitions with Tables

In MySQL 8.0, it is possible to exchange a table partition or subpartition with a table using `ALTER TABLE pt EXCHANGE PARTITION p WITH TABLE nt`, where `pt` is the partitioned table and `p` is the partition or subpartition of `pt` to be exchanged with unpartitioned table `nt`, provided that the following statements are true:

1. Table `nt` is not itself partitioned.
2. Table `nt` is not a temporary table.
3. The structures of tables `pt` and `nt` are otherwise identical.
4. Table `nt` contains no foreign key references, and no other table has any foreign keys that refer to `nt`.
5. There are no rows in `nt` that lie outside the boundaries of the partition definition for `p`. This condition does not apply if `WITHOUT VALIDATION` is used.
6. For InnoDB tables, both tables use the same row format. To determine the row format of an InnoDB table, query `INFORMATION_SCHEMA.INNODB_TABLES`.
7. `nt` does not have any partitions that use the `DATA DIRECTORY` option. This restriction is lifted for InnoDB tables in MySQL 8.0.14 and later.

In addition to the `ALTER`, `INSERT`, and `CREATE` privileges usually required for `ALTER TABLE` statements, you must have the `DROP` privilege to perform `ALTER TABLE ... EXCHANGE PARTITION`.

You should also be aware of the following effects of `ALTER TABLE ... EXCHANGE PARTITION`:

- Executing `ALTER TABLE ... EXCHANGE PARTITION` does not invoke any triggers on either the partitioned table or the table to be exchanged.
- Any `AUTO_INCREMENT` columns in the exchanged table are reset.
- The `IGNORE` keyword has no effect when used with `ALTER TABLE ... EXCHANGE PARTITION`.

The number following `COALESCE PARTITION` is the number of partitions to merge into the remainder—in other words, it is the number of partitions to remove from the table.

Attempting to remove more partitions than are in the table results in an error like this one:

```
mysql> ALTER TABLE clients COALESCE PARTITION 18;
ERROR 1478 (HY000): Cannot remove all partitions, use DROP TABLE instead
```

To increase the number of partitions for the `clients` table from 12 to 18, use `ALTER TABLE ... ADD PARTITION` as shown here:

```
ALTER TABLE clients ADD PARTITION PARTITIONS 6;
```
Exchanging Partitions and Subpartitions with Tables

The syntax for `ALTER TABLE ... EXCHANGE PARTITION` is shown here, where `pt` is the partitioned table, `p` is the partition (or subpartition) to be exchanged, and `nt` is the nonpartitioned table to be exchanged with `p`:

```
ALTER TABLE pt
  EXCHANGE PARTITION p
WITH TABLE nt;
```

Optionally, you can append `WITH VALIDATION` or `WITHOUT VALIDATION`. When `WITHOUT VALIDATION` is specified, the `ALTER TABLE ... EXCHANGE PARTITION` operation does not perform any row-by-row validation when exchanging a partition a nonpartitioned table, allowing database administrators to assume responsibility for ensuring that rows are within the boundaries of the partition definition. `WITH VALIDATION` is the default.

One and only one partition or subpartition may be exchanged with one and only one nonpartitioned table in a single `ALTER TABLE EXCHANGE PARTITION` statement. To exchange multiple partitions or subpartitions, use multiple `ALTER TABLE EXCHANGE PARTITION` statements. `EXCHANGE` may not be combined with other `ALTER TABLE` options. The partitioning and (if applicable) subpartitioning used by the partitioned table may be of any type or types supported in MySQL 8.0.

Exchanging a Partition with a Nonpartitioned Table

Suppose that a partitioned table `e` has been created and populated using the following SQL statements:

```
CREATE TABLE e (  
  id INT NOT NULL,  
  fname VARCHAR(30),  
  lname VARCHAR(30) 
)  
PARTITION BY RANGE (id)  
  (PARTITION p0 VALUES LESS THAN (50),  
    PARTITION p1 VALUES LESS THAN (100),  
    PARTITION p2 VALUES LESS THAN (150),  
    PARTITION p3 VALUES LESS THAN (MAXVALUE)  
);  
INSERT INTO e VALUES  
(1669, "Jim", "Smith"),  
(337, "Mary", "Jones"),  
(16, "Frank", "White"),  
(2005, "Linda", "Black");
```

Now we create a nonpartitioned copy of `e` named `e2`. This can be done using the `mysql` client as shown here:

```
mysql> CREATE TABLE e2 LIKE e;
Query OK, 0 rows affected (0.04 sec)
mysql> ALTER TABLE e2 REMOVE PARTITIONING;
Query OK, 0 rows affected (0.07 sec)
Records: 0  Duplicates: 0  Warnings: 0
```

You can see which partitions in table `e` contain rows by querying the `INFORMATION_SCHEMA.PARTITIONS` table, like this:

```
mysql> SELECT PARTITION_NAME, TABLE_ROWS  
    FROM INFORMATION_SCHEMA.PARTITIONS  
    WHERE TABLE_NAME = 'e';
+----------------+------------+
| PARTITION_NAME | TABLE_ROWS |
+----------------+------------+
| p0             |          1 |
| p1             |          0 |
| p2             |          0 |
| p3             |          3 |
```
Exchanging Partitions and Subpartitions with Tables

For partitioned InnoDB tables, the row count given in the TABLE_ROWS column of the INFORMATION_SCHEMA.PARTITIONS table is only an estimated value used in SQL optimization, and is not always exact.

To exchange partition p0 in table e with table e2, you can use ALTER TABLE, as shown here:

```sql
mysql> ALTER TABLE e EXCHANGE PARTITION p0 WITH TABLE e2;
Query OK, 0 rows affected (0.04 sec)
```

More precisely, the statement just issued causes any rows found in the partition to be swapped with those found in the table. You can observe how this has happened by querying the INFORMATION_SCHEMA.PARTITIONS table, as before. The table row that was previously found in partition p0 is no longer present:

```sql
mysql> SELECT PARTITION_NAME, TABLE_ROWS
    > FROM INFORMATION_SCHEMA.PARTITIONS
    > WHERE TABLE_NAME = 'e';
```

```
+----------------+------------+
| PARTITION_NAME | TABLE_ROWS |
+----------------+------------+
| p0             | 0          |
| p1             | 0          |
| p2             | 0          |
| p3             | 3          |
+----------------+------------+
4 rows in set (0.00 sec)
```

If you query table e2, you can see that the “missing” row can now be found there:

```sql
mysql> SELECT * FROM e2;
+----+-------+-------+
| id | fname | lname |
+----+-------+-------+
| 16 | Frank | White |
+----+-------+-------+
```

The table to be exchanged with the partition does not necessarily have to be empty. To demonstrate this, we first insert a new row into table e, making sure that this row is stored in partition p0 by choosing an id column value that is less than 50, and verifying this afterward by querying the PARTITIONS table:

```sql
mysql> INSERT INTO e VALUES (41, "Michael", "Green");
Query OK, 1 row affected (0.05 sec)
```

```sql
mysql> SELECT PARTITION_NAME, TABLE_ROWS
    > FROM INFORMATION_SCHEMA.PARTITIONS
    > WHERE TABLE_NAME = 'e';
```

```
+----------------+------------+
| PARTITION_NAME | TABLE_ROWS |
+----------------+------------+
| p0             | 1          |
| p1             | 0          |
| p2             | 0          |
| p3             | 3          |
+----------------+------------+
4 rows in set (0.00 sec)
```

Now we once again exchange partition p0 with table e2 using the same ALTER TABLE statement as previously:

```sql
mysql> ALTER TABLE e EXCHANGE PARTITION p0 WITH TABLE e2;
Query OK, 0 rows affected (0.28 sec)
```
The output of the following queries shows that the table row that was stored in partition p0 and the table row that was stored in table e2, prior to issuing the `ALTER TABLE` statement, have now switched places:

```
mysql> SELECT * FROM e;
+------+-------+-------+
<table>
<thead>
<tr>
<th>id</th>
<th>fname</th>
<th>lname</th>
</tr>
</thead>
<tbody>
<tr>
<td>16</td>
<td>Frank</td>
<td>White</td>
</tr>
<tr>
<td>1669</td>
<td>Jim</td>
<td>Smith</td>
</tr>
<tr>
<td>337</td>
<td>Mary</td>
<td>Jones</td>
</tr>
<tr>
<td>2005</td>
<td>Linda</td>
<td>Black</td>
</tr>
</tbody>
</table>
+------+-------+-------+
4 rows in set (0.00 sec)
```

```
mysql> SELECT PARTITION_NAME, TABLE_ROWS
    FROM INFORMATION_SCHEMA.PARTITIONS
    WHERE TABLE_NAME = 'e';
+----------------+------------+
<table>
<thead>
<tr>
<th>PARTITION_NAME</th>
<th>TABLE_ROWS</th>
</tr>
</thead>
<tbody>
<tr>
<td>p0</td>
<td>1</td>
</tr>
<tr>
<td>p1</td>
<td>0</td>
</tr>
<tr>
<td>p2</td>
<td>0</td>
</tr>
<tr>
<td>p3</td>
<td>3</td>
</tr>
</tbody>
</table>
+----------------+------------+
4 rows in set (0.00 sec)
```

```
mysql> SELECT * FROM e2;
+----+---------+-------+
<table>
<thead>
<tr>
<th>id</th>
<th>fname</th>
<th>lname</th>
</tr>
</thead>
<tbody>
<tr>
<td>41</td>
<td>Michael</td>
<td>Green</td>
</tr>
</tbody>
</table>
+----+---------+-------+
1 row in set (0.00 sec)
```

**Nonmatching Rows**

You should keep in mind that any rows found in the nonpartitioned table prior to issuing the `ALTER TABLE ... EXCHANGE PARTITION` statement must meet the conditions required for them to be stored in the target partition; otherwise, the statement fails. To see how this occurs, first insert a row into e2 that is outside the boundaries of the partition definition for partition p0 of table e. For example, insert a row with an id column value that is too large; then, try to exchange the table with the partition again:

```
mysql> INSERT INTO e2 VALUES (51, "Ellen", "McDonald");
Query OK, 1 row affected (0.08 sec)
```

```
mysql> ALTER TABLE e EXCHANGE PARTITION p0 WITH TABLE e2;
ERROR 1707 (HY000): Found row that does not match the partition
```

Only the `WITHOUT VALIDATION` option would permit this operation to succeed:

```
mysql> ALTER TABLE e EXCHANGE PARTITION p0 WITH TABLE e2 WITHOUT VALIDATION;
Query OK, 0 rows affected (0.02 sec)
```

When a partition is exchanged with a table that contains rows that do not match the partition definition, it is the responsibility of the database administrator to fix the non-matching rows, which can be performed using `REPAIR TABLE` or `ALTER TABLE ... REPAIR PARTITION`.

**Exchanging Partitions Without Row-By-Row Validation**

To avoid time consuming validation when exchanging a partition with a table that has many rows, it is possible to skip the row-by-row validation step by appending `WITHOUT VALIDATION` to the `ALTER TABLE ... EXCHANGE PARTITION` statement.

The following example compares the difference between execution times when exchanging a partition with a nonpartitioned table, with and without validation. The partitioned table (table e) contains two
partitions of 1 million rows each. The rows in p0 of table e are removed and p0 is exchanged with a nonpartitioned table of 1 million rows. The WITH VALIDATION operation takes 0.74 seconds. By comparison, the WITHOUT VALIDATION operation takes 0.01 seconds.

```sql
# Create a partitioned table with 1 million rows in each partition
CREATE TABLE e (  
id INT NOT NULL,  
fname VARCHAR(30),  
lname VARCHAR(30)  );
PARTITION BY RANGE (id) (  
    PARTITION p0 VALUES LESS THAN (1000001),  
    PARTITION p1 VALUES LESS THAN (2000001),  
);  

mysql> SELECT COUNT(*) FROM e;  
| COUNT(*) |  
+----------+  
| 2000000 |  
+----------+  
1 row in set (0.27 sec)  

# View the rows in each partition
SELECT PARTITION_NAME, TABLE_ROWS FROM INFORMATION_SCHEMA.PARTITIONS WHERE TABLE_NAME = 'e';  
+----------------+-------------+  
| PARTITION_NAME | TABLE_ROWS  |  
+----------------+-------------+  
| p0             | 1000000     |  
| p1             | 1000000     |  
+----------------+-------------+  
2 rows in set (0.00 sec)  

# Create a nonpartitioned table of the same structure and populate it with 1 million rows
CREATE TABLE e2 (  
id INT NOT NULL,  
fname VARCHAR(30),  
lname VARCHAR(30)  );  

mysql> SELECT COUNT(*) FROM e2;  
| COUNT(*) |  
+----------+  
| 1000000 |  
+----------+  
1 row in set (0.24 sec)  

# Create another nonpartitioned table of the same structure and populate it with 1 million rows
CREATE TABLE e3 (  
id INT NOT NULL,  
fname VARCHAR(30),  
lname VARCHAR(30)  );  

mysql> SELECT COUNT(*) FROM e3;  
| COUNT(*) |  
+----------+  
| 1000000 |  
+----------+  
1 row in set (0.25 sec)  

# Drop the rows from p0 of table e
mysql> DELETE FROM e WHERE id < 1000001;  
Query OK, 1000000 rows affected (5.55 sec)  

# Confirm that there are no rows in partition p0
"
Exchanging Partitions and Subpartitions with Tables

```sql
mysql> SELECT PARTITION_NAME, TABLE_ROWS FROM INFORMATION_SCHEMA.PARTITIONS WHERE TABLE_NAME = 'e';
+----------------+------------+
| PARTITION_NAME | TABLE_ROWS |
|----------------+------------+
| p0             |          0 |
| p1             |    1000000 |
+----------------+------------+
2 rows in set (0.00 sec)

# Exchange partition p0 of table e with the table e2 'WITH VALIDATION'
mysql> ALTER TABLE e EXCHANGE PARTITION p0 WITH TABLE e2 WITH VALIDATION;
Query OK, 0 rows affected (0.74 sec)

# Confirm that the partition was exchanged with table e2
mysql> SELECT PARTITION_NAME, TABLE_ROWS FROM INFORMATION_SCHEMA.PARTITIONS WHERE TABLE_NAME = 'e';
+----------------+------------+
| PARTITION_NAME | TABLE_ROWS |
|----------------+------------+
| p0             |    1000000 |
| p1             |    1000000 |
+----------------+------------+
2 rows in set (0.00 sec)

# Once again, drop the rows from p0 of table e
mysql> DELETE FROM e WHERE id < 1000001;
Query OK, 1000000 rows affected (5.55 sec)

# Confirm that there are no rows in partition p0
mysql> SELECT PARTITION_NAME, TABLE_ROWS FROM INFORMATION_SCHEMA.PARTITIONS WHERE TABLE_NAME = 'e';
+----------------+------------+
| PARTITION_NAME | TABLE_ROWS |
|----------------+------------+
| p0             |          0 |
| p1             |    1000000 |
+----------------+------------+
2 rows in set (0.00 sec)

# Exchange partition p0 of table e with the table e3 'WITHOUT VALIDATION'
mysql> ALTER TABLE e EXCHANGE PARTITION p0 WITH TABLE e3 WITHOUT VALIDATION;
Query OK, 0 rows affected (0.01 sec)

# Confirm that the partition was exchanged with table e3
mysql> SELECT PARTITION_NAME, TABLE_ROWS FROM INFORMATION_SCHEMA.PARTITIONS WHERE TABLE_NAME = 'e';
+----------------+------------+
| PARTITION_NAME | TABLE_ROWS |
|----------------+------------+
| p0             |    1000000 |
| p1             |    1000000 |
+----------------+------------+
2 rows in set (0.00 sec)
```

If a partition is exchanged with a table that contains rows that do not match the partition definition, it is the responsibility of the database administrator to fix the non-matching rows, which can be performed using `REPAIR TABLE` or `ALTER TABLE ... REPAIR PARTITION`.

### Exchanging a Subpartition with a Nonpartitioned Table

You can also exchange a subpartition of a subpartitioned table (see Section 23.2.6, “Subpartitioning”) with a nonpartitioned table using an `ALTER TABLE ... EXCHANGE PARTITION` statement. In the following example, we first create a table `es` that is partitioned by `RANGE` and subpartitioned by `KEY`, populate this table as we did table `e`, and then create an empty, nonpartitioned copy `es2` of the table, as shown here:
Exchanging Partitions and Subpartitions with Tables

```sql
CREATE TABLE es (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30)
) PARTITION BY RANGE (id)
SUBPARTITION BY KEY (lname)
SUBPARTITIONS 2 (
  PARTITION p0 VALUES LESS THAN (50),
  PARTITION p1 VALUES LESS THAN (100),
  PARTITION p2 VALUES LESS THAN (150),
  PARTITION p3 VALUES LESS THAN (MAXVALUE)
);
Query OK, 0 rows affected (2.76 sec)
```

```sql
INSERT INTO es VALUES
(1669, "Jim", "Smith"),
(337, "Mary", "Jones"),
(16, "Frank", "White"),
(2005, "Linda", "Black");
Query OK, 4 rows affected (0.04 sec)
```

```sql
CREATE TABLE es2 LIKE es;
Query OK, 0 rows affected (1.27 sec)
```

```sql
ALTER TABLE es2 REMOVE PARTITIONING;
Query OK, 0 rows affected (0.70 sec)
```

Although we did not explicitly name any of the subpartitions when creating table `es`, we can obtain generated names for these by including the `SUBPARTITION_NAME` column of the `PARTITIONS` table from `INFORMATION_SCHEMA` when selecting from that table, as shown here:

```sql
SELECT PARTITION_NAME, SUBPARTITION_NAME, TABLE_ROWS
FROM INFORMATION_SCHEMA.PARTITIONS
WHERE TABLE_NAME = 'es';
```

```plaintext
+----------------+-------------------+------------+
| PARTITION_NAME | SUBPARTITION_NAME | TABLE_ROWS |
|----------------+-------------------+------------|
| p0             | p0sp0             |          1 |
| p0             | p0sp1             |          0 |
| p1             | p1sp0             |          0 |
| p1             | p1sp1             |          0 |
| p2             | p2sp0             |          0 |
| p2             | p2sp1             |          0 |
| p3             | p3sp0             |          3 |
| p3             | p3sp1             |          0 |
+----------------+-------------------+------------+
8 rows in set (0.00 sec)
```

The following `ALTER TABLE` statement exchanges subpartition `p3sp0` in table `es` with the nonpartitioned table `es2`:

```sql
ALTER TABLE es EXCHANGE PARTITION p3sp0 WITH TABLE es2;
Query OK, 0 rows affected (0.29 sec)
```

You can verify that the rows were exchanged by issuing the following queries:

```sql
SELECT PARTITION_NAME, SUBPARTITION_NAME, TABLE_ROWS
FROM INFORMATION_SCHEMA.PARTITIONS
WHERE TABLE_NAME = 'es';
```

```plaintext
+----------------+-------------------+------------+
| PARTITION_NAME | SUBPARTITION_NAME | TABLE_ROWS |
|----------------+-------------------+------------|
| p0             | p0sp0             |          1 |
| p0             | p0sp1             |          0 |
| p1             | p1sp0             |          0 |
| p1             | p1sp1             |          0 |
| p2             | p2sp0             |          0 |
| p2             | p2sp1             |          0 |
| p3             | p3sp0             |          3 |
+----------------+-------------------+------------+
4136
```
Maintenance of Partitions

A number of table and partition maintenance tasks can be carried out on partitioned tables using SQL statements intended for such purposes.

Table maintenance of partitioned tables can be accomplished using the statements `CHECK TABLE`, `OPTIMIZE TABLE`, `ANALYZE TABLE`, and `REPAIR TABLE`, which are supported for partitioned tables.

You can use a number of extensions to `ALTER TABLE` for performing operations of this type on one or more partitions directly, as described in the following list:

- **Rebuilding partitions.** Rebuilds the partition; this has the same effect as dropping all records stored in the partition, then reinserting them. This can be useful for purposes of defragmentation.

  Example:

  ```sql
  ALTER TABLE t1 REBUILD PARTITION p0, p1;
  ```

- **Optimizing partitions.** If you have deleted a large number of rows from a partition or if you have made many changes to a partitioned table with variable-length rows (that is, having `VARCHAR`, `BLOB`,
or TEXT columns), you can use `ALTER TABLE ... OPTIMIZE PARTITION` to reclaim any unused space and to defragment the partition data file.

Example:

```
ALTER TABLE t1 OPTIMIZE PARTITION p0, p1;
```

Using `OPTIMIZE PARTITION` on a given partition is equivalent to running `CHECK PARTITION`, `ANALYZE PARTITION`, and `REPAIR PARTITION` on that partition.

Some MySQL storage engines, including InnoDB, do not support per-partition optimization; in these cases, `ALTER TABLE ... OPTIMIZE PARTITION` analyzes and rebuilds the entire table, and causes an appropriate warning to be issued. (Bug #11751825, Bug #42822) Use `ALTER TABLE ... REBUILD PARTITION` and `ALTER TABLE ... ANALYZE PARTITION` instead, to avoid this issue.

- **Analyzing partitions.** This reads and stores the key distributions for partitions.

  Example:

  ```
  ALTER TABLE t1 ANALYZE PARTITION p3;
  ```

- **Repairing partitions.** This repairs corrupted partitions.

  Example:

  ```
  ALTER TABLE t1 REPAIR PARTITION p0, p1;
  ```

  Normally, `REPAIR PARTITION` fails when the partition contains duplicate key errors. You can use `ALTER IGNORE TABLE` with this option, in which case all rows that cannot be moved due to the presence of duplicate keys are removed from the partition (Bug #16900947).

- **Checking partitions.** You can check partitions for errors in much the same way that you can use `CHECK TABLE` with nonpartitioned tables.

  Example:

  ```
  ALTER TABLE tbl3 CHECK PARTITION p1;
  ```

  This command will tell you whether the data or indexes in partition p1 of table t1 are corrupted. If this is the case, use `ALTER TABLE ... REPAIR PARTITION` to repair the partition.

  Normally, `CHECK PARTITION` fails when the partition contains duplicate key errors. You can use `ALTER IGNORE TABLE` with this option, in which case the statement returns the contents of each row in the partition where a duplicate key violation is found. Only the values for the columns in the partitioning expression for the table are reported. (Bug #16900947)

Each of the statements in the list just shown also supports the keyword `ALL` in place of the list of partition names. Using `ALL` causes the statement to act on all partitions in the table.

You can also truncate partitions using `ALTER TABLE ... TRUNCATE PARTITION`. This statement can be used to delete all rows from one or more partitions in much the same way that `TRUNCATE TABLE` deletes all rows from a table.

```
ALTER TABLE ... TRUNCATE PARTITION ALL
```

23.3.5 Obtaining Information About Partitions

This section discusses obtaining information about existing partitions, which can be done in a number of ways. Methods of obtaining such information include the following:

- Using the `SHOW CREATE TABLE` statement to view the partitioning clauses used in creating a partitioned table.
Obtaining Information About Partitions

- Using the `SHOW TABLE STATUS` statement to determine whether a table is partitioned.

- Querying the `INFORMATION_SCHEMA.PARTITIONS` table.

- Using the statement `EXPLAIN SELECT` to see which partitions are used by a given `SELECT`.

From MySQL 8.0.16, when insertions, deletions, or updates are made to partitioned tables, the binary log records information about the partition and (if any) the subpartition in which the row event took place. A new row event is created for a modification that takes place in a different partition or subpartition, even if the table involved is the same. So if a transaction involves three partitions or subpartitions, three row events are generated. For an update event, the partition information is recorded for both the “before” image and the “after” image. The partition information is displayed if you specify the `-v` or `--verbose` option when viewing the binary log using `mysqlbinlog`. Partition information is only recorded when row-based logging is in use (`binlog_format=ROW`).

As discussed elsewhere in this chapter, `SHOW CREATE TABLE` includes in its output the `PARTITION BY` clause used to create a partitioned table. For example:

```sql
mysql> SHOW CREATE TABLE trb3;
```

```
Table: trb3
Create Table: CREATE TABLE `trb3` (  `id` int(11) DEFAULT NULL,  `name` varchar(50) DEFAULT NULL,  `purchased` date DEFAULT NULL ) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4
*/
*/
PARTITION BY RANGE (YEAR(purchased))
```

The output from `SHOW TABLE STATUS` for partitioned tables is the same as that for nonpartitioned tables, except that the `Create_options` column contains the string `partitioned`. The `Engine` column contains the name of the storage engine used by all partitions of the table. (See Section 13.7.7.36, “SHOW TABLE STATUS Statement”, for more information about this statement.)

You can also obtain information about partitions from `INFORMATION_SCHEMA`, which contains a `PARTITIONS` table. See Section 25.20, “The INFORMATION_SCHEMA PARTITIONS Table”.

It is possible to determine which partitions of a partitioned table are involved in a given `SELECT` query using `EXPLAIN`. The `partitions` column in the `EXPLAIN` output lists the partitions from which records would be matched by the query.

Suppose that a table `trb1` is created and populated as follows:

```sql
CREATE TABLE trb1 (id INT, name VARCHAR(50), purchased DATE) PARTITION BY RANGE(id)
(PARTITION p0 VALUES LESS THAN (3),  PARTITION p1 VALUES LESS THAN (7),  PARTITION p2 VALUES LESS THAN (9),  PARTITION p3 VALUES LESS THAN (11));
```

```sql
```
#### 23.4 Partition Pruning

The optimization known as *partition pruning* is based on a relatively simple concept which can be described as “Do not scan partitions where there can be no matching values”. Suppose a partitioned table `t1` is created by this statement:

```sql
ALTER TABLE t1 ADD PRIMARY KEY (id);
```

You can see which partitions are used in a query such as `SELECT * FROM t1;`, as shown here:

```sql
mysql> EXPLAIN SELECT * FROM t1;
```

<table>
<thead>
<tr>
<th>id</th>
<th>select_type</th>
<th>table</th>
<th>partitions</th>
<th>type</th>
<th>possible_keys</th>
<th>key</th>
<th>key_len</th>
<th>ref</th>
<th>rows</th>
<th>Extra</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>SIMPLE</td>
<td>t1</td>
<td>p0,p1,p2,p3</td>
<td>ALL</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
<td>10</td>
<td>Using filesort</td>
</tr>
</tbody>
</table>

In this case, all four partitions are searched. However, when a limiting condition making use of the partitioning key is added to the query, you can see that only those partitions containing matching values are scanned, as shown here:

```sql
mysql> EXPLAIN SELECT * FROM t1 WHERE id < 5;
```

<table>
<thead>
<tr>
<th>id</th>
<th>select_type</th>
<th>table</th>
<th>partitions</th>
<th>type</th>
<th>possible_keys</th>
<th>key</th>
<th>key_len</th>
<th>ref</th>
<th>rows</th>
<th>Extra</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>SIMPLE</td>
<td>t1</td>
<td>p0,p1</td>
<td>ALL</td>
<td>PRIMARY</td>
<td>PRIMARY</td>
<td>4</td>
<td>NULL</td>
<td>7</td>
<td>Using where</td>
</tr>
</tbody>
</table>

`EXPLAIN` also provides information about keys used and possible keys:

```sql
mysql> ALTER TABLE t1 ADD PRIMARY KEY (id);
```

```
Query OK, 10 rows affected (0.03 sec)
Records: 10  Duplicates: 0  Warnings: 0
```

```sql
mysql> EXPLAIN SELECT * FROM t1 WHERE id < 5;
```

<table>
<thead>
<tr>
<th>id</th>
<th>select_type</th>
<th>table</th>
<th>partitions</th>
<th>type</th>
<th>possible_keys</th>
<th>key</th>
<th>key_len</th>
<th>ref</th>
<th>rows</th>
<th>Extra</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>SIMPLE</td>
<td>t1</td>
<td>p0,p1</td>
<td>range</td>
<td>PRIMARY</td>
<td>PRIMARY</td>
<td>4</td>
<td>NULL</td>
<td>7</td>
<td>Using where</td>
</tr>
</tbody>
</table>

If `EXPLAIN` is used to examine a query against a nonpartitioned table, no error is produced, but the value of the `partitions` column is always `NULL`.

The `rows` column of `EXPLAIN` output displays the total number of rows in the table.

See also Section 13.8.2, “EXPLAIN Statement”.

---

---
CREATE TABLE t1 (  
    fname VARCHAR(50) NOT NULL,  
    lname VARCHAR(50) NOT NULL,  
    region_code TINYINT UNSIGNED NOT NULL,  
    dob DATE NOT NULL  
)  
PARTITION BY RANGE( region_code ) (  
    PARTITION p0 VALUES LESS THAN (64),  
    PARTITION p1 VALUES LESS THAN (128),  
    PARTITION p2 VALUES LESS THAN (192),  
    PARTITION p3 VALUES LESS THAN MAXVALUE  
);

Suppose that you wish to obtain results from a `SELECT` statement such as this one:

```
SELECT fname, lname, region_code, dob  
FROM t1  
WHERE region_code > 125 AND region_code < 130;
```

It is easy to see that none of the rows which ought to be returned are in either of the partitions `p0` or `p3`; that is, we need search only in partitions `p1` and `p2` to find matching rows. By limiting the search, it is possible to expend much less time and effort in finding matching rows than by scanning all partitions in the table. This “cutting away” of unneeded partitions is known as pruning. When the optimizer can make use of partition pruning in performing this query, execution of the query can be an order of magnitude faster than the same query against a nonpartitioned table containing the same column definitions and data.

The optimizer can perform pruning whenever a `WHERE` condition can be reduced to either one of the following two cases:

- `partition_column = constant`
- `partition_column IN (constant1, constant2, ..., constantN)`

In the first case, the optimizer simply evaluates the partitioning expression for the value given, determines which partition contains that value, and scans only this partition. In many cases, the equal sign can be replaced with another arithmetic comparison, including `<`, `>`, `<=`, `>=`, and `<>`. Some queries using `BETWEEN` in the `WHERE` clause can also take advantage of partition pruning. See the examples later in this section.

In the second case, the optimizer evaluates the partitioning expression for each value in the list, creates a list of matching partitions, and then scans only the partitions in this partition list.

`SELECT`, `DELETE`, and `UPDATE` statements support partition pruning. An `INSERT` statement also accesses only one partition per inserted row; this is true even for a table that is partitioned by `HASH` or `KEY` although this is not currently shown in the output of `EXPLAIN`.

Pruning can also be applied to short ranges, which the optimizer can convert into equivalent lists of values. For instance, in the previous example, the `WHERE` clause can be converted to `WHERE region_code IN (126, 127, 128, 129)`. Then the optimizer can determine that the first two values in the list are found in partition `p1`, the remaining two values in partition `p2`, and that the other partitions contain no relevant values and so do not need to be searched for matching rows.

The optimizer can also perform pruning for `WHERE` conditions that involve comparisons of the preceding types on multiple columns for tables that use `RANGE COLUMNS` or `LIST COLUMNS` partitioning.

This type of optimization can be applied whenever the partitioning expression consists of an equality or a range which can be reduced to a set of equalities, or when the partitioning expression represents an increasing or decreasing relationship. Pruning can also be applied for tables partitioned on a `DATE` or `DATETIME` column when the partitioning expression uses the `YEAR()` or `TO_DAYS()` function. Pruning can also be applied for such tables when the partitioning expression uses the `TO_SECONDS()` function.

Suppose that table `t2`, partitioned on a `DATE` column, is created using the statement shown here:

```sql
CREATE TABLE t2 (  
    id INT,  
    dob DATE  
)  
PARTITION BY RANGE( dob ) (  
    PARTITION p0 VALUES LESS THAN (DATE('2000-01-01')),  
    PARTITION p1 VALUES LESS THAN (DATE('2005-01-01')),  
    PARTITION p2 VALUES LESS THAN (DATE('2010-01-01')),  
    PARTITION p3 VALUES LESS THAN MAXVALUE  
);
```

Here are two examples using `DATE` columns:

```
-- Example 1
SELECT dob FROM t2  
WHERE dob > '2005-01-01' AND dob < '2010-01-01';

-- Example 2
SELECT dob FROM t2  
WHERE dob BETWEEN '2010-01-01' AND '2015-01-01';
```
CREATE TABLE t2 (  
  fname VARCHAR(50) NOT NULL,  
  lname VARCHAR(50) NOT NULL,  
  region_code TINYINT UNSIGNED NOT NULL,  
  dob DATE NOT NULL  
)  
PARTITION BY RANGE( YEAR(dob) ) (  
  PARTITION d0 VALUES LESS THAN (1970),  
  PARTITION d1 VALUES LESS THAN (1975),  
  PARTITION d2 VALUES LESS THAN (1980),  
  PARTITION d3 VALUES LESS THAN (1985),  
  PARTITION d4 VALUES LESS THAN (1990),  
  PARTITION d5 VALUES LESS THAN (2000),  
  PARTITION d6 VALUES LESS THAN (2005),  
  PARTITION d7 VALUES LESS THAN MAXVALUE  
);

The following statements using t2 can make of use partition pruning:

SELECT * FROM t2 WHERE dob = '1982-06-23';
UPDATE t2 SET region_code = 8 WHERE dob BETWEEN '1991-02-15' AND '1997-04-25';
DELETE FROM t2 WHERE dob >= '1984-06-21' AND dob <= '1999-06-21'

In the case of the last statement, the optimizer can also act as follows:

1. Find the partition containing the low end of the range.
   YEAR('1984-06-21') yields the value 1984, which is found in partition d3.

2. Find the partition containing the high end of the range.
   YEAR('1999-06-21') evaluates to 1999, which is found in partition d5.

3. Scan only these two partitions and any partitions that may lie between them.
   In this case, this means that only partitions d3, d4, and d5 are scanned. The remaining partitions may be safely ignored (and are ignored).

Important
Invalid DATE and DATETIME values referenced in the WHERE condition of a statement against a partitioned table are treated as NULL. This means that a query such as SELECT * FROM partitioned_table WHERE date_column < '2008-12-00' does not return any values (see Bug #40972).

So far, we have looked only at examples using RANGE partitioning, but pruning can be applied with other partitioning types as well.

Consider a table that is partitioned by LIST, where the partitioning expression is increasing or decreasing, such as the table t3 shown here. (In this example, we assume for the sake of brevity that the region_code column is limited to values between 1 and 10 inclusive.)

CREATE TABLE t3 (  
  fname VARCHAR(50) NOT NULL,  
  lname VARCHAR(50) NOT NULL,  
  region_code TINYINT UNSIGNED NOT NULL,  
  dob DATE NOT NULL  
)  
PARTITION BY LIST(region_code) (  
  PARTITION r0 VALUES IN (1, 3),  
  PARTITION r1 VALUES IN (2, 5, 8),  
  PARTITION r2 VALUES IN (4, 9),  
  PARTITION r3 VALUES IN (6, 7, 10)  
);
Partition Selection

For a statement such as `SELECT * FROM t3 WHERE region_code BETWEEN 1 AND 3`, the optimizer determines in which partitions the values 1, 2, and 3 are found (r0 and r1) and skips the remaining ones (r2 and r3).

For tables that are partitioned by `HASH` or `[LINEAR] KEY`, partition pruning is also possible in cases in which the `WHERE` clause uses a simple `=` relation against a column used in the partitioning expression. Consider a table created like this:

```
CREATE TABLE t4 (
    fname VARCHAR(50) NOT NULL,
    lname VARCHAR(50) NOT NULL,
    region_code TINYINT UNSIGNED NOT NULL,
    dob DATE NOT NULL
) PARTITION BY KEY(region_code)
PARTITIONS 8;
```

A statement that compares a column value with a constant can be pruned:

```
UPDATE t4 WHERE region_code = 7;
```

Pruning can also be employed for short ranges, because the optimizer can turn such conditions into `IN` relations. For example, using the same table `t4` as defined previously, queries such as these can be pruned:

```
SELECT * FROM t4 WHERE region_code > 2 AND region_code < 6;
SELECT * FROM t4 WHERE region_code BETWEEN 3 AND 5;
```

In both these cases, the `WHERE` clause is transformed by the optimizer into `WHERE region_code IN (3, 4, 5)`.

---

**Important**

This optimization is used only if the range size is smaller than the number of partitions. Consider this statement:

```
DELETE FROM t4 WHERE region_code BETWEEN 4 AND 12;
```

The range in the `WHERE` clause covers 9 values (4, 5, 6, 7, 8, 9, 10, 11, 12), but `t4` has only 8 partitions. This means that the `DELETE` cannot be pruned.

When a table is partitioned by `HASH` or `[LINEAR] KEY`, pruning can be used only on integer columns. For example, this statement cannot use pruning because `dob` is a `DATE` column:

```
SELECT * FROM t4 WHERE dob >= '2001-04-14' AND dob <= '2005-10-15';
```

However, if the table stores year values in an `INT` column, then a query having `WHERE year_col >= 2001 AND year_col <= 2005` can be pruned.

Tables using a storage engine that provides automatic partitioning, such as the `NDB` storage engine used by MySQL Cluster can be pruned if they are explicitly partitioned.

### 23.5 Partition Selection

Explicit selection of partitions and subpartitions for rows matching a given `WHERE` condition is supported. Partition selection is similar to partition pruning, in that only specific partitions are checked for matches, but differs in two key respects:

1. The partitions to be checked are specified by the issuer of the statement, unlike partition pruning, which is automatic.
2. Whereas partition pruning applies only to queries, explicit selection of partitions is supported for both queries and a number of DML statements.
SQL statements supporting explicit partition selection are listed here:

- SELECT
- DELETE
- INSERT
- REPLACE
- UPDATE
- LOAD DATA
- LOAD XML.

The remainder of this section discusses explicit partition selection as it applies generally to the statements just listed, and provides some examples.

Explicit partition selection is implemented using a PARTITION option. For all supported statements, this option uses the syntax shown here:

```
PARTITION (partition_names)

partition_names:
  partition_name, ...
```

This option always follows the name of the table to which the partition or partitions belong. `partition_names` is a comma-separated list of partitions or subpartitions to be used. Each name in this list must be the name of an existing partition or subpartition of the specified table; if any of the partitions or subpartitions are not found, the statement fails with an error (`partition 'partition_name' doesn't exist`). Partitions and subpartitions named in `partition_names` may be listed in any order, and may overlap.

When the PARTITION option is used, only the partitions and subpartitions listed are checked for matching rows. This option can be used in a SELECT statement to determine which rows belong to a given partition. Consider a partitioned table named `employees`, created and populated using the statements shown here:

```sql
SET @@SQL_MODE = '';
CREATE TABLE employees  (
  id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  fname VARCHAR(25) NOT NULL,
  lname VARCHAR(25) NOT NULL,
  store_id INT NOT NULL,
  department_id INT NOT NULL
);
PARTITION BY RANGE(id)  (
  PARTITION p0 VALUES LESS THAN (5),
  PARTITION p1 VALUES LESS THAN (10),
  PARTITION p2 VALUES LESS THAN (15),
  PARTITION p3 VALUES LESS THAN MAXVALUE
);
INSERT INTO employees VALUES
  ('', 'Bob', 'Taylor', 3, 2), ('', 'Frank', 'Williams', 1, 2),
  ('', 'Eileen', 'Johnson', 3, 4), ('', 'Jim', 'Smith', 2, 4),
  ('', 'Mary', 'Jones', 1, 1), ('', 'Linda', 'Black', 2, 3),
  ('', 'Ed', 'Jones', 2, 1), ('', 'June', 'Wilson', 3, 1),
  ('', 'Andy', 'Smith', 1, 3), ('', 'Lou', 'Waters', 2, 4),
  ('', 'Jill', 'Stone', 1, 4), ('', 'Roger', 'White', 3, 2),
  ('', 'Howard', 'Andrews', 1, 2), ('', 'Fred', 'Goldberg', 3, 3),
  ('', 'Barbara', 'Brown', 2, 3), ('', 'Alice', 'Rogers', 2, 2),
  ('', 'Mark', 'Morgan', 3, 3), ('', 'Karen', 'Cole', 3, 2);
```

You can see which rows are stored in partition `p1` like this:
Partition Selection

The result is the same as obtained by the query

```
SELECT * FROM employees WHERE id BETWEEN 5 AND 9.
```

To obtain rows from multiple partitions, supply their names as a comma-delimited list. For example, `SELECT * FROM employees PARTITION (p1, p2)` returns all rows from partitions `p1` and `p2` while excluding rows from the remaining partitions.

Any valid query against a partitioned table can be rewritten with a `PARTITION` option to restrict the result to one or more desired partitions. You can use `WHERE` conditions, `ORDER BY` and `LIMIT` options, and so on. You can also use aggregate functions with `HAVING` and `GROUP BY` options. Each of the following queries produces a valid result when run on the `employees` table as previously defined:

```
mysql> SELECT * FROM employees PARTITION (p0, p2) WHERE lname LIKE 'S%';
```

```
+----+-------+-------+----------+---------------+
<table>
<thead>
<tr>
<th>id</th>
<th>fname</th>
<th>lname</th>
<th>store_id</th>
<th>department_id</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
<td>Jim</td>
<td>Smith</td>
<td>2</td>
<td>4</td>
</tr>
<tr>
<td>11</td>
<td>Jill</td>
<td>Stone</td>
<td>1</td>
<td>4</td>
</tr>
</tbody>
</table>
+----+-------+-------+----------+---------------+
2 rows in set (0.00 sec)

mysql> SELECT id, CONCAT(fname, ' ', lname) AS name
    ---> FROM employees PARTITION (p0) ORDER BY lname;
```

```
+----+----------------+
<table>
<thead>
<tr>
<th>id</th>
<th>name</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>Ellen Johnson</td>
</tr>
<tr>
<td>4</td>
<td>Jim Smith</td>
</tr>
<tr>
<td>1</td>
<td>Bob Taylor</td>
</tr>
<tr>
<td>2</td>
<td>Frank Williams</td>
</tr>
</tbody>
</table>
+----+----------------+
4 rows in set (0.06 sec)

mysql> SELECT store_id, COUNT(department_id) AS c
    ---> FROM employees PARTITION (p1,p2,p3)
    ---> GROUP BY store_id HAVING c > 4;
```

```
+----+----------+
<table>
<thead>
<tr>
<th>c</th>
<th>store_id</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>2</td>
</tr>
<tr>
<td>5</td>
<td>3</td>
</tr>
</tbody>
</table>
+----+----------+
2 rows in set (0.00 sec)
```

Statements using partition selection can be employed with tables using any of the supported partitioning types. When a table is created using `LINEAR HASH` or `LINEAR KEY` partitioning and the names of the partitions are not specified, MySQL automatically names the partitions `p0, p1, p2, ..., pN-1`, where `N` is the number of partitions. For subpartitions not explicitly named, MySQL assigns automatically to the subpartitions in each partition `pX` the names `pXsp0, pXsp1, pXsp2, ..., pXspM-1`, where `M` is the number of subpartitions. When executing against this table a `SELECT` (or other SQL statement for which explicit partition selection is allowed), you can use these generated names in a `PARTITION` option, as shown here:

```
mysql> CREATE TABLE employees_sub (id INT NOT NULL AUTO_INCREMENT,
```
Partition Selection

```sql
-> CREATE TABLE employees (
  ->  fname VARCHAR(25) NOT NULL,
  ->  lname VARCHAR(25) NOT NULL,
  ->  store_id INT NOT NULL,
  ->  department_id INT NOT NULL,
  ->  PRIMARY KEY pk (id, lname)
  -> )
  -> PARTITION BY RANGE(id)
  -> SUBPARTITION BY KEY (lname)
  -> SUBPARTITIONS 2 (
  ->  PARTITION p0 VALUES LESS THAN (5),
  ->  PARTITION p1 VALUES LESS THAN (10),
  ->  PARTITION p2 VALUES LESS THAN (15),
  ->  PARTITION p3 VALUES LESS THAN MAXVALUE
  -> );
Query OK, 0 rows affected (1.14 sec)
```

```sql
mysql> INSERT INTO employees_sub # reuse data in employees table
  -> SELECT * FROM employees;
Query OK, 18 rows affected (0.09 sec)
Records: 18  Duplicates: 0  Warnings: 0
```

```sql
mysql> SELECT id, CONCAT(fname, ' ', lname) AS name
  -> FROM employees_sub PARTITION (p2sp1);
```

```
<table>
<thead>
<tr>
<th>id</th>
<th>name</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>Lou Waters</td>
</tr>
<tr>
<td>14</td>
<td>Fred Goldberg</td>
</tr>
</tbody>
</table>
```

2 rows in set (0.00 sec)

You may also use a `PARTITION` option in the `SELECT` portion of an `INSERT ... SELECT` statement, as shown here:

```sql
mysql> CREATE TABLE employees_copy LIKE employees;
Query OK, 0 rows affected (0.28 sec)
```

```sql
mysql> INSERT INTO employees_copy
  -> SELECT * FROM employees PARTITION (p2);
Query OK, 5 rows affected (0.04 sec)
Records: 5  Duplicates: 0  Warnings: 0
```

```sql
mysql> SELECT * FROM employees_copy;
```

```
<table>
<thead>
<tr>
<th>id</th>
<th>fname</th>
<th>lname</th>
<th>store_id</th>
<th>department_id</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>Lou</td>
<td>Waters</td>
<td>2</td>
<td>4</td>
</tr>
<tr>
<td>11</td>
<td>Jill</td>
<td>Stone</td>
<td>1</td>
<td>4</td>
</tr>
<tr>
<td>12</td>
<td>Roger</td>
<td>White</td>
<td>3</td>
<td>2</td>
</tr>
<tr>
<td>13</td>
<td>Howard</td>
<td>Andrews</td>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>14</td>
<td>Fred</td>
<td>Goldberg</td>
<td>3</td>
<td>3</td>
</tr>
</tbody>
</table>
```

5 rows in set (0.00 sec)

Partition selection can also be used with joins. Suppose we create and populate two tables using the statements shown here:

```sql
CREATE TABLE stores (
  id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  city VARCHAR(30) NOT NULL
) PARTITION BY HASH(id)
PARTITIONS 2;
INSERT INTO stores VALUES
('', 'Nambucca'), ('', 'Uranga'),
('', 'Bellingen'), ('', 'Grafton');
```

```sql
CREATE TABLE departments (
  id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  name VARCHAR(30) NOT NULL
)
Partition Selection

```sql
PARTITION BY KEY(id)
PARTITIONS 2;

INSERT INTO departments VALUES
('', 'Sales'), ('', 'Customer Service'),
('', 'Delivery'), ('', 'Accounting');
```

You can explicitly select partitions (or subpartitions, or both) from any or all of the tables in a join. (The `PARTITION` option used to select partitions from a given table immediately follows the name of the table, before all other options, including any table alias.) For example, the following query gets the name, employee ID, department, and city of all employees who work in the Sales or Delivery department (partition `p1` of the `departments` table) at the stores in either of the cities of Nambucca and Bellingen (partition `p0` of the `stores` table):

```sql
mysql> SELECT e.id AS 'Employee ID', CONCAT(e.fname, ' ', e.lname) AS Name,
    > s.city AS City, d.name AS department
    > FROM employees AS e
    > JOIN stores PARTITION (p1) AS s ON e.store_id=s.id
    > JOIN departments PARTITION (p0) AS d ON e.department_id=d.id
    > ORDER BY e.lname;

+-------------+---------------+-----------+------------+
| Employee ID | Name          | City      | department |
+-------------+---------------+-----------+------------+
|          14 | Fred Goldberg | Bellingen | Delivery   |
|           5 | Mary Jones    | Nambucca  | Sales      |
|          17 | Mark Morgan   | Bellingen | Delivery   |
|           9 | Andy Smith    | Nambucca  | Delivery   |
|           8 | June Wilson   | Bellingen | Sales      |
+-------------+---------------+-----------+------------+
5 rows in set (0.00 sec)
```

For general information about joins in MySQL, see Section 13.2.10.2, “JOIN Clause”.

When the `PARTITION` option is used with `DELETE` statements, only those partitions (and subpartitions, if any) listed with the option are checked for rows to be deleted. Any other partitions are ignored, as shown here:

```sql
mysql> SELECT * FROM employees WHERE fname LIKE 'j%';
+----+-------+--------+----------+---------------+
| id | fname | lname  | store_id | department_id |
+----+-------+--------+----------+---------------+
|  4 | Jim   | Smith  |        2 |             4 |
|  8 | June  | Wilson |        3 |             1 |
| 11 | Jill  | Stone  |        1 |             4 |
+----+-------+--------+----------+---------------+
3 rows in set (0.00 sec)

mysql> DELETE FROM employees PARTITION (p0, p1) WHERE fname LIKE 'j%';
Query OK, 2 rows affected (0.09 sec)

mysql> SELECT * FROM employees WHERE fname LIKE 'j%';
+----+-------+--------+----------+---------------+
| id | fname | lname  | store_id | department_id |
+----+-------+--------+----------+---------------+
| 11 | Jill  | Stone  |        1 |             4 |
+----+-------+--------+----------+---------------+
1 row in set (0.00 sec)
```

Only the two rows in partitions `p0` and `p1` matching the `WHERE` condition were deleted. As you can see from the result when the `SELECT` is run a second time, there remains a row in the table matching the `WHERE` condition, but residing in a different partition (`p2`).

`UPDATE` statements using explicit partition selection behave in the same way; only rows in the partitions referenced by the `PARTITION` option are considered when determining the rows to be updated, as can be seen by executing the following statements:

```sql
mysql> UPDATE employees PARTITION (p0)
```

4147
In the same way, when `PARTITION` is used with `DELETE`, only rows in the partition or partitions named in the partition list are checked for deletion.

For statements that insert rows, the behavior differs in that failure to find a suitable partition causes the statement to fail. This is true for both `INSERT` and `REPLACE` statements, as shown here:

```sql
mysql> INSERT INTO employees PARTITION (p2) VALUES (20, 'Jan', 'Jones', 1, 3);
ERROR 1729 (HY000): Found a row not matching the given partition set
mysql> INSERT INTO employees PARTITION (p3) VALUES (20, 'Jan', 'Jones', 1, 3);
Query OK, 1 row affected (0.07 sec)
mysql> REPLACE INTO employees PARTITION (p0) VALUES (20, 'Jan', 'Jones', 3, 2);
ERROR 1729 (HY000): Found a row not matching the given partition set
mysql> REPLACE INTO employees PARTITION (p3) VALUES (20, 'Jan', 'Jones', 3, 2);
Query OK, 2 rows affected (0.09 sec)
```

For statements that write multiple rows to a partitioned table that using the `InnoDB` storage engine:

If any row in the list following `VALUES` cannot be written to one of the partitions specified in the `partition_names` list, the entire statement fails and no rows are written. This is shown for `INSERT` statements in the following example, reusing the `employees` table created previously:

```sql
mysql> ALTER TABLE employees
    -> REORGANIZE PARTITION p3 INTO (    -> PARTITION p3 VALUES LESS THAN (20),    -> PARTITION p4 VALUES LESS THAN (25),    -> PARTITION p5 VALUES LESS THAN MAXVALUE    -> );
Query OK, 6 rows affected (2.09 sec)
mysql> SHOW CREATE TABLE employees\G
*************************** 1. row ***************************
Table: employees
Create Table: CREATE TABLE `employees` (    `id` int(11) NOT NULL AUTO_INCREMENT,    `fname` varchar(25) NOT NULL,    `lname` varchar(25) NOT NULL,    `store_id` int(11) NOT NULL,    `department_id` int(11) NOT NULL,    PRIMARY KEY (`id`)    ) ENGINE=InnoDB AUTO_INCREMENT=27 DEFAULT CHARSET=utf8mb4
/*!/50100 PARTITION BY RANGE (id)
(PARTITION p0 VALUES LESS THAN (5) ENGINE = InnoDB,
 PARTITION p1 VALUES LESS THAN (10) ENGINE = InnoDB,
```
23.6 Restrictions and Limitations on Partitioning

This section discusses current restrictions and limitations on MySQL partitioning support.

Prohibited constructs. The following constructs are not permitted in partitioning expressions:

- Stored procedures, stored functions, UDFs, or plugins.
- Declared variables or user variables.

For a list of SQL functions which are permitted in partitioning expressions, see Section 23.6.3, “Partitioning Limitations Relating to Functions”.

Arithmetic and logical operators. Use of the arithmetic operators +, −, and * is permitted in partitioning expressions. However, the result must be an integer value or NULL (except in the case of [LINEAR] KEY partitioning, as discussed elsewhere in this chapter; see Section 23.2, “Partitioning Types”, for more information).

The DIV operator is also supported; the / operator is not permitted.

The bit operators |, &, ^, <<, >>, and ~ are not permitted in partitioning expressions.

Server SQL mode. Tables employing user-defined partitioning do not preserve the SQL mode in effect at the time that they were created. As discussed elsewhere in this Manual (see Section 5.1.11, “Server SQL Modes”), the results of many MySQL functions and operators may change according to the server SQL mode. Therefore, a change in the SQL mode at any time after the creation of partitioned tables may lead to major changes in the behavior of such tables, and could easily lead to corruption or loss of data. For these reasons, it is strongly recommended that you never change the server SQL mode after creating partitioned tables.

For one such change in the server SQL mode making a partitioned tables unusable, consider the following CREATE TABLE statement, which can be executed successfully only if the NO UNSIGNED_SUBTRACTION mode is in effect:

```sql
mysql> SELECT @sql_mode;
+-------+
| @sql_mode |
+-------+
|       |
|       |
1 row in set (0.00 sec)

mysql> CREATE TABLE tu (c1 BIGINT UNSIGNED)
-> PARTITION BY RANGE(c1 - 10) (PARTITION p2 VALUES LESS THAN (15) ENGINE = InnoDB,
PARTITION p3 VALUES LESS THAN (20) ENGINE = InnoDB,
PARTITION p4 VALUES LESS THAN (25) ENGINE = InnoDB,
PARTITION p5 VALUES LESS THAN MAXVALUE ENGINE = InnoDB) */
1 row in set (0.00 sec)
```
Restrictions and Limitations on Partitioning

```sql
-> PARTITION p0 VALUES LESS THAN (-5),
-> PARTITION p1 VALUES LESS THAN (0),
-> PARTITION p2 VALUES LESS THAN (5),
-> PARTITION p3 VALUES LESS THAN (10),
-> PARTITION p4 VALUES LESS THAN (MAXVALUE)
->);
ERROR 1563 (HY000): Partition constant is out of partition function domain
```

```sql
mysql> SET sql_mode='NO_UNSIGNED_SUBTRACTION';
Query OK, 0 rows affected (0.00 sec)
```

```sql
mysql> SELECT @@sql_mode;
+-------------------------+
| @@sql_mode              |
+-------------------------+
| NO_UNSIGNED_SUBTRACTION |
+-------------------------+
1 row in set (0.00 sec)
```

```sql
mysql> CREATE TABLE tu (c1 BIGINT UNSIGNED)
    -> PARTITION BY RANGE(c1 - 10) (
    -> PARTITION p0 VALUES LESS THAN (-5),
    -> PARTITION p1 VALUES LESS THAN (0),
    -> PARTITION p2 VALUES LESS THAN (5),
    -> PARTITION p3 VALUES LESS THAN (10),
    -> PARTITION p4 VALUES LESS THAN (MAXVALUE)
    -> );
Query OK, 0 rows affected (0.05 sec)
```

If you remove the `NO_UNSIGNED_SUBTRACTION` server SQL mode after creating `tu`, you may no longer be able to access this table:

```sql
mysql> SET sql_mode='';
Query OK, 0 rows affected (0.00 sec)
```

```sql
mysql> SELECT * FROM tu;
ERROR 1563 (HY000): Partition constant is out of partition function domain
```

```sql
mysql> INSERT INTO tu VALUES (20);
ERROR 1563 (HY000): Partition constant is out of partition function domain
```

See also Section 5.1.11, “Server SQL Modes”.

Server SQL modes also impact replication of partitioned tables. Disparate SQL modes on master and slave can lead to partitioning expressions being evaluated differently; this can cause the distribution of data among partitions to be different in the master's and slave's copies of a given table, and may even cause inserts into partitioned tables that succeed on the master to fail on the slave. For best results, you should always use the same server SQL mode on the master and on the slave.

**Performance considerations.** Some effects of partitioning operations on performance are given in the following list:

- **File system operations.** Partitioning and repartitioning operations (such as `ALTER TABLE` with `PARTITION BY ...`, `REORGANIZE PARTITION`, or `REMOVE PARTITIONING`) depend on file system operations for their implementation. This means that the speed of these operations is affected by such factors as file system type and characteristics, disk speed, swap space, file handling efficiency of the operating system, and MySQL server options and variables that relate to file handling. In particular, you should make sure that `large_files_support` is enabled and that `open_files_limit` is set properly. Partitioning and repartitioning operations involving InnoDB tables may be made more efficient by enabling `innodb_file_per_table`.

See also Maximum number of partitions.

- **Table locks.** Generally, the process executing a partitioning operation on a table takes a write lock on the table. Reads from such tables are relatively unaffected; pending `INSERT` and `UPDATE` operations are performed as soon as the partitioning operation has completed. For InnoDB-specific exceptions to this limitation, see Partitioning Operations.
Restrictions and Limitations on Partitioning

- **Indexes; partition pruning.** As with nonpartitioned tables, proper use of indexes can speed up queries on partitioned tables significantly. In addition, designing partitioned tables and queries on these tables to take advantage of partition pruning can improve performance dramatically. See Section 23.4, “Partition Pruning”, for more information.

  Index condition pushdown is supported for partitioned tables. See Section 8.2.1.6, “Index Condition Pushdown Optimization”.

- **Performance with LOAD DATA.** In MySQL 8.0, LOAD DATA uses buffering to improve performance. You should be aware that the buffer uses 130 KB memory per partition to achieve this.

**Maximum number of partitions.**

The maximum possible number of partitions for a given table not using the NDB storage engine is 8192. This number includes subpartitions.

The maximum possible number of user-defined partitions for a table using the NDB storage engine is determined according to the version of the NDB Cluster software being used, the number of data nodes, and other factors. See NDB and user-defined partitioning, for more information.

If, when creating tables with a large number of partitions (but less than the maximum), you encounter an error message such as Got error ... from storage engine: Out of resources when opening file, you may be able to address the issue by increasing the value of the open_files_limit system variable. However, this is dependent on the operating system, and may not be possible or advisable on all platforms; see Section B.4.2.17, “File Not Found and Similar Errors”, for more information. In some cases, using large numbers (hundreds) of partitions may also not be advisable due to other concerns, so using more partitions does not automatically lead to better results.

See also File system operations.

**Foreign keys not supported for partitioned InnoDB tables.**

Partitioned tables using the InnoDB storage engine do not support foreign keys. More specifically, this means that the following two statements are true:

1. No definition of an InnoDB table employing user-defined partitioning may contain foreign key references; no InnoDB table whose definition contains foreign key references may be partitioned.

2. No InnoDB table definition may contain a foreign key reference to a user-partitioned table; no InnoDB table with user-defined partitioning may contain columns referenced by foreign keys.

The scope of the restrictions just listed includes all tables that use the InnoDB storage engine. CREATE TABLE and ALTER TABLE statements that would result in tables violating these restrictions are not allowed.

**ALTER TABLE ... ORDER BY.** An ALTER TABLE ... ORDER BY column statement run against a partitioned table causes ordering of rows only within each partition.

**Effects on REPLACE statements by modification of primary keys.** It can be desirable in some cases (see Section 23.6.1, “Partitioning Keys, Primary Keys, and Unique Keys”) to modify a table’s primary key. Be aware that, if your application uses REPLACE statements and you do this, the results of these statements can be drastically altered. See Section 13.2.9, “REPLACE Statement”, for more information and an example.

**FULLTEXT indexes.**

Partitioned tables do not support FULLTEXT indexes or searches.

**Spatial columns.** Columns with spatial data types such as POINT or GEOMETRY cannot be used in partitioned tables.

**Temporary tables.** Temporary tables cannot be partitioned.
Restrictions and Limitations on Partitioning

Log tables. It is not possible to partition the log tables; an ALTER TABLE ... PARTITION BY ... statement on such a table fails with an error.

Data type of partitioning key. A partitioning key must be either an integer column or an expression that resolves to an integer. Expressions employing ENUM columns cannot be used. The column or expression value may also be NULL; see Section 23.2.7, “How MySQL Partitioning Handles NULL”.

There are two exceptions to this restriction:

1. When partitioning by [LINEAR] KEY, it is possible to use columns of any valid MySQL data type other than TEXT or BLOB as partitioning keys, because the internal key-hashing functions produce the correct data type from these types. For example, the following two CREATE TABLE statements are valid:

   ```sql
   CREATE TABLE tkc (c1 CHAR)
   PARTITION BY KEY(c1)
   PARTITIONS 4;
   CREATE TABLE tke
   ( c1 ENUM('red', 'orange', 'yellow', 'green', 'blue', 'indigo', 'violet') )
   PARTITION BY LINEAR KEY(c1)
   PARTITIONS 6;
   ```

2. When partitioning by RANGE COLUMNS or LIST COLUMNS, it is possible to use string, DATE, and DATETIME columns. For example, each of the following CREATE TABLE statements is valid:

   ```sql
   CREATE TABLE rc (c1 INT, c2 DATE)
   PARTITION BY RANGE COLUMNS(c2) (
     PARTITION p0 VALUES LESS THAN ('1990-01-01'),
     PARTITION p1 VALUES LESS THAN ('1995-01-01'),
     PARTITION p2 VALUES LESS THAN ('2000-01-01'),
     PARTITION p3 VALUES LESS THAN ('2005-01-01'),
     PARTITION p4 VALUES LESS THAN (MAXVALUE)
   );
   CREATE TABLE lc (c1 INT, c2 CHAR(1))
   PARTITION BY LIST COLUMNS(c2) (
     PARTITION p0 VALUES IN ('a', 'd', 'g', 'j', 'm', 'p', 's', 'v', 'y'),
     PARTITION p1 VALUES IN ('b', 'e', 'h', 'k', 'n', 'q', 't', 'w', 'z'),
     PARTITION p2 VALUES IN ('c', 'f', 'i', 'l', 'o', 'r', 'u', 'x', NULL)
   );
   ```

Neither of the preceding exceptions applies to BLOB or TEXT column types.

Subqueries. A partitioning key may not be a subquery, even if that subquery resolves to an integer value or NULL.

Column index prefixes not supported for key partitioning. When creating a table that is partitioned by key, any columns in the partitioning key which use column prefixes are not used in the table's partitioning function. Consider the following CREATE TABLE statement, which has three VARCHAR columns, and whose primary key uses all three columns and specifies prefixes for two of them:

```sql
CREATE TABLE t1 (a VARCHAR(10000),
                 b VARCHAR(25),
                 c VARCHAR(10),
                 PRIMARY KEY (a(10), b, c(2)))
PARTITION BY KEY() PARTITIONS 2;
```

This statement is accepted, but the resulting table is actually created as if you had issued the following statement, using only the primary key column which does not include a prefix (column b) for the partitioning key:

```sql
CREATE TABLE t1 {
   a VARCHAR(10000),
   b VARCHAR(25),
   c VARCHAR(10),
   PRIMARY KEY (a, b, c)
} PARTITION BY KEY() PARTITIONS 2;
```
Restrictions and Limitations on Partitioning

Prior to MySQL 8.0.21, no warning was issued or any other indication provided that this occurred, except in the event that all columns specified for the partitioning key used prefixes, in which case the statement failed, but with a misleading error message, as shown here:

```
mysql> CREATE TABLE t2 (  
  > a VARCHAR(10000),  
  > b VARCHAR(25),  
  > c VARCHAR(10),  
  > PRIMARY KEY (a(10), b(5) c(2))  
) PARTITION BY KEY() PARTITIONS 2;
ERROR 1503 (HY000): A PRIMARY KEY must include all columns in the table's partitioning function.
```

This also occurred when performing ALTER TABLE or when upgrading such tables.

This permissive behavior is deprecated as of MySQL 8.0.21 (and is subject to removal in a future version of MySQL). Beginning with MySQL 8.0.21, using one or more columns having a prefix in the partitioning key results in a warning for each such column, as shown here:

```
mysql> CREATE TABLE t1 (  
  > a VARCHAR(10000),  
  > b VARCHAR(25),  
  > c VARCHAR(10),  
  > PRIMARY KEY (a(10), b, c(2))  
) PARTITION BY KEY() PARTITIONS 2;
Query OK, 0 rows affected, 2 warnings (1.25 sec)
```

```
mysql> SHOW WARNINGS\G
*************************** 1. row ***************************
    Level: Warning
    Code: 1681
    Message: Column 'test.t1.a' having prefix key part 'a(10)' is ignored by the partitioning function. Use of prefixed columns in the PARTITION BY KEY() clause is deprecated and will be removed in a future release.
*************************** 2. row ***************************
    Level: Warning
    Code: 1681
    Message: Column 'test.t1.c' having prefix key part 'c(2)' is ignored by the partitioning function. Use of prefixed columns in the PARTITION BY KEY() clause is deprecated and will be removed in a future release.
2 rows in set (0.00 sec)
```

This includes cases in which the columns used in the partitioning function are defined implicitly as those in the table’s primary key by employing an empty PARTITION BY KEY() clause.

In MySQL 8.0.21 and later, if all columns specified for the partitioning key employ prefixes, the CREATE TABLE statement used fails with an error message that identifies the issue correctly:

```
mysql> CREATE TABLE t1 (  
  > a VARCHAR(10000),  
  > b VARCHAR(25),  
  > c VARCHAR(10),  
  > PRIMARY KEY (a(10), b(5), c(2))  
) PARTITION BY KEY() PARTITIONS 2;
ERROR 1503 (HY000): A PRIMARY KEY must include all columns in the table's partitioning function (prefixed columns are not considered).
```

```
For general information about partitioning tables by key, see Section 23.2.5, “KEY Partitioning”.

Issues with subpartitions.
Subpartitions must use HASH or KEY partitioning. Only RANGE and LIST partitions may be subpartitioned; HASH and KEY partitions cannot be subpartitioned.

4153
Restrictions and Limitations on Partitioning

**SUBPARTITION BY KEY** requires that the subpartitioning column or columns be specified explicitly, unlike the case with **PARTITION BY KEY**, where it can be omitted (in which case the table’s primary key column is used by default). Consider the table created by this statement:

```sql
CREATE TABLE ts (  
id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,  
name VARCHAR(30)
);
```

You can create a table having the same columns, partitioned by **KEY**, using a statement such as this one:

```sql
CREATE TABLE ts (  
id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,  
name VARCHAR(30)
)  
PARTITION BY KEY()
PARTITIONS 4;
```

The previous statement is treated as though it had been written like this, with the table’s primary key column used as the partitioning column:

```sql
CREATE TABLE ts (  
id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,  
name VARCHAR(30)
)  
PARTITION BY KEY(id)  
PARTITIONS 4;
```

However, the following statement that attempts to create a subpartitioned table using the default column as the subpartitioning column fails, and the column must be specified for the statement to succeed, as shown here:

```sql
mysql> CREATE TABLE ts (  
    -> id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,  
    -> name VARCHAR(30)  
    -> )  
    -> PARTITION BY RANGE(id)  
    -> SUBPARTITION BY KEY()  
    -> SUBPARTITIONS 4  
    -> (  
    -> PARTITION p0 VALUES LESS THAN (100),  
    -> PARTITION p1 VALUES LESS THAN (MAXVALUE)  
    -> );
ERROR 1064 (42000): You have an error in your SQL syntax; check the manual that corresponds to your MySQL server version for the right syntax to use near ')'
```

mysql> CREATE TABLE ts (  
    -> id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,  
    -> name VARCHAR(30)  
    -> )  
    -> PARTITION BY RANGE(id)  
    -> SUBPARTITION BY KEY(id)  
    -> SUBPARTITIONS 4  
    -> (  
    -> PARTITION p0 VALUES LESS THAN (100),  
    -> PARTITION p1 VALUES LESS THAN (MAXVALUE)  
    -> );
Query OK, 0 rows affected (0.07 sec)
```

This is a known issue (see Bug #51470).

**DATA DIRECTORY and INDEX DIRECTORY options.** Table-level **DATA DIRECTORY** and **INDEX DIRECTORY** options are ignored (see Bug #32091). You can employ these options for individual partitions or subpartitions of InnoDB tables.

**Repairing and rebuilding partitioned tables.** The statements **CHECK TABLE**, **OPTIMIZE TABLE**, **ANALYZE TABLE**, and **REPAIR TABLE** are supported for partitioned tables.
In addition, you can use ALTER TABLE ... REBUILD PARTITION to rebuild one or more partitions of a partitioned table; ALTER TABLE ... REORGANIZE PARTITION also causes partitions to be rebuilt. See Section 13.1.9, “ALTER TABLE Statement”, for more information about these two statements.

ANALYZE, CHECK, OPTIMIZE, REPAIR, and TRUNCATE operations are supported with subpartitions. See Section 13.1.9.1, “ALTER TABLE Partition Operations”.

**File name delimiters for partitions and subpartitions.** Table partition and subpartition file names include generated delimiters such as #P# and #SP#. The lettercase of such delimiters can vary and should not be depended upon.

### 23.6.1 Partitioning Keys, Primary Keys, and Unique Keys

This section discusses the relationship of partitioning keys with primary keys and unique keys. The rule governing this relationship can be expressed as follows: All columns used in the partitioning expression for a partitioned table must be part of every unique key that the table may have.

In other words, *every unique key on the table must use every column in the table's partitioning expression.* (This also includes the table's primary key, since it is by definition a unique key. This particular case is discussed later in this section.) For example, each of the following table creation statements is invalid:

```sql
CREATE TABLE t1 (  
    col1 INT NOT NULL,  
    col2 DATE NOT NULL,  
    col3 INT NOT NULL,  
    col4 INT NOT NULL,  
    UNIQUE KEY (col1, col2)  
)  
PARTITION BY HASH(col3)  
PARTITIONS 4;
```

```sql
CREATE TABLE t2 (  
    col1 INT NOT NULL,  
    col2 DATE NOT NULL,  
    col3 INT NOT NULL,  
    col4 INT NOT NULL,  
    UNIQUE KEY (col1),  
    UNIQUE KEY (col3)  
)  
PARTITION BY HASH(col1 + col3)  
PARTITIONS 4;
```

In each case, the proposed table would have at least one unique key that does not include all columns used in the partitioning expression.

Each of the following statements is valid, and represents one way in which the corresponding invalid table creation statement could be made to work:

```sql
CREATE TABLE t1 (  
    col1 INT NOT NULL,  
    col2 DATE NOT NULL,  
    col3 INT NOT NULL,  
    col4 INT NOT NULL,  
    UNIQUE KEY (col1, col2, col3)  
)  
PARTITION BY HASH(col3)  
PARTITIONS 4;
```

```sql
CREATE TABLE t2 (  
    col1 INT NOT NULL,  
    col2 DATE NOT NULL,  
    col3 INT NOT NULL,  
    col4 INT NOT NULL,  
    UNIQUE KEY (col1, col3)  
)  
PARTITION BY HASH(col1 + col3)  
PARTITIONS 4;
```
This example shows the error produced in such cases:

```
mysql> CREATE TABLE t3 (
    ->  col1 INT NOT NULL,
    ->  col2 DATE NOT NULL,
    ->  col3 INT NOT NULL,
    ->  col4 INT NOT NULL,
    ->  UNIQUE KEY (col1, col2),
    ->  UNIQUE KEY (col3)
    -> )
    -> PARTITION BY HASH(col1 + col3)
    -> PARTITIONS 4;
ERROR 1491 (HY000): A PRIMARY KEY must include all columns in the table's partitioning function
```

The `CREATE TABLE` statement fails because both `col1` and `col3` are included in the proposed partitioning key, but neither of these columns is part of both of unique keys on the table. This shows one possible fix for the invalid table definition:

```
mysql> CREATE TABLE t3 (
    ->  col1 INT NOT NULL,
    ->  col2 DATE NOT NULL,
    ->  col3 INT NOT NULL,
    ->  col4 INT NOT NULL,
    ->  UNIQUE KEY (col1, col2, col3),
    ->  UNIQUE KEY (col3)
    -> )
    -> PARTITION BY HASH(col3)
    -> PARTITIONS 4;
Query OK, 0 rows affected (0.05 sec)
```

In this case, the proposed partitioning key `col3` is part of both unique keys, and the table creation statement succeeds.

The following table cannot be partitioned at all, because there is no way to include in a partitioning key any columns that belong to both unique keys:

```
CREATE TABLE t4 (  
    col1 INT NOT NULL,
    col2 INT NOT NULL,
    col3 INT NOT NULL,
    col4 INT NOT NULL,
    UNIQUE KEY (col1, col3),
    UNIQUE KEY (col2, col4)
);
```

Since every primary key is by definition a unique key, this restriction also includes the table's primary key, if it has one. For example, the next two statements are invalid:

```
CREATE TABLE t5 (  
    col1 INT NOT NULL,
    col2 DATE NOT NULL,
    col3 INT NOT NULL,
    col4 INT NOT NULL,
    PRIMARY KEY(col1, col2)
)  
PARTITION BY HASH(col3)
PARTITIONS 4;
```

```
CREATE TABLE t6 (  
    col1 INT NOT NULL,
    col2 DATE NOT NULL,
    col3 INT NOT NULL,
    col4 INT NOT NULL,
    PRIMARY KEY(col1, col3),
    UNIQUE KEY(col2)
)  
PARTITION BY HASH( YEAR(col2) )
```
PARTITIONS 4;

In both cases, the primary key does not include all columns referenced in the partitioning expression. However, both of the next two statements are valid:

```sql
CREATE TABLE t7 (  
col1 INT NOT NULL,
col2 DATE NOT NULL,
col3 INT NOT NULL,
col4 INT NOT NULL,
PRIMARY KEY(col1, col2)  
)
PARTITION BY HASH(col1 + YEAR(col2))
PARTITIONS 4;

CREATE TABLE t8 (  
col1 INT NOT NULL,
col2 DATE NOT NULL,
col3 INT NOT NULL,
col4 INT NOT NULL,
PRIMARY KEY(col1, col2, col4),
UNIQUE KEY(col2, col1)  
)
PARTITION BY HASH(col1 + YEAR(col2))
PARTITIONS 4;
```

If a table has no unique keys—this includes having no primary key—then this restriction does not apply, and you may use any column or columns in the partitioning expression as long as the column type is compatible with the partitioning type.

For the same reason, you cannot later add a unique key to a partitioned table unless the key includes all columns used by the table’s partitioning expression. Consider the partitioned table created as shown here:

```sql
mysql> CREATE TABLE t_no_pk (c1 INT, c2 INT)
PARTITION BY RANGE(c1)  
-> PARTITION p0 VALUES LESS THAN (10),
-> PARTITION p1 VALUES LESS THAN (20),
-> PARTITION p2 VALUES LESS THAN (30),
-> PARTITION p3 VALUES LESS THAN (40)  
-> ;
Query OK, 0 rows affected (0.12 sec)
```

It is possible to add a primary key to `t_no_pk` using either of these `ALTER TABLE` statements:

```sql
# possible PK
mysql> ALTER TABLE t_no_pk ADD PRIMARY KEY(c1);
Query OK, 0 rows affected (0.13 sec)
Records: 0  Duplicates: 0  Warnings: 0

# drop this PK
mysql> ALTER TABLE t_no_pk DROP PRIMARY KEY;
Query OK, 0 rows affected (0.10 sec)
Records: 0  Duplicates: 0  Warnings: 0

# use another possible PK
mysql> ALTER TABLE t_no_pk ADD PRIMARY KEY(c1, c2);
Query OK, 0 rows affected (0.12 sec)
Records: 0  Duplicates: 0  Warnings: 0

# drop this PK
mysql> ALTER TABLE t_no_pk DROP PRIMARY KEY;
Query OK, 0 rows affected (0.09 sec)
Records: 0  Duplicates: 0  Warnings: 0
```

However, the next statement fails, because `c1` is part of the partitioning key, but is not part of the proposed primary key:

```sql
# fails with error 1503
mysql> ALTER TABLE t_no_pk ADD PRIMARY KEY(c2);
```

4157
Partitioning Limitations Relating to Storage Engines

Since `t_no_pk` has only `c1` in its partitioning expression, attempting to adding a unique key on `c2` alone fails. However, you can add a unique key that uses both `c1` and `c2`.

These rules also apply to existing nonpartitioned tables that you wish to partition using `ALTER TABLE ... PARTITION BY`. Consider a table `np_pk` created as shown here:

```sql
mysql> CREATE TABLE np_pk (  
  -> id INT NOT NULL AUTO_INCREMENT,  
  -> name VARCHAR(50),  
  -> added DATE,  
  -> PRIMARY KEY (id)  
  -> );  
Query OK, 0 rows affected (0.08 sec)
```

The following `ALTER TABLE` statement fails with an error, because the `added` column is not part of any unique key in the table:

```sql
mysql> ALTER TABLE np_pk  
  -> PARTITION BY HASH( TO_DAYS(added) )  
  -> PARTITIONS 4;  
ERROR 1503 (HY000): A PRIMARY KEY must include all columns in the table's partitioning function
```

However, this statement using the `id` column for the partitioning column is valid, as shown here:

```sql
mysql> ALTER TABLE np_pk  
  -> PARTITION BY HASH(id)  
  -> PARTITIONS 4;  
Query OK, 0 rows affected (0.11 sec)  
Records: 0  Duplicates: 0  Warnings: 0
```

In the case of `np_pk`, the only column that may be used as part of a partitioning expression is `id`; if you wish to partition this table using any other column or columns in the partitioning expression, you must first modify the table, either by adding the desired column or columns to the primary key, or by dropping the primary key altogether.

23.6.2 Partitioning Limitations Relating to Storage Engines

In MySQL 8.0, partitioning support is not actually provided by the MySQL Server, but rather by a table storage engine's own or native partitioning handler. In MySQL 8.0, only the InnoDB storage engine provides a native partitioning handler. This means that partitioned tables cannot be created using any other storage engine.

**Note**

MySQL Cluster's NDB storage engine also provides native partitioning support, but is not currently supported in MySQL 8.0.

`ALTER TABLE ... OPTIMIZE PARTITION` does not work correctly with partitioned tables that use InnoDB. Use `ALTER TABLE ... REBUILD PARTITION` and `ALTER TABLE ... ANALYZE PARTITION`, instead, for such tables. For more information, see Section 13.1.9.1, “ALTER TABLE Partition Operations”.

User-defined partitioning and the NDB storage engine (NDB Cluster). Partitioning by `KEY` (including `LINEAR KEY`) is the only type of partitioning supported for the NDB storage engine. It is not possible under normal circumstances in NDB Cluster to create an NDB Cluster table using any partitioning type other than `LINEAR KEY`, and attempting to do so fails with an error.

**Exception (not for production):** It is possible to override this restriction by setting the `new` system variable on NDB Cluster SQL nodes to `ON`. If you choose to do this, you should be aware that tables using partitioning types other than `LINEAR KEY` are not supported in production. In such cases, you can create and use tables with partitioning types other than `KEY` or `LINEAR KEY`, but you do this entirely at your own risk.
The maximum number of partitions that can be defined for an NDB table depends on the number of data nodes and node groups in the cluster, the version of the NDB Cluster software in use, and other factors. See NDB and user-defined partitioning, for more information.

The maximum amount of fixed-size data that can be stored per partition in an NDB table is 128 TB. Previously, this was 16 GB.

CREATE TABLE and ALTER TABLE statements that would cause a user-partitioned NDB table not to meet either or both of the following two requirements are not permitted, and fail with an error:

1. The table must have an explicit primary key.
2. All columns listed in the table’s partitioning expression must be part of the primary key.

Exception. If a user-partitioned NDB table is created using an empty column-list (that is, using PARTITION BY KEY() or PARTITION BY LINEAR KEY()), then no explicit primary key is required.

Upgrading partitioned tables. When performing an upgrade, tables which are partitioned by KEY must be dumped and reloaded. Partitioned tables using storage engines other than InnoDB cannot be upgraded from MySQL 5.7 or earlier to MySQL 8.0 or later; you must either drop the partitioning from such tables with ALTER TABLE ... REMOVE PARTITIONING or convert them to InnoDB using ALTER TABLE ... ENGINE=INNODB prior to the upgrade.

For information about converting MyISAM tables to InnoDB, see Section 15.6.1.5, “Converting Tables from MyISAM to InnoDB”.

23.6.3 Partitioning Limitations Relating to Functions

This section discusses limitations in MySQL Partitioning relating specifically to functions used in partitioning expressions.

Only the MySQL functions shown in the following list are allowed in partitioning expressions:

- ABS()
- CEILING() (see CEILING() and FLOOR())
- DATEDIFF()
- DAY()
- DAYOFMONTH()
- DAYOFWEEK()
- DAYOFYEAR()
- EXTRACT() (see EXTRACT() function with WEEK specifier)
- FLOOR() (see CEILING() and FLOOR())
- HOUR()
- MICROSECOND()
- MINUTE()
- MOD()
- MONTH()
- QUARTER()
Partitioning Limitations Relating to Functions

- `SECOND()`
- `TIME_TO_SEC()`
- `TO_DAYS()`
- `TO_SECONDS()`
- `UNIX_TIMESTAMP()` (with `TIMESTAMP` columns)
- `WEEKDAY()`
- `YEAR()`
- `YEARWEEK()`

In MySQL 8.0, partition pruning is supported for the `TO_DAYS()`, `TO_SECONDS()`, `YEAR()`, and `UNIX_TIMESTAMP()` functions. See Section 23.4, “Partition Pruning”, for more information.

`CEILING()` and `FLOOR()`. Each of these functions returns an integer only if it is passed an argument of an exact numeric type, such as one of the `INT` types or `DECIMAL`. This means, for example, that the following `CREATE TABLE` statement fails with an error, as shown here:

```sql
mysql> CREATE TABLE t (c FLOAT) PARTITION BY LIST(FLOOR(c)) (>
    -> PARTITION p0 VALUES IN (1,3,5),
    -> PARTITION p1 VALUES IN (2,4,6)
    -> );
ERROR 1490 (HY000): The PARTITION function returns the wrong type
```

`EXTRACT()` function with `WEEK` specifier. The value returned by the `EXTRACT()` function, when used as `EXTRACT(WEEK FROM col)`, depends on the value of the `default_week_format` system variable. For this reason, `EXTRACT()` is not permitted as a partitioning function when it specifies the unit as `WEEK`. (Bug #54483)

See Section 12.5.2, “Mathematical Functions”, for more information about the return types of these functions, as well as Section 11.1, “Numeric Data Types”.

This chapter discusses stored database objects that are defined in terms of SQL code that is stored on the server for later execution.

Stored objects include these object types:

- Stored procedure: An object created with CREATE PROCEDURE and invoked using the CALL statement. A procedure does not have a return value but can modify its parameters for later inspection by the caller. It can also generate result sets to be returned to the client program.

- Stored function: An object created with CREATE FUNCTION and used much like a built-in function. You invoke it in an expression and it returns a value during expression evaluation.

- Trigger: An object created with CREATE TRIGGER that is associated with a table. A trigger is activated when a particular event occurs for the table, such as an insert or update.

- Event: An object created with CREATE EVENT and invoked by the server according to schedule.

- View: An object created with CREATE VIEW that when referenced produces a result set. A view acts as a virtual table.

Terminology used in this document reflects the stored object hierarchy:

- Stored routines include stored procedures and functions.
- Stored programs include stored routines, triggers, and events.
- Stored objects include stored programs and views.
Defining Stored Programs

This chapter describes how to use stored objects. The following sections provide additional information about SQL syntax for statements related to these objects, and about object processing:

- For each object type, there are CREATE, ALTER, and DROP statements that control which objects exist and how they are defined. See Section 13.1, “Data Definition Statements”.

- The CALL statement is used to invoke stored procedures. See Section 13.2.1, “CALL Statement”.

- Stored program definitions include a body that may use compound statements, loops, conditionals, and declared variables. See Section 13.6, “Compound Statement Syntax”.

- Metadata changes to objects referred to by stored programs are detected and cause automatic reparsing of the affected statements when the program is next executed. For more information, see Section 8.10.3, “Caching of Prepared Statements and Stored Programs”.

24.1 Defining Stored Programs

Each stored program contains a body that consists of an SQL statement. This statement may be a compound statement made up of several statements separated by semicolon (; ) characters. For example, the following stored procedure has a body made up of a BEGIN ... END block that contains a SET statement and a REPEAT loop that itself contains another SET statement:

```sql
CREATE PROCEDURE dorepeat(p1 INT)
BEGIN
  SET @x = 0;
  REPEAT
    SET @x = @x + 1;
  UNTIL @x > p1 END REPEAT;
END;
```

If you use the mysql client program to define a stored program containing semicolon characters, a problem arises. By default, mysql itself recognizes the semicolon as a statement delimiter, so you must redefine the delimiter temporarily to cause mysql to pass the entire stored program definition to the server.

To redefine the mysql delimiter, use the delimiter command. The following example shows how to do this for the dorepeat() procedure just shown. The delimiter is changed to // to enable the entire definition to be passed to the server as a single statement, and then restored to ; before invoking the procedure. This enables the ; delimiter used in the procedure body to be passed through to the server rather than being interpreted by mysql itself.

```sql
mysql> delimiter //
mysql> CREATE PROCEDURE dorepeat(p1 INT)
    -> BEGIN
    -> SET @x = 0;
    -> REPEAT SET @x = @x + 1; UNTIL @x > p1 END REPEAT;
    -> END
    -> //
Query OK, 0 rows affected (0.00 sec)

mysql> delimiter ;
mysql> CALL dorepeat(1000); Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @x;
+------+
<table>
<thead>
<tr>
<th>@x</th>
</tr>
</thead>
<tbody>
<tr>
<td>1001</td>
</tr>
</tbody>
</table>
+-------+
1 row in set (0.00 sec)
```

You can redefine the delimiter to a string other than //, and the delimiter can consist of a single character or multiple characters. You should avoid the use of the backslash (\) character because that is the escape character for MySQL.
24.2 Using Stored Routines

MySQL supports stored routines (procedures and functions). A stored routine is a set of SQL statements that can be stored in the server. Once this has been done, clients don’t need to keep reissuing the individual statements but can refer to the stored routine instead.

Stored routines can be particularly useful in certain situations:

- When multiple client applications are written in different languages or work on different platforms, but need to perform the same database operations.
- When security is paramount. Banks, for example, use stored procedures and functions for all common operations. This provides a consistent and secure environment, and routines can ensure that each operation is properly logged. In such a setup, applications and users would have no access to the database tables directly, but can only execute specific stored routines.

Stored routines can provide improved performance because less information needs to be sent between the server and the client. The tradeoff is that this does increase the load on the database server because more of the work is done on the server side and less is done on the client (application) side. Consider this if many client machines (such as Web servers) are serviced by only one or a few database servers.

Stored routines also enable you to have libraries of functions in the database server. This is a feature shared by modern application languages that enable such design internally (for example, by using classes). Using these client application language features is beneficial for the programmer even outside the scope of database use.

MySQL follows the SQL:2003 syntax for stored routines, which is also used by IBM’s DB2. All syntax described here is supported and any limitations and extensions are documented where appropriate.

Additional Resources

- You may find the Stored Procedures User Forum of use when working with stored procedures and functions.
- For answers to some commonly asked questions regarding stored routines in MySQL, see Section A.4, “MySQL 8.0 FAQ: Stored Procedures and Functions”.
- There are some restrictions on the use of stored routines. See Section 24.8, “Restrictions on Stored Programs”.
- Binary logging for stored routines takes place as described in Section 24.7, “Stored Program Binary Logging”.

The following is an example of a function that takes a parameter, performs an operation using an SQL function, and returns the result. In this case, it is unnecessary to use `delimiter` because the function definition contains no internal ; statement delimiters:

```sql
mysql> CREATE FUNCTION hello (s CHAR(20))
-> RETURNS CHAR(50) DETERMINISTIC
-> RETURN CONCAT('Hello, ',s,'!');
Query OK, 0 rows affected (0.00 sec)
mysql> SELECT hello('world');
+----------------+
| hello('world') |
+----------------+
| Hello, world!  |
+----------------+
1 row in set (0.00 sec)
```
24.2.1 Stored Routine Syntax

A stored routine is either a procedure or a function. Stored routines are created with the `CREATE PROCEDURE` and `CREATE FUNCTION` statements (see Section 13.1.17, “CREATE PROCEDURE and CREATE FUNCTION Statements”). A procedure is invoked using a `CALL` statement (see Section 13.2.1, “CALL Statement”), and can only pass back values using output variables. A function can be called from inside a statement just like any other function (that is, by invoking the function’s name), and can return a scalar value. The body of a stored routine can use compound statements (see Section 13.6, “Compound Statement Syntax”).

Stored routines can be dropped with the `DROP PROCEDURE` and `DROP FUNCTION` statements (see Section 13.1.29, “DROP PROCEDURE and DROP FUNCTION Statements”), and altered with the `ALTER PROCEDURE` and `ALTER FUNCTION` statements (see Section 13.1.7, “ALTER PROCEDURE Statement”).

A stored procedure or function is associated with a particular database. This has several implications:

- When the routine is invoked, an implicit `USE db_name` is performed (and undone when the routine terminates). `USE` statements within stored routines are not permitted.

- You can qualify routine names with the database name. This can be used to refer to a routine that is not in the current database. For example, to invoke a stored procedure `p` or function `f` that is associated with the `test` database, you can say `CALL test.p()` or `test.f()`.

- When a database is dropped, all stored routines associated with it are dropped as well.

Stored functions cannot be recursive.

Recursion in stored procedures is permitted but disabled by default. To enable recursion, set the `max_sp_recursion_depth` server system variable to a value greater than zero. Stored procedure recursion increases the demand on thread stack space. If you increase the value of `max_sp_recursion_depth`, it may be necessary to increase thread stack size by increasing the value of `thread_stack` at server startup. See Section 5.1.8, “Server System Variables”, for more information.

MySQL supports a very useful extension that enables the use of regular `SELECT` statements (that is, without using cursors or local variables) inside a stored procedure. The result set of such a query is simply sent directly to the client. Multiple `SELECT` statements generate multiple result sets, so the client must use a MySQL client library that supports multiple result sets. This means the client must use a client library from a version of MySQL at least as recent as 4.1. The client should also specify the `CLIENT.MULTI_RESULTS` option when it connects. For C programs, this can be done with the `mysql_real_connect()` C API function. See Section 28.7.6.54, “mysql_real_connect()”, and Section 28.7.22, “C API Multiple Statement Execution Support”.

24.2.2 Stored Routines and MySQL Privileges

The MySQL grant system takes stored routines into account as follows:

- The `CREATE ROUTINE` privilege is needed to create stored routines.

- The `ALTER ROUTINE` privilege is needed to alter or drop stored routines. This privilege is granted automatically to the creator of a routine if necessary, and dropped from the creator when the routine is dropped.

- The `EXECUTE` privilege is required to execute stored routines. However, this privilege is granted automatically to the creator of a routine if necessary (and dropped from the creator when the routine is dropped). Also, the default `SQL SECURITY` characteristic for a routine is `DEFINER`, which enables users who have access to the database with which the routine is associated to execute the routine.

- If the `automatic_sp_privileges` system variable is 0, the `EXECUTE` and `ALTER ROUTINE` privileges are not automatically granted to and dropped from the routine creator.
• The creator of a routine is the account used to execute the `CREATE` statement for it. This might not
be the same as the account named as the `DEFINER` in the routine definition.

• The account named as a routine `DEFINER` can see all routine properties, including its definition. The
account thus has full access to the routine output as produced by:
  • The contents of the `INFORMATION_SCHEMA.ROUTINES` table.
  • The `SHOW CREATE FUNCTION` and `SHOW CREATE PROCEDURE` statements.
  • The `SHOW FUNCTION CODE` and `SHOW PROCEDURE CODE` statements.
  • The `SHOW FUNCTION STATUS` and `SHOW PROCEDURE STATUS` statements.

• For an account other than the account named as the routine `DEFINER`, access to routine properties
depends on the privileges granted to the account:
  • With the `SHOW_ROUTINE` privilege or the global `SELECT` privilege, the account can see all routine
properties, including its definition.
  • With the `CREATE ROUTINE`, `ALTER ROUTINE` or `EXECUTE` privilege granted at a scope that
includes the routine, the account can see all routine properties except its definition.

24.2.3 Stored Routine Metadata

To obtain metadata about stored routines:

• Query the `ROUTINES` table of the `INFORMATION_SCHEMA` database. See Section 25.29, “The
`INFORMATION_SCHEMA ROUTINES` Table”.

• Use the `SHOW CREATE PROCEDURE` and `SHOW CREATE FUNCTION` statements to see routine
definitions. See Section 13.7.7.9, “SHOW CREATE PROCEDURE Statement”.

• Use the `SHOW PROCEDURE STATUS` and `SHOW FUNCTION STATUS` statements to see routine
characteristics. See Section 13.7.7.28, “SHOW PROCEDURE STATUS Statement”.

• Use the `SHOW PROCEDURE CODE` and `SHOW FUNCTION CODE` statements to see a representation
of the internal implementation of the routine. See Section 13.7.7.27, “SHOW PROCEDURE CODE
Statement”.

24.2.4 Stored Procedures, Functions, Triggers, and LAST_INSERT_ID()

Within the body of a stored routine (procedure or function) or a trigger, the value of
`LAST_INSERT_ID()` changes the same way as for statements executed outside the body of these
kinds of objects (see Section 12.15, “Information Functions”). The effect of a stored routine or trigger
upon the value of `LAST_INSERT_ID()` that is seen by following statements depends on the kind of
routine:

• If a stored procedure executes statements that change the value of `LAST_INSERT_ID()`, the
changed value is seen by statements that follow the procedure call.

• For stored functions and triggers that change the value, the value is restored when the function or
trigger ends, so following statements do not see a changed value.

24.3 Using Triggers

A trigger is a named database object that is associated with a table, and that activates when a
particular event occurs for the table. Some uses for triggers are to perform checks of values to be
inserted into a table or to perform calculations on values involved in an update.

A trigger is defined to activate when a statement inserts, updates, or deletes rows in the associated
table. These row operations are trigger events. For example, rows can be inserted by `INSERT` or `LOAD`
Additional Resources

DATA statements, and an insert trigger activates for each inserted row. A trigger can be set to activate either before or after the trigger event. For example, you can have a trigger activate before each row that is inserted into a table or after each row that is updated.

Important
MySQL triggers activate only for changes made to tables by SQL statements. This includes changes to base tables that underlie updatable views. Triggers do not activate for changes to tables made by APIs that do not transmit SQL statements to the MySQL Server. This means that triggers are not activated by updates made using the NDB API.

Triggers are not activated by changes in INFORMATION_SCHEMA or performance_schema tables. Those tables are actually views and triggers are not permitted on views.

The following sections describe the syntax for creating and dropping triggers, show some examples of how to use them, and indicate how to obtain trigger metadata.

Additional Resources

• You may find the Triggers User Forum of use when working with triggers.

• For answers to commonly asked questions regarding triggers in MySQL, see Section A.5, “MySQL 8.0 FAQ: Triggers”.

• There are some restrictions on the use of triggers; see Section 24.8, “Restrictions on Stored Programs”.

• Binary logging for triggers takes place as described in Section 24.7, “Stored Program Binary Logging”.

24.3.1 Trigger Syntax and Examples

To create a trigger or drop a trigger, use the CREATE TRIGGER or DROP TRIGGER statement, described in Section 13.1.22, “CREATE TRIGGER Statement”, and Section 13.1.34, “DROP TRIGGER Statement”.

Here is a simple example that associates a trigger with a table, to activate for INSERT operations. The trigger acts as an accumulator, summing the values inserted into one of the columns of the table.

```
mysql> CREATE TABLE account (acct_num INT, amount DECIMAL(10,2));
Query OK, 0 rows affected (0.03 sec)
mysql> CREATE TRIGGER ins_sum BEFORE INSERT ON account
    FOR EACH ROW SET @sum = @sum + NEW.amount;
Query OK, 0 rows affected (0.01 sec)
```

The CREATE TRIGGER statement creates a trigger named ins_sum that is associated with the account table. It also includes clauses that specify the trigger action time, the triggering event, and what to do when the trigger activates:

• The keyword BEFORE indicates the trigger action time. In this case, the trigger activates before each row inserted into the table. The other permitted keyword here is AFTER.

• The keyword INSERT indicates the trigger event; that is, the type of operation that activates the trigger. In the example, INSERT operations cause trigger activation. You can also create triggers for DELETE and UPDATE operations.

• The statement following FOR EACH ROW defines the trigger body; that is, the statement to execute each time the trigger activates, which occurs once for each row affected by the triggering event. In the example, the trigger body is a simple SET that accumulates into a user variable the values...
inserted into the `amount` column. The statement refers to the column as `NEW.amount` which means “the value of the `amount` column to be inserted into the new row.”

To use the trigger, set the accumulator variable to zero, execute an `INSERT` statement, and then see what value the variable has afterward:

```
mysql> SET @sum = 0;
mysql> INSERT INTO account VALUES(137,14.98),(141,1937.50),(97,-100.00);
mysql> SELECT @sum AS 'Total amount inserted';
+-----------------------+
<table>
<thead>
<tr>
<th>Total amount inserted</th>
</tr>
</thead>
<tbody>
<tr>
<td>1852.48</td>
</tr>
</tbody>
</table>
+-----------------------+
```

In this case, the value of `@sum` after the `INSERT` statement has executed is `14.98 + 1937.50 - 100`, or `1852.48`.

To destroy the trigger, use a `DROP TRIGGER` statement. You must specify the schema name if the trigger is not in the default schema:

```
mysql> DROP TRIGGER test.ins_sum;
```

If you drop a table, any triggers for the table are also dropped.

Trigger names exist in the schema namespace, meaning that all triggers must have unique names within a schema. Triggers in different schemas can have the same name.

It is possible to define multiple triggers for a given table that have the same trigger event and action time. For example, you can have two `BEFORE UPDATE` triggers for a table. By default, triggers that have the same trigger event and action time activate in the order they were created. To affect trigger order, specify a clause after `FOR EACH ROW` that indicates `FOLLOWS` or `PRECEDES` and the name of an existing trigger that also has the same trigger event and action time. With `FOLLOWS`, the new trigger activates after the existing trigger. With `PRECEDES`, the new trigger activates before the existing trigger.

For example, the following trigger definition defines another `BEFORE INSERT` trigger for the `account` table:

```
mysql> CREATE TRIGGER ins_transaction BEFORE INSERT ON account
      FOR EACH ROW PRECEDES ins_sum
      SET @deposits = @deposits + IF(NEW.amount>0,NEW.amount,0),
      @withdrawals = @withdrawals + IF(NEW.amount<0,-NEW.amount,0);
Query OK, 0 rows affected (0.01 sec)
```

This trigger, `ins_transaction`, is similar to `ins_sum` but accumulates deposits and withdrawals separately. It has a `PRECEDES` clause that causes it to activate before `ins_sum`; without that clause, it would activate after `ins_sum` because it is created after `ins_sum`.

Within the trigger body, the `OLD` and `NEW` keywords enable you to access columns in the rows affected by a trigger. `OLD` and `NEW` are MySQL extensions to triggers; they are not case-sensitive.

In an `INSERT` trigger, only `NEW.col_name` can be used; there is no old row. In a `DELETE` trigger, only `OLD.col_name` can be used; there is no new row. In an `UPDATE` trigger, you can use `OLD.col_name` to refer to the columns of a row before it is updated and `NEW.col_name` to refer to the columns of the row after it is updated.

A column named with `OLD` is read only. You can refer to it (if you have the `SELECT` privilege), but not modify it. You can refer to a column named with `NEW` if you have the `SELECT` privilege for it. In a `BEFORE` trigger, you can also change its value with `SET NEW.col_name = value` if you have the `UPDATE` privilege for it. This means you can use a trigger to modify the values to be inserted into a new row or used to update a row. (Such a `SET` statement has no effect in an `AFTER` trigger because the row change will have already occurred.)
In a **BEFORE** trigger, the **NEW** value for an **AUTO_INCREMENT** column is 0, not the sequence number that is generated automatically when the new row actually is inserted.

By using the `BEGIN ... END` construct, you can define a trigger that executes multiple statements. Within the `BEGIN` block, you also can use other syntax that is permitted within stored routines such as conditionals and loops. However, just as for stored routines, if you use the `mysql` program to define a trigger that executes multiple statements, it is necessary to redefine the `mysql` statement delimiter so that you can use the `;` statement delimiter within the trigger definition. The following example illustrates these points. It defines an **UPDATE** trigger that checks the new value to be used for updating each row, and modifies the value to be within the range from 0 to 100. This must be a **BEFORE** trigger because the value must be checked before it is used to update the row:

```sql
mysql> delimiter //
mysql> CREATE TRIGGER upd_check BEFORE UPDATE ON account
    > FOR EACH ROW
    > BEGIN
    >     IF NEW.amount < 0 THEN
    >         SET NEW.amount = 0;
    >     ELSEIF NEW.amount > 100 THEN
    >         SET NEW.amount = 100;
    >     END IF;
    > END; //
mysql> delimiter ;
```

It can be easier to define a stored procedure separately and then invoke it from the trigger using a simple `CALL` statement. This is also advantageous if you want to execute the same code from within several triggers.

There are limitations on what can appear in statements that a trigger executes when activated:

- The trigger cannot use the `CALL` statement to invoke stored procedures that return data to the client or that use dynamic SQL. (Stored procedures are permitted to return data to the trigger through **OUT** or **INOUT** parameters.)

- The trigger cannot use statements that explicitly or implicitly begin or end a transaction, such as `START TRANSACTION`, `COMMIT`, or `ROLLBACK`. (`ROLLBACK to SAVEPOINT` is permitted because it does not end a transaction.).

See also Section 24.8, “Restrictions on Stored Programs”.

MySQL handles errors during trigger execution as follows:

- If a **BEFORE** trigger fails, the operation on the corresponding row is not performed.

- A **BEFORE** trigger is activated by the attempt to insert or modify the row, regardless of whether the attempt subsequently succeeds.

- An **AFTER** trigger is executed only if any **BEFORE** triggers and the row operation execute successfully.

- An error during either a **BEFORE** or **AFTER** trigger results in failure of the entire statement that caused trigger invocation.

- For transactional tables, failure of a statement should cause rollback of all changes performed by the statement. Failure of a trigger causes the statement to fail, so trigger failure also causes rollback. For nontransactional tables, such rollback cannot be done, so although the statement fails, any changes performed prior to the point of the error remain in effect.

Triggers can contain direct references to tables by name, such as the trigger named `testref` shown in this example:

```sql
CREATE TABLE test1(a1 INT);
CREATE TABLE test2(a2 INT);
CREATE TABLE test3(a3 INT NOT NULL AUTO_INCREMENT PRIMARY KEY);
CREATE TABLE test4(
```
CREATE TRIGGER testref BEFORE INSERT ON test1
FOR EACH ROW
BEGIN
    INSERT INTO test2 SET a2 = NEW.a1;
    DELETE FROM test3 WHERE a3 = NEW.a1;
    UPDATE test4 SET b4 = b4 + 1 WHERE a4 = NEW.a1;
END;

INSERT INTO test3 (a3) VALUES
(NULL), (NULL), (NULL), (NULL), (NULL),
(NULL), (NULL), (NULL), (NULL), (NULL);

INSERT INTO test4 (a4) VALUES
(0), (0), (0), (0), (0), (0), (0), (0), (0), (0);

Suppose that you insert the following values into table test1 as shown here:

mysql> INSERT INTO test1 VALUES
(1), (3), (1), (7), (1), (8), (4), (4);
Query OK, 8 rows affected (0.01 sec)
Records: 8  Duplicates: 0  Warnings: 0

As a result, the four tables contain the following data:

mysql> SELECT * FROM test1;
+------+
| a1   |
+------+
|    1 |
|    3 |
|    1 |
|    7 |
|    1 |
|    8 |
|    4 |
|    4 |
+------+
8 rows in set (0.00 sec)

mysql> SELECT * FROM test2;
+------+
| a2   |
+------+
|    1 |
|    3 |
|    1 |
|    7 |
|    1 |
|    8 |
|    4 |
|    4 |
+------+
8 rows in set (0.00 sec)

mysql> SELECT * FROM test3;
+----+
| a3 |
+----+
|  2 |
|  5 |
|  6 |
|  9 |
| 10 |

4169
24.3.2 Trigger Metadata

To obtain metadata about triggers:

- Query the TRIGGERS table of the INFORMATION_SCHEMA database. See Section 25.41, “The INFORMATION_SCHEMA TRIGGERS Table”.
- Use the SHOW CREATE TRIGGER statement. See Section 13.7.7.11, “SHOW CREATE TRIGGER Statement”.
- Use the SHOW TRIGGERS statement. See Section 13.7.7.38, “SHOW TRIGGERS Statement”.

24.4 Using the Event Scheduler

The MySQL Event Scheduler manages the scheduling and execution of events, that is, tasks that run according to a schedule. The following discussion covers the Event Scheduler and is divided into the following sections:

- Section 24.4.1, “Event Scheduler Overview”, provides an introduction to and conceptual overview of MySQL Events.
- Section 24.4.3, “Event Syntax”, discusses the SQL statements for creating, altering, and dropping MySQL Events.
- Section 24.4.4, “Event Metadata”, shows how to obtain information about events and how this information is stored by the MySQL Server.
- Section 24.4.6, “The Event Scheduler and MySQL Privileges”, discusses the privileges required to work with events and the ramifications that events have with regard to privileges when executing.

Stored routines require the events data dictionary table in the mysql system database. This table is created during the MySQL 8.0 installation procedure. If you are upgrading to MySQL 8.0 from an earlier version, be sure to perform the upgrade procedure to make sure that your system database is up to date. See Section 2.11, “Upgrading MySQL”.

Additional Resources

- You may find the MySQL Event Scheduler User Forum of use when working with scheduled events.
- There are some restrictions on the use of events; see Section 24.8, “Restrictions on Stored Programs”.
- Binary logging for events takes place as described in Section 24.7, “Stored Program Binary Logging”.

24.4.1 Event Scheduler Overview
MySQL Events are tasks that run according to a schedule. Therefore, we sometimes refer to them as *scheduled* events. When you create an event, you are creating a named database object containing one or more SQL statements to be executed at one or more regular intervals, beginning and ending at a specific date and time. Conceptually, this is similar to the idea of the Unix `cron` (also known as a “cron job”) or the Windows Task Scheduler.

Scheduled tasks of this type are also sometimes known as “temporal triggers”, implying that these are objects that are triggered by the passage of time. While this is essentially correct, we prefer to use the term *events* to avoid confusion with triggers of the type discussed in Section 24.3, “Using Triggers”. Events should more specifically not be confused with “temporary triggers”. Whereas a trigger is a database object whose statements are executed in response to a specific type of event that occurs on a given table, a (scheduled) event is an object whose statements are executed in response to the passage of a specified time interval.

While there is no provision in the SQL Standard for event scheduling, there are precedents in other database systems, and you may notice some similarities between these implementations and that found in the MySQL Server.

MySQL Events have the following major features and properties:

- In MySQL, an event is uniquely identified by its name and the schema to which it is assigned.

- An event performs a specific action according to a schedule. This action consists of an SQL statement, which can be a compound statement in a `BEGIN ... END` block if desired (see Section 13.6, “Compound Statement Syntax”). An event's timing can be either *one-time* or *recurrent*. A one-time event executes one time only. A recurrent event repeats its action at a regular interval, and the schedule for a recurring event can be assigned a specific start day and time, end day and time, both, or neither. (By default, a recurring event's schedule begins as soon as it is created, and continues indefinitely, until it is disabled or dropped.)

- Users can create, modify, and drop scheduled events using SQL statements intended for these purposes. Syntactically invalid event creation and modification statements fail with an appropriate error message. A *user may include statements in an event's action which require privileges that the user does not actually have*. The event creation or modification statement succeeds but the event's action fails. See Section 24.4.6, “The Event Scheduler and MySQL Privileges” for details.

- Many of the properties of an event can be set or modified using SQL statements. These properties include the event's name, timing, persistence (that is, whether it is preserved following the expiration of its schedule), status (enabled or disabled), action to be performed, and the schema to which it is assigned. See Section 13.1.3, “ALTER EVENT Statement”.

- The default definer of an event is the user who created the event, unless the event has been altered, in which case the definer is the user who issued the last `ALTER EVENT` statement affecting that event. An event can be modified by any user having the `EVENT` privilege on the database for which the event is defined. See Section 24.4.6, “The Event Scheduler and MySQL Privileges”.

- An event's action statement may include most SQL statements permitted within stored routines. For restrictions, see Section 24.8, “Restrictions on Stored Programs”.

### 24.4.2 Event Scheduler Configuration

Events are executed by a special *event scheduler thread*; when we refer to the Event Scheduler, we actually refer to this thread. When running, the event scheduler thread and its current state can be seen by users having the `PROCESS` privilege in the output of `SHOW PROCESSLIST`, as shown in the discussion that follows.
The global `event_scheduler` system variable determines whether the Event Scheduler is enabled and running on the server. It has one of these 3 values, which affect event scheduling as described here. The default is **ON**.

- **ON**: The Event Scheduler is started; the event scheduler thread runs and executes all scheduled events.

  When the Event Scheduler is **ON**, the event scheduler thread is listed in the output of `SHOW PROCESSLIST` as a daemon process, and its state is represented as shown here:

  ```
  mysql> SHOW PROCESSLIST\G
  *************************** 1. row ***************************
  | Id | User    | Host | db   | Command | Time | State | Info              |
  +---+---------+------+------|--------+------|-------+-------------------|
  | 1 | root    | localhost | NULL | Query   | 0    | NULL | show processlist  |
  +---+---------+------+------|--------+------|-------+-------------------|
  | 2 | event_scheduler | localhost | NULL | Daemon  | 3    | Waiting for next activation | NULL |
  +---+---------+------+------|--------+------|-------+-------------------|
  2 rows in set (0.00 sec)
  ```

  Event scheduling can be stopped by setting the value of `event_scheduler` to **OFF**.

- **OFF**: The Event Scheduler is stopped. The event scheduler thread does not run, is not shown in the output of `SHOW PROCESSLIST`, and no scheduled events are executed.

  When the Event Scheduler is stopped (`event_scheduler` is **OFF**), it can be started by setting the value of `event_scheduler` to **ON**. (See next item.)

- **DISABLED**: This value renders the Event Scheduler nonoperational. When the Event Scheduler is **DISABLED**, the event scheduler thread does not run (and so does not appear in the output of `SHOW PROCESSLIST`). In addition, the Event Scheduler state cannot be changed at runtime.

  If the Event Scheduler status has not been set to **DISABLED**, `event_scheduler` can be toggled between **ON** and **OFF** (using `SET`). It is also possible to use 0 for **OFF**, and 1 for **ON** when setting this variable. Thus, any of the following 4 statements can be used in the `mysql` client to turn on the Event Scheduler:

  ```
  SET GLOBAL event_scheduler = ON;
  SET @@GLOBAL.event_scheduler = ON;
  SET GLOBAL event_scheduler = 1;
  SET @@GLOBAL.event_scheduler = 1;
  ```

  Similarly, any of these 4 statements can be used to turn off the Event Scheduler:

  ```
  SET GLOBAL event_scheduler = OFF;
  SET @@GLOBAL.event_scheduler = OFF;
  SET GLOBAL event_scheduler = 0;
  SET @@GLOBAL.event_scheduler = 0;
  ```

  Although **ON** and **OFF** have numeric equivalents, the value displayed for `event_scheduler` by `SELECT` or `SHOW VARIABLES` is always one of **OFF**, **ON**, or **DISABLED**. **DISABLED** has no numeric equivalent. For this reason, **ON** and **OFF** are usually preferred over 1 and 0 when setting this variable.

  Note that attempting to set `event_scheduler` without specifying it as a global variable causes an error:
mysql< SET @event_scheduler = OFF;
ERROR 1229 (HY000): Variable 'event_scheduler' is a GLOBAL variable and should be set with SET GLOBAL

Important

It is possible to set the Event Scheduler to DISABLED only at server startup. If event_scheduler is ON or OFF, you cannot set it to DISABLED at runtime. Also, if the Event Scheduler is set to DISABLED at startup, you cannot change the value of event_scheduler at runtime.

To disable the event scheduler, use one of the following two methods:

• As a command-line option when starting the server:

   --event-scheduler=DISABLED

• In the server configuration file (my.cnf, or my.ini on Windows systems), include the line where it will be read by the server (for example, in a [mysqld] section):

   event_scheduler=DISABLED

To enable the Event Scheduler, restart the server without the --event-scheduler=DISABLED command-line option, or after removing or commenting out the line containing event-scheduler=DISABLED in the server configuration file, as appropriate. Alternatively, you can use ON (or 1) or OFF (or 0) in place of the DISABLED value when starting the server.

Note

You can issue event-manipulation statements when event_scheduler is set to DISABLED. No warnings or errors are generated in such cases (provided that the statements are themselves valid). However, scheduled events cannot execute until this variable is set to ON (or 1). Once this has been done, the event scheduler thread executes all events whose scheduling conditions are satisfied.

Starting the MySQL server with the --skip-grant-tables option causes event_scheduler to be set to DISABLED, overriding any other value set either on the command line or in the my.cnf or my.ini file (Bug #26807).

For SQL statements used to create, alter, and drop events, see Section 24.4.3, “Event Syntax”.

MySQL provides an EVENTS table in the INFORMATION_SCHEMA database. This table can be queried to obtain information about scheduled events which have been defined on the server. See Section 24.4.4, “Event Metadata”, and Section 25.13, “The INFORMATION_SCHEMA EVENTS Table”, for more information.

For information regarding event scheduling and the MySQL privilege system, see Section 24.4.6, “The Event Scheduler and MySQL Privileges”.

24.4.3 Event Syntax

MySQL provides several SQL statements for working with scheduled events:

• New events are defined using the CREATE EVENT statement. See Section 13.1.13, “CREATE EVENT Statement”.

• The definition of an existing event can be changed by means of the ALTER EVENT statement. See Section 13.1.3, “ALTER EVENT Statement”.

• When a scheduled event is no longer wanted or needed, it can be deleted from the server by its definer using the DROP EVENT statement. See Section 13.1.25, “DROP EVENT Statement”. Whether an event persists past the end of its schedule also depends on its ON COMPLETION clause, if it has one. See Section 13.1.13, “CREATE EVENT Statement”.

4173
Event Metadata

An event can be dropped by any user having the EVENT privilege for the database on which the event is defined. See Section 24.4.6, “The Event Scheduler and MySQL Privileges”.

24.4.4 Event Metadata

To obtain metadata about events:

- Query the EVENTS table of the INFORMATION_SCHEMA database. See Section 25.13, “The INFORMATION_SCHEMA EVENTS Table”.
- Use the SHOW CREATE EVENT statement. See Section 13.7.7.7, “SHOW CREATE EVENT Statement”.
- Use the SHOW EVENTS statement. See Section 13.7.7.18, “SHOW EVENTS Statement”.

Event Scheduler Time Representation

Each session in MySQL has a session time zone (STZ). This is the session time_zone value that is initialized from the server's global time_zone value when the session begins but may be changed during the session.

The session time zone that is current when a CREATE EVENT or ALTER EVENT statement executes is used to interpret times specified in the event definition. This becomes the event time zone (ETZ); that is, the time zone that is used for event scheduling and is in effect within the event as it executes.

For representation of event information in the data dictionary, the execute_at, starts, and ends times are converted to UTC and stored along with the event time zone. This enables event execution to proceed as defined regardless of any subsequent changes to the server time zone or daylight saving time effects. The last_executed time is also stored in UTC.

Event times can be obtained by selecting from the INFORMATION_SCHEMA.EVENTS table or from SHOW EVENTS, but they are reported as ETZ or STZ values. The following table summarizes representation of event times.

<table>
<thead>
<tr>
<th>Value</th>
<th>INFORMATION_SCHEMA.EVENTS</th>
<th>SHOW EVENTS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Execute at</td>
<td>ETZ</td>
<td>ETZ</td>
</tr>
<tr>
<td>Starts</td>
<td>ETZ</td>
<td>ETZ</td>
</tr>
<tr>
<td>Ends</td>
<td>ETZ</td>
<td>ETZ</td>
</tr>
<tr>
<td>Last executed</td>
<td>ETZ</td>
<td>n/a</td>
</tr>
<tr>
<td>Created</td>
<td>STZ</td>
<td>n/a</td>
</tr>
<tr>
<td>Last altered</td>
<td>STZ</td>
<td>n/a</td>
</tr>
</tbody>
</table>

24.4.5 Event Scheduler Status

The Event Scheduler writes information about event execution that terminates with an error or warning to the MySQL Server's error log. See Section 24.4.6, “The Event Scheduler and MySQL Privileges” for an example.

To obtain information about the state of the Event Scheduler for debugging and troubleshooting purposes, run mysqladmin debug (see Section 4.5.2, “mysqladmin — Client for Administering a MySQL Server”); after running this command, the server's error log contains output relating to the Event Scheduler, similar to what is shown here:

```bash
Events status:
LLA = Last Locked At  LUA = Last Unlocked At
WOC = Waiting On Condition  DL = Data Locked

Event scheduler status:
```
In statements that occur as part of events executed by the Event Scheduler, diagnostics messages (not only errors, but also warnings) are written to the error log, and, on Windows, to the application event log. For frequently executed events, it is possible for this to result in many logged messages. For example, for `SELECT ... INTO var_list` statements, if the query returns no rows, a warning with error code 1329 occurs (No data), and the variable values remain unchanged. If the query returns multiple rows, error 1172 occurs (Result consisted of more than one row). For either condition, you can avoid having the warnings be logged by declaring a condition handler; see Section 13.6.7.2, “DECLARE ... HANDLER Statement”. For statements that may retrieve multiple rows, another strategy is to use `LIMIT 1` to limit the result set to a single row.

### 24.4.6 The Event Scheduler and MySQL Privileges

To enable or disable the execution of scheduled events, it is necessary to set the value of the global `event_scheduler` system variable. This requires privileges sufficient to set global system variables. See Section 5.1.9.1, “System Variable Privileges”.

The `EVENT` privilege governs the creation, modification, and deletion of events. This privilege can be bestowed using `GRANT`. For example, this `GRANT` statement confers the `EVENT` privilege for the schema named `myschema` on the user `jon@ghidora`:

```
GRANT EVENT ON myschema.* TO jon@ghidora;
```

(We assume that this user account already exists, and that we wish for it to remain unchanged otherwise.)

To grant this same user the `EVENT` privilege on all schemas, use the following statement:

```
GRANT EVENT ON *.* TO jon@ghidora;
```

The `EVENT` privilege has global or schema-level scope. Therefore, trying to grant it on a single table results in an error as shown:

```
mysql> GRANT EVENT ON myschema.mytable TO jon@ghidora;
ERROR 1144 (42000): Illegal GRANT/REVOKE command; please consult the manual to see which privileges can be used
```

It is important to understand that an event is executed with the privileges of its definer, and that it cannot perform any actions for which its definer does not have the requisite privileges. For example, suppose that `jon@ghidora` has the `EVENT` privilege for `myschema`. Suppose also that this user has the `SELECT` privilege for `myschema`, but no other privileges for this schema. It is possible for `jon@ghidora` to create a new event such as this one:

```
CREATE EVENT e_store_ts
ON SCHEDULE
    EVERY 10 SECOND
DO
    INSERT INTO myschema.mytable VALUES (UNIX_TIMESTAMP());
```

The user waits for a minute or so, and then performs a `SELECT * FROM mytable;` query, expecting to see several new rows in the table. Instead, the table is empty. Since the user does not have the `INSERT` privilege for the table in question, the event has no effect.

If you inspect the MySQL error log (hostname.err), you can see that the event is executing, but the action it is attempting to perform fails:

```
2013-09-24T12:41:31.261992Z 25 [ERROR] Event Scheduler: [jon@ghidora][cookbook.e_store_ts] INSERT command denied to user 'jon'@'ghidora' for table 'mytable'
```

Since this user very likely does not have access to the error log, it is possible to verify whether the event's action statement is valid by executing it directly:

```
mysql> INSERT INTO myschema.mytable VALUES (UNIX_TIMESTAMP());
ERROR 1142 (42000): INSERT command denied to user 'jon'@'ghidora' for table 'mytable'
```

Inspection of the `INFORMATION_SCHEMA.EVENTS` table shows that `e_store_ts` exists and is enabled, but its `LAST_EXECUTED` column is NULL:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.EVENTS
    -> WHERE EVENT_NAME='e_store_ts'
    -> AND EVENT_SCHEMA='myschema'
```

```
*************************** 1. row ***************************
EVENT_CATALOG: NULL
EVENT_SCHEMA: myschema
EVENT_NAME: e_store_ts
DEFINER: jon@ghidora
EVENT_BODY: SQL
EVENT_DEFINITION: INSERT INTO myschema.mytable VALUES (UNIX_TIMESTAMP())
EVENT_TYPE: RECURRING
EXECUTE_AT: NULL
INTERVAL_VALUE: 5
INTERVAL_FIELD: SECOND
SQL_MODE: NULL
STARTS: 0000-00-00 00:00:00
ENDS: 0000-00-00 00:00:00
STATUS: ENABLED
ON_COMPLETION: NOT PRESERVE
CREATED: 2006-02-09 22:36:06
LAST Altered: 2006-02-09 22:36:06
LAST_EXECUTED: NULL
EVENT_COMMENT: 
1 row in set (0.00 sec)
```

To rescind the `EVENT` privilege, use the `REVOKE` statement. In this example, the `EVENT` privilege on the schema `myschema` is removed from the `jon@ghidora` user account:

```
REVOKE EVENT ON myschema.* FROM jon@ghidora;
```

**Important**

Revoking the `EVENT` privilege from a user does not delete or disable any events that may have been created by that user.

An event is not migrated or dropped as a result of renaming or dropping the user who created it.

Suppose that the user `jon@ghidora` has been granted the `EVENT` and `INSERT` privileges on the `myschema` schema. This user then creates the following event:
CREATE EVENT e_insert
ON SCHEDULE
   EVERY 7 SECOND
DO
   INSERT INTO myschema.mytable;

After this event has been created, root revokes the EVENT privilege for jon@ghidora. However, e_insert continues to execute, inserting a new row into mytable each seven seconds. The same would be true if root had issued either of these statements:

• DROP USER jon@ghidora;

• RENAME USER jon@ghidora TO someotherguy@ghidora;

You can verify that this is true by examining the INFORMATION_SCHEMA.EVENTS table (see Section 25.13, "The INFORMATION_SCHEMA EVENTS Table") before and after issuing a DROP USER or RENAME USER statement.

Event definitions are stored in the data dictionary. To drop an event created by another user account, you must be the MySQL root user or another user with the necessary privileges.

Users' EVENT privileges are stored in the Event_priv columns of the mysql.user and mysql.db tables. In both cases, this column holds one of the values 'Y' or 'N'. 'N' is the default. mysql.user.Event_priv is set to 'Y' for a given user only if that user has the global EVENT privilege (that is, if the privilege was bestowed using GRANT EVENT ON *.*). For a schema-level EVENT privilege, GRANT creates a row in mysql.db and sets that row's Db column to the name of the schema, the User column to the name of the user, and the Event_priv column to 'Y'. There should never be any need to manipulate these tables directly, since the GRANT EVENT and REVOKE EVENT statements perform the required operations on them.

Five status variables provide counts of event-related operations (but not of statements executed by events; see Section 24.8, "Restrictions on Stored Programs"). These are:

• Com_create_event: The number of CREATE EVENT statements executed since the last server restart.

• Com_alter_event: The number of ALTER EVENT statements executed since the last server restart.

• Com_drop_event: The number of DROP EVENT statements executed since the last server restart.

• Com_show_create_event: The number of SHOW CREATE EVENT statements executed since the last server restart.

• Com_show_events: The number of SHOW EVENTS statements executed since the last server restart.

You can view current values for all of these at one time by running the statement SHOW STATUS LIKE '%event%';

24.5 Using Views

MySQL supports views, including updatable views. Views are stored queries that when invoked produce a result set. A view acts as a virtual table.

The following discussion describes the syntax for creating and dropping views, and shows some examples of how to use them.

Additional Resources

• You may find the Views User Forum of use when working with views.
24.5.1 View Syntax

The `CREATE VIEW` statement creates a new view (see Section 13.1.23, “CREATE VIEW Statement”). To alter the definition of a view or drop a view, use `ALTER VIEW` (see Section 13.1.11, “ALTER VIEW Statement”), or `DROP VIEW` (see Section 13.1.35, “DROP VIEW Statement”).

A view can be created from many kinds of `SELECT` statements. It can refer to base tables or other views. It can use joins, `UNION`, and subqueries. The `SELECT` need not even refer to any tables. The following example defines a view that selects two columns from another table, as well as an expression calculated from those columns:

```sql
CREATE TABLE t (qty INT, price INT);
INSERT INTO t VALUES(3, 50), (5, 60);
CREATE VIEW v AS SELECT qty, price, qty*price AS value FROM t;
SELECT * FROM v;
```

```
+-------+-------+-------+
<table>
<thead>
<tr>
<th>qty</th>
<th>price</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>50</td>
<td>150</td>
</tr>
<tr>
<td>5</td>
<td>60</td>
<td>300</td>
</tr>
</tbody>
</table>
```

```sql
SELECT * FROM v WHERE qty = 5;
```

```
+-------+-------+-------+
<table>
<thead>
<tr>
<th>qty</th>
<th>price</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>60</td>
<td>300</td>
</tr>
</tbody>
</table>
```

24.5.2 View Processing Algorithms

The optional `ALGORITHM` clause for `CREATE VIEW` or `ALTER VIEW` is a MySQL extension to standard SQL. It affects how MySQL processes the view. `ALGORITHM` takes three values: `MERGE`, `TEMPTABLE`, or `UNDEFINED`.

- For `MERGE`, the text of a statement that refers to the view and the view definition are merged such that parts of the view definition replace corresponding parts of the statement.
- For `TEMPTABLE`, the results from the view are retrieved into a temporary table, which then is used to execute the statement.
- For `UNDEFINED`, MySQL chooses which algorithm to use. It prefers `MERGE` over `TEMPTABLE` if possible, because `MERGE` is usually more efficient and because a view cannot be updatable if a temporary table is used.

- If no `ALGORITHM` clause is present, the default algorithm is determined by the value of the `derived_merge` flag of the `optimizer_switch` system variable. For additional discussion, see Section 8.2.2.4, “Optimizing Derived Tables, View References, and Common Table Expressions with Merging or Materialization”.

A reason to specify `TEMPTABLE` explicitly is that locks can be released on underlying tables after the temporary table has been created and before it is used to finish processing the statement. This might result in quicker lock release than the `MERGE` algorithm so that other clients that use the view are not blocked as long.

A view algorithm can be `UNDEFINED` for three reasons:

- No `ALGORITHM` clause is present in the `CREATE VIEW` statement.
- The `CREATE VIEW` statement has an explicit `ALGORITHM = UNDEFINED` clause.
• **ALGORITHM = MERGE** is specified for a view that can be processed only with a temporary table. In this case, MySQL generates a warning and sets the algorithm to **UNDEFINED**.

As mentioned earlier, **MERGE** is handled by merging corresponding parts of a view definition into the statement that refers to the view. The following examples briefly illustrate how the **MERGE** algorithm works. The examples assume that there is a view `v_merge` that has this definition:

```
CREATE ALGORITHM = MERGE VIEW v_merge (vc1, vc2) AS
SELECT c1, c2 FROM t WHERE c3 > 100;
```

Example 1: Suppose that we issue this statement:

```
SELECT * FROM v_merge;
```

MySQL handles the statement as follows:

- **v_merge** becomes **t**
- ***** becomes **vc1, vc2**, which corresponds to **c1, c2**
- The view **WHERE** clause is added

The resulting statement to be executed becomes:

```
SELECT c1, c2 FROM t WHERE c3 > 100;
```

Example 2: Suppose that we issue this statement:

```
SELECT * FROM v_merge WHERE vc1 < 100;
```

This statement is handled similarly to the previous one, except that **vc1 < 100** becomes **c1 < 100** and the view **WHERE** clause is added to the statement **WHERE** clause using an **AND** connective (and parentheses are added to make sure the parts of the clause are executed with correct precedence).

The resulting statement to be executed becomes:

```
SELECT c1, c2 FROM t WHERE (c3 > 100) AND (c1 < 100);
```

Effectively, the statement to be executed has a **WHERE** clause of this form:

```
WHERE (select WHERE) AND (view WHERE)
```

If the **MERGE** algorithm cannot be used, a temporary table must be used instead. Constructs that prevent merging are the same as those that prevent merging in derived tables and common table expressions. Examples are **SELECT DISTINCT** or **LIMIT** in the subquery. For details, see Section 8.2.2.4, “Optimizing Derived Tables, View References, and Common Table Expressions with Merging or Materialization”.

### 24.5.3 Updatable and Insertable Views

Some views are updatable and references to them can be used to specify tables to be updated in data change statements. That is, you can use them in statements such as **UPDATE**, **DELETE**, or **INSERT** to update the contents of the underlying table. Derived tables and common table expressions can also be specified in multiple-table **UPDATE** and **DELETE** statements, but can only be used for reading data to specify rows to be updated or deleted. Generally, the view references must be updatable, meaning that they may be merged and not materialized. Composite views have more complex rules.

For a view to be updatable, there must be a one-to-one relationship between the rows in the view and the rows in the underlying table. There are also certain other constructs that make a view nonupdatable. To be more specific, a view is not updatable if it contains any of the following:

- Aggregate functions or window functions (**SUM()**, **MIN()**, **MAX()**, **COUNT()**, and so forth)
- **DISTINCT**
- **GROUP BY**
Updatable and Insertable Views

- **HAVING**
- **UNION** or **UNION ALL**
- Subquery in the select list

  Nondependent subqueries in the select list fail for **INSERT**, but are okay for **UPDATE, DELETE**. For dependent subqueries in the select list, no data change statements are permitted.

- Certain joins (see additional join discussion later in this section)
- Reference to nonupdatable view in the **FROM** clause
- Subquery in the **WHERE** clause that refers to a table in the **FROM** clause
- Refers only to literal values (in this case, there is no underlying table to update)
- **ALGORITHM = TEMPTABLE** (use of a temporary table always makes a view nonupdatable)
- Multiple references to any column of a base table (fails for **INSERT**, okay for **UPDATE, DELETE**)

A generated column in a view is considered updatable because it is possible to assign to it. However, if such a column is updated explicitly, the only permitted value is **DEFAULT**. For information about generated columns, see Section 13.1.20.8, “CREATE TABLE and Generated Columns”.

It is sometimes possible for a multiple-table view to be updatable, assuming that it can be processed with the **MERGE** algorithm. For this to work, the view must use an inner join (not an outer join or a **UNION**). Also, only a single table in the view definition can be updated, so the **SET** clause must name only columns from one of the tables in the view. Views that use **UNION ALL** are not permitted even though they might be theoretically updatable.

With respect to insertability (being updatable with **INSERT** statements), an updatable view is insertable if it also satisfies these additional requirements for the view columns:

- There must be no duplicate view column names.
- The view must contain all columns in the base table that do not have a default value.
- The view columns must be simple column references. They must not be expressions, such as these:

  - 3.14159
  - `col1 + 3`
  - `UPPER(col2)`
  - `col3 / col4`
  - (subquery)

MySQL sets a flag, called the view updatability flag, at **CREATE VIEW** time. The flag is set to **YES** (true) if **UPDATE** and **DELETE** (and similar operations) are legal for the view. Otherwise, the flag is set to **NO** (false). The **IS_UPDATABLE** column in the **INFORMATION_SCHEMA.VIEWS** table displays the status of this flag. It means that the server always knows whether a view is updatable.

If a view is not updatable, statements such **UPDATE, DELETE, and INSERT** are illegal and are rejected. (Even if a view is updatable, it might not be possible to insert into it, as described elsewhere in this section.)

The updatability of views may be affected by the value of the **updatable_views_with_limit** system variable. See Section 5.1.8, “Server System Variables”.

For the following discussion, suppose that these tables and views exist:

```sql
CREATE TABLE t1 (x INTEGER);
CREATE TABLE t2 (c INTEGER);
CREATE VIEW vmat AS SELECT SUM(x) AS s FROM t1;
```
CREATE VIEW vup AS SELECT * FROM t2;
CREATE VIEW vjoin AS SELECT * FROM vmat JOIN vup ON vmat.s=vup.c;

**INSERT, UPDATE, and DELETE statements** are permitted as follows:

- **INSERT**: The insert table of an **INSERT** statement may be a view reference that is merged. If the view is a join view, all components of the view must be updatable (not materialized). For a multiple-table updatable view, **INSERT** can work if it inserts into a single table.

This statement is invalid because one component of the join view is nonupdatable:

```
INSERT INTO vjoin (c) VALUES (1);
```

This statement is valid; the view contains no materialized components:

```
INSERT INTO vup (c) VALUES (1);
```

- **UPDATE**: The table or tables to be updated in an **UPDATE** statement may be view references that are merged. If a view is a join view, at least one component of the view must be updatable (this differs from **INSERT**).

In a multiple-table **UPDATE** statement, the updated table references of the statement must be base tables or updatable view references. Nonupdated table references may be materialized views or derived tables.

This statement is valid; column `c` is from the updatable part of the join view:

```
UPDATE vjoin SET c=c+1;
```

This statement is invalid; column `x` is from the nonupdatable part:

```
UPDATE vjoin SET x=x+1;
```

This statement is valid; the updated table reference of the multiple-table **UPDATE** is an updatable view (`vup`):

```
UPDATE vup JOIN (SELECT SUM(x) AS s FROM t1) AS dt ON ... SET c=c+1;
```

This statement is invalid; it tries to update a materialized derived table:

```
UPDATE vup JOIN (SELECT SUM(x) AS s FROM t1) AS dt ON ... SET s=s+1;
```

- **DELETE**: The table or tables to be deleted from in a **DELETE** statement must be merged views. Join views are not allowed (this differs from **INSERT** and **UPDATE**).

This statement is invalid because the view is a join view:

```
DELETE vjoin WHERE ...;
```

This statement is valid because the view is a merged (updatable) view:

```
DELETE vup WHERE ...;
```

This statement is valid because it deletes from a merged (updatable) view:

```
DELETE vup FROM vup JOIN (SELECT SUM(x) AS s FROM t1) AS dt ON ...;
```

Additional discussion and examples follow.

Earlier discussion in this section pointed out that a view is not insertable if not all columns are simple column references (for example, if it contains columns that are expressions or composite expressions). Although such a view is not insertable, it can be updatable if you update only columns that are not expressions. Consider this view:
The View WITH CHECK OPTION Clause

CREATE VIEW v AS SELECT col1, 1 AS col2 FROM t;

This view is not insertable because col2 is an expression. But it is updatable if the update does not try to update col2. This update is permissible:

UPDATE v SET col1 = 0;

This update is not permissible because it attempts to update an expression column:

UPDATE v SET col2 = 0;

If a table contains an AUTO_INCREMENT column, inserting into an insertable view on the table that does not include the AUTO_INCREMENT column does not change the value of LAST_INSERT_ID(), because the side effects of inserting default values into columns not part of the view should not be visible.

24.5.4 The View WITH CHECK OPTION Clause

The WITH CHECK OPTION clause can be given for an updatable view to prevent inserts to rows for which the WHERE clause in the select_statement is not true. It also prevents updates to rows for which the WHERE clause is true but the update would cause it to be not true (in other words, it prevents visible rows from being updated to nonvisible rows).

In a WITH CHECK OPTION clause for an updatable view, the LOCAL and CASCADED keywords determine the scope of check testing when the view is defined in terms of another view. When neither keyword is given, the default is CASCADED.

WITH CHECK OPTION testing is standard-compliant:

- With LOCAL, the view WHERE clause is checked, then checking recurses to underlying views and applies the same rules.

- With CASCADED, the view WHERE clause is checked, then checking recurses to underlying views, adds WITH CASCADED CHECK OPTION to them (for purposes of the check; their definitions remain unchanged), and applies the same rules.

- With no check option, the view WHERE clause is not checked, then checking recurses to underlying views, and applies the same rules.

Consider the definitions for the following table and set of views:

CREATE TABLE t1 (a INT);
CREATE VIEW v1 AS SELECT * FROM t1 WHERE a < 2
WITH CHECK OPTION;
CREATE VIEW v2 AS SELECT * FROM v1 WHERE a > 0
WITH LOCAL CHECK OPTION;
CREATE VIEW v3 AS SELECT * FROM v1 WHERE a > 0
WITH CASCADED CHECK OPTION;

Here the v2 and v3 views are defined in terms of another view, v1.

Inserts for v2 are checked against its LOCAL check option, then the check recurses to v1 and the rules are applied again. The rules for v1 cause a check failure. The check for v3 also fails:

mysql> INSERT INTO v2 VALUES (2);
ERROR 1369 (HY000): CHECK OPTION failed 'test.v2'
mysql> INSERT INTO v3 VALUES (2);
ERROR 1369 (HY000): CHECK OPTION failed 'test.v3'

24.5.5 View Metadata

To obtain metadata about views:

- Query the VIEWS table of the INFORMATION_SCHEMA database. See Section 25.44, “The INFORMATION_SCHEMA VIEWS Table”.

4182
• Use the `SHOW CREATE VIEW` statement. See Section 13.7.7.13, “SHOW CREATE VIEW Statement”.

24.6 Stored Object Access Control

Stored programs (procedures, functions, triggers, and events) and views are defined prior to use and, when referenced, execute within a security context that determines their privileges. These privileges are controlled by their `DEFINER` attribute and `SQL SECURITY` characteristic.

• The `DEFINER` Attribute

• The `SQL SECURITY` Characteristic

• Examples

• Risk-Minimization Guidelines

The `DEFINER` Attribute

All stored object definitions can include a `DEFINER` attribute that names a MySQL account. If a definition omits the `DEFINER` attribute, the default definer is the user who creates the object.

MySQL uses the following rules to control which accounts a user can specify in an object `DEFINER` attribute:

• If you have the `SET_USER_ID` privilege (or the deprecated `SUPER` privilege), you can specify any account as the `DEFINER` value, although a warning is generated if the account does not exist. Additionally, as of MySQL 8.0.16, to set the `DEFINER` attribute for a stored object to an account that has the `SYSTEM_USER` privilege, you must have the `SYSTEM_USER` privilege.

• Otherwise, the only permitted account is your own, either specified literally or as `CURRENT_USER` or `CURRENT_USER()`. You cannot set the definer to some other account.

Creating a stored object with a nonexistent `DEFINER` account may have negative consequences:

• For a stored routine, an error occurs at routine execution time if the `SQL SECURITY` value is `DEFINER` but the definer account does not exist.

• For a trigger, it is not a good idea for trigger activation to occur until the account actually does exist. Otherwise, the behavior with respect to privilege checking is undefined.

• For an event, an error occurs at event execution time if the account does not exist.

• For a view, an error occurs when the view is referenced if the `SQL SECURITY` value is `DEFINER` but the definer account does not exist.

The `SQL SECURITY` Characteristic

Definitions for stored routines (procedures and functions) and views can include an `SQL SECURITY` characteristic with a value of `DEFINER` or `INVOKER` to specify whether the object executes in definer or invoker context. If a definition omits the `SQL SECURITY` characteristic, the default is definer context.

Triggers and events have no `SQL SECURITY` characteristic and always execute in definer context. The server invokes these objects automatically as necessary, so there is no invoking user.

Definer and invoker security contexts differ as follows:

• A stored object that executes in definer security context executes with the privileges of the account named by its `DEFINER` attribute. These privileges may be entirely different from those of the invoking user. The invoker must have appropriate privileges to reference the object (for example, `EXECUTE` to call a stored procedure or `SELECT` to select from a view), but during object execution, the invoker’s...
privileges are ignored and only the `DEFINER` account privileges matter. If the `DEFINER` account has few privileges, the object is correspondingly limited in the operations it can perform. If the `DEFINER` account is highly privileged (such as a root account), the object can perform powerful operations no matter who invokes it.

- A stored routine or view that executes in invoker security context can perform only operations for which the invoker has privileges. The `DEFINER` attribute has no effect during object execution.

Examples

Consider the following stored procedure, which is declared with SQL SECURITY DEFINER to execute in definer security context:

```sql
CREATE DEFINER = 'admin'@'localhost' PROCEDURE p1()
SQL SECURITY DEFINER
BEGIN
    UPDATE t1 SET counter = counter + 1;
END;
```

Any user who has the EXECUTE privilege for `p1` can invoke it with a CALL statement. However, when `p1` executes, it does so in definer security context and thus executes with the privileges of 'admin'@'localhost', the account named in the `DEFINER` attribute. This account must have the EXECUTE privilege for `p1` as well as the UPDATE privilege for the table `t1` referenced within the object body. Otherwise, the procedure fails.

Now consider this stored procedure, which is identical to `p1` except that its SQL SECURITY characteristic is INVOKER:

```sql
CREATE DEFINER = 'admin'@'localhost' PROCEDURE p2()
SQL SECURITY INVOKER
BEGIN
    UPDATE t1 SET counter = counter + 1;
END;
```

Unlike `p1`, `p2` executes in invoker security context and thus with the privileges of the invoking user regardless of the `DEFINER` attribute value. `p2` fails if the invoker lacks the EXECUTE privilege for `p2` or the UPDATE privilege for the table `t1`.

Risk-Minimization Guidelines

To minimize the risk potential for stored object creation and use, follow these guidelines:

- For a stored routine or view, use SQL SECURITY INVOKER in the object definition when possible so that it can be used only by users with permissions appropriate for the operations performed by the object.

- If you create definer-context stored objects while using an account that has the SET_USER_ID privilege (or the deprecated SUPER privilege), specify an explicit `DEFINER` attribute that names an account possessing only the privileges required for the operations performed by the object. Specify a highly privileged `DEFINER` account only when absolutely necessary.

- Administrators can prevent users from creating stored objects that specify highly privileged `DEFINER` accounts by not granting them the SET_USER_ID privilege (or the deprecated SUPER privilege).

- Definer-context objects should be written keeping in mind that they may be able to access data for which the invoking user has no privileges. In some cases, you can prevent references to these objects by not granting unauthorized users particular privileges:

  - A stored routine cannot be referenced by a user who does not have the EXECUTE privilege for it.

  - A view cannot be referenced by a user who does not have the appropriate privilege for it (SELECT to select from it, INSERT to insert into it, and so forth).
However, no such control exists for triggers and events because they always execute in definer context. The server invokes these objects automatically as necessary; users do not reference them directly:

- A trigger is activated by access to the table with which it is associated, even ordinary table accesses by users with no special privileges.
- An event is executed by the server on a scheduled basis.

In both cases, if the **DEFINER** account is highly privileged, the object may be able to perform sensitive or dangerous operations. This remains true if the privileges needed to create the object are revoked from the account of the user who created it. Administrators should be especially careful about granting users object-creation privileges.

### 24.7 Stored Program Binary Logging

The binary log contains information about SQL statements that modify database contents. This information is stored in the form of "events" that describe the modifications. (Binary log events differ from scheduled event stored objects.) The binary log has two important purposes:

- For replication, the binary log is used on master replication servers as a record of the statements to be sent to slave servers. The master server sends the events contained in its binary log to its slaves, which execute those events to make the same data changes that were made on the master. See Section 17.2, "Replication Implementation".

- Certain data recovery operations require use of the binary log. After a backup file has been restored, the events in the binary log that were recorded after the backup was made are re-executed. These events bring databases up to date from the point of the backup. See Section 7.3.2, "Using Backups for Recovery".

However, if logging occurs at the statement level, there are certain binary logging issues with respect to stored programs (stored procedures and functions, triggers, and events):

- In some cases, a statement might affect different sets of rows on master and slave.
- Replicated statements executed on a slave are processed by the slave SQL thread, which has full privileges. It is possible for a procedure to follow different execution paths on master and slave servers, so a user can write a routine containing a dangerous statement that will execute only on the slave where it is processed by a thread that has full privileges.
- If a stored program that modifies data is nondeterministic, it is not repeatable. This can result in different data on master and slave, or cause restored data to differ from the original data.

This section describes how MySQL handles binary logging for stored programs. It states the current conditions that the implementation places on the use of stored programs, and what you can do to avoid logging problems. It also provides additional information about the reasons for these conditions.

In general, the issues described here result when binary logging occurs at the SQL statement level (statement-based binary logging). If you use row-based binary logging, the log contains changes made to individual rows as a result of executing SQL statements. When routines or triggers execute, row changes are logged, not the statements that make the changes. For stored procedures, this means that the **CALL** statement is not logged. For stored functions, row changes made within the function are logged, not the function invocation. For triggers, row changes made by the trigger are logged. On the slave side, only the row changes are seen, not the stored program invocation.

Mixed format binary logging (**binlog_format=MIXED**) uses statement-based binary logging, except for cases where only row-based binary logging is guaranteed to lead to proper results. With mixed format, when a stored function, stored procedure, trigger, event, or prepared statement contains anything that is not safe for statement-based binary logging, the entire statement is marked as unsafe and logged in row format. The statements used to create and drop procedures, functions, triggers,
and events are always safe, and are logged in statement format. For more information about row-based, mixed, and statement-based logging, and how safe and unsafe statements are determined, see Section 17.2.1, “Replication Formats”.

Unless noted otherwise, the remarks here assume that binary logging is enabled on the server (see Section 5.4.4, “The Binary Log”). If the binary log is not enabled, replication is not possible, nor is the binary log available for data recovery.

The conditions on the use of stored functions in MySQL can be summarized as follows. These conditions do not apply to stored procedures or Event Scheduler events and they do not apply unless binary logging is enabled.

- To create or alter a stored function, you must have the `SET_USER_ID` privilege (or the deprecated `SUPER` privilege), in addition to the `CREATE ROUTINE` or `ALTER ROUTINE` privilege that is normally required. (Depending on the `DEFINER` value in the function definition, `SET_USER_ID` or `SUPER` might be required regardless of whether binary logging is enabled. See Section 13.1.17, “CREATE PROCEDURE and CREATE FUNCTION Statements”.)

- When you create a stored function, you must declare either that it is deterministic or that it does not modify data. Otherwise, it may be unsafe for data recovery or replication.

By default, for a `CREATE FUNCTION` statement to be accepted, at least one of `DETERMINISTIC`, `NO SQL`, or `READS SQL DATA` must be specified explicitly. Otherwise an error occurs:

```
ERROR 1418 (HY000): This function has none of DETERMINISTIC, NO SQL, or READS SQL DATA in its declaration and binary logging is enabled (you *might* want to use the less safe log_bin_trust_function_creators variable)
```

This function is deterministic (and does not modify data), so it is safe:

```
CREATE FUNCTION f1(i INT)
RETURNS INT
DETERMINISTIC
READS SQL DATA
BEGIN
    RETURN i;
END;
```

This function uses `UUID()`, which is not deterministic, so the function also is not deterministic and is not safe:

```
CREATE FUNCTION f2()
RETURNS CHAR(36) CHARACTER SET utf8
BEGIN
    RETURN UUID();
END;
```

This function modifies data, so it may not be safe:

```
CREATE FUNCTION f3(p_id INT)
RETURNS INT
BEGIN
    UPDATE t SET modtime = NOW() WHERE id = p_id;
    RETURN ROW_COUNT();
END;
```

Assessment of the nature of a function is based on the “honesty” of the creator. MySQL does not check that a function declared `DETERMINISTIC` is free of statements that produce nondeterministic results.

- When you attempt to execute a stored function, if `binlog_format=STATEMENT` is set, the `DETERMINISTIC` keyword must be specified in the function definition. If this is not the case, an error is generated and the function does not run, unless `log_bin_trust_function_creators=1` is specified to override this check (see below). For recursive function calls, the `DETERMINISTIC`
keyword is required on the outermost call only. If row-based or mixed binary logging is in use, the statement is accepted and replicated even if the function was defined without the `DETERMINISTIC` keyword.

- Because MySQL does not check if a function really is deterministic at creation time, the invocation of a stored function with the `DETERMINISTIC` keyword might carry out an action that is unsafe for statement-based logging, or invoke a function or procedure containing unsafe statements. If this occurs when `binlog_format=STATEMENT` is set, a warning message is issued. If row-based or mixed binary logging is in use, no warning is issued, and the statement is replicated in row-based format.

- To relax the preceding conditions on function creation (that you must have the `SUPER` privilege and that a function must be declared deterministic or to not modify data), set the global `log_bin_trust_function_creators` system variable to 1. By default, this variable has a value of 0, but you can change it like this:

  ```mysql
  mysql> SET GLOBAL log_bin_trust_function_creators = 1;
  ```

  You can also set this variable at server startup.

  If binary logging is not enabled, `log_bin_trust_function_creators` does not apply. `SUPER` is not required for function creation unless, as described previously, the `DEFINER` value in the function definition requires it.

- For information about built-in functions that may be unsafe for replication (and thus cause stored functions that use them to be unsafe as well), see Section 17.5.1, “Replication Features and Issues”.

Triggers are similar to stored functions, so the preceding remarks regarding functions also apply to triggers with the following exception: `CREATE TRIGGER` does not have an optional `DETERMINISTIC` characteristic, so triggers are assumed to be always deterministic. However, this assumption might be invalid in some cases. For example, the `UUID()` function is nondeterministic (and does not replicate). Be careful about using such functions in triggers.

Triggers can update tables, so error messages similar to those for stored functions occur with `CREATE TRIGGER` if you do not have the required privileges. On the slave side, the slave uses the trigger `DEFINER` attribute to determine which user is considered to be the creator of the trigger.

The rest of this section provides additional detail about the logging implementation and its implications. You need not read it unless you are interested in the background on the rationale for the current logging-related conditions on stored routine use. This discussion applies only for statement-based logging, and not for row-based logging, with the exception of the first item: `CREATE` and `DROP` statements are logged as statements regardless of the logging mode.

- The server writes `CREATE EVENT`, `CREATE PROCEDURE`, `CREATE FUNCTION`, `ALTER EVENT`, `ALTER PROCEDURE`, `ALTER FUNCTION`, `DROP EVENT`, `DROP PROCEDURE`, and `DROP FUNCTION` statements to the binary log.

- A stored function invocation is logged as a `SELECT` statement if the function changes data and occurs within a statement that would not otherwise be logged. This prevents nonreplication of data changes that result from use of stored functions in nonlogged statements. For example, `SELECT` statements are not written to the binary log, but a `SELECT` might invoke a stored function that makes changes. To handle this, a `SELECT func_name()` statement is written to the binary log when the given function makes a change. Suppose that the following statements are executed on the master:

```sql
CREATE FUNCTION f1(a INT) RETURNS INT
BEGIN
  IF (a < 3) THEN
    INSERT INTO t2 VALUES (a);
  END IF;
  RETURN 0;
END;

CREATE TABLE t1 (a INT);
```
INSERT INTO t1 VALUES (1),(2),(3);
SELECT f1(a) FROM t1;

When the `SELECT` statement executes, the function `f1()` is invoked three times. Two of those invocations insert a row, and MySQL logs a `SELECT` statement for each of them. That is, MySQL writes the following statements to the binary log:

```
SELECT f1(1);
SELECT f1(2);
```

The server also logs a `SELECT` statement for a stored function invocation when the function invokes a stored procedure that causes an error. In this case, the server writes the `SELECT` statement to the log along with the expected error code. On the slave, if the same error occurs, that is the expected result and replication continues. Otherwise, replication stops.

- Logging stored function invocations rather than the statements executed by a function has a security implication for replication, which arises from two factors:
  - It is possible for a function to follow different execution paths on master and slave servers.
  - Statements executed on a slave are processed by the slave SQL thread which has full privileges.

The implication is that although a user must have the `CREATE ROUTINE` privilege to create a function, the user can write a function containing a dangerous statement that will execute only on the slave where it is processed by a thread that has full privileges. For example, if the master and slave servers have server ID values of 1 and 2, respectively, a user on the master server could create and invoke an unsafe function `unsafe_func()` as follows:

```
mysql> delimiter //
mysql> CREATE FUNCTION unsafe_func () RETURNS INT
    -> BEGIN
    -> IF @@server_id=2 THEN dangerous_statement; END IF;
    -> RETURN 1;
    -> END;
    -> //
mysql> delimiter ;
mysql> INSERT INTO t VALUES(unsafe_func());
```

The `CREATE FUNCTION` and `INSERT` statements are written to the binary log, so the slave will execute them. Because the slave SQL thread has full privileges, it will execute the dangerous statement. Thus, the function invocation has different effects on the master and slave and is not replication-safe.

To guard against this danger for servers that have binary logging enabled, stored function creators must have the `SUPER` privilege, in addition to the usual `CREATE ROUTINE` privilege that is required. Similarly, to use `ALTER FUNCTION`, you must have the `SUPER` privilege in addition to the `ALTER ROUTINE` privilege. Without the `SUPER` privilege, an error will occur:

```
ERROR 1419 (HY000): You do not have the SUPER privilege and binary logging is enabled (you *might* want to use the less safe log_bin_trust_function_creators variable)
```

If you do not want to require function creators to have the `SUPER` privilege (for example, if all users with the `CREATE ROUTINE` privilege on your system are experienced application developers), set the global `log_bin_trust_function_creators` system variable to 1. You can also set this variable at server startup. If binary logging is not enabled, `log_bin_trust_function_creators` does not apply. `SUPER` is not required for function creation unless, as described previously, the `DEFINER` value in the function definition requires it.

- If a function that performs updates is nondeterministic, it is not repeatable. This can have two undesirable effects:
  - It will make a slave different from the master.
• Restored data will be different from the original data.

To deal with these problems, MySQL enforces the following requirement: On a master server, creation and alteration of a function is refused unless you declare the function to be deterministic or to not modify data. Two sets of function characteristics apply here:

• The **DETERMINISTIC** and **NOT DETERMINISTIC** characteristics indicate whether a function always produces the same result for given inputs. The default is **NOT DETERMINISTIC** if neither characteristic is given. To declare that a function is deterministic, you must specify **DETERMINISTIC** explicitly.

• The **CONTAINS SQL**, **NO SQL**, **READS SQL DATA**, and **MODIFIES SQL DATA** characteristics provide information about whether the function reads or writes data. Either **NO SQL** or **READS SQL DATA** indicates that a function does not change data, but you must specify one of these explicitly because the default is **CONTAINS SQL** if no characteristic is given.

By default, for a **CREATE FUNCTION** statement to be accepted, at least one of **DETERMINISTIC**, **NO SQL**, or **READS SQL DATA** must be specified explicitly. Otherwise an error occurs:

```sql
ERROR 1418 (HY000): This function has none of DETERMINISTIC, NO SQL, or READS SQL DATA in its declaration and binary logging is enabled (you *might* want to use the less safe log_bin_trust_function_creators variable)
```

If you set **log_bin_trust_function_creators** to 1, the requirement that functions be deterministic or not modify data is dropped.

• Stored procedure calls are logged at the statement level rather than at the **CALL** level. That is, the server does not log the **CALL** statement, it logs those statements within the procedure that actually execute. As a result, the same changes that occur on the master will be observed on slave servers. This prevents problems that could result from a procedure having different execution paths on different machines.

In general, statements executed within a stored procedure are written to the binary log using the same rules that would apply were the statements to be executed in standalone fashion. Some special care is taken when logging procedure statements because statement execution within procedures is not quite the same as in nonprocedure context:

• A statement to be logged might contain references to local procedure variables. These variables do not exist outside of stored procedure context, so a statement that refers to such a variable cannot be logged literally. Instead, each reference to a local variable is replaced by this construct for logging purposes:

```sql
NAME_CONST(var_name, var_value)
```
