This system variable should have the same value on all group members. The value of this system variable can be changed while Group Replication is running. The change takes effect on each group member after you stop and restart Group Replication on the member. During this process, the value of the system variable is permitted to differ between group members, but members might be unable to reconnect in the event of a disconnection.

**group_replication_message_cache_size** sets the maximum amount of memory that is available for the message cache in the group communication engine for Group Replication (XCom). The XCom message cache holds messages (and their metadata) that are exchanged between the group members as a part of the consensus protocol. Among other functions, the message cache is used for recovery of missed messages by members that reconnect with the group after a period where they were unable to communicate with the other group members.

The **group_replication_member_expel_timeout** system variable determines the waiting period (up to an hour) that is allowed in addition to the initial 5-second detection period for members to return to the group rather than being expelled. The size of the XCom message cache should be set with reference to the expected volume of messages in this time period, so that it contains all the missed messages required for members to return successfully. Up to MySQL 8.0.20, the default is only the 5-second detection period, but from MySQL 8.0.21, the default is a 5-second waiting period after the 5-second detection period, for a total time period of 10 seconds.

Ensure that sufficient memory is available on your system for your chosen cache size limit, considering the size of MySQL Server’s other caches and object pools. The default setting is 1073741824 bytes (1 GB). The minimum setting is also 1 GB up to MySQL 8.0.20. From MySQL 8.0.21, the minimum setting is 134217728 bytes (128 MB), which enables deployment on a host that has a restricted amount of available memory, and good network connectivity to minimize the frequency
and duration of transient losses of connectivity for group members. Note that the limit set using `group_replication_message_cache_size` applies only to the data stored in the cache, and the cache structures require an additional 50 MB of memory.

The cache size limit can be increased or reduced dynamically at runtime. If you reduce the cache size limit, XCom removes the oldest entries that have been decided and delivered until the current size is below the limit. Group Replication's Group Communication System (GCS) alerts you, by a warning message, when a message that is likely to be needed for recovery by a member that is currently unreachable is removed from the message cache. For more information on tuning the message cache size, see Section 18.6.5, "XCom Cache Management".

• `group_replication_poll_spin_loops`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--group-replication-poll-spin-loops=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>group_replication_poll_spin_loops</code></td>

<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value (64-bit platforms)</td>
<td><code>18446744073709551615</code></td>
</tr>
<tr>
<td>Maximum Value (32-bit platforms)</td>
<td><code>4294967295</code></td>
</tr>
</tbody>
</table>

The value of this system variable can be changed while Group Replication is running, but the change only takes effect after you stop and restart Group Replication on the group member.

`group_replication_poll_spin_loops` specifies the number of times the group communication thread waits for the communication engine mutex to be released before the thread waits for more incoming network messages.

• `group_replication_recovery_complete_at`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--group-replication-recovery-complete-at=value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>group_replication_recovery_complete_at</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>TRANSACTIONS_APPLIED</code></td>
</tr>
<tr>
<td>Valid Values</td>
<td><code>TRANSACTIONS_CERTIFIED</code></td>
</tr>
</tbody>
</table>
**Group Replication System Variables**

**TRANSACTIONS_APPLIED**

The value of this system variable can be changed while Group Replication is running, but the change only takes effect after you stop and restart Group Replication on the group member.

`group_replication_recovery_complete_at` specifies the policy applied during the distributed recovery process when handling cached transactions after state transfer from an existing member. You can choose whether a member is marked online after it has received and certified all transactions that it missed before it joined the group (TRANSACTIONS_CERTIFIED), or only after it has received, certified, and applied them (TRANSACTIONS_APPLIED).

- **group_replication_recovery_compression_algorithm**

  Command-Line Format
  
  `--group-replication-recovery-compression-algorithm=value`

  Introduced 8.0.18

  System Variable `group_replication_recovery_compression_algorithm`

  Scope Global

  Dynamic Yes

  SET_VAR Hint Applies No

  Type Set

  Default Value `uncompressed`

  Valid Values `zlib`, `zstd`, `uncompressed`

  The value of this system variable can be changed while Group Replication is running, but the change only takes effect after you stop and restart Group Replication on the group member.

  `group_replication_recovery_compression_algorithm` specifies the compression algorithms permitted for Group Replication distributed recovery connections for state transfer from a donor's binary log. The available algorithms are the same as for the `protocol_compression_algorithms` system variable. For more information, see Section 4.2.8, “Connection Compression Control”.

  This setting does not apply if the server has been set up to support cloning (see Section 18.4.3.2, “Cloning for Distributed Recovery”) and a remote cloning operation is used during distributed recovery. For this method of state transfer, the clone plugin's `clone_enable_compression` setting applies.

- **group_replication_recovery_get_public_key**

  Command-Line Format
  
  `--group-replication-recovery-get-public-key=[OFF|ON]`

  System Variable `group_replication_recovery_get_public_key`

  Scope Global

  Dynamic Yes

  SET_VAR Hint Applies No

  Type Boolean
The value of this system variable can be changed while Group Replication is running, but the change only takes effect after you stop and restart Group Replication on the group member.

`group_replication_recovery_get_public_key` specifies whether to request from the source the public key required for RSA key pair-based password exchange. If `group_replication_recovery_public_key_path` is set to a valid public key file, it takes precedence over `group_replication_recovery_get_public_key`. This variable applies if you are not using SSL for distributed recovery over the `group_replication_recovery` channel (`group_replication_recovery_use_ssl=OFF`), and the replication user account for Group Replication authenticates with the `caching_sha2_password` plugin (which is the default in MySQL 8.0). For more details, see `Replication User With The Caching SHA-2 Authentication Plugin`.

- `group_replication_recovery_public_key_path`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--group-replication-recovery-public-key-path=file_name</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>System Variable</strong></td>
<td><code>group_replication_recovery_public_key_path</code></td>
</tr>
<tr>
<td><strong>Scope</strong></td>
<td>Global</td>
</tr>
<tr>
<td><strong>Dynamic</strong></td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>File name</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>NULL</td>
</tr>
</tbody>
</table>

The value of this system variable can be changed while Group Replication is running, but the change only takes effect after you stop and restart Group Replication on the group member.

`group_replication_recovery_public_key_path` specifies the path name to a file containing a replica-side copy of the public key required by the source for RSA key pair-based password exchange. The file must be in PEM format. If `group_replication_recovery_public_key_path` is set to a valid public key file, it takes precedence over `group_replication_recovery_get_public_key`. This variable applies if you are not using SSL for distributed recovery over the `group_replication_recovery` channel (so `group_replication_recovery_use_ssl` is set to `OFF`), and the replication user account for Group Replication authenticates with the `caching_sha2_password` plugin (which is the default in MySQL 8.0) or the `sha256_password` plugin. (For `sha256_password`, setting `group_replication_recovery_public_key_path` applies only if MySQL was built using OpenSSL.) For more details, see `Replication User With The Caching SHA-2 Authentication Plugin`.

- `group_replication_recovery_reconnect_interval`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--group-replication-recovery-reconnect-interval=#</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>System Variable</strong></td>
<td><code>group_replication_recovery_reconnect_interval</code></td>
</tr>
<tr>
<td><strong>Scope</strong></td>
<td>Global</td>
</tr>
<tr>
<td><strong>Dynamic</strong></td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Integer</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>60</td>
</tr>
</tbody>
</table>
Group Replication System Variables

<table>
<thead>
<tr>
<th>Minimum Value</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum Value</td>
<td>31536000</td>
</tr>
</tbody>
</table>

The value of this system variable can be changed while Group Replication is running, but the change only takes effect after you stop and restart Group Replication on the group member.

`group_replication_recovery_reconnect_interval` specifies the sleep time, in seconds, between reconnection attempts when no suitable donor was found in the group for distributed recovery.

- **`group_replication_recovery_reconnect_interval`**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--group-replication-recovery-reconnect-interval=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>group_replication_recovery_reconnect_interval</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>31536000</td>
</tr>
</tbody>
</table>

The value of this system variable can be changed while Group Replication is running, but the change only takes effect after you stop and restart Group Replication on the group member.

`group_replication_recovery_retry_count` specifies the number of times that the member that is joining tries to connect to the available donors for distributed recovery before giving up.

- **`group_replication_recovery_retry_count`**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--group-replication-recovery-retry-count=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>group_replication_recovery_retry_count</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>10</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>31536000</td>
</tr>
</tbody>
</table>

The value of this system variable can be changed while Group Replication is running, but the change only takes effect after you stop and restart Group Replication on the group member.

`group_replication_recovery_ssl_ca` specifies the path to a file that contains a list of trusted SSL certificate authorities for distributed recovery connections. See Section 18.5.2, “Securing Group Communication Connections with Secure Socket Layer (SSL)” for information on configuring SSL for distributed recovery.

If this server has been set up to support cloning (see Section 18.4.3.2, “Cloning for Distributed Recovery”), and you have set `group_replication_recovery_use_ssl` to ON, Group Replication automatically configures the setting for the clone SSL option `clone_ssl_ca` to match your setting for `group_replication_recovery_ssl_ca`.

- **`group_replication_recovery_ssl_ca`**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--group-replication-recovery-ssl-ca=value</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>group_replication_recovery_ssl_ca</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

The value of this system variable can be changed while Group Replication is running, but the change only takes effect after you stop and restart Group Replication on the group member.

`group_replication_recovery_ssl_capath`
The value of this system variable can be changed while Group Replication is running, but the change only takes effect after you stop and restart Group Replication on the group member.

`group_replication_recovery_ssl_capath` specifies the path to a directory that contains trusted SSL certificate authority certificates for distributed recovery connections. See Section 18.5.2, “Securing Group Communication Connections with Secure Socket Layer (SSL)” for information on configuring SSL for distributed recovery.

• `group_replication_recovery_ssl_cert`

The value of this system variable can be changed while Group Replication is running, but the change only takes effect after you stop and restart Group Replication on the group member.

`group_replication_recovery_ssl_cert` specifies the name of the SSL certificate file to use for establishing a secure connection for distributed recovery. See Section 18.5.2, “Securing Group Communication Connections with Secure Socket Layer (SSL)” for information on configuring SSL for distributed recovery.

If this server has been set up to support cloning (see Section 18.4.3.2, “Cloning for Distributed Recovery”), and you have set `group_replication_recovery_use_ssl` to ON, Group Replication automatically configures the setting for the clone SSL option `clone_ssl_cert` to match your setting for `group_replication_recovery_ssl_cert`.

• `group_replication_recovery_ssl_cipher`
### Group Replication System Variables

<table>
<thead>
<tr>
<th>Type</th>
<th>String</th>
</tr>
</thead>
</table>

The value of this system variable can be changed while Group Replication is running, but the change only takes effect after you stop and restart Group Replication on the group member.

`group_replication_recovery_ssl_cipher` specifies the list of permissible ciphers for SSL encryption. See Section 18.5.2, “Securing Group Communication Connections with Secure Socket Layer (SSL)” for information on configuring SSL for distributed recovery.

- **`group_replication_recovery_ssl_cipher`**

  - **Command-Line Format**: `--group-replication-recovery-ssl-cipher=value`
  - **System Variable**: `group_replication_recovery_ssl_cipher`
  - **Scope**: Global
  - **Dynamic**: Yes
  - **SET_VAR Hint Applies**: No
  - **Type**: File name

The value of this system variable can be changed while Group Replication is running, but the change only takes effect after you stop and restart Group Replication on the group member.

`group_replication_recovery_ssl_cipher` specifies the path to a directory that contains files containing certificate revocation lists. See Section 18.5.2, “Securing Group Communication Connections with Secure Socket Layer (SSL)” for information on configuring SSL for distributed recovery.

- **`group_replication_recovery_ssl_crlpath`**

  - **Command-Line Format**: `--group-replication-recovery-ssl-crlpath=value`
  - **System Variable**: `group_replication_recovery_ssl_crlpath`
  - **Scope**: Global
  - **Dynamic**: Yes
  - **SET_VAR Hint Applies**: No
  - **Type**: Directory name

The value of this system variable can be changed while Group Replication is running, but the change only takes effect after you stop and restart Group Replication on the group member.

`group_replication_recovery_ssl_crlpath` specifies the path to a directory that contains files containing certificate revocation lists. See Section 18.5.2, “Securing Group Communication Connections with Secure Socket Layer (SSL)” for information on configuring SSL for distributed recovery.

- **`group_replication_recovery_ssl_key`**

  - **Command-Line Format**: `--group-replication-recovery-ssl-key=value`
  - **System Variable**: `group_replication_recovery_ssl_key`
  - **Scope**: Global
  - **Dynamic**: Yes
  - **SET_VAR Hint Applies**: No
  - **Type**: String
Group Replication System Variables

The value of this system variable can be changed while Group Replication is running, but the change only takes effect after you stop and restart Group Replication on the group member.

`group_replication_recovery_ssl_key` specifies the name of the SSL key file to use for establishing a secure connection. See Section 18.5.2, “Securing Group Communication Connections with Secure Socket Layer (SSL)” for information on configuring SSL for distributed recovery.

If this server has been set up to support cloning (see Section 18.4.3.2, “Cloning for Distributed Recovery”), and you have set `group_replication_recovery_use_ssl` to `ON`, Group Replication automatically configures the setting for the clone SSL option `clone_ssl_key` to match your setting for `group_replication_recovery_ssl_key`.

- `group_replication_recovery_ssl_verify_server_cert`

| Command-Line Format | `--group-replication-recovery-ssl-verify-server-cert=[OFF|ON]` |
|---------------------|-------------------------------------------------------------|
| System Variable     | `group_replication_recovery_ssl_verify_server_cert` |
| Scope               | Global |
| Dynamic             | Yes |
| `SET_VAR` Hint Applies | No |
| Type                | Boolean |
| Default Value       | `OFF` |

The value of this system variable can be changed while Group Replication is running, but the change only takes effect after you stop and restart Group Replication on the group member.

`group_replication_recovery_ssl_verify_server_cert` specifies whether the distributed recovery connection should check the server’s Common Name value in the certificate sent by the donor. See Section 18.5.2, “Securing Group Communication Connections with Secure Socket Layer (SSL)” for information on configuring SSL for distributed recovery.

- `group_replication_recovery_tls_ciphersuites`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--group-replication-recovery-tls-ciphersuites=value</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.19</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>group_replication_recovery_tls_ciphersuites</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>NULL</code></td>
</tr>
</tbody>
</table>

The value of this system variable can be changed while Group Replication is running, but the change only takes effect after you stop and restart Group Replication on the group member.

`group_replication_recovery_tls_ciphersuites` specifies a colon-separated list of one or more permitted ciphersuites when TLSv1.3 is used for connection encryption for the distributed recovery connection, and this server instance is the client in the distributed recovery connection, that is, the joining member. If this system variable is set to `NULL` when TLSv1.3 is used (which is the default
Group Replication System Variables

if you do not set the system variable), the ciphersuites that are enabled by default are allowed, as
listed in Section 6.3.2, “Encrypted Connection TLS Protocols and Ciphers”. If this system variable is
set to the empty string, no cipher suites are allowed, and TLSv1.3 is therefore not used. This system
variable is available beginning with MySQL 8.0.19. See Section 18.5.2, “Securing Group Communication
Connections with Secure Socket Layer (SSL)”, for information on configuring SSL for distributed
recovery.

• group_replication_recovery_tls_version

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--group-replication-recovery-tls-version=value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.19</td>
</tr>
<tr>
<td>System Variable</td>
<td>group_replication_recovery_tls_version</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>TLSv1,TLSv1.1,TLSv1.2,TLSv1.3</td>
</tr>
</tbody>
</table>

The value of this system variable can be changed while Group Replication is running, but the change
only takes effect after you stop and restart Group Replication on the group member.

group_replication_recovery_tls_version specifies a comma-separated list of one or
more permitted TLS protocols for connection encryption when this server instance is the client in
the distributed recovery connection, that is, the joining member. Ensure the specified versions are
contiguous (for example, “TLSv1,TLSv1.1,TLSv1.2”). If this system variable is not set, the default
“TLSv1,TLSv1.1,TLSv1.2,TLSv1.3” is used. The group members involved in each distributed
recovery connection as the client (joining member) and server (donor) negotiate the highest protocol
version that they are both set up to support. This system variable is available from MySQL 8.0.19. See
Section 18.5.2, “Securing Group Communication Connections with Secure Socket Layer (SSL)” for
information on configuring SSL for distributed recovery.

• group_replication_recovery_use_ssl

| Command-Line Format                  | --group-replication-recovery-use-ssl[={OFF|ON}] |
|--------------------------------------|-----------------------------------------------|
| System Variable                      | group_replication_recovery_use_ssl            |
| Scope                                | Global                                        |
| Dynamic                              | Yes                                           |
| SET_VAR Hint Applies                 | No                                            |
| Type                                 | Boolean                                       |
| Default Value                        | OFF                                           |

The value of this system variable can be changed while Group Replication is running, but the change
only takes effect after you stop and restart Group Replication on the group member.

group_replication_recovery_use_ssl specifies whether Group Replication distributed recovery
connections between group members should use SSL or not. See Section 18.5.2, “Securing Group
Communication Connections with Secure Socket Layer (SSL)” for information on configuring SSL for
distributed recovery.
**Group Replication System Variables**

*Communication Connections with Secure Socket Layer (SSL)* for information on configuring SSL for distributed recovery.

If this server has been set up to support cloning (see Section 18.4.3.2, “Cloning for Distributed Recovery”), and you set this option to **ON**, Group Replication uses SSL for remote cloning operations as well as for state transfer from a donor's binary log. If you set this option to **OFF**, Group Replication does not use SSL for remote cloning operations.

- **group_replication_recovery_zstd_compression_level**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--group-replication-recovery-zstd-compression-level=</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.18</td>
</tr>
<tr>
<td>System Variable</td>
<td>group_replication_recovery_zstd_compression_level</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>3</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>22</td>
</tr>
</tbody>
</table>

The value of this system variable can be changed while Group Replication is running, but the change only takes effect after you stop and restart Group Replication on the group member.

**group_replication_recovery_zstd_compression_level** specifies the compression level to use for Group Replication distributed recovery connections that use the **zstd** compression algorithm. The permitted levels are from 1 to 22, with larger values indicating increasing levels of compression. The default **zstd** compression level is 3. For distributed recovery connections that do not use **zstd** compression, this variable has no effect.

For more information, see Section 4.2.8, “Connection Compression Control”.

- **group_replication_single_primary_mode**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--group-replication-single-primary-mode={OFF|ON}</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>group_replication_single_primary_mode</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>ON</td>
</tr>
</tbody>
</table>

This system variable is a group-wide configuration setting. It must have the same value on all group members, cannot be changed while Group Replication is running, and requires a full reboot of the group (a bootstrap by a server with **group_replication_bootstrap_group=ON**) in order for the value change to take effect. From MySQL 8.0.16, you can use the **group_replication_switch_to_single_primary_mode()** and **group_replication_switch_to_multi_primary_mode()** UDFs to change the value of this...
system variable while the group is still running. For more information, see Section 18.4.1.2, “Changing a Group’s Mode”.

*group_replication_single_primary_mode* instructs the group to automatically pick a single server to be the one that handles read/write workload. This server is the PRIMARY and all others are SECONDARIES.

- **group_replication_ssl_mode**

<table>
<thead>
<tr>
<th>Command-Line Format</th>

</tr>
<tr>
<td></td>
<td>VERIFY_IDENTITY</td>
</tr>
</tbody>
</table>

The value of this system variable can be changed while Group Replication is running, but the change only takes effect after you stop and restart Group Replication on the group member.

*group_replication_ssl_mode* sets the security state of group communication connections between Group Replication members. The possible values are as follows:

- **DISABLED**
  Establish an unencrypted connection (the default).
- **REQUIRED**
  Establish a secure connection if the server supports secure connections.
- **VERIFY_CA**
  Like **REQUIRED**, but additionally verify the server TLS certificate against the configured Certificate Authority (CA) certificates.
- **VERIFY_IDENTITY**
  Like **VERIFY_CA**, but additionally verify that the server certificate matches the host to which the connection is attempted.

See Section 18.5.2, “Securing Group Communication Connections with Secure Socket Layer (SSL)” for information on configuring SSL for group communication.

- **group_replication_start_on_boot**

| Command-Line Format          | --group-replication-start-on-boot[={OFF|ON}] |
|------------------------------|-----------------------------------------------|
| System Variable              | group_replication_start_on_boot               |
| Scope                        | Global                                        |
| Dynamic                      | Yes                                           |
| SET_VAR Hint Applies         | No                                            |
### Group Replication System Variables

<table>
<thead>
<tr>
<th>Type</th>
<th>Boolean</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>ON</td>
</tr>
</tbody>
</table>

The value of this system variable can be changed while Group Replication is running, but the change only takes effect after you stop and restart Group Replication on the group member.

`group_replication_start_on_boot` specifies whether the server should start Group Replication automatically (ON) or not (OFF) during server start. When you set this option to ON, Group Replication restarts automatically after a remote cloning operation is used for distributed recovery.

To start Group Replication automatically during server start, the user credentials for distributed recovery must be stored in the replication metadata repositories on the server using the `CHANGE MASTER TO` statement. If you prefer to specify the user credentials on the `START GROUP_REPLICATION` statement, which stores the user credentials only in memory, ensure that `group_replication_start_on_boot` is set to OFF.

- **group_replication_tls_source**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--group-replication-tls-source=value</code></th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td>Default Value</td>
<td><code>mysql_main</code></td>
</tr>
<tr>
<td>Valid Values</td>
<td><code>mysql_main</code></td>
</tr>
<tr>
<td></td>
<td><code>mysql_admin</code></td>
</tr>
</tbody>
</table>

The value of this system variable can be changed while Group Replication is running, but the change only takes effect after you stop and restart Group Replication on the group member.

`group_replication_tls_source` specifies the source of TLS material for Group Replication.

- **group_replication_transaction_size_limit**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--group-replication-transaction-size-limit=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>group_replication_transaction_size_limit</code></td>
</tr>
<tr>
<td>Scope</td>

<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>150000000</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
</tbody>
</table>

3663
This system variable should have the same value on all group members. The value of this system variable can be changed while Group Replication is running. The change takes effect immediately on the group member, and applies from the next transaction started on that member. During this process, the value of the system variable is permitted to differ between group members, but some transactions might be rejected.

`group_replication_transaction_size_limit` configures the maximum transaction size in bytes which the replication group accepts. Transactions larger than this size are rolled back by the receiving member and are not broadcast to the group. Large transactions can cause problems for a replication group in terms of memory allocation, which can cause the system to slow down, or in terms of network bandwidth consumption, which can cause a member to be suspected of having failed because it is busy processing the large transaction.

When this system variable is set to 0 there is no limit to the size of transactions the group accepts. From MySQL 8.0, the default setting for this system variable is 150000000 bytes (approximately 143 MB). Adjust the value of this system variable depending on the maximum message size that you need the group to tolerate, bearing in mind that the time taken to process a transaction is proportional to its size. The value of `group_replication_transaction_size_limit` should be the same on all group members. For further mitigation strategies for large transactions, see Section 18.9.2, “Group Replication Limitations”.

- `group_replication_unreachable_majority_timeout`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--group-replication-unreachable-majority-timeout=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>group_replication_unreachable_majority_timeout</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>31536000</td>
</tr>
</tbody>
</table>

The value of this system variable can be changed while Group Replication is running, and the change takes effect immediately. The current value of the system variable is read when an issue occurs that means the behavior is needed.

`group_replication_unreachable_majority_timeout` specifies a number of seconds for which members that suffer a network partition and cannot connect to the majority wait before leaving the group. In a group of 5 servers (S1,S2,S3,S4,S5), if there is a disconnection between (S1,S2) and (S3,S4,S5) there is a network partition. The first group (S1,S2) is now in a minority because it cannot contact more than half of the group. While the majority group (S3,S4,S5) remains running, the minority group waits for the specified time for a network reconnection. For a detailed description of this scenario, see Section 18.4.4, “Network Partitioning”.

By default, `group_replication_unreachable_majority_timeout` is set to 0, which means that members that find themselves in a minority due to a network partition wait forever to leave the group. If you set a timeout, when the specified time elapses, all pending transactions processed by the minority are rolled back, and the servers in the minority partition move to the ERROR state. If a member
has the `group_replication_autorejoin_tries` system variable set to specify a number of auto-rejoin attempts, it proceeds to make the specified number of attempts to rejoin the group while in super read only mode. If the member does not have any auto-rejoin attempts specified, or if it has exhausted the specified number of attempts, it follows the action specified by the system variable `group_replication_exit_state_action`.

**Warning**
When you have a symmetric group, with just two members for example (S0,S2), if there is a network partition and there is no majority, after the configured timeout all members enter the `ERROR` state.

For more information on using this option, see Section 18.6.6.2, “Unreachable Majority Timeout”.

### Group Replication Status Variable

This section describes the status variable which provides information about Group Replication. The variable has the following meaning:

- **group_replication_primary_member**

  Shows the primary member's UUID when the group is operating in single-primary mode. If the group is operating in multi-primary mode, shows an empty string.

**Warning**
The `group_replication_primary_member` status variable has been deprecated and is scheduled to be removed in a future version.

See Finding the Primary.

### 18.9 Requirements and Limitations

This section lists and explains the requirements and limitations of Group Replication.

#### 18.9.1 Group Replication Requirements

Server instances that you want to use for Group Replication must satisfy the following requirements.

**Infrastructure**

- **InnoDB Storage Engine.** Data must be stored in the InnoDB transactional storage engine. Transactions are executed optimistically and then, at commit time, are checked for conflicts. If there are conflicts, in order to maintain consistency across the group, some transactions are rolled back. This means that a transactional storage engine is required. Moreover, InnoDB provides some additional functionality that enables better management and handling of conflicts when operating together with Group Replication. The use of other storage engines, including the temporary MEMORY storage engine, might cause errors in Group Replication. You can prevent the use of other storage engines by setting the `disabled_storage_engines` system variable on group members, for example:

  
  `disabled_storage_engines="MyISAM,BLACKHOLE,FEDERATED,ARCHIVE,MEMORY"`

- **Primary Keys.** Every table that is to be replicated by the group must have a defined primary key, or primary key equivalent where the equivalent is a non-null unique key. Such keys are required as a unique identifier for every row within a table, enabling the system to determine which transactions conflict by identifying exactly which rows each transaction has modified. Group
Replication has its own built-in set of checks for primary keys or primary key equivalents, and does not use the checks carried out by the `sql_require_primary_key` system variable. You may set `sql_require_primary_key=ON` for a server instance where Group Replication is running, and you may set the `REQUIRE_TABLE_PRIMARY_KEY_CHECK` option of the `CHANGE MASTER TO` statement to `ON` for a Group Replication channel. However, be aware that you might find some transactions that are permitted under Group Replication's built-in checks are not permitted under the checks carried out when you set `sql_require_primary_key=ON` or `REQUIRE_TABLE_PRIMARY_KEY_CHECK=ON`.

- **Network Performance.** MySQL Group Replication is designed to be deployed in a cluster environment where server instances are very close to each other. The performance and stability of a group can be impacted by both network latency and network bandwidth. Bi-directional communication must be maintained at all times between all group members. If either inbound or outbound communication is blocked for a server instance (for example, by a firewall, or by connectivity issues), the member cannot function in the group, and the group members (including the member with issues) might not be able to report the correct member status for the affected server instance.

From MySQL 8.0.14, you can use an IPv4 or IPv6 network infrastructure, or a mix of the two, for TCP communication between remote Group Replication servers. There is also nothing preventing Group Replication from operating over a virtual private network (VPN).

Also from MySQL 8.0.14, where Group Replication server instances are co-located and share a local group communication engine (XCom) instance, a dedicated input channel with lower overhead is used for communication where possible instead of the TCP socket. For certain Group Replication tasks that require communication between remote XCom instances, such as joining a group, the TCP network is still used, so network performance influences the group's performance.

**Server Instance Configuration**

The following options must be configured as shown on server instances that are members of a group.

- **Binary Log Active.** Set `--log-bin[=log_file_name]`. MySQL Group Replication replicates binary log contents, therefore the binary log needs to be on for it to operate. This option is enabled by default. See Section 5.4.4, “The Binary Log”.

- **Replica Updates Logged.** Set `--log-slave-updates`. This option is enabled by default. Group members need to log transactions that are received from their donors at joining time and applied through the replication applier, and to log all transactions that they receive and apply from the group. This enables Group Replication to carry out distributed recovery by state transfer from an existing group member's binary log.

- **Binary Log Row Format.** Set `--binlog-format=row`. Group Replication relies on row-based replication format to propagate changes consistently among the servers in the group. It relies on row-based infrastructure to be able to extract the necessary information to detect conflicts among transactions that execute concurrently in different servers in the group. From MySQL 8.0.19, the `REQUIRE_ROW_FORMAT` setting is automatically added to Group Replication's channels to enforce the use of row-based replication when the transactions are applied. See Section 17.2.1, “Replication Formats” and Section 17.3.3, “Replication Privilege Checks”.

- **Binary Log Checksums Off (to MySQL 8.0.20).** Up to and including MySQL 8.0.20, set `--binlog-checksum=NONE`. In these releases, Group Replication cannot make use of checksums and does not support their presence in the binary log. From MySQL 8.0.21, Group Replication supports checksums, so group members may use the default setting.

- **Global Transaction Identifiers On.** Set `gtid_mode=ON`. Group Replication uses global transaction identifiers to track exactly which transactions have been committed on every server instance and thus be able to infer which servers have executed transactions that could conflict with already committed
transactions elsewhere. In other words, explicit transaction identifiers are a fundamental part of the framework to be able to determine which transactions may conflict. See Section 17.1.3, “Replication with Global Transaction Identifiers”.

- **Replication Information Repositories.** Set `master_info_repository=TABLE` and `relay_log_info_repository=TABLE`. The replication applier needs to have the replication metadata written to the `mysql.slave_master_info` and `mysql.slave_relay_log_info` system tables. This ensures the Group Replication plugin has consistent recoverability and transactional management of the replication metadata. From MySQL 8.0.2, these options are set to `TABLE` by default, and from MySQL 8.0.3, the `FILE` setting is deprecated. See Section 17.2.4.2, “Replication Metadata Repositories”.

- **Transaction Write Set Extraction.** Set `--transaction-write-set-extraction=XXHASH64` so that while collecting rows to log them to the binary log, the server collects the write set as well. The write set is based on the primary keys of each row and is a simplified and compact view of a tag that uniquely identifies the row that was changed. This tag is then used for detecting conflicts. This option is enabled by default.

- **Binary Log Dependency Tracking.** Setting `binlog_transaction_dependency_tracking=WRITESET_SESSION` can improve performance for a group member, depending on the group’s workload. Group Replication carries out its own parallelization after certification when applying transactions from the relay log, independently of the value set for `binlog_transaction_dependency_tracking`. However, the value of `binlog_transaction_dependency_tracking` does affect how transactions are written to the binary logs on Group Replication members. The dependency information in those logs is used to assist the process of state transfer from a donor’s binary log for distributed recovery, which takes place whenever a member joins or rejoins the group.

- **Default Table Encryption.** Set `--default-table-encryption` to the same value on all group members. Default schema and tablespace encryption can be either enabled (ON) or disabled (OFF, the default) as long as the setting is the same on all members.

- **Lower Case Table Names.** Set `--lower-case-table-names` to the same value on all group members. A setting of 1 is correct for the use of the InnoDB storage engine, which is required for Group Replication. Note that this setting is not the default on all platforms.

- **Multithreaded Appliers.** Group Replication members can be configured as multithreaded replicas, enabling transactions to be applied in parallel. A nonzero value for `slave_parallel_workers` enables the multithreaded applier on the member, and up to 1024 parallel applier threads can be specified. Setting `slave_preserve_commit_order=1` ensures that the final commit of parallel transactions is in the same order as the original transactions, as required for Group Replication, which relies on consistency mechanisms built around the guarantee that all participating members receive and apply committed transactions in the same order. Finally, the setting `slave_parallel_type=LOGICAL_CLOCK` specifies the policy used to decide which transactions are allowed to execute in parallel on the replica, is required with `slave_preserve_commit_order=1`. Setting `slave_parallel_workers=0` disables parallel execution and gives the replica a single applier thread and no coordinator thread. With that setting, the `slave_parallel_type` and `slave_preserve_commit_order` options have no effect and are ignored.

### 18.9.2 Group Replication Limitations

The following known limitations exist for Group Replication. Note that the limitations and issues described for multi-primary mode groups can also apply in single-primary mode clusters during a failover event, while the newly elected primary flushes out its applier queue from the old primary.
Group Replication Limitations

Tip
Group Replication is built on GTID based replication, therefore you should also be aware of Section 17.1.3.6, “Restrictions on Replication with GTIDs”.

- **--upgrade=MINIMAL option.** Group Replication cannot be started following a MySQL Server upgrade that uses the MINIMAL option (--upgrade=MINIMAL), which does not upgrade system tables on which the replication internals depend.

- **Gap Locks.** Group Replication’s certification process for concurrent transactions does not take into account gap locks, as information about gap locks is not available outside of InnoDB. See Gap Locks for more information.

Note
For a group in multi-primary mode, unless you rely on REPEATABLE_READ semantics in your applications, we recommend using the READ COMMITTED isolation level with Group Replication. InnoDB does not use gap locks in READ COMMITTED, which aligns the local conflict detection within InnoDB with the distributed conflict detection performed by Group Replication. For a group in single-primary mode, only the primary accepts writes, so the READ COMMITTED isolation level is not important to Group Replication.

- **Table Locks and Named Locks.** The certification process does not take into account table locks (see Section 13.3.6, “LOCK TABLES and UNLOCK TABLES Statements”) or named locks (see GET_LOCK()).

- **Binary Log Checksums.** Up to and including MySQL 8.0.20, Group Replication cannot make use of checksums and does not support their presence in the binary log, so you must set binlog_checksum=NONE when configuring a server instance to become a group member. From MySQL 8.0.21, Group Replication supports checksums, so group members may use the default setting binlog_checksum=CRC32. The setting for binlog_checksum does not have to be the same for all members of a group.

When checksums are available, Group Replication does not use them to verify incoming events on the group_replication_applier channel, because events are written to that relay log from multiple sources and before they are actually written to the originating server’s binary log, which is when a checksum is generated. Checksums are used to verify the integrity of events on the group_replication_recovery channel and on any other replication channels on group members.

- **SERIALIZABLE Isolation Level.** SERIALIZABLE isolation level is not supported in multi-primary groups by default. Setting a transaction isolation level to SERIALIZABLE configures Group Replication to refuse to commit the transaction.

- **Concurrent DDL versus DML Operations.** Concurrent data definition statements and data manipulation statements executing against the same object but on different servers is not supported when using multi-primary mode. During execution of Data Definition Language (DDL) statements on an object, executing concurrent Data Manipulation Language (DML) on the same object but on a different server instance has the risk of conflicting DDL executing on different instances not being detected.

- **Foreign Keys with Cascading Constraints.** Multi-primary mode groups (members all configured with group_replication_single_primary_mode=OFF) do not support tables with multi-level foreign key dependencies, specifically tables that have defined CASCADING foreign key constraints. This is because foreign key constraints that result in cascading operations executed by a multi-primary mode group can result in undetected conflicts and lead to inconsistent data across the members of the group. Therefore we recommend setting
**Group Replication Limitations**

`group_replication_enforce_update_everywhere_checks=ON` on server instances used in multi-primary mode groups to avoid undetected conflicts.

In single-primary mode this is not a problem as it does not allow concurrent writes to multiple members of the group and thus there is no risk of undetected conflicts.

- **Multi-primary Mode Deadlock.** When a group is operating in multi-primary mode, `SELECT .. FOR UPDATE` statements can result in a deadlock. This is because the lock is not shared across the members of the group, therefore the expectation for such a statement might not be reached.

- **Replication Filters.** Global replication filters cannot be used on a MySQL server instance that is configured for Group Replication, because filtering transactions on some servers would make the group unable to reach agreement on a consistent state. Channel specific replication filters can be used on replication channels that are not directly involved with Group Replication, such as where a group member also acts as a replica to a source that is outside the group. They cannot be used on the `group_replication_applier` or `group_replication_recovery` channels.

- **Encrypted Connections.** Support for the TLSv1.3 protocol is available in MySQL Server as of MySQL 8.0.16, provided that MySQL was compiled using OpenSSL 1.1.1 or higher. In MySQL 8.0.16 and MySQL 8.0.17, if the server supports TLSv1.3, the protocol is not supported in the group communication engine and cannot be used by Group Replication. Group Replication supports TLSv1.3 from MySQL 8.0.18, where it can be used for group communication connections and distributed recovery connections.

  In MySQL 8.0.18, TLSv1.3 can be used in Group Replication for the distributed recovery connection, but the `group_replication_recovery_tls_version` and `group_replication_recovery_tls_ciphersuites` system variables are not available. The donor servers must therefore permit the use of at least one TLSv1.3 ciphersuite that is enabled by default, as listed in Section 6.3.2, “Encrypted Connection TLS Protocols and Ciphers”. From MySQL 8.0.19, you can use the options to configure client support for any selection of ciphersuites, including only non-default ciphersuites if you want.

- **Cloning Operations.** Group Replication initiates and manages cloning operations for distributed recovery, but group members that have been set up to support cloning may also participate in cloning operations that a user initiates manually. In releases before MySQL 8.0.20, you cannot initiate a cloning operation manually if the operation involves a group member on which Group Replication is running. From MySQL 8.0.20, you can do this, provided that the cloning operation does not remove and replace the data on the recipient. The statement to initiate the cloning operation must therefore include the `DATA DIRECTORY` clause if Group Replication is running. See Cloning for Other Purposes.

**Limit on Group Size**

The maximum number of MySQL servers that can be members of a single replication group is 9. If further members attempt to join the group, their request is refused. This limit has been identified from testing and benchmarking as a safe boundary where the group performs reliably on a stable local area network.

**Limits on Transaction Size**

If an individual transaction results in message contents which are large enough that the message cannot be copied between group members over the network within a 5-second window, members can be suspected of having failed, and then expelled, just because they are busy processing the transaction. Large transactions can also cause the system to slow due to problems with memory allocation. To avoid these issues use the following mitigations:

- If unnecessary expulsions occur due to large messages, use the system variable `group_replication_member_expel_timeout` to allow additional time before a member under
suspicion of having failed is expelled. You can allow up to an hour after the initial 5-second detection period before a suspect member is expelled from the group. From MySQL 8.0.21, an additional 5 seconds is allowed by default.

- Where possible, try and limit the size of your transactions before they are handled by Group Replication. For example, split up files used with `LOAD DATA` into smaller chunks.

- Use the system variable `group_replication_transaction_size_limit` to specify a maximum transaction size that the group accepts. In MySQL 8.0, this system variable defaults to a maximum transaction size of 15000000 bytes (approximately 143 MB). Transactions above this size are rolled back and are not sent to Group Replication's Group Communication System (GCS) for distribution to the group. Adjust the value of this variable depending on the maximum message size that you need the group to tolerate, bearing in mind that the time taken to process a transaction is proportional to its size.

- Use the system variable `group_replication_compression_threshold` to specify a message size above which compression is applied. This system variable defaults to 1000000 bytes (1 MB), so large messages are automatically compressed. Compression is carried out by Group Replication's Group Communication System (GCS) when it receives a message that was permitted by the `group_replication_transaction_size_limit` setting but exceeds the `group_replication_compression_threshold` setting. For more information, see Section 18.6.3, “Message Compression”.

- Use the system variable `group_replication_communication_max_message_size` to specify a message size above which messages are fragmented. This system variable defaults to 10485760 bytes (10 MiB), so large messages are automatically fragmented. GCS carries out fragmentation after compression if the compressed message still exceeds the `group_replication_communication_max_message_size` limit. In order for a replication group to use fragmentation, all group members must be at MySQL 8.0.16 or above, and the Group Replication communication protocol version in use by the group must allow fragmentation. For more information, see Section 18.6.4, “Message Fragmentation”.

The maximum transaction size, message compression, and message fragmentation can all be deactivated by specifying a zero value for the relevant system variable. If you have deactivated all these safeguards, the upper size limit for a message that can be handled by the applier thread on a member of a replication group is the value of the member's `slave_max_allowed_packet` system variable, which has a default and maximum value of 1073741824 bytes (1 GB). A message that exceeds this limit fails when the receiving member attempts to handle it. The upper size limit for a message that a group member can originate and attempt to transmit to the group is 4294967295 bytes (approximately 4 GB). This is a hard limit on the packet size that is accepted by the group communication engine for Group Replication (XCom, a Paxos variant), which receives messages after GCS has handled them. A message that exceeds this limit fails when the originating member attempts to broadcast it.

18.10 Frequently Asked Questions

This section provides answers to frequently asked questions.

What is the maximum number of MySQL servers in a group?

A group can consist of maximum 9 servers. Attempting to add another server to a group with 9 members causes the request to join to be refused. This limit has been identified from testing and benchmarking as a safe boundary where the group performs reliably on a stable local area network.
How are servers in a group connected?

Servers in a group connect to the other servers in the group by opening a peer-to-peer TCP connection. These connections are only used for internal communication and message passing between servers in the group. This address is configured by the `group_replication_local_address` variable.

What is the `group_replication_bootstrap_group` option used for?

The bootstrap flag instructs a member to create a group and act as the initial seed server. The second member joining the group needs to ask the member that bootstrapped the group to dynamically change the configuration in order for it to be added to the group.

A member needs to bootstrap the group in two scenarios. When the group is originally created, or when shutting down and restarting the entire group.

How do I set credentials for the distributed recovery process?

You can set the user credentials permanently as the credentials for the `group_replication_recovery` channel, using a `CHANGE MASTER TO` statement. Alternatively, from MySQL 8.0.21, you can specify them on the `START GROUP_REPLICATION` statement each time Group Replication is started.

User credentials set using `CHANGE MASTER TO` are stored in plain text in the replication metadata repositories on the server, but user credentials specified on `START GROUP_REPLICATION` are saved in memory only, and are removed by a `STOP GROUP_REPLICATION` statement or server shutdown. Using `START GROUP_REPLICATION` to specify the user credentials therefore helps to secure the Group Replication servers against unauthorized access. However, this method is not compatible with starting Group Replication automatically, as specified by the `group_replication_start_on_boot` system variable. For more information, see Section 18.5.3.1, “Secure User Credentials for Distributed Recovery”.

Can I scale-out my write-load using Group Replication?

Not directly, but MySQL Group replication is a shared nothing full replication solution, where all servers in the group replicate the same amount of data. Therefore if one member in the group writes N bytes to storage as the result of a transaction commit operation, then roughly N bytes are written to storage on other members as well, because the transaction is replicated everywhere.

However, given that other members do not have to do the same amount of processing that the original member had to do when it originally executed the transaction, they apply the changes faster. Transactions are replicated in a format that is used to apply row transformations only, without having to re-execute transactions again (row-based format).

Furthermore, given that changes are propagated and applied in row-based format, this means that they are received in an optimized and compact format, and likely reducing the number of IO operations required when compared to the originating member.

To summarize, you can scale-out processing, by spreading conflict free transactions throughout different members in the group. And you can likely scale-out a small fraction of your IO operations, since remote servers receive only the necessary changes to read-modify-write changes to stable storage.

Does Group Replication require more network bandwidth and CPU, when compared to simple replication and under the same workload?

Some additional load is expected because servers need to be constantly interacting with each other for synchronization purposes. It is difficult to quantify how much more data. It also depends on the size of the group (three servers puts less stress on the bandwidth requirements than nine servers in the group).
Can I deploy Group Replication across wide-area networks?

Yes, but the network connection between each member must be reliable and have suitable performance. Low latency, high bandwidth network connections are a requirement for optimal performance.

If network bandwidth alone is an issue, then Section 18.6.3, “Message Compression” can be used to lower the bandwidth required. However, if the network drops packets, leading to re-transmissions and higher end-to-end latency, throughput and latency are both negatively affected.

Warning

When the network round-trip time (RTT) between any group members is 5 seconds or more you could encounter problems as the built-in failure detection mechanism could be incorrectly triggered.

Do members automatically rejoin a group in case of temporary connectivity problems?

This depends on the reason for the connectivity problem. If the connectivity problem is transient and the reconnection is quick enough that the failure detector is not aware of it, then the server may not be removed from the group. If it is a "long" connectivity problem, then the failure detector eventually suspects a problem and the server is removed from the group.

From MySQL 8.0, two settings are available to increase the chances of a member remaining in or rejoining a group:

- `group_replication_member_expel_timeout` increases the time between the creation of a suspicion (which happens after an initial 5-second detection period) and the expulsion of the member. You can set a waiting period of up to 1 hour. From MySQL 8.0.21, a waiting period of 5 seconds is set by default.

- `group_replication_autorejoin_tries` makes a member try to rejoin the group after an expulsion or unreachable majority timeout. The member makes the specified number of auto-rejoin attempts five minutes apart. From MySQL 8.0.21, this feature is activated by default and the member makes three auto-rejoin attempts.

If a server is expelled from the group and any auto-rejoin attempts do not succeed, you need to join it back again. In other words, after a server is removed explicitly from the group you need to rejoin it manually (or have a script doing it automatically).

When is a member excluded from a group?

If the member becomes silent, the other members remove it from the group configuration. In practice this may happen when the member has crashed or there is a network disconnection.

The failure is detected after a given timeout elapses for a given member and a new configuration without the silent member in it is created.

What happens when one node is significantly lagging behind?

There is no method for defining policies for when to expel members automatically from the group. You need to find out why a member is lagging behind and fix that or remove the member from the group.
Upon suspicion of a problem in the group, is there a special member responsible for triggering a reconfiguration?

No, there is no special member in the group in charge of triggering a reconfiguration.

Any member can suspect that there is a problem. All members need to (automatically) agree that a given member has failed. One member is in charge of expelling it from the group, by triggering a reconfiguration. Which member is responsible for expelling the member is not something you can control or set.

Can I use Group Replication for sharding?

Group Replication is designed to provide highly available replica sets; data and writes are duplicated on each member in the group. For scaling beyond what a single system can provide, you need an orchestration and sharding framework built around a number of Group Replication sets, where each replica set maintains and manages a given shard or partition of your total dataset. This type of setup, often called a “sharded cluster”, allows you to scale reads and writes linearly and without limit.

How do I use Group Replication with SELinux?

If SELinux is enabled, which you can verify using `sestatus -v`, then you need to enable the use of the Group Replication communication port. See Setting the TCP Port Context for Group Replication.

How do I use Group Replication with iptables?

If `iptables` is enabled, then you need to open up the Group Replication port for communication between the machines. To see the current rules in place on each machine, issue `iptables -L`. Assuming the port configured is 33061, enable communication over the necessary port by issuing `iptables -A INPUT -p tcp --dport 33061 -j ACCEPT`.

How do I recover the relay log for a replication channel used by a group member?

The replication channels used by Group Replication behave in the same way as replication channels used in asynchronous source to replica replication, and as such rely on the relay log. In the event of a change of the `relay_log` variable, or when the option is not set and the host name changes, there is a chance of errors. See Section 17.2.4.1, “The Relay Log” for a recovery procedure in this situation. Alternatively, another way of fixing the issue specifically in Group Replication is to issue a `STOP GROUP_REPLICATION` statement and then a `START GROUP_REPLICATION` statement to restart the instance. The Group Replication plugin creates the `group_replication_applier` channel again.

Why does Group Replication use two bind addresses?

Group Replication uses two bind addresses in order to split network traffic between the SQL address, used by clients to communicate with the member, and the `group_replication_local_address`, used internally by the group members to communicate. For example, assume a server with two network interfaces assigned to the network addresses `203.0.113.1` and `198.51.100.179`. In such a situation you could use `203.0.113.1:33061` for the internal group network address by setting `group_replication_local_address=203.0.113.1:33061`. Then you could use `198.51.100.179` for `hostname` and `3306` for the `port`. Client SQL applications would then connect to the member at `198.51.100.179:3306`. This enables you to configure different rules on the different networks.
How does Group Replication use network addresses and hostnames?

Group Replication uses network connections between members and therefore its functionality is directly impacted by how you configure hostnames and ports. For example, Group Replication's distributed recovery process creates a connection to an existing group member using the server's hostname and port. When a member joins a group it receives the group membership information, using the network address information that is listed at `performance_schema.replication_group_members`. One of the members listed in that table is selected as the donor of the missing data from the group to the joining member.

This means that any value you configure using a hostname, such as the SQL network address or the group seeds address, must be a fully qualified name and resolvable by each member of the group. You can ensure this for example through DNS, or correctly configured `/etc/hosts` files, or other local processes. If you want to configure the `MEMBER_HOST` value on a server, specify it using the `--report-host` option on the server before joining it to the group.

**Important**

The assigned value is used directly and is not affected by the `skip_name_resolve` system variable.

To configure `MEMBER_PORT` on a server, specify it using the `report_port` system variable.

Why did the auto increment setting on the server change?

When Group Replication is started on a server, the value of `auto_increment_increment` is changed to the value of `group_replication_auto_increment_increment`, which defaults to 7, and the value of `auto_increment_offset` is changed to the server ID. The changes are reverted when Group Replication is stopped. These settings avoid the selection of duplicate auto-increment values for writes on group members, which causes rollback of transactions. The default auto increment value of 7 for Group Replication represents a balance between the number of usable values and the permitted maximum size of a replication group (9 members).

The changes are only made and reverted if `auto_increment_increment` and `auto_increment_offset` each have their default value of 1. If their values have already been modified from the default, Group Replication does not alter them. From MySQL 8.0, the system variables are also not modified when Group Replication is in single-primary mode, where only one server writes.

How do I find the primary?

If the group is operating in single-primary mode, it can be useful to find out which member is the primary. See Finding the Primary
Chapter 19 MySQL Shell

MySQL Shell is an advanced client and code editor for MySQL Server. In addition to the provided SQL functionality, similar to mysql, MySQL Shell provides scripting capabilities for JavaScript and Python and includes APIs for working with MySQL. MySQL Shell is a component that you can install separately.

The following discussion briefly describes MySQL Shell's capabilities. For more information, see the MySQL Shell manual, available at https://dev.mysql.com/doc/mysql-shell/en/.

MySQL Shell includes the following APIs implemented in JavaScript and Python which you can use to develop code that interacts with MySQL.

- The X DevAPI enables developers to work with both relational and document data when MySQL Shell is connected to a MySQL server using the X Protocol. This enables you to use MySQL as a Document Store, sometimes referred to as “using NoSQL”. For more information, see Chapter 20, Using MySQL as a Document Store. For documentation on the concepts and usage of X DevAPI, which is implemented in MySQL Shell, see X DevAPI User Guide.

- The AdminAPI enables database administrators to work with InnoDB Cluster, which provides an integrated solution for high availability and scalability using InnoDB based MySQL databases, without requiring advanced MySQL expertise. The AdminAPI also includes support for InnoDB ReplicaSet, which enables you to administer a set of MySQL instances running asynchronous GTID-based replication in a similar way to InnoDB Cluster. Additionally, the AdminAPI makes administration of MySQL Router easier, including integration with both InnoDB Cluster and InnoDB ReplicaSet. See Chapter 21, Using MySQL AdminAPI.

MySQL Shell is available in two editions, the Community Edition and the Commercial Edition. The Community Edition is available free of charge. The Commercial Edition provides additional Enterprise features at low cost.

This chapter introduces an alternative way of working with MySQL as a document store, sometimes referred to as “using NoSQL”. If your intention is to use MySQL in a traditional (SQL) way, this chapter is probably not relevant to you.

Traditionally, relational databases such as MySQL have usually required a schema to be defined before documents can be stored. The features described in this section enable you to use MySQL as a document store, which is a schema-less, and therefore schema-flexible, storage system for documents. For example, when you create documents describing products, you do not need to know and define all possible attributes of any products before storing and operating with the documents. This differs from working with a relational database and storing products in a table, when all columns of the table must be known and defined before adding any products to the database. The features described in this chapter enable you to choose how you configure MySQL, using only the document store model, or combining the flexibility of the document store model with the power of the relational model.

To use MySQL as a document store, you use the following server features:

- X Plugin enables MySQL Server to communicate with clients using X Protocol, which is a prerequisite for using MySQL as a document store. X Plugin is enabled by default in MySQL Server as of MySQL 8.0. For instructions to verify X Plugin installation and to configure and monitor X Plugin, see Section 20.5, “X Plugin”.

- X Protocol supports both CRUD and SQL operations, authentication via SASL, allows streaming (pipelining) of commands and is extensible on the protocol and the message layer. Clients compatible with X Protocol include MySQL Shell and MySQL 8.0 Connectors.
• Clients that communicate with a MySQL Server using X Protocol can use X DevAPI to develop applications. X DevAPI offers a modern programming interface with a simple yet powerful design which provides support for established industry standard concepts. This chapter explains how to get started using either the JavaScript or Python implementation of X DevAPI in MySQL Shell as a client. See X DevAPI User Guide for in-depth tutorials on using X DevAPI.

20.1 Interfaces to a MySQL Document Store

To work with MySQL as a document store, you use dedicated components and a choice of clients that support communicating with the MySQL server to develop document based applications.

• The following MySQL products support X Protocol and enable you to use X DevAPI in your chosen language to develop applications that communicate with a MySQL Server functioning as a document store:
  • MySQL Shell (which provides implementations of X DevAPI in JavaScript and Python)
  • Connector/C++
  • Connector/J
  • Connector/Node.js
  • Connector/NET
  • Connector/Python

MySQL Shell is an interactive interface to MySQL supporting JavaScript, Python, or SQL modes. You can use MySQL Shell to prototype applications, execute queries and update data. Installing MySQL Shell has instructions to download and install MySQL Shell.

• The quick-start guides (tutorials) in this chapter help you to get started using MySQL Shell with MySQL as a document store.

  The quick-start guide for Python is here: Section 20.4, “Python Quick-Start Guide: MySQL Shell for Document Store”.

• The MySQL Shell User Guide at MySQL Shell 8.0 (part of MySQL 8.0) provides detailed information about configuring and using MySQL Shell.

20.2 Document Store Concepts

This section explains the concepts introduced as part of using MySQL as a document store.

• JSON Document

• Collection

• CRUD Operations

JSON Document

A JSON document is a data structure composed of key-value pairs and is the fundamental structure for using MySQL as document store. For example, the world_x schema (installed later in this chapter) contains this document:
This document shows that the values of keys can be simple data types, such as integers or strings, but can also contain other documents, arrays, and lists of documents. For example, the `geography` key's value consists of multiple key-value pairs. A JSON document is represented internally using the MySQL binary JSON object, through the `JSON` MySQL datatype.

The most important differences between a document and the tables known from traditional relational databases are that the structure of a document does not have to be defined in advance, and a collection can contain multiple documents with different structures. Relational tables on the other hand require that their structure be defined, and all rows in the table must contain the same columns.

**Collection**

A collection is a container that is used to store JSON documents in a MySQL database. Applications usually run operations against a collection of documents, for example to find a specific document.

**CRUD Operations**

The four basic operations that can be issued against a collection are Create, Read, Update and Delete (CRUD). In terms of MySQL this means:

- Create a new document (insertion or addition)
- Read one or more documents (queries)
- Update one or more documents
- Delete one or more documents

**20.3 JavaScript Quick-Start Guide: MySQL Shell for Document Store**

This quick-start guide provides instructions to begin prototyping document store applications interactively with MySQL Shell. The guide includes the following topics:

- Introduction to MySQL functionality, MySQL Shell, and the world_x example schema.
- Operations to manage collections and documents.
- Operations to manage relational tables.
- Operations that apply to documents within tables.
Related Information

To follow this quick-start guide you need a MySQL server with X Plugin installed, the default in 8.0, and MySQL Shell to use as the client. MySQL Shell 8.0 (part of MySQL 8.0) provides more in-depth information about MySQL Shell. The Document Store is accessed using X DevAPI, and MySQL Shell provides this API in both JavaScript and Python.

Related Information

- MySQL Shell 8.0 (part of MySQL 8.0) provides more in-depth information about MySQL Shell.
- See Installing MySQL Shell and Section 20.5, “X Plugin” for more information about the tools used in this quick-start guide.
- X DevAPI User Guide provides more examples of using X DevAPI to develop applications which use Document Store.
- A Python quick-start guide is also available.

20.3.1 MySQL Shell

This quick-start guide assumes a certain level of familiarity with MySQL Shell. The following section is a high level overview, see the MySQL Shell documentation for more information. MySQL Shell is a unified scripting interface to MySQL Server. It supports scripting in JavaScript and Python. JavaScript is the default processing mode.

Start MySQL Shell

After you have installed and started MySQL server, connect MySQL Shell to the server instance. You need to know the address of the MySQL server instance you plan to connect to. To be able to use the instance as a Document Store, the server instance must have X Plugin installed and you should connect to the server using X Protocol. For example to connect to the instance `ds1.example.com` on the default X Protocol port of 33060 use the network string `user@ds1.example.com:33060`.

Tip

If you connect to the instance using classic MySQL protocol, for example by using the default port of 3306 instead of the `mysqlx_port`, you cannot use the Document Store functionality shown in this tutorial. For example the `db` global object is not populated. To use the Document Store, always connect using X Protocol.

If MySQL Shell is not already running, open a terminal window and issue:

```
mysqlsh user@ds1.example.com:33060/world_x
```

Alternatively, if MySQL Shell is already running use the `\connect` command by issuing:

```
\connect user@ds1.example.com:33060/world_x
```

You need to specify the address of the MySQL server instance which you want to connect MySQL Shell to. For example in the previous example:

- `user` represents the user name of your MySQL account.
- `ds1.example.com` is the hostname of the server instance running MySQL. Replace this with the hostname of the MySQL server instance you are using as a Document Store.
- The default schema for this session is `world_x`. For instructions on setting up the `world_x` schema, see Section 20.3.2, “Download and Import world_x Database”.

3680
Download and Import world_x Database

For more information, see Section 4.2.5, “Connecting to the Server Using URI-Like Strings or Key-Value Pairs”.

Once MySQL Shell opens, the mysql-js> prompt indicates that the active language for this session is JavaScript.

MySQL Shell supports input-line editing as follows:

- **left-arrow** and **right-arrow** keys move horizontally within the current input line.
- **up-arrow** and **down-arrow** keys move up and down through the set of previously entered lines.
- **Backspace** deletes the character before the cursor and typing new characters enters them at the cursor position.
- **Enter** sends the current input line to the server.

Get Help for MySQL Shell

Type `mysqlsh --help` at the prompt of your command interpreter for a list of command-line options.

```
mysqlsh --help
```

Type `\help` at the MySQL Shell prompt for a list of available commands and their descriptions.

```
mysql-js> \help
```

Type `\help` followed by a command name for detailed help about an individual MySQL Shell command. For example, to view help on the `\connect` command, issue:

```
mysql-js> \help \connect
```

Quit MySQL Shell

To quit MySQL Shell, issue the following command:

```
mysql-js> \quit
```

Related Information

- See Interactive Code Execution for an explanation of how interactive code execution works in MySQL Shell.
- See Getting Started with MySQL Shell to learn about session and connection alternatives.

**20.3.2 Download and Import world_x Database**

As part of this quick-start guide, an example schema is provided which is referred to as the world_x schema. Many of the examples demonstrate Document Store functionality using this schema. Start your MySQL server so that you can load the world_x schema, then follow these steps:

1. Download `world_x-db.zip`.
2. Extract the installation archive to a temporary location such as `/tmp/`. Unpacking the archive results in a single file named `world_x.sql`. 
3. Import the `world_x.sql` file to your server. You can either:

- Start MySQL Shell in SQL mode and import the file by issuing:
  ```bash
  mysqlsh -u root --sql --file /tmp/world_x-db/world_x.sql
  Enter password: ****
  ```

- Set MySQL Shell to SQL mode while it is running and source the schema file by issuing:
  ```bash
  \sql
  Switching to SQL mode... Commands end with ;
  \source /tmp/world_x-db/world_x.sql
  ```

Replace `/tmp/` with the path to the `world_x.sql` file on your system. Enter your password if prompted. A non-root account can be used as long as the account has privileges to create new schemas.

**The `world_x` Schema**

The `world_x` example schema contains the following JSON collection and relational tables:

- **Collection**
  - `countryinfo`: Information about countries in the world.

- **Tables**
  - `country`: Minimal information about countries of the world.
  - `city`: Information about some of the cities in those countries.
  - `countrylanguage`: Languages spoken in each country.

**Related Information**

- [MySQL Shell Sessions](#) explains session types.

**20.3.3 Documents and Collections**

When you are using MySQL as a Document Store, collections are containers within a schema that you can create, list, and drop. Collections contain JSON documents that you can add, find, update, and remove.

The examples in this section use the `countryinfo` collection in the `world_x` schema. For instructions on setting up the `world_x` schema, see Section 20.3.2, “Download and Import world_x Database”.

**Documents**

In MySQL, documents are represented as JSON objects. Internally, they are stored in an efficient binary format that enables fast lookups and updates.

- Simple document format for JavaScript:
  ```json
  { field1: "value", field2: 10, "field 3": null }
  ```

  An array of documents consists of a set of documents separated by commas and enclosed within `[` and `]` characters.

- Simple array of documents for JavaScript: 
  ```json
  ```
MySQL supports the following JavaScript value types in JSON documents:

- numbers (integer and floating point)
- strings
- boolean (False and True)
- null
- arrays of more JSON values
- nested (or embedded) objects of more JSON values

**Collections**

Collections are containers for documents that share a purpose and possibly share one or more indexes. Each collection has a unique name and exists within a single schema.

The term schema is equivalent to a database, which means a group of database objects as opposed to a relational schema, used to enforce structure and constraints over data. A schema does not enforce conformity on the documents in a collection.

In this quick-start guide:

- Basic objects include:

<table>
<thead>
<tr>
<th>Object form</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>db</code></td>
<td><code>db</code> is a global variable assigned to the current active schema. When you want to run operations against the schema, for example to retrieve a collection, you use methods available for the <code>db</code> variable.</td>
</tr>
<tr>
<td><code>db.getCollections()</code></td>
<td><code>db.getCollections()</code> returns a list of collections in the schema. Use the list to get references to collection objects, iterate over them, and so on.</td>
</tr>
</tbody>
</table>

- Basic operations scoped by collections include:

<table>
<thead>
<tr>
<th>Operation form</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>db.name.add()</code></td>
<td>The <code>add()</code> method inserts one document or a list of documents into the named collection.</td>
</tr>
<tr>
<td><code>db.name.find()</code></td>
<td>The <code>find()</code> method returns some or all documents in the named collection.</td>
</tr>
<tr>
<td><code>db.name.modify()</code></td>
<td>The <code>modify()</code> method updates documents in the named collection.</td>
</tr>
<tr>
<td><code>db.name.remove()</code></td>
<td>The <code>remove()</code> method deletes one document or a list of documents from the named collection.</td>
</tr>
</tbody>
</table>

**Related Information**

- See [Working with Collections](#) for a general overview.
20.3.3.1 Create, List, and Drop Collections

In MySQL Shell, you can create new collections, get a list of the existing collections in a schema, and remove an existing collection from a schema. Collection names are case-sensitive and each collection name must be unique.

Confirm the Schema

To show the value that is assigned to the schema variable, issue:

```
mysql-js> db
```

If the schema value is not `Schema:world_x`, then set the `db` variable by issuing:

```
mysql-js> \use world_x
```

Create a Collection

To create a new collection in an existing schema, use the `db` object's `createCollection()` method. The following example creates a collection called `flags` in the `world_x` schema.

```
mysql-js> db.createCollection("flags")
```

The method returns a collection object.

```
<Collection:flags>
```

List Collections

To display all collections in the `world_x` schema, use the `db` object's `getCollections()` method. Collections returned by the server you are currently connected to appear between brackets.

```
mysql-js> db.getCollections()
[  
    <Collection:countryinfo>,
    <Collection:flags>
]
```

Drop a Collection

To drop an existing collection from a schema, use the `db` object's `dropCollection()` method. For example, to drop the `flags` collection from the current schema, issue:

```
mysql-js> db.dropCollection("flags")
```

The `dropCollection()` method is also used in MySQL Shell to drop a relational table from a schema.

Related Information

- See Collection Objects for more examples.

20.3.3.2 Working with Collections

To work with the collections in a schema, use the `db` global object to access the current schema. In this example we are using the `world_x` schema imported previously, and the `countryinfo` collection.
Therefore, the format of the operations you issue is `db.collection_name.operation`, where `collection_name` is the name of the collection which the operation is executed against. In the following examples, the operations are executed against the `countryinfo` collection.

**Add a Document**

Use the `add()` method to insert one document or a list of documents into an existing collection. Insert the following document into the `countryinfo` collection. As this is multi-line content, press `Enter` twice to insert the document.

```javascript
mysql-js> db.countryinfo.add({
  GNP: 0.6,
  IndepYear: 1967,
  Name: "Sealand",
  Code: "SEA",
  demographics: {
    LifeExpectancy: 79,
    Population: 27
  },
  geography: {
    Continent: "Europe",
    Region: "British Islands",
    SurfaceArea: 193
  },
  government: {
    GovernmentForm: "Monarchy",
    HeadOfState: "Michael Bates"
  }
})
```

The method returns the status of the operation. You can verify the operation by searching for the document. For example:

```javascript
mysql-js> db.countryinfo.find("Name = 'Sealand'")
{ "GNP": 0.6,
  "_id": "00005e2ff4af00000000000000004f4",
  "Name": "Sealand",
  "Code": "SEA",
  "IndepYear": 1967,
  "geography": {
    "Region": "British Islands",
    "Continent": "Europe",
    "SurfaceArea": 193
  },
  "government": {
    "HeadOfState": "Michael Bates",
    "GovernmentForm": "Monarchy"
  },
  "demographics": {
    "Population": 27,
    "LifeExpectancy": 79
  }
}
```

Note that in addition to the fields specified when the document was added, there is one more field, the `_id`. Each document requires an identifier field called `_id`. The value of the `_id` field must be unique among all documents in the same collection. In MySQL 8.0.11 and higher, document IDs are generated by the server, not the client, so MySQL Shell does not automatically set an `_id` value. A MySQL server at 8.0.11 or higher sets an `_id` value if the document does not contain the `_id` field. A MySQL server at an earlier 8.0 release or at 5.7 does not set an `_id` value in this situation, so you must specify it explicitly. If
you do not, MySQL Shell returns error 5115 Document is missing a required field. For more information see Understanding Document IDs.

Related Information

- See CollectionAddFunction for the full syntax definition.
- See Understanding Document IDs.

20.3.3.3 Find Documents

You can use the `find()` method to query for and return documents from a collection in a schema. MySQL Shell provides additional methods to use with the `find()` method to filter and sort the returned documents.

MySQL provides the following operators to specify search conditions: OR (| |), AND (&&), XOR, IS, NOT, BETWEEN, IN, LIKE, !=, <>, >=, <, <=, |, <<, >>, +, -, *, /, and %.

Find All Documents in a Collection

To return all documents in a collection, use the `find()` method without specifying search conditions. For example, the following operation returns all documents in the `countryinfo` collection.

```
mysql-js> db.countryinfo.find()
[ { 
  "GNP": 828,
  "Code": "ABW",
  "Name": "Aruba",
  "IndepYear": null,
  "geography": {
    "Continent": "North America",
    "Region": "Caribbean",
    "SurfaceArea": 193
  },
  "government": {
    "GovernmentForm": "Nonmetropolitan Territory of The Netherlands",
    "HeadOfState": "Beatrix"
  }
} ...
]
240 documents in set (0.00 sec)
```

The method produces results that contain operational information in addition to all documents in the collection.

An empty set (no matching documents) returns the following information:

```
Empty set (0.00 sec)
```

Filter Searches

You can include search conditions with the `find()` method. The syntax for expressions that form a search condition is the same as that of traditional MySQL Chapter 12, Functions and Operators. You must enclose all expressions in quotes. For the sake of brevity, some of the examples do not display output.
A simple search condition could consist of the Name field and a value we know is in a document. The following example returns a single document:

```javascript
mysql-js> db.countryinfo.find("Name = 'Australia'")
[
    {
        "GNP": 351182,
        "Code": "AUS",
        "Name": "Australia",
        "IndepYear": 1901,
        "geography": {
            "Continent": "Oceania",
            "Region": "Australia and New Zealand",
            "SurfaceArea": 7741220
        },
        "government": {
            "GovernmentForm": "Constitutional Monarchy, Federation",
            "HeadOfState": "Elisabeth II"
        },
        "demographics": {
            "LifeExpectancy": 79.80000305175781,
            "Population": 18886000
        }
    }
]
```

The following example searches for all countries that have a GNP higher than $500 billion. The countryinfo collection measures GNP in units of million.

```javascript
mysql-js> db.countryinfo.find("GNP > 500000")
...[output removed]
10 documents in set (0.00 sec)
```

The Population field in the following query is embedded within the demographics object. To access the embedded field, use a period between demographics and Population to identify the relationship. Document and field names are case-sensitive.

```javascript
mysql-js> db.countryinfo.find("GNP > 500000 and demographics.Population < 100000000")
...[output removed]
6 documents in set (0.00 sec)
```

Arithmetic operators in the following expression are used to query for countries with a GNP per capita higher than $30000. Search conditions can include arithmetic operators and most MySQL functions.

```javascript
mysql-js> db.countryinfo.find("GNP*1000000/demographics.Population > 30000")
...[output removed]
9 documents in set, 7 warnings (0.00 sec)
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
```

You can separate a value from the search condition by using the `bind()` method. For example, instead of specifying a hard-coded country name as the condition, substitute a named placeholder consisting of a colon followed by a name that begins with a letter, such as `country`. Then use the `bind(placeholder, value)` method as follows:
Within a program, binding enables you to specify placeholders in your expressions, which are filled in with values before execution and can benefit from automatic escaping, as appropriate.

Always use binding to sanitize input. Avoid introducing values in queries using string concatenation, which can produce invalid input and, in some cases, can cause security issues.

You can use placeholders and the `bind()` method to create saved searches which you can then call with different values. For example to create a saved search for a country:

```
> var myFind = db.countryinfo.find("Name = :country")
> myFind.bind("country", "France")

{  
  "GNP": 1424285,  
  "_id": "00005de917d800000000000048",  
  "Code": "FRA",  
  "Name": "France",  
  "IndepYear": 843,  
  "geography": {  
    "Region": "Western Europe",  
    "Continent": "Europe",  
    "SurfaceArea": 551500  
  },  
  "government": {  
    "HeadOfState": "Jacques Chirac",  
    "GovernmentForm": "Republic"  
  },  
  "demographics": {  
    "Population": 59225700,  
    "LifeExpectancy": 78.80000305175781  
  }  
}

1 document in set (0.0028 sec)
```

```
> myFind.bind("country", "Germany")

{  
  "GNP": 2133367,  
  "_id": "00005de917d800000000000038",  
  "Code": "DE",  
  "Name": "Germany",  
  "IndepYear": 1871,  
  "geography": {  
    "Region": "Western Europe",  
    "Continent": "Europe",  
    "SurfaceArea": 357022  
  },  
  "government": {  
    "HeadOfState": "Kurt Seehofer",  
    "GovernmentForm": "Federal Republic"  
  },  
  "demographics": {  
    "Population": 81910000,  
    "LifeExpectancy": 76.9  
  }  
}

1 document in set (0.0015 sec)
```
Project Results

You can return specific fields of a document, instead of returning all the fields. The following example returns the GNP and Name fields of all documents in the `countryinfo` collection matching the search conditions.

Use the `fields()` method to pass the list of fields to return.

```javascript
mysql> db.countryinfo.find("GNP > 5000000").fields(['"GNP", "Name"])
```

```json
[
  {
    "GNP": 8510700,
    "Name": "United States"
  }
]
```

In addition, you can alter the returned documents—adding, renaming, nesting and even computing new field values—with an expression that describes the document to return. For example, alter the names of the fields with the following expression to return only two documents.

```javascript
mysql> db.countryinfo.find().fields(
    mysqlx.expr('"Name": upper(Name), "GNPPerCapita": GNP*1000000/demographics.Population'))
```

```json
{
  "Name": "ARUBA",
  "GNPPerCapita": 8038.834951456311
}
{
  "Name": "AFGHANISTAN",
  "GNPPerCapita": 263.0281690140845
}
```

Limit, Sort, and Skip Results

You can apply the `limit()`, `sort()`, and `skip()` methods to manage the number and order of documents returned by the `find()` method.

To specify the number of documents included in a result set, append the `limit()` method with a value to the `find()` method. The following query returns the first five documents in the `countryinfo` collection.

```javascript
mysql> db.countryinfo.find().limit(5)
```
To specify an order for the results, append the `sort()` method to the `find()` method. Pass to the
`sort()` method a list of one or more fields to sort by and, optionally, the descending (`desc`) or ascending
(`asc`) attribute as appropriate. Ascending order is the default order type.

For example, the following query sorts all documents by the `IndepYear` field and then returns the first eight
documents in descending order.

```sql
mysql-js> db.countryinfo.find().sort(["IndepYear desc"]).limit(8)
... [output removed]
8 documents in set (0.00 sec)
```

By default, the `limit()` method starts from the first document in the collection. You can use the `skip()`
method to change the starting document. For example, to ignore the first document and return the next
eight documents matching the condition, pass to the `skip()` method a value of 1.

```sql
mysql-js> db.countryinfo.find().sort(["IndepYear desc"]).limit(8).skip(1)
... [output removed]
8 documents in set (0.00 sec)
```

**Related Information**

- See [CollectionFindFunction](https://dev.mysql.com/doc/refman/) for the full syntax definition.

### 20.3.3.4 Modify Documents

You can use the `modify()` method to update one or more documents in a collection. The X DevAPI
provides additional methods for use with the `modify()` method to:

- Set and unset fields within documents.
- Append, insert, and delete arrays.
- Bind, limit, and sort the documents to be modified.

**Set and Unset Document Fields**

The `modify()` method works by filtering a collection to include only the documents to be modified and
then applying the operations that you specify to those documents.

In the following example, the `modify()` method uses the search condition to identify the document to
change and then the `set()` method replaces two values within the nested `demographics` object.

```sql
mysql-js> db.countryinfo.modify("Code = 'SEA'").set(  
"demographics", {"LifeExpectancy": 78, "Population": 28})
```

After you modify a document, use the `find()` method to verify the change.

To remove content from a document, use the `modify()` and `unset()` methods. For example, the
following query removes the GNP from a document that matches the search condition.

```sql
mysql-js> db.countryinfo.modify("Name = 'Sealand'").unset("GNP")
```

Use the `find()` method to verify the change.

```sql
mysql-js> db.countryinfo.find("Name = 'Sealand'")
Append, Insert, and Delete Arrays

To append an element to an array field, or insert, or delete elements in an array, use the `arrayAppend()`, `arrayInsert()`, or `arrayDelete()` methods. The following examples modify the `countryinfo` collection to enable tracking of international airports.

The first example uses the `modify()` and `set()` methods to create a new `Airports` field in all documents.

```
Caution
Use care when you modify documents without specifying a search condition; doing so modifies all documents in the collection.
```

```
mysql-js> db.countryinfo.modify("true").set("Airports", [])
```

With the `Airports` field added, the next example uses the `arrayAppend()` method to add a new airport to one of the documents. `$Airports` in the following example represents the `Airports` field of the current document.

```
mysql-js> db.countryinfo.modify("Name = 'France'").arrayAppend("$Airports", "ORY")
```

Use `find()` to see the change.

```
mysql-js> db.countryinfo.find("Name = 'France'")
{  
  "_id": "00005de917d800000000000000000048",  
  "Code": "FRA",  
  "Name": "France",  
  "Airports": [  
    "ORY"  
  ],  
  "IndepYear": 843,  
  "geography": {  
    "Region": "Western Europe",  
    "Continent": "Europe",  
    "SurfaceArea": 551500  
  },  
  "government": {  
    "HeadOfState": "Jacques Chirac",  
    "GovernmentForm": "Republic"  
  },  
  "demographics": {  
    "Population": 59225700,
```
To insert an element at a different position in the array, use the `arrayInsert()` method to specify which index to insert in the path expression. In this case, the index is 0, or the first element in the array.

```javascript
mysql-ja> db.countryinfo.modify("Name = 'France'").arrayInsert("$.Airports[0]", "CDG")
```

To delete an element from the array, you must pass to the `arrayDelete()` method the index of the element to be deleted.

```javascript
mysql-ja> db.countryinfo.modify("Name = 'France'").arrayDelete("$.Airports[1]")
```

### Related Information

- See [CollectionModifyFunction](https://dev.mysql.com/doc/refman/8.0/en/json.html) for the full syntax definition.

### 20.3.3.5 Remove Documents

You can use the `remove()` method to delete some or all documents from a collection in a schema. The X DevAPI provides additional methods for use with the `remove()` method to filter and sort the documents to be removed.

#### Remove Documents Using Conditions

The following example passes a search condition to the `remove()` method. All documents matching the condition are removed from the `countryinfo` collection. In this example, one document matches the condition.

```javascript
mysql-ja> db.countryinfo.remove("Code = 'SEA'")
```

#### Remove the First Document

To remove the first document in the `countryinfo` collection, use the `limit()` method with a value of 1.

```javascript
mysql-ja> db.countryinfo.remove("true").limit(1)
```

#### Remove the Last Document in an Order

The following example removes the last document in the `countryinfo` collection by country name.

```javascript
mysql-ja> db.countryinfo.remove("true").sort(["Name desc"]).limit(1)
```

#### Remove All Documents in a Collection

You can remove all documents in a collection. To do so, use the `remove("true")` method without specifying a search condition.

---

**Caution**

Use care when you remove documents without specifying a search condition. This action deletes all documents from the collection.

Alternatively, use the `db.drop_collection('countryinfo')` operation to delete the `countryinfo` collection.
Related Information

- See CollectionRemoveFunction for the full syntax definition.
- See Section 20.3.2, “Download and Import world_x Database” for instructions to recreate the world_x schema.

20.3.3.6 Create and Drop Indexes

Indexes are used to find documents with specific field values quickly. Without an index, MySQL must begin with the first document and then read through the entire collection to find the relevant fields. The larger the collection, the more this costs. If a collection is large and queries on a specific field are common, then consider creating an index on a specific field inside a document.

For example, the following query performs better with an index on the Population field:

```javascript
mysql> db.countryinfo.find("demographics.Population < 100")
...
[output removed]
8 documents in set (0.00 sec)
```

The `createIndex()` method creates an index that you can define with a JSON document that specifies which fields to use. This section is a high level overview of indexing. For more information see Indexing Collections.

Add a Nonunique Index

To create a nonunique index, pass an index name and the index information to the `createIndex()` method. Duplicate index names are prohibited.

The following example specifies an index named `popul`, defined against the Population field from the demographics object, indexed as an Integer numeric value. The final parameter indicates whether the field should require the NOT NULL constraint. If the value is false, the field can contain NULL values. The index information is a JSON document with details of one or more fields to include in the index. Each field definition must include the full document path to the field, and specify the type of the field.

```javascript
mysql> db.countryinfo.createIndex("popul", {fields:
[{{field: '$.demographics.Population', type: 'INTEGER'}}])
```

Here, the index is created using an integer numeric value. Further options are available, including options for use with GeoJSON data. You can also specify the type of index, which has been omitted here because the default type “index” is appropriate.

Add a Unique Index

To create a unique index, pass an index name, the index definition, and the index type “unique” to the `createIndex()` method. This example shows a unique index created on the country name ("Name"), which is another common field in the countryinfo collection to index. In the index field description, "TEXT(40)" represents the number of characters to index, and "required": True specifies that the field is required to exist in the document.

```javascript
mysql> db.countryinfo.createIndex("name",
["fields": [{"field": "$Name", "type": "TEXT(40)", "required": true}], "unique": true})
```

Drop an Index

To drop an index, pass the name of the index to drop to the `dropIndex()` method. For example, you can drop the “popul” index as follows:
Relational Tables

```sql
mysql-js> db.countryinfo.dropIndex("popul")
```

Related Information

- See [Indexing Collections](#) for more information.
- See [Defining an Index](#) for more information on the JSON document that defines an index.
- See [Collection Index Management Functions](#) for the full syntax definition.

20.3.4 Relational Tables

You can also use X DevAPI to work with relational tables. In MySQL, each relational table is associated with a particular storage engine. The examples in this section use InnoDB tables in the `world_x` schema.

Confirm the Schema

To show the schema that is assigned to the `db` global variable, issue `db`.

```sql
mysql-js> db
<Schema:world_x>
```

If the returned value is not `Schema:world_x`, set the `db` variable as follows:

```sql
mysql-js> \use world_x
```

Schema `world_x` accessible through `db`.

Show All Tables

To display all relational tables in the `world_x` schema, use the `getTables()` method on the `db` object.

```sql
mysql-js> db.getTables()
{
    "city": <Table:city>,
    "country": <Table:country>,
    "countrylanguage": <Table:countrylanguage>
}
```

Basic Table Operations

Basic operations scoped by tables include:

<table>
<thead>
<tr>
<th>Operation form</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>db.name.insert()</code></td>
<td>The <code>insert()</code> method inserts one or more records into the named table.</td>
</tr>
<tr>
<td><code>db.name.select()</code></td>
<td>The <code>select()</code> method returns some or all records in the named table.</td>
</tr>
<tr>
<td><code>db.name.update()</code></td>
<td>The <code>update()</code> method updates records in the named table.</td>
</tr>
<tr>
<td><code>db.name.delete()</code></td>
<td>The <code>delete()</code> method deletes one or more records from the named table.</td>
</tr>
</tbody>
</table>

Related Information

- See [Working with Relational Tables](#) for more information.
- [CRUD EBNF Definitions](#) provides a complete list of operations.
- See [Section 20.3.2, "Download and Import world_x Database"](#) for instructions on setting up the `world_x` schema sample.
20.3.4.1 Insert Records into Tables

You can use the `insert()` method with the `values()` method to insert records into an existing relational table. The `insert()` method accepts individual columns or all columns in the table. Use one or more `values()` methods to specify the values to be inserted.

**Insert a Complete Record**

To insert a complete record, pass to the `insert()` method all columns in the table. Then pass to the `values()` method one value for each column in the table. For example, to add a new record to the city table in the `world_x` schema, insert the following record and press Enter twice.

```
```

The city table has five columns: ID, Name, CountryCode, District, and Info. Each value must match the data type of the column it represents.

**Insert a Partial Record**

The following example inserts values into the ID, Name, and CountryCode columns of the city table.

```
mysql-js> db.city.insert("ID", "Name", "CountryCode").values(None, "Little Falls", "USA").values(None, "Happy Valley", "USA")
```

When you specify columns using the `insert()` method, the number of values must match the number of columns. In the previous example, you must supply three values to match the three columns specified.

**Related Information**

- See `TableInsertFunction` for the full syntax definition.

20.3.4.2 Select Tables

You can use the `select()` method to query for and return records from a table in a database. The X DevAPI provides additional methods to use with the `select()` method to filter and sort the returned records.

MySQL provides the following operators to specify search conditions: **OR** ( | | ), **AND** ( && ), **XOR** ( ^= ), **IS** ( IS ), **NOT** ( NOT ), **BETWEEN** ( BETWEEN ), **IN** ( IN ), **LIKE** ( LIKE ), **!=** ( <> ), **<>** ( <> ), **>=** ( >= ), **<=** ( <= ), **&** ( & ), **|** ( | ), **<<** ( << ), **>>** ( >> ), **+** ( + ), **-** ( - ), ***”** ( *’’ ), **/”** ( ‘’/’’ ), and **%** ( % ).

**Select All Records**

To issue a query that returns all records from an existing table, use the `select()` method without specifying search conditions. The following example selects all records from the city table in the `world_x` database.

```
mysql-js> db.city.select()
```

Limit the use of the empty `select()` method to interactive statements. Always use explicit column-name selections in your application code.
An empty set (no matching records) returns the following information:

Empty set (0.00 sec)

Filter Searches

To issue a query that returns a set of table columns, use the `select()` method and specify the columns to return between square brackets. This query returns the Name and CountryCode columns from the city table.

```sql
mysql-ja> db.city.select(["Name", "CountryCode"])
```

<table>
<thead>
<tr>
<th>Name</th>
<th>CountryCode</th>
</tr>
</thead>
<tbody>
<tr>
<td>Kabul</td>
<td>AFG</td>
</tr>
<tr>
<td>Qandahar</td>
<td>AFG</td>
</tr>
<tr>
<td>Herat</td>
<td>AFG</td>
</tr>
<tr>
<td>Mazar-e-Sharif</td>
<td>AFG</td>
</tr>
<tr>
<td>Amsterdam</td>
<td>NLD</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
</tr>
<tr>
<td>Rafah</td>
<td>PSE</td>
</tr>
<tr>
<td>Olympia</td>
<td>USA</td>
</tr>
<tr>
<td>Little Falls</td>
<td>USA</td>
</tr>
<tr>
<td>Happy Valley</td>
<td>USA</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
</tr>
</tbody>
</table>

4082 rows in set (0.00 sec)

To issue a query that returns rows matching specific search conditions, use the `where()` method to include those conditions. For example, the following example returns the names and country codes of the cities that start with the letter Z.

```sql
mysql-ja> db.city.select(["Name", "CountryCode"]).where("Name like 'Z%'")
```

<table>
<thead>
<tr>
<th>Name</th>
<th>CountryCode</th>
</tr>
</thead>
<tbody>
<tr>
<td>Zaanstad</td>
<td>NLD</td>
</tr>
<tr>
<td>Zoetermeer</td>
<td>NLD</td>
</tr>
<tr>
<td>Zwolle</td>
<td>NLD</td>
</tr>
<tr>
<td>Zenica</td>
<td>BIH</td>
</tr>
<tr>
<td>Zagazig</td>
<td>EGY</td>
</tr>
<tr>
<td>Zaragoza</td>
<td>ESP</td>
</tr>
<tr>
<td>Zamboanga</td>
<td>PHL</td>
</tr>
<tr>
<td>Zahedan</td>
<td>IRN</td>
</tr>
<tr>
<td>Zanjan</td>
<td>IRN</td>
</tr>
<tr>
<td>Zabol</td>
<td>IRN</td>
</tr>
<tr>
<td>Zama</td>
<td>JPN</td>
</tr>
<tr>
<td>Zhequezgian</td>
<td>KAZ</td>
</tr>
<tr>
<td>Zhengzhou</td>
<td>CHN</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
</tr>
<tr>
<td>Zeleznozorsk</td>
<td>RUS</td>
</tr>
</tbody>
</table>

59 rows in set (0.00 sec)

You can separate a value from the search condition by using the `bind()` method. For example, instead of using "Name = 'Z%'" as the condition, substitute a named placeholder consisting of a colon followed by a name that begins with a letter, such as `name`. Then include the placeholder and value in the `bind()` method as follows:

```sql
mysql-ja> db.city.select(["Name", "CountryCode"]).where("Name like 'Z%'").bind("name", "Z"")
```

<table>
<thead>
<tr>
<th>Name</th>
<th>CountryCode</th>
</tr>
</thead>
<tbody>
<tr>
<td>Zaanstad</td>
<td>NLD</td>
</tr>
<tr>
<td>Zoetermeer</td>
<td>NLD</td>
</tr>
<tr>
<td>Zwolle</td>
<td>NLD</td>
</tr>
<tr>
<td>Zenica</td>
<td>BIH</td>
</tr>
<tr>
<td>Zagazig</td>
<td>EGY</td>
</tr>
<tr>
<td>Zaragoza</td>
<td>ESP</td>
</tr>
<tr>
<td>Zamboanga</td>
<td>PHL</td>
</tr>
<tr>
<td>Zahedan</td>
<td>IRN</td>
</tr>
<tr>
<td>Zanjan</td>
<td>IRN</td>
</tr>
<tr>
<td>Zabol</td>
<td>IRN</td>
</tr>
<tr>
<td>Zama</td>
<td>JPN</td>
</tr>
<tr>
<td>Zhequezgian</td>
<td>KAZ</td>
</tr>
<tr>
<td>Zhengzhou</td>
<td>CHN</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
</tr>
<tr>
<td>Zeleznozorsk</td>
<td>RUS</td>
</tr>
</tbody>
</table>

...
Relational Tables

Where

```javascript
where("Name like :name").bind("name", "Z%")
```

**Tip**

Within a program, binding enables you to specify placeholders in your expressions, which are filled in with values before execution and can benefit from automatic escaping, as appropriate.

Always use binding to sanitize input. Avoid introducing values in queries using string concatenation, which can produce invalid input and, in some cases, can cause security issues.

Project Results

To issue a query using the **AND** operator, add the operator between search conditions in the `where()` method.

```javascript
mysql-js> db.city.select(['Name', 'CountryCode']).where("Name like 'Z%' and CountryCode = 'CHN'")
+----------------+-------------+
<table>
<thead>
<tr>
<th>Name</th>
<th>CountryCode</th>
</tr>
</thead>
<tbody>
<tr>
<td>Zhengzhou</td>
<td>CHN</td>
</tr>
<tr>
<td>Zibo</td>
<td>CHN</td>
</tr>
<tr>
<td>Zhangjiakou</td>
<td>CHN</td>
</tr>
<tr>
<td>Zhuzhou</td>
<td>CHN</td>
</tr>
<tr>
<td>Zhangjiang</td>
<td>CHN</td>
</tr>
<tr>
<td>Zigong</td>
<td>CHN</td>
</tr>
<tr>
<td>Zaozhuang</td>
<td>CHN</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
</tr>
<tr>
<td>Zhangjiagang</td>
<td>CHN</td>
</tr>
</tbody>
</table>
+----------------+-------------+
22 rows in set (0.01 sec)
```

To specify multiple conditional operators, you can enclose the search conditions in parenthesis to change the operator precedence. The following example demonstrates the placement of **AND** and **OR** operators.

```javascript
mysql-js> db.city.select(['Name', 'CountryCode']).where("Name like 'Z%' and (CountryCode = 'CHN' or CountryCode = 'RUS')")
+-------------------+-------------+
<table>
<thead>
<tr>
<th>Name</th>
<th>CountryCode</th>
</tr>
</thead>
<tbody>
<tr>
<td>Zhengzhou</td>
<td>CHN</td>
</tr>
<tr>
<td>Zibo</td>
<td>CHN</td>
</tr>
<tr>
<td>Zhangjiakou</td>
<td>CHN</td>
</tr>
<tr>
<td>Zhuzhou</td>
<td>CHN</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
</tr>
<tr>
<td>Zeleznogorsk</td>
<td>RUS</td>
</tr>
</tbody>
</table>
+-------------------+-------------+
29 rows in set (0.01 sec)
```

Limit, Order, and Offset Results

You can apply the **limit()**, **orderBy()**, and **offset()** methods to manage the number and order of records returned by the `select()` method.

To specify the number of records included in a result set, append the **limit()** method with a value to the `select()` method. For example, the following query returns the first five records in the country table.

```javascript
mysql-js> db.country.select(['Code', 'Name']).limit(5)
+----+------------------+
| Code | Name             |
+----+------------------+
3697
To specify an order for the results, append the `orderBy()` method to the `select()` method. Pass to the `orderBy()` method a list of one or more columns to sort by and, optionally, the descending (`desc`) or ascending (`asc`) attribute as appropriate. Ascending order is the default order type.

For example, the following query sorts all records by the `Name` column and then returns the first three records in descending order:

```javascript
mysql-js> db.country.select(["Code", "Name"]).orderBy(["Name desc"]).limit(3)
```

```
+------+------------+
| Code | Name       |
+------+------------+
| ZWE  | Zimbabwe   |
| ZMB  | Zambia     |
| YUG  | Yugoslavia |
+------+------------+
3 rows in set (0.00 sec)
```

By default, the `limit()` method starts from the first record in the table. You can use the `offset()` method to change the starting record. For example, to ignore the first record and return the next three records matching the condition, pass to the `offset()` method a value of 1.

```javascript
mysql-js> db.country.select(["Code", "Name"]).orderBy(["Name desc"]).limit(3).offset(1)
```

```
+------+------------+
| Code | Name       |
+------+------------+
| ZMB  | Zambia     |
| YUG  | Yugoslavia |
| YEM  | Yemen      |
+------+------------+
3 rows in set (0.00 sec)
```

Related Information

- See [TableSelectFunction](https://dev.mysql.com/doc/refman/) for the full syntax definition.

### 20.3.4.3 Update Tables

You can use the `update()` method to modify one or more records in a table. The `update()` method works by filtering a query to include only the records to be updated and then applying the operations you specify to those records.

To replace a city name in the city table, pass to the `set()` method the new city name. Then, pass to the `where()` method the city name to locate and replace. The following example replaces the city Peking with Beijing.

```javascript
mysql-js> db.city.update().set("Name", "Beijing").where("Name = 'Peking'")
```

Use the `select()` method to verify the change.

```javascript
mysql-js> db.city.select(["ID", "Name", "CountryCode", "District", "Info"])
```

```
<table>
<thead>
<tr>
<th>ID</th>
<th>Name</th>
<th>CountryCode</th>
<th>District</th>
<th>Info</th>
</tr>
</thead>
</table>
```
Documents in Tables

Related Information

- See TableUpdateFunction for the full syntax definition.

20.3.4.4 Delete Tables

You can use the delete() method to remove some or all records from a table in a database. The X DevAPI provides additional methods to use with the delete() method to filter and order the records to be deleted.

Delete Records Using Conditions

The following example passes search conditions to the delete() method. All records matching the condition are deleted from the city table. In this example, one record matches the condition.

```javascript
mysql-js> db.city.delete().where("Name = 'Olympia'")
```

Delete the First Record

To delete the first record in the city table, use the limit() method with a value of 1.

```javascript
mysql-js> db.city.delete().limit(1)
```

Delete All Records in a Table

You can delete all records in a table. To do so, use the delete() method without specifying a search condition.

**Caution**

Use care when you delete records without specifying a search condition; doing so deletes all records from the table.

Drop a Table

The dropCollection() method is also used in MySQL Shell to drop a relational table from a database. For example, to drop the citytest table from the world_x database, issue:

```javascript
mysql-js> session.dropCollection("world_x", "citytest")
```

Related Information

- See TableDeleteFunction for the full syntax definition.
- See Section 20.3.2, “Download and Import world_x Database” for instructions to recreate the world_x database.

20.3.5 Documents in Tables

In MySQL, a table may contain traditional relational data, JSON values, or both. You can combine traditional data with JSON documents by storing the documents in columns having a native JSON data type.

Examples in this section use the city table in the world_x schema.
city Table Description

The city table has five columns (or fields).

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Null</th>
<th>Key</th>
<th>Default</th>
<th>Extra</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID</td>
<td>int(11)</td>
<td>NO</td>
<td>PRI</td>
<td>null</td>
<td>auto_increment</td>
</tr>
<tr>
<td>Name</td>
<td>char(35)</td>
<td>NO</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>CountryCode</td>
<td>char(3)</td>
<td>NO</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>District</td>
<td>char(20)</td>
<td>NO</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Info</td>
<td>json</td>
<td>YES</td>
<td></td>
<td>null</td>
<td></td>
</tr>
</tbody>
</table>

Insert a Record

To insert a document into the column of a table, pass to the `values()` method a well-formed JSON document in the correct order. In the following example, a document is passed as the final value to be inserted into the Info column.

```mysql
mysql-js> db.city.insert().values(
    None, "San Francisco", "USA", "California", '{"Population":830000}')
```

Select a Record

You can issue a query with a search condition that evaluates document values in the expression.

```mysql
```

Related Information

- See Working with Relational Tables and Documents for more information.
- See Section 11.5, “The JSON Data Type” for a detailed description of the data type.

20.4 Python Quick-Start Guide: MySQL Shell for Document Store

This quick-start guide provides instructions to begin prototyping document store applications interactively with MySQL Shell. The guide includes the following topics:

- Introduction to MySQL functionality, MySQL Shell, and the `world_x` example schema.
- Operations to manage collections and documents.
- Operations to manage relational tables.
Related Information

- Operations that apply to documents within tables.

To follow this quick-start guide you need a MySQL server with X Plugin installed, the default in 8.0, and MySQL Shell to use as the client. MySQL Shell includes X DevAPI, implemented in both JavaScript and Python, which enables you to connect to the MySQL server instance using X Protocol and use the server as a Document Store.

Related Information

- MySQL Shell 8.0 (part of MySQL 8.0) provides more in-depth information about MySQL Shell.
- See Installing MySQL Shell and Section 20.5, "X Plugin" for more information about the tools used in this quick-start guide.
- See Supported Languages for more information about the languages MySQL Shell supports.
- X DevAPI User Guide provides more examples of using X DevAPI to develop applications which use MySQL as a Document Store.
- A JavaScript quick-start guide is also available.

20.4.1 MySQL Shell

This quick-start guide assumes a certain level of familiarity with MySQL Shell. The following section is a high level overview, see the MySQL Shell documentation for more information. MySQL Shell is a unified scripting interface to MySQL Server. It supports scripting in JavaScript and Python. JavaScript is the default processing mode.

Start MySQL Shell

After you have installed and started MySQL server, connect MySQL Shell to the server instance. You need to know the address of the MySQL server instance you plan to connect to. To be able to use the instance as a Document Store, the server instance must have X Plugin installed and you should connect to the server using X Protocol. For example to connect to the instance `ds1.example.com` on the default X Protocol port of 33060 use the network string `user@ds1.example.com:33060`.

Tip

If you connect to the instance using classic MySQL protocol, for example by using the default `port` of 3306 instead of the `mysqlx_port`, you *cannot* use the Document Store functionality shown in this tutorial. For example the `db` global object is not populated. To use the Document Store, always connect using X Protocol.

If MySQL Shell is not already running, open a terminal window and issue:

```
mysqlsh user@ds1.example.com:33060/world_x
```

Alternatively, if MySQL Shell is already running use the \connect command by issuing:

```
\connect user@ds1.example.com:33060/world_x
```

You need to specify the address of the MySQL server instance which you want to connect MySQL Shell to. For example in the previous example:

- `user` represents the user name of your MySQL account.
• **ds1.example.com** is the hostname of the server instance running MySQL. Replace this with the hostname of the MySQL server instance you are using as a Document Store.

• The default schema for this session is **world_x**. For instructions on setting up the world_x schema, see Section 20.4.2, “Download and Import world_x Database”.

For more information, see Section 4.2.5, “Connecting to the Server Using URI-Like Strings or Key-Value Pairs”.

Once MySQL Shell opens, the mysql-js> prompt indicates that the active language for this session is JavaScript. To switch MySQL Shell to Python mode, use the \py command.

```plaintext
mysql-js> \py
Switching to Python mode...
mysql-py>
```

MySQL Shell supports input-line editing as follows:

• **left-arrow** and **right-arrow** keys move horizontally within the current input line.

• **up-arrow** and **down-arrow** keys move up and down through the set of previously entered lines.

• **Backspace** deletes the character before the cursor and typing new characters enters them at the cursor position.

• **Enter** sends the current input line to the server.

**Get Help for MySQL Shell**

Type `mysqlsh --help` at the prompt of your command interpreter for a list of command-line options.

```plaintext
mysqlsh --help
```

Type `\help` at the MySQL Shell prompt for a list of available commands and their descriptions.

```plaintext
mysql-py> \help
```

Type `\help` followed by a command name for detailed help about an individual MySQL Shell command. For example, to view help on the `\connect` command, issue:

```plaintext
mysql-py> \help \connect
```

**Quit MySQL Shell**

To quit MySQL Shell, issue the following command:

```plaintext
mysql-py> \quit
```

**Related Information**

• See **Interactive Code Execution** for an explanation of how interactive code execution works in MySQL Shell.

• See **Getting Started with MySQL Shell** to learn about session and connection alternatives.

**20.4.2 Download and Import world_x Database**

As part of this quick-start guide, an example schema is provided which is referred to as the **world_x** schema. Many of the examples demonstrate Document Store functionality using this schema. Start your MySQL server so that you can load the world_x schema, then follow these steps:
1. Download world_x-db.zip.

2. Extract the installation archive to a temporary location such as /tmp/. Unpacking the archive results in a single file named world_x.sql.

3. Import the world_x.sql file to your server. You can either:
   - Start MySQL Shell in SQL mode and import the file by issuing:
     ```
     mysqlsh -u root --sql --file /tmp/world_x-db/world_x.sql
     Enter password: ****
     ```
   - Set MySQL Shell to SQL mode while it is running and source the schema file by issuing:
     ```
     \sql
     Switching to SQL mode... Commands end with ;
     \source /tmp/world_x-db/world_x.sql
     ```

Replace /tmp/ with the path to the world_x.sql file on your system. Enter your password if prompted. A non-root account can be used as long as the account has privileges to create new schemas.

The world_x Schema

The world_x example schema contains the following JSON collection and relational tables:

- Collection
  - countryinfo: Information about countries in the world.

- Tables
  - country: Minimal information about countries of the world.
  - city: Information about some of the cities in those countries.
  - countrylanguage: Languages spoken in each country.

Related Information

- MySQL Shell Sessions explains session types.

20.4.3 Documents and Collections

When you are using MySQL as a Document Store, collections are containers within a schema that you can create, list, and drop. Collections contain JSON documents that you can add, find, update, and remove.

The examples in this section use the countryinfo collection in the world_x schema. For instructions on setting up the world_x schema, see Section 20.4.2, “Download and Import world_x Database”.

Documents

In MySQL, documents are represented as JSON objects. Internally, they are stored in an efficient binary format that enables fast lookups and updates.

- Simple document format for Python:
  ```json
  {"field1": "value", "field2": 10, "field 3": null}
  ```
An array of documents consists of a set of documents separated by commas and enclosed within [ and ] characters.

- Simple array of documents for Python:
  ```python
dict(["Name": "Aruba", "Code": "ABW"], ["Name": "Angola", "Code": "AGO"])
  ```

MySQL supports the following Python value types in JSON documents:

- numbers (integer and floating point)
- strings
- boolean (False and True)
- None
- arrays of more JSON values
- nested (or embedded) objects of more JSON values

Collections

Collections are containers for documents that share a purpose and possibly share one or more indexes. Each collection has a unique name and exists within a single schema.

The term schema is equivalent to a database, which means a group of database objects as opposed to a relational schema, used to enforce structure and constraints over data. A schema does not enforce conformity on the documents in a collection.

In this quick-start guide:

- Basic objects include:

<table>
<thead>
<tr>
<th>Object form</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>db</code></td>
<td><code>db</code> is a global variable assigned to the current active schema. When you want to run operations against the schema, for example to retrieve a collection, you use methods available for the <code>db</code> variable.</td>
</tr>
<tr>
<td><code>db.get_collections()</code></td>
<td><code>db.get_collections()</code> returns a list of collections in the schema. Use the list to get references to collection objects, iterate over them, and so on.</td>
</tr>
</tbody>
</table>

- Basic operations scoped by collections include:

<table>
<thead>
<tr>
<th>Operation form</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>db.name.add()</code></td>
<td>The <code>add()</code> method inserts one document or a list of documents into the named collection.</td>
</tr>
<tr>
<td><code>db.name.find()</code></td>
<td>The <code>find()</code> method returns some or all documents in the named collection.</td>
</tr>
<tr>
<td><code>db.name.modify()</code></td>
<td>The <code>modify()</code> method updates documents in the named collection.</td>
</tr>
<tr>
<td><code>db.name.remove()</code></td>
<td>The <code>remove()</code> method deletes one document or a list of documents from the named collection.</td>
</tr>
</tbody>
</table>
20.4.3.1 Create, List, and Drop Collections

In MySQL Shell, you can create new collections, get a list of the existing collections in a schema, and remove an existing collection from a schema. Collection names are case-sensitive and each collection name must be unique.

**Confirm the Schema**

To show the value that is assigned to the schema variable, issue:

```
mysql-py> db
```

If the schema value is not `Schema:world_x`, then set the `db` variable by issuing:

```
mysql-py> \use world_x
```

**Create a Collection**

To create a new collection in an existing schema, use the `db` object's `createCollection()` method. The following example creates a collection called `flags` in the `world_x` schema.

```
mysql-py> db.create_collection("flags")
```

The method returns a collection object.

```
<Collection:flags>
```

**List Collections**

To display all collections in the `world_x` schema, use the `db` object's `get_collections()` method. Collections returned by the server you are currently connected to appear between brackets.

```
mysql-py> db.get_collections()
[
  <Collection:countryinfo>,
  <Collection:flags>
]
```

**Drop a Collection**

To drop an existing collection from a schema, use the `db` object's `drop_collection()` method. For example, to drop the `flags` collection from the current schema, issue:

```
mysql-py> db.drop_collection("flags")
```

The `drop_collection()` method is also used in MySQL Shell to drop a relational table from a schema.

**Related Information**

- See [Collection Objects](#) for more examples.
To work with the collections in a schema, use the \texttt{db} global object to access the current schema. In this example we are using the \texttt{world_x} schema imported previously, and the \texttt{countryinfo} collection. Therefore, the format of the operations you issue is \texttt{db.collection\_name.operation}, where \texttt{collection\_name} is the name of the collection which the operation is executed against. In the following examples, the operations are executed against the \texttt{countryinfo} collection.

**Add a Document**

Use the \texttt{add()} method to insert one document or a list of documents into an existing collection. Insert the following document into the \texttt{countryinfo} collection. As this is multi-line content, press \texttt{Enter} twice to insert the document.

```python
mysql-py> db.countryinfo.add(
    {
        "GNP": 0.6,
        "IndepYear": 1967,
        "Name": "Sealand",
        "Code": "SEA",
        "demographics": {
            "LifeExpectancy": 79,
            "Population": 27
        },
        "geography": {
            "Continent": "Europe",
            "Region": "British Islands",
            "SurfaceArea": 193
        },
        "government": {
            "GovernmentForm": "Monarchy",
            "HeadOfState": "Michael Bates"
        }
    }
)
```

The method returns the status of the operation. You can verify the operation by searching for the document. For example:

```python
mysql-py> db.countryinfo.find("Name = 'Sealand'")
{
    "GNP": 0.6,
    "_id": "00005e2ff4af000000000000000000f4",
    "Name": "Sealand",
    "Code": "SEA",
    "IndepYear": 1967,
    "geography": {
        "Region": "British Islands",
        "Continent": "Europe",
        "SurfaceArea": 193
    },
    "government": {
        "HeadOfState": "Michael Bates",
        "GovernmentForm": "Monarchy"
    },
    "demographics": {
        "Population": 27,
        "LifeExpectancy": 79
    }
}
```

Note that in addition to the fields specified when the document was added, there is one more field, the \texttt{_id}. Each document requires an identifier field called \texttt{_id}. The value of the \texttt{_id} field must be unique among all documents in the same collection. In MySQL 8.0.11 and higher, document IDs are generated by the server, not the client, so MySQL Shell does not automatically set an \texttt{_id} value. A MySQL server at
8.0.11 or higher sets an _id value if the document does not contain the _id field. A MySQL server at an earlier 8.0 release or at 5.7 does not set an _id value in this situation, so you must specify it explicitly. If you do not, MySQL Shell returns error 5115 Document is missing a required field. For more information see Understanding Document IDs.

Related Information

- See CollectionAddFunction for the full syntax definition.
- See Understanding Document IDs.

20.4.3.3 Find Documents

You can use the find() method to query for and return documents from a collection in a schema. MySQL Shell provides additional methods to use with the find() method to filter and sort the returned documents.

MySQL provides the following operators to specify search conditions: OR (| |), AND (&&), XOR, IS, NOT, BETWEEN, IN, LIKE, !=, <>, >, >=, <, <=, |, <<, >>, +, *, /, and %.

Find All Documents in a Collection

To return all documents in a collection, use the find() method without specifying search conditions. For example, the following operation returns all documents in the countryinfo collection.

```
mysql-py> db.countryinfo.find()
[
    
    "GNP": 828,
    "Code": "ABW",
    "Name": "Aruba",
    "IndepYear": null,
    "geography": {
        "Continent": "North America",
        "Region": "Caribbean",
        "SurfaceArea": 193
    },
    "government": {
        "GovernmentForm": "Nonmetropolitan Territory of The Netherlands",
        "HeadOfState": "Beatrix"
    }
]
```

The method produces results that contain operational information in addition to all documents in the collection.

An empty set (no matching documents) returns the following information:

```
Empty set (0.00 sec)
```

Filter Searches

You can include search conditions with the find() method. The syntax for expressions that form a search condition is the same as that of traditional MySQL Chapter 12, Functions and Operators. You must enclose all expressions in quotes. For the sake of brevity, some of the examples do not display output.
A simple search condition could consist of the `Name` field and a value we know is in a document. The following example returns a single document:

```python
mysql-py> db.countryinfo.find("Name = 'Australia'")
[{
    "GNP": 351182,
    "Code": "AUS",
    "Name": "Australia",
    "IndepYear": 1901,
    "geography": {
        "Continent": "Oceania",
        "Region": "Australia and New Zealand",
        "SurfaceArea": 7741220
    },
    "government": {
        "GovernmentForm": "Constitutional Monarchy, Federation",
        "HeadOfState": "Elisabeth II"
    },
    "demographics": {
        "LifeExpectancy": 79.80000305175781,
        "Population": 18886000
    }
},
]```

The following example searches for all countries that have a GNP higher than $500 billion. The `countryinfo` collection measures GNP in units of million.

```python
mysql-py> db.countryinfo.find("GNP > 500000")
...[output removed]
10 documents in set (0.00 sec)
```

The Population field in the following query is embedded within the demographics object. To access the embedded field, use a period between demographics and Population to identify the relationship. Document and field names are case-sensitive.

```python
mysql-py> db.countryinfo.find("GNP > 500000 and demographics.Population < 100000000")
...[output removed]
6 documents in set (0.00 sec)
```

Arithmetic operators in the following expression are used to query for countries with a GNP per capita higher than $30000. Search conditions can include arithmetic operators and most MySQL functions.

```python
mysql-py> db.countryinfo.find("GNP*1000000/demographics.Population > 30000")
...[output removed]
9 documents in set, 7 warnings (0.00 sec)
```

**Note**

Seven documents in the `countryinfo` collection have a population value of zero. Therefore warning messages appear at the end of the output.

You can separate a value from the search condition by using the `bind()` method. For example, instead of specifying a hard-coded country name as the condition, substitute a named placeholder consisting of a colon followed by a name that begins with a letter, such as `country`. Then use the `bind(placeholder, value)` method as follows:
Within a program, binding enables you to specify placeholders in your expressions, which are filled in with values before execution and can benefit from automatic escaping, as appropriate.

Always use binding to sanitize input. Avoid introducing values in queries using string concatenation, which can produce invalid input and, in some cases, can cause security issues.

You can use placeholders and the `bind()` method to create saved searches which you can then call with different values. For example to create a saved search for a country:

```
mysql-py> myFind = db.countryinfo.find("Name = :country")
mysql-py> myFind.bind('country', 'Italy')
```
Project Results

You can return specific fields of a document, instead of returning all the fields. The following example returns the GNP and Name fields of all documents in the `countryinfo` collection matching the search conditions.

Use the `fields()` method to pass the list of fields to return.

```sql
mysql-py> db.countryinfo.find("GNP > 5000000").fields(["GNP", "Name"])
```

```json
[  {    "GNP": 8510700,    "Name": "United States"  }  ]
```

In addition, you can alter the returned documents—adding, renaming, nesting and even computing new field values—with an expression that describes the document to return. For example, alter the names of the fields with the following expression to return only two documents.

```sql
mysql-py> db.countryinfo.find().fields(
  mysqlx.expr('{"Name": upper(Name), "GNPPerCapita": GNP*1000000/demographics.Population}')).limit(2)
```

```json
{    "Name": "ARUBA",    "GNPPerCapita": 8038.834951456311  }
{    "Name": "AFGHANISTAN",    "GNPPerCapita": 263.0281690140845  }
```

Limit, Sort, and Skip Results

You can apply the `limit()`, `sort()`, and `skip()` methods to manage the number and order of documents returned by the `find()` method.

To specify the number of documents included in a result set, append the `limit()` method with a value to the `find()` method. The following query returns the first five documents in the `countryinfo` collection.

```sql
mysql-py> db.countryinfo.find().limit(5)
```

```
... [output removed]
```
To specify an order for the results, append the `sort()` method to the `find()` method. Pass to the `sort()` method a list of one or more fields to sort by and, optionally, the descending (desc) or ascending (asc) attribute as appropriate. Ascending order is the default order type.

For example, the following query sorts all documents by the `IndepYear` field and then returns the first eight documents in descending order.

```python
mysql-py> db.countryinfo.find().sort(["IndepYear desc"]).limit(8)
... [output removed]
8 documents in set (0.00 sec)
```

By default, the `limit()` method starts from the first document in the collection. You can use the `skip()` method to change the starting document. For example, to ignore the first document and return the next eight documents matching the condition, pass to the `skip()` method a value of 1.

```python
mysql-py> db.countryinfo.find().sort(["IndepYear desc"]).limit(8).skip(1)
... [output removed]
8 documents in set (0.00 sec)
```

### Related Information

- The [MySQL Reference Manual](#) provides detailed documentation on functions and operators.
- See [CollectionFindFunction](#) for the full syntax definition.

### 20.4.3.4 Modify Documents

You can use the `modify()` method to update one or more documents in a collection. The X DevAPI provides additional methods for use with the `modify()` method to:

- Set and unset fields within documents.
- Append, insert, and delete arrays.
- Bind, limit, and sort the documents to be modified.

#### Set and Unset Document Fields

The `modify()` method works by filtering a collection to include only the documents to be modified and then applying the operations that you specify to those documents.

In the following example, the `modify()` method uses the search condition to identify the document to change and then the `set()` method replaces two values within the nested demographics object.

```python
mysql-py> db.countryinfo.modify("Code = 'SEA'").set("demographics", {"LifeExpectancy": 78, "Population": 28})
```

After you modify a document, use the `find()` method to verify the change.

To remove content from a document, use the `modify()` and `unset()` methods. For example, the following query removes the GNP from a document that matches the search condition.

```python
mysql-py> db.countryinfo.modify("Name = 'Sealand'").unset("GNP")
```

Use the `find()` method to verify the change.
Append, Insert, and Delete Arrays

To append an element to an array field, or insert, or delete elements in an array, use the `array_append()`, `array_insert()`, or `array_delete()` methods. The following examples modify the `countryinfo` collection to enable tracking of international airports.

The first example uses the `modify()` and `set()` methods to create a new Airports field in all documents.

```
Caution
Use care when you modify documents without specifying a search condition; doing so modifies all documents in the collection.
```

```
mysql-py> db.countryinfo.modify("true").set("Airports", [])
```

With the Airports field added, the next example uses the `array_append()` method to add a new airport to one of the documents. `$Airports` in the following example represents the Airports field of the current document.

```
mysql-py> db.countryinfo.modify("Name = 'France'").array_append("$.Airports", "ORY"
```

Use `find()` to see the change.

```
mysql-py> db.countryinfo.find("Name = 'France'")
```
To insert an element at a different position in the array, use the `array_insert()` method to specify which index to insert in the path expression. In this case, the index is 0, or the first element in the array.

```python
mysql-py> db.countryinfo.modify("Name = 'France'").array_insert("$.Airports[0]", "CDG")
```

To delete an element from the array, you must pass to the `array_delete()` method the index of the element to be deleted.

```python
mysql-py> db.countryinfo.modify("Name = 'France'").array_delete("$.Airports[1]")
```

**Related Information**

- The [MySQL Reference Manual](https://dev.mysql.com/doc/) provides instructions to help you search for and modify JSON values.
- See [CollectionModifyFunction](https://dev.mysql.com/doc/) for the full syntax definition.

### 20.4.3.5 Remove Documents

You can use the `remove()` method to delete some or all documents from a collection in a schema. The X DevAPI provides additional methods for use with the `remove()` method to filter and sort the documents to be removed.

#### Remove Documents Using Conditions

The following example passes a search condition to the `remove()` method. All documents matching the condition are removed from the `countryinfo` collection. In this example, one document matches the condition.

```python
mysql-py> db.countryinfo.remove("Code = 'SEA'")
```

#### Remove the First Document

To remove the first document in the `countryinfo` collection, use the `limit()` method with a value of 1.

```python
mysql-py> db.countryinfo.remove("true").limit(1)
```

#### Remove the Last Document in an Order

The following example removes the last document in the `countryinfo` collection by country name.

```python
mysql-py> db.countryinfo.remove("true").sort(["Name desc"]).limit(1)
```

#### Remove All Documents in a Collection

You can remove all documents in a collection. To do so, use the `remove("true")` method without specifying a search condition.

**Caution**

Use care when you remove documents without specifying a search condition. This action deletes all documents from the collection.

Alternatively, use the `db.drop_collection('countryinfo')` operation to delete the `countryinfo` collection.
20.4.3.6 Create and Drop Indexes

Indexes are used to find documents with specific field values quickly. Without an index, MySQL must begin with the first document and then read through the entire collection to find the relevant fields. The larger the collection, the more this costs. If a collection is large and queries on a specific field are common, then consider creating an index on a specific field inside a document.

For example, the following query performs better with an index on the Population field:

```
mysql-py> db.countryinfo.find("demographics.Population < 100")
...
8 documents in set (0.00 sec)
```

The `create_index()` method creates an index that you can define with a JSON document that specifies which fields to use. This section is a high level overview of indexing. For more information see Indexing Collections.

Add a Nonunique Index

To create a nonunique index, pass an index name and the index information to the `create_index()` method. Duplicate index names are prohibited.

The following example specifies an index named `popul`, defined against the `Population` field from the `demographics` object, indexed as an `Integer` numeric value. The final parameter indicates whether the field should require the `NOT NULL` constraint. If the value is `false`, the field can contain `NULL` values. The index information is a JSON document with details of one or more fields to include in the index. Each field definition must include the full document path to the field, and specify the type of the field.

```
mysql-py> db.countryinfo.create_index("popul", {"fields": ["$.demographics.Population", "type": "INTEGER"]}, "unique": false)
```

Here, the index is created using an integer numeric value. Further options are available, including options for use with GeoJSON data. You can also specify the type of index, which has been omitted here because the default type “index” is appropriate.

Add a Unique Index

To create a unique index, pass an index name, the index definition, and the index type “unique” to the `create_index()` method. This example shows a unique index created on the country name ("Name"), which is another common field in the `countryinfo` collection to index. In the index field description, "TEXT(40)" represents the number of characters to index, and "required": True specifies that the field is required to exist in the document.

```
mysql-py> db.countryinfo.create_index("name", {"fields": ["$.Name", "type": "TEXT(40)", "required": True], "unique": True})
```

Drop an Index

To drop an index, pass the name of the index to drop to the `drop_index()` method. For example, you can drop the “popul” index as follows:
Relational Tables

You can also use X DevAPI to work with relational tables. In MySQL, each relational table is associated with a particular storage engine. The examples in this section use InnoDB tables in the world_x schema.

Confirm the Schema

To show the schema that is assigned to the db global variable, issue db.

```mysql
mysql-py> db
<Schema:world_x>
```

If the returned value is not Schema:world_x, set the db variable as follows:

```mysql
mysql-py> \use world_x
Schema `world_x` accessible through db.
```

Show All Tables

To display all relational tables in the world_x schema, use the get_tables() method on the db object.

```mysql
mysql-py> db.get_tables()
[
    <Table:city>,
    <Table:country>,
    <Table:countrylanguage>
]
```

Basic Table Operations

Basic operations scoped by tables include:

<table>
<thead>
<tr>
<th>Operation form</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>db.name.insert()</td>
<td>The insert() method inserts one or more records into the named table.</td>
</tr>
<tr>
<td>db.name.select()</td>
<td>The select() method returns some or all records in the named table.</td>
</tr>
<tr>
<td>db.name.update()</td>
<td>The update() method updates records in the named table.</td>
</tr>
<tr>
<td>db.name.delete()</td>
<td>The delete() method deletes one or more records from the named table.</td>
</tr>
</tbody>
</table>

Related Information

- See Working with Relational Tables for more information.
- CRUD EBNF Definitions provides a complete list of operations.
- See Section 20.4.2, “Download and Import world_x Database” for instructions on setting up the world_x schema sample.
20.4.4.1 Insert Records into Tables

You can use the `insert()` method with the `values()` method to insert records into an existing relational table. The `insert()` method accepts individual columns or all columns in the table. Use one or more `values()` methods to specify the values to be inserted.

Insert a Complete Record

To insert a complete record, pass to the `insert()` method all columns in the table. Then pass to the `values()` method one value for each column. For example, to add a new record to the city table in the `world_x` database, insert the following record and press Enter twice.

```
mysql-py> db.city.insert("ID", "Name", "CountryCode", "District", "Info").values(
    None, "Olympia", "USA", "Washington", '{"Population": 5000}')
```

The city table has five columns: ID, Name, CountryCode, District, and Info. Each value must match the data type of the column it represents.

Insert a Partial Record

The following example inserts values into the ID, Name, and CountryCode columns of the city table.

```
mysql-py> db.city.insert("ID", "Name", "CountryCode").values(
    None, "Little Falls", "USA").values(None, "Happy Valley", "USA")
```

When you specify columns using the `insert()` method, the number of values must match the number of columns. In the previous example, you must supply three values to match the three columns specified.

Related Information

- See `TableInsertFunction` for the full syntax definition.

20.4.4.2 Select Tables

You can use the `select()` method to query for and return records from a table in a database. The X DevAPI provides additional methods to use with the `select()` method to filter and sort the returned records.

MySQL provides the following operators to specify search conditions: OR (| |), AND (&&), XOR, IS, NOT, BETWEEN, IN, LIKE, !=, <>, >=, <=, &, |, <<>>, +, -, *, ~, and %.

Select All Records

To issue a query that returns all records from an existing table, use the `select()` method without specifying search conditions. The following example selects all records from the city table in the `world_x` database.

```
mysql-py> db.city.select()
```

<table>
<thead>
<tr>
<th>ID</th>
<th>Name</th>
<th>CountryCode</th>
<th>District</th>
<th>Info</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Kabul</td>
<td>AFG</td>
<td>Kabol</td>
<td>{&quot;Population&quot;: 1780000}</td>
</tr>
<tr>
<td>2</td>
<td>Qandahar</td>
<td>AFG</td>
<td>Qandahar</td>
<td>{&quot;Population&quot;: 237500}</td>
</tr>
<tr>
<td>3</td>
<td>Herat</td>
<td>AFG</td>
<td>Herat</td>
<td>{&quot;Population&quot;: 1868000}</td>
</tr>
</tbody>
</table>

Note

Limit the use of the empty `select()` method to interactive statements. Always use explicit column-name selections in your application code.
Relational Tables

An empty set (no matching records) returns the following information:

Empty set (0.00 sec)

Filter Searches

To issue a query that returns a set of table columns, use the `select()` method and specify the columns to return between square brackets. This query returns the Name and CountryCode columns from the city table.

```python
mysql-py> db.city.select(["Name", "CountryCode"])
```

```
<table>
<thead>
<tr>
<th>Name</th>
<th>CountryCode</th>
</tr>
</thead>
<tbody>
<tr>
<td>Kabul</td>
<td>AFG</td>
</tr>
<tr>
<td>Qandahar</td>
<td>AFG</td>
</tr>
<tr>
<td>Herat</td>
<td>AFG</td>
</tr>
<tr>
<td>Mazar-e-Sharif</td>
<td>AFG</td>
</tr>
<tr>
<td>Amsterdam</td>
<td>NLD</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
</tr>
<tr>
<td>Rafah</td>
<td>PSE</td>
</tr>
<tr>
<td>Olympia</td>
<td>USA</td>
</tr>
<tr>
<td>Little Falls</td>
<td>USA</td>
</tr>
<tr>
<td>Happy Valley</td>
<td>USA</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
</tr>
</tbody>
</table>

4082 rows in set (0.00 sec)
```

To issue a query that returns rows matching specific search conditions, use the `where()` method to include those conditions. For example, the following example returns the names and country codes of the cities that start with the letter Z.

```python
mysql-py> db.city.select(["Name", "CountryCode"]).where("Name like 'Z%'")
```

```
<table>
<thead>
<tr>
<th>Name</th>
<th>CountryCode</th>
</tr>
</thead>
<tbody>
<tr>
<td>Zaanstad</td>
<td>NLD</td>
</tr>
<tr>
<td>Zoetermeer</td>
<td>NLD</td>
</tr>
<tr>
<td>Zwolle</td>
<td>NLD</td>
</tr>
<tr>
<td>Zenica</td>
<td>BIN</td>
</tr>
<tr>
<td>Zagazig</td>
<td>EGY</td>
</tr>
<tr>
<td>Zaragoza</td>
<td>ESP</td>
</tr>
<tr>
<td>Zamboanga</td>
<td>PHL</td>
</tr>
<tr>
<td>Zahedan</td>
<td>IRN</td>
</tr>
<tr>
<td>Zanjan</td>
<td>IRN</td>
</tr>
<tr>
<td>Zabol</td>
<td>IRN</td>
</tr>
<tr>
<td>Zama</td>
<td>JPN</td>
</tr>
<tr>
<td>Zhezqazghan</td>
<td>KAZ</td>
</tr>
<tr>
<td>Zhengzhou</td>
<td>CHN</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
</tr>
<tr>
<td>Zeleznogorsk</td>
<td>RUS</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
</tr>
</tbody>
</table>
```

59 rows in set (0.00 sec)

You can separate a value from the search condition by using the `bind()` method. For example, instead of using "Name = 'Z%'" as the condition, substitute a named placeholder consisting of a colon followed by a name that begins with a letter, such as `name`. Then include the placeholder and value in the `bind()` method as follows:

```python
mysql-py> db.city.select(["Name", "CountryCode"]).where("Name like '\%\%'").bind(name="name")
```

```
<table>
<thead>
<tr>
<th>Name</th>
<th>CountryCode</th>
</tr>
</thead>
<tbody>
<tr>
<td>Zaanstad</td>
<td>NLD</td>
</tr>
<tr>
<td>Zoetermeer</td>
<td>NLD</td>
</tr>
<tr>
<td>Zwolle</td>
<td>NLD</td>
</tr>
<tr>
<td>Zenica</td>
<td>BIN</td>
</tr>
<tr>
<td>Zagazig</td>
<td>EGY</td>
</tr>
<tr>
<td>Zaragoza</td>
<td>ESP</td>
</tr>
<tr>
<td>Zamboanga</td>
<td>PHL</td>
</tr>
<tr>
<td>Zahedan</td>
<td>IRN</td>
</tr>
<tr>
<td>Zanjan</td>
<td>IRN</td>
</tr>
<tr>
<td>Zabol</td>
<td>IRN</td>
</tr>
<tr>
<td>Zama</td>
<td>JPN</td>
</tr>
<tr>
<td>Zhezqazghan</td>
<td>KAZ</td>
</tr>
<tr>
<td>Zhengzhou</td>
<td>CHN</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
</tr>
<tr>
<td>Zeleznogorsk</td>
<td>RUS</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
</tr>
</tbody>
</table>
```

59 rows in set (0.00 sec)
Relational Tables

Tip

Within a program, binding enables you to specify placeholders in your expressions, which are filled in with values before execution and can benefit from automatic escaping, as appropriate.

Always use binding to sanitize input. Avoid introducing values in queries using string concatenation, which can produce invalid input and, in some cases, can cause security issues.

Project Results

To issue a query using the AND operator, add the operator between search conditions in the where() method.

```
mysql-py> db.city.select(["Name", "CountryCode"]).where("Name like 'Z%' and CountryCode = 'CHN'")
```

<table>
<thead>
<tr>
<th>Name</th>
<th>CountryCode</th>
</tr>
</thead>
<tbody>
<tr>
<td>Zhengzhou</td>
<td>CHN</td>
</tr>
<tr>
<td>Zibo</td>
<td>CHN</td>
</tr>
<tr>
<td>Zhangjiakou</td>
<td>CHN</td>
</tr>
<tr>
<td>Zhuzhou</td>
<td>CHN</td>
</tr>
<tr>
<td>Zhangjiang</td>
<td>CHN</td>
</tr>
<tr>
<td>Zigong</td>
<td>CHN</td>
</tr>
<tr>
<td>Zaozhuang</td>
<td>CHN</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
</tr>
<tr>
<td>Zhangjiagang</td>
<td>CHN</td>
</tr>
</tbody>
</table>

22 rows in set (0.01 sec)

To specify multiple conditional operators, you can enclose the search conditions in parenthesis to change the operator precedence. The following example demonstrates the placement of AND and OR operators.

```
mysql-py> db.city.select(["Name", "CountryCode"]).where("Name like 'Z%' and (CountryCode = 'CHN' or CountryCode = 'RUS')")
```

<table>
<thead>
<tr>
<th>Name</th>
<th>CountryCode</th>
</tr>
</thead>
<tbody>
<tr>
<td>Zhengzhou</td>
<td>CHN</td>
</tr>
<tr>
<td>Zibo</td>
<td>CHN</td>
</tr>
<tr>
<td>Zhangjiakou</td>
<td>CHN</td>
</tr>
<tr>
<td>Zhuzhou</td>
<td>CHN</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
</tr>
<tr>
<td>Zeleznogorsk</td>
<td>RUS</td>
</tr>
</tbody>
</table>

29 rows in set (0.01 sec)

Limit, Order, and Offset Results

You can apply the limit(), order_by(), and offset() methods to manage the number and order of records returned by the select() method.

To specify the number of records included in a result set, append the limit() method with a value to the select() method. For example, the following query returns the first five records in the country table.

```
mysql-py> db.country.select(["Code", "Name"]).limit(5)
```

<table>
<thead>
<tr>
<th>Code</th>
<th>Name</th>
</tr>
</thead>
</table>

3718
Relational Tables

<table>
<thead>
<tr>
<th>ABW</th>
<th>Aruba</th>
</tr>
</thead>
<tbody>
<tr>
<td>AFG</td>
<td>Afghanistan</td>
</tr>
<tr>
<td>AGO</td>
<td>Angola</td>
</tr>
<tr>
<td>AIA</td>
<td>Anguilla</td>
</tr>
<tr>
<td>ALB</td>
<td>Albania</td>
</tr>
</tbody>
</table>

5 rows in set (0.00 sec)

To specify an order for the results, append the `order_by()` method to the `select()` method. Pass to the `order_by()` method a list of one or more columns to sort by and, optionally, the descending (`desc`) or ascending (`asc`) attribute as appropriate. Ascending order is the default order type.

For example, the following query sorts all records by the Name column and then returns the first three records in descending order.

```python
mysql-py> db.country.select(["Code", "Name"]).order_by(["Name desc"]).limit(3)
```

<table>
<thead>
<tr>
<th>Code</th>
<th>Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>ZWE</td>
<td>Zimbabwe</td>
</tr>
<tr>
<td>ZMB</td>
<td>Zambia</td>
</tr>
<tr>
<td>YUG</td>
<td>Yugoslavia</td>
</tr>
</tbody>
</table>

3 rows in set (0.00 sec)

By default, the `limit()` method starts from the first record in the table. You can use the `offset()` method to change the starting record. For example, to ignore the first record and return the next three records matching the condition, pass to the `offset()` method a value of 1.

```python
mysql-py> db.country.select(["Code", "Name"]).order_by(["Name desc"]).limit(3).offset(1)
```

<table>
<thead>
<tr>
<th>Code</th>
<th>Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>ZMB</td>
<td>Zambia</td>
</tr>
<tr>
<td>YUG</td>
<td>Yugoslavia</td>
</tr>
<tr>
<td>YEM</td>
<td>Yemen</td>
</tr>
</tbody>
</table>

3 rows in set (0.00 sec)

Related Information

- The MySQL Reference Manual provides detailed documentation on functions and operators.
- See TableSelectFunction for the full syntax definition.

20.4.4.3 Update Tables

You can use the `update()` method to modify one or more records in a table. The `update()` method works by filtering a query to include only the records to be updated and then applying the operations you specify to those records.

To replace a city name in the city table, pass to the `set()` method the new city name. Then, pass to the `where()` method the city name to locate and replace. The following example replaces the city Peking with Beijing.

```python
mysql-py> db.city.update().set("Name", "Beijing").where("Name = 'Peking'")
```

Use the `select()` method to verify the change.

```python
mysql-py> db.city.select(["ID", "Name", "CountryCode", "District", "Info"]).where("Name = 'Beijing'")
```

<table>
<thead>
<tr>
<th>ID</th>
<th>Name</th>
<th>CountryCode</th>
<th>District</th>
<th>Info</th>
</tr>
</thead>
</table>
Related Information

- See TableUpdateFunction for the full syntax definition.

### 20.4.4.4 Delete Tables

You can use the `delete()` method to remove some or all records from a table in a database. The X DevAPI provides additional methods to use with the `delete()` method to filter and order the records to be deleted.

#### Delete Records Using Conditions

The example that follows passes search conditions to the `delete()` method. All records matching the condition are deleted from the `city` table. In this example, one record matches the condition.

```python
mysql-py> db.city.delete().where("Name = 'Olympia'")
```

#### Delete the First Record

To delete the first record in the city table, use the `limit()` method with a value of 1.

```python
mysql-py> db.city.delete().limit(1)
```

#### Delete All Records in a Table

You can delete all records in a table. To do so, use the `delete()` method without specifying a search condition.

⚠️ **Caution**

Use care when you delete records without specifying a search condition; doing so deletes all records from the table.

#### Drop a Table

The `drop_collection()` method is also used in MySQL Shell to drop a relational table from a database. For example, to drop the `citytest` table from the `world_x` database, issue:

```python
mysql-py> db.drop_collection("citytest")
```

Related Information

- See TableDeleteFunction for the full syntax definition.
- See Section 20.4.2, "Download and Import world_x Database" for instructions to recreate the `world_x` database.

### 20.4.5 Documents in Tables

In MySQL, a table may contain traditional relational data, JSON values, or both. You can combine traditional data with JSON documents by storing the documents in columns having a native JSON data type.

Examples in this section use the city table in the `world_x` schema.
city Table Description

The city table has five columns (or fields).

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Null</th>
<th>Key</th>
<th>Default</th>
<th>Extra</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID</td>
<td>int(11)</td>
<td>NO</td>
<td>PRI</td>
<td>null</td>
<td>auto_increment</td>
</tr>
<tr>
<td>Name</td>
<td>char(35)</td>
<td>NO</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>CountryCode</td>
<td>char(3)</td>
<td>NO</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>District</td>
<td>char(20)</td>
<td>NO</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Info</td>
<td>json</td>
<td>YES</td>
<td></td>
<td>null</td>
<td></td>
</tr>
</tbody>
</table>

Insert a Record

To insert a document into the column of a table, pass to the `values()` method a well-formed JSON document in the correct order. In the following example, a document is passed as the final value to be inserted into the Info column.

```python
mysql-py> db.city.insert().values(None, "San Francisco", "USA", "California", '{"Population":830000}')
```

Select a Record

You can issue a query with a search condition that evaluates document values in the expression.

```python
```

Related Information

- See Working with Relational Tables and Documents for more information.
- See Section 11.5, “The JSON Data Type” for a detailed description of the data type.

20.5 X Plugin

This section explains how to use, configure and monitor X Plugin.

20.5.1 Checking X Plugin Installation

X Plugin is enabled by default in MySQL 8, therefore installing or upgrading to MySQL 8 makes the plugin available. You can verify X Plugin is installed on an instance of MySQL server by using the `SHOW plugins` statement to view the plugins list.
To use MySQL Shell to verify X Plugin is installed, issue:

```
shell> mysqlsh -u user --sqlc -P 3306 -e "SHOW plugins"
```

To use MySQL Client to verify X Plugin is installed, issue:

```
shell> mysql -u user -p -e "SHOW plugins"
```

An example result if X Plugin is installed is highlighted here:

```
+----------------------------+----------+--------------------+---------+---------+
| Name                       | Status   | Type               | Library | License |
|-----------------------------+----------+--------------------+---------+---------|
| ...                         |          |                    |         |         |
| mysqlx                      | ACTIVE   | DAEMON             | NULL    | GPL     |
| ...                         |          |                    |         |         |
```

### 20.5.2 Disabling X Plugin

The X Plugin can be disabled at startup by either setting `mysqlx=0` in your MySQL configuration file, or by passing in either `--mysqlx=0` or `--skip-mysqlx` when starting the MySQL server.

Alternatively, use the `--WITH_MYSQLX=OFF` CMake option to compile MySQL Server without X Plugin.

### 20.5.3 Using Encrypted Connections with X Plugin

This section explains how to configure X Plugin to use encrypted connections. For more background information, see Section 6.3, “Using Encrypted Connections”.

To enable configuring support for encrypted connections, X Plugin has `mysqlx_ssl_xxx` system variables, which can have different values from the `ssl_xxx` system variables used with MySQL Server. For example, X Plugin can have SSL key, certificate, and certificate authority files that differ from those used for MySQL Server. These variables are described at Section 20.5.6.2, “X Plugin Options and System Variables”. Similarly, X Plugin has its own `Mysqlx_ssl_xxx` status variables that correspond to the MySQL Server encrypted-connection `Ssl_xxx` status variables. See Section 20.5.6.3, “X Plugin Status Variables”.

At initialization, X Plugin determines its TLS context for encrypted connections as follows:

- If all `mysqlx_ssl_xxx` system variables have their default values, X Plugin uses the same TLS context as the MySQL Server main connection interface, which is determined by the values of the `ssl_xxx` system variables.
- If any `mysqlx_ssl_xxx` variable has a nondefault value, X Plugin uses the TLS context defined by the values of its own system variables. (This is the case if any `mysqlx_ssl_xxx` system variable is set to a value different from its default.)

This means that, on a server with X Plugin enabled, you can choose to have MySQL Protocol and X Protocol connections share the same encryption configuration by setting only the `ssl_xxx` variables, or have separate encryption configurations for MySQL Protocol and X Protocol connections by configuring the `ssl_xxx` and `mysqlx_ssl_xxx` variables separately.

To have MySQL Protocol and X Protocol connections use the same encryption configuration, set only the `ssl_xxx` system variables in `my.cnf`:
Using X Plugin with the Caching SHA-2 Authentication Plugin

To configure encryption separately for MySQL Protocol and X Protocol connections, set both the `ssl_`xxx and `mysqlx_ssl_`xxx system variables in `my.cnf`:

```
[mysqld]
ssl_ca=ca.pem
ssl_cert=server-cert.pem
ssl_key=server-key.pem
mysqlx_ssl_ca=ca2.pem
mysqlx_ssl_cert=server-cert2.pem
mysqlx_ssl_key=server-key2.pem
```

For general information about configuring connection-encryption support, see Section 6.3.1, "Configuring MySQL to Use Encrypted Connections". That discussion is written for MySQL Server, but the parameter names are similar for X Plugin. (The X Plugin `mysqlx_ssl_`xxx system variable names correspond to the MySQL Server `ssl_`xxx system variable names.)

The `tls_version` system variable that determines the permitted TLS versions for MySQL Protocol connections also applies to X Protocol connections. The permitted TLS versions for both types of connections are therefore the same.

Encryption per connection is optional, but a specific user can be required to use encryption for X Protocol and MySQL Protocol connections by including an appropriate `REQUIRE` clause in the `CREATE USER` statement that creates the user. For details, see Section 13.7.1.3, "CREATE USER Statement". Alternatively, to require all users to use encryption for X Protocol and MySQL Protocol connections, enable the `require_secure_transport` system variable. For additional information, see Configuring Encrypted Connections as Mandatory.

### 20.5.4 Using X Plugin with the Caching SHA-2 Authentication Plugin

X Plugin supports MySQL user accounts created with the `caching_sha2_password` authentication plugin. For more information on this plugin, see Section 6.4.1.2, "Caching SHA-2 Pluggable Authentication". You can use X Plugin to authenticate against such accounts using non-SSL connections with `SHA256_MEMORY` authentication and SSL connections with `PLAIN` authentication.

Although the `caching_sha2_password` authentication plugin holds an authentication cache, this cache is not shared with X Plugin, so X Plugin uses its own authentication cache for `SHA256_MEMORY` authentication. The X Plugin authentication cache stores hashes of user account passwords, and cannot be accessed using SQL. If a user account is modified or removed, the relevant entries are removed from the cache. The X Plugin authentication cache is maintained by the `mysqlx_cache_cleaner` plugin, which is enabled by default, and has no related system variables or status variables.

Before you can use non-SSL X Protocol connections to authenticate an account that uses the `caching_sha2_password` authentication plugin, the account must have authenticated at least once over an X Protocol connection with SSL, to supply the password to the X Plugin authentication cache. Once this initial authentication over SSL has succeeded, non-SSL X Protocol connections can be used.

It is possible to disable the `mysqlx_cache_cleaner` plugin by starting the MySQL server with the option `--mysqlx_cache_cleaner=0`. If you do this, the X Plugin authentication cache is disabled, and therefore SSL must always be used for X Protocol connections when authenticating with `SHA256_MEMORY` authentication.

### 20.5.5 Connection Compression with X Plugin

3723
Connection Compression with X Plugin

From MySQL 8.0.19, X Plugin supports compression of messages sent over X Protocol connections. Connections can be compressed if the server and the client agree on a mutually supported compression algorithm. Enabling compression reduces the number of bytes sent over the network, but adds to the server and client an additional CPU cost for compression and decompression operations. The benefits of compression therefore occur primarily when there is low network bandwidth, network transfer time dominates the cost of compression and decompression operations, and result sets are large.

Note
Different MySQL clients implement support for connection compression differently; consult your client documentation for details. For example, for classic MySQL protocol connections, see Section 4.2.8, “Connection Compression Control”.

• Configuring Connection Compression for X Plugin
• Compressed Connection Characteristics for X Plugin
• Monitoring Connection Compression for X Plugin

Configuring Connection Compression for X Plugin

By default, X Plugin supports the zstd, LZ4, and Deflate compression algorithms. Compression with the Deflate algorithm is carried out using the zlib software library, so the deflate_stream compression algorithm setting for X Protocol connections is equivalent to the zlib setting for classic MySQL protocol connections.

On the server side, you can disallow any of the compression algorithms by setting the mysqlx_compression_algorithms system variable to include only those permitted. The algorithm names zstd_stream, lz4_message, and deflate_stream can be specified in any combination, and the order and lettercase are not important. If the system variable value is the empty string, no compression algorithms are permitted and connections are uncompressed.

The following table compares the characteristics of the different compression algorithms and shows their assigned priorities. By default, the server chooses the highest-priority algorithm permitted in common by the server and the client; clients may change the priorities as described later. The short form alias for the algorithms can be used by clients when specifying them.

<table>
<thead>
<tr>
<th>Algorithm</th>
<th>Alias</th>
<th>Compression Ratio</th>
<th>Throughput</th>
<th>CPU Cost</th>
<th>Default Priority</th>
</tr>
</thead>
<tbody>
<tr>
<td>zsth_stream</td>
<td>zstd</td>
<td>High</td>
<td>High</td>
<td>Medium</td>
<td>First</td>
</tr>
<tr>
<td>lz4_message</td>
<td>lz4</td>
<td>Low</td>
<td>High</td>
<td>Lowest</td>
<td>Second</td>
</tr>
<tr>
<td>deflate_stream</td>
<td>deflate</td>
<td>High</td>
<td>Low</td>
<td>Highest</td>
<td>Third</td>
</tr>
</tbody>
</table>

The X Protocol set of permitted compression algorithms (whether user-specified or default) is independent of the set of compression algorithms permitted by MySQL Server for classic MySQL protocol connections, which is specified by the protocol_compression_algorithms server system variable. If you do not specify the mysqlx_compression_algorithms system variable, X Plugin does not fall back to using compression settings for classic MySQL protocol connections. Instead, its default is to permit all algorithms shown in Table 20.1, “X Protocol Compression Algorithm Characteristics”. This is unlike the situation for the TLS context, where MySQL Server settings are used if the X Plugin system variables are not set, as described in Section 20.5.3, “Using Encrypted Connections with X Plugin”. For information about compression for classic MySQL protocol connections, see Section 4.2.8, “Connection Compression Control”.
On the client side, an X Protocol connection request can specify several parameters for compression control:

- The compression mode.
- The compression level (from MySQL 8.0.20).
- The list of permitted compression algorithms in priority order (from MySQL 8.0.22).

**Note**

Some clients or Connectors might not support a given compression-control feature. For example, specifying compression level for X Protocol connections is supported only by MySQL Shell, not by other MySQL clients or Connectors. See the documentation for specific products for details about supported features and how to use them.

The connection mode has these permitted values:

- **disabled**: The connection is uncompressed.
- **preferred**: The server and client negotiate to find a compression algorithm they both permit. If no common algorithm is available, the connection is uncompressed. This is the default mode if not specified explicitly.
- **required**: Compression algorithm negotiation occurs as for preferred mode, but if no common algorithm is available, the connection request terminates with an error.

In addition to agreeing on a compression algorithm for each connection, the server and client can agree on a compression level from the numeric range that applies to the agreed algorithm. As the compression level for an algorithm increases, the data compression ratio increases, which reduces the network bandwidth and transfer time needed to send the message to the client. However, the effort required for data compression also increases, taking up time and CPU and memory resources on the server. Increases in the compression effort do not have a linear relationship to increases in the compression ratio.

In MySQL 8.0.19, X Plugin always uses the library default compression level for each algorithm (3 for zstd, 0 for LZ4, and 6 for Deflate), and the client cannot negotiate this. From MySQL 8.0.20, the client can request a specific compression level during capability negotiations with the server for an X Protocol connection.

The default compression levels used by X Plugin from MySQL 8.0.20 have been selected through performance testing as being a good trade-off between compression time and network transit time. These defaults are not necessarily the same as the library default for each algorithm. They apply if the client does not request a compression level for the algorithm. The default compression levels are initially set to 3 for zstd, 2 for LZ4, and 3 for Deflate. You can adjust these settings using the `mysqlx_zstd_default_compression_level`, `mysqlx_lz4_default_compression_level`, and `mysqlx_deflate_default_compression_level` system variables.

To prevent excessive resource consumption on the server, X Plugin sets a maximum compression level that the server permits for each algorithm. If a client requests a compression level that exceeds this setting, the server uses its maximum permitted compression level (compression level requests by a client are supported only by MySQL Shell). The maximum compression levels are initially set to 11 for zstd, 8 for LZ4, and 5 for Deflate. You can adjust these settings using the `mysqlx_zstd_max_client_compression_level`, `mysqlx_lz4_max_client_compression_level`, and `mysqlx_deflate_max_client_compression_level` system variables.
If the server and client permit more than one algorithm in common, the default priority order for choosing an algorithm during negotiation is shown in Table 20.1, “X Protocol Compression Algorithm Characteristics”. From MySQL 8.0.22, for clients that support specifying compression algorithms, the connection request can include a list of algorithms permitted by the client, specified using the algorithm name or its alias. The order of these algorithms in the list is taken as a priority order by the server. The algorithm used in this case is the first of those in the client list that is also permitted on the server side. However, the option for compression algorithms is subject to the compression mode:

- If the compression mode is `disabled`, the compression algorithms option is ignored.
- If the compression mode is `preferred` but no algorithm permitted on the client side is permitted on the server side, the connection is uncompressed.
- If the compression mode is `required` but no algorithm permitted on the client side is permitted on the server side, an error occurs.

To monitor the effects of message compression, use the X Plugin status variables described in Monitoring Connection Compression for X Plugin. You can use these status variables to calculate the benefit of message compression with your current settings, and use that information to tune your settings.

**Compressed Connection Characteristics for X Plugin**

X Protocol connection compression operates with the following behaviors and boundaries:

- The `_stream` and `_message` suffixes in algorithm names refer to two different operational modes:
  - In stream mode, all X Protocol messages in a single connection are compressed into a continuous stream and must be decompressed in the same manner—following the order they were compressed and without skipping any messages. In message mode, each message is compressed individually and independently, and need not be decompressed in the order in which they were compressed. Also, message mode does not require all compressed messages to be decompressed.
- Compression is not applied to any messages that are sent before authentication succeeds.
- Compression is not applied to control flow messages such as `Mysqlx.Ok`, `Mysqlx.Error`, and `Mysqlx.Sql.StmtExecuteOk` messages.
- All other X Protocol messages can be compressed if the server and client agree on a mutually permitted compression algorithm during capability negotiation. If the client does not request compression at that stage, neither the client nor the server applies compression to messages.
- When messages sent over X Protocol connections are compressed, the limit specified by the `mysqlx_max_allowed_packet` system variable still applies. The network packet must be smaller than this limit after the message payload has been decompressed. If the limit is exceeded, X Plugin returns a decompression error and closes the connection.
- The following points pertain to compression level requests by clients, which is supported only by MySQL Shell:
  - Compression levels must be specified by the client as an integer. If any other type of value is supplied, the connection closes with an error.
  - If a client specifies an algorithm but not a compression level, the server uses its default compression level for the algorithm.
  - If a client requests an algorithm compression level that exceeds the server maximum permitted level, the server uses the maximum permitted level.
• If a client requests an algorithm compression level that is less than the server minimum permitted level, the server uses the minimum permitted level.

Monitoring Connection Compression for X Plugin

You can monitor the effects of message compression using the X Plugin status variables. When message compression is in use, the session `Mysqlx_compression_algorithm` status variable shows which compression algorithm is in use for the current X Protocol connection, and `Mysqlx_compression_level` shows the compression level that was selected. These session status variables are available from MySQL 8.0.20.

From MySQL 8.0.19, X Plugin status variables can be used to calculate the efficiency of the compression algorithms that are selected (the data compression ratio), and the overall effect of using message compression. Use the session value of the status variables in the following calculations to see what the benefit of message compression was for a specific session with a known compression algorithm. Or use the global value of the status variables to check the overall benefit of message compression for your server across all sessions using X Protocol connections, including all the compression algorithms that have been used for those sessions, and all sessions that did not use message compression. You can then tune message compression by adjusting the permitted compression algorithms, maximum compression level, and default compression level, as described in Configuring Connection Compression for X Plugin.

When message compression is in use, the `Mysqlx_bytes_sent` status variable shows the total number of bytes sent out from the server, including compressed message payloads measured after compression, any items in compressed messages that were not compressed such as X Protocol headers, and any uncompressed messages. The `Mysqlx_bytes_sent_compressed_payload` status variable shows the total number of bytes sent as compressed message payloads, measured after compression, and the `Mysqlx_bytes_sent_uncompressed_frame` status variable shows the total number of bytes for those same message payloads but measured before compression. The compression ratio, which shows the efficiency of the compression algorithm, can therefore be calculated using the following expression:

\[
\text{compression ratio} = \frac{\text{mysqlx_bytes_sent_uncompressed_frame}}{\text{mysqlx_bytes_sent_compressed_payload}}
\]

The effectiveness of compression for X Protocol messages sent by the server can be calculated using the following expression:

\[
\frac{(\text{mysqlx_bytes_sent} - \text{mysqlx_bytes_sent_compressed_payload} + \text{mysqlx_bytes_sent_uncompressed_frame})}{\text{mysqlx_bytes_sent}}
\]

For messages received by the server from clients, the `Mysqlx_bytes_received_compressed_payload` status variable shows the total number of bytes received as compressed message payloads, measured before decompression, and the `Mysqlx_bytes_received_uncompressed_frame` status variable shows the total number of bytes for those same message payloads but measured after decompression. The `Mysqlx_bytes_received` status variable includes compressed message payloads measured before decompression, any uncompressed items in compressed messages, and any uncompressed messages.

20.5.6 X Plugin Options and Variables

This section describes the command options and system variables that configure X Plugin, as well as the status variables available for monitoring purposes. If configuration values specified at startup time are incorrect, X Plugin could fail to initialize properly and the server does not load it. In this case, the server could also produce error messages for other X Plugin settings because it cannot recognize them.

20.5.6.1 X Plugin Option and Variable Reference

This table provides an overview of the command options, system variables, and status variables provided by X Plugin.

### 20.5.6.2 X Plugin Options and System Variables

To control activation of X Plugin, use this option:

- `--mysqlx[=value]

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>Type</th>
<th>Default Value</th>
<th>Valid Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--mysqlx[=value]</code></td>
<td>Enumeration</td>
<td>ON</td>
<td>ON, OFF, FORCE</td>
</tr>
</tbody>
</table>
X Plugin Options and Variables

| FORCE_PLUS_PERMANENT |

This option controls how the server loads X Plugin at startup. In MySQL 8.0, X Plugin is enabled by default, but this option may be used to control its activation state.

The option value should be one of those available for plugin-loading options, as described in Section 5.6.1, “Installing and Uninstalling Plugins”.

If X Plugin is enabled, it exposes several system variables that permit control over its operation:

- **mysqlx_bind_address**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--mysqlx-bind-address=addr</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>mysqlx_bind_address</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR</td>
<td>No</td>
</tr>
<tr>
<td>Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>*</td>
</tr>
</tbody>
</table>

The network address on which X Plugin listens for TCP/IP connections. This variable is not dynamic and can be configured only at startup. This is the X Plugin equivalent of the `bind_address` system variable; see that variable description for more information.

By default, X Plugin accepts TCP/IP connections on all server host IPv4 interfaces, and, if the server host supports IPv6, on all IPv6 interfaces. If `mysqlx_bind_address` is specified, its value must satisfy these requirements:

- Prior to MySQL 8.0.21, `mysqlx_bind_address` accepts a single address value, which may specify a single non-wildcard IP address (either IPv4 or IPv6), or a host name, or one of the wildcard address formats that permit listening on multiple network interfaces (`*`, `0.0.0.0`, or `::`).

- As of MySQL 8.0.21, `mysqlx_bind_address` accepts either a single value as just described, or a list of comma-separated values. When the variable names a list of multiple values, each value must specify a single non-wildcard IP address (either IPv4 or IPv6) or a host name. Wildcard address formats (`*`, `0.0.0.0`, or `::`) are not allowed in a list of values.

- As of MySQL 8.0.22, the value may include a network namespace specifier.

IP addresses can be specified as IPv4 or IPv6 addresses. For any value that is a host name, X Plugin resolves the name to an IP address and binds to that address. If a host name resolves to multiple IP addresses, X Plugin uses the first IPv4 address if there are any, or the first IPv6 address otherwise.

X Plugin treats different types of addresses as follows:

- If the address is `*`, X Plugin accepts TCP/IP connections on all server host IPv4 interfaces, and, if the server host supports IPv6, on all IPv6 interfaces. Use this address to permit both IPv4 and IPv6 connections for X Plugin. This value is the default. If the variable specifies a list of multiple values, this value is not permitted.

- If the address is `0.0.0.0`, X Plugin accepts TCP/IP connections on all server host IPv4 interfaces. If the variable specifies a list of multiple values, this value is not permitted.
• If the address is ::, X Plugin accepts TCP/IP connections on all server host IPv4 and IPv6 interfaces. If the variable specifies a list of multiple values, this value is not permitted.

• If the address is an IPv4-mapped address, X Plugin accepts TCP/IP connections for that address, in either IPv4 or IPv6 format. For example, if X Plugin is bound to ::ffff:127.0.0.1, a client such as MySQL Shell can connect using --host=127.0.0.1 or --host=::ffff:127.0.0.1.

• If the address is a “regular” IPv4 or IPv6 address (such as 127.0.0.1 or ::1), X Plugin accepts TCP/IP connections only for that IPv4 or IPv6 address.

These rules apply to specifying a network namespace for an address:

• A network namespace can be specified for an IP address or a host name.

• A network namespace cannot be specified for a wildcard IP address.

• For a given address, the network namespace is optional. If given, it must be specified as a /ns suffix immediately following the address.

• An address with no /ns suffix uses the host system global namespace. The global namespace is therefore the default.

• An address with a /ns suffix uses the namespace named ns.

• The host system must support network namespaces and each named namespace must previously have been set up. Naming a nonexistent namespace produces an error.

• If the variable value specifies multiple addresses, it can include addresses in the global namespace, in named namespaces, or a mix.

For additional information about network namespaces, see Section 5.1.14, "Network Namespace Support".

---

**Important**

Because X Plugin is not a mandatory plugin, it does not prevent server startup if there is an error in the specified address or list of addresses (as MySQL Server does for bind_address errors). With X Plugin, if one of the listed addresses cannot be parsed or if X Plugin cannot bind to it, the address is skipped, an error message is logged, and X Plugin attempts to bind to each of the remaining addresses. X Plugin's Mysqlx_address status variable displays only those addresses from the list for which the bind succeeded. If none of the listed addresses results in a successful bind, or if a single specified address fails, X Plugin logs the error message ER_XPLUGIN_FAILED_TO_PREPARE_IO_INTERFACES stating that X Protocol cannot be used. mysqlx_bind_address is not dynamic, so fix any issues you must stop the server, correct the system variable value, and restart the server.

• mysqlx_compression_algorithms

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--mysqlx-compression-algorithms=value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.19</td>
</tr>
<tr>
<td>System Variable</td>
<td>mysqlx_compression_algorithms</td>
</tr>
</tbody>
</table>
The compression algorithms that are permitted for use on X Protocol connections. By default, the Deflate, LZ4, and zstd algorithms are all permitted. To disallow any of the algorithms, set `mysqlx_compression_algorithms` to include only the ones you permit. The algorithm names `deflate_stream`, `lz4_message`, and `zstd_stream` can be specified in any combination, and the order and case are not important. If you set the system variable to the empty string, no compression algorithms are permitted and only uncompressed connections are used. Use the algorithm-specific system variables to adjust the default and maximum compression level for each permitted algorithm. For more details, and information on how connection compression for X Protocol relates to the equivalent settings for MySQL Server, see Section 20.5.5, “Connection Compression with X Plugin”. 

- `mysqlx_connect_timeout`

The number of seconds X Plugin waits for the first packet to be received from newly connected clients. This is the X Plugin equivalent of `connect_timeout`; see that variable description for more information.

- `mysqlx_deflate_default_compression_level`

```markdown
<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--mysqlx-deflate-default-compression-level=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.20</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>mysqlx_deflate_default_compression_level</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>3</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1000000000</td>
</tr>
</tbody>
</table>
```
**X Plugin Options and Variables**

<table>
<thead>
<tr>
<th>Minimum Value</th>
<th>1</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum Value</td>
<td>9</td>
</tr>
</tbody>
</table>

The default compression level that the server uses for the Deflate algorithm on X Protocol connections. Specify the level as an integer from 1 (the lowest compression effort) to 9 (the highest effort). This level is used if the client does not request a compression level during capability negotiation. If you do not specify this system variable, the server uses level 3 as the default. For more information, see Section 20.5.5, “Connection Compression with X Plugin”.

- **mysqlx_deflate_max_client_compression_level**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--mysqlx_deflate_max_client_compression_level=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.20</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>mysqlx_deflate_max_client_compression_level</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>5</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>9</td>
</tr>
</tbody>
</table>

The maximum compression level that the server permits for the Deflate algorithm on X Protocol connections. The range is the same as for the default compression level for this algorithm. If the client requests a higher compression level than this, the server uses the level you set here. If you do not specify this system variable, the server sets a maximum compression level of 5.

- **mysqlx_document_id_unique_prefix**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--mysqlx-document-id-unique-prefix=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>mysqlx_document_id_unique_prefix</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>65535</td>
</tr>
</tbody>
</table>

Sets the first 4 bytes of document IDs generated by the server when documents are added to a collection. By setting this variable to a unique value per instance, you can ensure document IDs are unique across instances. See Understanding Document IDs.

- **mysqlx_enable_hello_notice**

  | Command-Line Format | `--mysqlx-enable-hello-notice[={OFF|ON}]` |
  |---------------------|----------------------------------|
  | System Variable     | `mysqlx_enable_hello_notice` |
### X Plugin Options and Variables

<table>
<thead>
<tr>
<th>Option</th>
<th>Command-Line Format</th>
<th>System Variable</th>
<th>Scope</th>
<th>Dynamic</th>
<th>SET_VAR Hint Applies</th>
<th>Type</th>
<th>Default Value</th>
<th>Minimum Value</th>
<th>Maximum Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>mysqlx_idle_worker_thread_timeout</td>
<td>--mysqlx-idle-worker-thread-timeout=#</td>
<td>mysqlx_idle_worker_thread_timeout</td>
<td>Global</td>
<td>Yes</td>
<td>No</td>
<td>Integer</td>
<td>60</td>
<td>0</td>
<td>3600</td>
</tr>
<tr>
<td>mysqlx_interactive_timeout</td>
<td>--mysqlx-interactive-timeout=#</td>
<td>mysqlx_interactive_timeout</td>
<td>Global</td>
<td>Yes</td>
<td>No</td>
<td>Integer</td>
<td>28800</td>
<td>1</td>
<td>2147483</td>
</tr>
</tbody>
</table>

**mysqlx_idle_worker_thread_timeout**

The number of seconds after which idle worker threads are terminated.

**mysqlx_interactive_timeout**

The default value of the `mysqlx_wait_timeout` session variable for interactive clients. (The number of seconds to wait for interactive clients to timeout.)

**mysqlx_lz4_default_compression_level**

Introduced 8.0.20

- **Command-Line Format**: `--mysqlx_lz4_default_compression_level=#`
- **System Variable**: `mysqlx_lz4_default_compression_level`
- **Scope**: Global

Controls messages sent to classic MySQL protocol clients that try to connect over X Protocol. When enabled, clients which do not support X Protocol that attempt to connect to the server X Protocol port receive an error explaining they are using the wrong protocol.
The default compression level that the server uses for the LZ4 algorithm on X Protocol connections. Specify the level as an integer from 0 (the lowest compression effort) to 16 (the highest effort). This level is used if the client does not request a compression level during capability negotiation. If you do not specify this system variable, the server uses level 2 as the default. For more information, see Section 20.5.5, “Connection Compression with X Plugin”:

- `mysqlx_lz4_max_client_compression_level`
message has been decompressed. This is the X Plugin equivalent of `max_allowed_packet`; see that variable description for more information.

- **mysqlx_max_connections**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--mysqlx-max-connections=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>mysqlx_max_connections</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>100</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>65535</td>
</tr>
</tbody>
</table>

The maximum number of concurrent client connections X Plugin can accept. This is the X Plugin equivalent of `max_connections`; see that variable description for more information.

For modifications to this variable, if the new value is smaller than the current number of connections, the new limit is taken into account only for new connections.

- **mysqlx_min_worker_threads**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--mysqlx-min-worker-threads=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>mysqlx_min_worker_threads</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>2</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>100</td>
</tr>
</tbody>
</table>

The minimum number of worker threads used by X Plugin for handling client requests.

- **mysqlx_port**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--mysqlx-port=port_num</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>mysqlx_port</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>33060</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
</tbody>
</table>
X Plugin Options and Variables

<table>
<thead>
<tr>
<th>Maximum Value</th>
<th>65535</th>
</tr>
</thead>
</table>

The network port on which X Plugin listens for TCP/IP connections. This is the X Plugin equivalent of `port`; see that variable description for more information.

- **mysqlx_port_open_timeout**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--mysqlx-port-open-timeout=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>mysqlx_port_open_timeout</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>120</td>
</tr>
</tbody>
</table>

The number of seconds X Plugin waits for a TCP/IP port to become free.

- **mysqlx_read_timeout**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--mysqlx-read-timeout=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>mysqlx_read_timeout</td>
</tr>
<tr>
<td>Scope</td>
<td>Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>28800</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>30</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>2147483</td>
</tr>
</tbody>
</table>

The number of seconds that X Plugin waits for blocking read operations to complete. After this time, if the read operation is not successful, the connection is aborted.

- **mysqlx_socket**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--mysqlx-socket=file_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>mysqlx_socket</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>
The path to a Unix socket file which X Plugin uses for connections. This setting is only used by MySQL Server when running on Unix operating systems. Clients can use this socket to connect to MySQL Server using X Plugin.

The default `mysqlx_socket` path and file name is based on the default path and file name for the main socket file for MySQL Server, with the addition of an `x` appended to the file name. The default path and file name for the main socket file is `/tmp/mysql.sock`, therefore the default path and file name for the X Plugin socket file is `/tmp/mysqlx.sock`.

If you specify an alternative path and file name for the main socket file at server startup using the `socket` system variable, this does not affect the default for the X Plugin socket file. In this situation, if you want to store both sockets at a single path, you must set the `mysqlx_socket` system variable as well. For example in a configuration file:

```
socket=/home/sockets/mysqld/mysql.sock
mysqlx_socket=/home/sockets/xplugin/xplugin.sock
```

If you change the default path and file name for the main socket file at compile time using the `MYSQL_UNIX_ADDR` compile option, this does affect the default for the X Plugin socket file, which is formed by appending an `x` to the `MYSQL_UNIX_ADDR` file name. If you want to set a different default for the X Plugin socket file at compile time, use the `MYSQLX_UNIX_ADDR` compile option.

The `MYSQL_UNIX_PORT` environment variable can also be used to set a default for the X Plugin socket file at server startup (see Section 4.9, “Environment Variables”). If you set this environment variable, it overrides the compiled `MYSQL_UNIX_ADDR` value, but is overridden by the `mysqlx_socket` value.

- `mysqlx_ssl_ca`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--mysqlx-ssl-ca=file_name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>mysqlx_ssl_ca</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td>NULL</td>
</tr>
</tbody>
</table>

The `mysqlx_ssl_ca` system variable is like `ssl_ca`, except that it applies to X Plugin rather than the MySQL Server main connection interface. For information about configuring encryption support for X Plugin, see Section 20.5.3, “Using Encrypted Connections with X Plugin”.

- `mysqlx_ssl_capath`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--mysqlx-ssl-capath=dir_name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>mysqlx_ssl_capath</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Directory name</td>
</tr>
</tbody>
</table>
X Plugin Options and Variables

<table>
<thead>
<tr>
<th>Default Value</th>
<th>NULL</th>
</tr>
</thead>
</table>

The `mysqlx_ssl_capath` system variable is like `ssl_capath`, except that it applies to X Plugin rather than the MySQL Server main connection interface. For information about configuring encryption support for X Plugin, see Section 20.5.3, “Using Encrypted Connections with X Plugin”.

• `mysqlx_ssl_cert`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--mysqlx-ssl-cert=file_name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>mysqlx_ssl_cert</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td>NULL</td>
</tr>
</tbody>
</table>

The `mysqlx_ssl_cert` system variable is like `ssl_cert`, except that it applies to X Plugin rather than the MySQL Server main connection interface. For information about configuring encryption support for X Plugin, see Section 20.5.3, “Using Encrypted Connections with X Plugin”.

• `mysqlx_ssl_cipher`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--mysqlx-ssl-cipher=name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>mysqlx_ssl_cipher</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>NULL</td>
</tr>
</tbody>
</table>

The `mysqlx_ssl_cipher` system variable is like `ssl_cipher`, except that it applies to X Plugin rather than the MySQL Server main connection interface. For information about configuring encryption support for X Plugin, see Section 20.5.3, “Using Encrypted Connections with X Plugin”.

• `mysqlx_ssl_crl`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--mysqlx-ssl-crl=file_name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>mysqlx_ssl_crl</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td>NULL</td>
</tr>
</tbody>
</table>

The `mysqlx_ssl_crl` system variable is like `ssl_crl`, except that it applies to X Plugin rather than the MySQL Server main connection interface. For information about configuring encryption support for X Plugin, see Section 20.5.3, “Using Encrypted Connections with X Plugin”.
X Plugin Options and Variables

- **mysqlx_ssl_crlpath**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--mysqlx-ssl-crlpath=dir_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>mysqlx_ssl_crlpath</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Directory name</td>
</tr>
<tr>
<td>Default Value</td>
<td>NULL</td>
</tr>
</tbody>
</table>

  The `mysqlx_ssl_crlpath` system variable is like `ssl_crlpath`, except that it applies to X Plugin rather than the MySQL Server main connection interface. For information about configuring encryption support for X Plugin, see Section 20.5.3, “Using Encrypted Connections with X Plugin”.

- **mysqlx_ssl_key**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--mysqlx-ssl-key=file_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>mysqlx_ssl_key</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td>NULL</td>
</tr>
</tbody>
</table>

  The `mysqlx_ssl_key` system variable is like `ssl_key`, except that it applies to X Plugin rather than the MySQL Server main connection interface. For information about configuring encryption support for X Plugin, see Section 20.5.3, “Using Encrypted Connections with X Plugin”.

- **mysqlx_wait_timeout**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--mysqlx-wait-timeout=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>mysqlx_wait_timeout</td>
</tr>
<tr>
<td>Scope</td>
<td>Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>28800</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>2147483</td>
</tr>
</tbody>
</table>

  The number of seconds that X Plugin waits for activity on a connection. After this time, if the read operation is not successful, the connection is aborted. If the client is noninteractive, the initial value of the session variable is copied from the global `mysqlx_wait_timeout` variable. For interactive clients, the initial value is copied from the session `mysqlx_interactive_timeout`.
• **mysqlx_write_timeout**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--mysqlx-write-timeout=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>mysqlx_write_timeout</td>
</tr>
<tr>
<td>Scope</td>
<td>Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>60</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>2147483</td>
</tr>
</tbody>
</table>

The number of seconds that X Plugin waits for blocking write operations to complete. After this time, if the write operation is not successful, the connection is aborted.

• **mysqlx_zstd_default_compression_level**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--mysqlx_zstd_default_compression_level=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.20</td>
</tr>
<tr>
<td>System Variable</td>
<td>mysqlx_zstd_default_compression_level</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>3</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>-131072</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>22</td>
</tr>
</tbody>
</table>

The default compression level that the server uses for the zstd algorithm on X Protocol connections. For versions of the zstd library from 1.4.0, you can set positive values from 1 to 22 (the highest compression effort), or negative values which represent progressively lower effort. A value of 0 is converted to a value of 1. For earlier versions of the zstd library, you can only specify the value 3. This level is used if the client does not request a compression level during capability negotiation. If you do not specify this system variable, the server uses level 3 as the default. For more information, see Section 20.5.5, “Connection Compression with X Plugin”.

• **mysqlx_zstd_max_client_compression_level**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--mysqlx_zstd_max_client_compression_level=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.20</td>
</tr>
<tr>
<td>System Variable</td>
<td>mysqlx_zstd_max_client_compression_level</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
</tbody>
</table>

3742
The maximum compression level that the server permits for the zstd algorithm on X Protocol connections. The range is the same as for the default compression level for this algorithm. If the client requests a higher compression level than this, the server uses the level you set here. If you do not specify this system variable, the server sets a maximum compression level of 11.

### 20.5.6.3 X Plugin Status Variables

The X Plugin status variables have the following meanings.

- **Mysqlx_aborted_clients**
  The number of clients that were disconnected because of an input or output error.

- **Mysqlx_address**
  The network address or addresses for which X Plugin accepts TCP/IP connections. If multiple addresses were specified using the `mysqlx_bind_address` system variable, `Mysqlx_address` displays only those addresses for which the bind succeeded. If the bind has failed for every network address specified by `mysqlx_bind_address`, or if the `skip_networking` option has been used, the value of `Mysqlx_address` is `UNDEFINED`. If X Plugin startup is not yet complete, the value of `Mysqlx_address` is empty.

- **Mysqlx_bytes_received**
  The total number of bytes received through the network. If compression is used for the connection, this figure comprises compressed message payloads measured before decompression (`Mysqlx_bytes_received_compressed_payload`), any items in compressed messages that were not compressed such as X Protocol headers, and any uncompressed messages.

- **Mysqlx_bytes_received_compressed_payload**
  The number of bytes received as compressed message payloads, measured before decompression.

- **Mysqlx_bytes_received_uncompressed_frame**
  The number of bytes received as compressed message payloads, measured after decompression.

- **Mysqlx_bytes_sent**
  The total number of bytes sent through the network. If compression is used for the connection, this figure comprises compressed message payloads measured after compression (`Mysqlx_bytes_sent_compressed_payload`), any items in compressed messages that were not compressed such as X Protocol headers, and any uncompressed messages.

- **Mysqlx_bytes_sent_compressed_payload**
  The number of bytes sent as compressed message payloads, measured after compression.

- **Mysqlx_bytes_sent_uncompressed_frame**
  The number of bytes sent as compressed message payloads, measured before compression.
(Session scope) The compression algorithm in use for the X Protocol connection for this session. The permitted compression algorithms are listed by the `mysqlx_compression_algorithms` system variable.

- **Mysqlx_compression_level**
  (Session scope) The compression level in use for the X Protocol connection for this session.

- **Mysqlx_connection_accept_errors**
  The number of connections which have caused accept errors.

- **Mysqlx_connection_errors**
  The number of connections which have caused errors.

- **Mysqlx_connections_accepted**
  The number of connections which have been accepted.

- **Mysqlx_connections_closed**
  The number of connections which have been closed.

- **Mysqlx_connections_rejected**
  The number of connections which have been rejected.

- **Mysqlx_crud_create_view**
  The number of create view requests received.

- **Mysqlx_crud_delete**
  The number of delete requests received.

- **Mysqlx_crud_drop_view**
  The number of drop view requests received.

- **Mysqlx_crud_find**
  The number of find requests received.

- **Mysqlx_crud_insert**
  The number of insert requests received.

- **Mysqlx_crud_modify_view**
  The number of modify view requests received.

- **Mysqlx_crud_update**
  The number of update requests received.

- **Mysqlx_cursor_close**
  The number of cursor-close messages received
• **Mysqlx_cursor_fetch**
The number of cursor-fetch messages received

• **Mysqlx_cursor_open**
The number of cursor-open messages received

• **Mysqlx_errors_sent**
The number of errors sent to clients.

• **Mysqlx_expect_close**
The number of expectation blocks closed.

• **Mysqlx_expect_open**
The number of expectation blocks opened.

• **Mysqlx_init_error**
The number of errors during initialisation.

• **Mysqlx_notice_global_sent**
The number of global notifications sent to clients.

• **Mysqlx_notice_other_sent**
The number of other types of notices sent back to clients.

• **Mysqlx_notice_warning_sent**
The number of warning notices sent back to clients.

• **Mysqlx_notified_by_group_replication**
Number of Group Replication notifications sent to clients

• **Mysqlx_port**
The TCP port which X Plugin is listening to. If a network bind has failed, or if the `skip_networking` system variable is enabled, the value shows **UNDEFINED**.

• **Mysqlx_prep_deallocate**
The number of prepared-statement-deallocate messages received

• **Mysqlx_prep_execute**
The number of prepared-statement-execute messages received

• **Mysqlx_prep_prepare**
The number of prepared-statement messages received

• **Mysqlx_rows_sent**
The number of rows sent back to clients.
• **Mysqlx_sessions**
  The number of sessions that have been opened.

• **Mysqlx_sessions_accepted**
  The number of session attempts which have been accepted.

• **Mysqlx_sessions_closed**
  The number of sessions that have been closed.

• **Mysqlx_sessions_fatal_error**
  The number of sessions that have closed with a fatal error.

• **Mysqlx_sessions_killed**
  The number of sessions which have been killed.

• **Mysqlx_sessions_rejected**
  The number of session attempts which have been rejected.

• **Mysqlx_socket**
  The Unix socket which X Plugin is listening to.

• **Mysqlx_ssl_accept_renegotiates**
  The number of negotiations needed to establish the connection.

• **Mysqlx_ssl_accepts**
  The number of accepted SSL connections.

• **Mysqlx_ssl_active**
  If SSL is active.

• **Mysqlx_ssl_cipher**
  The current SSL cipher (empty for non-SSL connections).

• **Mysqlx_ssl_cipher_list**
  A list of possible SSL ciphers (empty for non-SSL connections).

• **Mysqlx_ssl_ctx_verify_depth**
  The certificate verification depth limit currently set in ctx.

• **Mysqlx_ssl_ctx_verify_mode**
  The certificate verification mode currently set in ctx.

• **Mysqlx_ssl_finished_accepts**
  The number of successful SSL connections to the server.
X Plugin Options and Variables

- **Mysqlx_ssl_server_not_after**
  The last date for which the SSL certificate is valid.

- **Mysqlx_ssl_server_not_before**
  The first date for which the SSL certificate is valid.

- **Mysqlx_ssl_verify_depth**
  The certificate verification depth for SSL connections.

- **Mysqlx_ssl_verify_mode**
  The certificate verification mode for SSL connections.

- **Mysqlx_ssl_version**
  The name of the protocol used for SSL connections.

- **Mysqlx_stmt_create_collection**
  The number of create collection statements received.

- **Mysqlx_stmt_create_collection_index**
  The number of create collection index statements received.

- **Mysqlx_stmt_disable_notices**
  The number of disable notice statements received.

- **Mysqlx_stmt_drop_collection**
  The number of drop collection statements received.

- **Mysqlx_stmt_drop_collection_index**
  The number of drop collection index statements received.

- **Mysqlx_stmt_enable_notices**
  The number of enable notice statements received.

- **Mysqlx_stmt_ensure_collection**
  The number of ensure collection statements received.

- **Mysqlx_stmt_execute_mysqlx**
  The number of StmtExecute messages received with namespace set to `mysqlx`.

- **Mysqlx_stmt_execute_sql**
  The number of StmtExecute requests received for the SQL namespace.

- **Mysqlx_stmt_execute_xplugin**
  The number of StmtExecute requests received for the `xplugin` namespace. From MySQL 8.0.19, the `xplugin` namespace has been removed so this status variable is no longer used.
• **Mysqlx_stmt_get_collection_options**
  The number of get collection object statements received.

• **Mysqlx_stmt_kill_client**
  The number of kill client statements received.

• **Mysqlx_stmt_list_clients**
  The number of list client statements received.

• **Mysqlx_stmt_list_notices**
  The number of list notice statements received.

• **Mysqlx_stmt_list_objects**
  The number of list object statements received.

• **Mysqlx_stmt_modify_collection_options**
  The number of modify collection options statements received.

• **Mysqlx_stmt_ping**
  The number of ping statements received.

• **Mysqlx_worker_threads**
  The number of worker threads available.

• **Mysqlx_worker_threads_active**
  The number of worker threads currently used.

### 20.5.7 Monitoring X Plugin

For general X Plugin monitoring, use the status variables that it exposes. See [Section 20.5.6.3, “X Plugin Status Variables”](#). For information specifically about monitoring the effects of message compression, see [Monitoring Connection Compression for X Plugin](#).

#### Monitoring SQL Generated by X Plugin

This section describes how to monitor the SQL statements which X Plugin generates when you run X DevAPI operations. When you execute a CRUD statement, it is translated into SQL and executed against the server. To be able to monitor the generated SQL, the Performance Schema tables must be enabled. The SQL is registered under the `performance_schema.events_statements_current`, `performance_schema.events_statements_history`, and `performance_schema.events_statements_history_long` tables. The following example uses the `world_x` schema, imported as part of the quickstart tutorials in this section. We use MySQL Shell in Python mode, and the `\sql` command which enables you to issue SQL statements without changing to SQL mode. This is important, because if you instead try to switch to SQL mode, the procedure shows the result of this operation rather than the X DevAPI operation. The `\sql` command is used in the same way if you are using MySQL Shell in JavaScript mode.

1. Check if the `events_statements_history` consumer is enabled. Issue:
Monitoring X Plugin

```sql
mysql-py> \sql SELECT enabled FROM performance_schema.setup_consumers WHERE NAME = 'events_statements_history
+---------+
| enabled |
+---------+
| YES     |
+---------+
```

2. Check if all instruments report data to the consumer. Issue:

```sql
mysql-py> \sql SELECT NAME, ENABLED, TIMED FROM performance_schema.setup_instruments WHERE NAME LIKE 'statement/%
```

If this statement reports at least one row, you need to enable the instruments. See Section 26.4, “Performance Schema Runtime Configuration”.

3. Get the thread ID of the current connection. Issue:

```sql
mysql-py> \sql SELECT thread_id INTO @id FROM performance_schema.threads WHERE processlist_id=connection_id()
```

4. Execute the X DevAPI CRUD operation for which you want to see the generated SQL. For example, issue:

```sql
mysql-py> db.CountryInfo.find("Name = :country").bind("country", "Italy")
```

You must not issue any further operations for the next step to show the correct result.

5. Show the last SQL query made by this thread ID. Issue:

```sql
mysql-py> \sql SELECT THREAD_ID, MYSQL_ERRNO, SQL_TEXT FROM performance_schema.events_statements_history WHERE THREAD_ID=@id ORDER BY TIMER_START DESC LIMIT 1;
```

<table>
<thead>
<tr>
<th>THREAD_ID</th>
<th>MYSQL_ERRNO</th>
<th>SQL_TEXT</th>
</tr>
</thead>
<tbody>
<tr>
<td>29</td>
<td>0</td>
<td>SELECT doc FROM <code>world_x</code>.'CountryInfo' WHERE (JSON_EXTRACT(doc,'$.Name') = 'Italy')</td>
</tr>
</tbody>
</table>

The result shows the SQL generated by X Plugin based on the most recent statement, in this case the X DevAPI CRUD operation from the previous step.
# Chapter 21 Using MySQL AdminAPI

21.5 AdminAPI MySQL Sandboxes ............................................ 3826

This chapter covers MySQL AdminAPI, provided with MySQL Shell, which enables you to administer MySQL instances, using them to create InnoDB Clusters, InnoDB ReplicaSets, and integrating MySQL Router.

## 21.1 MySQL AdminAPI

This section provides an overview of AdminAPI and what you need to know to get started.

MySQL Shell includes the AdminAPI, which is accessed through the `dba` global variable and its associated methods. The `dba` variable's methods provide operations which enable you to deploy, configure, and administer InnoDB Cluster and InnoDB ReplicaSet. For example, use the `dba.createCluster()` method to create an InnoDB Cluster. In addition, AdminAPI supports administration of some MySQL Router related tasks, such as creating and updating users that enable you to integrate your InnoDB Cluster and InnoDB ReplicaSet.

MySQL Shell provides two scripting language modes, JavaScript and Python, in addition to a native SQL mode. Throughout this guide MySQL Shell is used primarily in JavaScript mode. When MySQL Shell starts it is in JavaScript mode by default. Switch modes by issuing `\js` for JavaScript mode, and `\py` for Python mode. Ensure you are in JavaScript mode by issuing the `\js`.

### Important

MySQL Shell enables you to connect to servers over a socket connection, but AdminAPI requires TCP connections to a server instance. Socket based connections are not supported in AdminAPI.
This section assumes familiarity with MySQL Shell, see MySQL Shell 8.0 (part of MySQL 8.0) for further information. MySQL Shell also provides online help for the AdminAPI. To list all available `dba` commands, use the `dba.help()` method. For online help on a specific method, use the general format `object.help('methodname')`. For example:

```
mysql-js> dba.help('getCluster')
```

Retrieves a cluster from the Metadata Store.

**SYNTAX**

```
dba.getCluster([name[, options]])
```

**WHERE**

- `name`: Parameter to specify the name of the cluster to be returned.
- `options`: Dictionary with additional options.

>trimmed for brevity<

In addition to this documentation, there is developer documentation for all AdminAPI methods in the MySQL Shell JavaScript API Reference or MySQL Shell Python API Reference, available from Connectors and APIs.

This section applies to using InnoDB Cluster or InnoDB ReplicaSet and consists of:

- **Deployment Scenarios**
- **Installing the Components**
- **Configuring Host Name**
- **Specifying Instances**
- **Persisting Settings**
- **Retrieving a Handler Object**
- **Creating User Accounts for Administration**
- **Verbose Logging**
- **Finding the Primary**
- **Scripting AdminAPI**

### Deployment Scenarios

AdminAPI supports the following deployment scenarios:

- **Production deployment**: if you want to use a full production environment you need to configure the required number of machines and then deploy your server instances to the machines.

- **Sandbox deployment**: if you want to test a deployment before committing to a full production deployment, the provided sandbox feature enables you to quickly set up a test environment on your local machine. Sandbox server instances are created with the required configuration and you can experiment to become familiar with the technologies employed.

<table>
<thead>
<tr>
<th>Important</th>
</tr>
</thead>
<tbody>
<tr>
<td>A sandbox deployment is not suitable for use in a full production environment.</td>
</tr>
</tbody>
</table>
Installing the Components

How you install the software components required by AdminAPI depends on the type of deployment you intend to use. For a production deployment, install the components to each machine. A production deployment uses multiple remote host machines running MySQL server instances, so you need to connect to each machine using a tool such as SSH or Windows remote desktop to carry out tasks such as installing components. For a sandbox deployment, install the components to a single machine. A sandbox deployment is local to a single machine, therefore the install needs to only be done once on the local machine. The following methods of installing are available:

Downloading and installing the components using the following documentation:

- MySQL Server - see Chapter 2, *Installing and Upgrading MySQL*.
- MySQL Shell - see *Installing MySQL Shell*.
- MySQL Router - see *Installing MySQL Router*.

**Important**

Always use the matching version of components, for example run MySQL Shell 8.0.24 to administer instances running MySQL 8.0.24 with MySQL Router 8.0.24.

Once you have installed the software required, choose to follow either Section 21.2, “MySQL InnoDB Cluster” or Section 21.3, “MySQL InnoDB ReplicaSet”.

Configuring Host Name

In a production deployment, the instances which you use run on separate machines, therefore each machine must have a unique host name and be able to resolve the host names of the other machines which run server instances. If this is not the case, you can:

- configure each machine to map the IP of each other machine to a host name. See your operating system documentation for details. This is the recommended solution.
- set up a DNS service
- configure the `report_host` variable in the MySQL configuration of each instance to a suitable externally reachable address

AdminAPI supports using IP addresses instead of host names. From MySQL Shell 8.0.18, AdminAPI supports IPv6 addresses if the target MySQL Server version is higher than 8.0.13. When using MySQL Shell 8.0.18 or higher, if all cluster instances are running 8.0.14 or higher then you can use an IPv6 or hostname that resolves to an IPv6 address for instance connection strings and with options such as `localAddress`, `groupSeeds` and `ipAllowlist`. For more information on using IPv6 see Section 18.4.5, “Support For IPv6 And For Mixed IPv6 And IPv4 Groups”. Previous versions support IPv4 addresses only.

To verify whether the hostname of a MySQL server is correctly configured, execute the following query to see how the instance reports its own address to other servers and try to connect to that MySQL server from other hosts using the returned address:

```
SELECT coalesce(@@report_host, @@hostname);
```

Specifying Instances
Persisting Settings

One of the core concepts of using AdminAPI is understanding connections to the MySQL instances which make up your InnoDB Cluster or InnoDB ReplicaSet. The requirements for connections to the instances when administering, and for the connections between the instances themselves, are:

- only TCP/IP connections are supported, using Unix sockets or named pipes is not supported. InnoDB Cluster and InnoDB ReplicaSet are intended to be used in a local area network, running over a wide area network is not recommended.

- only classic MySQL protocol connections are supported, X Protocol is not supported.

Tip

Your applications can use X Protocol, this requirement is for administration operations using AdminAPI.

MySQL Shell enables you to work with various APIs, and supports specifying connections as explained in Section 4.2.5, “Connecting to the Server Using URI-Like Strings or Key-Value Pairs”. You can specify connections using either URI-like strings, or key-value pairs. The Additional Connection parameters are not supported in AdminAPI. This documentation demonstrates AdminAPI using URI-like connection strings. For example, to connect as the user myuser to the MySQL server instance at www.example.com, on port 3306 use the connection string:

myuser@www.example.com:3306

To use this connection string with an AdminAPI operation such as dba.configureInstance(), you need to ensure the connection string is interpreted as a string, for example by surrounding the connection string with either single (’) or double (”) quote marks. If you are using the JavaScript implementation of AdminAPI issue:

MySQL JS > dba.configureInstance('myuser@www.example.com:3306')

Assuming you are running MySQL Shell in the default interactive mode, you are prompted for your password. AdminAPI supports MySQL Shell's Pluggable Password Store, and once you store the password you used to connect to the instance you are no longer prompted for it.

Persisting Settings

The AdminAPI commands you use to work with an InnoDB Cluster, InnoDB ReplicaSet, and their server instances modify the configuration of the MySQL on the instance. Depending on the way MySQL Shell is connected to an instance and the version of MySQL installed on the instance, these configuration changes can be persisted to the instance automatically. Persisting settings to the instance ensures that configuration changes are retained after the instance restarts, for background information see SET PERSIST. This is essential for reliable usage, for example if settings are not persisted then an instance which has been added to a cluster does not rejoin the cluster after a restart because configuration changes are lost.

Instances which meet the following requirements support persisting configuration changes automatically:

- the instance is running MySQL version 8.0.11 or later
- persisted_globals_load is set to ON
- the instance has not been started with the --no-defaults option

Instances which do not meet these requirements do not support persisting configuration changes automatically, and when AdminAPI operations result in changes to the instance's settings to be persisted you receive warnings such as:
Retrieving a Handler Object

When AdminAPI commands are issued against the MySQL instance which MySQL Shell is currently running on, in other words the local instance, MySQL Shell persists configuration changes directly to the instance. On local instances which support persisting configuration changes automatically, configuration changes are persisted to the instance's `mysqld-auto.cnf` file and the configuration change does not require any further steps. On local instances which do not support persisting configuration changes automatically, you need to make the changes locally, see Configuring Instances with `dba.configureLocalInstance()`.

When run against a remote instance, in other words an instance other than the one which MySQL Shell is currently running on, if the instance supports persisting configuration changes automatically, the AdminAPI commands persist configuration changes to the instance's `mysql-auto.conf` option file. If a remote instance does not support persisting configuration changes automatically, the AdminAPI commands can not automatically configure the instance's option file. This means that AdminAPI commands can read information from the instance, for example to display the current configuration, but changes to the configuration cannot be persisted to the instance's option file. In this case, you need to persist the changes locally, see Configuring Instances with `dba.configureLocalInstance()`.

Retrieving a Handler Object

When you are working with AdminAPI, you use a handler object which represents the InnoDB Cluster or InnoDB ReplicaSet. You assign this object to a variable, and then use the operations available to monitor and administer the InnoDB Cluster or InnoDB ReplicaSet. To be able to retrieve the handler object, you establish a connection to one of the instances which belong to the InnoDB Cluster or InnoDB ReplicaSet. For example, when you create a cluster using `dba.createCluster()`, the operation returns a Cluster object which can be assigned to a variable. You use this object to work with the cluster, for example to add instances or check the cluster's status. If you want to retrieve a cluster again at a later date, for example after restarting MySQL Shell, use the `dba.getCluster([name],[options])` function. For example:

```javascript
mysql-js> var cluster1 = dba.getCluster()
```

Similarly, use the `dba.getReplicaSet()` operation to retrieve an InnoDB ReplicaSet. For example:

```javascript
mysql-js> var replicaset1 = dba.getReplicaSet()
```

If you do not specify a `name` then the default object is returned. By default MySQL Shell attempts to connect to the primary instance when you retrieve a handler. Set the `connectToPrimary` option to configure this behavior. If `connectToPrimary` is `true` and the active global MySQL Shell session is not to a primary instance, MySQL Shell queries for the primary instance. If there is no quorum in a cluster, the operation fails. If `connectToPrimary` is `false`, the retrieved object uses the active session, in other words the same instance as the MySQL Shell's current global session. If `connectToPrimary` is not specified, MySQL Shell treats `connectToPrimary` as `true`, and falls back to `connectToPrimary` being `false`.

To force connecting to a secondary, establish a connection to the secondary instance and use the `connectToPrimary` option by issuing:

```javascript
mysql-js> shell.connect(secondary_member)
mysql-js> var cluster1 = dba.getCluster(testCluster, {connectToPrimary:false})
```

Tip

Remember that secondary instances have `super_read_only=ON`, so you cannot write changes to them.
Creating User Accounts for Administration

The user account used to administer an instance does not have to be the root account, however the user needs to be assigned full read and write privileges on the metadata tables in addition to full MySQL administrator privileges (SUPER, GRANT OPTION, CREATE, DROP and so on). In this procedure the user icadmin is shown in InnoDB Cluster examples, and rsadmin in InnoDB ReplicaSet examples.

Important

The user name and password of an administrator must be the same on all instances.

In version 8.0.20 and later, use the setupAdminAccount(user) operation to create or upgrade a MySQL user account with the necessary privileges to administer an InnoDB Cluster or InnoDB ReplicaSet. To use the setupAdminAccount() operation, you must be connected as a MySQL user with privileges to create users, for example as root. The setupAdminAccount(user) operation also enables you to upgrade an existing MySQL account with the necessary privileges before a dba.upgradeMetadata() operation.

The mandatory user argument is the name of the MySQL account you want to create or upgrade to be used to administrator the account. The format of the user names accepted by the setupAdminAccount() operation follows the standard MySQL account name format, see Section 6.2.4, “Specifying Account Names”. The user argument format is username[@host] where host is optional and if it is not provided it defaults to the % wildcard character.

For example, to create a user named icadmin to administer an InnoDB Cluster assigned to the variable myCluster, issue:

```
mysql-js> myCluster.setupAdminAccount('icadmin')
```

Missing the password for new account icadmin@%. Please provide one.
Password for new account: ********
Confirm password: ********

Creating user icadmin@%.
Setting user password.
Account icadmin@% was successfully created.

If you already have an administration user, for example created with a version prior to 8.0.20, use the update option with the setupAdminAccount() operation to upgrade the privileges of the existing user. This is relevant during an upgrade, to ensure that the administration user is compatible. For example, to upgrade the user named icadmin issue:

```
mysql-js> myCluster.setupAdminAccount('icadmin', {'update':1})
```

Updating user icadmin@%.
Account icadmin@% was successfully updated.

In versions prior to 8.0.20, the preferred method to create users for administration is using the clusterAdmin option with the dba.configureInstance() operation. The clusterAdmin option must be used with a MySQL Shell connection based on a user which has the privileges to create users with suitable privileges, in this example the root user is used. For example:

```
mysql-js> dba.configureInstance('root@ic-1:3306', {clusterAdmin: "'icadmin'@'ic-1%'"});
```

The format of the user names accepted by the setupAdminAccount() operation and the clusterAdmin option follows the standard MySQL account name format, see Section 6.2.4, “Specifying Account Names”.

If only read operations are needed (such as for monitoring purposes), an account with more restricted privileges can be used. See Configuring Users for AdminAPI.
Verbose Logging

When working with a production deployment it can be useful to configure verbose logging for MySQL Shell. For example, the information in the log can help you to find and resolve any issues that might occur when you are preparing server instances to work as part of InnoDB Cluster. To start MySQL Shell with a verbose logging level, use the `--log-level` option:

```
shell> mysqlsh --log-level=DEBUG3
```

The DEBUG3 level is recommended, see `--log-level` for more information. When DEBUG3 is set the MySQL Shell log file contains lines such as `Debug: execute_sql( ... )` which contain the SQL queries that are executed as part of each AdminAPI call. The log file generated by MySQL Shell is located in `~/.mysqlsh/mysqlsh.log` for Unix-based systems; on Microsoft Windows systems it is located in `%APPDATA%\MySQL\mysqlsh\mysqlsh.log`. See MySQL Shell Logging and Debug for more information.

In addition to enabling the MySQL Shell log level, you can configure the amount of output AdminAPI provides in MySQL Shell after issuing each command. To enable the amount of AdminAPI output, in MySQL Shell issue:

```
mysql-js> dba.verbose=2
```

This enables the maximum output from AdminAPI calls. The available levels of output are:

- 0 or OFF is the default. This provides minimal output and is the recommended level when not troubleshooting.
- 1 or ON adds verbose output from each call to the AdminAPI.
- 2 adds debug output to the verbose output providing full information about what each call to AdminAPI executes.

MySQL Shell can optionally log the SQL statements used by AdminAPI operations (with the exception of sandbox operations), and can also display them in the terminal as they are executed. To configure MySQL Shell to do this, see Logging AdminAPI Operations.

Finding the Primary

When you are working with a single-primary InnoDB Cluster or an InnoDB ReplicaSet, you need to connect to the primary instance for administration tasks so that configuration changes can be written to the metadata. To find the current primary you can:

- use the `--redirect-primary` option at MySQL Shell start up to ensure that the target server is part of an InnoDB Cluster or InnoDB ReplicaSet. If the target instance is not the primary, MySQL Shell finds the primary and connects to it.
- use the `shell.connectToPrimary([instance, password])` operation (added in version 8.0.20), which checks whether the target instance belongs to a cluster or ReplicaSet. If so, MySQL Shell opens a new session to the primary, sets the active global MySQL Shell session to the established session and returns it.

If an instance is not provided, the operation attempts to use the active global MySQL Shell session. If an instance is not provided and there is no active global MySQL Shell session, an exception is thrown. If the target instance does not belong to a cluster or ReplicaSet the operation fails with an error.

- use the status operation, find the primary in the result, and manually connect to that instance.

Scripting AdminAPI
You can automate cluster configuration with scripts, which can be run using MySQL Shell. For example:

```shell
mysqlsh -f setup-innodb-cluster.js
```

**Note**

Any command line options specified after the script file name are passed to the script and **not** to MySQL Shell. You can access those options using the `os.argv` array in JavaScript, or the `sys.argv` array in Python. In both cases, the first option picked up in the array is the script name.

The contents of an example script file is shown here:

```javascript
print('InnoDB Cluster sandbox set up\n');
print('==================================\n');
print('Setting up a MySQL InnoDB cluster with 3 MySQL Server sandbox instances,\n');
print('installed in ~/mysql-sandboxes, running on ports 3310, 3320 and 3330.\n\n');
var dbPass = shell.prompt('Please enter a password for the MySQL root account: ', {type:"password"});

try {
    print('Deploying the sandbox instances.\n');
    dba.deploySandboxInstance(3310, {password: dbPass});
    print('.\n');
    dba.deploySandboxInstance(3320, {password: dbPass});
    print('.\n');
    dba.deploySandboxInstance(3330, {password: dbPass});
    print('.\n
    \n    Sandbox instances deployed successfully.\n
    '); print('Setting up InnoDB cluster...
');
    shell.connect('root@localhost:3310', dbPass);
    var cluster = dba.createCluster("prodCluster");

    print('Adding instances to the cluster.\n');
    cluster.addInstance({user: "root", host: "localhost", port: 3320, password: dbPass});
    print('.\n');
    cluster.addInstance({user: "root", host: "localhost", port: 3330, password: dbPass});
    print('.\n
    \n    Instances successfully added to the cluster.\n
    '); print('InnoDB cluster deployed successfully.\n');
} catch(e) {
    print('The InnoDB cluster could not be created.\n    Error: ' + e.message + '\n');
}
```

## 21.2 MySQL InnoDB Cluster

MySQL InnoDB Cluster provides a complete high availability solution for MySQL. By using the AdminAPI included with MySQL Shell you can easily configure and administer a group of at least three MySQL server instances to function as an InnoDB Cluster. In this procedure the host name `ic-number` is used in examples. Each MySQL server instance runs MySQL Group Replication, which provides the mechanism to replicate data within InnoDB Clusters, with built-in failover. AdminAPI removes the need to work directly with Group Replication in InnoDB Clusters, but for more information see Chapter 18, Group Replication which explains the details. MySQL Router can automatically configure itself based on the cluster you deploy, connecting client applications transparently to the server instances. In the event of an unexpected failure of a server instance the cluster reconfigures automatically. In the default single-primary mode, an InnoDB Cluster has a single read-write server instance - the primary. Multiple secondary server instances are replicas of the primary. If the primary fails, a secondary is automatically promoted to the role of primary. Advanced users can also configure a cluster to have multiple-primaries.
Important

InnoDB Cluster does not provide support for MySQL NDB Cluster. NDB Cluster depends on the NDB storage engine as well as a number of programs specific to NDB Cluster which are not furnished with MySQL Server 8.0; NDB is available only as part of the MySQL NDB Cluster distribution. In addition, the MySQL server binary (mysqld) that is supplied with MySQL Server 8.0 cannot be used with NDB Cluster. For more information about MySQL NDB Cluster, see Chapter 22, MySQL NDB Cluster 8.0. Section 22.1.6, “MySQL Server Using InnoDB Compared with NDB Cluster”, provides information about the differences between the InnoDB and NDB storage engines.

The following diagram shows an overview of how these technologies work together:
21.2.1 MySQL InnoDB Cluster Requirements
Before installing a production deployment of InnoDB Cluster, ensure that the server instances you intend to use meet the following requirements.

- InnoDB Cluster uses Group Replication and therefore your server instances must meet the same requirements. See Section 18.9.1, “Group Replication Requirements”. AdminAPI provides the `dba.checkInstanceConfiguration()` method to verify that an instance meets the Group Replication requirements, and the `dba.configureInstance()` method to configure an instance to meet the requirements.

  **Note** When using a sandbox deployment the instances are configured to meet these requirements automatically.

- Group Replication members can contain tables using a storage engine other than InnoDB, for example MyISAM. Such tables cannot be written to by Group Replication, and therefore when using InnoDB Cluster. To be able to write to such tables with InnoDB Cluster, convert all such tables to InnoDB before using the instance in an InnoDB Cluster.

- The Performance Schema must be enabled on any instance which you want to use with InnoDB Cluster.

- The provisioning scripts that MySQL Shell uses to configure servers for use in InnoDB Cluster require access to Python. On Windows MySQL Shell includes Python and no user configuration is required. On Unix Python must be found as part of the shell environment. To check that your system has Python configured correctly issue:

```
$ /usr/bin/env python
```

If a Python interpreter starts, no further action is required. If the previous command fails, create a soft link between `/usr/bin/python` and your chosen Python binary. For more information, see Supported Languages.

- From version 8.0.17, instances must use a unique `server_id` within an InnoDB Cluster. When you use the `Cluster.addInstance(instance)` operation, if the `server_id` of `instance` is already used by an instance in the cluster then the operation fails with an error.

- During the process of configuring an instance for InnoDB Cluster, the majority of the system variables required for using an instance are configured. But AdminAPI does not configure the `transaction_isolation` system variable, which means that it defaults to REPEATABLE READ. This does not impact a single-primary cluster, but if you are using a multi-primary cluster then unless you rely on REPEATABLE READ semantics in your applications, we recommend using the READ COMMITTED isolation level. See Section 18.9.2, “Group Replication Limitations”.

### 21.2.2 Deploying a Production InnoDB Cluster

When working in a production environment, the MySQL server instances which make up an InnoDB Cluster run on multiple host machines as part of a network rather than on single machine as described in Section 21.5, “AdminAPI MySQL Sandboxes”. Before proceeding with these instructions you must install the required software to each machine that you intend to add as a server instance to your cluster, see Installing the Components.

The following diagram illustrates the scenario you work with in this section:

---

3761
Deploying a Production InnoDB Cluster

![Diagram of a Production InnoDB Cluster]

- Client Application
- MySQL Shell Admin
- MySQL Router
- MySQL Server 139.59.177.10
  - MySQL Server 139.59.177.11
  - MySQL Server 139.59.177.12
- Production InnoDB cluster
Deploying a Production InnoDB Cluster

Important

Unlike a sandbox deployment, where all instances are deployed locally to one machine which AdminAPI has local file access to and can persist configuration changes, for a production deployment you must persist any configuration changes on the instance. How you do this depends on the version of MySQL running on the instance, see Persisting Settings.

To pass a server's connection information to AdminAPI, use URI-like connection strings or a data dictionary; see Section 4.2.5, “Connecting to the Server Using URI-Like Strings or Key-Value Pairs”. In this documentation, URI-like strings are shown.

This section assumes that you have:

• installed the MySQL components to your instances
• installed MySQL Shell and can connect by specifying instances
• created a suitable administration user

21.2.2.1 Deploying a New Production InnoDB Cluster

The following sections describe how to deploy a new production InnoDB Cluster.

• Configuring Production Instances
• Creating the Cluster
• Adding Instances to a Cluster
• User Accounts Created by InnoDB Cluster
• Configuring InnoDB Cluster Ports

Configuring Production Instances

AdminAPI provides the `dba.configureInstance()` function that checks if an instance is suitably configured for InnoDB Cluster usage, and configures the instance if it finds any settings which are not compatible with InnoDB Cluster. You run the `dba.configureInstance()` command against an instance and it checks all of the settings required to enable the instance to be used for InnoDB Cluster usage. If the instance does not require configuration changes, there is no need to modify the configuration of the instance, and the `dba.configureInstance()` command output confirms that the instance is ready for InnoDB Cluster usage. If any changes are required to make the instance compatible with InnoDB Cluster, a report of the incompatible settings is displayed, and you can choose to let the command make the changes to the instance's option file. Depending on the way MySQL Shell is connected to the instance, and the version of MySQL running on the instance, you can make these changes permanent by persisting them to a remote instance's option file, see Persisting Settings. Instances which do not support persisting configuration changes automatically require that you configure the instance locally, see Configuring Instances with `dba.configureLocalInstance()`. Alternatively you can make the changes to the instance's option file manually, see Section 4.2.2.2, “Using Option Files” for more information. Regardless of the way you make the configuration changes, you might have to restart MySQL to ensure the configuration changes are detected.

The syntax of the `dba.configureInstance()` command is:

```
dba.configureInstance([instance][, options])
```
where instance is an instance definition, and options is a data dictionary with additional options to configure the operation. The command returns a descriptive text message about the operation's result.

The instance definition is the connection data for the instance, see Section 4.2.5, “Connecting to the Server Using URI-Like Strings or Key-Value Pairs”. If the target instance already belongs to an InnoDB Cluster an error is generated and the process fails.

The options dictionary can contain the following:

- mycnfPath - the path to the MySQL option file of the instance.
- outputMycnfPath - alternative output path to write the MySQL option file of the instance.
- password - the password to be used by the connection.
- clusterAdmin - the name of an InnoDB Cluster administrator user to be created. The supported format is the standard MySQL account name format. Supports identifiers or strings for the user name and host name. By default if unquoted it assumes input is a string. See Creating User Accounts for Administration.
- clusterAdminPassword - the password for the InnoDB Cluster administrator account being created using clusterAdmin. Although you can specify using this option, this is a potential security risk. If you do not specify this option, but do specify the clusterAdmin option, you are prompted for the password at the interactive prompt.
- deprecated, and scheduled for removal in a future version
  - clearReadOnly - a boolean value used to confirm that super_read_only should be set to off, see Super Read-only and Instances.
- interactive - a boolean value used to disable the interactive wizards in the command execution, so that prompts are not provided to the user and confirmation prompts are not shown.
- restart - a boolean value used to indicate that a remote restart of the target instance should be performed to finalize the operation.

Although the connection password can be contained in the instance definition, this is insecure and not recommended. Use the MySQL Shell Pluggable Password Store to store instance passwords securely.

Once dba.configureInstance() is issued against an instance, the command checks if the instance's settings are suitable for InnoDB Cluster usage. A report is displayed which shows the settings required by InnoDB Cluster. If the instance does not require any changes to its settings you can use it in an InnoDB Cluster, and can proceed to Creating the Cluster. If the instance's settings are not valid for InnoDB Cluster usage the dba.configureInstance() command displays the settings which require modification. Before configuring the instance you are prompted to confirm the changes shown in a table with the following information:

- Variable - the invalid configuration variable.
- Current Value - the current value for the invalid configuration variable.
- Required Value - the required value for the configuration variable.

How you proceed depends on whether the instance supports persisting settings, see Persisting Settings. When dba.configureInstance() is issued against the MySQL instance which MySQL Shell is currently running on, in other words the local instance, it attempts to automatically configure the instance. When dba.configureInstance() is issued against a remote instance, if the instance supports persisting configuration changes automatically, you can choose to do this. If a remote instance does not support persisting the changes to configure it for InnoDB Cluster usage, you have to configure the instance locally. See Configuring Instances with dba.configureLocalInstance().
Deploying a Production InnoDB Cluster

In general, a restart of the instance is not required after `dba.configureInstance()` configures the option file, but for some specific settings a restart might be required. This information is shown in the report generated after issuing `dba.configureInstance()`. If the instance supports the `RESTART` statement, MySQL Shell can shutdown and then start the instance. This ensures that the changes made to the instance’s option file are detected by `mysqld`. For more information see `RESTART`.

Note

After executing a `RESTART` statement, the current connection to the instance is lost. If auto-reconnect is enabled, the connection is reestablished after the server restarts. Otherwise, the connection must be reestablished manually.

The `dba.configureInstance()` method verifies that a suitable user is available for cluster usage, which is used for connections between members of the cluster, see Creating User Accounts for Administration.

If you do not specify a user to administer the cluster, in interactive mode a wizard enables you to choose one of the following options:

• enable remote connections for the root user, not recommended in a production environment
• create a new user
• no automatic configuration, in which case you need to manually create the user

Tip

If the instance has `super_read_only=ON` then you might need to confirm that AdminAPI can set `super_read_only=OFF`. See Super Read-only and Instances for more information.

Creating the Cluster

Once you have prepared your instances, use the `dba.createCluster()` function to create the cluster, using the instance which MySQL Shell is connected to as the seed instance for the cluster. The seed instance is replicated to the other instances that you add to the cluster, making them replicas of the seed instance. In this procedure the ic-1 instance is used as the seed. When you issue `dba.createCluster(name)` MySQL Shell creates a classic MySQL protocol session to the server instance connected to the MySQL Shell's current global session. For example, to create a cluster called `testCluster` and assign the returned cluster to a variable called `cluster`:

```javascript
mysql-js> var cluster = dba.createCluster('testCluster')
Validating instance at icadmin@ic-1:3306...
This instance reports its own address as ic-1
Instance configuration is suitable.
Creating InnoDB cluster 'testCluster' on 'icadmin@ic-1:3306'...
Adding Seed Instance...
Cluster successfully created. Use Cluster.addInstance() to add MySQL instances.
At least 3 instances are needed for the cluster to be able to withstand up to one server failure.
```

This pattern of assigning the returned cluster to a variable enables you to then execute further operations against the cluster using the Cluster object's methods. The returned Cluster object uses a new session, independent from the MySQL Shell's global session. This ensures that if you change the MySQL Shell global session, the Cluster object maintains its session to the instance.

To be able to administer a cluster, you must ensure that you have a suitable user which has the required privileges. The recommended approach is to create an administration user. If you did not create an
Deploying a Production InnoDB Cluster

administration user when configuring your instances, use the `Cluster.setupAdminAccount()` operation. For example to create a user named `icadmin` that can administer the InnoDB Cluster assigned to the variable `cluster`, issue:

```javascript
mysql-js> cluster.setupAdminAccount(icadmin)
```

See [Configuring Users for AdminAPI](#) for more information on cluster administration users.

The `dba.createCluster()` operation supports MySQL Shell’s `interactive` option. When `interactive` is on, prompts appear in the following situations:

- when run on an instance that belongs to a cluster and the `adoptFromGr` option is false, you are asked if you want to adopt an existing cluster
- when the `force` option is not used (not set to `true`), you are asked to confirm the creation of a multi-primary cluster

**Note**

If you encounter an error related to metadata being inaccessible you might have the loopback network interface configured. For correct InnoDB Cluster usage disable the loopback interface.

To check the cluster has been created, use the cluster instance’s `status()` function. See [Checking a cluster’s Status with `Cluster.status()`](#).

**Tip**

Once server instances belong to a cluster it is important to only administer them using MySQL Shell and AdminAPI. Attempting to manually change the configuration of Group Replication on an instance once it has been added to a cluster is not supported. Similarly, modifying server variables critical to InnoDB Cluster, such as `server_uuid`, after an instance is configured using AdminAPI is not supported.

When you create a cluster using MySQL Shell 8.0.14 and later, you can set the timeout before instances are expelled from the cluster, for example when they become unreachable. Pass the `expelTimeout` option to the `dba.createCluster()` operation, which configures the `group_replication_member_expel_timeout` variable on the seed instance. The `expelTimeout` option can take an integer value in the range of 0 to 3600. All instances running MySQL server 8.0.13 and later which are added to a cluster with `expelTimeout` configured are automatically configured to have the same `expelTimeout` value as configured on the seed instance.

For information on the other options which you can pass to `dba.createCluster()`, see Section 21.2.5, “Working with InnoDB Cluster”.

### Adding Instances to a Cluster

Use the `Cluster.addInstance(instance)` function to add more instances to the cluster, where `instance` is connection information to a configured instance, see [Configuring Production Instances](#). From version 8.0.17, Group Replication implements compatibility policies which consider the patch version of the instances, and the `Cluster.addInstance()` operation detects this and in the event of an incompatibility the operation terminates with an error. See [Checking the MySQL Version on Instances](#) and Section 18.7.1, “Combining Different Member Versions in a Group”

You need a minimum of three instances in the cluster to make it tolerant to the failure of one instance. Adding further instances increases the tolerance to failure of an instance. To add an instance to the cluster issue:
Deploying a Production InnoDB Cluster

mysql-j> `cluster.addInstance('icadmin@ic-2:3306')`
A new instance will be added to the InnoDB cluster. Depending on the amount of
data on the cluster this might take from a few seconds to several hours.
Please provide the password for 'icadmin@ic-2:3306': ********
Adding instance to the cluster ...
Validating instance at ic-2:3306...
This instance reports its own address as ic-2
Instance configuration is suitable.
The instance 'icadmin@ic-2:3306' was successfully added to the cluster.

When a new instance is added to the cluster, the local address for this instance is automatically added to
the `group_replication_group_seeds` variable on all online cluster instances in order to allow them to
use the new instance to rejoin the group, if needed.

Note

The instances listed in `group_replication_group_seeds` are used according
to the order in which they appear in the list. This ensures user specified settings are
used first and preferred. See Customizing InnoDB Clusters for more information.

If you are using MySQL 8.0.17 or later you can choose how the instance recovers the transactions
it requires to synchronize with the cluster. Only when the joining instance has recovered all of the
transactions previously processed by the cluster can it then join as an online instance and begin
processing transactions. For more information, see Section 21.2.2.2, “Using MySQL Clone with InnoDB
Cluster”.

Also in 8.0.17 and later, you can configure how `Cluster.addInstance()` behaves, letting recovery
operations proceed in the background or monitoring different levels of progress in MySQL Shell.

Depending on which option you chose to recover the instance from the cluster, you see different output in
MySQL Shell. Suppose that you are adding the instance ic-2 to the cluster, and ic-1 is the seed or donor.

- When you use MySQL Clone to recover an instance from the cluster, the output looks like:

Validating instance at ic-2:3306...
This instance reports its own address as ic-2:3306
Instance configuration is suitable.
A new instance will be added to the InnoDB cluster. Depending on the amount of
data on the cluster this might take from a few seconds to several hours.
Adding instance to the cluster...
Monitoring recovery process of the new cluster member. Press 'c' to stop monitoring and let it continue in
background.
Clone based state recovery is now in progress.
NOTE: A server restart is expected to happen as part of the clone process. If the
server does not support the RESTART command or does not come back after a
while, you may need to manually start it back.
* Waiting for clone to finish...
NOTE: ic-2:3306 is being cloned from ic-1:3306
** Stage DROP DATA: Completed
** Clone Transfer
FILE COPY ############################################################ 100% Completed
PAGE COPY ############################################################ 100% Completed
REDO COPY ############################################################ 100% Completed
NOTE: ic-2:3306 is shutting down...
* Waiting for server restart... ready
* ic-2:3306 has restarted, waiting for clone to finish...
** Stage RESTART: Completed
* Clone process has finished: 2.18 GB transferred in 7 sec (311.26 MB/s)
State recovery already finished for 'ic-2:3306'
The instance 'ic-2:3306' was successfully added to the cluster.

The warnings about server restart should be observed, you might have to manually restart an instance.
See Section 13.7.8.8, “RESTART Statement”.

3767
• When you use incremental recovery to recover an instance from the cluster, the output looks like:

```
Incremental distributed state recovery is now in progress.
* Waiting for incremental recovery to finish...
NOTE: 'ic-2:3306' is being recovered from 'ic-1:3306'
* Distributed recovery has finished
```

To cancel the monitoring of the recovery phase, issue `CONTROL+C`. This stops the monitoring but the recovery process continues in the background. The `waitRecovery` integer option can be used with the `Cluster.addInstance()` operation to control the behavior of the command regarding the recovery phase. The following values are accepted:

- 0: do not wait and let the recovery process finish in the background;
- 1: wait for the recovery process to finish;
- 2: wait for the recovery process to finish; and show detailed static progress information;
- 3: wait for the recovery process to finish; and show detailed dynamic progress information (progress bars);

By default, if the standard output which MySQL Shell is running on refers to a terminal, the `waitRecovery` option defaults to 3. Otherwise, it defaults to 2. See Monitoring Recovery Operations.

To verify the instance has been added, use the cluster instance’s `status()` function. For example this is the status output of a sandbox cluster after adding a second instance:

```
mysql-js> cluster.status()
{
  "clusterName": "testCluster",
  "defaultReplicaSet": {
    "name": "default",
    "primary": "ic-1:3306",
    "ssl": "REQUIRED",
    "status": "OK_NO_TOLERANCE",
    "statusText": "Cluster is NOT tolerant to any failures.",
    "topology": {
      "ic-1:3306": {
        "address": "ic-1:3306",
        "mode": "R/W",
        "readReplicas": {},
        "role": "HA",
        "status": "ONLINE"
      },
      "ic-2:3306": {
        "address": "ic-2:3306",
        "mode": "R/O",
        "readReplicas": {},
        "role": "HA",
        "status": "ONLINE"
      }
    }
  },
  "groupInformationSourceMember": "mysql://icadmin@ic-1:3306"
}
```

How you proceed depends on whether the instance is local or remote to the instance MySQL Shell is running on, and whether the instance supports persisting configuration changes automatically, see Persisting Settings. If the instance supports persisting configuration changes automatically, you do not need to persist the settings manually and can either add more instances or continue to the next step. If the instance does not support persisting configuration changes automatically, you have to configure the instance locally. See Configuring Instances with `dba.configureLocalInstance()`. This is essential to ensure that instances rejoin the cluster in the event of leaving the cluster.
Deploying a Production InnoDB Cluster

Tip

If the instance has `super_read_only=ON` then you might need to confirm that AdminAPI can set `super_read_only=OFF`. See Super Read-only and Instances for more information.

Once you have your cluster deployed you can configure MySQL Router to provide high availability, see Section 21.4, “MySQL Router”.

User Accounts Created by InnoDB Cluster

As part of using Group Replication, InnoDB Cluster creates internal recovery users which enable connections between the servers in the cluster. These users are internal to the cluster, and the user name of the generated users follows a naming scheme of `mysql_innodb_cluster_server_id@%`, where `server_id` is unique to the instance. In versions earlier than 8.0.17 the user name of the generated users followed a naming scheme of `mysql_innodb_cluster_r[10_numbers]`. The hostname used for the internal users depends on whether the `ipAllowlist` option has been configured. If `ipAllowlist` is not configured, it defaults to `AUTOMATIC` and the internal users are created using both the wildcard `%` character and `localhost` for the hostname value. When `ipAllowlist` has been configured, for each address in the `ipAllowlist` list an internal user is created. For more information, see Creating an Allowlist of Servers.

Each internal user has a randomly generated password. From version 8.0.18, AdminAPI enables you to change the generated password for internal users. See Resetting Recovery Account Passwords. The randomly generated users are given the following grants:

```
GRANT REPLICATION SLAVE ON *.* to internal_user;
```

The internal user accounts are created on the seed instance and then replicated to the other instances in the cluster. The internal users are:

- generated when creating a new cluster by issuing `dba.createCluster()`
- generated when adding a new instance to the cluster by issuing `Cluster.addInstance()`.

In addition, the `Cluster.rejoinInstance()` operation can also result in a new internal user being generated when the `ipAllowlist` option is used to specify a hostname. For example by issuing:

```
Cluster.rejoinInstance({ipAllowlist: "192.168.1.1/22");
```

all previously existing internal users are removed and a new internal user is created, taking into account the `ipAllowlist` value used.

For more information on the internal users required by Group Replication, see Section 18.2.1.3, “User Credentials For Distributed Recovery”.

Configuring InnoDB Cluster Ports

Instances that belong to a cluster use different ports for different types of communication. In addition to the default `port` at 3306, which is used for client connections over classic MySQL protocol, and the `mysqlx_port`, which defaults to 33060 and is used for X Protocol client connections, there is also a port for internal connections between the instances in the cluster which is not used for client connections. This port is configured by the `localAddress` option, which configures the `group_replication_local_address` system variable, and this port must be open so that the instances in the cluster can communicate with each other. For example, if your firewall is blocking this port then the instances cannot communicate with each other, and the cluster cannot function. Similarly, if your instances are using SELinux, you need to ensure that all of the required ports used by InnoDB Cluster are
open so that the instances can communicate with each other. See Section 6.7.5.2, “Setting the TCP Port Context for MySQL Features” and MySQL Shell Ports.

When you create a cluster or add instances to a cluster, by default the `localAddress` port is calculated by multiplying the target instance’s `port` value by 10 and then adding one to the result. For example, when the `port` of the target instance is the default value of 3306, the calculated `localAddress` port is 33061. You should ensure that port numbers used by your cluster instances are compatible with the way `localAddress` is calculated. For example, if the server instance being used to create a cluster has a `port` number higher than 6553, the `dba.createCluster()` operation fails because the calculated `localAddress` port number exceeds the maximum valid port which is 65535. To avoid this situation either use a lower `port` value on the instances you use for InnoDB Cluster, or manually assign the `localAddress` value, for example:

```sql
mysql-js> dba.createCluster('testCluster', {'localAddress':'icadmin@ic-1:33061'})
```

### 21.2.2 Using MySQL Clone with InnoDB Cluster

In MySQL 8.0.17, InnoDB Cluster integrates the MySQL Clone plugin to provide automatic provisioning of joining instances. The process of retrieving the cluster's data so that the instance can synchronize with the cluster is called distributed recovery. When an instance needs to recover a cluster's transactions we distinguish between the `donor`, which is the cluster instance that provides the data, and the `receiver`, which is the instance that receives the data from the donor. In previous versions, Group Replication provided only asynchronous replication to recover the transactions required for the joining instance to synchronize with the cluster so that it could join the cluster. For a cluster with a large amount of previously processed transactions it could take a long time for the new instance to recover all of the transactions before being able to join the cluster. Or a cluster which had purged GTIDs, for example as part of regular maintenance, could be missing some of the transactions required to recover the new instance. In such cases the only alternative was to manually provision the instance using tools such as MySQL Enterprise Backup, as shown in Section 18.4.6, “Using MySQL Enterprise Backup with Group Replication”.

MySQL Clone provides an alternative way for an instance to recover the transactions required to synchronize with a cluster. Instead of relying on asynchronous replication to recover the transactions, MySQL Clone takes a snapshot of the data on the donor instance and then transfers the snapshot to the receiver.

**Warning**

All previous data in the receiver is destroyed during a clone operation. All MySQL settings not stored in tables are however maintained.

Once a clone operation has transferred the snapshot to the receiver, if the cluster has processed transactions while the snapshot was being transferred, asynchronous replication is used to recover any required data for the receiver to be synchronized with the cluster. This can be much more efficient than the instance recovering all of the transactions using asynchronous replication, and avoids any issues caused by purged GTIDs, enabling you to quickly provision new instances for InnoDB Cluster. For more information, see Section 5.6.7, “The Clone Plugin” and Section 18.4.3.2, “Cloning for Distributed Recovery”

In contrast to using MySQL Clone, incremental recovery is the process where an instance joining a cluster uses only asynchronous replication to recover an instance from the cluster. When an InnoDB Cluster is configured to use MySQL Clone, instances which join the cluster use either MySQL Clone or incremental recovery to recover the cluster's transactions. By default, the cluster automatically chooses the most suitable method, but you can optionally configure this behavior, for example to force cloning, which replaces any transactions already processed by the joining instance. When you are using MySQL Shell in interactive mode, the default, if the cluster is not sure it can proceed with recovery it provides an interactive prompt. This section describes the different options you are offered, and the different scenarios which influence which of the options you can choose.
In addition, the output of `Cluster.status()` for members in `RECOVERING` state includes recovery progress information to enable you to easily monitor recovery operations, whether they are using MySQL Clone or incremental recovery. InnoDB Cluster provides additional information about instances using MySQL Clone in the output of `Cluster.status()`.

**Working with a Cluster that uses MySQL Clone**

An InnoDB Cluster that uses MySQL Clone provides the following additional behavior.

**`dba.createCluster()` and MySQL Clone**

From version 8.0.17, by default when a new cluster is created on an instance where the MySQL Clone plugin is available then it is automatically installed and the cluster is configured to support cloning. The InnoDB Cluster recovery accounts are created with the required `BACKUP_ADMIN` privilege.

Set the `disableClone` Boolean option to `true` to disable MySQL Clone for the cluster. In this case a metadata entry is added for this configuration and the MySQL Clone plugin is uninstalled if it is installed. You can set the `disableClone` option when you issue `dba.createCluster()`, or at any time when the cluster is running using `Cluster.setOption()`.

**`Cluster.addInstance(instance)` and MySQL Clone**

MySQL Clone can be used for a joining `instance` if the new instance is running MySQL 8.0.17 or later, and there is at least one donor in the cluster (included in the `group_replication_group_seeds` list) running MySQL 8.0.17 or later. A cluster using MySQL Clone follows the behavior documented at [Adding Instances to a Cluster](#), with the addition of a possible choice of how to transfer the data required to recover the instance from the cluster. How `Cluster.addInstance(instance)` behaves depends on the following factors:

- Whether MySQL Clone is supported.
- Whether incremental recovery is possible or not, which depends on the availability of binary logs. For example, if a donor instance has all binary logs required (`GTID_PURGED` is empty) then incremental recovery is possible. If no cluster instance has all binary logs required then incremental recovery is not possible.
- Whether incremental recovery is appropriate or not. Even though incremental recovery might be possible, because it has the potential to clash with data already on the instance, the GTID sets on the donor and receiver are checked to make sure that incremental recovery is appropriate. The following are possible results of the comparison:
  - New: the receiver has an empty `GTID_EXECUTED` GTID set
  - Identical: the receiver has a GTID set identical to the donor’s GTID set
  - Recoverable: the receiver has a GTID set that is missing transactions but these can be recovered from the donor
  - Irrecoverable: the donor has a GTID set that is missing transactions, possibly they have been purged
  - Diverged: the GTID sets of the donor and receiver have diverged

When the result of the comparison is determined to be Identical or Recoverable, incremental recovery is considered appropriate. When the result of the comparison is determined to be Irrecoverable or Diverged, incremental recovery is not considered appropriate.

For an instance considered New, incremental recovery cannot be considered appropriate because it is impossible to determine if the binary logs have been purged, or even if the `GTID_PURGED` and...
GTID_EXECUTED variables were reset. Alternatively, it could be that the server had already processed transactions before binary logs and GTIDs were enabled. Therefore in interactive mode, you have to confirm that you want to use incremental recovery.

- The state of the `gtidSetIsComplete` option. If you are sure a cluster has been created with a complete GTID set, and therefore instances with empty GTID sets can be added to it without extra confirmations, set the cluster level `gtidSetIsComplete` Boolean option to `true`.

**Warning**

Setting the `gtidSetIsComplete` option to `true` means that joining servers are recovered regardless of any data they contain, use with caution. If you try to add an instance which has applied transactions you risk data corruption.

The combination of these factors influence how instances join the cluster when you issue `Cluster.addInstance()`. The `recoveryMethod` option is set to `auto` by default, which means that in MySQL Shell's interactive mode, the cluster selects the best way to recover the instance from the cluster, and the prompts advise you how to proceed. In other words the cluster recommends using MySQL Clone or incremental recovery based on the best approach and what the server supports. If you are not using interactive mode and are scripting MySQL Shell, you must set `recoveryMethod` to the type of recovery you want to use - either `clone` or `incremental`. This section explains the different possible scenarios.

When you are using MySQL Shell in interactive mode, the main prompt with all of the possible options for adding the instance is:

```
Please select a recovery method [C]lone/[I]ncremental recovery/[A]bort (default Clone):
```

Depending on the factors mentioned, you might not be offered all of these options. The scenarios described later in this section explain which options you are offered. The options offered by this prompt are:

- **Clone**: choose this option to clone the donor to the instance which you are adding to the cluster, deleting any transactions the instance contains. The MySQL Clone plugin is automatically installed. The InnoDB Cluster recovery accounts are created with the required `BACKUP_ADMIN` privilege. Assuming you are adding an instance which is either empty (has not processed any transactions) or which contains transactions you do not want to retain, select the Clone option. The cluster then uses MySQL Clone to completely overwrite the joining instance with a snapshot from an donor cluster member. To use this method by default and disable this prompt, set the cluster's `recoveryMethod` option to `clone`.

- **Incremental recovery** choose this option to use incremental recovery to recover all transactions processed by the cluster to the joining instance using asynchronous replication. Incremental recovery is appropriate if you are sure all updates ever processed by the cluster were done with GTIDs enabled, there are no purged transactions and the new instance contains the same GTID set as the cluster or a subset of it. To use this method by default, set the `recoveryMethod` option to `incremental`.

The combination of factors mentioned influences which of these options is available at the prompt as follows:

**Note**

If the `group_replication_clone_threshold` system variable has been manually changed outside of AdminAPI, then the cluster might decide to use Clone recovery instead of following these scenarios.

- In a scenario where
  - incremental recovery is possible
Deploying a Production InnoDB Cluster

• incremental recovery is not appropriate
• Clone is supported

you can choose between any of the options. It is recommended that you use MySQL Clone, the default.

• In a scenario where
  • incremental recovery is possible
  • incremental recovery is appropriate
  you are not provided with the prompt, and incremental recovery is used.

• In a scenario where
  • incremental recovery is possible
  • incremental recovery is not appropriate
  • Clone is not supported or is disabled

you cannot use MySQL Clone to add the instance to the cluster. You are provided with the prompt, and the recommended option is to proceed with incremental recovery.

• In a scenario where
  • incremental recovery is not possible
  • Clone is not supported or is disabled

you cannot add the instance to the cluster and an ERROR: The target instance must be either cloned or fully provisioned before it can be added to the target cluster. Cluster.addInstance: Instance provisioning required (RuntimeError) is shown. This could be the result of binary logs being purged from all cluster instances. It is recommended to use MySQL Clone, by either upgrading the cluster or setting the disableClone option to false.

• In a scenario where
  • incremental recovery is not possible
  • Clone is supported

you can only use MySQL Clone to add the instance to the cluster. This could be the result of the cluster missing binary logs, for example when they have been purged.

Once you select an option from the prompt, by default the progress of the instance recovering the transactions from the cluster is displayed. This monitoring enables you to check the recovery phase is working and also how long it should take for the instance to join the cluster and come online. To cancel the monitoring of the recovery phase, issue CONTROL+C.

Cluster.checkInstanceState() and MySQL Clone

When the Cluster.checkInstanceState() operation is run to verify an instance against a cluster that is using MySQL Clone, if the instance does not have the binary logs, for example because they were purged but Clone is available and not disabled (disableClone is false) the operation provides a warning that the Clone can be used. For example:
Monitoring InnoDB Cluster

The cluster transactions cannot be recovered on the instance, however, Clone is available and can be used when adding it to a cluster.

```json
{
"reason": "all_purged",
"state": "warning"
}
```

Similarly, on an instance where Clone is either not available or has been disabled and the binary logs are not available, for example because they were purged, then the output includes:

The cluster transactions cannot be recovered on the instance.

```json
{
"reason": "all_purged",
"state": "warning"
}
```

dba.checkInstanceConfiguration() and MySQL Clone

When the `dba.checkInstanceConfiguration()` operation is run against an instance that has MySQL Clone available but it is disabled, a warning is displayed.

### 21.2.2.3 Adopting a Group Replication Deployment

If you have an existing deployment of Group Replication and you want to use it to create a cluster, pass the `adoptFromGR` option to the `dba.createCluster()` function. The created InnoDB Cluster matches whether the replication group is running as single-primary or multi-primary.

To adopt an existing Group Replication group, connect to a group member using MySQL Shell. In the following example a single-primary group is adopted. We connect to `gr-member-2`, a secondary instance, while `gr-member-1` is functioning as the group’s primary. Create a cluster using `dba.createCluster()`, passing in the `adoptFromGR` option. For example:

```javascript
mysql-js> var cluster = dba.createCluster('prodCluster', {adoptFromGR: true});
```

A new InnoDB cluster will be created on instance 'root@gr-member-2:3306'.

Creating InnoDB cluster 'prodCluster' on 'root@gr-member-2:3306'...

Adding Seed Instance...

Cluster successfully created. Use cluster.addInstance() to add MySQL instances. At least 3 instances are needed for the cluster to be able to withstand up to one server failure.

**Tip**

If the instance has `super_read_only=ON` then you might need to confirm that AdminAPI can set `super_read_only=OFF`. See [Super Read-only and Instances](#) for more information.

The new cluster matches the mode of the group. If the adopted group was running in single-primary mode then a single-primary cluster is created. If the adopted group was running in multi-primary mode then a multi-primary cluster is created.

### 21.2.3 Monitoring InnoDB Cluster

This section describes how to use AdminAPI to monitor an InnoDB Cluster.

- **Using** `Cluster.describe()`
• Checking a cluster’s Status with `Cluster.status()`

• Monitoring Recovery Operations

• InnoDB Cluster and Group Replication Protocol

• Checking the MySQL Version on Instances

**Using `Cluster.describe()`**

To get information about the structure of the InnoDB Cluster itself, use the `Cluster.describe()` function:

```javascript
mysql-js> cluster.describe();
{
  "clusterName": "testCluster",
  "defaultReplicaSet": {
    "name": "default",
    "topology": [
      {
        "address": "ic-1:3306",
        "label": "ic-1:3306",
        "role": "HA"
      },
      {
        "address": "ic-2:3306",
        "label": "ic-2:3306",
        "role": "HA"
      },
      {
        "address": "ic-3:3306",
        "label": "ic-3:3306",
        "role": "HA"
      }
    ]
  }
}
```

The output from this function shows the structure of the InnoDB Cluster including all of its configuration information, and so on. The address, label and role values match those described at **Checking a cluster’s Status with `Cluster.status()`**.

**Checking a cluster’s Status with `Cluster.status()`**

Cluster objects provide the `status()` method that enables you to check how a cluster is running. Before you can check the status of the InnoDB Cluster, you need to get a reference to the InnoDB Cluster object by connecting to any of its instances. However, if you want to make changes to the configuration of the cluster, you must connect to a “R/W” instance. Issuing `status()` retrieves the status of the cluster based on the view of the cluster which the server instance you are connected to is aware of and outputs a status report.

**Important**

The instance’s state in the cluster directly influences the information provided in the status report. Therefore ensure the instance you are connected to has a status of `ONLINE`.

For information about how the InnoDB Cluster is running, use the cluster’s `status()` method:

```javascript
mysql-js> var cluster = dba.getCluster()
```
Monitoring InnoDB Cluster

```
mysql-j> cluster.status()
{
   "clusterName": "testcluster",
   "defaultReplicaSet": {
      "name": "default",
      "primary": "ic-1:3306",
      "ssl": "REQUIRED",
      "status": "OK",
      "statusText": "Cluster is ONLINE and can tolerate up to ONE failure."
   },
   "topology": {
      "ic-1:3306": {
         "address": "ic-1:3306",
         "mode": "R/W",
         "readReplicas": {},
         "role": "HA",
         "status": "ONLINE"
      },
      "ic-2:3306": {
         "address": "ic-2:3306",
         "mode": "R/O",
         "readReplicas": {},
         "role": "HA",
         "status": "ONLINE"
      },
      "ic-3:3306": {
         "address": "ic-3:3306",
         "mode": "R/O",
         "readReplicas": {},
         "role": "HA",
         "status": "ONLINE"
      }
   }
}
"groupInformationSourceMember": "mysql://icadmin@ic-1:3306"
}
```

The output of `Cluster.status()` provides the following information:

- **clusterName**: name assigned to this cluster during `dba.createCluster()`.

- **defaultReplicaSet**: the server instances which belong to an InnoDB Cluster and contain the data set.

- **primary**: displayed when the cluster is operating in single-primary mode only. Shows the address of the current primary instance. If this field is not displayed, the cluster is operating in multi-primary mode.

- **ssl**: whether secure connections are used by the cluster or not. Shows values of `REQUIRED` or `DISABLED`, depending on how the `memberSslMode` option was configured during either `createCluster()` or `addInstance()`. The value returned by this parameter corresponds to the value of the `group_replication_ssl_mode` server variable on the instance. See Securing your Cluster.

- **status**: The status of this element of the cluster. For the overall cluster this describes the high availability provided by this cluster. The status is one of the following:
  - **ONLINE**: The instance is online and participating in the cluster.
  - **OFFLINE**: The instance has lost connection to the other instances.
  - **RECOVERING**: The instance is attempting to synchronize with the cluster by retrieving transactions it needs before it can become an ONLINE member.
  - **UNREACHABLE**: The instance has lost communication with the cluster.
• **ERROR**: The instance has encountered an error during the recovery phase or while applying a transaction.

**Important**

Once an instance enters **ERROR** state, the `super_read_only` option is set to ON. To leave the **ERROR** state you must manually configure the instance with `super_read_only=OFF`.

• **(MISSING)**: The state of an instance which is part of the configured cluster, but is currently unavailable.

**Note**

The **MISSING** state is specific to InnoDB cluster, it is not a state generated by Group Replication. MySQL Shell uses this state to indicate instances that are registered in the metadata, but cannot be found in the live cluster view.

• **topology**: The instances which have been added to the cluster.

• **Host name of instance**: The host name of an instance, for example `localhost:3310`.

• **role**: what function this instance provides in the cluster. Currently only HA, for high availability.

• **mode**: whether the server is read-write ("R/W") or read-only ("R/O"). From version 8.0.17, this is derived from the current state of the `super_read_only` variable on the instance, and whether the cluster has quorum. In previous versions the value of mode was derived from whether the instance was serving as a primary or secondary instance. Usually if the instance is a primary, then the mode is "R/W", and if the instance is a secondary the mode is "R/O". Any instances in a cluster that have no visible quorum are marked as "R/O", regardless of the state of the `super_read_only` variable.

• **groupInformationSourceMember**: the internal connection used to get information about the cluster, shown as a URI-like connection string. Usually the connection initially used to create the cluster.

To display more information about the cluster use the `extended` option. From version 8.0.17, the `extended` option supports integer or Boolean values. To configure the additional information that `Cluster.status({'extended':value})` provides, use the following values:

• 0: disables the additional information, the default

• 1: includes information about the Group Replication Protocol Version, Group name, cluster member UUIDs, cluster member roles and states as reported by Group Replication, and the list of fenced system variables

• 2: includes information about transactions processed by connection and applier

• 3: includes more detailed statistics about the replication performed by each cluster member.

Setting `extended` using Boolean values is the equivalent of setting the integer values 0 and 1. In versions prior to 8.0.17, the `extended` option was only Boolean. Similarly prior versions used the `queryMembers` Boolean option to provide more information about the instances in the cluster, which is the equivalent of setting `extended` to 3. The `queryMembers` option is deprecated and scheduled to be removed in a future release.

When you issue `Cluster.status({'extended':1})`, or the `extended` option is set to `true`, the output includes:
Monitoring InnoDB Cluster

• the following additional attributes for the defaultReplicaSet object:
  
  • GRProtocolVersion is the Group Replication Protocol Version being used in the cluster.

  Tip
  InnoDB Cluster manages the Group Replication Protocol version being used automatically, see InnoDB Cluster and Group Replication Protocol for more information.

  • groupName is the group's name, a UUID.

  • the following additional attributes for each object of the topology object:

  • fenceSysVars a list containing the name of the fenced system variables which are enabled. Currently the fenced system variables considered are read_only, super_read_only and offline_mode.

  • memberId Each cluster member UUID.

  • memberRole the Member Role as reported by the Group Replication plugin, see the MEMBER_ROLE column of the replication_group_members table.

  • memberState the Member State as reported by the Group Replication plugin, see the MEMBER_STATE column of the replication_group_members table.

To see information about recovery and regular transaction I/O, applier worker thread statistics and any lags; applier coordinator statistics, if parallel apply is enabled; error, and other information from I/O and applier threads issue use the values 2 and 3. A value of 3 is the equivalent of setting the deprecated queryMembers option to true. When you use these values, a connection to each instance in the cluster is opened so that additional instance specific statistics can be queried. The exact statistics that are included in the output depend on the state and configuration of the instance and the server version. This information matches that shown in the replication_group_member_stats table, see the descriptions of the matching columns for more information. Instances which are ONLINE have a transactions section included in the output. Instances which are RECOVERING have a recovery section included in the output. When you set extended to 2, in either case, these sections can contain the following:

• appliedCount: see COUNT_TRANSACTIONS_REMOTE_APPLIED

• checkedCount: see COUNT_TRANSACTIONS_CHECKED

• committedAllMembers: see TRANSACTIONS_COMMITTED_ALL_MEMBERS

• conflictsDetectedCount: see COUNT_CONFLICTS_DETECTED

• inApplierQueueCount: see COUNT_TRANSACTIONS_REMOTE_IN_APPLIER_QUEUE

• inQueueCount: see COUNT_TRANSACTIONS_IN_QUEUE

• lastConflictFree: see LAST_CONFLICT_FREE_TRANSACTION

• proposedCount: see COUNT_TRANSACTIONS_LOCAL_PROPOSED

• rollbackCount: see COUNT_TRANSACTIONS_LOCAL_ROLLBACK

When you set extended to 3, the connection section shows information from the replication_connection_status table. The connection section can contain the following:

The currentlyQueueing section has information about the transactions currently queued:
Monitoring InnoDB Cluster

- immediateCommitTimestamp: see QUEUEING_TRANSACTION_IMMEDIATE_COMMIT_TIMESTAMP
- immediateCommitToNowTime: see QUEUEING_TRANSACTION_IMMEDIATE_COMMIT_TIMESTAMP minus NOW()
- originalCommitTimestamp: see QUEUEING_TRANSACTION_ORIGINAL_COMMIT_TIMESTAMP
- originalCommitToNowTime: see QUEUEING_TRANSACTION_ORIGINAL_COMMIT_TIMESTAMP minus NOW()
- startTimestamp: see QUEUEING_TRANSACTION_START_QUEUE_TIMESTAMP
- transaction: see QUEUEING_TRANSACTION
- lastHeartbeatTimestamp: see LAST_HEARTBEAT_TIMESTAMP

The lastQueued section has information about the most recently queued transaction:

- endTimestamp: see LAST_QUEUED_TRANSACTION_END_QUEUE_TIMESTAMP
- immediateCommitTimestamp: see LAST_QUEUED_TRANSACTION_IMMEDIATE_COMMIT_TIMESTAMP
- immediateCommitToEndTime: LAST_QUEUED_TRANSACTION_IMMEDIATE_COMMIT_TIMESTAMP minus NOW()
- originalCommitTimestamp: see LAST_QUEUED_TRANSACTION_ORIGINAL_COMMIT_TIMESTAMP
- originalCommitToEndTime: LAST_QUEUED_TRANSACTION_ORIGINAL_COMMIT_TIMESTAMP minus NOW()
- queueTime: LAST_QUEUED_TRANSACTION_END_QUEUE_TIMESTAMP minus LAST_QUEUED_TRANSACTION_START_QUEUE_TIMESTAMP
- startTimestamp: see LAST_QUEUED_TRANSACTION_START_QUEUE_TIMESTAMP
- transaction: see LAST_QUEUED_TRANSACTION
- receivedHeartbeats: see COUNT_RECEIVED_HEARTBEATS
- receivedTransactionSet: see RECEIVED_TRANSACTION_SET
- threadId: see THREAD_ID

Instances which are using a multithreaded replica have a workers section which contains information about the worker threads, and matches the information shown by the replication_applier_status_by_worker table.

The lastApplied section shows the following information about the last transaction applied by the worker:

- applyTime: see LAST_APPLIED_TRANSACTION_END_APPLY_TIMESTAMP minus LAST_APPLIED_TRANSACTION_START_APPLY_TIMESTAMP
- endTimestamp: see LAST_APPLIED_TRANSACTION_END_APPLY_TIMESTAMP
- immediateCommitTimestamp: see LAST_APPLIED_TRANSACTION_IMMEDIATE_COMMIT_TIMESTAMP
Monitoring InnoDB Cluster

- **immediateCommitToEndTime**: see `LAST_APPLIED_TRANSACTION_IMMEDIATE_COMMIT_TIMESTAMP` minus `NOW()`
- **originalCommitTimestamp**: see `LAST_APPLIED_TRANSACTION_ORIGINAL_COMMIT_TIMESTAMP`
- **originalCommitToEndTime**: see `LAST_APPLIED_TRANSACTION_ORIGINAL_COMMIT_TIMESTAMP` minus `NOW()`
- **startTimestamp**: see `LAST_APPLIED_TRANSACTION_START_APPLY_TIMESTAMP`
- **transaction**: see `LAST_APPLIED_TRANSACTION`

The **currentlyApplying** section shows the following information about the transaction currently being applied by the worker:

- **immediateCommitTimestamp**: see `APPLYING_TRANSACTION_IMMEDIATE_COMMIT_TIMESTAMP`
- **immediateCommitToNowTime**: see `APPLYING_TRANSACTION_IMMEDIATE_COMMIT_TIMESTAMP` minus `NOW()`
- **originalCommitTimestamp**: see `APPLYING_TRANSACTION_ORIGINAL_COMMIT_TIMESTAMP`
- **originalCommitToNowTime**: see `APPLYING_TRANSACTION_ORIGINAL_COMMIT_TIMESTAMP` minus `NOW()`
- **startTimestamp**: see `APPLYING_TRANSACTION_START_APPLY_TIMESTAMP`
- **transaction**: see `APPLYING_TRANSACTION`

The **lastProcessed** section has the following information about the last transaction processed by the worker:

- **bufferTime**: `LAST_PROCESSED_TRANSACTION_END_BUFFER_TIMESTAMP` minus `LAST_PROCESSED_TRANSACTION_START_BUFFER_TIMESTAMP`
- **endTimestamp**: see `LAST_PROCESSED_TRANSACTION_END_BUFFER_TIMESTAMP`
- **immediateCommitTimestamp**: see `LAST_PROCESSED_TRANSACTION_IMMEDIATE_COMMIT_TIMESTAMP`
- **immediateCommitToEndTime**: `LAST_PROCESSED_TRANSACTION_IMMEDIATE_COMMIT_TIMESTAMP` minus `LAST_PROCESSED_TRANSACTION_END_BUFFER_TIMESTAMP`
- **originalCommitTimestamp**: see `LAST_PROCESSED_TRANSACTION_ORIGINAL_COMMIT_TIMESTAMP`
- **originalCommitToEndTime**: `LAST_PROCESSED_TRANSACTION_ORIGINAL_COMMIT_TIMESTAMP` minus `LAST_PROCESSED_TRANSACTION_END_BUFFER_TIMESTAMP`
- **startTimestamp**: see `LAST_PROCESSED_TRANSACTION_START_BUFFER_TIMESTAMP`
- **transaction**: see `LAST_PROCESSED_TRANSACTION`

If parallel applier workers are enabled, then the number of objects in the workers array in `transactions` or `recovery` matches the number of configured workers and an additional coordinator object is included. The information shown matches the information in the `replication_applier_status_by_coordinator` table. The object can contain:
The `currentlyProcessing` section has the following information about the transaction being processed by the worker:

- `immediateCommitTimestamp`: see `PROCESSING_TRANSACTION_IMMEDIATE_COMMIT_TIMESTAMP`
- `immediateCommitToNowTime`: `PROCESSING_TRANSACTION_IMMEDIATE_COMMIT_TIMESTAMP` minus `NOW()`
- `originalCommitTimestamp`: see `PROCESSING_TRANSACTION_ORIGINAL_COMMIT_TIMESTAMP`
- `originalCommitToNowTime`: `PROCESSING_TRANSACTION_ORIGINAL_COMMIT_TIMESTAMP` minus `NOW()`
- `startTimestamp`: see `PROCESSING_TRANSACTION_START_BUFFER_TIMESTAMP`
- `transaction`: see `PROCESSING_TRANSACTION`

Worker objects have the following information if an error was detected in the `replication_applier_status_by_worker` table:

- `lastErrno`: see `LAST_ERROR_NUMBER`
- `lastError`: see `LAST_ERROR_MESSAGE`
- `lastErrorTimestamp`: see `LAST_ERROR_TIMESTAMP`

Connection objects have the following information if an error was detected in the `replication_connection_status` table:

- `lastErrno`: see `LAST_ERROR_NUMBER`
- `lastError`: see `LAST_ERROR_MESSAGE`
- `lastErrorTimestamp`: see `LAST_ERROR_TIMESTAMP`

Coordinator objects have the following information if an error was detected in the `replication_applier_status_by_coordinator` table:

- `lastErrno`: see `LAST_ERROR_NUMBER`
- `lastError`: see `LAST_ERROR_MESSAGE`
- `lastErrorTimestamp`: see `LAST_ERROR_TIMESTAMP`

### Monitoring Recovery Operations

The output of `Cluster.status()` shows information about the progress of recovery operations for instances in `RECOVERING` state. Information is shown for instances recovering using either MySQL Clone, or incremental recovery. Monitor these fields:

- The `recoveryStatusText` field includes information about the type of recovery being used. When MySQL Clone is working the field shows “Cloning in progress”. When incremental recovery is working the field shows “Distributed recovery in progress”.

- When MySQL Clone is being used, the `recovery` field includes a dictionary with the following fields:
  - `cloneStartTime`: The timestamp of the start of the clone process
Monitoring InnoDB Cluster

- **cloneState**: The state of the clone progress
- **currentStage**: The current stage which the clone process has reached
- **currentStageProgress**: The current stage progress as a percentage of completion
- **currentStageState**: The current stage state

Example `Cluster.status()` output, trimmed for brevity:

```
...
"recovery": {
"cloneState": "In Progress",
"currentStage": "FILE COPY",
"currentStageProgress": 61.726837675213865,
"currentStageState": "In Progress"},
"recoveryStatusText": "Cloning in progress",
...
```

- When incremental recovery is being used, the `recovery` field includes a dictionary with the following field:
  - **state**: The state of the `group_replication_recovery` channel

Example output `Cluster.status()`, trimmed for brevity:

```
...
"recovery": {
"state": "ON"
},
...
```

**InnoDB Cluster and Group Replication Protocol**

From MySQL 8.0.16, Group Replication has the concept of a communication protocol for the group, see Section 18.4.1.4, “Setting a Group’s Communication Protocol Version” for background information. The Group Replication communication protocol version usually has to be managed explicitly, and set to accommodate the oldest MySQL Server version that you want the group to support. However, InnoDB Cluster automatically and transparently manages the communication protocol versions of its members, whenever the cluster topology is changed using AdminAPI operations. A cluster always uses the most recent communication protocol version that is supported by all the instances that are currently part of the cluster or joining it.

- When an instance is added to, removed from, or rejoins the cluster, or a rescan or reboot operation is carried out on the cluster, the communication protocol version is automatically set to a version supported by the instance that is now at the earliest MySQL Server version.

- When you carry out a rolling upgrade by removing instances from the cluster, upgrading them, and adding them back into the cluster, the communication protocol version is automatically upgraded when the last remaining instance at the old MySQL Server version is removed from the cluster prior to its upgrade.

To see the communication protocol version being used in a cluster, use the `Cluster.status()` function with the `extended` option enabled. The communication protocol version is returned in the `GRProtocolVersion` field, provided that the cluster has quorum and no cluster members are unreachable.
Monitoring InnoDB Cluster

Checking the MySQL Version on Instances

The following operations can report information about the MySQL Server version running on the instance:

- \texttt{Cluster.status()}
- \texttt{Cluster.describe()}
- \texttt{Cluster.rescan()}

The behavior varies depending on the MySQL Server version of the \texttt{Cluster} object session.

- \texttt{Cluster.status()}

If either of the following requirements are met, a \texttt{version} string attribute is returned for each instance JSON object of the \texttt{topology} object:

- The \texttt{Cluster} object's current session is version 8.0.11 or later.
- The \texttt{Cluster} object's current session is running a version earlier than version 8.0.11 but the \texttt{extended} option is set to 3 (or the deprecated \texttt{queryMembers} is \texttt{true}).

For example on an instance running version 8.0.16:

```
"topology": {
  "ic-1:3306": {
    "address": "ic-1:3306",
    "mode": "R/W",
    "readReplicas": {},
    "role": "HA",
    "status": "ONLINE",
    "version": "8.0.16"
  }
}
```

For example on an instance running version 5.7.24:

```
"topology": {
  "ic-1:3306": {
    "address": "ic-1:3306",
    "mode": "R/W",
    "readReplicas": {},
    "role": "HA",
    "status": "ONLINE",
    "version": "5.7.24"
  }
}
```

- \texttt{Cluster.describe()}

If the \texttt{Cluster} object's current session is version 8.0.11 or later, a \texttt{version} string attribute is returned for each instance JSON object of the \texttt{topology} object.

For example on an instance running version 8.0.16:

```
"topology": [
  {
    "address": "ic-1:3306",
    "label": "ic-1:3306",
    "role": "HA",
    "version": "8.0.16"
  }
]
```

- \texttt{Cluster.rescan()}

3783
21.2.4 Working with Instances

This section describes the AdminAPI operations which apply to instances. You can configure instances before using them with InnoDB Cluster, check the state of an instance, and so on.

- **Using** `dba.checkInstanceConfiguration()`
- **Configuring Instances with** `dba.configureLocalInstance()`
- **Checking Instance State**

**Using `dba.checkInstanceConfiguration()`**

Before creating a production deployment from server instances you need to check that MySQL on each instance is correctly configured. In addition to `dba.configureInstance()`, which checks the configuration as part of configuring an instance, you can use the `dba.checkInstanceConfiguration(instance)` function. This ensures that the *instance* satisfies the [Section 21.2.1, "MySQL InnoDB Cluster Requirements"] without changing any configuration on the instance. This does not check any data that is on the instance, see [Checking Instance State] for more information.

The user which you use to connect to the *instance* must have suitable privileges, for example as configured at [Configuring Users for AdminAPI]. The following demonstrates issuing this in a running MySQL Shell:

```bash
mysql-js> dba.checkInstanceConfiguration('icadmin@ic-1:3306')
Please provide the password for 'icadmin@ic-1:3306': ***
Validating MySQL instance at ic-1:3306 for use in an InnoDB cluster...
This instance reports its own address as ic-1
Clients and other cluster members will communicate with it through this address by default.
If this is not correct, the report_host MySQL system variable should be changed.
Checking whether existing tables comply with Group Replication requirements...
No incompatible tables detected
Checking instance configuration...

Some configuration options need to be fixed:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Current Value</th>
<th>Required Value</th>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>enforce_gtid_consistency</td>
<td>OFF</td>
<td>ON</td>
<td>Update read-only variable and restart the server</td>
</tr>
<tr>
<td>gtid_mode</td>
<td>OFF</td>
<td>ON</td>
<td>Update read-only variable and restart the server</td>
</tr>
<tr>
<td>server_id</td>
<td>1</td>
<td></td>
<td>Update read-only variable and restart the server</td>
</tr>
</tbody>
</table>
```
Please use the `dba.configureInstance()` command to repair these issues.

```json
{
    "config_errors": [
        {
            "action": "restart",
            "current": "OFF",
            "option": "enforce_gtid_consistency",
            "required": "ON"
        },
        {
            "action": "restart",
            "current": "OFF",
            "option": "gtid_mode",
            "required": "ON"
        },
        {
            "action": "restart",
            "current": "1",
            "option": "server_id",
            "required": "".
        }
    ],
    "status": "error"
}
```

Repeat this process for each server instance that you plan to use as part of your cluster. The report generated after running `dba.checkInstanceConfiguration()` provides information about any configuration changes required before you can proceed. The `action` field in the `config_error` section of the report tells you whether MySQL on the instance requires a restart to detect any change made to the configuration file.

### Configuring Instances with `dba.configureLocalInstance()`

Instances which do not support persisting configuration changes automatically (see Persisting Settings) require you to connect to the server, run MySQL Shell, connect to the instance locally and issue `dba.configureLocalInstance()`. This enables MySQL Shell to modify the instance's option file after running the following commands against a remote instance:

- `dba.configureInstance()`
- `dba.createCluster()`
- `Cluster.addInstance()`
- `Cluster.removeInstance()`
- `Cluster.rejoinInstance()`

**Important**

Failing to persist configuration changes to an instance's option file can result in the instance not rejoining the cluster after the next restart.

The recommended method is to log in to the remote machine, for example using SSH, run MySQL Shell as the root user and then connect to the local MySQL server. For example, use the `--uri` option to connect to the local `instance`:

```sh
shell> sudo -i mysqlsh --uri=instance
```
Alternatively use the `\connect` command to log in to the local instance. Then issue `dba.configureInstance(instance)`, where `instance` is the connection information to the local instance, to persist any changes made to the local instance's option file.

```
mysql-js> dba.configureLocalInstance('icadmin@ic-2:3306')
```

Repeat this process for each instance in the cluster which does not support persisting configuration changes automatically. For example if you add 2 instances to a cluster which do not support persisting configuration changes automatically, you must connect to each server and persist the configuration changes required for InnoDB Cluster before the instance restarts. Similarly if you modify the cluster structure, for example changing the number of instances, you need to repeat this process for each server instance to update the InnoDB Cluster metadata accordingly for each instance in the cluster.

**Checking Instance State**

The `cluster.checkInstanceState()` function can be used to verify the existing data on an instance does not prevent it from joining a cluster. This process works by validating the instance's global transaction identifier (GTID) state compared to the GTIDs already processed by the cluster. For more information on GTIDs see Section 17.1.3.1, “GTID Format and Storage”. This check enables you to determine if an instance which has processed transactions can be added to the cluster.

The following demonstrates issuing this in a running MySQL Shell:

```
mysql-js> cluster.checkInstanceState('icadmin@ic-4:3306')
```

The output of this function can be one of the following:

- OK new: the instance has not executed any GTID transactions, therefore it cannot conflict with the GTIDs executed by the cluster
- OK recoverable: the instance has executed GTIDs which do not conflict with the executed GTIDs of the cluster seed instances
- ERROR diverged: the instance has executed GTIDs which diverge with the executed GTIDs of the cluster seed instances
- ERROR lost_transactions: the instance has more executed GTIDs than the executed GTIDs of the cluster seed instances

Instances with an OK status can be added to the cluster because any data on the instance is consistent with the cluster. In other words the instance being checked has not executed any transactions which conflict with the GTIDs executed by the cluster, and can be recovered to the same state as the rest of the cluster instances.

**21.2.5 Working with InnoDB Cluster**

This section explains how to work with InnoDB Cluster, and how to handle common administration tasks.

- Removing Instances from the InnoDB Cluster
- Dissolving an InnoDB Cluster
- Changing a Cluster's Topology

**Removing Instances from the InnoDB Cluster**
You can remove an instance from a cluster at any time should you wish to do so. This can be done with the `Cluster.removeInstance(instance)` method, as in the following example:

```javascript
mysql-js> cluster.removeInstance('root@localhost:3310')

The instance will be removed from the InnoDB cluster. Depending on the instance being the Seed or not, the Metadata session might become invalid. If so, please start a new session to the Metadata Storage R/W instance.

Attempting to leave from the Group Replication group...

The instance 'localhost:3310' was successfully removed from the cluster.
```

You can optionally pass in the `interactive` option to control whether you are prompted to confirm the removal of the instance from the cluster. In interactive mode, you are prompted to continue with the removal of the instance (or not) in case it is not reachable. The `cluster.removeInstance()` operation ensures that the instance is removed from the metadata of all the cluster members which are ONLINE, and the instance itself.

When the instance being removed has transactions which still need to be applied, AdminAPI waits for up to the number of seconds configured by the MySQL Shell `dba.gtidWaitTimeout` option for transactions (GTIDs) to be applied. The MySQL Shell `dba.gtidWaitTimeout` option has a default value of 60 seconds, see Configuring MySQL Shell Options for information on changing the default. If the timeout value defined by `dba.gtidWaitTimeout` is reached when waiting for transactions to be applied and the `force` option is `false` (or not defined) then an error is issued and the remove operation is aborted. If the timeout value defined by `dba.gtidWaitTimeout` is reached when waiting for transactions to be applied and the `force` option is set to `true` then the operation continues without an error and removes the instance from the cluster.

![Important]

The `force` option should only be used with `Cluster.removeInstance(instance)` when you want to ignore any errors, for example unprocessed transactions or an instance being UNREACHABLE, and do not plan to reuse the instance with the cluster. Ignoring errors when removing an instance from the cluster could result in an instance which is not in synchrony with the cluster, preventing it from rejoining the cluster at a later time. Only use the `force` option when you plan to no longer use the instance with the cluster, in all other cases you should always try to recover the instance and only remove it when it is available and healthy, in other words with the status ONLINE.

### Dissolving an InnoDB Cluster

To dissolve an InnoDB Cluster you connect to a read-write instance, for example the primary in a single-primary cluster, and use the `Cluster.dissolve()` command. This removes all metadata and configuration associated with the cluster, and disables Group Replication on the instances. Any data that was replicated between the instances is not removed.

![Important]

There is no way to undo the dissolving of a cluster. To create it again use `dba.createCluster()`.

The `Cluster.dissolve()` operation can only configure instances which are ONLINE or reachable. If members of a cluster cannot be reached by the member where you issued the `Cluster.dissolve()` command you have to decide how the dissolve operation should proceed. If there is any chance you want to rejoin any instances that are identified as missing from the cluster, it is strongly recommended to cancel...
the dissolve operation and first bring the missing instances back online, before proceeding with a dissolve operation. This ensures that all instances can have their metadata updated correctly, and that there is no chance of a split-brain situation. However, if the instances from the cluster which cannot be reached have permanently left the cluster there could be no choice but to force the dissolve operation, which means that the missing instances are ignored and only online instances are affected by the operation.

**Warning**

Forcing the dissolve operation to ignore cluster instances can result in instances which could not be reached during the dissolve operation continuing to operate, creating the risk of a split-brain situation. Only ever force a dissolve operation to ignore missing instances if you are sure there is no chance of the instance coming online again.

In interactive mode, if members of a cluster are not reachable during a dissolve operation then an interactive prompt is displayed, for example:

```
mysql-js> Cluster.dissolve()
The cluster still has the following registered instances:
{
    "clusterName": "testCluster",
    "defaultReplicaSet": {
        "name": "default",
        "topology": [
            {
                "address": "ic-1:3306",
                "label": "ic-1:3306",
                "role": "HA"
            },
            {
                "address": "ic-2:3306",
                "label": "ic-2:3306",
                "role": "HA"
            },
            {
                "address": "ic-3:3306",
                "label": "ic-3:3306",
                "role": "HA"
            }
        ]
    }
}
WARNING: You are about to dissolve the whole cluster and lose the high availability features provided by it. This operation cannot be reverted. All members will be removed from the cluster and replication will be stopped, internal recovery user accounts and the cluster metadata will be dropped. User data will be maintained intact in all instances.

Are you sure you want to dissolve the cluster? [y/N]: y

ERROR: The instance 'ic-2:3306' cannot be removed because it is on a '(MISSING)' state. Please bring the instance back ONLINE and try to dissolve the cluster again. If the instance is permanently not reachable, then you can choose to proceed with the operation and only remove the instance from the Cluster Metadata.

Do you want to continue anyway (only the instance metadata will be removed)? [y/N]: y

Instance 'ic-3:3306' is attempting to leave the cluster... Instance 'ic-1:3306' is attempting to leave the cluster...

WARNING: The cluster was successfully dissolved, but the following instance was skipped: 'ic-2:3306'. Please make sure this instance is permanently unavailable.
or take any necessary manual action to ensure the cluster is fully dissolved.

In this example, the cluster consisted of three instances, one of which was offline when dissolve was issued. The error is caught, and you are given the choice how to proceed. In this case the missing ic-2 instance is ignored and the reachable members have their metadata updated.

When MySQL Shell is running in non-interactive mode, for example when running a batch file, you can configure the behavior of the `Cluster.dissolve()` operation using the `force` option. To force the dissolve operation to ignore any instances which are unreachable, issue:

```
mysql-js> Cluster.dissolve({force: true})
```

Any instances which can be reached are removed from the cluster, and any unreachable instances are ignored. The warnings in this section about forcing the removal of missing instances from a cluster apply equally to this technique of forcing the dissolve operation.

You can also use the `interactive` option with the `Cluster.dissolve()` operation to override the mode which MySQL Shell is running in, for example to make the interactive prompt appear when running a batch script. For example:

```
mysql-js> Cluster.dissolve({interactive: true})
```

The `dba.gtidWaitTimeout` MySQL Shell option configures how long the `Cluster.dissolve()` operation waits for cluster transactions to be applied before removing a target instance from the cluster, but only if the target instance is `ONLINE`. An error is issued if the timeout is reached when waiting for cluster transactions to be applied on any of the instances being removed, except if force: true is used, which skips the error in that case.

**Note**

After issuing `cluster.dissolve()`, any variable assigned to the `Cluster` object is no longer valid.

**Changing a Cluster's Topology**

By default, an InnoDB Cluster runs in single-primary mode, where the cluster has one primary server that accepts read and write queries (R/W), and all of the remaining instances in the cluster accept only read queries (R/O). When you configure a cluster to run in multi-primary mode, all of the instances in the cluster are primaries, which means that they accept both read and write queries (R/W). If a cluster has all of its instances running MySQL server version 8.0.15 or later, you can make changes to the topology of the cluster while the cluster is online. In previous versions it was necessary to completely dissolve and re-create the cluster to make the configuration changes. This uses the group action coordinator exposed through the UDFs described at `Section 18.4.1, “Configuring an Online Group”`, and as such you should observe the rules for configuring online groups.

**Note**

multi-primary mode is considered an advanced mode

Usually a single-primary cluster elects a new primary when the current primary leaves the cluster unexpectedly, for example due to an unexpected halt. The election process is normally used to choose which of the current secondaries becomes the new primary. To override the election process and force a specific server to become the new primary, use the `Cluster.setPrimaryInstance(instance)` function, where `instance` specifies the connection to the instance which should become the new primary. This enables you to configure the underlying Group Replication group to choose a specific instance as the new primary, bypassing the election process.
You can change the mode (sometimes described as the topology) which a cluster is running in between single-primary and multi-primary using the following operations:

- `Cluster.switchToMultiPrimaryMode()`, which switches the cluster to multi-primary mode. All instances become primaries.
- `Cluster.switchToSinglePrimaryMode([instance])`, which switches the cluster to single-primary mode. If `instance` is specified, it becomes the primary and all the other instances become secondaries. If `instance` is not specified, the new primary is the instance with the highest member weight (and the lowest UUID in case of a tie on member weight).

### 21.2.6 Configuring InnoDB Cluster

This section describes how to use AdminAPI to configure an InnoDB Cluster.

- Setting Options for InnoDB Cluster
- Customizing InnoDB Clusters
- Configuring the Election Process
- Configuring Failover Consistency
- Configuring Automatic Rejoin of Instances
- Securing your Cluster
- Creating an Allowlist of Servers

#### Setting Options for InnoDB Cluster

You can check and modify the settings in place for an InnoDB Cluster while the instances are online. To check the current settings of a cluster, use the following operation:

- `Cluster.options()`, which lists the configuration options for the cluster and its instances. A boolean option `all` can also be specified to include information about all Group Replication system variables in the output.

You can configure the options of an InnoDB Cluster at a cluster level or instance level, while instances remain online. This avoids the need to remove, reconfigure and then again add the instance to change InnoDB Cluster options. Use the following operations:

- `Cluster.setOption(option, value)` to change the settings of all cluster instances globally or cluster global settings such as `clusterName`.
- `Cluster.getInstanceOption(instance, option, value)` to change the settings of individual cluster instances

The way which you use InnoDB Cluster options with the operations listed depends on whether the option can be changed to be the same on all instances or not. These options are changeable at both the cluster (all instances) and per instance level:

- `exitStateAction`
- `memberWeight`

This option is changeable at the per instance level only:
• label

These options are changeable at the cluster level only:

• consistency

• expelTimeout

• clusterName

### Customizing InnoDB Clusters

When you create a cluster and add instances to it, values such as the group name, the local address, and the seed instances are configured automatically by AdminAPI. These default values are recommended for most deployments, but advanced users can override the defaults by passing the following options to the `dba.createCluster()` and `Cluster.addInstance()`.

To customize the name of the replication group created by InnoDB Cluster, pass the `groupName` option to the `dba.createCluster()` command. This sets the `group_replication_group_name` system variable. The name must be a valid UUID.

To customize the address which an instance provides for connections from other instances, pass the `localAddress` option to the `dba.createCluster()` and `cluster.addInstance()` commands. Specify the address in the format `host:port`. This sets the `group_replication_local_address` system variable on the instance. The address must be accessible to all instances in the cluster, and must be reserved for internal cluster communication only. In other words do not use this address for communication with the instance.

To customize the instances used as seeds when an instance joins the cluster, pass the `groupSeeds` option to the `dba.createCluster()` and `Cluster.addInstance()` operations. Seed instances are contacted when a new instance joins a cluster and are used to provide data to the new instance. The addresses of the seed instances are specified as a comma separated list such as `host1:port1,host2:port2`. This configures the `group_replication_group_seeds` system variable. When a new instance is added to a cluster, the local address of this instance is automatically appended to the list of group seeds of all online cluster members in order to allow them to use the new instance to rejoin the group if necessary.

#### Note

The instances in the seed list are used according to the order in which they appear in the list. This means that a user specified seed is used first and preferred over automatically added instances.

For more information see the documentation of the system variables configured by these AdminAPI options.

### Configuring the Election Process

You can optionally configure how a single-primary cluster elects a new primary, for example to prefer one instance as the new primary to fail over to. Use the `memberWeight` option and pass it to the `dba.createCluster()` and `Cluster.addInstance()` methods when creating your cluster. The `memberWeight` option accepts an integer value between 0 and 100, which is a percentage weight for automatic primary election on failover. When an instance has a higher percentage number set by `memberWeight`, it is more likely to be elected as primary in a single-primary cluster. When a primary election takes place, if multiple instances have the same `memberWeight` value, the instances are then prioritized based on their server UUID in lexicographical order (the lowest) and by picking the first one.
Configuring InnoDB Cluster

Setting the value of `memberWeight` configures the `group_replication_member_weight` system variable on the instance. Group Replication limits the value range from 0 to 100, automatically adjusting it if a higher or lower value is provided. Group Replication uses a default value of 50 if no value is provided. See Section 18.1.3.1, “Single-Primary Mode” for more information.

For example to configure a cluster where `ic-3` is the preferred instance to fail over to in the event that `ic-1`, the current primary, leaves the cluster unexpectedly use `memberWeight` as follows:

```javascript
dba.createCluster('cluster1', {memberWeight:35})
var mycluster = dba.getCluster()
mycluster.getInstance('icadmin@ic2', {memberWeight:25})
mycluster.getInstance('icadmin@ic3', {memberWeight:50})
```

Configuring Failover Consistency

Group Replication provides the ability to specify the failover guarantees (eventual or “read your writes”) if a primary failover happens in single-primary mode (see Section 18.4.2.2, “Configuring Transaction Consistency Guarantees”). You can configure the failover guarantees of an InnoDB Cluster at creation by passing the `consistency` option (prior to version 8.0.16 this option was the `failoverConsistency` option, which is now deprecated) to the `dba.createCluster()` operation, which configures the `group_replication_consistency` system variable on the seed instance. This option defines the behavior of a new fencing mechanism used when a new primary is elected in a single-primary group. The fencing restricts connections from writing and reading from the new primary until it has applied any pending backlog of changes that came from the old primary (sometimes referred to as “read your writes”). While the fencing mechanism is in place, applications effectively do not see time going backward for a short period of time while any backlog is applied. This ensures that applications do not read stale information from the newly elected primary.

The `consistency` option is only supported if the target MySQL server version is 8.0.14 or later, and instances added to a cluster which has been configured with the `consistency` option are automatically configured to have `group_replication_consistency` the same on all cluster members that have support for the option. The variable default value is controlled by Group Replication and is `EVENTUAL`, change the `consistency` option to `BEFORE_ON_PRIMARY_FAILOVER` to enable the fencing mechanism. Alternatively use `consistency=0` for `EVENTUAL` and `consistency=1` for `BEFORE_ON_PRIMARY_FAILOVER`.

---

**Note**

Using the `consistency` option on a multi-primary InnoDB Cluster has no effect but is allowed because the cluster can later be changed into single-primary mode with the `Cluster.switchToSinglePrimaryMode()` operation.

Configuring Automatic Rejoin of Instances

Instances running MySQL 8.0.16 and later support the Group Replication automatic rejoin functionality, which enables you to configure instances to automatically rejoin the cluster after being expelled. See Section 18.6.6, “Responses to Failure Detection and Network Partitioning” for background information. AdminAPI provides the `autoRejoinTries` option to configure the number of tries instances make to rejoin the cluster after being expelled. By default instances do not automatically rejoin the cluster. You can configure the `autoRejoinTries` option at either the cluster level or for an individual instance using the following commands:

- `dba.createCluster()`
- `Cluster.addInstance()`
- `Cluster.setOption()`
• `Cluster.setInstanceOption()`

The `autoRejoinTries` option accepts positive integer values between 0 and 2016 and the default value is 0, which means that instances do not try to automatically rejoin. When you are using the automatic rejoin functionality, your cluster is more tolerant to faults, especially temporary ones such as unreliable networks. But if quorum has been lost, you should not expect members to automatically rejoin the cluster, because majority is required to rejoin instances.

Instances running MySQL version 8.0.12 and later have the `group_replication_exit_state_action` variable, which you can configure using the AdminAPI `exitStateAction` option. This controls what instances do in the event of leaving the cluster unexpectedly. By default the `exitStateAction` option is `READ_ONLY`, which means that instances which leave the cluster unexpectedly become read-only. If `exitStateAction` is set to `OFFLINE_MODE` (available from MySQL 8.0.18), instances which leave the cluster unexpectedly become read-only and also enter offline mode, where they disconnect existing clients and do not accept new connections (except from clients with administrator privileges). If `exitStateAction` is set to `ABORT_SERVER` then in the event of leaving the cluster unexpectedly, the instance shuts down MySQL, and it has to be started again before it can rejoin the cluster. Note that when you are using the automatic rejoin functionality, the action configured by the `exitStateAction` option only happens in the event that all attempts to rejoin the cluster fail.

There is a chance you might connect to an instance and try to configure it using the AdminAPI, but at that moment the instance could be rejoining the cluster. This could happen whenever you use any of these operations:

• `Cluster.status()`
• `dba.getCluster()`
• `Cluster.rejoinInstance()`
• `Cluster.addInstance()`
• `Cluster.removeInstance()`
• `Cluster.rescan()`
• `Cluster.checkInstanceState()`

These operations might provide extra information while the instance is automatically rejoining the cluster. In addition, when you are using `Cluster.removeInstance()`, if the target instance is automatically rejoining the cluster the operation aborts unless you pass in `force:true`.

**Securing your Cluster**

Server instances can be configured to use secure connections. For general information on using secure connections with MySQL see Section 6.3, “Using Encrypted Connections”. This section explains how to configure a cluster to use encrypted connections. An additional security possibility is to configure which servers can access the cluster, see Creating an Allowlist of Servers.

---

**Important**

Once you have configured a cluster to use encrypted connections you must add the servers to the `ipAllowlist`.

When using `dba.createCluster()` to set up a cluster, if the server instance provides encryption then it is automatically enabled on the seed instance. Pass the `memberSslMode` option to the `dba.createCluster()` method to specify a different SSL mode. The SSL mode of a cluster can only
be set at the time of creation. The memberSslMode option is a string that configures the SSL mode to be used, it defaults to AUTO. The permitted values are DISABLED, REQUIRED, and AUTO. These modes are defined as:

- Setting `createCluster({memberSslMode:'DISABLED'})` ensures SSL encryption is disabled for the seed instance in the cluster.
- Setting `createCluster({memberSslMode:'REQUIRED'})` then SSL encryption is enabled for the seed instance in the cluster. If it cannot be enabled an error is raised.
- Setting `createCluster({memberSslMode:'AUTO'})` (the default) then SSL encryption is automatically enabled if the server instance supports it, or disabled if the server does not support it.

**Note**

When using the commercial version of MySQL, SSL is enabled by default and you might need to configure the allowlist for all instances. See **Creating an Allowlist of Servers**.

When you issue the `cluster.addInstance()` and `cluster.rejoinInstance()` commands, SSL encryption on the instance is enabled or disabled based on the setting found for the seed instance.

When using `createCluster()` with the `adoptFromGR` option to adopt an existing Group Replication group, no SSL settings are changed on the adopted cluster:

- `memberSslMode` cannot be used with `adoptFromGR`.
- If the SSL settings of the adopted cluster are different from the ones supported by the MySQL Shell, in other words SSL for Group Replication recovery and Group Communication, both settings are not modified. This means you are not able to add new instances to the cluster, unless you change the settings manually for the adopted cluster.

MySQL Shell always enables or disables SSL for the cluster for both Group Replication recovery and Group Communication, see Section 18.5.2, “Securing Group Communication Connections with Secure Socket Layer (SSL)”. A verification is performed and an error issued in case those settings are different for the seed instance (for example as the result of a `dba.createCluster()` using `adoptFromGR`) when adding a new instance to the cluster. SSL encryption must be enabled or disabled for all instances in the cluster. Verifications are performed to ensure that this invariant holds when adding a new instance to the cluster.

The `dba.deploySandboxInstance()` command attempts to deploy sandbox instances with SSL encryption support by default. If it is not possible, the server instance is deployed without SSL support. Use the `ignoreSslError` option set to false to ensure that sandbox instances are deployed with SSL support, issuing an error if SSL support cannot be provided. When `ignoreSslError` is true, which is the default, no error is issued during the operation if the SSL support cannot be provided and the server instance is deployed without SSL support.

**Creating an Allowlist of Servers**

When using a cluster's `createCluster()`, `addInstance()`, and `rejoinInstance()` methods you can optionally specify a list of approved servers that belong to the cluster, referred to as an allowlist. By specifying the allowlist explicitly in this way you can increase the security of your cluster because only servers in the allowlist can connect to the cluster. Using the `ipAllowlist` option (previously `ipWhitelist`, now deprecated) configures the `group_replication_ip_allowlist` system variable on the instance. By default, if not specified explicitly, the allowlist is automatically set to the private network addresses that the server has network interfaces on. To configure the allowlist, specify the servers to add.
with the `ipAllowlist` option when using the method. IP addresses must be specified in IPv4 format. Pass the servers as a comma separated list, surrounded by quotes. For example:

```sql
mysql-ja> cluster.addInstance("icadmin@ic-3:3306", {ipAllowlist: "203.0.113.0/24, 198.51.100.110"})
```

This configures the instance to only accept connections from servers at addresses 203.0.113.0/24 and 198.51.100.110. The allowlist can also include host names, which are resolved only when a connection request is made by another server.

**Warning**

Host names are inherently less secure than IP addresses in an allowlist. MySQL carries out FCRDNS verification, which provides a good level of protection, but can be compromised by certain types of attack. Specify host names in your allowlist only when strictly necessary, and ensure that all components used for name resolution, such as DNS servers, are maintained under your control. You can also implement name resolution locally using the hosts file, to avoid the use of external components.

### 21.2.7 Troubleshooting InnoDB Cluster

This section describes how to troubleshoot an InnoDB Cluster.

- Rejoining an Instance to a Cluster
- Restoring a Cluster from Quorum Loss
- Rebooting a Cluster from a Major Outage
- Rescanning a Cluster

**Rejoining an Instance to a Cluster**

If an instance leaves the cluster, for example because it lost connection, and for some reason it could not automatically rejoin the cluster, it might be necessary to rejoin it to the cluster at a later stage. To rejoin an instance to a cluster issue `Cluster.rejoinInstance(instance)`.

**Tip**

If the instance has `super_read_only=ON` then you might need to confirm that AdminAPI can set `super_read_only=OFF`. See Super Read-only and Instances for more information.

In the case where an instance has not had its configuration persisted (see Persisting Settings), upon restart the instance does not rejoin the cluster automatically. The solution is to issue `cluster.rejoinInstance()` so that the instance is added to the cluster again and ensure the changes are persisted. Once the InnoDB Cluster configuration is persisted to the instance’s option file it rejoins the cluster automatically.

If you are rejoining an instance which has changed in some way then you might have to modify the instance to make the rejoin process work correctly. For example, when you restore a MySQL Enterprise Backup backup, the `server_uuid` changes. Attempting to rejoin such an instance fails because InnoDB Cluster instances are identified by the `server_uuid` variable. In such a situation, information about the instance’s old `server_uuid` must be removed from the InnoDB Cluster metadata and then a `Cluster.rescan()` must be executed to add the instance to the metadata using it's new `server_uuid`. For example:

```javascript
cluster.removeInstance("root@instanceWithOldUUID:3306", {force: true})
```
In this case you must pass the `force` option to the `Cluster.removeInstance()` method because the instance is unreachable from the cluster's perspective and we want to remove it from the InnoDB Cluster metadata anyway.

### Restoring a Cluster from Quorum Loss

If an instance (or instances) fail, then a cluster can lose its quorum, which is the ability to vote in a new primary. This can happen when there is a failure of enough instances that there is no longer a majority of the instances which make up the cluster to vote on Group Replication operations. See Section 18.1.4.3, "Fault-tolerance". When a cluster loses quorum you can no longer process transactions with the cluster, or change the cluster's topology, for example by adding, rejoining, or removing instances. However if you have an instance online which contains the InnoDB Cluster metadata, it is possible to restore a cluster with quorum. This assumes you can connect to an instance that contains the InnoDB Cluster metadata, and that instance can contact the other instances you want to use to restore the cluster.

**Important**

This operation is potentially dangerous because it can create a split-brain scenario if incorrectly used and should be considered a last resort. Make absolutely sure that there are no partitions of this group that are still operating somewhere in the network, but not accessible from your location.

Connect to an instance which contains the cluster's metadata, then use the `Cluster.forceQuorumUsingPartitionOf(instance)` operation, which restores the cluster based on the metadata on `instance`, and then all the instances that are `ONLINE` from the point of view of the given instance definition are added to the restored cluster.

```sql
mysql> cluster.forceQuorumUsingPartitionOf("icadmin@ic-1:3306")
```

Restoring replicaset 'default' from loss of quorum, by using the partition composed of [icadmin@ic-1:3306]

Please provide the password for 'icadmin@ic-1:3306': ******

Restoring the InnoDB cluster ... The InnoDB cluster was successfully restored using the partition from the instance 'icadmin@ic-1:3306'.

WARNING: To avoid a split-brain scenario, ensure that all other members of the replicaset are removed or joined back to the group that was restored.

In the event that an instance is not automatically added to the cluster, for example if its settings were not persisted, use `Cluster.rejoinInstance()` to manually add the instance back to the cluster.

The restored cluster might not, and does not have to, consist of all of the original instances which made up the cluster. For example, if the original cluster consisted of the following five instances:

- ic-1
- ic-2
- ic-3
- ic-4
- ic-5

and the cluster experiences a split-brain scenario, with `ic-1`, `ic-2`, and `ic-3` forming one partition while `ic-4` and `ic-5` form another partition. If you connect to `ic-1` and issue
Troubleshooting InnoDB Cluster

Cluster.forceQuorumUsingPartitionOf('icadmin@ic-1:3306') to restore the cluster the resulting cluster would consist of these three instances:

- ic-1
- ic-2
- ic-3

because ic-1 sees ic-2 and ic-3 as ONLINE and does not see ic-4 and ic-5.

Rebooting a Cluster from a Major Outage

If your cluster suffers from a complete outage, you can ensure it is reconfigured correctly using dba.rebootClusterFromCompleteOutage(). This operation takes the instance which MySQL Shell is currently connected to and uses its metadata to recover the cluster. In the event that a cluster's instances have completely stopped, the instances must be started and only then can the cluster be started. For example if the machine a sandbox cluster was running on has been restarted, and the instances were at ports 3310, 3320 and 3330, issue:

```mysql-javascript
mysql-ja> dba.startSandboxInstance(3310)
mysql-ja> dba.startSandboxInstance(3320)
mysql-ja> dba.startSandboxInstance(3330)
```

This ensures the sandbox instances are running. In the case of a production deployment you would have to start the instances outside of MySQL Shell. Once the instances have started, you need to connect to an instance with the GTID superset, which means the instance which had applied the most transaction before the outage. If you are unsure which instance contains the GTID superset, connect to any instance and follow the interactive messages from the dba.rebootClusterFromCompleteOutage(), which detects if the instance you are connected to contains the GTID superset. Reboot the cluster by issuing:

```mysql-javascript
mysql-ja> var cluster = dba.rebootClusterFromCompleteOutage();
```

The dba.rebootClusterFromCompleteOutage() operation then follows these steps to ensure the cluster is correctly reconfigured:

- The InnoDB Cluster metadata found on the instance which MySQL Shell is currently connected to is checked to see if it contains the GTID superset, in other words the transactions applied by the cluster. If the currently connected instance does not contain the GTID superset, the operation aborts with that information. See the subsequent paragraphs for more information.

- If the instance contains the GTID superset, the cluster is recovered based on the metadata of the instance.

- Assuming you are running MySQL Shell in interactive mode, a wizard is run that checks which instances of the cluster are currently reachable and asks if you want to rejoin any discovered instances to the rebooted cluster.

- Similarly, in interactive mode the wizard also detects instances which are currently not reachable and asks if you would like to remove such instances from the rebooted cluster.

If you are not using MySQL Shell's interactive mode, you can use the rejojoinInstances and removeInstances options to manually configure instances which should be joined or removed during the reboot of the cluster.

If you encounter an error such as The active session instance isn't the most updated in comparison with the ONLINE instances of the Cluster's metadata, then the instance you are connected to does not have the GTID superset of transactions applied by the cluster.
Troubleshooting InnoDB Cluster

In this situation, connect MySQL Shell to the instance suggested in the error message and issue `dba.rebootClusterFromCompleteOutage()` from that instance.

**Tip**

To manually detect which instance has the GTID superset rather than using the interactive wizard, check the `gtid_executed` variable on each instance. For example issue:

```sql
mysql-sql> SHOW VARIABLES LIKE 'gtid_executed';
```

The instance which has applied the largest GTID set of transactions contains the GTID superset.

If this process fails, and the cluster metadata has become badly corrupted, you might need to drop the metadata and create the cluster again from scratch. You can drop the cluster metadata using `dba.dropMetadataSchema()`.

**Warning**

The `dba.dropMetadataSchema()` method should only be used as a last resort, when it is not possible to restore the cluster. It cannot be undone.

If you are using MySQL Router with the cluster, when you drop the metadata, all current connections are dropped and new connections are forbidden. This causes a full outage.

**Rescanning a Cluster**

If you make configuration changes to a cluster outside of the AdminAPI commands, for example by changing an instance’s configuration manually to resolve configuration issues or after the loss of an instance, you need to update the InnoDB Cluster metadata so that it matches the current configuration of instances. In these cases, use the `Cluster.rescan()` operation, which enables you to update the InnoDB Cluster metadata either manually or using an interactive wizard. The `Cluster.rescan()` operation can detect new active instances that are not registered in the metadata and add them, or obsolete instances (no longer active) still registered in the metadata, and remove them. You can automatically update the metadata depending on the instances found by the command, or you can specify a list of instance addresses to either add to the metadata or remove from the metadata. You can also update the topology mode stored in the metadata, for example after changing from single-primary mode to multi-primary mode outside of AdminAPI.

The syntax of the command is `Cluster.rescan([options])`. The **options** dictionary supports the following:

- **`interactive`**: boolean value used to disable or enable the wizards in the command execution. Controls whether prompts and confirmations are provided. The default value is equal to MySQL Shell wizard mode, specified by `shell.options.useWizards`.

- **`addInstances`**: list with the connection data of the new active instances to add to the metadata, or “auto” to automatically add missing instances to the metadata. The value “auto” is case-insensitive.

  - Instances specified in the list are added to the metadata, without prompting for confirmation
  - In interactive mode, you are prompted to confirm the addition of newly discovered instances that are not included in the `addInstances` option
  - In non-interactive mode, newly discovered instances that are not included in the `addInstances` option are reported in the output, but you are not prompted to add them

3798
• **removeInstances**: list with the connection data of the obsolete instances to remove from the metadata, or “auto” to automatically remove obsolete instances from the metadata.

- Instances specified in the list are removed from the metadata, without prompting for confirmation.
- In interactive mode, you are prompted to confirm the removal of obsolete instances that are not included in the removeInstances option.
- In non-interactive mode, obsolete instances that are not included in the removeInstances option are reported in the output but you are not prompted to remove them.

• **updateTopologyMode**: boolean value used to indicate if the topology mode (single-primary or multi-primary) in the metadata should be updated (true) or not (false) to match the one being used by the cluster. By default, the metadata is not updated (false).

- If the value is **true** then the InnoDB Cluster metadata is compared to the current mode being used by Group Replication, and the metadata is updated if necessary. Use this option to update the metadata after making changes to the topology mode of your cluster outside of AdminAPI.
- If the value is **false** then InnoDB Cluster metadata about the cluster's topology mode is not updated even if it is different from the topology used by the cluster's Group Replication group.
- If the option is not specified and the topology mode in the metadata is different from the topology used by the cluster's Group Replication group then:
  - In interactive mode, you are prompted to confirm the update of the topology mode in the metadata.
  - In non-interactive mode, if there is a difference between the topology used by the cluster's Group Replication group and the InnoDB Cluster metadata, it is reported and no changes are made to the metadata.
  - When the metadata topology mode is updated to match the Group Replication mode, the auto-increment settings on all instances are updated as described at InnoDB Cluster and Auto-increment.

### 21.2.8 Upgrading an InnoDB Cluster

This section explains how to upgrade your cluster. Much of the process of upgrading an InnoDB Cluster consists of upgrading the instances in the same way as documented at Section 18.7, “Upgrading Group Replication”. This section focuses on the additional considerations for upgrading InnoDB Cluster. Before starting an upgrade, you can use the MySQL Shell Upgrade Checker Utility to verify instances are ready for the upgrade.

From version 8.0.19, if you try to bootstrap MySQL Router against a cluster and it discovers that the metadata version is 0.0.0, this indicates that a metadata upgrade is in progress, and the bootstrap fails. Wait for the metadata upgrade to complete before you try to bootstrap again. When MySQL Router is operating normally (not bootstrapping), if it discovers the metadata version is 0.0.0 (upgrade in progress) it does not proceed with the metadata refresh it was about to begin. Instead, MySQL Router continues using the last metadata it has cached. All the existing user connections are maintained, and any new connections are routed according to the cached metadata. The Metadata refresh restarts when the Metadata version is no longer 0.0.0. In the regular (not bootstrapping) mode, MySQL Router works with both version 1.x.x and 2.x.x metadata, and the version can change between TTL refreshes. This ensures routing continues while the cluster is upgraded.

Although it is possible to have instances in a cluster which run multiple MySQL versions, for example version 5.7 and 8.0, such a mix is not recommended for prolonged use. For example, in a cluster using a mix of versions, if an instance running version 5.7 leaves the cluster and then MySQL Clone is used for
a recovery operation, the instance running the lower version can no longer join the cluster because the `BACKUP_ADMIN` privilege becomes a requirement. Running a cluster with multiple versions is intended as a temporary situation to aid in migration from one version to another, and should not be relied on for long term use.

### 21.2.8.1 Rolling Upgrades

When upgrading the metadata schema of clusters deployed by MySQL Shell versions before 8.0.19, a rolling upgrade of existing MySQL Router instances is required. This process minimizes disruption to applications during the upgrade. The rolling upgrade process must be performed in the following order:

1. Run the latest MySQL Shell version, connect the global session to the cluster and issue `dba.upgradeMetadata()`. This step ensures that any MySQL Router accounts configured for the cluster have their privileges modified to be compatible with the new version. The upgrade function stops if an outdated MySQL Router instance is detected, at which point you can stop the upgrade process in MySQL Shell to resume later.

2. Upgrade any detected out of date MySQL Router instances to the latest version. It is recommended to use the same MySQL Router version as MySQL Shell version.

3. Continue or restart the `dba.upgradeMetadata()` operation to complete the metadata upgrade.

### 21.2.8.2 Upgrading InnoDB Cluster Metadata

As AdminAPI evolves, some releases might require you to upgrade the metadata of existing clusters to ensure they are compatible with newer versions of MySQL Shell. For example, the addition of InnoDB ReplicaSet in version 8.0.19 means that the metadata schema has been upgraded to version 2.0. Regardless of whether you plan to use InnoDB ReplicaSet or not, to use MySQL Shell 8.0.19 or later with a cluster deployed using an earlier version of MySQL Shell, you must upgrade the metadata of your cluster.

**Warning**

Without upgrading the metadata you cannot use MySQL Shell 8.0.19 to change the configuration of a cluster created with earlier versions. For example, you can only perform read operations against the cluster such as `Cluster.status()`, `Cluster.describe()`, and `Cluster.options()`.

This `dba.upgradeMetadata()` operation compares the version of the metadata schema found on the cluster MySQL Shell is currently connected to with the version of the metadata schema supported by this MySQL Shell version. If the installed metadata version is lower, an upgrade process is started. The `dba.upgradeMetadata()` operation then upgrades any automatically created MySQL Router users to have the correct privileges. Manually created MySQL Router users with a name not starting with `mysql_router_` are not automatically upgraded. This is an important step in upgrading your cluster, only then can the MySQL Router application be upgraded. To get information on which of the MySQL Router instances registered with a cluster require the metadata upgrade, issue:

```java
cluster.listRouters({'onlyUpgradeRequired': 'true'})
```

```
{  
  "clusterName": "mycluster",  
  "routers": [  
    {  
      "hostname": "example.com",  
      "lastCheckIn": "2019-11-26 10:10:37",  
      "roPort": 6447,  
      "roXPort": 64470,  
      "rwPort": 6446,  
      "rwXPort": 64460,  
      "version": "8.0.18"
    }
  ]
}
```
Warning
A cluster which is using the new metadata cannot be administered by earlier MySQL Shell versions, for example once you upgrade to version 8.0.19 you can no longer use version 8.0.18 or earlier to administer the cluster.

To upgrade a cluster's metadata, connect MySQL Shell's global session to your cluster and use the `dba.upgradeMetadata()` operation to upgrade the cluster's metadata to the new metadata. For example:

```
mysql-js> \connect user@example.com:3306
mysql-js> dba.upgradeMetadata()
InnoDB Cluster Metadata Upgrade

The cluster you are connected to is using an outdated metadata schema version 1.0.1 and needs to be upgraded to 2.0.0.

Without doing this upgrade, no AdminAPI calls except read only operations will be allowed.

The grants for the MySQL Router accounts that were created automatically when bootstrapping need to be updated to match the new metadata version's requirements.

Updating router accounts...
NOTE: 2 router accounts have been updated.

Upgrading metadata at 'example.com:3306' from version 1.0.1 to version 2.0.0.
Creating backup of the metadata schema...
Step 1 of 1: upgrading from 1.0.1 to 2.0.0...
Removing metadata backup...
Upgrade process successfully finished, metadata schema is now on version 2.0.0
```

If you encounter an error related to the cluster administration user missing privileges, use the `Cluster.setupAdminAccount()` operation with the update option to grant the user the correct privileges. See Configuring Users for AdminAPI.

21.2.8.3 Troubleshooting InnoDB Cluster Upgrades

This section covers trouble shooting the upgrade process.

Handling Host Name Changes

MySQL Shell uses the host value of the provided connection parameters as the target hostname used for AdminAPI operations, namely to register the instance in the metadata (for the `dba.createCluster()` and `Cluster.addInstance()` operations). However, the actual host used for the connection parameters might not match the `hostname` that is used or reported by Group Replication, which uses the value of the `report_host` system variable when it is defined (in other words it is not NULL), otherwise the value of `hostname` is used. Therefore, AdminAPI now follows the same logic to register the target instance in the metadata and as the default value for the `group_replication_local_address` variable on instances, instead of using the host value from the instance connection parameters. When the `report_host` variable is set to empty, Group Replication uses an empty value for the host but AdminAPI (for example in commands such as `dba.checkInstanceConfiguration()`, `dba.configureInstance()`, `dba.createCluster()`, and so on) reports the hostname as the value used which is inconsistent with the value reported by Group Replication. If an empty value is set for the `report_host` system variable, an error is generated. (Bug #28285389)
For a cluster created using a MySQL Shell version earlier than 8.0.16, an attempt to reboot the cluster from a complete outage performed using version 8.0.16 or higher results in this error. This is caused by a mismatch of the Metadata values with the `report_host` or `hostname` values reported by the instances. The workaround is to:

1. Identify which of the instances is the “seed”, in other words the one with the most recent GTID set. The `dba.rebootClusterFromCompleteOutage()` operation detects whether the instance is a seed and the operation generates an error if the current session is not connected to the most up-to-date instance.

2. Set the `report_host` system variable to the value that is stored in the Metadata schema for the target instance. This value is the `hostname:port` pair used in the instance definition upon cluster creation. The value can be consulted by querying the `mysql_innodb_cluster_metadata.instances` table.

For example, suppose a cluster was created using the following sequence of commands:

```
mysql-je> \c clusterAdmin@localhost:3306
mysql-je> dba.createCluster("myCluster")
```

Therefore the hostname value stored in the metadata is “localhost” and for that reason, `report_host` must be set to “localhost” on the seed.

3. Reboot the cluster using only the seed instance. At the interactive prompts do not add the remaining instances to the cluster.

4. Use `Cluster.rescan()` to add the other instances back to the cluster.

5. Remove the seed instance from the cluster

6. Stop mysqld on the seed instance and either remove the forced `report_host` setting (step 2), or replace it with the value previously stored in the Metadata value.

7. Restart the seed instance and add it back to the cluster using `Cluster.addInstance()`

This allows a smooth and complete upgrade of the cluster to the latest MySQL Shell version. Another possibility, that depends on the use-case, is to simply set the value of `report_host` on all cluster members to match what has been registered in the Metadata schema upon cluster creation.

### 21.2.9 Tagging the Metadata

From version 8.0.21, a configurable tag framework is available, to allow the metadata of a Cluster or ReplicaSet to be marked with additional information. Tags make it possible to associate custom key-value pairs to a Cluster, ReplicaSet, or instance. Tags have been reserved for MySQL Router usage, which enable a compatible MySQL Router to support hiding instances from applications. The following tags are reserved for this purpose:

- `_hidden` instructs MySQL Router to exclude the instance from the list of possible destinations for client applications
- `_disconnect_existing_sessions_when_hidden` instructs the router to disconnect existing connections from instances that are marked to be hidden

For more information, see [Removing Instances from Routing](#).

In addition, the tags framework is user configurable. Custom tags can consist of any ASCII character and provide a namespace, which serves as a dictionary of key-value pairs that can be associated with Clusters, ReplicaSets or their specific instances. Tag values may be any JSON value. This enables you to add your own attributes on top of the metadata.
Showing Tags

The `Cluster.options()` operation shows information about the tags assigned to individual cluster instances as well as to the cluster itself. For example, the InnoDB Cluster assigned to `myCluster` could show:

```javascript
mysql-js> myCluster.options()
{
  "cluster": {
    "name": "test1",
    "tags": {
      "ic-1:3306": [
        {
          "option": "_disconnect_existing_sessions_when_hidden",
          "value": true
        },
        {
          "option": "_hidden",
          "value": false
        }
      ],
      "ic-2:3306": [],
      "ic-3:3306": [],
      "global": [
        {
          "option": "location:",
          "value": "US East"
        }
      ]
    
  
  }
}
```

This cluster has a global tag named `location` which has the value `US East`, and instance `ic-1` has been tagged.

Setting Tags on a Cluster Instance

You can set tags at the instance level, which enables you for example to mark an instance as not available, so that applications and router treat it as offline. Use the `Cluster.setInstanceOption(instance, option, value)` operation to set the value of a tag for the instance. The `instance` argument is a connection string to the target instance. The `option` argument must be a string with the format `namespace:option`. The `value` parameter is the value that should be assigned to `option` in the specified `namespace`. If the value is `null`, the `option` is removed from the specified `namespace`. For instances which belong to a cluster, the `setInstanceOption()` operation only accepts the `tag` namespace. Any other namespace results in an `ArgumentError`.

For example, to set the tag `test` to `true` on the `myCluster` instance `ic-1`, issue:

```javascript
mysql-js> myCluster.setInstanceOption(icadmin@ic-1:3306, "tag:test", true);
```

Removing Instances from Routing

When AdminAPI and MySQL Router are working together, they support specific tags that enable you to mark instances as hidden and remove them from routing. MySQL Router then excludes such tagged instances from the routing destination candidates list. This enables you to safely take a server instance offline, so that applications and MySQL Router ignore it, for example while you perform maintenance tasks, such as server upgrade or configuration changes.

When the `_hidden` tag is set to true, this instructs MySQL Router to exclude the instance from the list of possible destinations for client applications. The instance remains online, but is not routed
Tagging the Metadata

to for new incoming connections. The `_disconnect_existing_sessions_when_hidden` tag controls how existing connections to the instance are closed. This tag is assumed to be true, and it instructs any MySQL Routers bootstrapped against the InnoDB Cluster or InnoDB ReplicaSet to disconnect any existing connections from the instance when the `_hidden` tag is true. When `_disconnect_existing_sessions_when_hidden` is false, any existing client connections to the instance are not closed if `_hidden` is true.

Warning

When the `use_gr_notifications` MySQL Router option is enabled, it defaults to 60 seconds. This means that when you set tags, it takes up to 60 seconds for MySQL Router to detect the change. To reduce the waiting time, change `use_gr_notifications` to a lower value.

For example, suppose the you want to remove the `ic-1` instance which is part of an InnoDB Cluster assigned to `myCluster` from the routing destinations. Use the `setInstanceOption()` operation to enable the `_hidden` and `_disconnect_existing_sessions_when_hidden` tags:

```mysql
mysql-ja> myCluster.setInstanceOption(icadmin@ic-1:3306, "tag:_hidden", true);
```

You can verify the change in the metadata by checking the options. For example the change made to `ic-1` would show in the options as:

```javascript
mysql-ja> myCluster.options()
{
    "cluster": {
        "name": "test1",
        "tags": {
            "ic-1:3306": [
                {
                    "option": "_disconnect_existing_sessions_when_hidden",
                    "value": true
                },
                {
                    "option": "_hidden",
                    "value": true
                }
            ],
            "ic-2:3306": [],
            "ic-3:3306": [],
            "global": []
        }
    }
}
```

You can verify that MySQL Router has detected the change in the metadata by viewing the log file. A MySQL Router that has detected the change made to `ic-1` would show a change such as:

```
2020-07-03 16:32:16 metadata_cache INFO [7fa9d164c700] Potential changes detected in cluster 'testCluster' after metadata refresh
2020-07-03 16:32:16 metadata_cache INFO [7fa9d164c700] view_id = 4, (3 members)
2020-07-03 16:32:16 metadata_cache INFO [7fa9d164c700] ic-1:3306 / 33060 - mode=RW
2020-07-03 16:32:16 metadata_cache INFO [7fa9d164c700] ic-1:3306 / 33060 - mode=RO hidden=yes disconnect_when_hidden=yes
2020-07-03 16:32:16 routing INFO [7fa9d164c700] Routing routing:testCluster_x_ro listening on 64470 got request to disconnect invalid connections: metadata change
2020-07-03 16:32:16 routing INFO [7fa9d164c700] Routing routing:testCluster_x_rw listening on 64460 got request to disconnect invalid connections: metadata change
2020-07-03 16:32:16 routing INFO [7fa9d164c700] Routing routing:testCluster_rw listening on 6446 got request to disconnect invalid connections: metadata change
2020-07-03 16:32:16 routing INFO [7fa9d164c700] Routing routing:testCluster_ro listening on 6447 got request to disconnect invalid connections: metadata change
```

To bring the instance back online, use the `setInstanceOption()` operation to remove the tags, and MySQL Router automatically adds the instance back to the routing destinations, and it becomes online for applications. For example:

```javascript
3804
```
Tagging the Metadata

```javascript
myCluster.setInstanceOption(icadmin@ic-1:3306, "tag:_hidden", false);
```

Verify the change in the metadata by checking the options again:

```javascript
myCluster.options()
```

```javascript
{
    "cluster": {
        "name": "test1",
        "tags": {
            "ic-1:3306": [
                {
                    "option": "_disconnect_existing_sessions_when_hidden",
                    "value": true
                },
                {
                    "option": "_hidden",
                    "value": false
                }
            ],
            "ic-2:3306": [],
            "ic-3:3306": [],
            "global": []
        }
    }
}
```

Setting Tags on a Cluster

The `Cluster.setOption(option, value)` operation enables you to change the value of a namespace option for the whole cluster. The `option` argument must be a string with the format `namespace:option`. The `value` parameter is the value to be assigned to `option` in the specified `namespace`. If the value is `null`, the `option` is removed from the specified `namespace`. For Clusters, the `setOption()` operation accepts the `tag` namespace. Any other namespace results in an `ArgumentError`.

There is no requirement for all the instances to be online, only that the cluster has quorum. To tag the InnoDB Cluster assigned to `myCluster` with the location tag set to US East, issue:

```javascript
myCluster.setOption("tag:location", "US East")
```

```javascript
myCluster.options()
```

```javascript
{
    "cluster": {
        "name": "test1",
        "tags": {
            "ic-1:3306": [],
            "ic-2:3306": [],
            "ic-3:3306": [],
            "global": [
                {
                    "option": "location:",
                    "value": "US East"
                }
            ]
        }
    }
}
```

User Defined Tagging

AdminAPI supports the `tag` namespace, where you can store information in the key-value pairs associated with a given Cluster, ReplicaSet or instance. The options under the `tag` namespace are not constrained, meaning you can tag with whatever information you choose, as long as it is a valid MySQL ASCII identifier.
You can use any name and value for a tag, as long as the name follows the following syntax: _ or letters followed by alphanumeric and _ characters.

The namespace option is a colon separated string with the format namespace:option, where namespace is the name of the namespace and option is the actual option name. You can set and remove tags at the instance level, or at the Cluster or ReplicaSet level.

Tag names can have any value as long as it starts with a letter or underscore, optionally followed by alphanumeric and _ characters, for example, ^[a-zA-Z_][0-9a-zA-Z_]*. Only built-in tags are allowed to start with the underscore _ character.

How you use custom tags is up to you. You could set a custom tag on a Cluster to mark the region which it is operating in. For example, you could set a custom tag named location, with a value of EMEA on the cluster.

### 21.2.10 InnoDB Cluster Tips

This section describes some information which is good to know when using InnoDB Cluster.

- Super Read-only and Instances
- Configuring Users for AdminAPI
- InnoDB Cluster and Auto-increment
- InnoDB Cluster and Binary Log Purging
- Resetting Recovery Account Passwords

#### Super Read-only and Instances

Whenever Group Replication stops, the super_read_only variable is set to ON to ensure no writes are made to the instance. When you try to use such an instance with the following AdminAPI commands you are given the choice to set super_read_only=OFF on the instance:

- dba.configureInstance()
- dba.configureLocalInstance()
- dba.dropMetadataSchema()

When AdminAPI encounters an instance which has super_read_only=ON, in interactive mode you are given the choice to set super_read_only=OFF. For example:

```javascript
mysql-jp> var myCluster = dba.dropMetadataSchema()
Are you sure you want to remove the Metadata? [y/N]: y
The MySQL instance at 'localhost:3310' currently has the super_read_only system variable set to protect it from inadvertent updates from applications. You must first unset it to be able to perform any changes to this instance.
For more information see: https://dev.mysql.com/doc/refman/en/server-system-variables.html#sysvar_super_read_only.

Do you want to disable super_read_only and continue? [y/N]: y
```

Metadata Schema successfully removed.

The number of current active sessions to the instance is shown. You must ensure that no applications can write to the instance inadvertently. By answering y you confirm that AdminAPI can write to the instance. If
there is more than one open session to the instance listed, exercise caution before permitting AdminAPI to set `super_read_only=OFF`.

**Configuring Users for AdminAPI**

Working with instances that belong to an InnoDB Cluster or InnoDB ReplicaSet requires that you connect to the instances with a user that has the correct privileges to administer the instances. AdminAPI provides the following ways to administer suitable users:

- In version 8.0.20 and later, use the `setupAdminAccount(user)` operation, which creates or upgrades a MySQL user account with the necessary privileges to administer an InnoDB Cluster or InnoDB ReplicaSet.

- In versions prior to 8.0.20, the preferred method to create users for administration is using the `clusterAdmin` option with the `dba.configureInstance()` operation.

For more information, see [Creating User Accounts for Administration](#). If you want to manually configure an administration user, that user requires the following privileges, all with `GRANT OPTION`:

- Global privileges on `*.*` for `RELOAD`, `SHUTDOWN`, `PROCESS`, `FILE`, `SELECT`, `SUPER`, `REPLICATION_SLAVE`, `REPLICATION_CLIENT`, `REPLICATION_APPLIER`, `CREATE_USER`, `SYSTEM_VARIABLES_ADMIN`, `PERSIST_RO_VARIABLES_ADMIN`, `BACKUP_ADMIN`, `CLONE_ADMIN`, and `EXECUTE`.

  **Note**  
  `SUPER` includes the following required privileges: `SYSTEM_VARIABLES_ADMIN`, `SESSION_VARIABLES_ADMIN`, `REPLICATION_SLAVE_ADMIN`, `GROUP_REPLICATION_ADMIN`, `ROLE_ADMIN`.

- Schema specific privileges for `mysql_innodb_cluster_metadata.*`, `mysql_innodb_cluster_metadata_bkp.*`, and `mysql_innodb_cluster_metadata_previous.*` are `ALTER`, `ALTER_ROUTINE`, `CREATE`, `CREATE_ROUTINE`, `CREATE_TEMPORARY_TABLES`, `CREATE_VIEW`, `DELETE`, `DROP`, `EVENT`, `EXECUTE`, `INDEX`, `INSERT`, `LOCK_TABLES`, `REFERENCES`, `SHOW_VIEW`, `TRIGGER`, `UPDATE`; and for `mysql.*` are `INSERT`, `UPDATE`, `DELETE`.

  **Note**  
  This list of privileges is based on the current version of MySQL Shell. The privileges are subject to change between releases. Therefore the recommended way to administer accounts is using the operations described at [Creating User Accounts for Administration](#).

If only read operations are needed, for example to create a user for monitoring purposes, an account with more restricted privileges can be used. To give the user `your_user` the privileges needed to monitor InnoDB Cluster issue:

```sql
GRANT SELECT ON mysql_innodb_cluster_metadata.* TO your_user@'\%';
GRANT SELECT ON performance_schema.global_status TO your_user@'\%';
GRANT SELECT ON performance_schema.replication_applier_configuration TO your_user@'\%';
GRANT SELECT ON performance_schema.replication_applier_status TO your_user@'\%';
GRANT SELECT ON performance_schema.replication_applier_status_by_coordinator TO your_user@'\%';
GRANT SELECT ON performance_schema.replication_applier_status_by_worker TO your_user@'\%';
GRANT SELECT ON performance_schema.replication_connection_configuration TO your_user@'\%';
GRANT SELECT ON performance_schema.replication_connection_status TO your_user@'\%';
GRANT SELECT ON performance_schema.replication_group_member_stats TO your_user@'\%';
GRANT SELECT ON performance_schema.replication_group_members TO your_user@'\%';
```
For more information, see Section 13.7.1, “Account Management Statements”.

**InnoDB Cluster and Auto-increment**

When you are using an instance as part of an InnoDB Cluster, the `auto_increment_increment` and `auto_increment_offset` variables are configured to avoid the possibility of auto increment collisions for multi-primary clusters up to a size of 9 (the maximum supported size of a Group Replication group). The logic used to configure these variables can be summarized as:

- If the group is running in single-primary mode, then set `auto_increment_increment` to 1 and `auto_increment_offset` to 2.
- If the group is running in multi-primary mode, then when the cluster has 7 instances or less set `auto_increment_increment` to 7 and `auto_increment_offset` to `1 + server_id % 7`. If a multi-primary cluster has 8 or more instances set `auto_increment_increment` to the number of instances and `auto_increment_offset` to `1 + server_id % the number of instances`.

**InnoDB Cluster and Binary Log Purging**

In MySQL 8, the binary log is automatically purged (as defined by `binlog_expire_logs_seconds`). This means that a cluster which has been running for a longer time than `binlog_expire_logs_seconds` could eventually not contain an instance with a complete binary log that contains all of the transactions applied by the instances. This could result in instances needing to be provisioned automatically, for example using MySQL Enterprise Backup, before they could join the cluster. Instances running 8.0.17 and later support the MySQL Clone plugin, which resolves this issue by providing an automatic provisioning solution which does not rely on incremental recovery, see Section 21.2.2.2, “Using MySQL Clone with InnoDB Cluster”. Instances running a version earlier than 8.0.17 only support incremental recovery, and the result is that, depending on which version of MySQL the instance is running, instances might have to be provisioned automatically. Otherwise operations which rely on distributed recovery, such as `Cluster.addInstance()` and so on might fail.

On instances running earlier versions of MySQL the following rules are used for binary log purging:

- Instances running a version earlier than 8.0.1 have no automatic binary log purging because the default value of `expire_logs_days` is 0.
- Instances running a version later than 8.0.1 but earlier than 8.0.4 purge the binary log after 30 days because the default value of `expire_logs_days` is 30.
- Instances running a version later than 8.0.10 purge the binary log after 30 days because the default value of `binlog_expire_logs_seconds` is 2592000 and the default value of `expire_logs_days` is 0.

Thus, depending on how long the cluster has been running binary logs could have been purged and you might have to provision instances manually. Similarly, if you manually purged binary logs you could encounter the same situation. Therefore you are strongly advised to upgrade to a version of MySQL later than 8.0.17 to take full advantage of the automatic provisioning provided by MySQL Clone for distributed recovery, and to minimize downtime while provisioning instances for your InnoDB Cluster.

**Resetting Recovery Account Passwords**

From version 8.0.18, you can use the `Cluster.resetRecoveryAccountsPassword()` operation to reset the passwords for the internal recovery accounts created by InnoDB Cluster, for example to follow a custom password lifetime policy. Use the `Cluster.resetRecoveryAccountsPassword()` operation to reset the passwords for all internal recovery accounts used by the cluster. The operation sets a new
random password for the internal recovery account on each instance which is online. If an instance cannot be reached, the operation fails. You can use the `force` option to ignore such instances, but this is not recommended, and it is safer to bring the instance back online before using this operation. This operation only applies to the passwords created by InnoDB cluster and cannot be used to update manually created passwords.

**Note**

The user which executes this operation must have all the required administer privileges, in particular `CREATE USER`, in order to ensure that the password of recovery accounts can be changed regardless of the password verification-required policy. In other words, independent of whether the `password_require_current` system variable is enabled or not.

### 21.2.11 Known Limitations

This section describes the known limitations of InnoDB Cluster. As InnoDB Cluster uses Group Replication, you should also be aware of its limitations, see Section 18.9.2, "Group Replication Limitations".

- If a session type is not specified when creating the global session, MySQL Shell provides automatic protocol detection which attempts to first create a `NodeSession` and if that fails it tries to create a `ClassicSession`. With an InnoDB cluster that consists of three server instances, where there is one read-write port and two read-only ports, this can cause MySQL Shell to only connect to one of the read-only instances. Therefore it is recommended to always specify the session type when creating the global session.

- When adding non-sandbox server instances (instances which you have configured manually rather than using `dba.deploySandboxInstance()`) to a cluster, MySQL Shell is not able to persist any configuration changes in the instance's configuration file. This leads to one or both of the following scenarios:

  1. The Group Replication configuration is not persisted in the instance's configuration file and upon restart the instance does not rejoin the cluster.

  2. The instance is not valid for cluster usage. Although the instance can be verified with `dba.checkInstanceConfiguration()`, and MySQL Shell makes the required configuration changes in order to make the instance ready for cluster usage, those changes are not persisted in the configuration file and so are lost once a restart happens.

If only a happens, the instance does not rejoin the cluster after a restart.

If b also happens, and you observe that the instance did not rejoin the cluster after a restart, you cannot use the recommended `dba.rebootClusterFromCompleteOutage()` in this situation to get the cluster back online. This is because the instance loses any configuration changes made by MySQL Shell, and because they were not persisted, the instance reverts to the previous state before being configured for the cluster. This causes Group Replication to stop responding, and eventually the command times out.

To avoid this problem it is strongly recommended to use `dba.configureInstance()` before adding instances to a cluster in order to persist the configuration changes.

- The use of the `--defaults-extra-file` option to specify an option file is not supported by InnoDB Cluster server instances. InnoDB Cluster only supports a single option file on instances and no extra option files are supported. Therefore for any operation working with the instance's option file the main one should be specified. If you want to use multiple option files you have to configure the files manually and make sure they are updated correctly considering the precedence rules of the use of multiple...
option files and ensuring that the desired settings are not incorrectly overwritten by options in an extra unrecognized option file.

- Attempting to use instances with a host name that resolves to an IP address which does not match a real network interface fails with an error that
  This instance reports its own address as the hostname. This is not supported by the Group Replication communication layer. On Debian based instances this means instances cannot use addresses such as user@localhost because localhost resolves to a non-existent IP (such as 127.0.1.1). This impacts on using a sandbox deployment, which usually uses local instances on a single machine.

  A workaround is to configure the report_host system variable on each instance to use the actual IP address of your machine. Retrieve the IP of your machine and add report_host=IP of your machine to the my.cnf file of each instance. You need to ensure the instances are then restarted to make the change.

- When executing dba.createCluster() or adding an instance to an existing InnoDB Cluster by running Cluster.addInstance(), the following errors are logged to MySQL error log:

```
2020-02-10T10:53:43.727246Z 12 [ERROR] [MY-011685] [Repl] Plugin group_replication reported: 'The group name option is mandatory'
2020-02-10T10:53:43.727292Z 12 [ERROR] [MY-011660] [Repl] Plugin group_replication reported: 'Unable to start Group Replication on boot'
```

  These messages are harmless and relate to the way AdminAPI starts Group Replication.

- When using a sandbox deployment, each sandbox instance uses a copy of the mysqld binary found in the $PATH in the local mysql-sandboxes directory. If the version of mysqld changes, for example after an upgrade, sandboxes based on the previous version fail to start. This is because the sandbox binary is outdated compared to the dependencies found under the basedir. Sandbox instances are not designed for production, therefore they are considered transient and are not supported for upgrade.

  A workaround for this issue is to manually copy the upgraded mysqld binary into the bin directory of each sandbox. Then start the sandbox by issuing dba.startSandboxInstance(). The operation fails with a timeout, and the error log contains:

```
2020-03-26T11:43:12.969131Z 5 [System] [MY-013381] [Server] Server upgrade from '80019' to '80020' started.
2020-03-26T11:44:03.543082Z 5 [System] [MY-013381] [Server] Server upgrade from '80019' to '80020' completed.
```

  Although the operation seems to fail with a timeout, the sandbox has started successfully.

## 21.3 MySQL InnoDB ReplicaSet

This section documents InnoDB ReplicaSet, added in version 8.0.19.

### 21.3.1 Introducing InnoDB ReplicaSet

The AdminAPI includes support for InnoDB ReplicaSet, that enables you to administer a set of MySQL instances running asynchronous GTID-based replication in a similar way to InnoDB Cluster. An InnoDB ReplicaSet consists of a single primary and multiple secondaries (traditionally referred to as the MySQL replication source and replicas). You administer your ReplicaSets using a ReplicaSet object and the AdminAPI operations, for example to check the status of the InnoDB ReplicaSet, and manually failover to a new primary in the event of a failure. Similar to InnoDB Cluster, MySQL Router supports bootstrapping against InnoDB ReplicaSet, which means you can automatically configure MySQL Router to use your InnoDB ReplicaSet without having to manually configure it. This makes InnoDB ReplicaSet a quick and easy way to get MySQL replication and MySQL Router up and running, making it well suited to scaling
Deploying InnoDB ReplicaSet

out reads, and provides manual failover capabilities in use cases that do not require the high availability offered by InnoDB Cluster.

In addition to deploying an InnoDB ReplicaSet using AdminAPI, you can adopt an existing replication setup. AdminAPI configures the InnoDB ReplicaSet based on the topology of the replication setup. Once the replication setup has been adopted, you administer it in the same way as an InnoDB ReplicaSet deployed from scratch. This enables you to take advantage of AdminAPI and MySQL Router without the need to create a new ReplicaSet. For more information see Section 21.3.4, “Adopting an Existing Replication Set Up”.

InnoDB ReplicaSet Limitations

An InnoDB ReplicaSet has several limitations compared to an InnoDB Cluster and thus, it is recommended that you deploy InnoDB Cluster wherever possible. Generally, an InnoDB ReplicaSet on its own does not provide high availability. Among the limitations of InnoDB ReplicaSet are:

- No automatic failover. In events where the primary becomes unavailable, a failover needs to be triggered manually using AdminAPI before any changes are possible again. However, secondary instances remain available for reads.
- No protection from partial data loss due to an unexpected halt or unavailability. Transactions that have not yet been applied by the time of the halt could become lost.
- No protection against inconsistencies after an unexpected exit or unavailability. If a failover promotes a secondary while the former primary is still available (for example due to a network partition), inconsistencies could be introduced because of the split-brain.

21.3.2 Deploying InnoDB ReplicaSet

You deploy InnoDB ReplicaSet in a similar way to InnoDB Cluster. First you configure some MySQL server instances, the minimum is two instances, see Section 21.1, “MySQL AdminAPI”. One functions as the primary, in this tutorial rs-1; the other instance functions as the secondary, in this tutorial rs-2; which replicates the transactions applied by the primary. This is the equivalent of the source and replica known from asynchronous MySQL replication. Then you connect to one of the instances using MySQL Shell, and create a ReplicaSet. Once the ReplicaSet has been created, you can add instances to it.

InnoDB ReplicaSet is compatible with sandbox instances, which you can use to deploy locally, for example for testing purposes. See Deploying Sandbox Instances for instructions. However, this tutorial assumes you are deploying a production InnoDB ReplicaSet, where each instance is running on a different host.

InnoDB ReplicaSet Prerequisites

To use InnoDB ReplicaSet you should be aware of the following prerequisites:

- Only instances running MySQL version 8.0 and later are supported
- Only GTID-based replication is supported, binary log file position replication is not compatible with InnoDB ReplicaSet
- Only Row Based Replication (RBR) is supported, Statement Based Replication (SBR) is unsupported
- Replication filters are not supported
- Unmanaged replication channels are not allowed on any instance
- A ReplicaSet consists of maximum one primary instance, and one or multiple secondaries are supported. Although there is no limit to the number of secondaries you can add to a ReplicaSet, each
Deploying InnoDB ReplicaSet

MySQL Router connected to a ReplicaSet has to monitor each instance. Therefore, the more instances that are added to a ReplicaSet, the more monitoring has to be done.

- The ReplicaSet must be entirely managed by MySQL Shell. For example, the replication account is created and managed by MySQL Shell. Making configuration changes to the instance outside of MySQL Shell, for example using SQL statements directly to change the primary, is not supported. Always use MySQL Shell to work with InnoDB ReplicaSet.

AdminAPI and InnoDB ReplicaSet enable you to work with MySQL replication without a deep understanding of the underlying concepts. However, for background information see Chapter 17, Replication.

Configuring InnoDB ReplicaSet Instances

Use `dba.configureReplicaSetInstance(instance)` to configure each instance you want to use in your replica set. MySQL Shell can either connect to an instance and then configure it, or you can pass in `instance` to configure a specific remote instance. To use an instance in a ReplicaSet, it must support persisting settings. See Persisting Settings.

When you connect to the instance for administration tasks you require a user with suitable privileges. The preferred method to create users to administer a ReplicaSet is using the `setupAdminAccount()` operation. See Creating User Accounts for Administration. Alternatively, the `dba.configureReplicaSetInstance()` operation can optionally create an administrator account, if the `clusterAdmin` option is provided. The account is created with the correct set of privileges required to manage InnoDB ReplicaSet.

Tip
The administrator account must have the same user name and password across all instances of the same cluster or replica set.

To configure the instance at `rs-1:3306`, with a cluster administrator named `rsadmin` issue:

```
mysql-js> dba.configureReplicaSetInstance('root@rs-1:3306', {clusterAdmin: '*rsadmin'@'rs-1%'});
```

The interactive prompt requests the password required by the specified user. To configure the instance MySQL Shell is currently connected to, you can specify a null instance definition. For example issue:

```
mysql-js> dba.configureReplicaSetInstance('', {clusterAdmin: '*rsadmin'@'rs-1%'});
```

The interactive prompt requests the password required by the specified user. This checks the instance which MySQL Shell is currently connected to is valid for use in an InnoDB ReplicaSet. Settings which are not compatible with InnoDB ReplicaSet are configured if possible. The cluster administrator account is created with the privileges required for InnoDB ReplicaSet.

Creating an InnoDB ReplicaSet

Once you have configured your instances, connect to an instance and use `dba.createReplicaSet()` to create a managed ReplicaSet that uses MySQL asynchronous replication, as opposed to MySQL Group Replication used by InnoDB Cluster. The MySQL instance which MySQL Shell is currently connected to is used as the initial primary of the ReplicaSet.

The `dba.createReplicaSet()` operation performs several checks to ensure that the instance state and configuration are compatible with a managed ReplicaSet and if so, a metadata schema is initialized on the instance. If you want to check the operation but not actually make any changes to the instances, use the `dryRun` option. This checks and shows what actions the MySQL Shell would take to create the ReplicaSet. If the ReplicaSet is created successfully, a `ReplicaSet` object is returned. Therefore it is best practice to...
assign the returned `ReplicaSet` to a variable. This enables you to work with the ReplicaSet, for example by calling the `ReplicaSet.status()` operation. To create a ReplicaSet named `example` on instance `rs-1` and assign it to the `rs` variable, issue:

```javascript
mysql-js> \connect root@rs-1:3306
...
mysql-js> var rs = dba.createReplicaSet("example")
A new replicaset with instance 'rs-1:3306' will be created.

* Checking MySQL instance at rs-1:3306
This instance reports its own address as rs-1:3306
rs-1:3306: Instance configuration is suitable.

* Updating metadata...
ReplicaSet object successfully created for rs-1:3306.
Use rs.add_instance() to add more asynchronously replicated instances to this replicaset and rs.status() to check its status.

To verify that the operation was successful, you work with the returned `ReplicaSet` object. For example this provides the `ReplicaSet.status()` operation, which displays information about the ReplicaSet. We already assigned the returned `ReplicaSet` to the variable `rs`, so issue:

```javascript
mysql-js> rs.status()
{
    "replicaSet": {
        "name": "example",
        "primary": "rs-1:3306",
        "status": "AVAILABLE",
        "statusText": "All instances available.",
        "topology": {
            "rs-1:3306": {
                "address": "rs-1:3306",
                "instanceRole": "PRIMARY",
                "mode": "R/W",
                "status": "ONLINE"
            }
        },
        "type": "ASYNC"
    }
}
```

This output shows that the ReplicaSet named `example` has been created, and that the primary is `rs-1`. Currently there is only one instance, and the next task is to add more instances to the ReplicaSet.

### 21.3.3 Adding Instances to a ReplicaSet

When you have created a ReplicaSet you can use the `ReplicaSet.addInstance()` operation to add an instance as a read-only secondary replica of the current primary of the ReplicaSet. The primary of the ReplicaSet must be reachable and available during this operation. MySQL Replication is configured between the added instance and the primary, using an automatically created MySQL account with a random password. Before the instance can be an operational secondary, it must be in synchrony with the primary. This process is called recovery, and InnoDB ReplicaSet supports different methods which you configure with the `recoveryMethod` option.

For an instance to be able to join a ReplicaSet, various prerequisites must be satisfied. They are automatically checked by `ReplicaSet.addInstance()`, and the operation fails if any issues are found. Use `dba.configureReplicaSetInstance()` to validate and configure binary log and replication related options before adding an instance. MySQL Shell connects to the target instance using the same user name and password used to obtain the `ReplicaSet` handle object. All instances of the ReplicaSet are expected to have the same administrator account with the same grants and passwords. A custom
Adding Instances to a ReplicaSet

Administrator account with the required grants can be created while an instance is configured with `dba.configureReplicaSetInstance()`. See Configuring InnoDB ReplicaSet Instances.

Recovery Methods for InnoDB ReplicaSet

When new instances are added to an InnoDB ReplicaSet they need to be provisioned with the existing data which it contains. This can be done automatically using one of the following methods:

- **MySQL Clone**, which takes a snapshot from an online instance and then replaces any data on the new instance with the snapshot. MySQL Clone is well suited for joining a new blank instance to an InnoDB ReplicaSet. It does not rely on there being a complete binary log of all transactions applied by the InnoDB ReplicaSet.

  Warning
  All previous data on the instance being added is destroyed during a clone operation. All MySQL settings not stored in tables are however maintained.

- **incremental recovery**, which relies on MySQL Replication to apply all missing transactions on the new instance. If the amount of transactions missing on the new instance is small, this can be the fastest method. However, this method is only usable if at least one online instance in the InnoDB ReplicaSet has a complete binary log, containing the entire transaction history of the InnoDB ReplicaSet. This method cannot be used if the binary logs have been purged from all members or if the binary log was only enabled after databases already existed in the instance. If there is a very large amount of transactions to apply, there could be a long delay before the instance can join the InnoDB ReplicaSet.

When an instance is joining a ReplicaSet, recovery is used in much the same way that it is in InnoDB Cluster. MySQL Shell attempts to automatically select a suitable recovery method. If it is not possible to choose a method safely, MySQL Shell prompts for what to use. For more information, see Section 21.2.2.2, “Using MySQL Clone with InnoDB Cluster”. This section covers the differences when adding instances to a ReplicaSet.

Adding Instances to a ReplicaSet

Use the `ReplicaSet.addInstance(instance)` operation to add secondary instances to the `ReplicaSet`. You specify the `instance` as a URI-like connection string. The user you specify must have the privileges required and must be the same on all instances in the ReplicaSet, see Configuring InnoDB ReplicaSet Instances.

For example, to add the instance at `rs-2` with user `rsadmin`, issue:

```sql
mysql-javascript> rs.addInstance('rsadmin@rs-2')
Adding instance to the replicaset...
* Performing validation checks
This instance reports its own address as rsadmin@rs-2
rsadmin@rs-2: Instance configuration is suitable.
* Checking async replication topology...
* Checking transaction state of the instance...
```

NOTE: The target instance 'rsadmin@rs-2' has not been pre-provisioned (GTID set is empty). The Shell is unable to decide whether replication can completely recover its state. The safest and most convenient way to provision a new instance is through automatic clone provisioning, which will completely overwrite the state of 'rsadmin@rs-2' with a physical snapshot from an existing
Adding Instances to a ReplicaSet

replicaset member. To use this method by default, set the 'recoveryMethod' option to 'clone'.

WARNING: It should be safe to rely on replication to incrementally recover the state of the new instance if you are sure all updates ever executed in the replicaset were done with GTIDs enabled, there are no purged transactions and the new instance contains the same GTID set as the replicaset or a subset of it. To use this method by default, set the 'recoveryMethod' option to 'incremental'. Please select a recovery method [C]lone/[I]ncremental recovery/[A]bort (default Clone):

In this case we did not specify the recovery method, so the operation advises you on how to best proceed. In this example we choose the clone option because we do not have any existing transactions on the instance joining the ReplicaSet. Therefore there is no risk of deleting data from the joining instance.

Please select a recovery method [C]lone/[I]ncremental recovery/[A]bort (default Clone): C

* Updating topology
* Waiting for clone process of the new member to complete. Press ^C to abort the operation.
* Waiting for clone to finish...
NOTE: rsadmin@rs-2 is being cloned from rsadmin@rs-1
** Stage DROP DATA: Completed
** Clone Transfer
FILE COPY ############################################################## 100% Completed
PAGE COPY ############################################################## 100% Completed
REDO COPY ############################################################## 100% Completed
** Stage RECOVERY:
NOTE: rsadmin@rs-2 is shutting down...

* Waiting for server restart... ready
* rsadmin@rs-2 has restarted, waiting for clone to finish...
* Clone process has finished: 59.63 MB transferred in about 1 second (~1.00 B/s)

** Configuring rsadmin@rs-2 to replicate from rsadmin@rs-1
** Waiting for new instance to synchronize with PRIMARY...

The instance 'rsadmin@rs-2' was added to the replicaset and is replicating from rsadmin@rs-1.

Assuming the instance is valid for InnoDB ReplicaSet usage, recovery proceeds. In this case the newly joining instance uses MySQL Clone to copy all of the transactions it has not yet applied from the primary, then it joins the ReplicaSet as an online instance. To verify, use the ReplicaSet.status() operation:

```
rs.status()
```

```json
{
  "replicaSet": {
    "name": "example",
    "primary": "rs-1:3306",
    "status": "AVAILABLE",
    "statusText": "All instances available.",
    "topology": {
      "rs-1:3306": {
        "address": "rs-1:3306",
        "instanceRole": "PRIMARY",
        "mode": "R/W",
        "status": "ONLINE"
      },
      "rs-2:3306": {
        "address": "rs-2:3306",
        "instanceRole": "SECONDARY",
        "mode": "R/O",
        "replication": {
          "applierStatus": "APPLIED_ALL",
          "applierThreadState": "Replica has read all relay log; waiting for more updates",
          "receiverStatus": "ON",
          "receiverThreadState": "Waiting for source to send event",
          "replicationLag": null
        },
        "status": "ONLINE"
    }
  }
}
```
This output shows that the ReplicaSet named `example` now consists of two MySQL instances, and that the primary is `rs-1`. Currently there is one secondary instance at `rs-2`, which is a replica of the primary. The ReplicaSet is online, which means that the primary and secondary are in synchrony. At this point the ReplicaSet is ready to process transactions.

If you want to override the interactive MySQL Shell mode trying to choose the most suitable recovery method, use the `recoveryMethod` option to configure how the instance recovers the data required to be able to join the ReplicaSet. For more information, see Section 21.2.2.2, “Using MySQL Clone with InnoDB Cluster”.

### 21.3.4 Adopting an Existing Replication Set Up

As an alternative to creating a new InnoDB ReplicaSet, you can also adopt an existing replication setup using the `adoptFromAR` option with `dba.createReplicaSet()`. The replication setup is scanned, and if it is compatible with the InnoDB ReplicaSet Prerequisites, AdminAPI creates the necessary metadata. Once the replication setup has been adopted, you can only use AdminAPI to administer the InnoDB ReplicaSet.

To convert an existing replication setup to an InnoDB ReplicaSet connect to the primary, also referred to as the source. The replication topology is automatically scanned and validated, starting from the instance MySQL Shell's global session is connected to. The configuration of all instances is checked during adoption, to ensure they are compatible with InnoDB ReplicaSet usage. All replication channels must be active and their transaction sets as verified through GTID sets must be consistent. Instances are assumed to have the same state or be able to converge. All instances that are part of the topology are automatically added to the ReplicaSet. The only changes made by this operation to an adopted ReplicaSet are the creation of the metadata schema. Existing replication channels are not changed during adoption, although they could be changed during subsequent primary switch operations.

For example, to adopt a replication topology consisting of the MySQL server instances on `example1` and `example2` to an InnoDB ReplicaSet, connect to the primary at `example1` and issue:

```sql
mysql-js> rs = dba.createReplicaSet('testadopt', {'adoptFromAR':1})
A new replicaset with the topology visible from 'example1:3306' will be created.
* Scanning replication topology...
** Scanning state of instance example1:3306
** Scanning state of instance example2:3306
* Discovering async replication topology starting with example1:3306
Discovered topology:
- example1:3306: uuid=00371d66-3c45-11ea-804b-080027337932 read_only=no
- example2:3306: uuid=59e4f26e-3c3c-11ea-8b65-080027337932 read_only=no

```
Working with InnoDB ReplicaSet

Replication state of example2:3306 is OK.
Validations completed successfully.
  * Updating metadata...

ReplicaSet object successfully created for example1:3306.
Use rs.add_instance() to add more asynchronously replicated instances to
this replicaset and rs.status() to check its status.

Once the InnoDB ReplicaSet has been adopted, you can use it in the same way that you would use a
ReplicaSet which was created from scratch. From this point you must administer the InnoDB ReplicaSet
using only AdminAPI.

21.3.5 Working with InnoDB ReplicaSet

You work with an InnoDB ReplicaSet in much the same way as you would work with an InnoDB Cluster.
For example as seen in Adding Instances to a ReplicaSet, you assign a ReplicaSet object to a variable
and call operations that administer the ReplicaSet, such as ReplicaSet.addInstance() to add
instances, which is the equivalent of Cluster.addInstance() in InnoDB Cluster. Thus, much of the
documentation at Section 21.2.5, “Working with InnoDB Cluster” also applies to InnoDB ReplicaSet. The
following operations are supported by ReplicaSet objects:

• You get online help for ReplicaSet objects, and the AdminAPI, using \help ReplicaSet or
  ReplicaSet.help() and \help dba or dba.help(). See Using AdminAPI.

• You can quickly check the name of a ReplicaSet object using either name or
  ReplicaSet.getName(). For example the following are equivalent:

  mysql-js> rs.name
  example
  mysql-js> rs.getName()
  example

• You check information about a ReplicaSet using the ReplicaSet.status() operation, which supports
  the extended option to get different levels of detail. For example:

  • the default for extended is 0, a regular level of details. Only basic information about the status of the
    instance and replication is included, in addition to non-default or unexpected replication settings and
    status.

  • setting extended to 1 includes Metadata Version, server UUID and the raw information used to derive
    the status of the instance, size of the applier queue, value of system variables that protect against
    unexpected writes and so on.

  • setting extended to 2 includes important replication related configuration settings, such as encrypted
    connections, worker threads, replication delay and heartbeat delay.

  See Checking a cluster's Status with Cluster.status().

• You change the instances being used for a ReplicaSet using the ReplicaSet.addInstance() and
  ReplicaSet.removeInstance() operations. See Adding Instances to a ReplicaSet, and Removing
  Instances from the InnoDB Cluster.

• Use ReplicaSet.rejoinInstance() to add an instance that was removed back to a ReplicaSet, for
  example after a failover.

• Use the ReplicaSet.setPrimaryInstance() operation to safely perform a change of the primary of
  a ReplicaSet to another instance. See Planned Changes of the ReplicaSet Primary.
Use the `ReplicaSet.forcePrimaryInstance()` operation to perform a forced failover of the primary. See Forcing the Primary Instance in a ReplicaSet.

You work with the MySQL Router instances which have been bootstrapped against a ReplicaSet in exactly the same way as with InnoDB Cluster. See Working with a Cluster's Routers for information on `ReplicaSet.listRouters()` and `ReplicaSet.removeRouterMetadata()`. For specific information on using MySQL Router with InnoDB ReplicaSet see Using ReplicaSets with MySQL Router.

For more information, see the linked InnoDB Cluster sections.

The following operations are specific to InnoDB ReplicaSet and can only be called against a ReplicaSet object:

**Planned Changes of the ReplicaSet Primary**

Use the `ReplicaSet.setPrimaryInstance()` operation to safely perform a change of the primary of a ReplicaSet to another instance. The current primary is demoted to a secondary and made read-only, while the promoted instance becomes the new primary and is made read-write. All other secondary instances are updated to replicate from the new primary. MySQL Router instances which have been bootstrapped against the ReplicaSet automatically start redirecting read-write clients to the new primary.

For a safe change of the primary to be possible, all replica set instances must be reachable by MySQL Shell and have consistent `GTID_EXECUTED` sets. If the primary is not available, and there is no way to restore it, a forced failover might be the only option instead, see Forcing the Primary Instance in a ReplicaSet.

During a change of primary, the promoted instance is synchronized with the old primary, ensuring that all transactions present on the primary are applied before the topology change is committed. If this synchronization step takes too long or is not possible on any of the secondary instances, the operation is aborted. In such a situation, these problematic secondary instances must be either repaired or removed from the ReplicaSet for the fail over to be possible.

**Forcing the Primary Instance in a ReplicaSet**

Unlike InnoDB Cluster, which supports automatic failover in the event of an unexpected failure of the primary, InnoDB ReplicaSet does not have automatic failure detection or a consensus based protocol such as that provided by Group Replication. If the primary is not available, a manual failover is required. An InnoDB ReplicaSet which has lost its primary is effectively read-only, and for any write changes to be possible a new primary must be chosen. In the event that you cannot connect to the primary, and you cannot use `ReplicaSet.setPrimaryInstance()` to safely perform a switchover to a new primary as described at Planned Changes of the ReplicaSet Primary, use the `ReplicaSet.forcePrimaryInstance()` operation to perform a forced failover of the primary. This is a last resort operation that must only be used in a disaster type scenario where the current primary is unavailable and cannot be restored in any way.

**Warning**

A forced failover is a potentially destructive action and must be used with caution.

If a target instance is not given (or is null), the most up-to-date instance is automatically selected and promoted to be the new primary. If a target instance is provided, it is promoted to a primary, while other reachable secondary instances are switched to replicate from the new primary. The target instance must have the most up-to-date `GTID_EXECUTED` set among reachable instances, otherwise the operation fails.

A failover is different from a planned primary change because it promotes a secondary instance without synchronizing with or updating the old primary. That has the following major consequences:
• Any transactions that had not yet been applied by a secondary at the time the old primary failed are lost.

• If the old primary is actually still running and processing transactions, there is a split-brain and the datasets of the old and new primaries diverge.

If the last known primary is still reachable, the `ReplicaSet.forcePrimaryInstance()` operation fails, to reduce the risk of split-brain situations. But it is the administrator's responsibility to ensure that the old primary it is not reachable by the other instances to prevent or minimize such scenarios.

After a forced failover, the old primary is considered invalid by the new primary and can no longer be part of the replica set. If at a later date you find a way to recover the instance, it must be removed from the ReplicaSet and re-added as a new instance. If there were any secondary instances that could not be switched to the new primary during the failover, they are also considered invalid.

Data loss is possible after a failover, because the old primary might have had transactions that were not yet replicated to the secondary being promoted. Moreover, if the instance that was presumed to have failed is still able to process transactions, for example because the network where it is located is still functioning but unreachable from MySQL Shell, it continues diverging from the promoted instances. Recovering once transaction sets on instances have diverged requires manual intervention and could not be possible in some situations, even if the failed instances can be recovered. In many cases, the fastest and simplest way to recover from a disaster that required a forced failover is by discarding such diverged transactions and re-provisioning a new instance from the newly promoted primary.

### InnoDB ReplicaSet Locking

From version 8.0.20, AdminAPI uses a locking mechanism to avoid different operations from performing changes on an InnoDB ReplicaSet simultaneously. Previously, different instances of MySQL Shell could connect to an InnoDB ReplicaSet at the same time and execute AdminAPI operations simultaneously. This could lead to inconsistent instance states and errors, for example if `ReplicaSet.addInstance()` and `ReplicaSet.setPrimaryInstance()` were executed in parallel.

The InnoDB ReplicaSet operations have the following locking:

• `dba.upgradeMetadata()` and `dba.createReplicaSet()` are globally exclusive operations. This means that if MySQL Shell executes these operations on an InnoDB ReplicaSet, no other operations can be executed against the InnoDB ReplicaSet or any of its instances.

• `ReplicaSet.forcePrimaryInstance()` and `ReplicaSet.setPrimaryInstance()` are operations that change the primary. This means that if MySQL Shell executes these operations against an InnoDB ReplicaSet, no other operations which change the primary, or instance change operations can be executed until the first operation completes.

• `ReplicaSet.addInstance()`, `ReplicaSet.rejoinInstance()`, and `ReplicaSet.removeInstance()` are operations that change an instance. This means that if MySQL Shell executes these operations on an instance, the instance is locked for any further instance change operations. However, this lock is only at the instance level and multiple instances in an InnoDB ReplicaSet can each execute one of this type of operation simultaneously. In other words, at most one instance change operation can be executed at a time, per instance in the InnoDB ReplicaSet.

• `dba.getReplicaSet()` and `ReplicaSet.status()` are InnoDB ReplicaSet read operations and do not require any locking.

In practice, if you try to execute an InnoDB ReplicaSet related operation while another operation that cannot be executed concurrently is still running, you get an error indicating that a lock on a needed resource failed to be acquired. In this case, you should wait for the running operation which holds the lock to complete, and only then try to execute the next operation. For example:
MySQL Router

```javascript
rs.addInstance("admin@rs2:3306");
```

ERROR: The operation cannot be executed because it failed to acquire the lock on instance 'rs1:3306'. Another operation requiring exclusive access to the instance is still in progress, please wait for it to finish and try again.

ReplicaSet.addInstance: Failed to acquire lock on instance 'rs1:3306' (MYSQLSH 51400)

In this example, the `ReplicaSet.addInstance()` operation failed because the lock on the primary instance (`rs1:3306`) could not be acquired, for example because a `ReplicaSet.setPrimaryInstance()` operation (or other similar operation) was still running.

Tagging ReplicaSets

Tagging is supported by ReplicaSets, and their instances. For the purpose of tagging, ReplicaSets support the `setOption()`, `setInstanceOption()` and `options()` operations. These operations function in generally the same way as their `Cluster` equivalents. For more information, see Section 21.2.9, "Tagging the Metadata". This section documents the differences in working with tags for ReplicaSets.

**Important**

There are no other options which can be configured for ReplicaSets and their instances. For ReplicaSets, the options documented at `Setting Options for InnoDB Cluster` are not supported. The only supported option is the tagging described here.

The `ReplicaSet.options()` operation shows information about the tags assigned to individual ReplicaSet instances as well as to the ReplicaSet itself.

The `option` argument of `ReplicaSet.setOption()` and `ReplicaSet.setInstanceOption()` only support options with the `tag` namespace and throw an error otherwise.

The `ReplicaSet.setInstanceOption(instance, option, value)` and `ReplicaSet.setOption(option, value)` operations behave in the same way as the `Cluster` equivalent operations.

**Note**

Setting or deleting a `Y` tag on a ReplicaSet does not override the `Y` tag value stored in the metadata for instances of that ReplicaSet.

There are no differences in hiding instances as described at `Removing Instances from Routing`. For example, to hide the ReplicaSet instance `rs-1`, issue:

```javascript
myReplicaSet.setInstanceOption(icadmin@rs-1:3306, "tag:_hidden", true);
```

A MySQL Router that has been bootstrapped against the ReplicaSet detects the change and removes the `rs-1` instance from the routing destinations.

21.4 MySQL Router

This section describes how to integrate MySQL Router with InnoDB Cluster and InnoDB ReplicaSet. For background information on MySQL Router, see MySQL Router 8.0.

21.4.1 Bootstrapping MySQL Router

You bootstrap MySQL Router against an InnoDB ReplicaSet or InnoDB Cluster to automatically configure routing. The bootstrap process is a specific way of running MySQL Router, which does not start the
usual routing and instead configures the mysqlrouter.conf file based on the metadata. To bootstrap MySQL Router at the command-line, pass in the --bootstrap option when you start the mysqlrouter command, and it retrieves the topology information from the metadata and configures routing connections to the server instances. Alternatively, on Windows use the MySQL Installer to bootstrap MySQL Router, see MySQL Router Configuration with MySQL Installer. Once MySQL Router has been bootstrapped, client applications then connect to the ports it publishes. MySQL Router automatically redirects client connections to the instances based on the incoming port, for example 6646 is used by default for read-write connections using classic MySQL protocol. In the event of a topology change, for example due to an unexpected failure of an instance, MySQL Router detects the change and adjusts the routing to the remaining instances automatically. This removes the need for client applications to handle failover, or to be aware of the underlying topology. For more information, see Routing for MySQL InnoDB Cluster.

**Note**

Do not attempt to configure MySQL Router manually to redirect to the server instances. Always use the --bootstrap option as this ensures that MySQL Router takes its configuration from the metadata. See Cluster Metadata and State.

**Configuring the MySQL Router User**

When MySQL Router connects to an InnoDB Cluster or InnoDB ReplicaSet, it requires a user account which has the correct privileges. From MySQL Router version 8.0.19 this internal user can be specified using the --account option. In previous versions, MySQL Router created internal accounts at each bootstrap of the cluster, which could result in a number of accounts building up over time. From MySQL Shell version 8.0.20, you can use AdminAPI to set up the user account required for MySQL Router. Use the setupRouterAccount (user, [options]) operation to create a MySQL user account or upgrade an existing account so that it can be used by MySQL Router to operate on an InnoDB Cluster or InnoDB ReplicaSet. This is the recommended method of configuring MySQL Router with InnoDB Cluster and InnoDB ReplicaSet.

To add a new MySQL Router account named myRouter1 to the InnoDB Cluster referenced by the variable testCluster, issue:

```bash
mysqlsh> testCluster.setupRouterAccount(myRouter1)
```

In this case, no domain is specified and so the account is created with the wildcard (%) character, which ensures that the created user can connect from any domain. To limit the account to only be able to connect from the example.com domain, issue:

```bash
mysqlsh> testCluster.setupRouterAccount(myRouter1@example.com)
```

The operation prompts for a password, and then sets up the MySQL Router user with the correct privileges. If the InnoDB Cluster or InnoDB ReplicaSet has multiple instances, the created MySQL Router user is propagated to all of the instances.

When you already have a MySQL Router user configured, for example if you were using a version prior to 8.0.20, you can use the setupRouterAccount () operation to reconfigure the existing user. In this case, pass in the update option set to true. For example, to reconfigure the myOldRouter user, issue:

```bash
mysqlsh> testCluster.setupRouterAccount(myOldRouter, {'update':1})
```

**Deploying MySQL Router**

The recommended deployment of MySQL Router is on the same host as the application. When using a sandbox deployment, everything is running on a single host, therefore you deploy MySQL Router to the same host. When using a production deployment, we recommend deploying one MySQL Router instance to each machine used to host one of your client applications. It is also possible to deploy MySQL Router to
a common machine through which your application instances connect. For more information, see Installing MySQL Router.

To bootstrap MySQL Router based on an InnoDB Cluster or InnoDB ReplicaSet, you need the URI-like connection string to an online instance. Run the `mysqlrouter` command and provide the `--bootstrap=instance` option, where `instance` is the URI-like connection string to an online instance. MySQL Router connects to the instance and uses the included metadata cache plugin to retrieve the metadata, consisting of a list of server instance addresses and their role. For example:

```shell
mysqlrouter --bootstrap icadmin@ic-1:3306 --user=mysqlrouter
```

You are prompted for the instance password and encryption key for MySQL Router to use. This encryption key is used to encrypt the instance password used by MySQL Router to connect to the cluster. The ports you can use for client connections are also displayed. For additional bootstrap related options, see Bootstrapping Options.

Tip
---

At this point MySQL Router has not been started so that it would route connections. Bootstrapping is a separate process.

The MySQL Router bootstrap process creates a `mysqlrouter.conf` file, with the settings based on the metadata retrieved from the address passed to the `--bootstrap` option, in the above example `icadmin@ic-1:3306`. Based on the metadata retrieved, MySQL Router automatically configures the `mysqlrouter.conf` file, including a `metadata_cache` section. If you are using MySQL Router 8.0.14 and later, the `--bootstrap` option automatically configures MySQL Router to track and store active MySQL metadata server addresses at the path configured by `dynamic_state`. This ensures that when MySQL Router is restarted it knows which MySQL metadata server addresses are current. For more information, see the `dynamic_state` documentation.

In earlier MySQL Router versions, metadata server information was defined during MySQL Router's initial bootstrap operation and stored statically as `bootstrap_server_addresses` in the configuration file, which contained the addresses for all server instances in the cluster. For example:

```ini
[metadata_cache:prodCluster]
router_id=1
bootstrap_server_addresses=mysql://icadmin@ic-1:3306,mysql://icadmin@ic-2:3306,mysql://icadmin@ic-3:3306
user=mysql_router1_jy95yozko3k2
metadata_cluster=prodCluster
ttl=300
```

Tip
---

If using MySQL Router 8.0.13 or earlier, when you change the topology of a cluster by adding another server instance after you have bootstrapped MySQL Router, you need to update `bootstrap_server_addresses` based on the updated metadata. Either restart MySQL Router using the `--bootstrap` option, or manually edit the `bootstrap_server_addresses` section of the `mysqlrouter.conf` file and restart MySQL Router.

The generated MySQL Router configuration creates TCP ports which you use to connect to the cluster. By default, ports for communicating with the cluster using both classic MySQL protocol and X Protocol are created. To use X Protocol the server instances must have X Plugin installed and configured, which is the default for MySQL 8.0 and later. The default available TCP ports are:

- **6446** - for classic MySQL protocol read-write sessions, which MySQL Router redirects incoming connections to primary server instances.
• **6447** - for classic MySQL protocol read-only sessions, which MySQL Router redirects incoming connections to one of the secondary server instances.

• **64460** - for X Protocol read-write sessions, which MySQL Router redirects incoming connections to primary server instances.

• **64470** - for X Protocol read-only sessions, which MySQL Router redirects incoming connections to one of the secondary server instances.

Depending on your MySQL Router configuration the port numbers might be different to the above. For example if you use the `--conf-base-port` option, or the `group_replication_single_primary_mode` variable. The exact ports are listed when you start MySQL Router.

The way incoming connections are redirected depends on the underlying topology being used. For example, when using a single-primary cluster, by default MySQL Router publishes a X Protocol and a classic MySQL protocol port, which clients connect to for read-write sessions and which are redirected to the cluster's single primary. With a multi-primary cluster read-write sessions are redirected to one of the primary instances in a round-robin fashion. For example, this means that the first connection to port 6446 would be redirected to the ic-1 instance, the second connection to port 6446 would be redirected to the ic-2 instance, and so on. For incoming read-only connections MySQL Router redirects connections to one of the secondary instances, also in a round-robin fashion. To modify this behavior see the `routing_strategy` option.

Once bootstrapped and configured, start MySQL Router. If you used a system wide install with the `--bootstrap` option then issue:

```shell>
mysqlrouter &
```

If you installed MySQL Router to a directory using the `--directory` option, use the `start.sh` script found in the directory you installed to. Alternatively set up a service to start MySQL Router automatically when the system boots, see Starting MySQL Router. You can now connect a MySQL client, such as MySQL Shell to one of the incoming MySQL Router ports as described above and see how the client gets transparently connected to one of the server instances.

```shell>
mysqlsh --uri root@localhost:6442
```

To verify which instance you are actually connected to, simply issue an SQL query against the `port` status variable.

```mysql-je> \sql
Switching to SQL mode... Commands end with ;
mysql-je> select @@port;
+--------+
| @@port |
| 3310   |
+--------+
```

**Using ReplicaSets with MySQL Router**

You can use MySQL Router 8.0.19 and later to bootstrap against an InnoDB ReplicaSet, see Section 21.4, “MySQL Router”. The only difference in the generated MySQL Router configuration file is the addition of the `cluster_type` option. When MySQL Router is bootstrapped against a ReplicaSet, the generated configuration file includes:

```
cluster_type=rs
```

When you use MySQL Router with InnoDB ReplicaSet, be aware that:
• The read-write port of MySQL Router directs client connections to the primary instance of the ReplicaSet
• The read-only port of MySQL Router direct client connections to a secondary instance of the ReplicaSet, although it could also direct them to the primary
• MySQL Router obtains information about the ReplicaSet's topology from the primary instance
• MySQL Router automatically recovers when the primary instance becomes unavailable and a different instance is promoted

You work with the MySQL Router instances which have been bootstrapped against a ReplicaSet in exactly the same way as with InnoDB Cluster. See Working with a Cluster's Routers for information on ReplicaSet.listRouters() and ReplicaSet.removeRouterMetadata().

21.4.2 Using AdminAPI and MySQL Router

This section explains how to use MySQL Router and AdminAPI.

Testing InnoDB Cluster High Availability

To test if InnoDB Cluster high availability works, simulate an unexpected halt by killing an instance. The cluster detects the fact that the instance left the cluster and reconfigures itself. Exactly how the cluster reconfigures itself depends on whether you are using a single-primary or multi-primary cluster, and the role the instance serves within the cluster.

In single-primary mode:

• If the current primary leaves the cluster, one of the secondary instances is elected as the new primary, with instances prioritized by the lowest server_uuid. MySQL Router redirects read-write connections to the newly elected primary.

• If a current secondary leaves the cluster, MySQL Router stops redirecting read-only connections to the instance.

For more information see Section 18.1.3.1, “Single-Primary Mode”.

In multi-primary mode:

• If a current "R/W" instance leaves the cluster, MySQL Router redirects read-write connections to other primaries. If the instance which left was the last primary in the cluster then the cluster is completely gone and you cannot connect to any MySQL Router port.

For more information see Section 18.1.3.2, “Multi-Primary Mode”.

There are various ways to simulate an instance leaving a cluster, for example you can forcibly stop the MySQL server on an instance, or use the AdminAPI dba.killSandboxInstance() if testing a sandbox deployment. In this example assume there is a single-primary sandbox cluster deployment with three server instances and the instance listening at port 3310 is the current primary. Simulate the instance leaving the cluster unexpectedly:

mysql-js> dba.killSandboxInstance(3310)

The cluster detects the change and elects a new primary automatically. Assuming your session is connected to port 6446, the default read-write classic MySQL protocol port, MySQL Router should detect the change to the cluster's topology and redirect your session to the newly elected primary. To verify this, switch to SQL mode in MySQL Shell using the \sql command and select the instance's port variable to
check which instance your session has been redirected to. Notice that the first SELECT statement fails as the connection to the original primary was lost. This means the current session has been closed, MySQL Shell automatically reconnects for you and when you issue the command again the new port is confirmed.

```
mysql-js> \sql
Switching to SQL mode... Commands end with ;
mysql-sql> SELECT @@port;
ERROR: 2013 (HY000): Lost connection to MySQL server during query
The global session got disconnected.
Attempting to reconnect to 'root@localhost:6446'...
The global session was successfully reconnected.
mysql-sql> SELECT @@port;
+--------+
| @@port |
+--------+
|   3330 |
+--------+
1 row in set (0.00 sec)
```

In this example, the instance at port 3330 has been elected as the new primary. This shows that the InnoDB Cluster provided us with automatic failover, that MySQL Router has automatically reconnected us to the new primary instance, and that we have high availability.

**Working with a Cluster’s Routers**

You can bootstrap multiple instances of MySQL Router against a cluster or ReplicaSet. From version 8.0.19, to show a list of all registered MySQL Router instances, issue:

```
Cluster.listRouters()
```

The result provides information about each registered MySQL Router instance, such as its name in the metadata, the hostname, ports, and so on. For example, issue:

```
mysql-js> Cluster.listRouters()
{
  "clusterName": "example",
  "routers": {
    "ic-1:3306": {
      "hostname": "ic-1:3306",
      "lastCheckIn": "2020-01-16 11:43:45",
      "roPort": 6447,
      "roXPort": 64470,
      "rwPort": 6446,
      "rwXPort": 64460,
      "version": "8.0.19"
    }
  }
}
```

The returned information shows:

- The name of the MySQL Router instance.
- Last check-in timestamp, which is generated by a periodic ping from the MySQL Router stored in the metadata
- Hostname where the MySQL Router instance is running
- Read-Only and Read-Write ports which the MySQL Router publishes for classic MySQL protocol connections
- Read-Only and Read-Write ports which the MySQL Router publishes for X Protocol connections
• Version of this MySQL Router instance. The support for returning `version` was added in 8.0.19. If this operation is run against an earlier version of MySQL Router, the version field is `null`.

Additionally, the `Cluster.listRouters()` operation can show a list of instances that do not support the metadata version supported by MySQL Shell. Use the `onlyUpgradeRequired` option, for example by issuing `Cluster.listRouters({'onlyUpgradeRequired':'true'})`. The returned list shows only the MySQL Router instances registered with the `Cluster` which require an upgrade of their metadata. See Section 21.2.8.2, “Upgrading InnoDB Cluster Metadata”.

MySQL Router instances are not automatically removed from the metadata, so for example as you bootstrap more instances the InnoDB Cluster metadata contains a growing number of references to instances. To remove a registered MySQL Router instance from a cluster's metadata, use the `Cluster.removeRouterMetadata(router)` operation, added in version 8.0.19. Use the `Cluster.listRouters()` operation to get the name of the MySQL Router instance you want to remove, and pass it in as `router`. For example suppose your MySQL Router instances registered with a cluster were:

```
mysql-js> Cluster.listRouters()

   "clusterName": "testCluster",
   "routers": {
     "myRouter1": {
       "hostname": "example1.com",
       "lastCheckIn": null,
       "routerId": "1",
       "roPort": "6447",
       "rwPort": "6446"
       "version": null
     },
     "myRouter2": {
       "hostname": "example2.com",
       "lastCheckIn": "2019-11-27 16:25:00",
       "routerId": "3",
       "roPort": "6447",
       "rwPort": "6446"
       "version": "8.0.19"
     }
   }
}
```

Based on the fact that the instance named “myRouter1” has `null` for “lastCheckIn” and “version”, we decide to remove this old instance from the metadata by issuing:

```
mysql-js> cluster.removeRouterMetadata('myRouter1')
```

The MySQL Router instance specified is unregistered from the cluster by removing it from the InnoDB Cluster metadata.

## 21.5 AdminAPI MySQL Sandboxes

This section explains how to set up a sandbox deployment with AdminAPI. Initially deploying and using local sandbox instances of MySQL is a good way to start your exploration of AdminAPI. You can fully test out the functionality locally, prior to deployment on your production servers. AdminAPI has built-in functionality for creating sandbox instances that are correctly configured to work with InnoDB Cluster and InnoDB ReplicaSet in a locally deployed scenario.

**Important**

Sandbox instances are only suitable for deploying and running on your local machine for testing purposes. In a production environment the MySQL
Deploying Sandbox Instances

Server instances are deployed to various host machines on the network. See Section 21.2.2, “Deploying a Production InnoDB Cluster” for more information.

Unlike a production deployment, where you work with instances and specify them by a connection string, sandbox instances run locally on the same machine as which you are running MySQL Shell. Therefore, to specify a sandbox instance you supply the port number which the MySQL sandbox instance is listening on.

- Deploying Sandbox Instances
- Managing Sandbox Instances

Deploying Sandbox Instances

The MySQL AdminAPI adds the `dba` global variable to MySQL Shell, which provides functions for administration of sandbox instances. In this example setup, you create three sandbox instances using `dba.deploySandboxInstance(port_number)`. To deploy a new sandbox instance which is bound to port 3310, issue:

```
mysql-js> dba.deploySandboxInstance(3310)
```

The argument passed to `deploySandboxInstance()` is the TCP port number where the MySQL Server instance listens for connections. By default the sandbox is created in a directory named `$HOME/mysql-sandboxes/port` on Unix systems. For Microsoft Windows systems the directory is `%userprofile%\MySQL\mysql-sandboxes\port`.

The root user's password for the instance is prompted for.

**Important**

Each sandbox instance uses the root user and password, and it must be the same on all sandbox instances which should work together. This is not recommended in production.

To deploy another sandbox server instance, repeat the steps followed for the sandbox instance at port 3310, choosing different port numbers for each instance. For each additional sandbox instance issue:

```
mysql-js> dba.deploySandboxInstance(port_number)
```

To follow this tutorial, use port numbers 3310, 3320 and 3330 for the three sandbox server instances. Issue:

```
mysql-js> dba.deploySandboxInstance(3320)
mysql-js> dba.deploySandboxInstance(3330)
```

To change the directory which sandboxes are stored in, for example to run multiple sandboxes on one host for testing purposes, use the MySQL Shell `sandboxDir` option. For example to use a sandbox in the `/home/user/sandbox1` directory, issue:

```
mysql-js> shell.options.sandboxDir='/home/user/sandbox1'
```

All subsequent sandbox related operations are then executed against the instances found at `/home/user/sandbox1`.

When you deploy sandboxes, MySQL Shell searches for the `mysqld` binary which it then uses to create the sandbox instance. You can configure where MySQL Shell searches for the `mysqld` binary by configuring the `PATH` environment variable. This can be useful to test a new version of MySQL locally before deploying it to production. For example, to use a `mysqld` binary at the path `/home/user/mysql-latest/bin/mysqld` issue:
PATH=/home/user/mysql-latest/bin/mysqld:$PATH

Then run MySQL Shell from the terminal where the PATH environment variable is set. Any sandboxes you deploy then use the mysqld binary found at the configured path.

Managing Sandbox Instances

Once a sandbox instance is running, it is possible to change its status at any time using the following:

• To stop a sandbox instance use `dba.stopSandboxInstance(instance)`. This stops the instance gracefully, unlike `dba.killSandboxInstance(instance)`.

• To start a sandbox instance use `dba.startSandboxInstance(instance)`.

• To kill a sandbox instance use `dba.killSandboxInstance(instance)`. This stops the instance without gracefully stopping it and is useful in simulating unexpected halts.

• To delete a sandbox instance use `dba.deleteSandboxInstance(instance)`.

This completely removes the sandbox instance from your file system.

</table>
MySQL NDB Cluster is a high-availability, high-redundancy version of MySQL adapted for the distributed computing environment. The most recent NDB Cluster release series uses version 8 of the NDB storage engine (also known as NDBCLUSTER) to enable running several computers with MySQL servers and other software in a cluster. NDB Cluster 8.0, now available as a General Availability (GA) release beginning with version 8.0.19, incorporates version 8.0 of the NDB storage engine. NDB Cluster 7.6 and NDB Cluster 7.5, still available as GA releases, use versions 7.6 and 7.5 of NDB, respectively. Previous GA releases still available for use in production, NDB Cluster 7.4 and NDB Cluster 7.3, incorporate NDB versions 7.4 and 7.3, respectively. NDB 7.2 and older release series are no longer supported or maintained.

Support for the NDB storage engine is not included in standard MySQL Server 8.0 binaries built by Oracle. Instead, users of NDB Cluster binaries from Oracle should upgrade to the most recent binary release of NDB Cluster for supported platforms—these include RPMs that should work with most Linux distributions.
NDB Cluster 8.0 users who build from source should use the sources provided for MySQL 8.0 and build with the options required to provide NDB support. (Locations where the sources can be obtained are listed later in this section.)

Important
MySQL NDB Cluster does not support InnoDB Cluster, which must be deployed using MySQL Server 8.0 with the InnoDB storage engine as well as additional applications that are not included in the NDB Cluster distribution. MySQL Server 8.0 binaries cannot be used with MySQL NDB Cluster. For more information about deploying and using InnoDB Cluster, see Chapter 21, Using MySQL AdminAPI, Section 22.1.6, “MySQL Server Using InnoDB Compared with NDB Cluster”, discusses differences between the NDB and InnoDB storage engines.

This chapter contains information about NDB Cluster 8.0 releases through 8.0.22. NDB Cluster 8.0 is now available (beginning with NDB 8.0.19) as a General Availability release, and recommended for new deployments; the latest available release is NDB 8.0.22. NDB Cluster 7.6 and 7.5 are previous GA releases still supported in production; for information about NDB Cluster 7.6, see What is New in NDB Cluster 7.6. For similar information about NDB Cluster 7.5, see What is New in NDB Cluster 7.5. NDB Cluster 7.4 and 7.3 are previous GA releases still supported in production, although we recommend that new deployments for production use NDB Cluster 8.0; see MySQL NDB Cluster 7.3 and NDB Cluster 7.4.

Supported Platforms. NDB Cluster is currently available and supported on a number of platforms. For exact levels of support available for on specific combinations of operating system versions, operating system distributions, and hardware platforms, please refer to https://www.mysql.com/support/supportedplatforms/cluster.html.

Availability. NDB Cluster binary and source packages are available for supported platforms from https://dev.mysql.com/downloads/cluster/.

NDB Cluster release numbers. NDB 8.0 follows the same release pattern as the MySQL Server 8.0 series of releases, beginning with MySQL 8.0.13 and MySQL NDB Cluster 8.0.13. In this Manual and other MySQL documentation, we identify these and later NDB Cluster releases employing a version number that begins with “NDB”. This version number is that of the NDBCLUSTER storage engine used in the NDB 8.0 release, and is the same as the MySQL 8.0 server version on which the NDB Cluster 8.0 release is based.

Version strings used in NDB Cluster software. The version string displayed by the mysql client supplied with the MySQL NDB Cluster distribution uses this format:

```
mysql-mysql_server_version-cluster
```

mysql_server_version represents the version of the MySQL Server on which the NDB Cluster release is based. For all NDB Cluster 8.0 releases, this is 8.0.\(n\), where \(n\) is the release number. Building from source using -DWITH_NDBCLUSTER or the equivalent adds the -cluster suffix to the version string. (See Section 22.2.1.4, “Building NDB Cluster from Source on Linux”, and Section 22.2.2.2, “Compiling and Installing NDB Cluster from Source on Windows”.) You can see this format used in the mysql client, as shown here:

```
shell> mysql
Welcome to the MySQL monitor. Commands end with ; or \g.
Your MySQL connection id is 2
Server version: 8.0.22-cluster Source distribution
Type 'help;' or '\' for help. Type '\' to clear the buffer.

mysql> SELECT VERSION()\G
*************************** 1. row ***************************
VERSION(): 8.0.22-cluster
1 row in set (0.00 sec)
```
The first General Availability release of NDB Cluster using MySQL 8.0 is NDB 8.0.19, using MySQL 8.0.19.

The version string displayed by other NDB Cluster programs not normally included with the MySQL 8.0 distribution uses this format:

```
mysql-mysql_server_version ndb-ndb_engine_version
```

`mysql_server_version` represents the version of the MySQL Server on which the NDB Cluster release is based. For all NDB Cluster 8.0 releases, this is `8.0.n`, where `n` is the release number. `ndb_engine_version` is the version of the NDB storage engine used by this release of the NDB Cluster software. For all NDB 8.0 releases, this number is the same as the MySQL Server version. You can see this format used in the output of the `SHOW` command in the `ndb_mgm` client, like this:

```
ndb_mgm> SHOW
Connected to Management Server at: localhost:1186
Cluster Configuration
---------------------
[ndbd(NDB)]     2 node(s)
id=1    @10.0.10.6  (mysql-8.0.24 ndb-8.0.22, Nodegroup: 0, *)
id=2    @10.0.10.8  (mysql-8.0.24 ndb-8.0.22, Nodegroup: 0)

[ndb_mgmd(MGM)] 1 node(s)
id=3    @10.0.10.2  (mysql-8.0.24 ndb-8.0.22)

[mysqld(API)]   2 node(s)
id=4    @10.0.10.10  (mysql-8.0.24 ndb-8.0.22)
id=5 (not connected, accepting connect from any host)
```

**Compatibility with standard MySQL 8.0 releases.** While many standard MySQL schemas and applications can work using NDB Cluster, it is also true that unmodified applications and database schemas may be slightly incompatible or have suboptimal performance when run using NDB Cluster (see Section 22.1.7, “Known Limitations of NDB Cluster”). Most of these issues can be overcome, but this also means that you are very unlikely to be able to switch an existing application datastore—that currently uses, for example, MyISAM or InnoDB—to use the NDB storage engine without allowing for the possibility of changes in schemas, queries, and applications. A `mysqld` compiled without NDB support (that is, built without `--with-ndbcluster-storage-engine` or its alias `--with-ndbothercluster`) cannot function as a drop-in replacement for a `mysqld` that is built with it.

**NDB Cluster development source trees.** NDB Cluster development trees can also be accessed from https://github.com/mysql/mysql-server.

The NDB Cluster development sources maintained at https://github.com/mysql/mysql-server are licensed under the GPL. For information about obtaining MySQL sources using Git and building them yourself, see Section 2.9.5, “Installing MySQL Using a Development Source Tree”.

**Note**

As with MySQL Server 8.0, NDB Cluster 8.0 releases are built using CMake.

NDB Cluster 8.0 is available beginning with NDB 8.0.19 as a General Availability release, and is recommended for new deployments. NDB Cluster 7.6 and 7.5 are previous GA releases still supported in production; for information about NDB Cluster 7.6, see What is New in NDB Cluster 7.6. For similar information about NDB Cluster 7.5, see What is New in NDB Cluster 7.5. NDB Cluster 7.4 and 7.3 are previous GA releases still supported in production, although we recommend that new deployments for production use NDB Cluster 8.0; see MySQL NDB Cluster 7.3 and NDB Cluster 7.4.

The contents of this chapter are subject to revision as NDB Cluster continues to evolve. Additional information regarding NDB Cluster can be found on the MySQL website at http://www.mysql.com/products/cluster/.
NDB Cluster Overview

Additional Resources. More information about NDB Cluster can be found in the following places:

- For answers to some commonly asked questions about NDB Cluster, see Section A.10, "MySQL 8.0 FAQ: NDB Cluster".
- Many NDB Cluster users and developers blog about their experiences with NDB Cluster, and make feeds of these available through PlanetMySQL.

22.1 NDB Cluster Overview

NDB Cluster is a technology that enables clustering of in-memory databases in a shared-nothing system. The shared-nothing architecture enables the system to work with very inexpensive hardware, and with a minimum of specific requirements for hardware or software.

NDB Cluster is designed not to have any single point of failure. In a shared-nothing system, each component is expected to have its own memory and disk, and the use of shared storage mechanisms such as network shares, network file systems, and SANs is not recommended or supported.

NDB Cluster integrates the standard MySQL server with an in-memory clustered storage engine called NDB (which stands for “Network DataBase”). In our documentation, the term NDB refers to the part of the setup that is specific to the storage engine, whereas “MySQL NDB Cluster” refers to the combination of one or more MySQL servers with the NDB storage engine.

An NDB Cluster consists of a set of computers, known as hosts, each running one or more processes. These processes, known as nodes, may include MySQL servers (for access to NDB data), data nodes (for storage of the data), one or more management servers, and possibly other specialized data access programs. The relationship of these components in an NDB Cluster is shown here:

Figure 22.1 NDB Cluster Components

All these programs work together to form an NDB Cluster (see Section 22.4, “NDB Cluster Programs”. When data is stored by the NDB storage engine, the tables (and table data) are stored in the data nodes. Such tables are directly accessible from all other MySQL servers (SQL nodes) in the cluster. Thus, in a
payroll application storing data in a cluster, if one application updates the salary of an employee, all other MySQL servers that query this data can see this change immediately.

Although an NDB Cluster SQL node uses the `mysqld` server daemon, it differs in a number of critical respects from the `mysqld` binary supplied with the MySQL 8.0 distributions, and the two versions of `mysqld` are not interchangeable.

In addition, a MySQL server that is not connected to an NDB Cluster cannot use the NDB storage engine and cannot access any NDB Cluster data.

The data stored in the data nodes for NDB Cluster can be mirrored; the cluster can handle failures of individual data nodes with no other impact than that a small number of transactions are aborted due to losing the transaction state. Because transactional applications are expected to handle transaction failure, this should not be a source of problems.

Individual nodes can be stopped and restarted, and can then rejoin the system (cluster). Rolling restarts (in which all nodes are restarted in turn) are used in making configuration changes and software upgrades (see Section 22.5.5, “Performing a Rolling Restart of an NDB Cluster”). Rolling restarts are also used as part of the process of adding new data nodes online (see Section 22.5.7, “Adding NDB Cluster Data Nodes Online”). For more information about data nodes, how they are organized in an NDB Cluster, and how they handle and store NDB Cluster data, see Section 22.1.2, “NDB Cluster Nodes, Node Groups, Fragment Replicas, and Partitions”.

Backing up and restoring NDB Cluster databases can be done using the NDB-native functionality found in the NDB Cluster management client and the `ndb_restore` program included in the NDB Cluster distribution. For more information, see Section 22.5.8, “Online Backup of NDB Cluster”, and Section 22.4.23, “ndb_restore — Restore an NDB Cluster Backup”. You can also use the standard MySQL functionality provided for this purpose in `mysqldump` and the MySQL server. See Section 4.5.4, “mysqldump — A Database Backup Program”, for more information.

NDB Cluster nodes can employ different transport mechanisms for inter-node communications; TCP/IP over standard 100 Mbps or faster Ethernet hardware is used in most real-world deployments.

22.1.1 NDB Cluster Core Concepts

**NDBCLUSTER** (also known as NDB) is an in-memory storage engine offering high-availability and data-persistence features.

The NDBCLUSTER storage engine can be configured with a range of failover and load-balancing options, but it is easiest to start with the storage engine at the cluster level. NDB Cluster's NDB storage engine contains a complete set of data, dependent only on other data within the cluster itself.

The “Cluster” portion of NDB Cluster is configured independently of the MySQL servers. In an NDB Cluster, each part of the cluster is considered to be a node.

**Note**

In many contexts, the term “node” is used to indicate a computer, but when discussing NDB Cluster it means a process. It is possible to run multiple nodes on a single computer; for a computer on which one or more cluster nodes are being run we use the term cluster host.

There are three types of cluster nodes, and in a minimal NDB Cluster configuration, there are at least three nodes, one of each of these types:

- **Management node**: The role of this type of node is to manage the other nodes within the NDB Cluster, performing such functions as providing configuration data, starting and stopping nodes, and running
backups. Because this node type manages the configuration of the other nodes, a node of this type should be started first, before any other node. A management node is started with the command `ndb_mgmd`.

- **Data node**: This type of node stores cluster data. There are as many data nodes as there are fragment replicas, times the number of fragments (see Section 22.1.2, “NDB Cluster Nodes, Node Groups, Fragment Replicas, and Partitions”). For example, with two fragment replicas, each having two fragments, you need four data nodes. One fragment replica is sufficient for data storage, but provides no redundancy; therefore, it is recommended to have two (or more) fragment replicas to provide redundancy, and thus high availability. A data node is started with the command `ndbd` (see Section 22.4.1, “ndbd — The NDB Cluster Data Node Daemon”) or `ndbmtd` (see Section 22.4.3, “ndbmtd — The NDB Cluster Data Node Daemon (Multi-Threaded)”).

NDB Cluster tables are normally stored completely in memory rather than on disk (this is why we refer to NDB Cluster as an in-memory database). However, some NDB Cluster data can be stored on disk; see Section 22.5.10, “NDB Cluster Disk Data Tables”, for more information.

- **SQL node**: This is a node that accesses the cluster data. In the case of NDB Cluster, an SQL node is a traditional MySQL server that uses the NDBCLUSTER storage engine. An SQL node is a `mysqld` process started with the `--ndbcluster` and `--ndb-connectstring` options, which are explained elsewhere in this chapter, possibly with additional MySQL server options as well.

An SQL node is actually just a specialized type of **API node**, which designates any application which accesses NDB Cluster data. Another example of an API node is the `ndb_restore` utility that is used to restore a cluster backup. It is possible to write such applications using the NDB API. For basic information about the NDB API, see Getting Started with the NDB API.

**Important**

It is not realistic to expect to employ a three-node setup in a production environment. Such a configuration provides no redundancy; to benefit from NDB Cluster’s high-availability features, you must use multiple data and SQL nodes. The use of multiple management nodes is also highly recommended.

For a brief introduction to the relationships between nodes, node groups, fragment replicas, and partitions in NDB Cluster, see Section 22.1.2, “NDB Cluster Nodes, Node Groups, Fragment Replicas, and Partitions”.

Configuration of a cluster involves configuring each individual node in the cluster and setting up individual communication links between nodes. NDB Cluster is currently designed with the intention that data nodes are homogeneous in terms of processor power, memory space, and bandwidth. In addition, to provide a single point of configuration, all configuration data for the cluster as a whole is located in one configuration file.

The management server manages the cluster configuration file and the cluster log. Each node in the cluster retrieves the configuration data from the management server, and so requires a way to determine where the management server resides. When interesting events occur in the data nodes, the nodes transfer information about these events to the management server, which then writes the information to the cluster log.

In addition, there can be any number of cluster client processes or applications. These include standard MySQL clients, NDB-specific API programs, and management clients. These are described in the next few paragraphs.

**Standard MySQL clients.** NDB Cluster can be used with existing MySQL applications written in PHP, Perl, C, C++, Java, Python, Ruby, and so on. Such client applications send SQL statements to and receive
responses from MySQL servers acting as NDB Cluster SQL nodes in much the same way that they interact with standalone MySQL servers.

MySQL clients using an NDB Cluster as a data source can be modified to take advantage of the ability to connect with multiple MySQL servers to achieve load balancing and failover. For example, Java clients using Connector/J 5.0.6 and later can use `jdbc:mysql:loadbalance://` URLs (improved in Connector/J 5.1.7) to achieve load balancing transparently; for more information about using Connector/J with NDB Cluster, see Using Connector/J with NDB Cluster.

**NDB client programs.** Client programs can be written that access NDB Cluster data directly from the NDBCLUSTER storage engine, bypassing any MySQL Servers that may be connected to the cluster, using the NDB API, a high-level C++ API. Such applications may be useful for specialized purposes where an SQL interface to the data is not needed. For more information, see The NDB API.

**NDB-specific Java applications** can also be written for NDB Cluster using the NDB Cluster Connector for Java. This NDB Cluster Connector includes ClusterJ, a high-level database API similar to object-relational mapping persistence frameworks such as Hibernate and JPA that connect directly to NDBCLUSTER, and so does not require access to a MySQL Server. See Java and NDB Cluster, and The ClusterJ API and Data Object Model, for more information.

NDB Cluster also supports applications written in JavaScript using Node.js. The MySQL Connector for JavaScript includes adapters for direct access to the NDB storage engine and as well as for the MySQL Server. Applications using this Connector are typically event-driven and use a domain object model similar in many ways to that employed by ClusterJ. For more information, see MySQL NoSQL Connector for JavaScript.

The Memcache API for NDB Cluster, implemented as the loadable ndbmemcache storage engine for memcached version 1.6 and later, can be used to provide a persistent NDB Cluster data store, accessed using the memcache protocol.

The standard memcached caching engine is included in the NDB Cluster 8.0 distribution. Each memcached server has direct access to data stored in NDB Cluster, but is also able to cache data locally and to serve (some) requests from this local cache.

For more information, see ndbmemcache—Memcache API for NDB Cluster (DEPRECATED).

**Management clients.** These clients connect to the management server and provide commands for starting and stopping nodes gracefully, starting and stopping message tracing (debug versions only), showing node versions and status, starting and stopping backups, and so on. An example of this type of program is the ndb_mgm management client supplied with NDB Cluster (see Section 22.4.5, "ndb_mgm — The NDB Cluster Management Client"). Such applications can be written using the MGM API, a C-language API that communicates directly with one or more NDB Cluster management servers. For more information, see The MGM API.

Oracle also makes available MySQL Cluster Manager, which provides an advanced command-line interface simplifying many complex NDB Cluster management tasks, such restarting an NDB Cluster with a large number of nodes. The MySQL Cluster Manager client also supports commands for getting and setting the values of most node configuration parameters as well as mysqld server options and variables relating to NDB Cluster. MySQL Cluster Manager 1.4.8 provides experimental support for NDB 8.0. See MySQL™ Cluster Manager 1.4.8 User Manual, for more information.

**Event logs.** NDB Cluster logs events by category (startup, shutdown, errors, checkpoints, and so on), priority, and severity. A complete listing of all reportable events may be found in Section 22.5.3, “Event Reports Generated in NDB Cluster”. Event logs are of the two types listed here:

- **Cluster log:** Keeps a record of all desired reportable events for the cluster as a whole.
• **Node log:** A separate log which is also kept for each individual node.

**Note**
Under normal circumstances, it is necessary and sufficient to keep and examine only the cluster log. The node logs need be consulted only for application development and debugging purposes.

**Checkpoint.** Generally speaking, when data is saved to disk, it is said that a checkpoint has been reached. More specific to NDB Cluster, a checkpoint is a point in time where all committed transactions are stored on disk. With regard to the NDB storage engine, there are two types of checkpoints which work together to ensure that a consistent view of the cluster’s data is maintained. These are shown in the following list:

• **Local Checkpoint (LCP):** This is a checkpoint that is specific to a single node; however, LCPs take place for all nodes in the cluster more or less concurrently. An LCP usually occurs every few minutes; the precise interval varies, and depends upon the amount of data stored by the node, the level of cluster activity, and other factors.

  NDB 8.0 supports partial LCPs, which can significantly improve performance under some conditions. See the descriptions of the `EnablePartialLcp` and `RecoveryWork` configuration parameters which enable partial LCPs and control the amount of storage they use.

• **Global Checkpoint (GCP):** A GCP occurs every few seconds, when transactions for all nodes are synchronized and the redo-log is flushed to disk.

For more information about the files and directories created by local checkpoints and global checkpoints, see [NDB Cluster Data Node File System Directory](#).

---

### 22.1.2 NDB Cluster Nodes, Node Groups, Fragment Replicas, and Partitions

This section discusses the manner in which NDB Cluster divides and duplicates data for storage.

A number of concepts central to an understanding of this topic are discussed in the next few paragraphs.

**Data node.** An `ndbd` or `ndbmtd` process, which stores one or more fragment replicas—that is, copies of the partitions (discussed later in this section) assigned to the node group of which the node is a member.

Each data node should be located on a separate computer. While it is also possible to host multiple data node processes on a single computer, such a configuration is not usually recommended.

It is common for the terms “node” and “data node” to be used interchangeably when referring to an `ndbd` or `ndbmtd` process; where mentioned, management nodes (`ndb_mgmd` processes) and SQL nodes (`mysqld` processes) are specified as such in this discussion.

**Node group.** A node group consists of one or more nodes, and stores partitions, or sets of fragment replicas (see next item).

The number of node groups in an NDB Cluster is not directly configurable; it is a function of the number of data nodes and of the number of fragment replicas (`NoOfReplicas` configuration parameter), as shown here:

\[
\text{[\# of node groups]} = \frac{\text{[\# of data nodes]}}{\text{NoOfReplicas}}
\]

Thus, an NDB Cluster with 4 data nodes has 4 node groups if `NoOfReplicas` is set to 1 in the `config.ini` file, 2 node groups if `NoOfReplicas` is set to 2, and 1 node group if `NoOfReplicas` is set to 4. Fragment replicas are discussed later in this section; for more information about `NoOfReplicas`, see Section 22.3.3.6, “Defining NDB Cluster Data Nodes”. 

---

3837
Note
All node groups in an NDB Cluster must have the same number of data nodes.

You can add new node groups (and thus new data nodes) online, to a running NDB Cluster; see Section 22.5.7, “Adding NDB Cluster Data Nodes Online”, for more information.

Partition. This is a portion of the data stored by the cluster. Each node is responsible for keeping at least one copy of any partitions assigned to it (that is, at least one fragment replica) available to the cluster.

The number of partitions used by default by NDB Cluster depends on the number of data nodes and the number of LDM threads in use by the data nodes, as shown here:

\[
[# \text{ of partitions}] = [# \text{ of data nodes}] \times [# \text{ of LDM threads}]
\]

When using data nodes running ndbmtd, the number of LDM threads is controlled by the setting for MaxNoOfExecutionThreads. When using ndbd there is a single LDM thread, which means that there are as many cluster partitions as nodes participating in the cluster. This is also the case when using ndbmtd with MaxNoOfExecutionThreads set to 3 or less. (You should be aware that the number of LDM threads increases with the value of this parameter, but not in a strictly linear fashion, and that there are additional constraints on setting it; see the description of MaxNoOfExecutionThreads for more information.)

NDB and user-defined partitioning. NDB Cluster normally partitions NDBCLUSTER tables automatically. However, it is also possible to employ user-defined partitioning with NDBCLUSTER tables. This is subject to the following limitations:

1. Only the KEY and LINEAR KEY partitioning schemes are supported in production with NDB tables.

2. The maximum number of partitions that may be defined explicitly for any NDB table is \(8 \times [\text{number of LDM threads}] \times [\text{number of node groups}]\), the number of node groups in an NDB Cluster being determined as discussed previously in this section. When running ndbd for data node processes, setting the number of LDM threads has no effect (since ThreadConfig applies only to ndbmtd); in such cases, this value can be treated as though it were equal to 1 for purposes of performing this calculation.

   See Section 22.4.3, “ndbmtd — The NDB Cluster Data Node Daemon (Multi-Threaded)”, for more information.

For more information relating to NDB Cluster and user-defined partitioning, see Section 22.1.7, “Known Limitations of NDB Cluster”, and Section 23.6.2, “Partitioning Limitations Relating to Storage Engines”.

Fragment replica. This is a copy of a cluster partition. Each node in a node group stores a fragment replica. Also sometimes known as a partition replica. The number of fragment replicas is equal to the number of nodes per node group.

A fragment replica belongs entirely to a single node; a node can (and usually does) store several fragment replicas.

The following diagram illustrates an NDB Cluster with four data nodes running ndbd, arranged in two node groups of two nodes each; nodes 1 and 2 belong to node group 0, and nodes 3 and 4 belong to node group 1.

Note
Only data nodes are shown here; although a working NDB Cluster requires an ndb_mgmd process for cluster management and at least one SQL node to access the data stored by the cluster, these have been omitted from the figure for clarity.
The data stored by the cluster is divided into four partitions, numbered 0, 1, 2, and 3. Each partition is stored—in multiple copies—on the same node group. Partitions are stored on alternate node groups as follows:

- Partition 0 is stored on node group 0; a primary fragment replica (primary copy) is stored on node 1, and a backup fragment replica (backup copy of the partition) is stored on node 2.
- Partition 1 is stored on the other node group (node group 1); this partition's primary fragment replica is on node 3, and its backup fragment replica is on node 4.
- Partition 2 is stored on node group 0. However, the placing of its two fragment replicas is reversed from that of Partition 0; for Partition 2, the primary fragment replica is stored on node 2, and the backup on node 1.
- Partition 3 is stored on node group 1, and the placement of its two fragment replicas are reversed from those of partition 1. That is, its primary fragment replica is located on node 4, with the backup on node 3.

What this means regarding the continued operation of an NDB Cluster is this: so long as each node group participating in the cluster has at least one node operating, the cluster has a complete copy of all data and remains viable. This is illustrated in the next diagram.
In this example, the cluster consists of two node groups each consisting of two data nodes. Each data node is running an instance of `ndbd`. Any combination of at least one node from node group 0 and at least one node from node group 1 is sufficient to keep the cluster “alive”. However, if both nodes from a single node group fail, the combination consisting of the remaining two nodes in the other node group is not sufficient. In this situation, the cluster has lost an entire partition and so can no longer provide access to a complete set of all NDB Cluster data.

The maximum number of node groups supported for a single NDB Cluster instance is 48.

### 22.1.3 NDB Cluster Hardware, Software, and Networking Requirements

One of the strengths of NDB Cluster is that it can be run on commodity hardware and has no unusual requirements in this regard, other than for large amounts of RAM, due to the fact that all live data storage is done in memory. (It is possible to reduce this requirement using Disk Data tables—see Section 22.5.10, “NDB Cluster Disk Data Tables”, for more information about these.) Naturally, multiple and faster CPUs can enhance performance. Memory requirements for other NDB Cluster processes are relatively small.

The software requirements for NDB Cluster are also modest. Host operating systems do not require any unusual modules, services, applications, or configuration to support NDB Cluster. For supported operating systems, a standard installation should be sufficient. The MySQL software requirements are simple: all that is needed is a production release of NDB Cluster. It is not strictly necessary to compile MySQL yourself merely to be able to use NDB Cluster. We assume that you are using the binaries appropriate to your platform, available from the NDB Cluster software downloads page at [https://dev.mysql.com/downloads/cluster/](https://dev.mysql.com/downloads/cluster/).

For communication between nodes, NDB Cluster supports TCP/IP networking in any standard topology, and the minimum expected for each host is a standard 100 Mbps Ethernet card, plus a switch, hub, or router to provide network connectivity for the cluster as a whole. We strongly recommend that an NDB Cluster be run on its own subnet which is not shared with machines not forming part of the cluster for the following reasons:

- **Security.** Communications between NDB Cluster nodes are not encrypted or shielded in any way. The only means of protecting transmissions within an NDB Cluster is to run your NDB Cluster on a
protected network. If you intend to use NDB Cluster for Web applications, the cluster should definitely reside behind your firewall and not in your network’s De-Militarized Zone (DMZ) or elsewhere.

See Section 22.5.17.1, “NDB Cluster Security and Networking Issues”, for more information.

• **Efficiency.** Setting up an NDB Cluster on a private or protected network enables the cluster to make exclusive use of bandwidth between cluster hosts. Using a separate switch for your NDB Cluster not only helps protect against unauthorized access to NDB Cluster data, it also ensures that NDB Cluster nodes are shielded from interference caused by transmissions between other computers on the network. For enhanced reliability, you can use dual switches and dual cards to remove the network as a single point of failure; many device drivers support failover for such communication links.

**Network communication and latency.** NDB Cluster requires communication between data nodes and API nodes (including SQL nodes), as well as between data nodes and other data nodes, to execute queries and updates. Communication latency between these processes can directly affect the observed performance and latency of user queries. In addition, to maintain consistency and service despite the silent failure of nodes, NDB Cluster uses heartbeating and timeout mechanisms which treat an extended loss of communication from a node as node failure. This can lead to reduced redundancy. Recall that, to maintain data consistency, an NDB Cluster shuts down when the last node in a node group fails. Thus, to avoid increasing the risk of a forced shutdown, breaks in communication between nodes should be avoided wherever possible.

The failure of a data or API node results in the abort of all uncommitted transactions involving the failed node. Data node recovery requires synchronization of the failed node’s data from a surviving data node, and re-establishment of disk-based redo and checkpoint logs, before the data node returns to service. This recovery can take some time, during which the Cluster operates with reduced redundancy.

Heartbeating relies on timely generation of heartbeat signals by all nodes. This may not be possible if the node is overloaded, has insufficient machine CPU due to sharing with other programs, or is experiencing delays due to swapping. If heartbeat generation is sufficiently delayed, other nodes treat the node that is slow to respond as failed.

This treatment of a slow node as a failed one may or may not be desirable in some circumstances, depending on the impact of the node’s slowed operation on the rest of the cluster. When setting timeout values such as `HeartbeatIntervalDbDb` and `HeartbeatIntervalDbApi` for NDB Cluster, care must be taken to achieve quick detection, failover, and return to service, while avoiding potentially expensive false positives.

Where communication latencies between data nodes are expected to be higher than would be expected in a LAN environment (on the order of 100 µs), timeout parameters must be increased to ensure that any allowed periods of latency periods are well within configured timeouts. Increasing timeouts in this way has a corresponding effect on the worst-case time to detect failure and therefore time to service recovery.

LAN environments can typically be configured with stable low latency, and such that they can provide redundancy with fast failover. Individual link failures can be recovered from with minimal and controlled latency visible at the TCP level (where NDB Cluster normally operates). WAN environments may offer a range of latencies, as well as redundancy with slower failover times. Individual link failures may require route changes to propagate before end-to-end connectivity is restored. At the TCP level this can appear as large latencies on individual channels. The worst-case observed TCP latency in these scenarios is related to the worst-case time for the IP layer to reroute around the failures.

### 22.1.4 What is New in NDB Cluster

The following sections describe changes in the implementation of NDB Cluster in MySQL NDB Cluster 8.0 through 8.0.22, as compared to earlier release series. NDB Cluster 8.0 is available as a General Availability (GA) release, beginning with NDB 8.0.19. NDB Cluster 7.6 and 7.5 are previous GA releases.
What is New in NDB Cluster

Major changes and new features in NDB Cluster 8.0 which are likely to be of interest are shown in the following list:

- **Compatibility enhancements.** The following changes reduce longstanding nonessential differences in NDB behavior as compared to that of other MySQL storage engines:

  - **Development in parallel with MySQL server.** Beginning with this release, MySQL NDB Cluster is being developed in parallel with the standard MySQL 8.0 server under a new unified release model with the following features:
    
    - NDB 8.0 is developed in, built from, and released with the MySQL 8.0 source code tree.
    
    - The numbering scheme for NDB Cluster 8.0 releases follows the scheme for MySQL 8.0, starting with version 8.0.13.
    
    - Building the source with NDB support appends `--cluster` to the version string returned by `mysql --version`, as shown here:

      ```
      mysql --version
      mysql Ver 8.0.22-cluster for Linux on x86_64 (Source distribution)
      ```

      NDB binaries continue to display both the MySQL Server version and the NDB engine version, like this:

      ```
      ndb_mgm --version
      MySQL distrib mysql-8.0.22 ndb-8.0.22, for Linux (x86_64)
      ```

      In MySQL Cluster NDB 8.0, these two version numbers are always the same.

      To build the MySQL 8.0.13 (or later) source with NDB Cluster support, use the CMake option `--with-ndbcluster`.

- **Platform support notes.** NDB 8.0 makes the following changes in platform support:

  - **NDBCluster** no longer supports 32-bit platforms. Beginning with NDB 8.0.21, the NDB build process checks the system architecture and aborts if it is not a 64-bit platform.

  - Beginning with NDB 8.0.18, it is possible to build NDB from source for 64-bit ARM CPUs. Currently, this support is source-only, and we do not provide any precompiled binaries for this platform.

- **Database and table names.** As of NDB 8.0.18, the 63-byte limit on identifiers for databases and tables is removed. These identifiers can now use up to 64 bytes, as for such objects using other MySQL storage engines. See Section 22.1.7.11, “Previous NDB Cluster Issues Resolved in NDB Cluster 8.0”.

- **Generated names for foreign keys.** NDB (version 8.0.18 and later) now uses the pattern `tbl_name_fk_N` for naming internally generated foreign keys. This is similar to the pattern used by InnoDB.

- **Schema and metadata distribution and synchronization.** NDB 8.0 makes use of the MySQL data dictionary to distribute schema information to SQL nodes joining a cluster and to synchronize new
schema changes between existing SQL nodes. The following list describes individual enhancements relating to this integration work:

- **Schema distribution enhancements.** The NDB schema distribution coordinator, which handles schema operations and tracks their progress, has been extended in NDB 8.0.17 to ensure that resources used during a schema operation are released at its conclusion. Previously, some of this work was done by the schema distribution client; this has been changed due to the fact that the client did not always have all needed state information, which could lead to resource leaks when the client decided to abandon the schema operation prior to completion and without informing the coordinator.

  To help fix this issue, schema operation timeout detection has been moved from the schema distribution client to the coordinator, providing the coordinator with an opportunity to clean up any resources used during the schema operation. The coordinator now checks ongoing schema operations for timeout at regular intervals, and marks participants that have not yet completed a given schema operation as failed when detecting timeout. It also provides suitable warnings whenever a schema operation timeout occurs. (It should be noted that, after such a timeout is detected, the schema operation itself continues.) Additional reporting is done by printing a list of active schema operations at regular intervals whenever one or more of these operations is ongoing.

  As an additional part of this work, a new `mysqld` option `--ndb-schema-dist-timeout` makes it possible to set the length of time to wait until a schema operation is marked as having timed out.

- **Disk data file distribution.** Beginning with NDB Cluster 8.0.14, NDB uses the MySQL data dictionary to make sure that disk data files and related constructs such as tablespaces and log file groups are correctly distributed between all connected SQL nodes.

- **Schema synchronization of tablespace objects.** When a MySQL Server connects as an SQL node to an NDB cluster, it checks its data dictionary against the information found in the NDB dictionary.

  Previously, the only NDB objects synchronized on connection of a new SQL node were databases and tables; MySQL NDB Cluster 8.0.14 and later also implement schema synchronization of disk data objects including tablespaces and log file groups. Among other benefits, this eliminates the possibility of a mismatch between the MySQL data dictionary and the NDB dictionary following a native backup and restore, in which tablespaces and log file groups were restored to the NDB dictionary, but not to the MySQL Server's data dictionary.

  It is also no longer possible to issue a `CREATE TABLE` statement that refers to a nonexistent tablespace. Such a statement now fails with an error.

- **Database DDL synchronization enhancements.** Work done in NDB 8.0.17 insures that synchronization of databases by newly joined (or rejoined) SQL nodes with those on existing SQL nodes now makes proper use of the data dictionary so that any database-level operations (`CREATE DATABASE`, `ALTER DATABASE`, or `DROP DATABASE`) that may have been missed by this SQL node are now correctly duplicated on it when it connects (or reconnects) to the cluster.

  As part of the schema synchronization procedure performed when starting, an SQL node now compares all databases on the cluster's data nodes with those in its own data dictionary, and if any of these is found to be missing from the SQL node's data dictionary, the SQL Node installs it locally by executing a `CREATE DATABASE` statement. A database thus created uses the default MySQL Server database properties (such as those as determined by `character_set_database` and `collation_database`) that are in effect on this SQL node at the time the statement is executed.

- **NDB metadata change detection and synchronization.** NDB 8.0.16 implements a new mechanism for detection of updates to metadata for data objects such as tables, tablespaces, and log
What is New in NDB Cluster

file groups with the MySQL data dictionary. This is done using a thread, the NDB metadata change monitor thread, which runs in the background and checks periodically for inconsistencies between the NDB dictionary and the MySQL data dictionary.

The monitor performs metadata checks every 60 seconds by default. The polling interval can be adjusted by setting the value of the ndb_metadata_check_interval system variable; polling can be disabled altogether by setting the ndb_metadata_check system variable to OFF. A status variable (also added in NDB 8.0.16) Ndb_metadata_detected_count shows the number of times since mysqld was last started that inconsistencies have been detected.

Beginning in version 8.0.18, NDB ensures that NDB table, log file group, and tablespace objects submitted by the metadata change monitor thread during operations following startup are automatically checked for mismatches and synchronized by the NDB binlog thread.

NDB 8.0.18 also adds two status variables relating to automatic synchronization:
Ndb_metadata_synced_count shows the number of objects synchronized automatically;
Ndb_metadata_excluded_count indicates the number of objects for which synchronization has failed (prior to NDB 8.0.22, this variable was named Ndb_metadata_blacklist_size). In addition, you can see which objects have been synchronized by inspecting the cluster log.

NDB 8.0.19 further enhances this functionality by adding databases to those objects in which changes are detected and synchronized. Only databases actually used by NDB tables are so handled; other databases which may be present in the MySQL data dictionary are ignored. This eliminates a previous requirement, for the case when a table existed in NDB but the table and the database to which it belonged did not exist on the SQL node, to create this database manually; now in such cases, the database and all NDB tables belonging to it should be created on the SQL node automatically.

NDB 8.0.19 also introduces the ndb_metadata_sync system variable; setting this variable to true overrides any settings that have been made for ndb_metadata_check_interval and ndb_metadata_check, causing the change monitor thread to begin continuous metadata change detection.

In NDB 8.0.22 and later, setting ndb_metadata_sync to true clears the list of objects for which synchronization has failed previously, which means it is no longer necessary to discover individual tables or to re-trigger synchronization by reconnecting the SQL node to the cluster. In addition, setting this variable to false clears the list of objects waiting to be retried.

Beginning with NDB 8.0.21, more detailed information about the current state of automatic synchronization than can be obtained from log messages or status variables is provided by two new tables added to the MySQL Performance Schema. The tables are listed here:

• ndb_sync_pending_objects: Contains information about database objects for which mismatches have been detected between the NDB dictionary and the MySQL data dictionary (and which have not been excluded from automatic synchronization).

• ndb_sync_excluded_objects: Contains information about NDB database objects which have been excluded because they cannot be synchronized between the NDB dictionary and the MySQL data dictionary, and thus require manual intervention.

A row in one of these tables provides the database object’s parent schema, name, and type. Types of objects include schemas, tablespaces, log file groups, and tables. (If the object is a log file group
What is New in NDB Cluster

or tablespace, the parent schema is NULL.) In addition, the \texttt{nbd_sync_excluded_objects} table shows the reason for which the object has been excluded.

These tables are present only if \textsc{NDBCluster} storage engine support is enabled. For more information about these tables, see Section 26.12.12, “Performance Schema NDB Cluster Tables”.

- **Changes in NDB table extra metadata.** In NDB 8.0.14 and later, the extra metadata property of an NDB table is used for storing serialized metadata from the MySQL data dictionary, rather than storing the binary representation of the table as in previous versions. (This was a \texttt{.frm} file, no longer used by the MySQL Server—see Chapter 14, MySQL Data Dictionary.) As part of the work to support this change, the available size of the table’s extra metadata has been increased. This means that NDB tables created in NDB Cluster 8.0.14 and later are not compatible with previous NDB Cluster releases. Tables created in previous releases can be used with NDB 8.0.14 and later, but cannot be opened afterwards by an earlier version.

This metadata is accessible using the NDB API methods \texttt{getExtraMetadata()} and \texttt{setExtraMetadata()} that were implemented in NDB 8.0.13.

For more information, see Section 22.2.7, “Upgrading and Downgrading NDB Cluster”.

- **On-the-fly upgrades of tables using .frm files.** A table created in NDB 7.6 and earlier contains metadata in the form of a compressed \texttt{.frm} file, which is no longer supported in MySQL 8.0. To facilitate online upgrades to NDB 8.0, NDB performs on-the-fly translation of this metadata and writes it into the MySQL Server’s data dictionary, which enables the \texttt{mysqld} in NDB Cluster 8.0 to work with the table without preventing subsequent use of the table by a previous version of the NDB software.

\begin{important}
\begin{itemize}
  \item Once a table’s structure has been modified in NDB 8.0, its metadata is stored using the data dictionary, and it can no longer be accessed by NDB 7.6 and earlier.
\end{itemize}
\end{important}

This enhancement also makes it possible to restore an NDB backup made using an earlier version to a cluster running NDB 8.0 (or later).

- **Synchronization of user privileges with \textsc{NDB\_STORED\_USER}.** A new mechanism for sharing and synchronizing users, roles, and privileges between SQL nodes is available beginning with NDB 8.0.18, using the \textsc{NDB\_STORED\_USER} privilege. Distributed privileges as implemented in NDB 7.6 and earlier (see Distributed Privileges Using Shared Grant Tables) are no longer supported.

Once a user account is created on an SQL node, the user and its privileges can be stored in NDB and thus shared between all SQL nodes in the cluster by issuing a \texttt{GRANT} statement such as this one:

\begin{verbatim}
GRANT NDB_STORED_USER ON *.* TO 'jon'@'localhost';
\end{verbatim}

\texttt{NDB\_STORED\_USER} always has global scope and must be granted using \texttt{ON *.*}. System reserved accounts such as \texttt{mysql.session@localhost} or \texttt{mysql.infoschema@localhost} cannot be assigned this privilege.

Roles can also be shared between SQL nodes by issuing the appropriate \texttt{GRANT NDB\_STORED\_USER} statement. Assigning such a role to a user does not cause the user to be shared; the \texttt{NDB\_STORED\_USER} privilege must be granted to each user explicitly.

A user or role having \texttt{NDB\_STORED\_USER}, along with its privileges, is shared with all SQL nodes as soon as they join a given NDB Cluster. Changes to the privileges of the user or role are synchronized immediately with all connected SQL nodes. It is possible to make such changes from any connected
SQL node, but recommended practice is to do so from a designated SQL node only, since the order of execution of statements affecting privileges from different SQL nodes cannot be guaranteed to be the same on all SQL nodes.

**Implications for upgrades.** Due to changes in the MySQL server's privilege system (see Section 6.2.3, "Grant Tables"), privilege tables using the NDB storage engine do not function correctly in NDB 8.0. It is safe but not necessary to retain such privilege tables created in NDB 7.6 or earlier, but they are no longer used for access control. Beginning with NDB 8.0.16, a mysqld acting as an SQL node and detecting such tables in NDB writes a warning to the MySQL server log, and creates InnoDB shadow tables local to itself; such shadow tables are created on each MySQL server connected to the cluster. When performing an upgrade from NDB 7.6 or earlier, the privilege tables using NDB can be removed safely using ndb_drop_table once all MySQL servers acting as SQL nodes have been upgraded (see Section 22.2.7, "Upgrading and Downgrading NDB Cluster").

The ndb_restore utility's --restore-privilege-tables option is deprecated but continues to be honored in NDB 8.0, and can still be used to restore distributed privilege tables present in a backup taken from a previous release of NDB Cluster to a cluster running NDB 8.0. These tables are handled as described in the preceding paragraph.

Shared users and grants are stored in the ndb_sql_metadata table, which in NDB 8.0.19 and later ndb_restore by default does not restore; you can specify the --include-stored-grants option to cause it to do so.

- **INFORMATION_SCHEMA changes.** The following changes are made in the display of information regarding Disk Data files in the INFORMATION_SCHEMA.FILES table:
  - Tablespaces and log file groups are no longer represented in the FILES table. (These constructs are not actually files.)
  - Each data file is now represented by a single row in the FILES table. Each undo log file is also now represented in this table by one row only. (Previously, a row was displayed for each copy of each of these files on each data node.)

In addition, INFORMATION_SCHEMA tables are now populated with tablespace statistics for MySQL Cluster tables. (Bug #27167728)

- **Error information with ndb_perror.** The deprecated --ndb option for perror has been removed. Instead, use ndb_perror to obtain error message information from NDB error codes. (Bug #81704, Bug #81705, Bug #23523926, Bug #23523957)

- **Condition pushdown enhancements.** Previously, condition pushdown was limited to predicate terms referring to column values from the same table to which the condition was being pushed. In NDB 8.0.16, this restriction is removed such that column values from tables earlier in the query plan can also be referred to from pushed conditions. As of NDB 8.0.18, joins comparing column expressions are supported, as are comparisons between columns in the same table. Columns and column expressions to be compared must be of exactly the same type; this means they must also be of the same signedness, length, character set, precision, and scale, whenever these attributes apply.

Pushing down larger parts of a condition allows more rows to be filtered out by the data nodes, thereby reducing the number of rows which mysqld must handle during join processing. Another benefit of these
enhancements is that filtering can be performed in parallel in the LDM threads, rather than in a single mysqld process on an SQL node; this has the potential to improve query performance significantly.

Existing rules for type compatibility between column values being compared continue to apply (see Section 8.2.1.5, “Engine Condition Pushdown Optimization”).

These additional improvements are made in NDB 8.0.21:

- **Antijoins** produced by the MySQL Optimizer through the transformation of `NOT EXISTS` and `NOT IN` queries (see Section 8.2.2.1, “Optimizing IN and EXISTS Subquery Predicates with Semijoin Transformations”) can be pushed down to the data nodes by NDB.

  This can be done when there is no unpushed condition on the table, and the query fulfills any other conditions which must be met for an outer join to be pushed down.

- **NDB** attempts to identify and evaluate a non-dependent scalar subquery before trying to retrieve any rows from the table to which it is attached. When it can do so, the value obtained is used as part of a pushed condition, instead of using the subquery which provided the value.

- **Increase in maximum row size.** NDB 8.0.18 increases the maximum number of bytes that can be stored in an `NDBCLUSTER` table from 14000 to 30000 bytes.

  A `BLOB` or `TEXT` column continues to use 264 bytes of this total, as before.

  The maximum offset for a fixed-width column of an `NDB` table is 8188 bytes; this is also unchanged from releases previous to 8.0.18.

  See Section 22.1.7.5, “Limits Associated with Database Objects in NDB Cluster”, for more information.

- **ndb_mgm SHOW command and single user mode.** Beginning with NDB 8.0.17, when the cluster is in single user mode, the output of the management client `SHOW` command indicates which API or SQL node has exclusive access while this mode is in effect.

- **Online column renames.** Beginning with NDB 8.0.18, columns of `NDB` tables can be renamed online, using `ALGORITHM=INPLACE`. See Section 22.5.11, “Online Operations with ALTER TABLE in NDB Cluster”, for more information.

- **Improved ndb_mgmd startup times.** Start times for management nodes daemon have been significantly improved in NDB 8.0.18 and later, in the following ways:

  - Due to replacing the list data structure formerly used by `ndb_mgmd` for handling node properties from configuration data with a hash table, overall startup times for the management server have been decreased by a factor of 6 or more.

  - In addition, in cases where data and SQL node host names not present in the management server’s `hosts` file are used in the cluster configuration file, `ndb_mgmd` start times can be up to 20 times shorter than was previously the case.

- **NDB API enhancements.** Beginning with NDB 8.0.18, `NdbScanFilter::cmp()` and several comparison methods of `NdbInterpretedCode` can be used to compare table column values with each other. The affected `NdbInterpretedCode` methods are listed here:

  - `branch_col_eq()`
  - `branch_col_ge()`
  - `branch_col_gt()`
What is New in NDB Cluster

• branch_col_le()
• branch_col_lt()
• branch_col_ne()

For all of the methods just listed, table column values to be compared much be of exactly matching types, including with respect to length, precision, signedness, scale, character set, and collation, as applicable.

See the descriptions of the individual API methods for more information.

• Offline multithreaded index builds. It is now possible to specify a set of cores to be used for I/O threads performing offline multithreaded builds of ordered indexes, as opposed to normal I/O duties such as file I/O, compression, or decompression. “Offline” in this context refers to building of ordered indexes performed when the parent table is not being written to; such building takes place when an NDB cluster performs a node or system restart, or as part of restoring a cluster from backup using ndb_restore --rebuild-indexes.

In addition, the default behaviour for offline index build work is modified to use all cores available to ndbmtcd, rather limiting itself to the core reserved for the I/O thread. Doing so can improve restart and restore times and performance, availability, and the user experience.

This enhancement is implemented as follows:

1. The default value for BuildIndexThreads is changed from 0 to 128. This means that offline ordered index builds are now multithreaded by default.

2. The default value for TwoPassInitialNodeRestartCopy is changed from false to true. This means that an initial node restart first copies all data from a “live” node to one that is starting —without creating any indexes—builds ordered indexes offline, and then again synchronizes its data with the live node, that is, synchronizing twice and building indexes offline between the two synchronizations. This causes an initial node restart to behave more like the normal restart of a node, and reduces the time required for building indexes.

3. A new thread type (idxbld) is defined for the ThreadConfig configuration parameter, to allow locking of offline index build threads to specific CPUs.

In addition, NDB now distinguishes the thread types that are accessible to ThreadConfig by these two criteria:

1. Whether the thread is an execution thread. Threads of types main, ldm, recv, rep, tc, and send are execution threads; thread types io, watchdog, and idxbld are not.

2. Whether the allocation of the thread to a given task is permanent or temporary. Currently all thread types except idxbld are permanent.

For additional information, see the descriptions of the indicated parameters in the Manual. (Bug #25835748, Bug #26928111)

• logbuffers table backup process information. When performing an NDB backup, the ndbinfo.logbuffers table now displays information regarding buffer usage by the backup process on each data node. This is implemented as rows reflecting two new log types in addition to REDO and DD-UNDO. One of these rows has the log type BACKUP-DATA, which shows the amount of data buffer used during backup to copy fragments to backup files. The other row has the log type BACKUP-LOG,
What is New in NDB Cluster

which displays the amount of log buffer used during the backup to record changes made after the backup has started. One each of these log_type rows is shown in the logbuffers table for each data node in the cluster. Rows having these two log types are present in the table only while an NDB backup is currently in progress. (Bug #25822988)

- **ndbinfo.processes table on Windows.** The process ID of the monitor process used on Windows platforms by RESTART to spawn and restart a mysqld is now shown in the processes table as an angel_pid.

- **String hashing improvements.** Prior to NDB 8.0, all string hashing was based on first transforming the string into a normalized form, then MD5-hashing the resulting binary image. This could give rise to some performance problems, for the following reasons:

  - The normalized string is always space padded to its full length. For a VARCHAR, this often involved adding more spaces than there were characters in the original string.
  
  - The string libraries were not optimized for this space padding, which added considerable overhead in some use cases.
  
  - The padding semantics varied between character sets, some of which were not padded to their full length.
  
  - The transformed string could become quite large, even without space padding; some Unicode 9.0 collations can transform a single code point into 100 bytes or more of character data.
  
  - Subsequent MD5 hashing consisted mainly of padding with spaces, and was not particularly efficient, possibly causing additional performance penalties by flushing significant portions of the L1 cache.

A collation provides its own hash function, which hashes the string directly without first creating a normalized string. In addition, for a Unicode 9.0 collation, the hash is computed without padding. NDB now takes advantage of this built-in function whenever hashing a string identified as using a Unicode 9.0 collation.

Since, for other collations, there are existing databases which are hash partitioned on the transformed string, NDB continues to employ the previous method for hashing strings that use these, to maintain compatibility. (Bug #89590, Bug #89604, Bug #89609, Bug #27515000, Bug #27523758, Bug #27522732)

- **RESET MASTER changes.** Because the MySQL Server now executes RESET MASTER with a global read lock, the behavior of this statement when used with NDB Cluster has changed in the following two respects:

  - It is no longer guaranteed to be synchronous; that is, it is now possible that a read coming immediately before RESET MASTER is issued may not be logged until after the binary log has been rotated.
  
  - It now behaves in exactly the same fashion, whether the statement is issued on the same SQL node that is writing the binary log, or on a different SQL node in the same cluster.

  **Note**

  SHOW BINLOG EVENTS, FLUSH LOGS, and most data definition statements continue, as they did in previous NDB versions, to operate in a synchronous fashion.

- **ndb_restore option usage.** Beginning with NDB 8.0.16, the **--nodeid** and **--backupid** options are both required when invoking ndb_restore.
• \textbf{ndb\_log\_bin default.} Beginning with NDB 8.0.16, the default value of the \texttt{ndb\_log\_bin} system variable has changed from \texttt{TRUE} to \texttt{FALSE}.

• \textbf{Dynamic transactional resource allocation.} Allocation of resources in the transaction coordinator (see \textit{The DBTC Block}) is now performed using dynamic memory pools. This means that resource allocation determined by data node configuration parameters such as \texttt{MaxDMLOperationsPerTransaction}, \texttt{MaxNoOfConcurrentIndexOperations}, \texttt{MaxNoOfConcurrentOperations}, \texttt{MaxNoOfConcurrentScans}, \texttt{MaxNoOfConcurrentTransactions}, \texttt{MaxNoOfFiredTriggers}, \texttt{MaxNoOfLocalScans}, and \texttt{TransactionBufferMemory} is now done in such a way that, if the load represented by each of these parameters is within the target load for all such resources, others of these resources can be limited so as not to exceed the total resources available.

As part of this work, several new data node parameters controlling transactional resources in \texttt{DBTC}, listed here, have been added:

- \texttt{ReservedConcurrentIndexOperations}
- \texttt{ReservedConcurrentOperations}
- \texttt{ReservedConcurrentScans}
- \texttt{ReservedConcurrentTransactions}
- \texttt{ReservedFiredTriggers}
- \texttt{ReservedLocalScans}
- \texttt{ReservedTransactionBufferMemory}.

See the descriptions of the parameters just listed for further information.

• \textbf{Backups using multiple LDMs per data node.} NDB backups can now be performed in a parallel fashion on individual data nodes using multiple local data managers (LDMs). (Previously, backups were done in parallel across data nodes, but were always serial within data node processes.) No special syntax is required for the \texttt{START BACKUP} command in the \texttt{ndb\_mgm} client to enable this feature, but all data nodes must be using multiple LDMs. This means that data nodes must be running \texttt{ndbmtd} (\texttt{ndbd} is single-threaded and thus always has only one LDM) and they must be configured to use multiple LDMs before taking the backup; you can do this by choosing an appropriate setting for one of the multi-threaded data node configuration parameters \texttt{MaxNoOfExecutionThreads} or \texttt{ThreadConfig}.

Backups using multiple LDMs create subdirectories, one per LDM, under the \texttt{BACKUP/BACKUP-\_backup\_id/} directory. \texttt{ndb\_restore} now detects these subdirectories automatically, and if they exist, attempts to restore the backup in parallel; see \textit{Section 22.4.23.2, “Restoring from a backup taken in parallel”}, for details. (Single-threaded backups are restored as in previous versions of NDB.) It is also possible to restore backups taken in parallel using an \texttt{ndb\_restore} binary from a previous version of NDB Cluster by modifying the usual restore procedure; \textit{Restoring a parallel backup serially}, provides information on how to do this.

• \textbf{Binary configuration file enhancements.} Beginning with NDB 8.0.18, a new format is used for the management server's binary configuration file. Previously, a maximum of 16381 sections could appear in the cluster configuration file; now the maximum number of sections is 4G. This is intended to support larger numbers of nodes in a cluster than was possible before this change.

Upgrades to the new format are relatively seamless, and should seldom if ever require manual intervention, as the management server continues to be able to read the old format without issue. A
downgrade from NDB 8.0.18 (or later) to an older version of the NDB Cluster software requires manual removal of any binary configuration files or, alternatively, starting the older management server binary with the --initial option.

For more information, see Section 22.2.7, “Upgrading and Downgrading NDB Cluster”.

• **Increased number of data nodes.** NDB 8.0.18 increases the maximum number of data nodes supported per cluster to 144 (previously, this was 48). Data nodes can now use node IDs in the range 1 to 144, inclusive.

Previously, the recommended node IDs for management nodes were 49 and 50. These are still supported for management nodes, but using them as such limits the maximum number of data nodes to 142; for this reason, it is now recommended that node IDs 145 and 146 are used for management nodes.

As part of this work, the format used for the data node sysfile has been updated to version 2. This file records information such as the last global checkpoint index, restart status, and node group membership of each node (see NDB Cluster Data Node File System Directory).

• **RedoOverCommitCounter and RedoOverCommitLimit changes.** Due to ambiguities in the semantics for setting them to 0, the minimum value for each of the data node configuration parameters RedoOverCommitCounter and RedoOverCommitLimit has been increased to 1, beginning with NDB 8.0.19.

• **ndb_autoincrement_prefetch_sz changes.** In NDB 8.0.19, the default value of the ndb_autoincrement_prefetch_sz server system variable is increased to 512.

• **Changes in parameter maximums and defaults.** NDB 8.0.19 makes the following changes in configuration parameter maximum and default values:

  • The maximum for DataMemory is increased to 16 terabytes.

  • The maximum for DiskPageBufferMemory is also increased to 16 terabytes.

  • The default value for StringMemory is increased to 25%.

  • The default for LcpScanProgressTimeout is increased to 180 seconds.

• **Disk Data checkpointing improvements.** NDB Cluster 8.0.19 provides a number of new enhancements which help to reduce the latency of checkpoints of Disk Data tables and tablespaces when using non-volatile memory devices such as solid-state drives and the NVMe specification for such devices. These improvements include those in the following list:

  • Avoiding bursts of checkpoint disk writes

  • Speeding up checkpoints for disk data tablespaces when the redo log or the undo log becomes full

  • Balancing checkpoints to disk and in-memory checkpoints against one other, when necessary

  • Protecting disk devices from overload to help ensure low latency under high loads

As part of this work, NDB 8.0.19 introduces two new data node configuration parameters. MaxDiskDataLatency places a ceiling on the degree of latency permitted for disk access and causes transactions taking longer than this length of time to be aborted. DiskDataUsingSameDisk makes it
What is New in NDB Cluster

possible to take advantage of housing Disk Data tablespaces on separate disks by increasing the rate at which checkpoints of such tablespaces can be performed.

In addition, three new tables in the ndbinfo database, also added in NDB 8.0.19 and listed here, provide information about Disk Data performance:

• The diskstat table reports on writes to Disk Data tablespaces during the past second

• The diskstats_1sec table reports on writes to Disk Data tablespaces for each of the last 20 seconds

• The pgman_time_track_stats table reports on the latency of disk operations relating to Disk Data tablespaces

• Memory allocation and TransactionMemory. NDB 8.0.19 introduces a new TransactionMemory parameter which simplifies allocation of data node memory for transactions as part of the work done to pool transactional and Local Data Manager (LDM) memory. This parameter is intended to replace several older transactional memory parameters which have been deprecated.

Transaction memory can now be set in any of the three ways listed here:

• Several configuration parameters are incompatible with TransactionMemory. If any of these are set, TransactionMemory cannot be set (see Parameters incompatible with TransactionMemory), and the data node's transaction memory is determined as it was previous to NDB 8.0.19.

• If TransactionMemory is set, this value is used for determining transaction memory. TransactionMemory cannot be set if any of the incompatible parameters mentioned in the previous item have also been set.

• If none of the incompatible parameters are set and TransactionMemory is also not set, transaction memory is set by NDB.

For more information, see the description of TransactionMemory, as well as Section 22.3.3.13, “Data Node Memory Management”.

• Support for additional fragment replicas. NDB 8.0.19 increases the maximum number of fragment replicas supported in production from two to four. (Previously, it was possible to set NoOfReplicas to 3 or 4, but this was not officially supported or verified in testing.)

• Restoring by slices. Beginning with NDB 8.0.20, it is possible to divide a backup into roughly equal portions (slices) and to restore these slices in parallel using two new options implemented for ndb_restore:

• --num-slices determines the number of slices into which the backup should be divided.

• --slice-id provides the ID of the slice to be restored by the current instance of ndb_restore.

This makes it possible to employ multiple instances of ndb_restore to restore subsets of the backup in parallel, potentially reducing the amount of time required to perform the restore operation.

For more information, see the description of the ndb_restore --num-slices option.
What is New in NDB Cluster

• **Read from any fragment replica enabled.** Beginning with NDB 8.0.19, read from any fragment replica is enabled by default for all NDB tables. This means that the default value for the `ndb_read_backup` system variable is now ON, and that the value of the `NDB_TABLE` comment option `READ_BACKUP` is 1 when creating a new NDB table. Enabling read from any fragment replica significantly improves performance for reads from NDB tables, with minimal impact on writes.

  For more information, see the description of the `ndb_read_backup` system variable, and Section 13.1.20.10, “Setting NDB_TABLE Options”.

• **ndb_blob_tool enhancements.** Beginning with NDB 8.0.20, the `ndb_blob_tool` utility can detect missing blob parts for which inline parts exist and replace these with placeholder blob parts (consisting of space characters) of the correct length. To check whether there are missing blob parts, use the `--check-missing` option with this program. To replace any missing blob parts with placeholders, use the `--add-missing` option.

  For more information, see Section 22.4.6, “ndb_blob_tool — Check and Repair BLOB and TEXT columns of NDB Cluster Tables”.

• **ndbinfo versioning.** NDB 8.0.20 and later supports versioning for ndbinfo tables, and maintains the current definitions for its tables internally. At startup, NDB compares its supported ndbinfo version with the version stored in the data dictionary. If the versions differ, NDB drops any old ndbinfo tables and recreates them using the current definitions.

• **Support for Fedora Linux.** Beginning with NDB 8.0.20, Fedora Linux is a supported platform for NDB Cluster Community releases and can be installed using the RPMs supplied for this purpose by Oracle. These can be obtained from the NDB Cluster downloads page.

• **NDB programs—NDBT dependency removal.** The dependency of a number of NDB utility programs on the NDBT library has been removed. This library is used internally for development, and is not required for normal use; its inclusion in these programs could lead to unwanted issues when testing.

  Affected programs are listed here, along with the NDB versions in which the dependency was removed:
  • `ndb_restore`, in NDB 8.0.17
  • `ndb_delete_all`, in NDB 8.0.18
  • `ndb_show_tables`, in NDB 8.0.20
  • `ndb_waiter`, in NDB 8.0.20

  The principal effect of this change for users is that these programs no longer print `NDBT_ProgramExit - status` following completion of a run. Applications that depend upon such behavior should be updated to reflect the change when upgrading to the indicated versions.

• **Pushdown of outer joins and semijoins.** Work done in NDB 8.0.20 allows many outer joins and semijoins, and not only those using a primary key or unique key lookup, to be pushed down to the data nodes (see Section 8.2.1.5, “Engine Condition Pushdown Optimization”).

  Outer joins using scans which can now be pushed include those which meet the following conditions:
  • There are no unpushed conditions on the table
  • There are no unpushed conditions on other tables in the same join nest, or in upper join nests on which it depends
  • All other tables in the same join nest, or in upper join nests on which it depends, are also pushed
What is New in NDB Cluster

A semijoin that uses an index scan can now be pushed if it meets the conditions just noted for a pushed outer join, and it uses the firstMatch strategy (see Section 8.2.2.1, “Optimizing IN and EXISTS Subquery Predicates with Semijoin Transformations”).

When a join cannot be pushed, EXPLAIN should provide the reason or reasons.

- **Foreign keys and lettercasing.** NDB stores the names of foreign keys using the case with which they were defined. Formerly, when the value of the lower_case_table_names system variable was set to 0, it performed case-sensitive comparisons of foreign key names as used in SELECT and other SQL statements with the names as stored. Beginning with NDB 8.0.20, such comparisons are now always performed in a case-insensitive fashion, regardless of the value of lower_case_table_names.

- **Multiple transporters.** NDB 8.0.20 introduces support for multiple transporters to handle node-to-node communication between pairs of data nodes. This facilitates higher rates of update operations for each node group in the cluster, and helps avoid constraints imposed by system or other limitations on inter-node communications using a single socket.

  By default, NDB now uses a number of transporters based on the number of local data management (LDM) threads or the number of transaction coordinator (TC) threads, whichever is greater. By default, the number of transporters is equal to half of this number. While the default should perform well for most workloads, it is possible to adjust the number of transporters employed by each node group by setting the NodeGroupTransporters data node configuration parameter (also introduced in NDB 8.0.20), up a maximum of the greater of the number of LDM threads or the number of TC threads. Setting it to 0 causes the number of transporters to be the same as the number of LDM threads.

- **ndb_restore: primary key schema changes.** NDB 8.0.21 (and later) supports different primary key definitions for source and target tables when restoring an NDB native backup with ndb_restore when it is run with the --allow-pk-changes option. Both increasing and decreasing the number of columns making up the original primary key are supported.

  When the primary key is extended with an additional column or columns, any columns added must be defined as NOT NULL, and no values in any such columns may be changed during the time that the backup is being taken. Because some applications set all column values in a row when updating it, whether or not all values are actually changed, this can cause a restore operation to fail even if no values in the column to be added to the primary key have changed. You can override this behavior using the --ignore-extended-pk-updates option added in NDB 8.0.21; in this case, you must ensure that no such values are changed.

  A column can be removed from the table's primary key whether or not this column remains part of the table.

  For more information, see the description of the --allow-pk-changes option for ndb_restore.

- **Merging backups with ndb_restore.** In some cases, it may be desirable to consolidate data originally stored in different instances of NDB Cluster (all using the same schema) into a single target NDB Cluster. This is now supported when using backups created in the ndb_mgm client (see Section 22.5.8.2, “Using The NDB Cluster Management Client to Create a Backup”) and restoring them with ndb_restore, using the --remap-column option added in NDB 8.0.21 along with --restore-data (and possibly additional compatible options as needed or desired). --remap-column can be employed to handle cases in which primary and unique key values are overlapping between source clusters, and it is necessary that they do not overlap in the target cluster, as well as to preserve other relationships between tables such as foreign keys.

  --remap-column takes as its argument a string having the format \texttt{db.tbl.col:fn:args}, where \texttt{db}, \texttt{tbl}, and \texttt{col} are, respectively, the names of the database, table, and column, \texttt{fn} is the name
of a remapping function, and `args` is one or more arguments to `fn`. There is no default value. Only `offset` is supported as the function name, with `args` as the integer offset to be applied to the value of the column when inserting it into the target table from the backup. This column must be one of `INT` or `BIGINT`; the allowed range of the offset value is the same as the signed version of that type (this allows the offset to be negative if desired).

The new option can be used multiple times in the same invocation of `ndb_restore`, so that you can remap to new values multiple columns of the same table, different tables, or both. The offset value does not have to be the same for all instances of the option.

In addition, two new options are provided for `ndb_desc`, also beginning in NDB 8.0.21:

- `--auto-inc` (short form `-a`): Includes the the next auto-increment value in the output, if the table has an `AUTO_INCREMENT` column.
- `--context` (short form `-x`): Provides extra information about the table, including the schema, database name, table name, and internal ID.

For more information and examples, see the description of the `--remap-column` option.

- **Send thread improvements.** As of NDB 8.0.20, each send thread now handles sends to a subset of transporters, and each block thread now assists only one send thread, resulting in more send threads, and thus better performance and data node scalability.

- **Adaptive spin control using SpinMethod.** NDB 8.0.20 introduces a simple interface for setting up adaptive CPU spin on platforms supporting it, using the `SpinMethod` data node parameter. This parameter has four settings, one each for static spinning, cost-based adaptive spinning, latency-optimized adaptive spinning, and adaptive spinning optimized for database machines on which each thread has its own CPU. Each of these settings causes the data node to use a set of predetermined values for one or more spin parameters which enable adaptive spinning, set spin timing, and set spin overhead, as appropriate to a given scenario, thus obviating the need to set these directly for common use cases.

For fine-tuning spin behavior, it is also possible to set these and additional spin parameters directly, using the existing `SchedulerSpinTimer` data node configuration parameter as well as the following `DUMP` commands in the `ndb_mgm` client:

- `DUMP 104000 (SetSchedulerSpinTimerAll)`: Sets spin time for all threads
- `DUMP 104001 (SetSchedulerSpinTimerThread)`: Sets spin time for a specified thread
- `DUMP 104002 (SetAllowedSpinOverhead)`: Sets spin overhead as the number of units of CPU time allowed to gain 1 unit of latency
- `DUMP 104003 (SetSpintimePerCall)`: Sets the time for a call to spin
- `DUMP 104004 (EnableAdaptiveSpinning)`: Enables or disables adaptive spinning

NDB 8.0.20 also adds a new TCP configuration parameter `TcpSpinTime` which sets the time to spin for a given TCP connection.

The `ndb_top` tool is also enhanced to provide spin time information per thread.

For additional information, see the description of the `SpinMethod` parameter, the listed `DUMP` commands, and Section 22.4.29, “`ndb_top — View CPU usage information for NDB threads`”.
What is New in NDB Cluster

• **Disk Data and cluster restarts.** Beginning with NDB 8.0.21, an initial restart of the cluster forces the removal of all Disk Data objects such as tablespaces and log file groups, including any data files and undo log files associated with these objects.

See Section 22.5.10, “NDB Cluster Disk Data Tables”, for more information.

• **Disk Data extent allocation.** Beginning with NDB 8.0.20, allocation of extents in data files is done in a round-robin fashion among all data files used by a given tablespace. This is expected to improve distribution of data in cases where multiple storage devices are used for Disk Data storage.

For more information, see Section 22.5.10.1, “NDB Cluster Disk Data Objects”.

• **--ndb-log-fail-terminate option.** Beginning with NDB 8.0.21, you can cause the SQL node to terminate whenever it is unable to log all row events fully. This can be done by starting `mysqld` with the `--ndb-log-fail-terminate` option.

• **AllowUnresolvedHostNames parameter.** By default, a management node refuses to start when it cannot resolve a host name present in the global configuration file, which can be problematic in some environments such as Kubernetes. Beginning with NDB 8.0.22, it is possible to override this behavior by setting `AllowUnresolvedHostNames` to `true` in the `[tcp default]` section of the cluster global configuration file (`config.ini` file). Doing so causes such errors to be treated as warnings instead, and to permit `ndb_mgmd` to continue starting.

• **Blob write performance enhancements.** NDB 8.0.22 implements a number of improvements which allow more efficient batching when modifying multiple blob columns in the same row, or when modifying multiple rows containing blob columns in the same statement, by reducing the number of round trips required between an SQL or other API node and the data nodes when applying these modifications. The performance of many `INSERT`, `UPDATE`, and `DELETE` statements can thus be improved. Examples of such statements are listed here, where `table` is an NDB table containing one or more Blob columns:

  • `INSERT INTO table VALUES ROW(1, blob_value1, blob_value2, ...),` that is, insertion of a row containing one or more Blob columns
  
  • `INSERT INTO table VALUES ROW(1, blob_value1), ROW(2, blob_value2), ROW(3, blob_value3), ...,` that is, insertion of multiple rows containing one or more Blob columns
  
  • `UPDATE table SET blob_column1 = blob_value1, blob_column2 = blob_value2, ...`
  
  • `UPDATE table SET blob_column = blob_value WHERE primary_key_column in (value_list),` where the primary key column is not aBlob type
  
  • `DELETE FROM table WHERE primary_key_column = value,` where the primary key column is not a Blob type
  
  • `DELETE FROM table WHERE primary_key_column IN (value_list),` where the primary key column is not a Blob type

Other SQL statements may benefit from these improvements as well. These include `LOAD DATA INFILE` and `CREATE TABLE ... SELECT ...`. In addition, `ALTER TABLE table ENGINE = NDB`, where `table` uses a storage engine other than NDB prior to execution of the statement, may also execute more efficiently.

This enhancement applies to statements affecting columns of MySQL type `BLOB`, `MEDIUMBLOB`, `LONGBLOB`, `TEXT`, `MEDIUMTEXT`, and `LONGTEXT`. Statements which update `TINYBLOB` or `TINYTEXT` columns (or both types) only are not affected by this work, and no changes in their performance should be expected.
The performance of some SQL statements is not noticeably improved by this enhancement, due to the fact that they require scans of table Blob columns, which breaks up batching. Such statements include those of the types listed here:

- **SELECT FROM table [WHERE key_column IN (blob_value_list)],** where rows are selected by matching on a primary key or unique key column which uses a Blob type

- **UPDATE table SET blob_column = blob_value WHERE condition,** using a condition which does not depend on a unique value

- **DELETE FROM table WHERE condition** to delete rows containing one or more Blob columns, using a condition which does not depend on a unique value

- A copying **ALTER TABLE** statement on a table which already used the **NDB** storage engine prior to executing the statement, and whose rows contain one or more Blob columns before or after the statement is executed (or both)

To take advantage of this improvement to its fullest extent, you may wish to increase the values used for the **--ndb-batch-size** and **--ndb-blob-write-batch-bytes** options for **mysqld**, to minimize the number of round trips required to modify Blobs. For replication, it is also recommended that you enable the **slave_allow_batching** system variable, which minimizes the number of round trips required by the replica cluster to apply epoch transactions.

**Node.js update.** Beginning with with NDB 8.0.22, the **NDB** adapter for Node.js is built using version 12.18.3, and only that version (or a later version of Node.js) is now supported.

**Encrypted backups.** NDB 8.0.22 adds support for backup files encrypted using AES-256-CBC; this is intended to protect against recovery of data from backups that have been accessed by unauthorized parties. When encrypted, backup data is protected by a user-supplied password. The password can be any string consisting of up to 256 characters from the range of printable ASCII characters other than !, ', ',', $, %, \, and ^. Retention of the password used to encrypt any given NDB Cluster backup must be performed by the user or application; **NDB** does not save the password. The password can be empty, although this is not recommended.

When taking an NDB Cluster backup, you can encrypt it by using **ENCRYPT PASSWORD=password** with the management client **START BACKUP** command. Users of the MGM API can also initiate an encrypted backup by calling **ndb_mgm_start_backup4()**.

To restore from an encrypted backup, use **ndb_restore** with the options **--decrypt** and **--backup-password**. Both options are required, along with any others that would be needed to restore the same backup if it were not encrypted. **ndb_print_backup_file** and **ndbxfrm** can also read encrypted files using, respectively, **-P password** and **--decrypt-password=password**.

In all cases in which a password is supplied for encryption or decryption, it must be quoted; you can use either single or double quotation marks to delimit the password.

You can encrypt existing backup files using the **ndbxfrm** utility which is added to the NDB Cluster distribution in the 8.0.22 release; this program can also be employed for decrypting encrypted backup files. In addition, **ndbxfrm** can compress backup files and decompress compressed backup files using the same method that is employed by NDB Cluster for creating backups when the **CompressedBackup** configuration parameter is set to 1.

This feature also implements the ability to enforce encrypted backups by setting **RequireEncryptedBackup=1** in the [ndbd default] section of the cluster global configuration file. When this is done, the **ndb_mgm** client rejects any attempt to perform a backup that is not encrypted.
Options, Variables, and Parameters Added, Deprecated or Removed in NDB 8.0

- **IPv6 support.** Beginning with NDB 8.0.22, IPv6 addressing is supported for connections to management and data nodes; this includes connections between management and data nodes with SQL nodes. When configuring a cluster, you can use numeric IPv6 addresses, host names which resolve to IPv6 addresses or both.

For IPv6 addressing to work, the operating platform and network on which the cluster is deployed must support IPv6. As when using IPv4 addressing, hostname resolution to IPv6 addresses must be provided by the operating platform.

IPv4 addressing continues to be supported by NDB. Using IPv4 and IPv6 addresses concurrently is not recommended, but can be made to work in the following cases:

- When the management node is configured with IPv6 and data nodes are configured with IPv4 addresses in the `config.ini` file: This works if `--bind-address` is not used with `mgmd`, and data nodes are started with `--ndb-connectstring` set to the IPv4 address of the management nodes.

- When the management node is configured with IPv4 and data nodes are configured with IPv6 addresses in `config.ini`: Similarly to the other case, this works if `--bind-address` is not passed to `mgmd` and data nodes are started with `--ndb-connectstring` set to the IPv6 address of the management node.

These cases work because `ndb_mgmd` does not bind to any IP address by default.

To perform an upgrade from a version of NDB that does not support IPv6 addressing to one that does, provided that the network supports IPv4 and IPv6, first perform the software upgrade; after this has been done, you can update IPv4 addresses used in the `config.ini` file with IPv6 addresses. After this, to cause the configuration changes to take effect and to make the cluster start using the IPv6 addresses, it is necessary to perform a system restart of the cluster.

- **Auto-Installer deprecated.** Beginning with NDB 8.0.22, the MySQL NDB Cluster Auto-Installer web-based installation tool (`ndb_setup.py`) is deprecated and is subject to removal in a future release of NDB Cluster.

- **ndbmemcache deprecation and removal.** `ndbmemcache` is no longer supported. It has been deprecated beginning with NDB 8.0.22, and is scheduled for removal in NDB 8.0.23.

MySQL Cluster Manager 1.4.8 also provides experimental support for NDB Cluster 8.0. MySQL Cluster Manager has an advanced command-line interface that can simplify many complex NDB Cluster management tasks. See MySQL™ Cluster Manager 1.4.8 User Manual, for more information.

22.1.5 Options, Variables, and Parameters Added, Deprecated or Removed in NDB 8.0

- **Node Configuration Parameters Introduced in NDB 8.0**
- **Node Configuration Parameters Deprecated in NDB 8.0**
- **Node Configuration Parameters Removed in NDB 8.0**
- **MySQL Server Options and Variables Introduced in NDB 8.0**
- **MySQL Server Options and Variables Deprecated in NDB 8.0**
- **MySQL Server Options and Variables Removed in NDB 8.0**

The next few sections contain information about NDB node configuration parameters and NDB-specific `mysqld` options and variables that have been added to, deprecated in, or removed from NDB 8.0.
Node Configuration Parameters Introduced in NDB 8.0

The following node configuration parameters have been added in NDB 8.0.

- **AllowUnresolvedHostNames**: When false (default), failure by management node to resolve host name results in fatal error; when true, unresolved host names are reported as warnings only. Added in NDB 8.0.22.

- **DiskDataUsingSameDisk**: Set to false if Disk Data tablespaces are located on separate physical disks. Added in NDB 8.0.19.

- **MaxDiskDataLatency**: Maximum allowed mean latency of disk access (ms) before starting to abort transactions. Added in NDB 8.0.19.

- **NodeGroupTransporters**: Number of transporters to use between nodes in same node group. Added in NDB 8.0.20.

- **RequireEncryptedBackup**: Whether backups must be encrypted (1 = encryption required, otherwise 0). Added in NDB 8.0.22.

- **ReservedConcurrentIndexOperations**: Number of simultaneous index operations having dedicated resources on one data node. Added in NDB 8.0.16.

- **ReservedConcurrentOperations**: Number of simultaneous operations having dedicated resources in transaction coordinators on one data node. Added in NDB 8.0.16.

- **ReservedConcurrentScans**: Number of simultaneous scans having dedicated resources on one data node. Added in NDB 8.0.16.

- **ReservedConcurrentTransactions**: Number of simultaneous transactions having dedicated resources on one data node. Added in NDB 8.0.16.

- **ReservedFiredTriggers**: Number of triggers having dedicated resources on one data node. Added in NDB 8.0.16.

- **ReservedLocalScans**: Number of simultaneous fragment scans having dedicated resources on one data node. Added in NDB 8.0.16.

- **ReservedTransactionBufferMemory**: Dynamic buffer space (in bytes) for key and attribute data allocated to each data node. Added in NDB 8.0.16.

- **SpinMethod**: Determines spin method used by data node; see documentation for details. Added in NDB 8.0.20.

- **TcpSpinTime**: Time to spin before going to sleep when receiving. Added in NDB 8.0.20.

- **TransactionMemory**: Memory allocated for transactions on each data node. Added in NDB 8.0.19.

Node Configuration Parameters Deprecated in NDB 8.0

The following node configuration parameters have been deprecated in NDB 8.0.

- **BatchSizePerLocalScan**: Used to calculate number of lock records for scan with hold lock. Deprecated as of NDB 8.0.19.

- **MaxNoOfConcurrentIndexOperations**: Total number of index operations that can execute simultaneously on one data node. Deprecated as of NDB 8.0.19.
Options, Variables, and Parameters Added, Deprecated or Removed in NDB 8.0

- **MaxNoOfConcurrentTransactions**: Maximum number of transactions executing concurrently on this data node, total number of transactions that can be executed concurrently is this value times number of data nodes in cluster. Deprecated as of NDB 8.0.19.

- **MaxNoOfFiredTriggers**: Total number of triggers that can fire simultaneously on one data node. Deprecated as of NDB 8.0.19.

- **MaxNoOfLocalOperations**: Maximum number of operation records defined on this data node. Deprecated as of NDB 8.0.19.

- **MaxNoOfLocalScans**: Maximum number of fragment scans in parallel on this data node. Deprecated as of NDB 8.0.19.

- **ReservedTransactionBufferMemory**: Dynamic buffer space (in bytes) for key and attribute data allocated to each data node. Deprecated as of NDB 8.0.19.

**Node Configuration Parameters Removed in NDB 8.0**

No node configuration parameters have been removed from NDB 8.0.

**MySQL Server Options and Variables Introduced in NDB 8.0**

The following `mysqld` system variables, status variables, and options have been added in NDB 8.0.

- **Ndb_metadata_blacklist_size**: Number of NDB metadata objects that NDB binlog thread has failed to synchronize; renamed in NDB 8.0.22 as Ndb_metadata_excluded_count. Added in NDB 8.0.18.

- **Ndb_metadata_detected_count**: Number of times NDB metadata change monitor thread has detected changes. Added in NDB 8.0.16.

- **Ndb_metadata_excluded_count**: Number of NDB metadata objects that NDB binlog thread has failed to synchronize. Added in NDB 8.0.22.

- **Ndb_metadata_synced_count**: Number of NDB metadata objects which have been synchronized. Added in NDB 8.0.18.

- **Ndb_trans_hint_count_session**: Number of transactions using hints that have been started in this session. Added in NDB 8.0.17.

- **ndb-log-fail-terminate**: Terminate mysqld process if complete logging of all found row events is not possible. Added in NDB 8.0.21.

- **ndb-schema-dist-timeout**: How long to wait before detecting timeout during schema distribution. Added in NDB 8.0.17.

- **ndb dbg_check_shares**: Check for any lingering shares (debug builds only). Added in NDB 8.0.13.

- **ndb_metadata_check**: Enable auto-detection of NDB metadata changes with respect to MySQL data dictionary; enabled by default. Added in NDB 8.0.16.

- **ndb_metadata_check_interval**: Interval in seconds to perform check for NDB metadata changes with respect to MySQL data dictionary. Added in NDB 8.0.16.

- **ndb_metadata_sync**: Triggers immediate synchronization of all changes between NDB dictionary and MySQL data dictionary; causes ndb_metadata_check and ndb_metadata_check_interval values to be ignored. Resets to false when synchronization is complete. Added in NDB 8.0.19.

- **ndb_schema_dist_lock_wait_timeout**: Time during schema distribution to wait for lock before returning error. Added in NDB 8.0.18.
MySQL Server Using InnoDB Compared with NDB Cluster

- **ndb_schema_dist_timeout**: Time to wait before detecting timeout during schema distribution. Added in NDB 8.0.16.
- **ndb_schema_dist_upgrade_allowed**: Allow schema distribution table upgrade when connecting to NDB. Added in NDB 8.0.17.
- **ndbinfo**: Enable ndbinfo plugin, if supported. Added in NDB 8.0.13.

**MySQL Server Options and Variables Deprecated in NDB 8.0**

The following `mysqld` system variables, status variables, and options have been deprecated in NDB 8.0.

- **Ndb_metadata_blacklist_size**: Number of NDB metadata objects that NDB binlog thread has failed to synchronize; renamed in NDB 8.0.22 as Ndb_metadata_excluded_count. Deprecated as of NDB 8.0.21.

**MySQL Server Options and Variables Removed in NDB 8.0**

The following `mysqld` system variables, status variables, and options have been removed in NDB 8.0.

- **Ndb_metadata_blacklist_size**: Number of NDB metadata objects that NDB binlog thread has failed to synchronize; renamed in NDB 8.0.22 as Ndb_metadata_excluded_count. Removed in NDB 8.0.22.

**22.1.6 MySQL Server Using InnoDB Compared with NDB Cluster**

MySQL Server offers a number of choices in storage engines. Since both NDB and InnoDB can serve as transactional MySQL storage engines, users of MySQL Server sometimes become interested in NDB Cluster. They see NDB as a possible alternative or upgrade to the default InnoDB storage engine in MySQL 8.0. While NDB and InnoDB share common characteristics, there are differences in architecture and implementation, so that some existing MySQL Server applications and usage scenarios can be a good fit for NDB Cluster, but not all of them.

In this section, we discuss and compare some characteristics of the NDB storage engine used by NDB 8.0 with InnoDB used in MySQL 8.0. The next few sections provide a technical comparison. In many instances, decisions about when and where to use NDB Cluster must be made on a case-by-case basis, taking all factors into consideration. While it is beyond the scope of this documentation to provide specifics for every conceivable usage scenario, we also attempt to offer some very general guidance on the relative suitability of some common types of applications for NDB as opposed to InnoDB back ends.

NDB Cluster 8.0 uses a `mysqld` based on MySQL 8.0, including support for InnoDB 1.1. While it is possible to use InnoDB tables with NDB Cluster, such tables are not clustered. It is also not possible to use programs or libraries from an NDB Cluster 8.0 distribution with MySQL Server 8.0, or the reverse.

While it is also true that some types of common business applications can be run either on NDB Cluster or on MySQL Server (most likely using the InnoDB storage engine), there are some important architectural and implementation differences. Section 22.1.6.1, “Differences Between the NDB and InnoDB Storage Engines”, provides a summary of the these differences. Due to the differences, some usage scenarios are clearly more suitable for one engine or the other; see Section 22.1.6.2, “NDB and InnoDB Workloads”. This in turn has an impact on the types of applications that better suited for use with NDB or InnoDB. See Section 22.1.6.3, “NDB and InnoDB Feature Usage Summary”, for a comparison of the relative suitability of each for use in common types of database applications.

For information about the relative characteristics of the NDB and MEMORY storage engines, see When to Use MEMORY or NDB Cluster.
22.1.6.1 Differences Between the NDB and InnoDB Storage Engines

The NDB storage engine is implemented using a distributed, shared-nothing architecture, which causes it to behave differently from InnoDB in a number of ways. For those unaccustomed to working with NDB, unexpected behaviors can arise due to its distributed nature with regard to transactions, foreign keys, table limits, and other characteristics. These are shown in the following table:

Table 22.1 Differences between InnoDB and NDB storage engines

<table>
<thead>
<tr>
<th>Feature</th>
<th>InnoDB (MySQL 8.0)</th>
<th>NDB 8.0</th>
</tr>
</thead>
<tbody>
<tr>

### 22.1.6.2 NDB and InnoDB Workloads

NDB Cluster has a range of unique attributes that make it ideal to serve applications requiring high availability, fast failover, high throughput, and low latency. Due to its distributed architecture and multi-node implementation, NDB Cluster also has specific constraints that may keep some workloads from performing well. A number of major differences in behavior between the NDB and InnoDB storage engines with regard to some common types of database-driven application workloads are shown in the following table:

#### Table 22.2 Differences between InnoDB and NDB storage engines, common types of data-driven application workloads.

<table>
<thead>
<tr>
<th>Workload</th>

### 22.1.6.3 NDB and InnoDB Feature Usage Summary

When comparing application feature requirements to the capabilities of InnoDB with NDB, some are clearly more compatible with one storage engine than the other.
The following table lists supported application features according to the storage engine to which each feature is typically better suited.

**Table 22.3 Supported application features according to the storage engine to which each feature is typically better suited**

<table>
<thead>
<tr>
<th>Preferred application requirements for <strong>InnoDB</strong></th>
<th>Preferred application requirements for <strong>NDB</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>• Foreign keys</td>
<td>• Write scaling</td>
</tr>
<tr>
<td>• Full table scans</td>
<td>• 99.999% uptime</td>
</tr>
<tr>
<td>• Very large databases, rows, or transactions</td>
<td>• Online addition of nodes and online schema operations</td>
</tr>
<tr>
<td>• Transactions other than <strong>READ COMMITTED</strong></td>
<td>• Multiple SQL and NoSQL APIs (see NDB Cluster APIs: Overview and Concepts)</td>
</tr>
</tbody>
</table>

**22.1.7 Known Limitations of NDB Cluster**

In the sections that follow, we discuss known limitations in current releases of NDB Cluster as compared with the features available when using the **MyISAM** and **InnoDB** storage engines. If you check the “Cluster” category in the MySQL bugs database at [http://bugs.mysql.com](http://bugs.mysql.com), you can find known bugs in the following categories under “MySQL Server:” in the MySQL bugs database at [http://bugs.mysql.com](http://bugs.mysql.com), which we intend to correct in upcoming releases of NDB Cluster:

- NDB Cluster
- Cluster Direct API (NDBAPI)
- Cluster Disk Data
- Cluster Replication
- ClusterJ

This information is intended to be complete with respect to the conditions just set forth. You can report any discrepancies that you encounter to the MySQL bugs database using the instructions given in Section 1.6, “How to Report Bugs or Problems”. Any problem which we do not plan to fix in NDB Cluster 8.0, is added to the list.

See Section 22.1.7.11, “Previous NDB Cluster Issues Resolved in NDB Cluster 8.0” for a list of issues in earlier releases that have been resolved in NDB Cluster 8.0.

**Note**

Limitations and other issues specific to NDB Cluster Replication are described in Section 22.6.3, “Known Issues in NDB Cluster Replication”.

3864
22.1.7.1 Noncompliance with SQL Syntax in NDB Cluster

Some SQL statements relating to certain MySQL features produce errors when used with NDB tables, as described in the following list:

- **Temporary tables.** Temporary tables are not supported. Trying either to create a temporary table that uses the NDB storage engine or to alter an existing temporary table to use NDB fails with the error `Table storage engine 'ndbcluster' does not support the create option 'TEMPORARY'`.

- **Indexes and keys in NDB tables.** Keys and indexes on NDB Cluster tables are subject to the following limitations:
  - **Column width.** Attempting to create an index on an NDB table column whose width is greater than 3072 bytes succeeds, but only the first 3072 bytes are actually used for the index. In such cases, a warning `Specified key was too long; max key length is 3072 bytes` is issued, and a `SHOW CREATE TABLE` statement shows the length of the index as 3072.
  - **TEXT and BLOB columns.** You cannot create indexes on NDB table columns that use any of the TEXT or BLOB data types.
  - **FULLTEXT indexes.** The NDB storage engine does not support FULLTEXT indexes, which are possible for MyISAM and InnoDB tables only. However, you can create indexes on VARCHAR columns of NDB tables.
  - **USING HASH keys and NULL.** Using nullable columns in unique keys and primary keys means that queries using these columns are handled as full table scans. To work around this issue, make the column NOT NULL, or re-create the index without the USING HASH option.
  - **Prefixes.** There are no prefix indexes; only entire columns can be indexed. (The size of an NDB column index is always the same as the width of the column in bytes, up to and including 3072 bytes, as described earlier in this section. Also see Section 22.1.7.6, “Unsupported or Missing Features in NDB Cluster”, for additional information.)
  - **BIT columns.** A BIT column cannot be a primary key, unique key, or index, nor can it be part of a composite primary key, unique key, or index.
  - **AUTO_INCREMENT columns.** Like other MySQL storage engines, the NDB storage engine can handle a maximum of one AUTO_INCREMENT column per table. However, in the case of an NDB table with no explicit primary key, an AUTO_INCREMENT column is automatically defined and used as a “hidden” primary key. For this reason, you cannot define a table that has an explicit AUTO_INCREMENT column unless that column is also declared using the PRIMARY KEY option. Attempting to create a table with an AUTO_INCREMENT column that is not the table's primary key, and using the NDB storage engine, fails with an error.
  - **Restrictions on foreign keys.** Support for foreign key constraints in NDB 8.0 is comparable to that provided by InnoDB, subject to the following restrictions:
    - Every column referenced as a foreign key requires an explicit unique key, if it is not the table's primary key.
    - ON UPDATE CASCADE is not supported when the reference is to the parent table’s primary key.

This is because an update of a primary key is implemented as a delete of the old row (containing the old primary key) plus an insert of the new row (with a new primary key). This is not visible to the
NDB kernel, which views these two rows as being the same, and thus has no way of knowing that this update should be cascaded.

- As of NDB 8.0.16: `ON DELETE CASCADE` is not supported where the child table contains one or more columns of any of the TEXT or BLOB types. (Bug #89511, Bug #27484882)

- `SET DEFAULT` is not supported. (Also not supported by InnoDB.)

- The NO ACTION keyword is accepted but treated as RESTRICT.NO ACTION, which is a standard SQL keyword, is the default in MySQL 8.0. (Also the same as with InnoDB.)

- In earlier versions of NDB Cluster, when creating a table with foreign key referencing an index in another table, it sometimes appeared possible to create the foreign key even if the order of the columns in the indexes did not match, due to the fact that an appropriate error was not always returned internally. A partial fix for this issue improved the error used internally to work in most cases; however, it remains possible for this situation to occur in the event that the parent index is a unique index. (Bug #18094360)

For more information, see Section 13.1.20.5, “FOREIGN KEY Constraints”, and Section 1.7.3.2, “FOREIGN KEY Constraints”.

- **NDB Cluster and geometry data types.**
  Geometry data types (WKT and WKB) are supported for NDB tables. However, spatial indexes are not supported.

- **Character sets and binary log files.** Currently, the `ndb_apply_status` and `ndb_binlog_index` tables are created using the latin1 (ASCII) character set. Because names of binary logs are recorded in this table, binary log files named using non-Latin characters are not referenced correctly in these tables. This is a known issue, which we are working to fix. (Bug #50226)

  To work around this problem, use only Latin-1 characters when naming binary log files or setting any the `--basedir`, `--log-bin`, or `--log-bin-index` options.

- **Creating NDB tables with user-defined partitioning.** Support for user-defined partitioning in NDB Cluster is restricted to [LINEAR] KEY partitioning. Using any other partitioning type with ENGINE=NDB or ENGINE=NDBCLUSTER in a CREATE TABLE statement results in an error.

  It is possible to override this restriction, but doing so is not supported for use in production settings. For details, see User-defined partitioning and the NDB storage engine (NDB Cluster).

- **Default partitioning scheme.** All NDB Cluster tables are by default partitioned by KEY using the table’s primary key as the partitioning key. If no primary key is explicitly set for the table, the “hidden” primary key automatically created by the NDB storage engine is used instead. For additional discussion of these and related issues, see Section 23.2.5, “KEY Partitioning”.

  CREATE TABLE and ALTER TABLE statements that would cause a user-partitioned NDBCLUSTER table not to meet either or both of the following two requirements are not permitted, and fail with an error:

  1. The table must have an explicit primary key.
  2. All columns listed in the table’s partitioning expression must be part of the primary key.

  **Exception.** If a user-partitioned NDBCLUSTER table is created using an empty column-list (that is, using PARTITION BY [LINEAR] KEY()), then no explicit primary key is required.

- **Maximum number of partitions for NDBCLUSTER tables.** The maximum number of partitions that can defined for a NDBCLUSTER table when employing user-defined partitioning is 8 per node group.
Known Limitations of NDB Cluster

(See Section 22.1.2, “NDB Cluster Nodes, Node Groups, Fragment Replicas, and Partitions”, for more information about NDB Cluster node groups.

**DROP PARTITION not supported.** It is not possible to drop partitions from NDB tables using `ALTER TABLE ... DROP PARTITION`. The other partitioning extensions to `ALTER TABLE`—`ADD PARTITION`, `REORGANIZE PARTITION`, and `COALESCE PARTITION`—are supported for NDB tables, but use copying and so are not optimized. See Section 23.3.1, “Management of RANGE and LIST Partitions” and Section 13.1.9, “ALTER TABLE Statement”.

- **Row-based replication.** When using row-based replication with NDB Cluster, binary logging cannot be disabled. That is, the NDB storage engine ignores the value of `sql_log_bin`.

- **JSON data type.** The MySQL JSON data type is supported for NDB tables in the `mysqld` supplied with NDB 8.0.

  An NDB table can have a maximum of 3 JSON columns.

  The NDB API has no special provision for working with JSON data, which it views simply as BLOB data. Handling data as JSON must be performed by the application.

22.1.7.2 Limits and Differences of NDB Cluster from Standard MySQL Limits

In this section, we list limits found in NDB Cluster that either differ from limits found in, or that are not found in, standard MySQL.

**Memory usage and recovery.** Memory consumed when data is inserted into an NDB table is not automatically recovered when deleted, as it is with other storage engines. Instead, the following rules hold true:

- A `DELETE` statement on an NDB table makes the memory formerly used by the deleted rows available for re-use by inserts on the same table only. However, this memory can be made available for general re-use by performing `OPTIMIZE TABLE`.

  A rolling restart of the cluster also frees any memory used by deleted rows. See Section 22.5.5, “Performing a Rolling Restart of an NDB Cluster”.

- A `DROP TABLE` or `TRUNCATE TABLE` operation on an NDB table frees the memory that was used by this table for re-use by any NDB table, either by the same table or by another NDB table.

  **Note**

  Recall that TRUNCATE TABLE drops and re-creates the table. See Section 13.1.37, “TRUNCATE TABLE Statement”.

- **Limits imposed by the cluster's configuration.** A number of hard limits exist which are configurable, but available main memory in the cluster sets limits. See the complete list of configuration parameters in Section 22.3.3, “NDB Cluster Configuration Files”. Most configuration parameters can be upgraded online. These hard limits include:

  - Database memory size and index memory size (`DataMemory` and `IndexMemory`, respectively).

    `DataMemory` is allocated as 32KB pages. As each `DataMemory` page is used, it is assigned to a specific table; once allocated, this memory cannot be freed except by dropping the table.

    See Section 22.3.3.6, “Defining NDB Cluster Data Nodes”, for more information.
Known Limitations of NDB Cluster

- The maximum number of operations that can be performed per transaction is set using the configuration parameters `MaxNoOfConcurrentOperations` and `MaxNoOfLocalOperations`.

  **Note**
  Bulk loading, `TRUNCATE TABLE`, and `ALTER TABLE` are handled as special cases by running multiple transactions, and so are not subject to this limitation.

- Different limits related to tables and indexes. For example, the maximum number of ordered indexes in the cluster is determined by `MaxNoOfOrderedIndexes`, and the maximum number of ordered indexes per table is 16.

- **Node and data object maximums.** The following limits apply to numbers of cluster nodes and metadata objects:
  - As of NDB 8.0.18, the maximum number of data nodes is 145. (Previously, this was 48.)
  
  A data node must have a node ID in the range of 1 to 144, inclusive. (In NDB 8.0.17 and earlier releases, this was 1 to 48, inclusive.)

  Management and API nodes may use node IDs in the range 1 to 255, inclusive.

  - The total maximum number of nodes in an NDB Cluster is 255. This number includes all SQL nodes (MySQL Servers), API nodes (applications accessing the cluster other than MySQL servers), data nodes, and management servers.

  - The maximum number of metadata objects in current versions of NDB Cluster is 20320. This limit is hard-coded.

  See Section 22.1.7.11, “Previous NDB Cluster Issues Resolved in NDB Cluster 8.0”, for more information.

22.1.7.3 Limits Relating to Transaction Handling in NDB Cluster

A number of limitations exist in NDB Cluster with regard to the handling of transactions. These include the following:

- **Transaction isolation level.** The `NDBCLUSTER` storage engine supports only the `READ COMMITTED` transaction isolation level. (InnoDB, for example, supports `READ COMMITTED`, `READ UNCOMMITTED`, `REPEATABLE READ`, and `SERIALIZABLE`.) You should keep in mind that NDB implements `READ COMMITTED` on a per-row basis; when a read request arrives at the data node storing the row, what is returned is the last committed version of the row at that time.

  Uncommitted data is never returned, but when a transaction modifying a number of rows commits concurrently with a transaction reading the same rows, the transaction performing the read can observe “before” values, “after” values, or both, for different rows among these, due to the fact that a given row read request can be processed either before or after the commit of the other transaction.

  To ensure that a given transaction reads only before or after values, you can impose row locks using `SELECT ... LOCK IN SHARE MODE`. In such cases, the lock is held until the owning transaction is committed. Using row locks can also cause the following issues:

  - Increased frequency of lock wait timeout errors, and reduced concurrency
  - Increased transaction processing overhead due to reads requiring a commit phase
Known Limitations of NDB Cluster

- Possibility of exhausting the available number of concurrent locks, which is limited by MaxNoOfConcurrentOperations

NDB uses READ COMMITTED for all reads unless a modifier such as LOCK IN SHARE MODE or FOR UPDATE is used. LOCK IN SHARE MODE causes shared row locks to be used; FOR UPDATE causes exclusive row locks to be used. Unique key reads have their locks upgraded automatically by NDB to ensure a self-consistent read; BLOB reads also employ extra locking for consistency.

See Section 22.5.8.4, “NDB Cluster Backup Troubleshooting”, for information on how NDB Cluster's implementation of transaction isolation level can affect backup and restoration of NDB databases.

- Transactions and BLOB or TEXT columns. NDBCLUSTER stores only part of a column value that uses any of MySQL's BLOB or TEXT data types in the table visible to MySQL; the remainder of the BLOB or TEXT is stored in a separate internal table that is not accessible to MySQL. This gives rise to two related issues of which you should be aware whenever executing SELECT statements on tables that contain columns of these types:

  1. For any SELECT from an NDB Cluster table: If the SELECT includes a BLOB or TEXT column, the READ COMMITTED transaction isolation level is converted to a read with read lock. This is done to guarantee consistency.

  2. For any SELECT which uses a unique key lookup to retrieve any columns that use any of the BLOB or TEXT data types and that is executed within a transaction, a shared read lock is held on the table for the duration of the transaction—that is, until the transaction is either committed or aborted.

This issue does not occur for queries that use index or table scans, even against NDB tables having BLOB or TEXT columns.

For example, consider the table t defined by the following CREATE TABLE statement:

```sql
CREATE TABLE t (
    a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    b INT NOT NULL,
    c INT NOT NULL,
    d TEXT,
    INDEX i(b),
    UNIQUE KEY u(c)
) ENGINE = NDB,
```

The following query on t causes a shared read lock, because it uses a unique key lookup:

```sql
SELECT * FROM t WHERE c = 1;
```

However, none of the four queries shown here causes a shared read lock:

```sql
SELECT * FROM t WHERE b = 1;
SELECT * FROM t WHERE d = '1';
SELECT * FROM t;
```
This is because, of these four queries, the first uses an index scan, the second and third use table scans, and the fourth, while using a primary key lookup, does not retrieve the value of any BLOB or TEXT columns.

You can help minimize issues with shared read locks by avoiding queries that use unique key lookups that retrieve BLOB or TEXT columns, or, in cases where such queries are not avoidable, by committing transactions as soon as possible afterward.

• **Unique key lookups and transaction isolation.** Unique indexes are implemented in NDB using a hidden index table which is maintained internally. When a user-created NDB table is accessed using a unique index, the hidden index table is first read to find the primary key that is then used to read the user-created table. To avoid modification of the index during this double-read operation, the row found in the hidden index table is locked. When a row referenced by a unique index in the user-created NDB table is updated, the hidden index table is subject to an exclusive lock by the transaction in which the update is performed. This means that any read operation on the same (user-created) NDB table must wait for the update to complete. This is true even when the transaction level of the read operation is READ COMMITTED.

One workaround which can be used to bypass potentially blocking reads is to force the SQL node to ignore the unique index when performing the read. This can be done by using the `IGNORE INDEX` index hint as part of the `SELECT` statement reading the table (see Section 8.9.4, “Index Hints”). Because the MySQL server creates a shadowing ordered index for every unique index created in NDB, this lets the ordered index be read instead, and avoids unique index access locking. The resulting read is as consistent as a committed read by primary key, returning the last committed value at the time the row is read.

Reading via an ordered index makes less efficient use of resources in the cluster, and may have higher latency.

It is also possible to avoid using the unique index for access by querying for ranges rather than for unique values.

• **Rollbacks.** There are no partial transactions, and no partial rollbacks of transactions. A duplicate key or similar error causes the entire transaction to be rolled back.

This behavior differs from that of other transactional storage engines such as InnoDB that may roll back individual statements.

• **Transactions and memory usage.**
As noted elsewhere in this chapter, NDB Cluster does not handle large transactions well; it is better to perform a number of small transactions with a few operations each than to attempt a single large transaction containing a great many operations. Among other considerations, large transactions require very large amounts of memory. Because of this, the transactional behavior of a number of MySQL statements is affected as described in the following list:

• **TRUNCATE TABLE** is not transactional when used on NDB tables. If a TRUNCATE TABLE fails to empty the table, then it must be re-run until it is successful.

• **DELETE FROM** (even with no WHERE clause) is transactional. For tables containing a great many rows, you may find that performance is improved by using several DELETE FROM ... LIMIT ...
known limitations of ndb cluster

statements to “chunk” the delete operation. if your objective is to empty the table, then you may wish to use
\texttt{TRUNCATE TABLE} instead.

\begin{itemize}
\item \textbf{LOAD DATA statements.} \texttt{LOAD DATA} is not transactional when used on \texttt{NDB} tables.
\end{itemize}

\begin{itemize}
\item \textbf{Important}
\end{itemize}

when executing a \texttt{LOAD DATA} statement, the \texttt{NDB} engine performs commits at irregular intervals that enable better utilization of the communication network. it is not possible to know ahead of time when such commits take place.

\begin{itemize}
\item \textbf{ALTER TABLE and transactions.} when copying an \texttt{NDB} table as part of an \texttt{ALTER TABLE}, the creation of the copy is nontransactional. (in any case, this operation is rolled back when the copy is deleted.)
\end{itemize}

\begin{itemize}
\item \textbf{Transactions and the \texttt{COUNT}() function.} when using ndb cluster replication, it is not possible to guarantee the transactional consistency of the \texttt{COUNT()} function on the replica. in other words, when performing on the source a series of statements (\texttt{INSERT}, \texttt{DELETE}, or both) that changes the number of rows in a table within a single transaction, executing \texttt{SELECT COUNT(*) FROM} \texttt{table} queries on the replica may yield intermediate results. this is due to the fact that \texttt{SELECT COUNT(...) may perform dirty reads, and is not a bug in the \texttt{NDB} storage engine. (see bug \#31321 for more information.)}
\end{itemize}

\begin{section}{22.1.7.4 NDB Cluster Error Handling}

starting, stopping, or restarting a node may give rise to temporary errors causing some transactions to fail. these include the following cases:

\begin{itemize}
\item \textbf{Temporary errors.} when first starting a node, it is possible that you may see error 1204 \texttt{Temporary failure, distribution changed} and similar temporary errors.
\end{itemize}

\begin{itemize}
\item \textbf{Errors due to node failure.} the stopping or failure of any data node can result in a number of different node failure errors. (however, there should be no aborted transactions when performing a planned shutdown of the cluster.)
\end{itemize}

in either of these cases, any errors that are generated must be handled within the application. this should be done by retrying the transaction.

see also section 22.1.7.2, “limits and differences of ndb cluster from standard mysql limits”.

\begin{section}{22.1.7.5 Limits Associated with Database Objects in NDB Cluster}

some database objects such as tables and indexes have different limitations when using the \texttt{NDBCLUSTER} storage engine:

\begin{itemize}
\item \textbf{Number of database objects.} the maximum number of all \texttt{NDB} database objects in a single ndb cluster—including databases, tables, and indexes—is limited to 20320.
\end{itemize}

\begin{itemize}
\item \textbf{Attributes per table.} the maximum number of attributes (that is, columns and indexes) that can belong to a given table is 512.
\end{itemize}

\begin{itemize}
\item \textbf{Attributes per key.} the maximum number of attributes per key is 32.
\end{itemize}

\begin{itemize}
\item \textbf{Row size.} beginning with ndb 8.0.18, the maximum permitted size of any one row is 30000 bytes, in ndb 8.0.17 and earlier releases, this limit is 14000 bytes.
\end{itemize}

Each \texttt{BLOB} or \texttt{TEXT} column contributes \(256 + 8 = 264\) bytes to this total; this includes \texttt{JSON} columns. see \texttt{String Type Storage Requirements}, as well as \texttt{JSON Storage Requirements}, for more information relating to these types.
In addition, the maximum offset for a fixed-width column of an NDB table is 8188 bytes; attempting to create a table that violates this limitation fails with NDB error 851 Maximum offset for fixed-size columns exceeded. For memory-based columns, you can work around this limitation by using a variable-width column type such as VARCHAR or defining the column as COLUMN_FORMAT=DYNAMIC; this does not work with columns stored on disk. For disk-based columns, you may be able to do so by reordering one or more of the table's disk-based columns such that the combined width of all but the disk-based column defined last in the CREATE TABLE statement used to create the table does not exceed 8188 bytes, less any possible rounding performed for some data types such as CHAR or VARCHAR; otherwise it is necessary to use memory-based storage for one or more of the offending column or columns instead.

- **BIT column storage per table.** The maximum combined width for all BIT columns used in a given NDB table is 4096.

- **FIXED column storage.** NDB Cluster 8.0 supports a maximum of 128 TB per fragment of data in FIXED columns.

### 22.1.7.6 Unsupported or Missing Features in NDB Cluster

A number of features supported by other storage engines are not supported for NDB tables. Trying to use any of these features in NDB Cluster does not cause errors in or of itself; however, errors may occur in applications that expects the features to be supported or enforced. Statements referencing such features, even if effectively ignored by NDB, must be syntactically and otherwise valid.

- **Index prefixes.** Prefixes on indexes are not supported for NDB tables. If a prefix is used as part of an index specification in a statement such as CREATE TABLE, ALTER TABLE, or CREATE INDEX, the prefix is not created by NDB.

A statement containing an index prefix, and creating or modifying an NDB table, must still be syntactically valid. For example, the following statement always fails with Error 1089 Incorrect prefix key; the used key part isn't a string, the used length is longer than the key part, or the storage engine doesn't support unique prefix keys, regardless of storage engine:

```sql
CREATE TABLE t1 (  
    c1 INT NOT NULL,  
    c2 VARCHAR(100),  
    INDEX i1 (c2(500))  
);
```

This happens on account of the SQL syntax rule that no index may have a prefix larger than itself.

- **Savepoints and rollbacks.** Savepoints and rollbacks to savepoints are ignored as in MyISAM.

- **Durability of commits.** There are no durable commits on disk. Commits are replicated, but there is no guarantee that logs are flushed to disk on commit.

- **Replication.** Statement-based replication is not supported. Use --binlog-format=ROW (or --binlog-format=MIXED) when setting up cluster replication. See Section 22.6, “NDB Cluster Replication”, for more information.

Replication using global transaction identifiers (GTIDs) is not compatible with NDB Cluster, and is not supported in NDB Cluster 8.0. Do not enable GTIDs when using the NDB storage engine, as this is very likely to cause problems up to and including failure of NDB Cluster Replication.

Semisynchronous replication is not supported in NDB Cluster.
Known Limitations of NDB Cluster

- **Generated columns.** The NDB storage engine does not support indexes on virtual generated columns.

  As with other storage engines, you can create an index on a stored generated column, but you should bear in mind that NDB uses DataMemory for storage of the generated column as well as IndexMemory for the index. See JSON columns and indirect indexing in NDB Cluster, for an example.

  NDB Cluster writes changes in stored generated columns to the binary log, but does log not those made to virtual columns. This should not effect NDB Cluster Replication or replication between NDB and other MySQL storage engines.

  **Note**

  See Section 22.1.7.3, “Limits Relating to Transaction Handling in NDB Cluster”, for more information relating to limitations on transaction handling in NDB.

### 22.1.7.7 Limitations Relating to Performance in NDB Cluster

The following performance issues are specific to or especially pronounced in NDB Cluster:

- **Range scans.** There are query performance issues due to sequential access to the NDB storage engine; it is also relatively more expensive to do many range scans than it is with either MyISAM or InnoDB.

- **Reliability of Records in range.** The Records in range statistic is available but is not completely tested or officially supported. This may result in nonoptimal query plans in some cases. If necessary, you can employ USE INDEX or FORCE INDEX to alter the execution plan. See Section 8.9.4, “Index Hints”, for more information on how to do this.

- **Unique hash indexes.** Unique hash indexes created with USING HASH cannot be used for accessing a table if NULL is given as part of the key.

### 22.1.7.8 Issues Exclusive to NDB Cluster

The following are limitations specific to the NDB storage engine:

- **Machine architecture.** All machines used in the cluster must have the same architecture. That is, all machines hosting nodes must be either big-endian or little-endian, and you cannot use a mixture of both. For example, you cannot have a management node running on a PowerPC which directs a data node that is running on an x86 machine. This restriction does not apply to machines simply running mysql or other clients that may be accessing the cluster’s SQL nodes.

- **Binary logging.**

  NDB Cluster has the following limitations or restrictions with regard to binary logging:

  - `sql_log_bin` has no effect on data operations; however, it is supported for schema operations.
  - NDB Cluster cannot produce a binary log for tables having BLOB columns but no primary key.
  - Only the following schema operations are logged in a cluster binary log which is not on the mysqld executing the statement:

    - **CREATE TABLE**
    - **ALTER TABLE**
    - **DROP TABLE**
Known Limitations of NDB Cluster

- **CREATE DATABASE**/CREATE SCHEMA
- **DROP DATABASE**/DROP SCHEMA
- **CREATE TABLESPACE**
- **ALTER TABLESPACE**
- **DROP TABLESPACE**
- **CREATE LOGFILE GROUP**
- **ALTER LOGFILE GROUP**
- **DROP LOGFILE GROUP**

- **Schema operations.** Schema operations (DDL statements) are rejected while any data node restarts. Schema operations are also not supported while performing an online upgrade or downgrade.

- **Number of fragment replicas.** The number of fragment replicas, as determined by the `NoOfReplicas` data node configuration parameter, is the number of copies of all data stored by NDB Cluster. Setting this parameter to 1 means there is only a single copy; in this case, no redundancy is provided, and the loss of a data node entails loss of data. To guarantee redundancy, and thus preservation of data even if a data node fails, set this parameter to 2, which is the default and recommended value in production.

  Setting `NoOfReplicas` to a value greater than 2 is supported (to a maximum of 4) but unnecessary to guard against loss of data.

  See also Section 22.1.7.10, “Limitations Relating to Multiple NDB Cluster Nodes”.

### 22.1.7.9 Limitations Relating to NDB Cluster Disk Data Storage

**Disk Data object maximums and minimums.** Disk data objects are subject to the following maximums and minimums:

- Maximum number of tablespaces: $2^{32}$ (4294967296)
- Maximum number of data files per tablespace: $2^{16}$ (65536)
- The minimum and maximum possible sizes of extents for tablespace data files are 32K and 2G, respectively. See Section 13.1.21, “CREATE TABLESPACE Statement”, for more information.

In addition, when working with NDB Disk Data tables, you should be aware of the following issues regarding data files and extents:

- Data files use `DataMemory`. Usage is the same as for in-memory data.
- Data files use file descriptors. It is important to keep in mind that data files are always open, which means the file descriptors are always in use and cannot be re-used for other system tasks.
- Extents require sufficient `DiskPageBufferMemory`; you must reserve enough for this parameter to account for all memory used by all extents (number of extents times size of extents).

**Disk Data tables and diskless mode.** Use of Disk Data tables is not supported when running the cluster in diskless mode.
22.1.7.10 Limitations Relating to Multiple NDB Cluster Nodes

Multiple SQL nodes.
The following are issues relating to the use of multiple MySQL servers as NDB Cluster SQL nodes, and are specific to the NDBCLUSTER storage engine:

- **Stored programs not distributed.** Stored procedures, stored functions, triggers, and scheduled events are all supported by tables using the NDB storage engine, but these do not propagate automatically between MySQL Servers acting as Cluster SQL nodes, and must be re-created separately on each SQL node. See Stored routines and triggers in NDB Cluster.

- **No distributed table locks.** A LOCK TABLES works only for the SQL node on which the lock is issued; no other SQL node in the cluster "sees" this lock. This is also true for a lock issued by any statement that locks tables as part of its operations. (See next item for an example.)

- **ALTER TABLE operations.** ALTER TABLE is not fully locking when running multiple MySQL servers (SQL nodes). (As discussed in the previous item, NDB Cluster does not support distributed table locks.)

Multiple management nodes.
When using multiple management servers:

- If any of the management servers are running on the same host, you must give nodes explicit IDs in connection strings because automatic allocation of node IDs does not work across multiple management servers on the same host. This is not required if every management server resides on a different host.

- When a management server starts, it first checks for any other management server in the same NDB Cluster, and upon successful connection to the other management server uses its configuration data. This means that the management server --reload and --initial startup options are ignored unless the management server is the only one running. It also means that, when performing a rolling restart of an NDB Cluster with multiple management nodes, the management server reads its own configuration file if (and only if) it is the only management server running in this NDB Cluster. See Section 22.5.5, "Performing a Rolling Restart of an NDB Cluster", for more information.

Multiple network addresses. Multiple network addresses per data node are not supported. Use of these is liable to cause problems: In the event of a data node failure, an SQL node waits for confirmation that the data node went down but never receives it because another route to that data node remains open. This can effectively make the cluster inoperable.

```
Note
It is possible to use multiple network hardware interfaces (such as Ethernet cards) for a single data node, but these must be bound to the same address. This also means that it is not possible to use more than one [tcp] section per connection in the config.ini file. See Section 22.3.3.10, "NDB Cluster TCP/IP Connections", for more information.
```

22.1.7.11 Previous NDB Cluster Issues Resolved in NDB Cluster 8.0

A number of limitations and related issues that existed in earlier versions of NDB Cluster have been resolved in NDB 8.0. These are described briefly in the following list:

- **Database and table names.** Prior to NDB 8.0.18, when using the NDB storage engine, the maximum allowed length both for database names and for table names is 63 characters, and a statement using a database name or table name longer than this limit failed with an appropriate error. As of NDB 8.0.18, this restriction is lifted and identifiers for NDB databases and tables may now use up to 64 bytes, as with other MySQL database and table names.
IPv6 support. Prior to NDB 8.0.22, it was necessary for all network addresses used for connections between nodes within an NDB Cluster to use or to be resolvable to IPv4 addresses. Beginning with NDB 8.0.22, NDB supports IPv6 addresses for all types of cluster nodes, as well as for applications that use the NDB API or MGM API.

22.2 NDB Cluster Installation

This section describes the basics for planning, installing, configuring, and running an NDB Cluster. Whereas the examples in Section 22.3, “Configuration of NDB Cluster” provide more in-depth information on a variety of clustering options and configuration, the result of following the guidelines and procedures outlined here should be a usable NDB Cluster which meets the minimum requirements for availability and safeguarding of data.

For information about upgrading or downgrading an NDB Cluster between release versions, see Section 22.2.7, “Upgrading and Downgrading NDB Cluster”.

This section covers hardware and software requirements; networking issues; installation of NDB Cluster; basic configuration issues; starting, stopping, and restarting the cluster; loading of a sample database; and performing queries.

NDB Cluster also provides the NDB Cluster Auto-Installer (now deprecated), a web-based graphical installer, as part of the NDB Cluster distribution. The Auto-Installer can be used to perform basic installation and setup of an NDB Cluster on one (for testing) or more host computers. See Section 22.2.8, “The NDB Cluster Auto-Installer (DEPRECATED)”, for more information.

Assumptions. The following sections make a number of assumptions regarding the cluster’s physical and network configuration. These assumptions are discussed in the next few paragraphs.

Cluster nodes and host computers. The cluster consists of four nodes, each on a separate host computer, and each with a fixed network address on a typical Ethernet network as shown here:

<table>
<thead>
<tr>
<th>Node</th>
<th>IP Address</th>
</tr>
</thead>
<tbody>
<tr>
<td>Management node (mgmd)</td>
<td>198.51.100.10</td>
</tr>
<tr>
<td>SQL node (mysqld)</td>
<td>198.51.100.20</td>
</tr>
<tr>
<td>Data node &quot;A&quot; (ndbd)</td>
<td>198.51.100.30</td>
</tr>
<tr>
<td>Data node &quot;B&quot; (ndbd)</td>
<td>198.51.100.40</td>
</tr>
</tbody>
</table>

This setup is also shown in the following diagram:
Network addressing. In the interest of simplicity (and reliability), this How-To uses only numeric IP addresses. However, if DNS resolution is available on your network, it is possible to use host names in lieu of IP addresses in configuring Cluster. Alternatively, you can use the hosts file (typically /etc/hosts for Linux and other Unix-like operating systems, C:\WINDOWS\system32\drivers\etc\hosts on Windows, or your operating system’s equivalent) for providing a means to do host lookup if such is available.

Prior to NDB 8.0.22, all network addresses used for connections to or from data and management nodes must use or be resolvable using IPv4. This includes addresses used by SQL nodes to contact the other nodes. Beginning with NDB 8.0.22, NDB Cluster supports IPv6 for connections between any and all cluster nodes.

Potential hosts file issues. A common problem when trying to use host names for Cluster nodes arises because of the way in which some operating systems (including some Linux distributions) set up the system's own host name in the /etc/hosts during installation. Consider two machines with the host names ndb1 and ndb2, both in the cluster network domain. Red Hat Linux (including some derivatives such as CentOS and Fedora) places the following entries in these machines' /etc/hosts files:

```bash
# ndb1 /etc/hosts:
127.0.0.1   ndb1.cluster ndb1 localhost.localdomain localhost

# ndb2 /etc/hosts:
127.0.0.1   localhost
127.0.0.2   ndb2.cluster ndb2
```

SUSE Linux (including OpenSUSE) places these entries in the machines’ /etc/hosts files:

```bash
# ndb1 /etc/hosts:
127.0.0.1   localhost
127.0.0.2   ndb1.cluster ndb1

# ndb2 /etc/hosts:
127.0.0.1   localhost
127.0.0.2   ndb2.cluster ndb2
```

In both instances, ndb1 routes ndb1.cluster to a loopback IP address, but gets a public IP address from DNS for ndb2.cluster, while ndb2 routes ndb2.cluster to a loopback address and obtains a
public address for ndb1.cluster. The result is that each data node connects to the management server, but cannot tell when any other data nodes have connected, and so the data nodes appear to hang while starting.

**Caution**

You cannot mix localhost and other host names or IP addresses in config.ini. For these reasons, the solution in such cases (other than to use IP addresses for all config.ini HostName entries) is to remove the fully qualified host names from /etc/hosts and use these in config.ini for all cluster hosts.

**Host computer type.** Each host computer in our installation scenario is an Intel-based desktop PC running a supported operating system installed to disk in a standard configuration, and running no unnecessary services. The core operating system with standard TCP/IP networking capabilities should be sufficient. Also for the sake of simplicity, we also assume that the file systems on all hosts are set up identically. In the event that they are not, you should adapt these instructions accordingly.

**Network hardware.** Standard 100 Mbps or 1 gigabit Ethernet cards are installed on each machine, along with the proper drivers for the cards, and that all four hosts are connected through a standard-issue Ethernet networking appliance such as a switch. (All machines should use network cards with the same throughput. That is, all four machines in the cluster should have 100 Mbps cards or all four machines should have 1 Gbps cards.) NDB Cluster works in a 100 Mbps network; however, gigabit Ethernet provides better performance.

**Important**

NDB Cluster is not intended for use in a network for which throughput is less than 100 Mbps or which experiences a high degree of latency. For this reason (among others), attempting to run an NDB Cluster over a wide area network such as the Internet is not likely to be successful, and is not supported in production.

**Sample data.** We use the world database which is available for download from the MySQL website (see https://dev.mysql.com/doc/index-other.html). We assume that each machine has sufficient memory for running the operating system, required NDB Cluster processes, and (on the data nodes) storing the database.

For general information about installing MySQL, see Chapter 2, Installing and Upgrading MySQL. For information about installation of NDB Cluster on Linux and other Unix-like operating systems, see Section 22.2.1, “Installation of NDB Cluster on Linux”. For information about installation of NDB Cluster on Windows operating systems, see Section 22.2.2, “Installing NDB Cluster on Windows”.

For general information about NDB Cluster hardware, software, and networking requirements, see Section 22.1.3, “NDB Cluster Hardware, Software, and Networking Requirements”.

### 22.2.1 Installation of NDB Cluster on Linux

This section covers installation methods for NDB Cluster on Linux and other Unix-like operating systems. While the next few sections refer to a Linux operating system, the instructions and procedures given there should be easily adaptable to other supported Unix-like platforms. For manual installation and setup instructions specific to Windows systems, see Section 22.2.2, “Installing NDB Cluster on Windows”.

Each NDB Cluster host computer must have the correct executable programs installed. A host running an SQL node must have installed on it a MySQL Server binary (mysqld). Management nodes require the management server daemon (ndb_mgmd); data nodes require the data node daemon (ndbd or ndbmtd). It is not necessary to install the MySQL Server binary on management node hosts and data node hosts. It is recommended that you also install the management client (ndb_mgmt) on the management server host.
Installation of NDB Cluster on Linux can be done using precompiled binaries from Oracle (downloaded as a .tar.gz archive), with RPM packages (also available from Oracle), or from source code. All three of these installation methods are described in the section that follow.

Regardless of the method used, it is still necessary following installation of the NDB Cluster binaries to create configuration files for all cluster nodes, before you can start the cluster. See Section 22.2.3, “Initial Configuration of NDB Cluster”.

22.2.1.1 Installing an NDB Cluster Binary Release on Linux

This section covers the steps necessary to install the correct executables for each type of Cluster node from precompiled binaries supplied by Oracle.

For setting up a cluster using precompiled binaries, the first step in the installation process for each cluster host is to download the binary archive from the NDB Cluster downloads page. (For the most recent 64-bit NDB 8.0 release, this is mysql-cluster-gpl-8.0.22-linux-glibc2.12-x86_64.tar.gz.) We assume that you have placed this file in each machine's /var/tmp directory.

If you require a custom binary, see Section 2.9.5, “Installing MySQL Using a Development Source Tree”.

**Note**

After completing the installation, do not yet start any of the binaries. We show you how to do so following the configuration of the nodes (see Section 22.2.3, “Initial Configuration of NDB Cluster”).

**SQL nodes.** On each of the machines designated to host SQL nodes, perform the following steps as the system root user:

1. Check your /etc/passwd and /etc/group files (or use whatever tools are provided by your operating system for managing users and groups) to see whether there is already a mysql group and mysql user on the system. Some OS distributions create these as part of the operating system installation process. If they are not already present, create a new mysql user group, and then add a mysql user to this group:

```
shell> groupadd mysql
shell> useradd -g mysql -s /bin/false mysql
```

The syntax for `useradd` and `groupadd` may differ slightly on different versions of Unix, or they may have different names such as `adduser` and `addgroup`.

2. Change location to the directory containing the downloaded file, unpack the archive, and create a symbolic link named `mysql` to the `mysql` directory.

```
shell> cd /var/tmp
shell> tar -C /usr/local -xzvf mysql-cluster-gpl-8.0.22-linux-glibc2.12-x86_64.tar.gz
shell> ln -s /usr/local/mysql-cluster-gpl-8.0.22-linux-glibc2.12-x86_64 /usr/local/mysql
```

3. Change location to the `mysql` directory and set up the system databases using `mysqld --initialize` as shown here:

```
shell> cd mysql
shell> mysqld --initialize
```
Installation of NDB Cluster on Linux

This generates a random password for the MySQL root account. If you do not want the random password to be generated, you can substitute the --initialize-insecure option for --initialize. In either case, you should review Section 2.10.1, “Initializing the Data Directory”, for additional information before performing this step. See also Section 4.4.2, "mysql_secure_installation — Improve MySQL Installation Security".

4. Set the necessary permissions for the MySQL server and data directories:

shell> chown -R root .
shell> chown -R mysql data
shell> chgrp -R mysql .

5. Copy the MySQL startup script to the appropriate directory, make it executable, and set it to start when the operating system is booted up:

shell> cp support-files/mysql.server /etc/rc.d/init.d/
shell> chmod +x /etc/rc.d/init.d/mysql.server
shell> chkconfig --add mysql.server

(The startup scripts directory may vary depending on your operating system and version—for example, in some Linux distributions, it is /etc/init.d.)

Here we use Red Hat's chkconfig for creating links to the startup scripts; use whatever means is appropriate for this purpose on your platform, such as update-rc.d on Debian.

Remember that the preceding steps must be repeated on each machine where an SQL node is to reside.

Data nodes. Installation of the data nodes does not require the mysqld binary. Only the NDB Cluster data node executable ndbd (single-threaded) or ndbmtd (multithreaded) is required. These binaries can also be found in the .tar.gz archive. Again, we assume that you have placed this archive in /var/tmp.

As system root (that is, after using sudo, su root, or your system's equivalent for temporarily assuming the system administrator account's privileges), perform the following steps to install the data node binaries on the data node hosts:

1. Change location to the /var/tmp directory, and extract the ndbd and ndbmtd binaries from the archive into a suitable directory such as /usr/local/bin:

shell> cd /var/tmp
shell> tar -zxvf mysql-cluster-gpl-8.0.22-linux-glibc2.12-x86_64.tar.gz
shell> cd mysql-cluster-gpl-8.0.22-linux-glibc2.12-x86_64
shell> cp bin/ndbd /usr/local/bin/ndbd
shell> cp bin/ndbmtd /usr/local/bin/ndbmtd

(You can safely delete the directory created by unpacking the downloaded archive, and the files it contains, from /var/tmp once ndb_mgm and ndb_mgmd have been copied to the executables directory.)

2. Change location to the directory into which you copied the files, and then make both of them executable:

shell> cd /usr/local/bin
shell> chmod +x ndb*

The preceding steps should be repeated on each data node host.

Although only one of the data node executables is required to run an NDB Cluster data node, we have shown you how to install both ndbd and ndbmtd in the preceding instructions. We recommend that you do
this when installing or upgrading NDB Cluster, even if you plan to use only one of them, since this saves time and trouble in the event that you later decide to change from one to the other.

**Note**

The data directory on each machine hosting a data node is `/usr/local/mysql/data`. This piece of information is essential when configuring the management node. (See Section 22.2.3, “Initial Configuration of NDB Cluster”.)

**Management nodes.** Installation of the management node does not require the `mysql` binary. Only the NDB Cluster management server (`ndb_mgmd`) is required; you most likely want to install the management client (`ndb_mgm`) as well. Both of these binaries also be found in the `.tar.gz` archive. Again, we assume that you have placed this archive in `/var/tmp`.

As system `root`, perform the following steps to install `ndb_mgmd` and `ndb_mgm` on the management node host:

1. Change location to the `/var/tmp` directory, and extract the `ndb_mgm` and `ndb_mgmd` from the archive into a suitable directory such as `/usr/local/bin`:

```
shell> cd /var/tmp
shell> tar -zxvf mysql-cluster-gpl-8.0.22-linux-glibc2.12-x86_64.tar.gz
shell> cd mysql-cluster-gpl-8.0.22-linux-glibc2.12-x86_64
shell> cp bin/ndb_mgm* /usr/local/bin
```

(You can safely delete the directory created by unpacking the downloaded archive, and the files it contains, from `/var/tmp` once `ndb_mgm` and `ndb_mgmd` have been copied to the executables directory.)

2. Change location to the directory into which you copied the files, and then make both of them executable:

```
shell> cd /usr/local/bin
shell> chmod +x ndb_mgm*
```

In Section 22.2.3, “Initial Configuration of NDB Cluster”, we create configuration files for all of the nodes in our example NDB Cluster.

### 22.2.1.2 Installing NDB Cluster from RPM

This section covers the steps necessary to install the correct executables for each type of NDB Cluster 8.0 node using RPM packages supplied by Oracle. For information about RPMs for previous versions of NDB Cluster, see Installation using old-style RPMs (NDB 7.5.3 and earlier).

As an alternative to the method described in this section, Oracle provides MySQL Repositories for NDB Cluster that are compatible with many common Linux distributions. Two repositories, listed here, are available for RPM-based distributions:

- For distributions using `yum` or `dnf`, you can use the MySQL Yum Repository for NDB Cluster. See Installing MySQL NDB Cluster Using the Yum Repository, for instructions and additional information.

- For SLES, you can use the MySQL SLES Repository for NDB Cluster. See Installing MySQL NDB Cluster Using the SLES Repository, for instructions and additional information.

RPMs are available for both 32-bit and 64-bit Linux platforms. The filenames for these RPMs use the following pattern:

```
mysql-cluster-community-data-node-8.0.22-1.el7.x86_64.rpm
```
Installation of NDB Cluster on Linux

`mysql-cluster-license-component-ver-rev.distro.arch.rpm`

- **license**: {commercial | community}
- **component**: {management-server | data-node | server | client | other—see text}
- **ver**: major.minor.release
- **rev**: major.minor
- **distro**: {el6 | el7 | sles12}
- **arch**: {i686 | x86_64}

`license` indicates whether the RPM is part of a Commercial or Community release of NDB Cluster. In the remainder of this section, we assume for the examples that you are installing a Community release.

Possible values for `component`, with descriptions, can be found in the following table:

**Table 22.5 Components of the NDB Cluster RPM distribution**

## Installation of NDB Cluster on Linux

### Component | Description
--- | ---
server | The MySQL server (*mysqld*) with NDB storage engine support included, and associated MySQL server programs
server-minimal | Minimal installation of the MySQL server for NDB and related tools
test | *mysqltest*, other MySQL test programs, and support files

A single bundle (.tar file) of all NDB Cluster RPMs for a given platform and architecture is also available. The name of this file follows the pattern shown here:

```
mysql-cluster-license-ver-rev.distro.arch.rpm-bundle.tar
```

You can extract the individual RPM files from this file using `tar` or your preferred tool for extracting archives.

The components required to install the three major types of NDB Cluster nodes are given in the following list:

- **Management node**: `management-server`
- **Data node**: `data-node`
- **SQL node**: `server` and `common`

In addition, the `client` RPM should be installed to provide the `ndb_mgm` management client on at least one management node. You may also wish to install it on SQL nodes, to have `mysql` and other MySQL client programs available on these. We discuss installation of nodes by type later in this section.

`ver` represents the three-part NDB storage engine version number in 8.0.x format, shown as `8.0.22` in the examples. `rev` provides the RPM revision number in `major.minor` format. In the examples shown in this section, we use `1.1` for this value.

The `distro` (Linux distribution) is one of `rhel5` (Oracle Linux 5, Red Hat Enterprise Linux 4 and 5), `el6` (Oracle Linux 6, Red Hat Enterprise Linux 6), `el7` (Oracle Linux 7, Red Hat Enterprise Linux 7), or `sles12` (SUSE Enterprise Linux 12). For the examples in this section, we assume that the host runs Oracle Linux 7, Red Hat Enterprise Linux 7, or the equivalent (el7).

`arch` is `i686` for 32-bit RPMs and `x86_64` for 64-bit versions. In the examples shown here, we assume a 64-bit platform.

The NDB Cluster version number in the RPM file names (shown here as `8.0.22`) can vary according to the version which you are actually using. **It is very important that all of the Cluster RPMs to be installed have the same version number.** The architecture should also be appropriate to the machine on which the RPM is to be installed; in particular, you should keep in mind that 64-bit RPMs (`x86_64`) cannot be used with 32-bit operating systems (use `i686` for the latter).

**Data nodes.** On a computer that is to host an NDB Cluster data node it is necessary to install only the `data-node` RPM. To do so, copy this RPM to the data node host, and run the following command as the system root user, replacing the name shown for the RPM as necessary to match that of the RPM downloaded from the MySQL website:

```
shell> rpm -Uhv mysql-cluster-community-data-node-8.0.22-1.el7.x86_64.rpm
```
This installs the `ndbd` and `ndbmtd` data node binaries in `/usr/sbin`. Either of these can be used to run a data node process on this host.

**SQL nodes.** Copy the `server` and `common` RPMs to each machine to be used for hosting an NDB Cluster SQL node (`server` requires `common`). Install the `server` RPM by executing the following command as the system root user, replacing the name shown for the RPM as necessary to match the name of the RPM downloaded from the MySQL website:

```
shell> rpm -Uhv mysql-cluster-community-server-8.0.22-1.el7.x86_64.rpm
```

This installs the MySQL server binary (`mysqld`), with NDB storage engine support, in the `/usr/sbin` directory. It also installs all needed MySQL Server support files and useful MySQL server programs, including the `mysql.server` and `mysqld_safe` startup scripts (in `/usr/share/mysql` and `/usr/bin`, respectively). The RPM installer should take care of general configuration issues (such as creating the `mysql` user and group, if needed) automatically.

**Important**  
You must use the versions of these RPMs released for NDB Cluster; those released for the standard MySQL server do not provide support for the NDB storage engine.

To administer the SQL node (MySQL server), you should also install the `client` RPM, as shown here:

```
shell> rpm -Uhv mysql-cluster-community-client-8.0.22-1.el7.x86_64.rpm
```

This installs the `mysql` client and other MySQL client programs, such as `mysqladmin` and `mysqldump`, to `/usr/bin`.

**Management nodes.** To install the NDB Cluster management server, it is necessary only to use the `management-server` RPM. Copy this RPM to the computer intended to host the management node, and then install it by running the following command as the system root user (replace the name shown for the RPM as necessary to match that of the `management-server` RPM downloaded from the MySQL website):

```
shell> rpm -Uhv mysql-cluster-commercial-management-server-8.0.22-1.el7.x86_64.rpm
```

This RPM installs the management server binary `ndb_mgmd` in the `/usr/sbin` directory. While this is the only program actually required for running a management node, it is also a good idea to have the `ndb_mgm` NDB Cluster management client available as well. You can obtain this program, as well as other NDB client programs such as `ndb_desc` and `ndb_config`, by installing the `client` RPM as described previously.

See Section 2.5.4, “Installing MySQL on Linux Using RPM Packages from Oracle”, for general information about installing MySQL using RPMs supplied by Oracle.

After installing from RPM, you still need to configure the cluster; see Section 22.2.3, “Initial Configuration of NDB Cluster”, for the relevant information.

*It is very important that all of the Cluster RPMs to be installed have the same version number.* The architecture designation should also be appropriate to the machine on which the RPM is to be installed; in particular, you should keep in mind that 64-bit RPMs cannot be used with 32-bit operating systems.

**Data nodes.** On a computer that is to host a cluster data node it is necessary to install only the `server` RPM. To do so, copy this RPM to the data node host, and run the following command as the system root user, replacing the name shown for the RPM as necessary to match that of the RPM downloaded from the MySQL website:
Installation of NDB Cluster on Linux

Although this installs all NDB Cluster binaries, only the program ndbd or ndbmtd (both in \texttt{/usr/sbin}) is actually needed to run an NDB Cluster data node.

**SQL nodes.** On each machine to be used for hosting a cluster SQL node, install the server RPM by executing the following command as the system root user, replacing the name shown for the RPM as necessary to match the name of the RPM downloaded from the MySQL website:

```
shell> rpm -Uhv MySQL-Cluster-server-gpl-8.0.22-1.sles11.i386.rpm
```

This installs the MySQL server binary (\texttt{mysqld}) with NDB storage engine support in the \texttt{/usr/sbin} directory, as well as all needed MySQL Server support files. It also installs the mysql.server and mysql_safe startup scripts (in \texttt{/usr/share/mysql} and \texttt{/usr/bin}, respectively). The RPM installer should take care of general configuration issues (such as creating the mysql user and group, if needed) automatically.

To administer the SQL node (MySQL server), you should also install the client RPM, as shown here:

```
shell> rpm -Uhv MySQL-Cluster-client-gpl-8.0.22-1.sles11.i386.rpm
```

This installs the mysql client program.

**Management nodes.** To install the NDB Cluster management server, it is necessary only to use the server RPM. Copy this RPM to the computer intended to host the management node, and then install it by running the following command as the system root user (replace the name shown for the RPM as necessary to match that of the server RPM downloaded from the MySQL website):

```
shell> rpm -Uhv MySQL-Cluster-server-gpl-8.0.22-1.sles11.i386.rpm
```

Although this RPM installs many other files, only the management server binary ndb_mgmd (in the \texttt{/usr/sbin} directory) is actually required for running a management node. The server RPM also installs ndb_mgm, the NDB management client.

See Section 2.5.4, “Installing MySQL on Linux Using RPM Packages from Oracle”, for general information about installing MySQL using RPMs supplied by Oracle. See Section 22.2.3, “Initial Configuration of NDB Cluster”, for information about required post-installation configuration.

### 22.2.1.3 Installing NDB Cluster Using .deb Files

The section provides information about installing NDB Cluster on Debian and related Linux distributions such Ubuntu using the .deb files supplied by Oracle for this purpose.

Oracle also provides an NDB Cluster APT repository for Debian and other distributions. See Installing MySQL NDB Cluster Using the APT Repository, for instructions and additional information.

Oracle provides .deb installer files for NDB Cluster for 32-bit and 64-bit platforms. For a Debian-based system, only a single installer file is necessary. This file is named using the pattern shown here, according to the applicable NDB Cluster version, Debian version, and architecture:

```
mysql-cluster-gpl-ndbver-debiandebianver-arch.deb
```

Here, ndbver is the 3-part NDB engine version number, debianver is the major version of Debian (8 or 9), and arch is one of \texttt{i686} or \texttt{x86_64}. In the examples that follow, we assume you wish to install NDB 8.0.22 on a 64-bit Debian 9 system; in this case, the installer file is named \texttt{mysql-cluster-gpl-8.0.22-debian9-x86_64.deb-bundle.tar}.
Once you have downloaded the appropriate .deb file, you can untar it, and then install it from the command line using dpkg, like this:

```
shell> dpkg -i mysql-cluster-gpl-8.0.22-debian9-i686.deb
```

You can also remove it using dpkg as shown here:

```
shell> dpkg -r mysql
```

The installer file should also be compatible with most graphical package managers that work with .deb files, such as GDebi for the Gnome desktop.

The .deb file installs NDB Cluster under /opt/mysql/server-version/, where version is the 2-part release series version for the included MySQL server. For NDB 8.0, this is always 5.7. The directory layout is the same as that for the generic Linux binary distribution (see Table 2.3, “MySQL Installation Layout for Generic Unix/Linux Binary Package”), with the exception that startup scripts and configuration files are found in support-files instead of share. All NDB Cluster executables, such as ndb_mgm, ndbd, and ndb_mgmd, are placed in the bin directory.

### 22.2.1.4 Building NDB Cluster from Source on Linux

This section provides information about compiling NDB Cluster on Linux and other Unix-like platforms. Building NDB Cluster from source is similar to building the standard MySQL Server, although it differs in a few key respects discussed here. For general information about building MySQL from source, see Section 2.9, “Installing MySQL from Source”. For information about compiling NDB Cluster on Windows platforms, see Section 22.2.2.2, “Compiling and Installing NDB Cluster from Source on Windows”.

Building MySQL NDB Cluster 8.0 requires using the MySQL Server 8.0 sources. These are available from the MySQL downloads page at https://dev.mysql.com/downloads/. The archived source file should have a name similar to mysql-8.0.22.tar.gz. You can also obtain the sources from GitHub at https://github.com/mysql/mysql-server.

**Note**  
In previous versions, building of NDB Cluster from standard MySQL Server sources was not supported. In MySQL 8.0 and NDB Cluster 8.0, this is no longer the case—both products are now built from the same sources.

The WITH_NDBCLUSTER option for CMake causes the binaries for the management nodes, data nodes, and other NDB Cluster programs to be built; it also causes mysqld to be compiled with NDB storage engine support. This option (or one of its aliases WITH_NDBCLUSTER_STORAGE_ENGINE and WITH_PLUGIN_NDBCLUSTER) is required when building NDB Cluster.

**Important**  
The WITH_NDB_JAVA option is enabled by default. This means that, by default, if CMake cannot find the location of Java on your system, the configuration process fails; if you do not wish to enable Java and ClusterJ support, you must indicate this explicitly by configuring the build using -DWITH_NDB_JAVA=OFF. Use WITH_CLASSPATH to provide the Java classpath if needed.

For more information about CMake options specific to building NDB Cluster, see Options for Compiling NDB Cluster.

After you have run make && make install (or your system’s equivalent), the result is similar to what is obtained by unpacking a precompiled binary to the same location.
Management nodes. When building from source and running the default `make install`, the management server and management client binaries (`ndb_mgmd` and `ndb_mgm`) can be found in `/usr/local/mysql/bin`. Only `ndb_mgmd` is required to be present on a management node host; however, it is also a good idea to have `ndb_mgm` present on the same host machine. Neither of these executables requires a specific location on the host machine's file system.

Data nodes. The only executable required on a data node host is the data node binary `ndbd` or `ndbmt`. (`mysqld`, for example, does not have to be present on the host machine.) By default, when building from source, this file is placed in the directory `/usr/local/mysql/bin`. For installing on multiple data node hosts, only `ndbd` or `ndbmt` need be copied to the other host machine or machines. (This assumes that all data node hosts use the same architecture and operating system; otherwise you may need to compile separately for each different platform.) The data node binary need not be in any particular location on the host's file system, as long as the location is known.

When compiling NDB Cluster from source, no special options are required for building multithreaded data node binaries. Configuring the build with NDB storage engine support causes `ndbmt` to be built automatically; `make install` places the `ndbmt` binary in the installation `bin` directory along with `mysqld`, `ndbd`, and `ndb_mgm`.

SQL nodes. If you compile MySQL with clustering support, and perform the default installation (using `make install` as the system root user), `mysqld` is placed in `/usr/local/mysql/bin`. Follow the steps given in Section 2.9, “Installing MySQL from Source” to make `mysqld` ready for use. If you want to run multiple SQL nodes, you can use a copy of the same `mysqld` executable and its associated support files on several machines. The easiest way to do this is to copy the entire `/usr/local/mysql` directory and all directories and files contained within it to the other SQL node host or hosts, then repeat the steps from Section 2.9, “Installing MySQL from Source” on each machine. If you configure the build with a nondefault `PREFIX` option, you must adjust the directory accordingly.

In Section 22.2.3, “Initial Configuration of NDB Cluster”, we create configuration files for all of the nodes in our example NDB Cluster.

### 22.2.2 Installing NDB Cluster on Windows

This section describes installation procedures for NDB Cluster on Windows hosts. NDB Cluster 8.0 binaries for Windows can be obtained from [https://dev.mysql.com/downloads/cluster/](https://dev.mysql.com/downloads/cluster/). For information about installing NDB Cluster on Windows from a binary release provided by Oracle, see Section 22.2.2.1, “Installing NDB Cluster on Windows from a Binary Release”.

It is also possible to compile and install NDB Cluster from source on Windows using Microsoft Visual Studio. For more information, see Section 22.2.2.2, “Compiling and Installing NDB Cluster from Source on Windows”.

### 22.2.2.1 Installing NDB Cluster on Windows from a Binary Release

This section describes a basic installation of NDB Cluster on Windows using a binary “no-install” NDB Cluster release provided by Oracle, using the same 4-node setup outlined in the beginning of this section (see Section 22.2, “NDB Cluster Installation”), as shown in the following table:

<table>
<thead>
<tr>
<th>Table 22.6 Network addresses of nodes in example cluster</th>
</tr>
</thead>
<tbody>
<tr>
<td>Node</td>
</tr>
<tr>
<td>Management node (mgmd)</td>
</tr>
<tr>
<td>SQL node (mysqld)</td>
</tr>
<tr>
<td>Data node “A” (ndbd)</td>
</tr>
</tbody>
</table>
Installing NDB Cluster on Windows

<table>
<thead>
<tr>
<th>Node</th>
<th>IP Address</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data node &quot;B&quot; (ndbd)</td>
<td>198.51.100.40</td>
</tr>
</tbody>
</table>

As on other platforms, the NDB Cluster host computer running an SQL node must have installed on it a MySQL Server binary (`mysqld.exe`). You should also have the MySQL client (`mysql.exe`) on this host. For management nodes and data nodes, it is not necessary to install the MySQL Server binary; however, each management node requires the management server daemon (`ndb_mgmd.exe`); each data node requires the data node daemon (`ndbd.exe` or `ndbmtd.exe`). For this example, we refer to `ndbd.exe` as the data node executable, but you can install `ndbmtd.exe`, the multithreaded version of this program, instead, in exactly the same way. You should also install the management client (`ndb_mgm.exe`) on the management server host. This section covers the steps necessary to install the correct Windows binaries for each type of NDB Cluster node.

As with other Windows programs, NDB Cluster executables are named with the `.exe` file extension. However, it is not necessary to include the `.exe` extension when invoking these programs from the command line. Therefore, we often simply refer to these programs in this documentation as `mysqld`, `mysql`, `ndb_mgmd`, and so on. You should understand that, whether we refer (for example) to `mysqld` or `mysqld.exe`, either name means the same thing (the MySQL Server program).

For setting up an NDB Cluster using Oracle's `no-install` binaries, the first step in the installation process is to download the latest NDB Cluster Windows ZIP binary archive from https://dev.mysql.com/downloads/cluster/. This archive has a filename of the `mysql-cluster-gpl-ver-winarch.zip`, where `ver` is the NDB storage engine version (such as 8.0.22), and `arch` is the architecture (32 for 32-bit binaries, and 64 for 64-bit binaries). For example, the NDB Cluster 8.0.22 archive for 64-bit Windows systems is named `mysql-cluster-gpl-8.0.22-win64.zip`.

You can run 32-bit NDB Cluster binaries on both 32-bit and 64-bit versions of Windows; however, 64-bit NDB Cluster binaries can be used only on 64-bit versions of Windows. If you are using a 32-bit version of Windows on a computer that has a 64-bit CPU, then you must use the 32-bit NDB Cluster binaries.

To minimize the number of files that need to be downloaded from the Internet or copied between machines, we start with the computer where you intend to run the SQL node.

**SQL node.** We assume that you have placed a copy of the archive in the directory `C:\Documents and Settings\username\My Documents\Downloads` on the computer having the IP address 198.51.100.20, where `username` is the name of the current user. (You can obtain this name using `ECHO %USERNAME%` on the command line.) To install and run NDB Cluster executables as Windows services, this user should be a member of the `Administrators` group.

Extract all the files from the archive. The Extraction Wizard integrated with Windows Explorer is adequate for this task. (If you use a different archive program, be sure that it extracts all files and directories from the archive, and that it preserves the archive's directory structure.) When you are asked for a destination directory, enter `C:\`, which causes the Extraction Wizard to extract the archive to the directory `C:\mysql-cluster-gpl-ver-winarch`. Rename this directory to `C:\mysql`.

It is possible to install the NDB Cluster binaries to directories other than `C:\mysql\bin`; however, if you do so, you must modify the paths shown in this procedure accordingly. In particular, if the MySQL Server (SQL node) binary is installed to a location other than `C:\mysql` or `C:\Program Files\MySQL\MySQL Server 8.0`, or if the SQL node's data directory is in a location other than `C:\mysql\data` or `C:\Program Files\MySQL\MySQL Server 8.0\data`, extra configuration options must be used on the command line or added to the `my.ini` or `my.cnf` file when starting the SQL node. For more information...
about configuring a MySQL Server to run in a nonstandard location, see Section 2.3.4, “Installing MySQL on Microsoft Windows Using a noinstall ZIP Archive”.

For a MySQL Server with NDB Cluster support to run as part of an NDB Cluster, it must be started with the options --ndbcluster and --ndb-connectstring. While you can specify these options on the command line, it is usually more convenient to place them in an option file. To do this, create a new text file in Notepad or another text editor. Enter the following configuration information into this file:

```
[mysqld]
# Options for mysqld process:
ndbcluster                       # run NDB storage engine
ndb-connectstring=198.51.100.10   # location of management server
```

You can add other options used by this MySQL Server if desired (see Section 2.3.4.2, “Creating an Option File”), but the file must contain the options shown, at a minimum. Save this file as C:\mysql\my.ini. This completes the installation and setup for the SQL node.

Data nodes. An NDB Cluster data node on a Windows host requires only a single executable, one of either ndbd.exe or ndbmtd.exe. For this example, we assume that you are using ndbd.exe, but the same instructions apply when using ndbmtd.exe. On each computer where you wish to run a data node (the computers having the IP addresses 198.51.100.30 and 198.51.100.40), create the directories C: \mysql, C:\mysql\bin, and C:\mysql\cluster-data; then, on the computer where you downloaded and extracted the no-install archive, locate ndbd.exe in the C:\mysql\bin directory. Copy this file to the C:\mysql\bin directory on each of the two data node hosts.

To function as part of an NDB Cluster, each data node must be given the address or hostname of the management server. You can supply this information on the command line using the --ndb-connectstring or -c option when starting each data node process. However, it is usually preferable to put this information in an option file. To do this, create a new text file in Notepad or another text editor and enter the following text:

```
[mysql_cluster]
# Options for data node process:
ndb-connectstring=198.51.100.10   # location of management server
```

Save this file as C:\mysql\my.ini on the data node host. Create another text file containing the same information and save it on as C:\mysql\my.ini on the other data node host, or copy the my.ini file from the first data node host to the second one, making sure to place the copy in the second data node’s C:\mysql directory. Both data node hosts are now ready to be used in the NDB Cluster, which leaves only the management node to be installed and configured.

Management node. The only executable program required on a computer used for hosting an NDB Cluster management node is the management server program ndb_mgmd.exe. However, in order to administer the NDB Cluster once it has been started, you should also install the NDB Cluster management client program ndb_mgm.exe on the same machine as the management server. Locate these two programs on the machine where you downloaded and extracted the no-install archive; this should be the directory C:\mysql\bin on the SQL node host. Create the directory C:\mysql\bin on the computer having the IP address 198.51.100.10, then copy both programs to this directory.

You should now create two configuration files for use by ndb_mgmd.exe:

1. A local configuration file to supply configuration data specific to the management node itself. Typically, this file needs only to supply the location of the NDB Cluster global configuration file (see item 2).

   To create this file, start a new text file in Notepad or another text editor, and enter the following information:

   ```
   [mysql_cluster]
   # Options for management node process
   ```
Installing NDB Cluster on Windows

config-file=C:/mysql/bin/config.ini

Save this file as the text file C:\mysql\bin\my.ini.

2. A global configuration file from which the management node can obtain configuration information governing the NDB Cluster as a whole. At a minimum, this file must contain a section for each node in the NDB Cluster, and the IP addresses or hostnames for the management node and all data nodes (HostName configuration parameter). It is also advisable to include the following additional information:

- The IP address or hostname of any SQL nodes
- The data memory and index memory allocated to each data node (DataMemory and IndexMemory configuration parameters)
- The number of fragment replicas, using the NoOfReplicas configuration parameter (see Section 22.1.2, "NDB Cluster Nodes, Node Groups, Fragment Replicas, and Partitions")
- The directory where each data node stores it data and log file, and the directory where the management node keeps its log files (in both cases, the DataDir configuration parameter)

Create a new text file using a text editor such as Notepad, and input the following information:

```
[ndbd default]
# Options affecting ndbd processes on all data nodes:
NoOfReplicas=2                      # Number of fragment replicas
DataDir=C:/mysql/cluster-data       # Directory for each data node's data files
# Forward slashes used in directory path, rather than backslashes. This is correct;
DataMemory=80M    # Memory allocated to data storage
IndexMemory=18M   # Memory allocated to index storage
# For DataMemory and IndexMemory, we have used the default values. Since the "world" database takes up
# only about 500KB, this should be more than enough for this example Cluster setup.

[ndb_mgmd]
# Management process options:
HostName=198.51.100.10              # Hostname or IP address of management node
DataDir=C:/mysql/bin/cluster-logs   # Directory for management node log files

[ndbd]
# Options for data node "A":
HostName=198.51.100.30          # (one [ndbd] section per data node)

[ndbd]
# Options for data node "B":
HostName=198.51.100.40          # Hostname or IP address

[mysqld]
# SQL node options:
HostName=198.51.100.20          # Hostname or IP address
```

Save this file as the text file C:\mysql\bin\config.ini.

---

**Important**

A single backslash character (\) cannot be used when specifying directory paths in program options or configuration files used by NDB Cluster on Windows. Instead, you must either escape each backslash character with a second backslash (\\), or replace the backslash with a forward slash character (/). For example, the following
line from the [ndb_mgmd] section of an NDB Cluster config.ini file does not work:

```
DataDir=C:\mysql\bin\cluster-logs
```

Instead, you may use either of the following:

```
DataDir=C:\\mysql\\bin\\cluster-logs  # Escaped backslashes
DataDir=C:/mysql/bin/cluster-logs     # Forward slashes
```

For reasons of brevity and legibility, we recommend that you use forward slashes in directory paths used in NDB Cluster program options and configuration files on Windows.

### 22.2.2 Compiling and Installing NDB Cluster from Source on Windows

Oracle provides precompiled NDB Cluster binaries for Windows which should be adequate for most users. However, if you wish, it is also possible to compile NDB Cluster for Windows from source code. The procedure for doing this is almost identical to the procedure used to compile the standard MySQL Server binaries for Windows, and uses the same tools. However, there are two major differences:

- Building MySQL NDB Cluster 8.0 requires using the MySQL Server 8.0 sources. These are available from the MySQL downloads page at [https://dev.mysql.com/downloads/](https://dev.mysql.com/downloads/). The archived source file should have a name similar to `mysql-8.0.22.tar.gz`. You can also obtain the sources from GitHub at [https://github.com/mysql/mysql-server](https://github.com/mysql/mysql-server).
- You must configure the build using the `WITH_NDBCLUSTER` option in addition to any other build options you wish to use with CMake. `WITH_NDBCLUSTER_STORAGE_ENGINE` and `WITH_PLUGIN_NDBCLUSTER` are supported as aliases for `WITH_NDBCLUSTER`, and work in exactly the same way.

**Important**

The `WITH_NDB_JAVA` option is enabled by default. This means that, by default, if CMake cannot find the location of Java on your system, the configuration process fails; if you do not wish to enable Java and ClusterJ support, you must indicate this explicitly by configuring the build using `-DWITH_NDB_JAVA=OFF`. (Bug #12379735)

Use `WITH_CLASSPATH` to provide the Java classpath if needed.

For more information about CMake options specific to building NDB Cluster, see [Options for Compiling NDB Cluster](#).

Once the build process is complete, you can create a Zip archive containing the compiled binaries; [Section 2.9.4, “Installing MySQL Using a Standard Source Distribution”](#) provides the commands needed to perform this task on Windows systems. The NDB Cluster binaries can be found in the `bin` directory of the resulting archive, which is equivalent to the `no-install` archive, and which can be installed and configured in the same manner. For more information, see [Section 22.2.2.1, “Installing NDB Cluster on Windows from a Binary Release”](#).

### 22.2.3 Initial Startup of NDB Cluster on Windows

Once the NDB Cluster executables and needed configuration files are in place, performing an initial start of the cluster is simply a matter of starting the NDB Cluster executables for all nodes in the cluster. Each cluster node process must be started separately, and on the host computer where it resides. The management node should be started first, followed by the data nodes, and then finally by any SQL nodes.

1. On the management node host, issue the following command from the command line to start the management node process. The output should appear similar to what is shown here:
Installing NDB Cluster on Windows

C:\mysql\bin> ndb_mgmd
2010-06-23 07:53:34 [MgmtSrvr] INFO -- Reading cluster configuration from 'config.ini'

The management node process continues to print logging output to the console. This is normal, because the management node is not running as a Windows service. (If you have used NDB Cluster on a Unix-like platform such as Linux, you may notice that the management node's default behavior in this regard on Windows is effectively the opposite of its behavior on Unix systems, where it runs by default as a Unix daemon process. This behavior is also true of NDB Cluster data node processes running on Windows.) For this reason, do not close the window in which ndb_mgmd.exe is running; doing so kills the management node process. (See Section 22.2.2.4, “Installing NDB Cluster Processes as Windows Services”, where we show how to install and run NDB Cluster processes as Windows services.)

The required -f option tells the management node where to find the global configuration file (config.ini). The long form of this option is --config-file.

Important
An NDB Cluster management node caches the configuration data that it reads from config.ini; once it has created a configuration cache, it ignores the config.ini file on subsequent starts unless forced to do otherwise. This means that, if the management node fails to start due to an error in this file, you must make the management node re-read config.ini after you have corrected any errors in it. You can do this by starting ndb_mgmd.exe with the --reload or --initial option on the command line. Either of these options works to refresh the configuration cache.

It is not necessary or advisable to use either of these options in the management node's my.ini file.

For additional information about options which can be used with ndb_mgmd, see Section 22.4.4, "ndb_mgmd — The NDB Cluster Management Server Daemon", as well as Section 22.4.32, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

2. On each of the data node hosts, run the command shown here to start the data node processes:

C:\mysql\bin> ndbd

In each case, the first line of output from the data node process should resemble what is shown in the preceding example, and is followed by additional lines of logging output. As with the management node process, this is normal, because the data node is not running as a Windows service. For this reason, do not close the console window in which the data node process is running; doing so kills ndbd.exe. (For more information, see Section 22.2.2.4, “Installing NDB Cluster Processes as Windows Services”.)

3. Do not start the SQL node yet; it cannot connect to the cluster until the data nodes have finished starting, which may take some time. Instead, in a new console window on the management node host, start the NDB Cluster management client ndb_mgm.exe, which should be in C:\mysql\bin on the management node host. (Do not try to re-use the console window where ndb_mgmd.exe is running by typing CTRL+C, as this kills the management node.) The resulting output should look like this:

C:\mysql\bin> ndb_mgm
-- NDB Cluster -- Management Client --
ndb_mgm>

When the prompt ndb_mgm> appears, this indicates that the management client is ready to receive NDB Cluster management commands. You can observe the status of the data nodes as they start by
entering `ALL_STATUS` at the management client prompt. This command causes a running report of the data nodes's startup sequence, which should look something like this:

```
ndb_mgm> ALL STATUS
Connected to Management Server at: localhost:1186
Node 2: starting (Last completed phase 3) (mysql-8.0.22-ndb-8.0.22)
Node 3: starting (Last completed phase 3) (mysql-8.0.22-ndb-8.0.22)

Node 2: starting (Last completed phase 4) (mysql-8.0.22-ndb-8.0.22)
Node 3: starting (Last completed phase 4) (mysql-8.0.22-ndb-8.0.22)

Node 2: Started (version 8.0.22)
Node 3: Started (version 8.0.22)
ndb_mgm>
```

**Note**

Commands issued in the management client are not case-sensitive; we use uppercase as the canonical form of these commands, but you are not required to observe this convention when inputting them into the `ndb_mgm` client. For more information, see Section 22.5.1, "Commands in the NDB Cluster Management Client".

The output produced by `ALL_STATUS` is likely to vary from what is shown here, according to the speed at which the data nodes are able to start, the release version number of the NDB Cluster software you are using, and other factors. What is significant is that, when you see that both data nodes have started, you are ready to start the SQL node.

You can leave `ndb_mgm.exe` running; it has no negative impact on the performance of the NDB Cluster, and we use it in the next step to verify that the SQL node is connected to the cluster after you have started it.

4. On the computer designated as the SQL node host, open a console window and navigate to the directory where you unpacked the NDB Cluster binaries (if you are following our example, this is `C:\mysql\bin`).

Start the SQL node by invoking `mysqld.exe` from the command line, as shown here:

```
C:\mysql\bin> mysqld --console
```

The `--console` option causes logging information to be written to the console, which can be helpful in the event of problems. (Once you are satisfied that the SQL node is running in a satisfactory manner, you can stop it and restart it out without the `--console` option, so that logging is performed normally.)

In the console window where the management client (`ndb_mgm.exe`) is running on the management node host, enter the `SHOW` command, which should produce output similar to what is shown here:

```
ndb_mgm> SHOW
Connected to Management Server at: localhost:1186
Cluster Configuration
-----------------------
[ndbd(NDB)] 2 node(s)
id=2 0198.51.100.30  (Version: 8.0.22-ndb-8.0.22, Nodegroup: 0, *)
id=3 0198.51.100.40  (Version: 8.0.22-ndb-8.0.22, Nodegroup: 0)

[ndb_mgmd(MGM)] 1 node(s)
id=1 0198.51.100.10  (Version: 8.0.22-ndb-8.0.22)

[mysqld(API)] 1 node(s)
```
You can also verify that the SQL node is connected to the NDB Cluster in the `mysql` client (`mysql.exe`) using the `SHOW ENGINE NDB STATUS` statement.

You should now be ready to work with database objects and data using NDB Cluster’s `NDBCLUSTER` storage engine. See Section 22.2.5, “NDB Cluster Example with Tables and Data”, for more information and examples.

You can also install `ndb_mgmd.exe`, `ndbd.exe`, and `ndbmtd.exe` as Windows services. For information on how to do this, see Section 22.2.2.4, “Installing NDB Cluster Processes as Windows Services”).

### 22.2.2.4 Installing NDB Cluster Processes as Windows Services

Once you are satisfied that NDB Cluster is running as desired, you can install the management nodes and data nodes as Windows services, so that these processes are started and stopped automatically whenever Windows is started or stopped. This also makes it possible to control these processes from the command line with the appropriate `SC START` and `SC STOP` commands, or using the Windows graphical Services utility. `NET START` and `NET STOP` commands can also be used.

Installing programs as Windows services usually must be done using an account that has Administrator rights on the system.

To install the management node as a service on Windows, invoke `ndb_mgmd.exe` from the command line on the machine hosting the management node, using the `--install` option, as shown here:

```
C:\> C:\mysql\bin\ndb_mgmd.exe --install
Installing service 'NDB Cluster Management Server'
   as '"C:\mysql\bin\ndbd.exe" "--service=ndb_mgmd"'
Service successfully installed.
```

**Important**

When installing an NDB Cluster program as a Windows service, you should always specify the complete path; otherwise the service installation may fail with the error `The system cannot find the file specified`.

The `--install` option must be used first, ahead of any other options that might be specified for `ndb_mgmd.exe`. However, it is preferable to specify such options in an options file instead. If your options file is not in one of the default locations as shown in the output of `ndb_mgmd.exe --help`, you can specify the location using the `--config-file` option.

Now you should be able to start and stop the management server like this:

```
C:\> SC START ndb_mgmd
C:\> SC STOP ndb_mgmd
```

**Note**

If using `NET` commands, you can also start or stop the management server as a Windows service using the descriptive name, as shown here:

```
C:\> NET START 'NDB Cluster Management Server'
The NDB Cluster Management Server service is starting.
The NDB Cluster Management Server service was started successfully.
C:\> NET STOP 'NDB Cluster Management Server'
The NDB Cluster Management Server service is stopping..
```
Installing NDB Cluster on Windows

The NDB Cluster Management Server service was stopped successfully.

It is usually simpler to specify a short service name or to permit the default service name to be used when installing the service, and then reference that name when starting or stopping the service. To specify a service name other than `ndb_mgmd`, append it to the `--install` option, as shown in this example:

```
C:\> C:\mysql\bin\ndb_mgmd.exe --install=mgmd1
Installing service 'NDB Cluster Management Server' as '"C:\mysql\bin\ndb_mgmd.exe" "--service=mgmd1"'
Service successfully installed.
```

Now you should be able to start or stop the service using the name you have specified, like this:

```
C:\> SC START mgmd1
C:\> SC STOP mgmd1
```

To remove the management node service, use `SC DELETE service_name`:

```
C:\> SC DELETE mgmd1
```

Alternatively, invoke `ndb_mgmd.exe` with the `--remove` option, as shown here:

```
C:\> C:\mysql\bin\ndb_mgmd.exe --remove
Removing service 'NDB Cluster Management Server'
Service successfully removed.
```

If you installed the service using a service name other than the default, pass the service name as the value of the `ndb_mgmd.exe --remove` option, like this:

```
C:\> C:\mysql\bin\ndb_mgmd.exe --remove=mgmd1
Removing service 'mgmd1'
Service successfully removed.
```

Installation of an NDB Cluster data node process as a Windows service can be done in a similar fashion, using the `--install` option for `ndbd.exe` (or `ndbmtd.exe`), as shown here:

```
C:\> C:\mysql\bin\ndbd.exe --install
Installing service 'NDB Cluster Data Node Daemon' as '"C:\mysql\bin\ndbd.exe" "--service=ndbd"'
Service successfully installed.
```

Now you can start or stop the data node as shown in the following example:

```
C:\> SC START ndbd
C:\> SC STOP ndbd
```

To remove the data node service, use `SC DELETE service_name`:

```
C:\> SC DELETE ndbd
```

Alternatively, invoke `ndbd.exe` with the `--remove` option, as shown here:

```
C:\> C:\mysql\bin\ndbd.exe --remove
Removing service 'NDB Cluster Data Node Daemon'
Service successfully removed.
```

As with `ndb_mgmd.exe` (and `mysqld.exe`), when installing `ndbd.exe` as a Windows service, you can also specify a name for the service as the value of `--install`, and then use it when starting or stopping the service, like this:

```
C:\> C:\mysql\bin\ndbd.exe --install=dnode1
```

```
1. Install service 'dnode1' as ""C:\mysql\bin\ndbd.exe" "--service=dnode1"");
2. Service successfully installed.

C:\> SC START dnode1
C:\> SC STOP dnode1

If you specified a service name when installing the data node service, you can use this name when removing it as well, as shown here:

C:\> SC DELETE dnode1

Alternatively, you can pass the service name as the value of the ndbd.exe --remove option, as shown here:

C:\> C:\mysql\bin\ndbd.exe --remove=dnode1
Removing service 'dnode1'
Service successfully removed.

Installation of the SQL node as a Windows service, starting the service, stopping the service, and removing the service are done in a similar fashion, using mysqld --install, SC START, SC STOP, and SC DELETE (or mysqld --remove). .NET commands can also be used to start or stop a service. For additional information, see Section 2.3.4.8, “Starting MySQL as a Windows Service”.

2.2.3 Initial Configuration of NDB Cluster

In this section, we discuss manual configuration of an installed NDB Cluster by creating and editing configuration files.

NDB Cluster also provides a GUI installer which can be used to perform the configuration without the need to edit text files in a separate application. For more information, see Section 22.2.8, “The NDB Cluster Auto-Installer (DEPRECATED)”.

For our four-node, four-host NDB Cluster (see Cluster nodes and host computers), it is necessary to write four configuration files, one per node host.

- Each data node or SQL node requires a my.cnf file that provides two pieces of information: a connection string that tells the node where to find the management node, and a line telling the MySQL server on this host (the machine hosting the data node) to enable the NDBCLUSTER storage engine.

For more information on connection strings, see Section 22.3.3.3, “NDB Cluster Connection Strings”.

- The management node needs a config.ini file telling it how many fragment replicas to maintain, how much memory to allocate for data and indexes on each data node, where to find the data nodes, where to save data to disk on each data node, and where to find any SQL nodes.

Configuring the data nodes and SQL nodes. The my.cnf file needed for the data nodes is fairly simple. The configuration file should be located in the /etc directory and can be edited using any text editor. (Create the file if it does not exist.) For example:

shell> vi /etc/my.cnf

Note
We show vi being used here to create the file, but any text editor should work just as well.

For each data node and SQL node in our example setup, my.cnf should look like this:
Initial Configuration of NDB Cluster

```
[mysqld]
# Options for mysqld process:
ndbcluster                      # run NDB storage engine

[mysql_cluster]
# Options for NDB Cluster processes:
ndb-connectstring=198.51.100.10  # location of management server
```

After entering the preceding information, save this file and exit the text editor. Do this for the machines hosting data node “A”, data node “B”, and the SQL node.

**Important**

Once you have started a `mysqld` process with the `ndbcluster` and `ndb-connectstring` parameters in the `[mysqld]` and `[mysql_cluster]` sections of the `my.cnf` file as shown previously, you cannot execute any `CREATE TABLE` or `ALTER TABLE` statements without having actually started the cluster. Otherwise, these statements fail with an error. This is by design.

**Configuring the management node.** The first step in configuring the management node is to create the directory in which the configuration file can be found and then to create the file itself. For example (running as `root`):

```
shell> mkdir /var/lib/mysql-cluster
shell> cd /var/lib/mysql-cluster
shell> vi config.ini
```

For our representative setup, the `config.ini` file should read as follows:

```
[ndbd default]
# Options affecting ndbd processes on all data nodes:
NoOfReplicas=2    # Number of fragment replicas
DataMemory=98M    # How much memory to allocate for data storage

[ndb_mgmd]
# Management process options:
HostName=198.51.100.10          # Hostname or IP address of management node
DataDir=/var/lib/mysql-cluster  # Directory for management node log files

[ndbd]
# Options for data node "A":
HostName=198.51.100.30          # Hostname or IP address
NodeId=2                        # Node ID for this data node
DataDir=/usr/local/mysql/data   # Directory for this data node's data files

[ndbd]
# Options for data node "B":
HostName=198.51.100.40          # Hostname or IP address
NodeId=3                        # Node ID for this data node
DataDir=/usr/local/mysql/data   # Directory for this data node's data files

[mysqld]
# SQL node options:
HostName=198.51.100.20          # Hostname or IP address
# (additional mysqld connections can be specified for this node for various purposes such as running ndb_restore)
```

**Note**

The `world` database can be downloaded from [https://dev.mysql.com/doc/index-other.html](https://dev.mysql.com/doc/index-other.html).
After all the configuration files have been created and these minimal options have been specified, you are ready to proceed with starting the cluster and verifying that all processes are running. We discuss how this is done in Section 22.2.4, “Initial Startup of NDB Cluster”.

For more detailed information about the available NDB Cluster configuration parameters and their uses, see Section 22.3.3, “NDB Cluster Configuration Files”, and Section 22.3, “Configuration of NDB Cluster”. For configuration of NDB Cluster as relates to making backups, see Section 22.5.8.3, “Configuration for NDB Cluster Backups”.

Note
The default port for Cluster management nodes is 1186; the default port for data nodes is 2202. However, the cluster can automatically allocate ports for data nodes from those that are already free.

22.2.4 Initial Startup of NDB Cluster

Starting the cluster is not very difficult after it has been configured. Each cluster node process must be started separately, and on the host where it resides. The management node should be started first, followed by the data nodes, and then finally by any SQL nodes:

1. On the management host, issue the following command from the system shell to start the management node process:

```
shell> ndb_mgmd -f /var/lib/mysql-cluster/config.ini
```

The first time that it is started, `ndb_mgmd` must be told where to find its configuration file, using the `-f` or `--config-file` option. (See Section 22.4.4, “`ndb_mgmd` — The NDB Cluster Management Server Daemon”, for details.)

For additional options which can be used with `ndb_mgmd`, see Section 22.4.32, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

2. On each of the data node hosts, run this command to start the `ndbd` process:

```
shell> ndbd
```

3. If you used RPM files to install MySQL on the cluster host where the SQL node is to reside, you can (and should) use the supplied startup script to start the MySQL server process on the SQL node.

If all has gone well, and the cluster has been set up correctly, the cluster should now be operational. You can test this by invoking the `ndb_mgm` management node client. The output should look like that shown here, although you might see some slight differences in the output depending upon the exact version of MySQL that you are using:

```
shell> ndb_mgm
-- NDB Cluster -- Management Client --
ndb_mgm> SHOW
Connected to Management Server at: localhost:1186
Cluster Configuration
---------------------
[ndbd(NDB)]     2 node(s)
id=2    @198.51.100.30  (Version: 8.0.22-ndb-8.0.22, Nodegroup: 0, *)
id=3    @198.51.100.40  (Version: 8.0.22-ndb-8.0.22, Nodegroup: 0)

[ndb_mgm(MGM)] 1 node(s)
id=1    @198.51.100.10  (Version: 8.0.22-ndb-8.0.22)
```
The SQL node is referenced here as [mysqld(API)], which reflects the fact that the mysqld process is acting as an NDB Cluster API node.

Note

The IP address shown for a given NDB Cluster SQL or other API node in the output of SHOW is the address used by the SQL or API node to connect to the cluster data nodes, and not to any management node.

You should now be ready to work with databases, tables, and data in NDB Cluster. See Section 22.2.5, "NDB Cluster Example with Tables and Data", for a brief discussion.

22.2.5 NDB Cluster Example with Tables and Data

Note

The information in this section applies to NDB Cluster running on both Unix and Windows platforms.

Working with database tables and data in NDB Cluster is not much different from doing so in standard MySQL. There are two key points to keep in mind:

• For a table to be replicated in the cluster, it must use the NDBCLUSTER storage engine. To specify this, use the ENGINE=NDBCLUSTER or ENGINE=NDB option when creating the table:

```sql
CREATE TABLE tbl_name (col_name column_definitions) ENGINE=NDBCLUSTER;
```

Alternatively, for an existing table that uses a different storage engine, use ALTER TABLE to change the table to use NDBCLUSTER:

```sql
ALTER TABLE tbl_name ENGINE=NDBCLUSTER;
```

• Every NDBCLUSTER table has a primary key. If no primary key is defined by the user when a table is created, the NDBCLUSTER storage engine automatically generates a hidden one. Such a key takes up space just as does any other table index. (It is not uncommon to encounter problems due to insufficient memory for accommodating these automatically created indexes.)

If you are importing tables from an existing database using the output of mysqldump, you can open the SQL script in a text editor and add the ENGINE option to any table creation statements, or replace any existing ENGINE options. Suppose that you have the world sample database on another MySQL server that does not support NDB Cluster, and you want to export the City table:

```shell
mysqldump --add-drop-table world City > city_table.sql
```

The resulting city_table.sql file contains this table creation statement (and the INSERT statements necessary to import the table data):

```sql
DROP TABLE IF EXISTS `City`;
CREATE TABLE `City` ( 
`ID` int(11) NOT NULL auto_increment, 
`Name` char(35) NOT NULL default '', 
`CountryCode` char(3) NOT NULL default '', 
`District` char(20) NOT NULL default '', 
`Population` int(11) NOT NULL default '0', 
PRIMARY KEY  (`ID`) 
) ENGINE=MyISAM DEFAULT CHARSET=latin1;
```
NDB Cluster Example with Tables and Data

```
INSERT INTO `City` VALUES (1,'Kabul','AFG','Kabol',1780000);
INSERT INTO `City` VALUES (2,'Qandahar','AFG','Qandahar',237500);
INSERT INTO `City` VALUES (3,'Herat','AFG','Herat',186800);
(remaining INSERT statements omitted)
```

You need to make sure that MySQL uses the NDBCLUSTER storage engine for this table. There are two ways that this can be accomplished. One of these is to modify the table definition before importing it into the Cluster database. Using the `City` table as an example, modify the ENGINE option of the definition as follows:

```
DROP TABLE IF EXISTS `City`;
CREATE TABLE `City` (
  `ID` int(11) NOT NULL auto_increment,
  `Name` char(35) NOT NULL default '',
  `CountryCode` char(3) NOT NULL default '',
  `District` char(20) NOT NULL default '',
  `Population` int(11) NOT NULL default '0',
  PRIMARY KEY  (`ID`) )
ENGINE=NDBCLUSTER DEFAULT CHARSET=latin1;
```

This must be done for the definition of each table that is to be part of the clustered database. The easiest way to accomplish this is to do a search-and-replace on the file that contains the definitions and replace all instances of `TYPE=engine_name` or `ENGINE=engine_name` with `ENGINE=NDBCLUSTER`. If you do not want to modify the file, you can use the unmodified file to create the tables, and then use `ALTER TABLE` to change their storage engine. The particulars are given later in this section.

Assuming that you have already created a database named `world` on the SQL node of the cluster, you can then use the `mysql` command-line client to read `city_table.sql`, and create and populate the corresponding table in the usual manner:

```
shell> mysql world < city_table.sql
```

It is very important to keep in mind that the preceding command must be executed on the host where the SQL node is running (in this case, on the machine with the IP address 198.51.100.20).

To create a copy of the entire `world` database on the SQL node, use `mysqldump` on the noncluster server to export the database to a file named `world.sql` (for example, in the `/tmp` directory). Then modify the table definitions as just described and import the file into the SQL node of the cluster like this:

```
shell> mysql world < /tmp/world.sql
```

If you save the file to a different location, adjust the preceding instructions accordingly.

Running `SELECT` queries on the SQL node is no different from running them on any other instance of a MySQL server. To run queries from the command line, you first need to log in to the MySQL Monitor in the usual way (specify the `root` password at the `Enter password:` prompt):

```
shell> mysql -u root -p
Enter password:
Welcome to the MySQL monitor. Commands end with ; or \g.
Your MySQL connection id is 1 to server version: 8.0.22-ndb-8.0.22
Type 'help;' or '''h' for help. Type '\c' to clear the buffer.
```
We simply use the MySQL server's root account and assume that you have followed the standard security precautions for installing a MySQL server, including setting a strong root password. For more information, see Section 2.10.4, “Securing the Initial MySQL Account”.

It is worth taking into account that NDB Cluster nodes do not make use of the MySQL privilege system when accessing one another. Setting or changing MySQL user accounts (including the root account) effects only applications that access the SQL node, not interaction between nodes. See Section 22.5.17.2, “NDB Cluster and MySQL Privileges”, for more information.

If you did not modify the ENGINE clauses in the table definitions prior to importing the SQL script, you should run the following statements at this point:

```
mysql> USE world;
mysql> ALTER TABLE City ENGINE=NDBCLUSTER;
mysql> ALTER TABLE Country ENGINE=NDBCLUSTER;
mysql> ALTER TABLE CountryLanguage ENGINE=NDBCLUSTER;
```

Selecting a database and running a `SELECT` query against a table in that database is also accomplished in the usual manner, as is exiting the MySQL Monitor:

```
mysql> USE world;
mysql> SELECT Name, Population FROM City ORDER BY Population DESC LIMIT 5;
```

```
+----------+------------+
| Name     | Population |
+----------+------------+
| Bombay   | 10500000   |
| Seoul    | 9981619    |
| São Paulo| 9968485    |
| Shanghai | 9696300    |
| Jakarta  | 9604900    |
+----------+------------+
5 rows in set (0.34 sec)
```

Applications that use MySQL can employ standard APIs to access NDB tables. It is important to remember that your application must access the SQL node, and not the management or data nodes. This brief example shows how we might execute the `SELECT` statement just shown by using the PHP 5.X `mysqli` extension running on a Web server elsewhere on the network:

```php
<?php
# connect to SQL node:
$link = new mysqli('198.51.100.20', 'root', 'root_password', 'world');
# parameters for mysqli constructor are:
# host, user, password, database
if( mysqli_connect_errno() )
die("Connect failed: ". mysqli_connect_error());

$query = "SELECT Name, Population
           FROM City
           ORDER BY Population DESC";
```
Safe Shutdown and Restart of NDB Cluster

We assume that the process running on the Web server can reach the IP address of the SQL node.

In a similar fashion, you can use the MySQL C API, Perl-DBI, Python-mysql, or MySQL Connectors to perform the tasks of data definition and manipulation just as you would normally with MySQL.

### 22.2.6 Safe Shutdown and Restart of NDB Cluster

To shut down the cluster, enter the following command in a shell on the machine hosting the management node:

```
shell> ndb_mgm -e shutdown
```

The `-e` option here is used to pass a command to the `ndb_mgm` client from the shell. (See Section 22.4.32, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”, for more information about this option.) The command causes the `ndb_mgm`, `ndb_mgmd`, and any `ndbd` or `ndbmt` processes to terminate gracefully. Any SQL nodes can be terminated using `mysqladmin shutdown` and other means. On Windows platforms, assuming that you have installed the SQL node as a Windows service, you can use `SC STOP service_name` or `NET STOP service_name`.

To restart the cluster on Unix platforms, run these commands:

- **On the management host** (198.51.100.10 in our example setup):

  ```
  shell> ndb_mgmd -f /var/lib/mysql-cluster/config.ini
  ```

- **On each of the data node hosts** (198.51.100.30 and 198.51.100.40):

  ```
  shell> ndbd
  ```
Upgrading and Downgrading NDB Cluster

- Use the `ndb_mgm` client to verify that both data nodes have started successfully.

- On the SQL host (198.51.100.20):
  ```shell
  mysqld_safe &
  ```

- On Windows platforms, assuming that you have installed all NDB Cluster processes as Windows services using the default service names (see Section 22.2.2.4, “Installing NDB Cluster Processes as Windows Services”), you can restart the cluster as follows:

- On the management host (198.51.100.10 in our example setup), execute the following command:
  ```
  C:\> SC START ndb_mgmd
  ```

- On each of the data node hosts (198.51.100.30 and 198.51.100.40), execute the following command:
  ```
  C:\> SC START ndbd
  ```

- On the management node host, use the `ndb_mgm` client to verify that the management node and both data nodes have started successfully (see Section 22.2.2.3, “Initial Startup of NDB Cluster on Windows”).

- On the SQL node host (198.51.100.20), execute the following command:
  ```
  C:\> SC START mysql
  ```

In a production setting, it is usually not desirable to shut down the cluster completely. In many cases, even when making configuration changes, or performing upgrades to the cluster hardware or software (or both), which require shutting down individual host machines, it is possible to do so without shutting down the cluster as a whole by performing a rolling restart of the cluster. For more information about doing this, see Section 22.5.5, “Performing a Rolling Restart of an NDB Cluster”.

### 22.2.7 Upgrading and Downgrading NDB Cluster

This section provides information about NDB Cluster software and table file compatibility between different NDB Cluster 8.0 releases with regard to performing upgrades and downgrades as well as compatibility matrices and notes. You should already be familiar with installing and configuring NDB Cluster prior to attempting an upgrade or downgrade. See Section 22.3, “Configuration of NDB Cluster”.

Schema operations, including SQL DDL statements, cannot be performed while any data nodes are restarting, and thus during an online upgrade or downgrade of the cluster. For other information regarding the rolling restart procedure used to perform an online upgrade, see Section 22.5.5, “Performing a Rolling Restart of an NDB Cluster”.

#### Important

Only compatibility between MySQL versions with regard to `NDBCLUSTER` is taken into account in this section, and there are likely other issues to be considered. *As with any other MySQL software upgrade or downgrade, you are strongly encouraged to review the relevant portions of the MySQL Manual for the MySQL versions from which and to which you intend to migrate, before attempting an upgrade or downgrade of the NDB Cluster software.* See Section 2.11, “Upgrading MySQL”.

The table shown here provides information on NDB Cluster upgrade and downgrade compatibility among different releases of NDB 8.0. Additional notes about upgrades and downgrades to, from, or within the NDB Cluster 8.0 release series can be found following the table.
Upgrading and Downgrading NDB Cluster

Upgrades and Downgrades, NDB Cluster 8.0

The following versions of NDB Cluster are supported for upgrades to GA releases of NDB Cluster 8.0 (8.0.19 and later):

- NDB Cluster 7.6: NDB 7.6.4 and later
- NDB Cluster 7.5: NDB 7.5.4 and later
- NDB Cluster 7.4: NDB 7.4.6 and later

To upgrade from a release series previous to NDB 7.4, you must upgrade in stages, first to one of the versions just listed, and then from that version to the latest NDB 8.0 release. In such cases, upgrading to the latest NDB 7.6 release is recommended as the first step.

Known Issues. The following issues are known to occur when upgrading to or between NDB 8.0 releases:

- Online downgrades from NDB 8.0.14 to previous releases are not supported. Tables created in NDB 8.0.14 are not backwards compatible with previous releases. This is due to a change in usage of the extra metadata property implemented by NDB tables to provide full support for the MySQL data dictionary.

  For more information, see Changes in NDB table extra metadata. See also Chapter 14, MySQL Data Dictionary.

- Distributed privileges shared between MySQL servers as implemented in prior release series (see Distributed Privileges Using Shared Grant Tables) are not supported in NDB Cluster 8.0. When started,
Upgrading and Downgrading NDB Cluster

the `mysqld` supplied with NDB 8.0.16 and later checks for the existence of any grant tables which use the NDB storage engine; if it finds any, it creates local copies ("shadow tables") of these using InnoDB. This is true for each MySQL server connected to NDB Cluster. After this has been performed on all MySQL servers acting as NDB Cluster SQL nodes, the NDB grant tables may be safely removed using the `ndb_drop_table` utility supplied with the NDB Cluster distribution, like this:

```
ndb_drop_table -d mysql user db columns_priv tables_priv proxies_priv procs_priv
```

It is safe to retain the NDB grant tables, but they are not used for access control and are effectively ignored.

For more information about the MySQL privileges system used in NDB 8.0, see Section 22.5.12, "Distributed MySQL Privileges with NDB_STORED_USER", as well as Section 6.2.3, "Grant Tables".

- In NDB 8.0.18, the binary configuration file format has been enhanced to provide support for greater numbers of nodes than in previous versions. The new format is not accessible to 8.0.17 and older nodes, although newer management servers can detect older nodes and communicate with them using the appropriate format.

Upgrades to NDB 8.0.18 or later from 8.0.17 and earlier should not be problematic in this regard. In the case of downgrades from NDB 8.0.18 or later to 8.0.17 or earlier, because older management servers cannot read the newer binary configuration file format, some manual intervention is required. When performing such a downgrade, it is necessary to remove any cached binary configuration files prior to starting the management using the older NDB software version, and to have the plaintext configuration file available for the management server to read. Alternatively, you can start the older management server using the `--initial` option (again, it is necessary to have the `config.ini` available). If the cluster uses multiple management servers, one of these two things must be done for each management server binary.

Also in connection with support for increased numbers of nodes, due to incompatible changes implemented in NDB 8.0.18 in the data node LCP Sysfile, it is necessary, when performing an online downgrade from NDB 8.0.18 (or later) to any prior release, to restart all data nodes using the `--initial` option.

Restarting the data nodes with `--initial` is also required when upgrading any release prior to NDB 7.6.4 to any NDB 8.0 release.

- Direct downgrades of clusters running more than 48 data nodes, or with data nodes using node IDs greater than 48, to NDB versions 8.0.17 and earlier from NDB 8.0.18 or later are not supported. It is necessary in such cases to reduce the number of data nodes, change the configurations for all data nodes such that they use node IDs less than or equal to 48, or both, as required not to exceed the old maximums.

- If you are downgrading from NDB 8.0 to NDB 7.5 or NDB 7.4, you must set an explicit value for `IndexMemory` in the cluster configuration file if none is already present. This is because NDB 8.0 does not use this parameter (which was removed in NDB 7.6) and sets it to 0 by default, whereas it is required in NDB 7.5 and NDB 7.4, in both of which the cluster refuses to start with `Invalid configuration received from Management Server...` if `IndexMemory` is not set to a nonzero value.

Setting `IndexMemory` is not required for downgrades from NDB 8.0 to NDB 7.6.
The NDB Cluster Auto-Installer (DEPRECATED)

- NDB 8.0.22 adds support for IPv6 addressing for management nodes and data nodes in the config.ini file. To begin using IPv6 addresses as part of an upgrade, perform the following steps:

1. Perform an upgrade of the cluster to version 8.0.22 or a later version of the NDB Cluster software in the usual manner.

2. Change the addresses used in the config.ini file to IPv6 addresses.

3. Perform a system restart of the cluster.

22.2.8 The NDB Cluster Auto-Installer (DEPRECATED)

Note

This feature is deprecated and should be avoided. It is subject to removal in a future version of NDB Cluster.

This section describes the web-based graphical configuration installer included as part of the NDB Cluster distribution. Topics discussed include an overview of the installer and its parts, software and other requirements for running the installer, navigating the GUI, and using the installer to set up and start or stop an NDB Cluster on one or more host computers.

The NDB Cluster Auto-Installer is made up of two components. The front end is a GUI client implemented as a Web page that loads and runs in a standard Web browser such as Firefox or Microsoft Internet Explorer. The back end is a server process (ndb_setup.py) that runs on the local machine or on another host to which you have access.

These two components (client and server) communicate with each other using standard HTTP requests and responses. The back end can manage NDB Cluster software programs on any host where the back end user has granted access. If the NDB Cluster software is on a different host, the back end relies on SSH for access.

22.2.8.1 NDB Cluster Auto-Installer Requirements

This section provides information on supported operating platforms and software, required software, and other prerequisites for running the NDB Cluster Auto-Installer.

Supported platforms. The NDB Cluster Auto-Installer is available with NDB 8.0 distributions for recent versions of Linux, Windows, Solaris, and macOS. For more detailed information about platform support for NDB Cluster and the NDB Cluster Auto-Installer, see https://www.mysql.com/support/supportedplatforms/cluster.html.

Supported web browsers. The web-based installer is supported with recent versions of Firefox and Microsoft Internet Explorer. It should also work with recent versions of Opera, Safari, and Chrome, although we have not thoroughly tested for compatibility with these browsers.

Required software—setup host. The following software must be installed on the host where the Auto-Installer is run:

- **Python 2.6 or higher.** The Auto-Installer requires the Python interpreter and standard libraries. If these are not already installed on the system, you may be able to add them using the system's package manager. Otherwise, you can download them from http://python.org/download/.

- ** Paramiko 2 or higher.** You can download this from http://www.lag.net/paramiko/ if it is not available from your system's package manager.
The NDB Cluster Auto-Installer (DEPRECATED)

- **Pycrypto version 1.9 or higher.** This cryptography module is required by Paramiko, and can be uninstalled using `pip install cryptography`. If `pip` is not installed, and the module is not available using your system's package manager, you can download it from https://www.dlitz.net/software/pycrypto/.

All of the software in the preceding list is included in the Windows version of the configuration tool, and does not need to be installed separately.

**Required software—remote hosts.** The only software required for remote hosts where you wish to deploy NDB Cluster nodes is the SSH server, which is usually installed by default on Linux and Solaris systems. Several alternatives are available for Windows; for an overview of these, see http://en.wikipedia.org/wiki/Comparison_of_SSH_servers.

An additional requirement when using multiple hosts is that it is possible to authenticate to any of the remote hosts using SSH and the proper keys or user credentials, as discussed in the next few paragraphs:

**Authentication and security.** Three basic security or authentication mechanisms for remote access are available to the Auto-Installer, which we list and describe here:

- **SSH.** A secure shell connection is used to enable the back end to perform actions on remote hosts. For this reason, an SSH server must be running on the remote host. In addition, the operating system user running the installer must have access to the remote server, either with a user name and password, or by using public and private keys.

  ![](https://example.com/important.png)

  Important

  You should never use the system `root` account for remote access, as this is extremely insecure. In addition, `mysqld` cannot normally be started by system `root`. For these and other reasons, you should provide SSH credentials for a regular user account on the target system, and not for system `root`. For more information about this issue, see Section 6.1.5, “How to Run MySQL as a Normal User”.

- **HTTPS.** Remote communication between the Web browser front end and the back end is not encrypted by default, which means that information such as the user's SSH password is transmitted as cleartext that is readable to anyone. For communication from a remote client to be encrypted, the back end must have a certificate, and the front end must communicate with the back end using HTTPS rather than HTTP. Enabling HTTPS is accomplished most easily through issuing a self-signed certificate. Once the certificate is issued, you must make sure that it is used. You can do this by starting `ndb_setup.py` from the command line with the `--use-https (-S)` and `--cert-file (-c)` options.

  A sample certificate file `cfg.pem` is included and is used by default. This file is located in the `mcc` directory under the installation share directory; on Linux, the full path to the file is normally `/usr/share/mysql/mcc/cfg.pem`. On Windows systems, this is usually `C:\Program Files\MySQL\MySQL Server 8.0\share\mcc\cfg.pem`. Letting the default be used means that, for testing purposes, you can simply start the installer with the `-S` option to use an HTTPS connection between the browser and the back end.

  The Auto-Installer saves the configuration file for a given cluster `mycluster01` as `mycluster01.mcc` in the home directory of the user invoking the `ndb_setup.py` executable. This file is encrypted with a passphrase supplied by the user (using Fernet); because HTTP transmits the passphrase in the clear, **it is strongly recommended that you always use an HTTPS connection to access the Auto-Installer on a remote host.**

- **Certificate-based authentication.** The back end `ndb_setup.py` process can execute commands on the local host as well as remote hosts. This means that anyone connecting to the back end can take charge of how commands are executed. To reject unwanted connections to the back end, a certificate
may be required for authentication of the client. In this case, a certificate must be issued by the user, installed in the browser, and made available to the back end for authentication purposes. You can enact this requirement (together with or in place of password or key authentication) by starting `ndb_setup.py` with the `--ca-certs-file (-a)` option.

There is no need or requirement for secure authentication when the client browser is running on the same host as the Auto-Installer back end.

See also Section 22.5.17, “NDB Cluster Security Issues”, which discusses security considerations to take into account when deploying NDB Cluster, as well as Chapter 6, Security, for more general MySQL security information.

### 22.2.8.2 Using the NDB Cluster Auto-Installer

The NDB Cluster Auto-Installer interface is made up of several pages, each corresponding to a step in the process used to configure and deploy an NDB Cluster. These pages are listed here, in order:

- **Welcome**: Begin using the Auto-Installer by choosing either to configure a new NDB Cluster, or to continue configuring an existing one.
- **Define Cluster**: Set basic information about the cluster as a whole, such as name, hosts, and load type. Here you can also set the SSH authentication type for accessing remote hosts, if needed.
- **Define Hosts**: Identify the hosts where you intend to run NDB Cluster processes.
- **Define Processes**: Assign one or more processes of a given type or types to each cluster host.
- **Define Parameters**: Set configuration attributes for processes or types of processes.
- **Deploy Configuration**: Deploy the cluster with the configuration set previously; start and stop the deployed cluster.

### NDB Cluster Installer Settings and Help Menus

These menus are shown on all screens except for the Welcome screen. They provide access to installer settings and information. The Settings menu is shown here in more detail:

#### Figure 22.6 NDB Cluster Auto-Installer Settings menu

The Settings menu has the following entries:

- **Automatically save configuration as cookies**: Save your configuration information—such as host names, process data, and parameter values—as a cookie in the browser. When this option is chosen, all
information except any SSH password is saved. This means that you can quit and restart the browser, and continue working on the same configuration from where you left off at the end of the previous session. This option is enabled by default.

The SSH password is never saved; if you use one, you must supply it at the beginning of each new session.

- **Show advanced configuration options**: Shows by default advanced configuration parameters where available.

Once set, the advanced parameters continue to be used in the configuration file until they are explicitly changed or reset. This is regardless of whether the advanced parameters are currently visible in the installer; in other words, disabling the menu item does not reset the values of any of these parameters.

You can also toggle the display of advanced parameters for individual processes on the Define Parameters screen.

This option is disabled by default.

- **Automatically get resource information for new hosts**: Query new hosts automatically for hardware resource information to pre-populate a number of configuration options and values. In this case, the suggested values are not mandatory, but they are used unless explicitly changed using the appropriate editing options in the installer.

This option is enabled by default.

The installer Help menu is shown here:

**Figure 22.7 NDB Cluster Auto-Installer Help menu**

The Help menu provides several options, described in the following list:

- **Contents**: Show the built-in user guide. This is opened in a separate browser window, so that it can be used simultaneously with the installer without interrupting workflow.

- **Current page**: Open the built-in user guide to the section describing the page currently displayed in the installer.

- **About**: open a dialog displaying the installer name and the version number of the NDB Cluster distribution with which it was supplied.

The Auto-Installer also provides context-sensitive help in the form of tooltips for most input widgets.
In addition, the names of most NDB configuration parameters are linked to their descriptions in the online documentation. The documentation is displayed in a separate browser window.

The next section discusses starting the Auto-Installer. The sections immediately following it describe in greater detail the purpose and function of each of these pages in the order listed previously.

### Starting the NDB Cluster Auto-Installer

The Auto-Installer is provided together with the NDB Cluster software. Separate RPM and `.deb` packages containing only the Auto-Installer are also available for many Linux distributions. (See Section 22.2, “NDB Cluster Installation”.)

The present section explains how to start the installer. You can do by invoking the `ndb_setup.py` executable.

#### User and privileges

You should run the `ndb_setup.py` as a normal user; no special privileges are needed to do so. You should *not* run this program as the `mysql` user, or using the system `root` or Administrator account; doing so may cause the installation to fail.

`ndb_setup.py` is found in the `bin` within the NDB Cluster installation directory; a typical location might be `/usr/local/mysql/bin` on a Linux system or `C:\Program Files\MySQL\MySQL Server 8.0\bin` on a Windows system. This can vary according to where the NDB Cluster software is installed on your system, and the installation method.

On Windows, you can also start the installer by running `setup.bat` in the NDB Cluster installation directory. When invoked from the command line, this batch file accepts the same options as `ndb_setup.py`.

`ndb_setup.py` can be started with any of several options that affect its operation, but it is usually sufficient to allow the default settings be used, in which case you can start `ndb_setup.py` by either of the following two methods:

1. Navigate to the NDB Cluster `bin` directory in a terminal and invoke it from the command line, without any additional arguments or options, like this:

```
shell> ndb_setup.py
Running out of install dir: /usr/local/mysql/bin
Starting web server on port 8081
URL is https://localhost:8081/welcome.html
deathkey=627876
Press CTRL+C to stop web server.
The application should now be running in your browser.
(Alternatively you can navigate to https://localhost:8081/welcome.html to start it)
```

This works regardless of operating platform.

2. Navigate to the NDB Cluster `bin` directory in a file browser (such as Windows Explorer on Windows, or Konqueror, Dolphin, or Nautilus on Linux) and activate (usually by double-clicking) the `ndb_setup.py` file icon. This works on Windows, and should work with most common Linux desktops as well.

On Windows, you can also navigate to the NDB Cluster installation directory and activate the `setup.bat` file icon.

In either case, once `ndb_setup.py` is invoked, the Auto-Installer’s **Welcome screen** should open in the system’s default web browser. If not, you should be able to open the page `http://localhost:8081/welcome.html` or `https://localhost:8081/welcome.html` manually in the browser.
In some cases, you may wish to use non-default settings for the installer, such as specifying HTTPS for connections, or a different port for the Auto-Installer's included web server to run on, in which case you must invoke `ndb_setup.py` with one or more startup options with values overriding the necessary defaults. The same startup options can be used on Windows systems with the `setup.bat` file supplied for such platforms in the NDB Cluster software distribution. This can be done using the command line, but if you want or need to start the installer from a desktop or file browser while employing one or more of these options, it is also possible to create a script or batch file containing the proper invocation, then to double-click its file icon in the file browser to start the installer. (On Linux systems, you might also need to make the script file executable first.) If you plan to use the Auto-Installer from a remote host, you should start using the `-S` option. For information about this and other advanced startup options for the NDB Cluster Auto-Installer, see Section 22.4.26, "`ndb_setup.py` — Start browser-based Auto-Installer for NDB Cluster (DEPRECATED)".

**NDB Cluster Auto-Installer Welcome Screen**

The **Welcome** screen is loaded in the default browser when `ndb_setup.py` is invoked. The first time the Auto-Installer is run (or if for some other reason there are no existing configurations), this screen appears as shown here:

![NDB Cluster Auto-Installer Welcome Screen](image)

In this case, the only choice of cluster listed is for configuration of a new cluster, and both the **View Cfg** and **Continue** buttons are inactive.

To create a new configuration, enter and confirm a passphrase in the text boxes provided. When this has been done, you can click **Continue** to proceed to the **Define Cluster** screen where you can assign a name to the new cluster.

If you have previously created one or more clusters with the Auto-Installer, they are listed by name. This example shows an existing cluster named **mycluster-1**:  

---

3911
To view the configuration for and work with a given cluster, select the radiobutton next to its name in the list, then enter and confirm the passphrase that was used to create it. When you have done this correctly, you can click **View Cfg** to view and edit this cluster's configuration.

**NDB Cluster Auto-Installer Define Cluster Screen**

The **Define Cluster** screen is appears following the **Welcome screen**, and is used for setting general properties of the cluster. The layout of the **Define Cluster** screen is shown here:
The NDB Cluster Auto-Installer (DEPRECATED)

Figure 22.10 The NDB Cluster Auto-Installer Define Cluster screen

This screen and subsequent screens also include Settings and Help menus which are described later in this section; see NDB Cluster Installer Settings and Help Menus.

The Define Cluster screen allows you to set three sorts of properties for the cluster: cluster properties, SSH properties, and installation properties.

Cluster properties that can be set on this screen are listed here:

- **Cluster name**: A name that identifies the cluster; in this example, this is mycluster-1. The name is set on the previous screen and cannot be changed here.

- **Host list**: A comma-delimited list of one or more hosts where cluster processes should run. By default, this is 127.0.0.1. If you add remote hosts to the list, you must be able to connect to them using the credentials supplied as SSH properties.

- **Application type**: Choose one of the following:
  1. **Simple testing**: Minimal resource usage for small-scale testing. This the default. Not intended for production environments.
  2. **Web**: Maximize performance for the given hardware.
  3. **Real-time**: Maximize performance while maximizing sensitivity to timeouts in order to minimize the time needed to detect failed cluster processes.

- **Write load**: Choose a level for the anticipated number of writes for the cluster as a whole. You can choose any one of the following levels:
  1. **Low**: The expected load includes fewer than 100 write transactions for second.
  2. **Medium**: The expected load includes 100 to 1000 write transactions per second; this is the default.
3. **High**: The expected load includes more than 1000 write transactions per second.

SSH properties are described in the following list:

- **Key-Based SSH**: Check this box to use key-enabled login to the remote host. If checked, the key user and passphrase must also be supplied; otherwise, a user and password for a remote login account are needed.

- **User**: Name of user with remote login access.

- **Password**: Password for remote user.

- **Key user**: Name of the user for whom the key is valid, if not the same as the operating system user.

- **Key passphrase**: Passphrase for the key, if required.

- **Key file**: Path to the key file. The default is `~/.ssh/id_rsa`.

The SSH properties set on this page apply to all hosts in the cluster. They can be overridden for a given host by editing that host's properties on the **Define Hosts** screen.

Two installation properties can also be set on this screen:

- **Install MySQL Cluster**: This setting determines the source from which the Auto-Installer installs NDB Cluster software, if any, on the cluster hosts. Possible values and their effects are listed here:

  1. **DOCKER**: Try to install the MySQL Cluster Docker image from [https://hub.docker.com/r/mysql/mysql-cluster/](https://hub.docker.com/r/mysql/mysql-cluster/) on each host

  2. **REPO**: Try to install the NDB Cluster software from the MySQL Repositories on each host

  3. **BOTH**: Try to install either the Docker image or the software from the repository on each host, giving preference to the repository

  4. **NONE**: Do not install the NDB Cluster software on the hosts; this is the default

- **Open FW Ports**: Check this check box to have the installer attempt to open ports required by NDB Cluster processes on all hosts.

The next figure shows the **Define Cluster** page with settings for a small test cluster with all nodes running on `localhost`:
After making the desired settings, you can save them to the configuration file and proceed to the Define Hosts screen by clicking the Save & Next button.

If you exit the installer without saving, no changes are made to the configuration file.

**NDB Cluster Auto-Installer Define Hosts Screen**

The Define Hosts screen, shown here, provides a means of viewing and specifying several key properties of each cluster host:
Properties shown include the following:

- **Host**: Name or IP address of this host
- **Res.info**: Shows **OK** if the installer was able to retrieve requested resource information from this host
- **Platform**: Operating system or platform
- **Memory (MB)**: Amount of RAM on this host
- **Cores**: Number of CPU cores available on this host
- **MySQL Cluster install directory**: Path to directory where the NDB Cluster software is installed on this host; defaults to `/usr/local/bin`
- **MySQL Cluster data directory**: Path to directory used for data by NDB Cluster processes on this host; defaults to `/var/lib/mysql-cluster`
- **DiskFree**: Free disk space in bytes
  
  For hosts with multiple disks, only the space available on the disk used for the data directory is shown.

This screen also provides an extended view for each host that includes the following properties:

- **FDQN**: This host's fully qualified domain name, used by the installer to connect with it, distribute configuration information to it, and start and stop cluster processes on it.
- **Internal IP**: The IP address used for communication with cluster processes running on this host by processes running elsewhere.
- **OS Details**: Detailed operating system name and version information.
- **Open FW**: If this check box is enabled, the installer attempts to open ports in the host's firewall needed by cluster processes.
- **REPO URL**: URL for MySQL NDB Cluster repository
• **DOCKER URL**: URL for MySQL NDB Cluster Docker images; for NDB 8.0, this is `mysql/mysql-cluster:8.0`.

• **Install**: If this check box is enabled, the Auto-Installer attempts to install the NDB Cluster software on this host

The extended view is shown here:

**Figure 22.13 NDB Cluster Define Hosts screen, extended host info view**

All cells in the display are editable, with the exceptions of those in the Host, Res.info, and FQDN columns.

Be aware that it may take some time for information to be retrieved from remote hosts. Fields for which no value could be retrieved are indicated with an ellipsis (...). You can retry the fetching of resource information from one or more hosts by selecting the hosts in the list and then clicking the **Refresh selected host(s)** button.

**Adding and Removing Hosts**

You can add one or more hosts by clicking the **Add Host** button and entering the required properties where indicated in the **Add new host** dialog, shown here:
This dialog includes the following fields:
The NDB Cluster Auto-Installer (DEPRECATED)

- **Host name**: A comma-separated list of one or more host names, IP addresses, or both. These must be accessible from the host where the Auto-Installer is running.

- **Host internal IP (VPN)**: If you are setting up the cluster to run on a VPN or other internal network, enter the IP address or addresses used for contact by cluster nodes on other hosts.

- **Key-based auth**: If checked, enables key-based authentication. You can enter any additional needed information in the **User**, **Passphrase**, and **Key file** fields.

- **Ordinary login**: If accessing this host using a password-based login, enter the appropriate information in the **User** and **Password** fields.

- **Open FW ports**: Selecting this check box allows the installer try opening any ports needed by cluster processes in this host's firewall.

- **Configure installation**: Checking this allows the Auto-Install to attempt to set up the NDB Cluster software on this host.

To save the new host and its properties, click **Add**. If you wish to cancel without saving any changes, click **Cancel** instead.

Similarly, you can remove one or more hosts using the button labelled **Remove selected host(s)**. *When you remove a host, any process which was configured for that host is also removed.*

**Warning**

**Remove selected host(s)** acts immediately. There is no confirmation dialog. If you remove a host in error, you must re-enter its name and properties manually using **Add host**.

If the SSH user credentials on the **Define Cluster screen** are changed, the Auto-Installer attempts to refresh the resource information from any hosts for which information is missing.

You can edit the host's platform name, hardware resource information, installation directory, and data directory by clicking the corresponding cell in the grid, by selecting one or more hosts and clicking the button labelled **Edit selected host(s)**. This causes a dialog box to appear, in which these fields can be edited, as shown here:
When more than one host is selected, any edited values are applied to all selected hosts.

Once you have entered all desired host information, you can use the **Save & Next** button to save the information to the cluster's configuration file and proceed to the **Define Processes** screen, where you can set up NDB Cluster processes on one or more hosts.

### NDB Cluster Auto-Installer Define Processes Screen

The **Define Processes** screen, shown here, provides a way to assign NDB Cluster processes (nodes) to cluster hosts:
The NDB Cluster Auto-Installer (DEPRECATED)

Figure 22.16 NDB Cluster Auto-Installer Define Processes dialog

This screen contains a process tree showing cluster hosts and processes set up to run on each one, as well as a panel which displays information about the item currently selected in the tree.

When this screen is accessed for the first time for a given cluster, a default set of processes is defined for you, based on the number of hosts. If you later return to the Define Hosts screen, remove all hosts, and add new hosts, this also causes a new default set of processes to be defined.

NDB Cluster processes are of the types described in this list:

• **Management node.** Performs administrative tasks such as stopping individual data nodes, querying node and cluster status, and making backups. Executable: `ndb_mgmd`.

• **Single-threaded data node.** Stores data and executes queries. Executable: `ndbd`.

• **Multi-threaded data node.** Stores data and executes queries with multiple worker threads executing in parallel. Executable: `ndbmtd`.

• **SQL node.** MySQL server for executing SQL queries against NDB. Executable: `mysqld`.

• **API node.** A client accessing data in NDB by means of the NDB API or other low-level client API, rather than by using SQL. See MySQL NDB Cluster API Developer Guide, for more information.

For more information about process (node) types, see Section 22.1.1, “NDB Cluster Core Concepts”.

Processes shown in the tree are numbered sequentially by type, for each host—for example, `SQL node 1`, `SQL node 2`, and so on—to simplify identification.

Each management node, data node, or SQL process must be assigned to a specific host, and is not allowed to run on any other host. An API node may be assigned to a single host, but this is not required. Instead, you can assign it to the special Any host entry which the tree also contains in addition to any
other hosts, and which acts as a placeholder for processes that are allowed to run on any host. *Only API processes may use this Any host entry.*

**Adding processes.** To add a new process to a given host, either right-click that host's entry in the tree, then select the *Add process* popup when it appears, or select a host in the process tree, and press the *Add process* button below the process tree. Performing either of these actions opens the add process dialog, as shown here:

![Add Process Dialog](image)

Here you can select from among the available process types described earlier this section; you can also enter an arbitrary process name to take the place of the suggested value, if desired.

**Removing processes.** To delete a process, select that process in the tree and use the *Del process* button.

When you select a process in the process tree, information about that process is displayed in the information panel, where you can change the process name and possibly its type. You can change a multi-threaded data node (*ndbmt.d*) to a single-threaded data node (*ndbd*), or the reverse, only; no other process type changes are allowed. *If you want to make a change between any other process types, you must delete the original process first, then add a new process of the desired type.*

**NDB Cluster Auto-Installer Define Parameters Screen**

Like the *Define Processes* screen, this screen includes a process tree; the *Define Parameters* process tree is organized by process or node type, in groups labelled *Management Layer, Data Layer, SQL Layer,* and *API Layer.* An information panel displays information regarding the item currently selected. The *Define Attributes* screen is shown here:
The check box labelled *Show advanced configuration*, when checked, makes advanced options for data node and SQL node processes visible in the information pane. These options are set and used whether or not they are visible. You can also enable this behavior globally by checking *Show advanced configuration options* under **Settings** (see [NDB Cluster Installer Settings and Help Menus](#)).

You can edit attributes for a single process by selecting that process from the tree, or for all processes of the same type in the cluster by selecting one of the **Layer** folders. A per-process value set for a given attribute overrides any per-group setting for that attribute that would otherwise apply to the process in question. An example of such an information panel (for an SQL process) is shown here:
Attributes whose values can be overridden are shown in the information panel with a button bearing a plus sign. This \( \text{+} \) button activates an input widget for the attribute, enabling you to change its value. When the value has been overridden, this button changes into a button showing an \( \text{X} \). The \( \text{X} \) button undoes any changes made to a given attribute, which immediately reverts to the predefined value.

All configuration attributes have predefined values calculated by the installer, based such factors as host name, node ID, node type, and so on. In most cases, these values may be left as they are. If you are not familiar with it already, it is highly recommended that you read the applicable documentation before making changes to any of the attribute values. To make finding this information easier, each attribute name shown in the information panel is linked to its description in the online NDB Cluster documentation.

**NDB Cluster Auto-Installer Deploy Configuration Screen**

This screen allows you to perform the following tasks:

- Review process startup commands and configuration files to be applied

- Distribute configuration files by creating any necessary files and directories on all cluster hosts—that is, deploy the cluster as presently configured

- Start and stop the cluster

The **Deploy Configuration** screen is shown here:
Like the Define Parameters screen, this screen features a process tree which is organized by process type. Next to each process in the tree is a status icon indicating the current status of the process: connected (CONNECTED), starting (STARTING), running (STARTED), stopping (STOPPING), or disconnected (NO_CONTACT). The icon shows green if the process is connected or running; yellow if it is starting or stopping; red if the process is stopped or cannot be contacted by the management server.

This screen also contains two information panels, one showing the startup command or commands needed to start the selected process. (For some processes, more than one command may be required—for example, if initialization is necessary.) The other panel shows the contents of the configuration file, if any, for the given process.

This screen also contains four buttons, labelled as and performing the functions described in the following list:

- **Install cluster**: Nonfunctional in this release; implementation intended for a future release.
- **Deploy cluster**: Verify that the configuration is valid. Create any directories required on the cluster hosts, and distribute the configuration files onto the hosts. A progress bar shows how far the deployment has proceeded, as shown here, and a dialog is displayed when the deployment has completed, as shown here:
Figure 22.21 Cluster Deployment Process
• **Start cluster:** The cluster is deployed as with **Deploy cluster**, after which all cluster processes are started in the correct order.

Starting these processes may take some time. If the estimated time to completion is too large, the installer provides an opportunity to cancel or to continue of the startup procedure. A progress bar indicates the current status of the startup procedure, as shown here:

**Figure 22.22 Cluster Startup Process with Progress Bar**

![Cluster Startup Process with Progress Bar](image)

The process status icons next to the items shown in the process tree also update with the status of each process.

A confirmation dialog is shown when the startup process has completed, as shown here:

**Figure 22.23 Cluster Startup, Process Completed Dialog**

![Cluster Startup, Process Completed Dialog](image)

• **Stop cluster:** After the cluster has been started, you can stop it using this. As with starting the cluster, cluster shutdown is not instantaneous, and may require some time complete. A progress bar, similar
Configuration of NDB Cluster

to that displayed during cluster startup, shows the approximate current status of the cluster shutdown procedure, as do the process status icons adjoining the process tree. The progress bar is shown here:

**Figure 22.24 Cluster Shutdown Process, with Progress Bar**

![Cluster Shutdown Progress Bar](image)

A confirmation dialog indicates when the shutdown process is complete:

**Figure 22.25 Cluster Shutdown, Process Completed Dialog**

![Cluster Shutdown Complete](image)

The Auto-Installer generates a `config.ini` file containing NDB node parameters for each management node, as well as a `my.cnf` file containing the appropriate options for each `mysqld` process in the cluster. No configuration files are created for data nodes or API nodes.

### 22.3 Configuration of NDB Cluster

A MySQL server that is part of an NDB Cluster differs in one chief respect from a normal (nonclustered) MySQL server, in that it employs the NDB storage engine. This engine is also referred to sometimes as NDBCLUSTER, although NDB is preferred.

To avoid unnecessary allocation of resources, the server is configured by default with the NDB storage engine disabled. To enable NDB, you must modify the server's `my.cnf` configuration file, or start the server with the `--ndbcluster` option.
Quick Test Setup of NDB Cluster

This MySQL server is a part of the cluster, so it also must know how to access a management node to obtain the cluster configuration data. The default behavior is to look for the management node on localhost. However, should you need to specify that its location is elsewhere, this can be done in my.cnf, or with the mysql client. Before the NDB storage engine can be used, at least one management node must be operational, as well as any desired data nodes.

For more information about --ndbcluster and other mysqld options specific to NDB Cluster, see MySQL Server Options for NDB Cluster.

For general information about installing NDB Cluster, see Section 22.2, “NDB Cluster Installation”.

22.3.1 Quick Test Setup of NDB Cluster

To familiarize you with the basics, we describe the simplest possible configuration for a functional NDB Cluster. After this, you should be able to design your desired setup from the information provided in the other relevant sections of this chapter.

First, you need to create a configuration directory such as /var/lib/mysql-cluster, by executing the following command as the system root user:

```
shell> mkdir /var/lib/mysql-cluster
```

In this directory, create a file named config.ini that contains the following information. Substitute appropriate values for HostName and DataDir as necessary for your system.

```
# file "config.ini" - showing minimal setup consisting of 1 data node, 1 management server, and 3 MySQL servers.
# The empty default sections are not required, and are shown only for the sake of completeness.
# Data nodes must provide a hostname but MySQL Servers are not required to do so.
# If you don't know the hostname for your machine, use localhost.
# The DataDir parameter also has a default value, but it is recommended to set it explicitly.
# Note: [db], [api], and [mgm] are aliases for [ndbd], [mysqld], and [ndb_mgmd], respectively. [db] is deprecated and should not be used in new installations.

[ndbd default]
NoOfReplicas= 1

[mysqld default]

[ndb_mgmd default]
[tcp default]

[ndb_mgmd]
HostName= myhost.example.com

[ndbd]
HostName= myhost.example.com
DataDir= /var/lib/mysql-cluster

[mysql]

[mysqld]

You can now start the ndb_mgmd management server. By default, it attempts to read the config.ini file in its current working directory, so change location into the directory where the file is located and then invoke ndb_mgmd:

```
shell> cd /var/lib/mysql-cluster
shell> ndb_mgmd
```

Then start a single data node by running ndbd:
Quick Test Setup of NDB Cluster

Note
If you have installed MySQL from a binary tarball, you must specify the path of the ndb_mgmd and ndbd servers explicitly. ( Normally, these can be found in /usr/local/mysql/bin.)

Finally, change location to the MySQL data directory (usually /var/lib/mysql or /usr/local/mysql/data), and make sure that the my.cnf file contains the option necessary to enable the NDB storage engine:

```
[mysqld]
ndbcluster
```

You can now start the MySQL server as usual:

```
shell> mysqld_safe --user=mysql &
```

Wait a moment to make sure the MySQL server is running properly. If you see the notice mysql ended, check the server's .err file to find out what went wrong.

If all has gone well so far, you now can start using the cluster. Connect to the server and verify that the NDBCLUSTER storage engine is enabled:

```
shell> mysql
Welcome to the MySQL monitor. Commands end with ; or \g.
Your MySQL connection id is 1 to server version: 8.0.24

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SHOW ENGINES\G
...  
*************************** 12. row ***************************
Engine: NDBCLUSTER
Support: YES
Comment: Clustered, fault-tolerant, memory-based tables
*************************** 13. row ***************************
Engine: NDB
Support: YES
Comment: Alias for NDBCLUSTER
...
```

The row numbers shown in the preceding example output may be different from those shown on your system, depending upon how your server is configured.

Try to create an NDBCLUSTER table:

```
shell> mysql
mysql> USE test;
Database changed

mysql> CREATE TABLE ctest (i INT) ENGINE=NDBCLUSTER;
Query OK, 0 rows affected (0.09 sec)

mysql> SHOW CREATE TABLE ctest \G
*************************** 1. row ***************************
Table: ctest
```
To check that your nodes were set up properly, start the management client:

```
shell> ndb_mgm
```

Use the `SHOW` command from within the management client to obtain a report on the cluster's status:

```
ndb_mgm> SHOW
Cluster Configuration
---------------------
[ndbd(NDB)]     1 node(s)
id=2    @127.0.0.1  (Version: 8.0.22-ndb-8.0.22, Nodegroup: 0, *)

[ndb_mgmd(MGM)] 1 node(s)
id=1    @127.0.0.1  (Version: 8.0.22-ndb-8.0.22)

[mysqld(API)]   3 node(s)
id=3    @127.0.0.1  (Version: 8.0.22-ndb-8.0.22)
id=4 (not connected, accepting connect from any host)
id=5 (not connected, accepting connect from any host)
```

At this point, you have successfully set up a working NDB Cluster. You can now store data in the cluster by using any table created with `ENGINE=NDBCLUSTER` or its alias `ENGINE=NDB`.

### 22.3.2 Overview of NDB Cluster Configuration Parameters, Options, and Variables

The next several sections provide summary tables of NDB Cluster node configuration parameters used in the `config.ini` file to govern various aspects of node behavior, as well as of options and variables read by `mysqld` from a `my.cnf` file or from the command line when run as an NDB Cluster process. Each of the node parameter tables lists the parameters for a given type (ndbd, ndb_mgmd, mysqld, computer, tcp, or shm). All tables include the data type for the parameter, option, or variable, as well as its default, minimum, and maximum values as applicable.

#### Considerations when restarting nodes.

For node parameters, these tables also indicate what type of restart is required (node restart or system restart)—and whether the restart must be done with `--initial`—to change the value of a given configuration parameter. When performing a node restart or an initial node restart, all of the cluster's data nodes must be restarted in turn (also referred to as a rolling restart). It is possible to update cluster configuration parameters marked as `node` online—that is, without shutting down the cluster—in this fashion. An initial node restart requires restarting each `ndbd` process with the `--initial` option.

A system restart requires a complete shutdown and restart of the entire cluster. An initial system restart requires taking a backup of the cluster, wiping the cluster file system after shutdown, and then restoring from the backup following the restart.

In any cluster restart, all of the cluster's management servers must be restarted for them to read the updated configuration parameter values.

---

**Important**

Values for numeric cluster parameters can generally be increased without any problems, although it is advisable to do so progressively, making such adjustments in relatively small increments. Many of these can be increased online, using a rolling restart.
However, decreasing the values of such parameters—whether this is done using a node restart, node initial restart, or even a complete system restart of the cluster—is not to be undertaken lightly; it is recommended that you do so only after careful planning and testing. This is especially true with regard to those parameters that relate to memory usage and disk space, such as `MaxNoOfTables`, `MaxNoOfOrderedIndexes`, and `MaxNoOfUniqueHashIndexes`. In addition, it is the generally the case that configuration parameters relating to memory and disk usage can be raised using a simple node restart, but they require an initial node restart to be lowered.

Because some of these parameters can be used for configuring more than one type of cluster node, they may appear in more than one of the tables.

**Note**

4294967039 often appears as a maximum value in these tables. This value is defined in the `NDBCLUSTER` sources as `MAX_INT_RNIL` and is equal to `0xFFFFFEFF`, or $2^{32} - 2^{8} - 1$.

### 22.3.2.1 NDB Cluster Data Node Configuration Parameters

The listings in this section provide information about parameters used in the `[ndbd]` or `[ndbd default]` sections of a `config.ini` file for configuring NDB Cluster data nodes. For detailed descriptions and other additional information about each of these parameters, see Section 22.3.3.6, “Defining NDB Cluster Data Nodes”.

These parameters also apply to `ndbmtd`, the multithreaded version of `ndbd`. For more information, see Section 22.4.3, “`ndbmtd` — The NDB Cluster Data Node Daemon (Multi-Threaded)”.

- **Arbitration**: How arbitration should be performed to avoid split-brain issues in event of node failure.
- **ArbitrationTimeout**: Maximum time (milliseconds) database partition waits for arbitration signal.
- **BackupDataBufferSize**: Default size of databuffer for a backup (in bytes).
- **BackupDataDir**: Path to where to store backups. Note that string `/BACKUP` is always appended to this setting, so that *effective* default is `FileSystemPath/BACKUP`.
- **BackupDiskWriteSpeedPct**: Sets percentage of data node’s allocated maximum write speed (`MaxDiskWriteSpeed`) to reserve for LCPs when starting a backup.
- **BackupLogBufferSize**: Default size of log buffer for a backup (in bytes).
- **BackupMaxWriteSize**: Maximum size of file system writes made by backup (in bytes).
- **BackupMemory**: Total memory allocated for backups per node (in bytes).
- **BackupReportFrequency**: Frequency of backup status reports during backup in seconds.
- **BackupWriteSize**: Default size of file system writes made by backup (in bytes).
- **BatchSizePerLocalScan**: Used to calculate number of lock records for scan with hold lock.
- **BuildIndexThreads**: Number of threads to use for building ordered indexes during a system or node restart. Also applies when running `ndb_restore --rebuild-indexes`. Setting this parameter to 0 disables multithreaded building of ordered indexes.
- **CompressedBackup**: Use zlib to compress backups as they are written.
Overview of NDB Cluster Configuration Parameters, Options, and Variables

- **CompressedLCP**: Write compressed LCPs using zlib.
- **ConnectCheckIntervalDelay**: Time between data node connectivity check stages. Data node is considered suspect after 1 interval and dead after 2 intervals with no response.
- **CrashOnCorruptedTuple**: When enabled, forces node to shut down whenever it detects a corrupted tuple.
- **DataDir**: Data directory for this node.
- **DataMemory**: Number of bytes on each data node allocated for storing data; subject to available system RAM and size of IndexMemory.
- **DefaultHashMapSize**: Set size (in buckets) to use for table hash maps. Three values are supported: 0, 240, and 3840.
- **DictTrace**: Enable DBDICT debugging; for NDB development.
- **DiskDataUsingSameDisk**: Set to false if Disk Data tablespaces are located on separate physical disks.
- **DiskIOThreadPool**: Number of unbound threads for file access, applies to disk data only.
- **Diskless**: Run without using disk.
- **DiskPageBufferEntries**: Memory to allocate in DiskPageBufferMemory; very large disk transactions may require increasing this value.
- **DiskPageBufferMemory**: Number of bytes on each data node allocated for disk page buffer cache.
- **DiskSyncSize**: Amount of data written to file before a synch is forced.
- **EnablePartialLcp**: Enable partial LCP (true); if this is disabled (false), all LCPs write full checkpoints.
- **EnableRedoControl**: Enable adaptive checkpointing speed for controlling redo log usage.
- **EventLogBufferSize**: Size of circular buffer for NDB log events within data nodes.
- **ExecuteOnComputer**: String referencing an earlier defined COMPUTER.
- **ExtraSendBufferMemory**: Memory to use for send buffers in addition to any allocated by TotalSendBufferMemory or SendBufferMemory. Default (0) allows up to 16MB.
- **FileSystemPath**: Path to directory where data node stores its data (directory must exist).
- **FileSystemPathDataFiles**: Path to directory where data node stores its Disk Data files. The default value is FilesystemPathDD, if set; otherwise, FilesystemPath is used if it is set; otherwise, value of DataDir is used.
- **FileSystemPathDD**: Path to directory where data node stores its Disk Data and undo files. Default value is FilesystemPath, if set; otherwise, value of DataDir is used.
- **FileSystemPathUndoFiles**: Path to directory where data node stores its undo files for Disk Data. Default value is FilesystemPathDD, if set; otherwise, FilesystemPath is used if it is set; otherwise, value of DataDir is used.
- **FragmentLogFileSize**: Size of each redo log file.
- **HeartbeatIntervalDbApi**: Time between API node-data node heartbeats. (API connection closed after 3 missed heartbeats).
Overview of NDB Cluster Configuration Parameters, Options, and Variables

- **HeartbeatIntervalDbDb**: Time between data node-to-data node heartbeats; data node considered dead after 3 missed heartbeats.

- **HeartbeatOrder**: Sets order in which data nodes check each others' heartbeats for determining whether given node is still active and connected to cluster. Must be zero for all data nodes or distinct nonzero values for all data nodes; see documentation for further guidance.

- **HostName**: Host name or IP address for this data node.

- **IndexMemory**: Number of bytes on each data node allocated for storing indexes; subject to available system RAM and size of DataMemory.

- **IndexStatAutoCreate**: Enable/disable automatic statistics collection when indexes are created.

- **IndexStatAutoUpdate**: Monitor indexes for changes and trigger automatic statistics updates.

- **IndexStatSaveScale**: Scaling factor used in determining size of stored index statistics.

- **IndexStatSaveSize**: Maximum size in bytes for saved statistics per index.

- **IndexStatTriggerPct**: Threshold percent change in DML operations for index statistics updates. Value is scaled down by IndexStatTriggerScale.

- **IndexStatTriggerScale**: Scale down IndexStatTriggerPct by this amount, multiplied by base 2 logarithm of index size, for a large index. Set to 0 to disable scaling.

- **IndexStatUpdateDelay**: Minimum delay between automatic index statistics updates for a given index. 0 means no delay.

- **InitFragmentLogFiles**: Initialize fragment logfiles (sparse/full).

- **InitialLogFileGroup**: Describes a log file group that is created during an initial start. See documentation for format.

- **InitialNoOfOpenFiles**: Initial number of files open per data node. (One thread is created per file).

- **InitialTablespace**: Describes a tablespace that is created during an initial start. See documentation for format.

- **InsertRecoveryWork**: Percentage of RecoveryWork used for inserted rows; has no effect unless partial local checkpoints are in use.

- **LateAlloc**: Allocate memory after connection to management server has been established.

- **LcpScanProgressTimeout**: Maximum time that local checkpoint fragment scan can be stalled before node is shut down to ensure systemwide LCP progress. Use 0 to disable.

- **LockExecuteThreadToCPU**: A comma-delimited list of CPU IDs.

- **LockMaintThreadsToCPU**: CPU ID indicating which CPU runs maintenance threads.

- **LockPagesInMainMemory**: 0=disable locking, 1=lock after memory allocation, 2=lock before memory allocation.

- **LogLevelCheckpoint**: Log level of local and global checkpoint information printed to stdout.

- **LogLevelCongestion**: Level of congestion information printed to stdout.

- **LogLevelConnection**: Level of node connect/disconnect information printed to stdout.

- **LogLevelError**: Transporter, heartbeat errors printed to stdout.
• **LogLevelInfo**: Heartbeat and log information printed to stdout.

• **LogLevelNodeRestart**: Level of node restart and node failure information printed to stdout.

• **LogLevelShutdown**: Level of node shutdown information printed to stdout.

• **LogLevelStartup**: Level of node startup information printed to stdout.

• **LogLevelStatistic**: Level of transaction, operation, and transporter information printed to stdout.

• **LongMessageBuffer**: Number of bytes allocated on each data node for internal long messages.

• **MaxAllocate**: Maximum size of allocation to use when allocating memory for tables.

• **MaxBufferedEpochs**: Allowed number of epochs that a subscribing node can lag behind (unprocessed epochs). Exceeding will cause lagging subscribers to be disconnected.

• **MaxBufferedEpochBytes**: Total number of bytes allocated for buffering epochs.

• **MaxDiskDataLatency**: Maximum allowed mean latency of disk access (ms) before starting to abort transactions.

• **MaxDiskWriteSpeed**: Maximum number of bytes per second that can be written by LCP and backup when no restarts are ongoing.

• **MaxDiskWriteSpeedOtherNodeRestart**: Maximum number of bytes per second that can be written by LCP and backup when another node is restarting.

• **MaxDiskWriteSpeedOwnRestart**: Maximum number of bytes per second that can be written by LCP and backup when this node is restarting.

• **MaxFKBuildBatchSize**: Maximum scan batch size to use for building foreign keys. Increasing this value may speed up builds of foreign keys but impacts ongoing traffic as well.

• **MaxDMLOperationsPerTransaction**: Limit size of a transaction; aborts transaction if it requires more than this many DML operations. Set to 0 to disable.

• **MaxLCPStartDelay**: Time in seconds that LCP polls for checkpoint mutex (to allow other data nodes to complete metadata synchronization), before putting itself in lock queue for parallel recovery of table data.

• **MaxNoOfAttributes**: Suggests a total number of attributes stored in database (sum over all tables).

• **MaxNoOfConcurrentIndexOperations**: Total number of index operations that can execute simultaneously on one data node.

• **MaxNoOfConcurrentOperations**: Maximum number of operation records in transaction coordinator.

• **MaxNoOfConcurrentScans**: Maximum number of scans executing concurrently on data node.

• **MaxNoOfConcurrentSubOperations**: Maximum number of concurrent subscriber operations.

• **MaxNoOfConcurrentTransactions**: Maximum number of transactions executing concurrently on this data node, total number of transactions that can be executed concurrently is this value times number of data nodes in cluster.

• **MaxNoOfFiredTriggers**: Total number of triggers that can fire simultaneously on one data node.

• **MaxNoOfLocalOperations**: Maximum number of operation records defined on this data node.

• **MaxNoOfLocalScans**: Maximum number of fragment scans in parallel on this data node.

• **MaxNoOfOpenFiles**: Maximum number of files open per data node. (One thread is created per file).
Overview of NDB Cluster Configuration Parameters, Options, and Variables

- **MaxNoOfOrderedIndexes**: Total number of ordered indexes that can be defined in system.
- **MaxNoOfSavedMessages**: Maximum number of error messages to write in error log and maximum number of trace files to retain.
- **MaxNoOfSubscribers**: Maximum number of subscribers (default 0 = MaxNoOfTables * 2).
- **MaxNoOfSubscriptions**: Maximum number of subscriptions (default 0 = MaxNoOfTables).
- **MaxNoOfTables**: Suggests a total number of NDB tables stored in database.
- **MaxNoOfTriggers**: Total number of triggers that can be defined in system.
- **MaxNoOfUniqueHashIndexes**: Total number of unique hash indexes that can be defined in the system.
- **MaxParallelCopyInstances**: Number of parallel copies during node restarts. Default is 0, which uses number of LDMs on both nodes, to a maximum of 16.
- **MaxParallelScansPerFragment**: Maximum number of parallel scans per fragment. Once this limit is reached, scans are serialized.
- **MaxReorgBuildBatchSize**: Maximum scan batch size to use for reorganization of table partitions. Increasing this value may speed up table partition reorganization but impacts ongoing traffic as well.
- **MaxStartFailRetries**: Maximum retries when data node fails on startup, requires StopOnError = 0. Setting to 0 causes start attempts to continue indefinitely.
- **MaxUIBuildBatchSize**: Maximum scan batch size to use for building unique keys. Increasing this value may speed up builds of unique keys but impacts ongoing traffic as well.
- **MemReportFrequency**: Frequency of memory reports in seconds; 0 = report only when exceeding percentage limits.
- **MinDiskWriteSpeed**: Minimum number of bytes per second that can be written by LCP and backup.
- **MinFreePct**: Percentage of memory resources to keep in reserve for restarts.
- **NodeGroup**: Node group to which data node belongs; used only during initial start of cluster.
- **NodeGroupTransporters**: Number of transporters to use between nodes in same node group.
- **NodeId**: Number uniquely identifying data node among all nodes in cluster.
- **NoOfFragmentLogFiles**: Number of 16 MB redo log files in each of 4 file sets belonging to data node.
- **NoOfReplicas**: Number of copies of all data in database.
- **Numa**: (Linux only; requires libnuma) Controls NUMA support. Setting to 0 permits system to determine use of interleaving by data node process; 1 means that it is determined by data node.
- **ODirect**: Use O_DIRECT file reads and writes when possible.
- **ODirectSyncFlag**: O_DIRECT writes are treated as synchronized writes; ignored when ODirect is not enabled, InitFragmentLogFiles is set to SPARSE, or both.
- **RealtimeScheduler**: When true, data node threads are scheduled as real-time threads. Default is false.
- **RecoveryWork**: Percentage of storage overhead for LCP files: greater value means less work in normal operations, more work during recovery.
Overview of NDB Cluster Configuration Parameters, Options, and Variables

- **RedoBuffer**: Number of bytes on each data node allocated for writing redo logs.
- **RedoOverCommitCounter**: When RedoOverCommitLimit has been exceeded this many times, transactions are aborted, and operations are handled as specified by DefaultOperationRedoProblemAction.
- **RedoOverCommitLimit**: Each time that flushing current redo buffer takes longer than this many seconds, number of times that this has happened is compared to RedoOverCommitCounter.
- **ReservedConcurrentIndexOperations**: Number of simultaneous index operations having dedicated resources on one data node.
- **ReservedConcurrentOperations**: Number of simultaneous operations having dedicated resources in transaction coordinators on one data node.
- **ReservedConcurrentScans**: Number of simultaneous scans having dedicated resources on one data node.
- **ReservedConcurrentTransactions**: Number of simultaneous transactions having dedicated resources on one data node.
- **ReservedFiredTriggers**: Number of triggers having dedicated resources on one data node.
- **ReservedLocalScans**: Number of simultaneous fragment scans having dedicated resources on one data node.
- **ReservedTransactionBufferMemory**: Dynamic buffer space (in bytes) for key and attribute data allocated to each data node.
- **RestartOnErrorInsert**: Control type of restart caused by inserting an error (when StopOnError is enabled).
- **SchedulerExecutionTimer**: Number of microseconds to execute in scheduler before sending.
- **SchedulerResponsiveness**: Set NDB scheduler response optimization 0-10; higher values provide better response time but lower throughput.
- **SchedulerSpinTimer**: Number of microseconds to execute in scheduler before sleeping.
- **ServerPort**: Port used to set up transporter for incoming connections from API nodes.
- **SharedGlobalMemory**: Total number of bytes on each data node allocated for any use.
- **SpinMethod**: Determines spin method used by data node; see documentation for details.
- **StartFailRetryDelay**: Delay in seconds after start failure prior to retry; requires StopOnError = 0.
- **StartFailureTimeout**: Milliseconds to wait before terminating. (0=Wait forever).
- **StartNoNodeGroupTimeout**: Time to wait for nodes without a nodegroup before trying to start (0=forever).
- **StartPartialTimeout**: Milliseconds to wait before trying to start without all nodes. (0=Wait forever).
- **StartPartitionedTimeout**: Milliseconds to wait before trying to start partitioned. (0=Wait forever).
- **StartupStatusReportFrequency**: Frequency of status reports during startup.
- **StopOnError**: When set to 0, data node automatically restarts and recovers following node failures.
- **StringMemory**: Default size of string memory (0 to 100 = % of maximum, 101+ = actual bytes).
• **TcpBind_INADDR_ANY**: Bind IP_ADDR_ANY so that connections can be made from anywhere (for autogenerated connections).

• **TimeBetweenEpochs**: Time between epochs (synchronization used for replication).

• **TimeBetweenEpochsTimeout**: Timeout for time between epochs. Exceeding will cause node shutdown.

• **TimeBetweenGlobalCheckpoints**: Time between group commits of transactions to disk.

• **TimeBetweenGlobalCheckpointsTimeout**: Minimum timeout for group commit of transactions to disk.

• **TimeBetweenInactiveTransactionAbortCheck**: Time between checks for inactive transactions.

• **TimeBetweenLocalCheckpoints**: Time between taking snapshots of database (expressed in base-2 logarithm of bytes).

• **TimeBetweenWatchDogCheck**: Time between execution checks inside a data node.

• **TimeBetweenWatchDogCheckInitial**: Time between execution checks inside a data node (early start phases when memory is allocated).

• **TotalSendBufferMemory**: Total memory to use for all transporter send buffers.

• **TransactionBufferMemory**: Dynamic buffer space (in bytes) for key and attribute data allocated for each data node.

• **TransactionDeadlockDetectionTimeout**: Time transaction can spend executing within a data node. This is time that transaction coordinator waits for each data node participating in transaction to execute a request. If data node takes more than this amount of time, transaction is aborted.

• **TransactionInactiveTimeout**: Milliseconds that application waits before executing another part of transaction. This is time transaction coordinator waits for application to execute or send another part (query, statement) of transaction. If application takes too much time, then transaction is aborted. Timeout = 0 means that application never times out.

• **TransactionMemory**: Memory allocated for transactions on each data node.

• **TwoPassInitialNodeRestartCopy**: Copy data in 2 passes during initial node restart, which enables multithreaded building of ordered indexes for such restarts.

• **UndoDataBuffer**: Number of bytes on each data node allocated for writing data undo logs.

• **UndoIndexBuffer**: Number of bytes on each data node allocated for writing index undo logs.

• **UseShm**: Use shared memory connections between this data node and API node also running on this host.

The following parameters are specific to ndbmtld:

• **MaxNoOfExecutionThreads**: For ndbmtld only, specify maximum number of execution threads.

• **NoOfFragmentLogParts**: Number of redo log file groups belonging to this data node.

• **ThreadConfig**: Used for configuration of multithreaded data nodes (ndbmtld). Default is an empty string; see documentation for syntax and other information.

### 22.3.2.2 NDB Cluster Management Node Configuration Parameters
The listing in this section provides information about parameters used in the [ndb_mgmd] or [mgm] section of a config.ini file for configuring NDB Cluster management nodes. For detailed descriptions and other additional information about each of these parameters, see Section 22.3.3.5, “Defining an NDB Cluster Management Server”.

- **ArbitrationDelay**: When asked to arbitrate, arbitrator waits this long before voting (milliseconds).
- **ArbitrationRank**: If 0, then management node is not arbitrator. Kernel selects arbitrators in order 1, 2.
- **DataDir**: Data directory for this node.
- **ExecuteOnComputer**: String referencing an earlier defined COMPUTER.
- **ExtraSendBufferMemory**: Memory to use for send buffers in addition to any allocated by TotalSendBufferMemory or SendBufferMemory. Default (0) allows up to 16MB.
- **HeartbeatIntervalMgmdMgmd**: Time between management-node-to-management-node heartbeats; connection between management nodes is considered lost after 3 missed heartbeats.
- **HeartbeatThreadPriority**: Set heartbeat thread policy and priority for management nodes; see manual for allowed values.
- **HostName**: Host name or IP address for this management node.
- **Id**: Number identifying management node. Now deprecated; use NodeId instead.
- **LogDestination**: Where to send log messages: console, system log, or specified log file.
- **NodeId**: Number uniquely identifying management node among all nodes in cluster.
- **PortNumber**: Port number to send commands to and fetch configuration from management server.
- **PortNumberStats**: Port number used to get statistical information from a management server.
- **TotalSendBufferMemory**: Total memory to use for all transporter send buffers.
- **wan**: Use WAN TCP setting as default.

**Note**

After making changes in a management node’s configuration, it is necessary to perform a rolling restart of the cluster for the new configuration to take effect. See Section 22.3.3.5, “Defining an NDB Cluster Management Server”, for more information.

To add new management servers to a running NDB Cluster, it is also necessary to perform a rolling restart of all cluster nodes after modifying any existing config.ini files. For more information about issues arising when using multiple management nodes, see Section 22.1.7.10, “Limitations Relating to Multiple NDB Cluster Nodes”.

### 22.3.2.3 NDB Cluster SQL Node and API Node Configuration Parameters

The listing in this section provides information about parameters used in the [mysqld] and [api] sections of a config.ini file for configuring NDB Cluster SQL nodes and API nodes. For detailed descriptions and other additional information about each of these parameters, see Section 22.3.3.7, “Defining SQL and Other API Nodes in an NDB Cluster”.

3939
Overview of NDB Cluster Configuration Parameters, Options, and Variables

- **ApiVerbose**: Enable NDB API debugging; for NDB development.
- **ArbitrationDelay**: When asked to arbitrate, arbitrator waits this many milliseconds before voting.
- **ArbitrationRank**: If 0, then API node is not arbitrator. Kernel selects arbitrators in order 1, 2.
- **AutoReconnect**: Specifies whether an API node should reconnect fully when disconnected from cluster.
- **BatchByteSize**: Default batch size in bytes.
- **BatchSize**: Default batch size in number of records.
- **ConnectBackoffMaxTime**: Specifies longest time in milliseconds (~100ms resolution) to allow between connection attempts to any given data node by this API node. Excludes time elapsed while connection attempts are ongoing, which in worst case can take several seconds. Disable by setting to 0. If no data nodes are currently connected to this API node, StartConnectBackoffMaxTime is used instead.
- **ConnectionMap**: Specifies which data nodes to connect.
- **DefaultHashMapSize**: Set size (in buckets) to use for table hash maps. Three values are supported: 0, 240, and 3840.
- **DefaultOperationRedoProblemAction**: How operations are handled in event that RedoOverCommitCounter is exceeded.
- **ExecuteOnComputer**: String referencing an earlier defined COMPUTER.
- **ExtraSendBufferMemory**: Memory to use for send buffers in addition to any allocated by TotalSendBufferMemory or SendBufferMemory. Default (0) allows up to 16MB.
- **HeartbeatThreadPriority**: Set heartbeat thread policy and priority for API nodes; see manual for allowed values.
- **HostName**: Host name or IP address for this SQL or API node.
- **Id**: Number identifying MySQL server or API node (Id). Now deprecated; use NodeId instead.
- **MaxScanBatchSize**: Maximum collective batch size for one scan.
- **NodeId**: Number uniquely identifying SQL node or API node among all nodes in cluster.
- **StartConnectBackoffMaxTime**: Same as ConnectBackoffMaxTime except that this parameter is used in its place if no data nodes are connected to this API node.
- **TotalSendBufferMemory**: Total memory to use for all transporter send buffers.
- **wan**: Use WAN TCP setting as default.

For a discussion of MySQL server options for NDB Cluster, see MySQL Server Options for NDB Cluster. For information about MySQL server system variables relating to NDB Cluster, see NDB Cluster System Variables.

---

**Note**

To add new SQL or API nodes to the configuration of a running NDB Cluster, it is necessary to perform a rolling restart of all cluster nodes after adding new [mysqld] or [api] sections to the config.ini file (or files, if you are using more than one management server). This must be done before the new SQL or API nodes can connect to the cluster.
It is not necessary to perform any restart of the cluster if new SQL or API nodes can employ previously unused API slots in the cluster configuration to connect to the cluster.

22.3.2.4 Other NDB Cluster Configuration Parameters

The listings in this section provide information about parameters used in the [computer], [tcp], and [shm] sections of a config.ini file for configuring NDB Cluster. For detailed descriptions and additional information about individual parameters, see Section 22.3.3.10, “NDB Cluster TCP/IP Connections”, or Section 22.3.3.12, “NDB Cluster Shared-Memory Connections”, as appropriate.

The following parameters apply to the config.ini file's [computer] section:

- **HostName**: Host name or IP address of this computer.
- **Id**: A unique identifier for this computer.

The following parameters apply to the config.ini file's [tcp] section:

- **AllowUnresolvedHostNames**: When false (default), failure by management node to resolve host name results in fatal error; when true, unresolved host names are reported as warnings only.
- **Checksum**: If checksum is enabled, all signals between nodes are checked for errors.
- **Group**: Used for group proximity; smaller value is interpreted as being closer.
- **NodeId1**: ID of node (data node, API node, or management node) on one side of connection.
- **NodeId2**: ID of node (data node, API node, or management node) on one side of connection.
- **NodeIdServer**: Set server side of TCP connection.
- **OverloadLimit**: When more than this many unsent bytes are in send buffer, connection is considered overloaded.
- **PreSendChecksum**: If this parameter and Checksum are both enabled, perform pre-send checksum checks, and check all TCP signals between nodes for errors.
- **Proxy**:.
- **ReceiveBufferMemory**: Bytes of buffer for signals received by this node.
- **SendBufferMemory**: Bytes of TCP buffer for signals sent from this node.
- **SendSignalId**: Sends ID in each signal. Used in trace files. Defaults to true in debug builds.
- **TCP_MAXSEG_SIZE**: Value used for TCP_MAXSEG.
- **TCP_RCV_BUF_SIZE**: Value used for SO_RCVBUF.
- **TCP_SND_BUF_SIZE**: Value used for SO_SNDBUF.
- **TcpBind_INADDR_ANY**: Bind InAddrAny instead of host name for server part of connection.

The following parameters apply to the config.ini file's [shm] section:

- **Checksum**: If checksum is enabled, all signals between nodes are checked for errors.
- **Group**: Used for group proximity; smaller value is interpreted as being closer.
- **NodeId1**: ID of node (data node, API node, or management node) on one side of connection.
Overview of NDB Cluster Configuration Parameters, Options, and Variables

- **NodeId**: ID of node (data node, API node, or management node) on one side of connection.
- **NodeIdServer**: Set server side of SHM connection.
- **OverloadLimit**: When more than this many unsent bytes are in send buffer, connection is considered overloaded.
- **PreSendChecksum**: If this parameter and Checksum are both enabled, perform pre-send checksum checks, and check all SHM signals between nodes for errors.
- **SendBufferMemory**: Bytes in shared memory buffer for signals sent from this node.
- **SendSignalId**: Sends ID in each signal. Used in trace files.
- **ShmKey**: A shared memory key; when set to 1, this is calculated by NDB.
- **ShmSpinTime**: When receiving, number of microseconds to spin before sleeping.
- **ShmSize**: Size of shared memory segment.
- **Signum**: Signal number to be used for signalling.

### 22.3.2.5 NDB Cluster mysqld Option and Variable Reference

The following table provides a list of the command-line options, server and status variables applicable within `mysqld` when it is running as an SQL node in an NDB Cluster. For a table showing all command-line options, server and status variables available for use with `mysqld`, see Section 5.1.4, “Server Option, System Variable, and Status Variable Reference”.

- **Com_show_ndb_status**: Count of SHOW NDB STATUS statements.
- **Handler_discover**: Number of times that tables have been discovered.
- **ndb-batch-size**: Size (in bytes) to use for NDB transaction batches.
- **ndb-blob-read-batch-bytes**: Specifies size in bytes that large BLOB reads should be batched into. 0 = no limit.
- **ndb-blob-write-batch-bytes**: Specifies size in bytes that large BLOB writes should be batched into. 0 = no limit.
- **ndb-cluster-connection-pool**: Number of connections to the cluster used by MySQL.
- **ndb-cluster-connection-pool-nodeids**: Comma-separated list of node IDs for connections to the cluster used by MySQL; the number of nodes in the list must be the same as the value set for --ndb-cluster-connection-pool.
- **ndb-connectstring**: Point to the management server that distributes the cluster configuration.
- **ndb-default-column-format**: Use this value (FIXED or DYNAMIC) by default for COLUMN_FORMAT and ROW_FORMAT options when creating or adding columns to a table.
- **ndb-deferred-constraints**: Specifies that constraint checks on unique indexes (where these are supported) should be deferred until commit time. Not normally needed or used; for testing purposes only.
- **ndb-distribution**: Default distribution for new tables in NDBCLUSTER (KEYHASH or LINHASH, default is KEYHASH).
- **ndb-log-apply-status**: Cause a MySQL server acting as a replica to log mysql.ndb_apply_status updates received from its immediate source in its own binary log, using its own server ID. Effective only if the server is started with the --ndbcluster option.
Overview of NDB Cluster Configuration Parameters, Options, and Variables

- **ndb-log-empty-epochs**: When enabled, causes epochs in which there were no changes to be written to the ndb_apply_status and ndb_binlog_index tables, even when --log-slave-updates is enabled.

- **ndb-log-empty-update**: When enabled, causes updates that produced no changes to be written to the ndb_apply_status and ndb_binlog_index tables, even when --log-slave-updates is enabled.

- **ndb-log-exclusive-reads**: Log primary key reads with exclusive locks; allow conflict resolution based on read conflicts.

- **ndb-log-fail-terminate**: Terminate mysqld process if complete logging of all found row events is not possible.

- **ndb-log-orig**: Log originating server id and epoch in mysql.ndb_binlog_index table.

- **ndb-log-transaction-id**: Write NDB transaction IDs in the binary log. Requires --log-bin-v1-events=OFF.

- **ndb-log-update-as-write**: Toggles logging of updates on the source between updates (OFF) and writes (ON).

- **ndb-mgmd-host**: Set the host (and port, if desired) for connecting to management server.

- **ndb-nodeid**: NDB Cluster node ID for this MySQL server.

- **ndb-transid-mysql-connection-map**: Enable or disable the ndb_transid_mysql_connection_map plugin; that is, enable or disable the INFORMATION_SCHEMA table having that name.

- **ndb-wait-connected**: Time (in seconds) for the MySQL server to wait for connection to cluster management and data nodes before accepting MySQL client connections.

- **ndb-wait-setup**: Time (in seconds) for the MySQL server to wait for NDB engine setup to complete.

- **ndb-allow-copying-alter-table**: Set to OFF to keep ALTER TABLE from using copying operations on NDB tables.

- **Ndb_api_bytes_received_count**: Amount of data (in bytes) received from the data nodes by this MySQL Server (SQL node).

- **Ndb_api_bytes_received_count_session**: Amount of data (in bytes) received from the data nodes in this client session.

- **Ndb_api_bytes_received_count_slave**: Amount of data (in bytes) received from the data nodes by this replica.

- **Ndb_api_bytes_sent_count**: Amount of data (in bytes) sent to the data nodes by this MySQL Server (SQL node).

- **Ndb_api_bytes_sent_count_session**: Amount of data (in bytes) sent to the data nodes in this client session.

- **Ndb_api_bytes_sent_count_slave**: Amount of data (in bytes) sent to the data nodes by this replica.

- **Ndb_api_event_bytes_count**: Number of bytes of events received by this MySQL Server (SQL node).

- **Ndb_api_event_bytes_count_injector**: Number of bytes of events received by the NDB binary log injector thread.

- **Ndb_api_event_data_count**: Number of row change events received by this MySQL Server (SQL node).
Overview of NDB Cluster Configuration Parameters, Options, and Variables

- **Ndb_api_event_data_count_injector**: Number of row change events received by the NDB binary log injector thread.
- **Ndb_api_event_nondata_count**: Number of events received, other than row change events, by this MySQL Server (SQL node).
- **Ndb_api_event_nondata_count_injector**: Number of events received, other than row change events, by the NDB binary log injector thread.
- **Ndb_api_pk_op_count**: Number of operations based on or using primary keys by this MySQL Server (SQL node).
- **Ndb_api_pk_op_count_session**: Number of operations based on or using primary keys in this client session.
- **Ndb_api_pk_op_count_slave**: Number of operations based on or using primary keys by this replica.
- **Ndb_api_pruned_scan_count**: Number of scans that have been pruned to a single partition by this MySQL Server (SQL node).
- **Ndb_api_pruned_scan_count_session**: Number of scans that have been pruned to a single partition in this client session.
- **Ndb_api_pruned_scan_count_slave**: Number of scans that have been pruned to a single partition by this replica.
- **Ndb_api_range_scan_count**: Number of range scans that have been started by this MySQL Server (SQL node).
- **Ndb_api_range_scan_count_session**: Number of range scans that have been started in this client session.
- **Ndb_api_range_scan_count_slave**: Number of range scans that have been started by this replica.
- **Ndb_api_read_row_count**: Total number of rows that have been read by this MySQL Server (SQL node).
- **Ndb_api_read_row_count_session**: Total number of rows that have been read in this client session.
- **Ndb_api_read_row_count_slave**: Total number of rows that have been read by this replica.
- **Ndb_api_scan_batch_count**: Number of batches of rows received by this MySQL Server (SQL node).
- **Ndb_api_scan_batch_count_session**: Number of batches of rows received in this client session.
- **Ndb_api_scan_batch_count_slave**: Number of batches of rows received by this replica.
- **Ndb_api_table_scan_count**: Number of table scans that have been started, including scans of internal tables, by this MySQL Server (SQL node).
- **Ndb_api_table_scan_count_session**: Number of table scans that have been started, including scans of internal tables, in this client session.
- **Ndb_api_table_scan_count_slave**: Number of table scans that have been started, including scans of internal tables, by this replica.
- **Ndb_api_trans_abort_count**: Number of transactions aborted by this MySQL Server (SQL node).
• **Ndb_api_trans_abort_count_session**: Number of transactions aborted in this client session.

• **Ndb_api_trans_abort_count_slave**: Number of transactions aborted by this replica.

• **Ndb_api_trans_close_count**: Number of transactions aborted (may be greater than the sum of TransCommitCount and TransAbortCount) by this MySQL Server (SQL node).

• **Ndb_api_trans_close_count_session**: Number of transactions aborted (may be greater than the sum of TransCommitCount and TransAbortCount) in this client session.

• **Ndb_api_trans_close_count_slave**: Number of transactions aborted (may be greater than the sum of TransCommitCount and TransAbortCount) by this replica.

• **Ndb_api_trans_commit_count**: Number of transactions committed by this MySQL Server (SQL node).

• **Ndb_api_trans_commit_count_session**: Number of transactions committed in this client session.

• **Ndb_api_trans_commit_count_slave**: Number of transactions committed by this replica.

• **Ndb_api_trans_local_read_row_count**: Total number of rows that have been read by this MySQL Server (SQL node).

• **Ndb_api_trans_local_read_row_count_session**: Total number of rows that have been read in this client session.

• **Ndb_api_trans_local_read_row_count_slave**: Total number of rows that have been read by this replica.

• **Ndb_api_trans_start_count**: Number of transactions started by this MySQL Server (SQL node).

• **Ndb_api_trans_start_count_session**: Number of transactions started in this client session.

• **Ndb_api_trans_start_count_slave**: Number of transactions started by this replica.

• **Ndb_api_uk_op_count**: Number of operations based on or using unique keys by this MySQL Server (SQL node).

• **Ndb_api_uk_op_count_session**: Number of operations based on or using unique keys in this client session.

• **Ndb_api_uk_op_count_slave**: Number of operations based on or using unique keys by this replica.

• **Ndb_api_wait_exec_complete_count**: Number of times thread has been blocked while waiting for execution of an operation to complete by this MySQL Server (SQL node).

• **Ndb_api_wait_exec_complete_count_session**: Number of times thread has been blocked while waiting for execution of an operation to complete in this client session.

• **Ndb_api_wait_exec_complete_count_slave**: Number of times thread has been blocked while waiting for execution of an operation to complete by this replica.

• **Ndb_api_wait_meta_request_count**: Number of times thread has been blocked waiting for a metadata-based signal by this MySQL Server (SQL node).

• **Ndb_api_wait_meta_request_count_session**: Number of times thread has been blocked waiting for a metadata-based signal in this client session.

• **Ndb_api_wait_meta_request_count_slave**: Number of times thread has been blocked waiting for a metadata-based signal by this replica.
Overview of NDB Cluster Configuration Parameters, Options, and Variables

- **Ndb_api_wait_nanos_count**: Total time (in nanoseconds) spent waiting for some type of signal from the data nodes by this MySQL Server (SQL node).
- **Ndb_api_wait_nanos_count_session**: Total time (in nanoseconds) spent waiting for some type of signal from the data nodes in this client session.
- **Ndb_api_wait_nanos_count_slave**: Total time (in nanoseconds) spent waiting for some type of signal from the data nodes by this replica.
- **Ndb_api_wait_scan_result_count**: Number of times thread has been blocked while waiting for a scan-based signal by this MySQL Server (SQL node).
- **Ndb_api_wait_scan_result_count_session**: Number of times thread has been blocked while waiting for a scan-based signal in this client session.
- **Ndb_api_wait_scan_result_count_slave**: Number of times thread has been blocked while waiting for a scan-based signal by this replica.
- **ndb_autoincrement_prefetch_sz**: NDB auto-increment prefetch size.
- **ndb_cache_check_time**: Number of milliseconds between checks of cluster SQL nodes made by the MySQL query cache.
- **ndb_clear_apply_status**: Causes RESET SLAVE to clear all rows from the ndb_apply_status table; ON by default.
- **Ndb_cluster_node_id**: If the server is acting as an NDB Cluster node, then the value of this variable its node ID in the cluster.
- **Ndb_config_from_host**: The host name or IP address of the Cluster management server Formerly Ndb_connected_host.
- **Ndb_config_from_port**: The port for connecting to Cluster management server. Formerly Ndb_connected_port.
- **Ndb_conflict_fn_epoch**: Number of rows that have been found in conflict by the NDB$EPOCH() conflict detection function.
- **Ndb_conflict_fn_epoch2**: Number of rows that have been found in conflict by the NDB$EPOCH2() conflict detection function.
- **Ndb_conflict_fn_epoch2_trans**: Number of rows that have been found in conflict by the NDB $EPOCH2_TRANS() conflict detection function.
- **Ndb_conflict_fn_epoch_trans**: Number of rows that have been found in conflict by the NDB $EPOCH_TRANS() conflict detection function.
- **Ndb_conflict_fn_max**: If the server is part of an NDB Cluster involved in cluster replication, the value of this variable indicates the number of times that conflict resolution based on “greater timestamp wins” has been applied.
- **Ndb_conflict_fn_old**: If the server is part of an NDB Cluster involved in cluster replication, the value of this variable indicates the number of times that “same timestamp wins” conflict resolution has been applied.
- **Ndb_conflict_last_conflict_epoch**: Most recent NDB epoch on this replica in which a conflict was detected.
- **Ndb_conflict_last_stable_epoch**: Number of rows found to be in conflict by a transactional conflict function.
Overview of NDB Cluster Configuration Parameters, Options, and Variables

- **Ndb_conflict_reflected_op_discard_count**: Number of reflected operations that were not applied due an error during execution.

- **Ndb_conflict_reflected_op_prepare_count**: Number of reflected operations received that have been prepared for execution.

- **Ndb_conflict_refresh_op_count**: Number of refresh operations that have been prepared.

- **Ndb_conflict_trans_conflict_commit_count**: Number of epoch transactions committed after requiring transactional conflict handling.

- **Ndb_conflict_trans_detect_iter_count**: Number of internal iterations required to commit an epoch transaction. Should be (slightly) greater than or equal to Ndb_conflict_trans_conflict_commit_count.

- **Ndb_conflict_trans_reject_count**: Number of transactions rejected after being found in conflict by a transactional conflict function.

- **Ndb_conflict_trans_row_conflict_count**: Number of rows found in conflict by a transactional conflict function. Includes any rows included in or dependent on conflicting transactions.

- **Ndb_conflict_trans_row_reject_count**: Total number of rows realigned after being found in conflict by a transactional conflict function. Includes Ndb_conflict_trans_row_conflict_count and any rows included in or dependent on conflicting transactions.

- **ndb_data_node_neighbour**: Specifies cluster data node "closest" to this MySQL Server, for transaction hinting and fully replicated tables.

- **ndb_default_column_format**: Sets default row format and column format (FIXED or DYNAMIC) used for new NDB tables.

- **ndb_deferred_constraints**: Specifies that constraint checks should be deferred (where these are supported). Not normally needed or used; for testing purposes only.

- **ndb_dbg_check_shares**: Check for any lingering shares (debug builds only).

- **ndb-schema-dist-timeout**: How long to wait before detecting timeout during schema distribution.

- **ndb_distribution**: Default distribution for new tables in NDBCLUSTER (KEYHASH or LINHASH, default is KEYHASH).

- **Ndb_epoch_delete_delete_count**: Number of delete-delete conflicts detected (delete operation is applied, but row does not exist).

- **ndb_eventbuffer_free_percent**: Percentage of free memory that should be available in event buffer before resumption of buffering, after reaching limit set by ndb_eventbuffer_max_alloc.

- **ndb_eventbuffer_max_alloc**: Maximum memory that can be allocated for buffering events by the NDB API. Defaults to 0 (no limit).

- **Ndb_execute_count**: Provides the number of round trips to the NDB kernel made by operations.

- **ndb_extra_logging**: Controls logging of NDB Cluster schema, connection, and data distribution events in the MySQL error log.

- **ndb_force_send**: Forces sending of buffers to NDB immediately, without waiting for other threads.

- **ndb_fully_replicated**: Whether new NDB tables are fully replicated.

- **ndb_index_stat_enable**: Use NDB index statistics in query optimization.
Overview of NDB Cluster Configuration Parameters, Options, and Variables

- **ndb_index_stat_option**: Comma-separated list of tunable options for NDB index statistics; the list should contain no spaces.

- **ndb_join_pushdown**: Enables pushing down of joins to data nodes.

- **Ndb_last_commit_epoch_server**: Epoch most recently committed by NDB.

- **Ndb_last_commit_epoch_session**: Epoch most recently committed by this NDB client.

- **ndb_log_apply_status**: Whether or not a MySQL server acting as a replica logs mysql.ndb_apply_status updates received from its immediate source in its own binary log, using its own server ID.

- **ndb_log_bin**: Write updates to NDB tables in the binary log. Effective only if binary logging is enabled with --log-bin.

- **ndb_log_binlog_index**: Insert mapping between epochs and binary log positions into the ndb_binlog_index table. Defaults to ON. Effective only if binary logging is enabled on the server.

- **ndb_log_empty_epochs**: When enabled, epochs in which there were no changes are written to the ndb_apply_status and ndb_binlog_index tables, even when log_slave_updates is enabled.

- **ndb_log_empty_update**: When enabled, updates which produce no changes are written to the ndb_apply_status and ndb_binlog_index tables, even when log_slave_updates is enabled.

- **ndb_log_exclusive_reads**: Log primary key reads with exclusive locks; allow conflict resolution based on read conflicts.

- **ndb_log_orig**: Whether the id and epoch of the originating server are recorded in the mysql.ndb_binlog_index table. Set using the --ndb-log-orig option when starting mysqld.

- **ndb_log_transaction_id**: Whether NDB transaction IDs are written into the binary log (Read-only.).

- **ndb-log-update-minimal**: Log updates in a minimal format.

- **ndb-log-updated-only**: Log complete rows (ON) or updates only (OFF).

- **ndb_metadata_check**: Enable auto-detection of NDB metadata changes with respect to MySQL data dictionary; enabled by default.

- **Ndb_metadata_blacklist_size**: Number of NDB metadata objects that NDB binlog thread has failed to synchronize; renamed in NDB 8.0.22 as Ndb_metadata_excluded_count.

- **ndb_metadata_check_interval**: Interval in seconds to perform check for NDB metadata changes with respect to MySQL data dictionary.

- **Ndb_metadata_detected_count**: Number of times NDB metadata change monitor thread has detected changes.

- **Ndb_metadata_excluded_count**: Number of NDB metadata objects that NDB binlog thread has failed to synchronize.

- **ndb_metadata_sync**: Triggers immediate synchronization of all changes between NDB dictionary and MySQL data dictionary; causes ndb_metadata_check and ndb_metadata_check_interval values to be ignored. Resets to false when synchronization is complete.

- **Ndb_metadata_synced_count**: Number of NDB metadata objects which have been synchronized.

- **Ndb_number_of_data_nodes**: If the server is part of an NDB Cluster, the value of this variable is the number of data nodes in the cluster.
Overview of NDB Cluster Configuration Parameters, Options, and Variables

- **ndb-optimization-delay**: Sets the number of milliseconds to wait between processing sets of rows by OPTIMIZE TABLE on NDB tables.

- **ndb_optimized_node_selection**: Determines how an SQL node chooses a cluster data node to use as transaction coordinator.

- **Ndb_pruned_scan_count**: Number of scans executed by NDB since the cluster was last started where partition pruning could be used.

- **Ndb_pushed_queries_defined**: Number of joins that API nodes have attempted to push down to the data nodes.

- **Ndb_pushed_queries_dropped**: Number of joins that API nodes have tried to push down, but failed.

- **Ndb_pushed_queries_executed**: Number of joins successfully pushed down and executed on the data nodes.

- **Ndb_pushed_reads**: Number of reads executed on the data nodes by pushed-down joins.

- **ndb_read_backup**: Enable read from any replica for all NDB tables; use NDB_TABLE=READ_BACKUP=0{1} with CREATE TABLE or ALTER TABLE to enable or disable for individual NDB tables.

- **ndb_recv_thread_activation_threshold**: Activation threshold when receive thread takes over the polling of the cluster connection (measured in concurrently active threads).

- **ndb_recv_thread_cpu_mask**: CPU mask for locking receiver threads to specific CPUs; specified as hexadecimal. See documentation for details.

- **ndb_report_thresh_binlog_epoch_slip**: NDB 7.5.4 and later: Threshold for number of epochs completely buffered, but not yet consumed by binlog injector thread which when exceeded generates BUFFERED_EPOCHS_OVER_THRESHOLD event buffer status message; prior to NDB 7.5.4: Threshold for number of epochs to lag behind before reporting binary log status.

- **ndb_report_thresh_binlog_mem_usage**: This is a threshold on the percentage of free memory remaining before reporting binary log status.

- **ndb_row_checksum**: When enabled, set row checksums; enabled by default.

- **Ndb_scan_count**: The total number of scans executed by NDB since the cluster was last started.

- **ndb_schema_dist_lock_wait_timeout**: Time during schema distribution to wait for lock before returning error.

- **ndb_schema_dist_timeout**: Time to wait before detecting timeout during schema distribution.

- **ndb_schema_dist_upgrade_allowed**: Allow schema distribution table upgrade when connecting to NDB.

- **ndb_show_foreign_key_mock_tables**: Show the mock tables used to support foreign_key_checks=0.

- **ndb_slave_conflict_role**: Role for replica to play in conflict detection and resolution. Value is one of PRIMARY, SECONDARY, PASS, or NONE (default). Can be changed only when replication SQL thread is stopped. See documentation for further information.

- **Ndb_slave_max_replicated_epoch**: The most recently committed NDB epoch on this replica. When this value is greater than or equal to Ndb_conflict_last_conflict_epoch, no conflicts have yet been detected.
NDB Cluster Configuration Files

- **Ndb_system_name**: Configured cluster system name; empty if server not connected to NDB.
- **ndb_table_no_logging**: NDB tables created when this setting is enabled are not checkpointed to disk (although table schema files are created). The setting in effect when the table is created with or altered to use NDBCluster persists for the lifetime of the table.
- **ndb_table_temporary**: NDB tables are not persistent on disk: no schema files are created and the tables are not logged.
- **Ndb_trans_hint_count_session**: Number of transactions using hints that have been started in this session.
- **ndb_use_copying_alternate_table**: Use copying ALTER TABLE operations in NDB Cluster.
- **ndb_use_exact_count**: Use exact row count when planning queries.
- **ndb_use_transactions**: Forces NDB to use a count of records during SELECT COUNT(*) query planning to speed up this type of query.
- **ndb_version**: Shows build and NDB engine version as an integer.
- **ndb_version_string**: Shows build information including NDB engine version in ndb-x.y.z format.
- **ndbcluster**: Enable NDB Cluster (if this version of MySQL supports it). Disabled by `--skip-ndbcluster`.
- **ndbinf**: Enable ndbinf plugin, if supported.
- **ndbinf_database**: The name used for the NDB information database; read only.
- **ndbinf_max_bytes**: Used for debugging only.
- **ndbinf_max_rows**: Used for debugging only.
- **ndbinf_offline**: Put the ndbinf database into offline mode, in which no rows are returned from tables or views.
- **ndbinf_show_hidden**: Whether to show ndbinf internal base tables in the mysql client. The default is OFF.
- **ndbinf_table_prefix**: The prefix to use for naming ndbinf internal base tables.
- **ndbinf_version**: The version of the ndbinf engine; read only.
- **server_id_bits**: Sets the number of least significant bits in the server_id actually used for identifying the server, permitting NDB API applications to store application data in the most significant bits. server_id must be less than 2 to the power of this value.
- **skip-ndbcluster**: Disable the NDB Cluster storage engine.
- **slave_allow_batching**: Turns update batching on and off for a replica.
- **transaction_allow_batching**: Allows batching of statements within a transaction. Disable AUTOCOMMIT to use.

### 22.3.3 NDB Cluster Configuration Files

Configuring NDB Cluster requires working with two files:

- **my.cnf**: Specifies options for all NDB Cluster executables. This file, with which you should be familiar with from previous work with MySQL, must be accessible by each executable running in the cluster.
NDB Cluster Configuration Files

- **config.ini**: This file, sometimes known as the global configuration file, is read only by the NDB Cluster management server, which then distributes the information contained therein to all processes participating in the cluster. config.ini contains a description of each node involved in the cluster. This includes configuration parameters for data nodes and configuration parameters for connections between all nodes in the cluster. For a quick reference to the sections that can appear in this file, and what sorts of configuration parameters may be placed in each section, see Sections of the config.ini File.

**Caching of configuration data.** NDB uses stateful configuration. Rather than reading the global configuration file every time the management server is restarted, the management server caches the configuration the first time it is started, and thereafter, the global configuration file is read only when one of the following conditions is true:

- **The management server is started using the --initial option.** When --initial is used, the global configuration file is re-read, any existing cache files are deleted, and the management server creates a new configuration cache.

- **The management server is started using the --reload option.** The --reload option causes the management server to compare its cache with the global configuration file. If they differ, the management server creates a new configuration cache; any existing configuration cache is preserved, but not used. If the management server's cache and the global configuration file contain the same configuration data, then the existing cache is used, and no new cache is created.

- **The management server is started using --config-cache=FALSE.** This disables --config-cache (enabled by default), and can be used to force the management server to bypass configuration caching altogether. In this case, the management server ignores any configuration files that may be present, always reading its configuration data from the config.ini file instead.

- **No configuration cache is found.** In this case, the management server reads the global configuration file and creates a cache containing the same configuration data as found in the file.

**Configuration cache files.** The management server by default creates configuration cache files in a directory named mysql-cluster in the MySQL installation directory. (If you build NDB Cluster from source on a Unix system, the default location is /usr/local/mysql-cluster.) This can be overridden at runtime by starting the management server with the --configdir option. Configuration cache files are binary files named according to the pattern ndb_node_id_config.bin.seq_id, where node_id is the management server's node ID in the cluster, and seq_id is a cache identifier. Cache files are numbered sequentially using seq_id, in the order in which they are created. The management server uses the latest cache file as determined by the seq_id.

**Note**

It is possible to roll back to a previous configuration by deleting later configuration cache files, or by renaming an earlier cache file so that it has a higher seq_id. However, since configuration cache files are written in a binary format, you should not attempt to edit their contents by hand.

For more information about the --configdir, --config-cache, --initial, and --reload options for the NDB Cluster management server, see Section 22.4.4, “ndb_mgmd — The NDB Cluster Management Server Daemon”.

We are continuously making improvements in NDB Cluster configuration and attempting to simplify this process. Although we strive to maintain backward compatibility, there may be times when introduce an incompatible change. In such cases we try to let NDB Cluster users know in advance if a change is not backward compatible. If you find such a change and we have not documented it, please report it in the MySQL bugs database using the instructions given in Section 1.6, “How to Report Bugs or Problems”.

**22.3.3.1 NDB Cluster Configuration: Basic Example**
To support NDB Cluster, you should update `my.cnf` as shown in the following example. You may also specify these parameters on the command line when invoking the executables.

```
# my.cnf
# example additions to my.cnf for NDB Cluster
# (valid in MySQL 8.0)
# enable ndbcluster storage engine, and provide connection string for
# management server host (default port is 1186)
[mysqld]
ndbcluster
ndb-connectstring=ndb_mgmd.mysql.com

# provide connection string for management server host (default port: 1186)
[ndbd]
connect-string=ndb_mgmd.mysql.com

# provide connection string for management server host (default port: 1186)
[ndb_mgm]
connect-string=ndb_mgmd.mysql.com

# provide location of cluster configuration file
[ndb_mgm]
config-file=/etc/config.ini

(For more information on connection strings, see Section 22.3.3.3, “NDB Cluster Connection Strings”.)
```

```
# my.cnf
# example additions to my.cnf for NDB Cluster
# (works on all versions)
# enable ndbcluster storage engine, and provide connection string for management
# server host to the default port 1186
[mysqld]
ndbcluster
ndb-connectstring=ndb_mgmd.mysql.com:1186

Important
Once you have started a `mysqld` process with the NDBCLUSTER and ndb-connectstring parameters in the [mysqld] in the my.cnf file as shown previously, you cannot execute any CREATE TABLE or ALTER TABLE statements without having actually started the cluster. Otherwise, these statements fail with an error. This is by design.

You may also use a separate [mysql_cluster] section in the cluster my.cnf file for settings to be read and used by all executables:

```
# cluster-specific settings
[mysql_cluster]
ndb-connectstring=ndb_mgmd.mysql.com:1186
```

For additional NDB variables that can be set in the my.cnf file, see NDB Cluster System Variables.

The NDB Cluster global configuration file is by convention named `config.ini` (but this is not required). If needed, it is read by `ndb_mgmd` at startup and can be placed in any location that can be read by it. The
location and name of the configuration are specified using \texttt{--config-file=path\_name} with \texttt{ndb\_mgmd} on the command line. This option has no default value, and is ignored if \texttt{ndb\_mgmd} uses the configuration cache.

The global configuration file for NDB Cluster uses INI format, which consists of sections preceded by section headings (surrounded by square brackets), followed by the appropriate parameter names and values. One deviation from the standard INI format is that the parameter name and value can be separated by a colon (:) as well as the equal sign (=); however, the equal sign is preferred. Another deviation is that sections are not uniquely identified by section name. Instead, unique sections (such as two different nodes of the same type) are identified by a unique ID specified as a parameter within the section.

Default values are defined for most parameters, and can also be specified in \texttt{config.ini}. To create a default value section, simply add the word \texttt{default} to the section name. For example, an [ndbd] section contains parameters that apply to a particular data node, whereas an [ndbd default] section contains parameters that apply to all data nodes. Suppose that all data nodes should use the same data memory size. To configure them all, create an [ndbd default] section that contains a \texttt{DataMemory} line to specify the data memory size.

If used, the [ndbd default] section must precede any [ndbd] sections in the configuration file. This is also true for default sections of any other type.

\section*{Note}
In some older releases of NDB Cluster, there was no default value for \texttt{NoOfReplicas}, which always had to be specified explicitly in the [ndbd default] section. Although this parameter now has a default value of 2, which is the recommended setting in most common usage scenarios, it is still recommended practice to set this parameter explicitly.

The global configuration file must define the computers and nodes involved in the cluster and on which computers these nodes are located. An example of a simple configuration file for a cluster consisting of one management server, two data nodes and two MySQL servers is shown here:

```
# file "config.ini" - 2 data nodes and 2 SQL nodes
# This file is placed in the startup directory of ndb_mgmd (the management server)
# The first MySQL Server can be started from any host. The second can be started only on the host mysqld_5.mysql.com

[ndbd default]
NoOfReplicas= 2
DataDir= /var/lib/mysql-cluster

[ndb_mgmd]
Hostname= ndb_mgmd.mysql.com
DataDir= /var/lib/mysql-cluster

[ndbd]
HostName= ndbd_2.mysql.com

[ndbd]
HostName= ndbd_3.mysql.com

[mysqld]
[mysqld]
HostName= mysqld_5.mysql.com
```

\section*{Note}
The preceding example is intended as a minimal starting configuration for purposes of familiarization with NDB Cluster, and is almost certain not to be sufficient for
production settings. See Section 22.3.3.2, “Recommended Starting Configuration for NDB Cluster”, which provides a more complete example starting configuration.

Each node has its own section in the config.ini file. For example, this cluster has two data nodes, so the preceding configuration file contains two [ndbd] sections defining these nodes.

**Note**

Do not place comments on the same line as a section heading in the config.ini file; this causes the management server not to start because it cannot parse the configuration file in such cases.

### Sections of the config.ini File

There are six different sections that you can use in the config.ini configuration file, as described in the following list:

- **[computer]**: Defines cluster hosts. This is not required to configure a viable NDB Cluster, but be may used as a convenience when setting up a large cluster. See Section 22.3.3.4, “Defining Computers in an NDB Cluster”, for more information.

- **[ndbd]**: Defines a cluster data node (ndbd process). See Section 22.3.3.6, “Defining NDB Cluster Data Nodes”, for details.

- **[mysqld]**: Defines the cluster’s MySQL server nodes (also called SQL or API nodes). For a discussion of SQL node configuration, see Section 22.3.3.7, “Defining SQL and Other API Nodes in an NDB Cluster”.

- **[mgm]** or **[ndb_mgmd]**: Defines a cluster management server (MGM) node. For information concerning the configuration of management nodes, see Section 22.3.3.5, “Defining an NDB Cluster Management Server”.

- **[tcp]**: Defines a TCP/IP connection between cluster nodes, with TCP/IP being the default transport protocol. Normally, [tcp] or [tcp default] sections are not required to set up an NDB Cluster, as the cluster handles this automatically; however, it may be necessary in some situations to override the defaults provided by the cluster. See Section 22.3.3.10, “NDB Cluster TCP/IP Connections”, for information about available TCP/IP configuration parameters and how to use them. (You may also find Section 22.3.3.11, “NDB Cluster TCP/IP Connections Using Direct Connections” to be of interest in some cases.)

- **[shm]**: Defines shared-memory connections between nodes. In MySQL 8.0, it is enabled by default, but should still be considered experimental. For a discussion of SHM interconnects, see Section 22.3.3.12, “NDB Cluster Shared-Memory Connections”.

- **[sci]**: Defines Scalable Coherent Interface connections between cluster data nodes. Not supported in NDB 8.0.

You can define default values for each section. If used, a default section should come before any other sections of that type. For example, an [ndbd default] section should appear in the configuration file before any [ndbd] sections.

NDB Cluster parameter names are case-insensitive, unless specified in MySQL Server my.cnf or my.ini files.

### 22.3.3.2 Recommended Starting Configuration for NDB Cluster

Achieving the best performance from an NDB Cluster depends on a number of factors including the following:
NDB Cluster Configuration Files

- NDB Cluster software version
- Numbers of data nodes and SQL nodes
- Hardware
- Operating system
- Amount of data to be stored
- Size and type of load under which the cluster is to operate

Therefore, obtaining an optimum configuration is likely to be an iterative process, the outcome of which can vary widely with the specifics of each NDB Cluster deployment. Changes in configuration are also likely to be indicated when changes are made in the platform on which the cluster is run, or in applications that use the NDB Cluster’s data. For these reasons, it is not possible to offer a single configuration that is ideal for all usage scenarios. However, in this section, we provide a recommended base configuration.

Starting config.ini file. The following config.ini file is a recommended starting point for configuring a cluster running NDB Cluster 8.0:

```ini
# TCP PARAMETERS
[tcp default]
SendBufferMemory=2M
ReceiveBufferMemory=2M

# Increasing the sizes of these 2 buffers beyond the default values
# helps prevent bottlenecks due to slow disk I/O.

# MANAGEMENT NODE PARAMETERS
[ndb_mgmd default]
DataDir=path/to/management/server/data/directory

# It is possible to use a different data directory for each management
# server, but for ease of administration it is preferable to be
# consistent.

[ndb_mgmd]
HostName=management-server-A-hostname
# NodeId=management-server-A-nodeid

[ndb_mgmd]
HostName=management-server-B-hostname
# NodeId=management-server-B-nodeid

# Using 2 management servers helps guarantee that there is always an
# arbitrator in the event of network partitioning, and so is
# recommended for high availability. Each management server must be
# identified by a HostName. You may for the sake of convenience specify
# a NodeId for any management server, although one is allocated
# for it automatically; if you do so, it must be in the range 1-255
# inclusive and must be unique among all IDs specified for cluster
# nodes.

# DATA NODE PARAMETERS
[ndbd default]
NoOfReplicas=2

# Using two fragment replicas is recommended to guarantee availability of data;
# using only one fragment replica does not provide any redundancy, which means
# that the failure of a single data node causes the entire cluster to
# shut down. As of NDB 8.0.19, it is also possible (but not required) to
```
# use more than two fragment replicas, although two fragment replicas are
# sufficient to provide high availability.

LockPagesInMainMemory=1

# On Linux and Solaris systems, setting this parameter locks data node
# processes into memory. Doing so prevents them from swapping to disk,
# which can severely degrade cluster performance.

DataMemory=3456M

# The value provided for DataMemory assumes 4 GB RAM
# per data node. However, for best results, you should first calculate
# the memory that would be used based on the data you actually plan to
# store (you may find the ndb_size.pl utility helpful in estimating
# this), then allow an extra 20% over the calculated values. Naturally,
# you should ensure that each data node host has at least as much
# physical memory as the sum of these two values.

# ODirect=1

# Enabling this parameter causes NDBCLUSTER to try using O_DIRECT
# writes for local checkpoints and redo logs; this can reduce load on
# CPUs. We recommend doing so when using NDB Cluster on systems running
# Linux kernel 2.6 or later.

NoOfFragmentLogFiles=300
DataDir=path/to/data/node/data/directory
MaxNoOfConcurrentOperations=100000

SchedulerSpinTimer=400
SchedulerExecutionTimer=100
RealTimeScheduler=1

# Setting these parameters allows you to take advantage of real-time scheduling
# of NDB threads to achieve increased throughput when using ndbd. They
# are not needed when using ndbmtd; in particular, you should not set
# RealTimeScheduler for ndbmtd data nodes.

TimeBetweenGlobalCheckpoints=1000
TimeBetweenEpochs=200
RedoBuffer=32M

# CompressedLCP=1
# CompressedBackup=1
# Enabling CompressedLCP and CompressedBackup causes, respectively, local
# checkpoint files and backup files to be compressed, which can result in a space
# savings of up to 50% over noncompressed LCPs and backups.

# MaxNoOfLocalScans=64
MaxNoOfTables=1024
MaxNoOfOrderedIndexes=256

[ndbd]
HostName=data-node-A-hostname
# NodeId=data-node-A-nodeid
LockExecuteThreadToCPU=1
LockMaintThreadsToCPU=0

# On systems with multiple CPUs, these parameters can be used to lock NDBCLUSTER
# threads to specific CPUs

[ndbd]
HostName=data-node-B-hostname
# NodeId=data-node-B-nodeid
LockExecuteThreadToCPU=1
LockMaintThreadsToCPU=0
You must have an [ndbd] section for every data node in the cluster; each of these sections must include a HostName. Each section may optionally include a NodeId for convenience, but in most cases, it is sufficient to allow the cluster to allocate node IDs dynamically. If you do specify the node ID for a data node, it must be in the range 1 to 144 inclusive and must be unique among all IDs specified for cluster nodes. (Previous to NDB 8.0.18, this range was 1 to 48 inclusive.)

SQL NODE / API NODE PARAMETERS

[mysqld]

HostName=sql-node-A-hostname
NodeId=sql-node-A-nodeid

Each API or SQL node that connects to the cluster requires a [mysqld] or [api] section of its own. Each such section defines a connection "slot"; you should have at least as many of these sections in the config.ini file as the total number of API nodes and SQL nodes that you wish to have connected to the cluster at any given time. There is no performance or other penalty for having extra slots available in case you find later that you want or need more API or SQL nodes to connect to the cluster at the same time. If no HostName is specified for a given [mysqld] or [api] section, then any API or SQL node may use that slot to connect to the cluster. You may wish to use an explicit HostName for one connection slot to guarantee that an API or SQL node from that host can always connect to the cluster. If you wish to prevent API or SQL nodes from connecting from other than a desired host or hosts, then use a HostName for every [mysqld] or [api] section in the config.ini file. You can if you wish define a node ID (NodeId parameter) for any API or SQL node, but this is not necessary; if you do so, it must be in the range 1 to 255 inclusive and must be unique among all IDs specified for cluster nodes.

Recommended my.cnf options for SQL nodes. MySQL Servers acting as NDB Cluster SQL nodes must always be started with the --ndbcluster and --ndb-connectstring options, either on the command line or in my.cnf. In addition, set the following options for all mysqld processes in the cluster, unless your setup requires otherwise:

- --ndb-use-exact-count=0
- --ndb-index-stat-enable=0
- --ndb-force-send=1
- --optimizer-switch=engine_condition_pushdown=on

22.3.3.3 NDB Cluster Connection Strings

With the exception of the NDB Cluster management server (ndb_mgmd), each node that is part of an NDB Cluster requires a connection string that points to the management server’s location. This connection string is used in establishing a connection to the management server as well as in performing other tasks depending on the node’s role in the cluster. The syntax for a connection string is as follows:

[nodeid=node_id, ]host-definition[, host-definition[, ...]]

host-definition:
    host_name[:port_number]
**node_id** is an integer greater than or equal to 1 which identifies a node in *config.ini*. **host_name** is a string representing a valid Internet host name or IP address. **port_number** is an integer referring to a TCP/IP port number.

**Example 1 (long):**  
```
nodeid=2,myhost1:1100,myhost2:1100,198.51.100.3:1200
```

**Example 2 (short):**  
```
myhost1
```

**localhost:**1186 is used as the default connection string value if none is provided. If **port_num** is omitted from the connection string, the default port is 1186. This port should always be available on the network because it has been assigned by IANA for this purpose (see [http://www.iana.org/assignments/port-numbers](http://www.iana.org/assignments/port-numbers) for details).

By listing multiple host definitions, it is possible to designate several redundant management servers. An NDB Cluster data or API node attempts to contact successive management servers on each host in the order specified, until a successful connection has been established.

It is also possible to specify in a connection string one or more bind addresses to be used by nodes having multiple network interfaces for connecting to management servers. A bind address consists of a hostname or network address and an optional port number. This enhanced syntax for connection strings is shown here:

```
[nodeid=node_id, ]  
[bind-address=host-definition, ]
host-definition[; bind-address=host-definition]  
host-definition[; bind-address=host-definition]
[,] ...

host-definition:
    host_name[::port_number]
```

If a single bind address is used in the connection string **prior** to specifying any management hosts, then this address is used as the default for connecting to any of them (unless overridden for a given management server; see later in this section for an example). For example, the following connection string causes the node to use 198.51.100.242 regardless of the management server to which it connects:

```
bind-address=198.51.100.242, poseidon:1186, perch:1186
```

If a bind address is specified **following** a management host definition, then it is used only for connecting to that management node. Consider the following connection string:

```
poseidon:1186;bind-address=localhost, perch:1186;bind-address=198.51.100.242
```

In this case, the node uses **localhost** to connect to the management server running on the host named **poseidon** and 198.51.100.242 to connect to the management server running on the host named **perch**.

You can specify a default bind address and then override this default for one or more specific management hosts. In the following example, **localhost** is used for connecting to the management server running on host **poseidon**; since 198.51.100.242 is specified first (before any management server definitions), it is the default bind address and so is used for connecting to the management servers on hosts **perch** and **orca**:

```
bind-address=198.51.100.242,poseidon:1186;bind-address=localhost,perch:1186,orca:2200
```

There are a number of different ways to specify the connection string:

- Each executable has its own command-line option which enables specifying the management server at startup. (See the documentation for the respective executable.)

- It is also possible to set the connection string for all nodes in the cluster at once by placing it in a **[mysql_cluster]** section in the management server’s *my.cnf* file.
• For backward compatibility, two other options are available, using the same syntax:
  1. Set the `NDB_CONNECTSTRING` environment variable to contain the connection string.
  2. Write the connection string for each executable into a text file named `Ndb.cfg` and place this file in the executable’s startup directory.

However, these are now deprecated and should not be used for new installations.

The recommended method for specifying the connection string is to set it on the command line or in the `my.cnf` file for each executable.

### 22.3.3.4 Defining Computers in an NDB Cluster

The `[computer]` section has no real significance other than serving as a way to avoid the need of defining host names for each node in the system. All parameters mentioned here are required.

- **Id**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>string</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>IS</td>
</tr>
</tbody>
</table>

This is a unique identifier, used to refer to the host computer elsewhere in the configuration file.

**Important**

The computer ID is *not* the same as the node ID used for a management, API, or data node. Unlike the case with node IDs, you cannot use `NodeId` in place of `Id` in the `[computer]` section of the `config.ini` file.

- **HostName**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>name or IP address</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>N</td>
</tr>
</tbody>
</table>

This is the computer's hostname or IP address.

**Restart types.** Information about the restart types used by the parameter descriptions in this section is shown in the following table:

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Restart Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>N</td>
<td>Node</td>
<td>The parameter can be updated using a rolling restart (see Section 22.5.5, “Performing a Rolling Restart of an NDB Cluster”)</td>
</tr>
</tbody>
</table>
### 22.3.3.5 Defining an NDB Cluster Management Server

The `[ndb_mgmd]` section is used to configure the behavior of the management server. If multiple management servers are employed, you can specify parameters common to all of them in an `[ndb_mgmd default]` section. `[mgm]` and `[mgm default]` are older aliases for these, supported for backward compatibility.

All parameters in the following list are optional and assume their default values if omitted.

- **Id**

  - **Type or units**: unsigned
  - **Default**: [none]
  - **Range**: 1 - 255
  - **Restart Type**: IS

  Each node in the cluster has a unique identity. For a management node, this is represented by an integer value in the range 1 to 255, inclusive. This ID is used by all internal cluster messages for addressing the node, and so must be unique for each NDB Cluster node, regardless of the type of node.

  - **Note**: Data node IDs must be less than 145. If you plan to deploy a large number of data nodes, it is a good idea to limit the node IDs for management nodes (and API nodes) to values greater than 144. (In NDB 8.0.17 and earlier, the maximum value for a data node ID was 48.)

  The use of the `Id` parameter for identifying management nodes is deprecated in favor of `NodeId`. Although `Id` continues to be supported for backward compatibility, it now generates a warning and is subject to removal in a future version of NDB Cluster.

- **NodeId**

  - **Type or units**: unsigned
  - **Default**: [none]
  - **Range**: 1 - 255
  - **Restart Type**: IS
Each node in the cluster has a unique identity. For a management node, this is represented by an integer value in the range 1 to 255 inclusive. This ID is used by all internal cluster messages for addressing the node, and so must be unique for each NDB Cluster node, regardless of the type of node.

**Note**

As of NDB 8.0.18, data node IDs must be less than 145. (Previously, this was less than 49.) If you plan to deploy a large number of data nodes, it is a good idea to limit the node IDs for management nodes (and API nodes) to values greater than 144.

NodeId is the preferred parameter name to use when identifying management nodes. Although the older Id continues to be supported for backward compatibility, it is now deprecated and generates a warning when used; it is also subject to removal in a future NDB Cluster release.

- **ExecuteOnComputer**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>name</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>S</td>
</tr>
<tr>
<td>Deprecated</td>
<td>Yes (in NDB 7.5)</td>
</tr>
</tbody>
</table>

This refers to the Id set for one of the computers defined in a [computer] section of the config.ini file.

**Important**

This parameter is deprecated, and is subject to removal in a future release. Use the HostName parameter instead.

- **PortNumber**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>1186</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 64K</td>
</tr>
<tr>
<td>Restart Type</td>
<td>S</td>
</tr>
</tbody>
</table>

This is the port number on which the management server listens for configuration requests and management commands.

The node ID for this node can be given out only to connections that explicitly request it. A management server that requests “any” node ID cannot use this one. This parameter can be used when running multiple management servers on the same host, and HostName is not sufficient for distinguishing among processes. Intended for use in testing.
**HostName**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>name or IP address</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Specifying this parameter defines the hostname of the computer on which the management node is to reside. To specify a hostname other than `localhost`, either this parameter or `ExecuteOnComputer` is required.

**LocationDomainId**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 16</td>
</tr>
<tr>
<td>Restart Type</td>
<td>S</td>
</tr>
</tbody>
</table>

Assigns a management node to a specific availability domain (also known as an availability zone) within a cloud. By informing NDB which nodes are in which availability domains, performance can be improved in a cloud environment in the following ways:

- If requested data is not found on the same node, reads can be directed to another node in the same availability domain.

- Communication between nodes in different availability domains are guaranteed to use NDB transporters' WAN support without any further manual intervention.

- The transporter's group number can be based on which availability domain is used, such that also SQL and other API nodes communicate with local data nodes in the same availability domain whenever possible.

- The arbitrator can be selected from an availability domain in which no data nodes are present, or, if no such availability domain can be found, from a third availability domain.

`LocationDomainId` takes an integer value between 0 and 16 inclusive, with 0 being the default; using 0 is the same as leaving the parameter unset.

**LogDestination**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>{CONSOLE</td>
</tr>
<tr>
<td>Default</td>
<td>FILE: filename=ndb_nodeid_cluster.log, maxsize=1000000, maxfiles=6</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
</tbody>
</table>
**Restart Type**

This parameter specifies where to send cluster logging information. There are three options in this regard—**CONSOLE, SYSLOG, and FILE**—with **FILE** being the default:

- **CONSOLE** outputs the log to **stdout:**
  
  ```
  CONSOLE
  ```

- **SYSLOG** sends the log to a **syslog** facility, possible values being one of **auth, authpriv, cron, daemon, ftp, kern, ipr, mail, news, syslog, user, uucp, local0, local1, local2, local3, local4, local5, local6, or local7.**
  
  ```
  SYSLOG:facility=syslog
  ```

- **FILE** pipes the cluster log output to a regular file on the same machine. The following values can be specified:
  
  - **filename**: The name of the log file.
    
    The default log file name used in such cases is **ndb_nodeid_cluster.log**.

  - **maxsize**: The maximum size (in bytes) to which the file can grow before logging rolls over to a new file. When this occurs, the old log file is renamed by appending **.N** to the file name, where **N** is the next number not yet used with this name.

  - **maxfiles**: The maximum number of log files.
    
    ```
    FILE:filename=cluster.log,maxsize=1000000,maxfiles=6
    ```

    The default value for the **FILE** parameter is **FILE:filename=ndb_node_id_cluster.log,maxsize=1000000,maxfiles=6**, where **node_id** is the ID of the node.

    It is possible to specify multiple log destinations separated by semicolons as shown here:

    ```
    CONSOLE;SYSLOG:facility=local0;FILE:filename=/var/log/mgmd
    ```

**ArbitrationRank**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>0-2</td>
</tr>
<tr>
<td>Default</td>
<td>1</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 2</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter is used to define which nodes can act as arbitrators. Only management nodes and SQL nodes can be arbitrators. **ArbitrationRank** can take one of the following values:

- **0**: The node is never used as an arbitrator.
NDB Cluster Configuration Files

- **1:** The node has high priority; that is, it is preferred as an arbitrator over low-priority nodes.
- **2:** Indicates a low-priority node which is used as an arbitrator only if a node with a higher priority is not available for that purpose.

Normally, the management server should be configured as an arbitrator by setting its `ArbitrationRank` to 1 (the default for management nodes) and those for all SQL nodes to 0 (the default for SQL nodes).

You can disable arbitration completely either by setting `ArbitrationRank` to 0 on all management and SQL nodes, or by setting the `Arbitration` parameter in the `[ndbd default]` section of the `config.ini` global configuration file. Setting `Arbitration` causes any settings for `ArbitrationRank` to be disregarded.

- **ArbitrationDelay**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

An integer value which causes the management server's responses to arbitration requests to be delayed by that number of milliseconds. By default, this value is 0; it is normally not necessary to change it.

- **DataDir**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>path</td>
</tr>
<tr>
<td>Default</td>
<td>.</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This specifies the directory where output files from the management server are placed. These files include cluster log files, process output files, and the daemon's process ID (PID) file. (For log files, this location can be overridden by setting the `FILE` parameter for `LogDestination`, as discussed previously in this section.)

The default value for this parameter is the directory in which `ndb_mgmd` is located.

- **PortNumberStats**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 64K</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter specifies the port number used to obtain statistical information from an NDB Cluster management server. It has no default value.
### NDB Cluster Configuration Files

- **Wan**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
</tbody>
</table>

Use WAN TCP setting as default.

- **HeartbeatThreadPriority**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>string</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
</tbody>
</table>

Set the scheduling policy and priority of heartbeat threads for management and API nodes.

The syntax for setting this parameter is shown here:

```plaintext
HeartbeatThreadPriority = policy[, priority]
```

**policy:**

- **FIFO**, **RR**

When setting this parameter, you must specify a policy. This is one of **FIFO** (first in, first out) or **RR** (round robin). The policy value is followed optionally by the priority (an integer).

- **ExtraSendBufferMemory**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 32G</td>
</tr>
</tbody>
</table>

This parameter specifies the amount of transporter send buffer memory to allocate in addition to any that has been set using **TotalSendBufferMemory**, **SendBufferMemory**, or both.

- **TotalSendBufferMemory**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>256K - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>
NDB Cluster Configuration Files

### Restart Type

| Restart Type | N |

This parameter is used to determine the total amount of memory to allocate on this node for shared send buffer memory among all configured transporters.

If this parameter is set, its minimum permitted value is 256KB; 0 indicates that the parameter has not been set. For more detailed information, see Section 22.3.3.14, "Configuring NDB Cluster Send Buffer Parameters".

- **HeartbeatIntervalMgmd**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>1500</td>
</tr>
<tr>
<td>Range</td>
<td>100 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Specify the interval between heartbeat messages used to determine whether another management node is on contact with this one. The management node waits after 3 of these intervals to declare the connection dead; thus, the default setting of 1500 milliseconds causes the management node to wait for approximately 1600 ms before timing out.

**Note**

After making changes in a management node's configuration, it is necessary to perform a rolling restart of the cluster for the new configuration to take effect.

To add new management servers to a running NDB Cluster, it is also necessary to perform a rolling restart of all cluster nodes after modifying any existing config.ini files. For more information about issues arising when using multiple management nodes, see Section 22.1.7.10, "Limitations Relating to Multiple NDB Cluster Nodes".

**Restart types.**  Information about the restart types used by the parameter descriptions in this section is shown in the following table:

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Restart Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>N</td>
<td>Node</td>
<td>The parameter can be updated using a rolling restart (see Section 22.5.5, “Performing a Rolling Restart of an NDB Cluster”)</td>
</tr>
<tr>
<td>S</td>
<td>System</td>
<td>All cluster nodes must be shut down completely, then restarted, to effect a change in this parameter</td>
</tr>
<tr>
<td>I</td>
<td>Initial</td>
<td>Data nodes must be restarted using the --initial option</td>
</tr>
</tbody>
</table>

### 22.3.3.6 Defining NDB Cluster Data Nodes

The [ndbd] and [ndbd default] sections are used to configure the behavior of the cluster's data nodes.

[ndbd] and [ndbd default] are always used as the section names whether you are using ndbd or ndbmtd binaries for the data node processes.
There are many parameters which control buffer sizes, pool sizes, timeouts, and so forth. The only mandatory parameter is either one of `ExecuteOnComputer` or `HostName`; this must be defined in the local `[ndbd]` section.

The parameter `NoOfReplicas` should be defined in the `[ndbd default]` section, as it is common to all Cluster data nodes. It is not strictly necessary to set `NoOfReplicas`, but it is good practice to set it explicitly.

Most data node parameters are set in the `[ndbd default]` section. Only those parameters explicitly stated as being able to set local values are permitted to be changed in the `[ndbd]` section. Where present, `HostName`, `NodeId` and `ExecuteOnComputer` must be defined in the local `[ndbd]` section, and not in any other section of `config.ini`. In other words, settings for these parameters are specific to one data node.

For those parameters affecting memory usage or buffer sizes, it is possible to use `K`, `M`, or `G` as a suffix to indicate units of 1024, 1024×1024, or 1024×1024×1024. (For example, `100K` means `100 × 1024 = 102400`.)

Parameter names and values are case-insensitive, unless used in a MySQL Server `my.cnf` or `my.ini` file, in which case they are case sensitive.

Information about configuration parameters specific to NDB Cluster Disk Data tables can be found later in this section (see Disk Data Configuration Parameters).

All of these parameters also apply to `ndbmtd` (the multithreaded version of `ndbd`). Three additional data node configuration parameters—`MaxNoOfExecutionThreads`, `ThreadConfig`, and `NoOfFragmentLogParts`—apply to `ndbmtd` only; these have no effect when used with `ndbd`. For more information, see Multi-Threading Configuration Parameters (ndbmtd). See also Section 22.4.3, “ndbmtd — The NDB Cluster Data Node Daemon (Multi-Threaded)”.

Identifying data nodes. The `NodeId` or `Id` value (that is, the data node identifier) can be allocated on the command line when the node is started or in the configuration file.

- **NodeId**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 48</td>
</tr>
<tr>
<td>Restart Type</td>
<td>IS</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.18</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 144</td>
</tr>
<tr>
<td>Restart Type</td>
<td>IS</td>
</tr>
</tbody>
</table>

A unique node ID is used as the node’s address for all cluster internal messages. For data nodes, this is an integer in the range 1 to 144 inclusive. (In NDB 8.0.17 and earlier, this was 1 to 48 inclusive.) Each node in the cluster must have a unique identifier.

`NodeId` is the only supported parameter name to use when identifying data nodes.

- **ExecuteOnComputer**
This refers to the ID set for one of the computers defined in a [computer] section.

**Important**

This parameter is deprecated, and is subject to removal in a future release. Use the HostName parameter instead.

The node ID for this node can be given out only to connections that explicitly request it. A management server that requests “any” node ID cannot use this one. This parameter can be used when running multiple management servers on the same host, and HostName is not sufficient for distinguishing among processes. Intended for use in testing.

### HostName

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>name or IP address</td>
</tr>
<tr>
<td>Default</td>
<td>localhost</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>N</td>
</tr>
</tbody>
</table>

Specifying this parameter defines the hostname of the computer on which the data node is to reside. To specify a hostname other than localhost, either this parameter or ExecuteOnComputer is required.

### ServerPort

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 64K</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>S</td>
</tr>
</tbody>
</table>

Each node in the cluster uses a port to connect to other nodes. By default, this port is allocated dynamically in such a way as to ensure that no two nodes on the same host computer receive the same port number, so it should normally not be necessary to specify a value for this parameter.

However, if you need to be able to open specific ports in a firewall to permit communication between data nodes and API nodes (including SQL nodes), you can set this parameter to the number of the desired port in an [ndbd] section or (if you need to do this for multiple data nodes) the [ndbd
default] section of the config.ini file, and then open the port having that number for incoming connections from SQL nodes, API nodes, or both.

**Note**

Connections from data nodes to management nodes is done using the ndb_mgmd management port (the management server’s PortNumber) so outgoing connections to that port from any data nodes should always be permitted.

- **TcpBind_INADDR_ANY**

  Setting this parameter to TRUE or 1 binds IP_ADDR_ANY so that connections can be made from anywhere (for autogenerated connections). The default is FALSE (0).

- **NodeGroup**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 65536</td>
</tr>
<tr>
<td>Restart Type</td>
<td>IS</td>
</tr>
</tbody>
</table>

This parameter can be used to assign a data node to a specific node group. It is read only when the cluster is started for the first time, and cannot be used to reassign a data node to a different node group online. It is generally not desirable to use this parameter in the [ndbd default] section of the config.ini file, and care must be taken not to assign nodes to node groups in such a way that an invalid numbers of nodes are assigned to any node groups.

The NodeGroup parameter is chiefly intended for use in adding a new node group to a running NDB Cluster without having to perform a rolling restart. For this purpose, you should set it to 65536 (the maximum value). You are not required to set a NodeGroup value for all cluster data nodes, only for those nodes which are to be started and added to the cluster as a new node group at a later time. For more information, see Section 22.5.7.3, “Adding NDB Cluster Data Nodes Online: Detailed Example”.

- **LocationDomainId**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 16</td>
</tr>
<tr>
<td>Restart Type</td>
<td>S</td>
</tr>
</tbody>
</table>

Assigns a data node to a specific availability domain (also known as an availability zone) within a cloud. By informing NDB which nodes are in which availability domains, performance can be improved in a cloud environment in the following ways:

- If requested data is not found on the same node, reads can be directed to another node in the same availability domain.

- Communication between nodes in different availability domains are guaranteed to use NDB transporters’ WAN support without any further manual intervention.
NDB Cluster Configuration Files

• The transporter's group number can be based on which availability domain is used, such that also SQL and other API nodes communicate with local data nodes in the same availability domain whenever possible.

• The arbitrator can be selected from an availability domain in which no data nodes are present, or, if no such availability domain can be found, from a third availability domain.

**LocationDomainId** takes an integer value between 0 and 16 inclusive, with 0 being the default; using 0 is the same as leaving the parameter unset.

• **NoOfReplicas**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>2</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 2</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>IS</td>
</tr>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.19</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>2</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 4</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>IS</td>
</tr>
</tbody>
</table>

This global parameter can be set only in the [ndbd default] section, and defines the number of fragment replicas for each table stored in the cluster. This parameter also specifies the size of node groups. A node group is a set of nodes all storing the same information.

Node groups are formed implicitly. The first node group is formed by the set of data nodes with the lowest node IDs, the next node group by the set of the next lowest node identities, and so on. By way of example, assume that we have 4 data nodes and that **NoOfReplicas** is set to 2. The four data nodes have node IDs 2, 3, 4 and 5. Then the first node group is formed from nodes 2 and 3, and the second node group by nodes 4 and 5. It is important to configure the cluster in such a manner that nodes in the same node groups are not placed on the same computer because a single hardware failure would cause the entire cluster to fail.

If no node IDs are provided, the order of the data nodes is the determining factor for the node group. Whether or not explicit assignments are made, they can be viewed in the output of the management client's SHOW command.

The default value for **NoOfReplicas** is 2. This is the recommended value for most production environments, and prior to NDB 8.0.18, it was the maximum value supported. Beginning with NDB 8.0.19, setting this parameter's value to 3 or 4 is fully tested and supported in production.

**Warning**

Setting **NoOfReplicas** to 1 means that there is only a single copy of all Cluster data; in this case, the loss of a single data node causes the cluster to fail because there are no additional copies of the data stored by that node.

The number of data nodes in the cluster must be evenly divisible by the value of this parameter. For example, if there are two data nodes, then **NoOfReplicas** must be equal to either 1 or 2, since 2/3 and
2/4 both yield fractional values; if there are four data nodes, then \textit{NoOfReplicas} must be equal to 1, 2, or 4.

- \textbf{DataDir}

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>path</td>
</tr>
<tr>
<td>Default</td>
<td></td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>\textbf{Restart Type}</td>
<td>IN</td>
</tr>
</tbody>
</table>

This parameter specifies the directory where trace files, log files, pid files and error logs are placed. The default is the data node process working directory.

- \textbf{FileSystemPath}

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>path</td>
</tr>
<tr>
<td>Default</td>
<td>DataDir</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>\textbf{Restart Type}</td>
<td>IN</td>
</tr>
</tbody>
</table>

This parameter specifies the directory where all files created for metadata, REDO logs, UNDO logs (for Disk Data tables), and data files are placed. The default is the directory specified by \textit{DataDir}.

\begin{itemize}
\item[\textbf{BackupDataDir}]
\end{itemize}

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>path</td>
</tr>
<tr>
<td>Default</td>
<td>FileSystemPath</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>\textbf{Restart Type}</td>
<td>IN</td>
</tr>
</tbody>
</table>

This parameter specifies the directory in which backups are placed.

\begin{itemize}
\item[\textbf{Important}]
\end{itemize}

The string '/\texttt{BACKUP}' is always appended to this value. For example, if you set the value of \textit{BackupDataDir} to /\texttt{var/lib/cluster-data}, then all backups are stored under /\texttt{var/lib/cluster-data/BACKUP}. This also means that...
the *effective* default backup location is the directory named `BACKUP` under the location specified by the `FileSystemPath` parameter.

### Data Memory, Index Memory, and String Memory

DataMemory and IndexMemory are `ndbd` parameters specifying the size of memory segments used to store the actual records and their indexes. In setting values for these, it is important to understand how DataMemory is used, as it usually needs to be updated to reflect actual usage by the cluster.

#### Note

IndexMemory is deprecated, and subject to removal in a future version of NDB Cluster. See the descriptions that follow for further information.

- **DataMemory**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>98M</td>
</tr>
<tr>
<td>Range</td>
<td>1M - 1T</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>N</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.19</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>98M</td>
</tr>
<tr>
<td>Range</td>
<td>1M - 16T</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter defines the amount of space (in bytes) available for storing database records. The entire amount specified by this value is allocated in memory, so it is extremely important that the machine has sufficient physical memory to accommodate it.

The memory allocated by DataMemory is used to store both the actual records and indexes. There is a 16-byte overhead on each record; an additional amount for each record is incurred because it is stored in a 32KB page with 128 byte page overhead (see below). There is also a small amount wasted per page due to the fact that each record is stored in only one page.

For variable-size table attributes, the data is stored on separate data pages, allocated from DataMemory. Variable-length records use a fixed-size part with an extra overhead of 4 bytes to reference the variable-size part. The variable-size part has 2 bytes overhead plus 2 bytes per attribute.

As of NDB 8.0.18, the maximum record size is 30000 bytes. Previously, this was 14000 bytes.

Resources assigned to DataMemory are used for storing all data and indexes. (Any memory configured as IndexMemory is automatically added to that used by DataMemory to form a common resource pool.)

Currently, NDB Cluster can use a maximum of 512 MB for hash indexes per partition, which means in some cases it is possible to get *Table is full* errors in MySQL client applications even when `ndb_mgm -e "ALL REPORT MEMORYUSAGE"` shows significant free DataMemory. This can also pose a problem with data node restarts on nodes that are heavily loaded with data.
You can control the number of partitions per local data manager for a given table by setting the `NDB_TABLE` option `PARTITION_BALANCE` to one of the values `FOR_RA_BY_LDM`, `FOR_RA_BY_LDM_X_2`, `FOR_RA_BY_LDM_X_3`, or `FOR_RA_BY_LDM_X_4`, for 1, 2, 3, or 4 partitions per LDM, respectively, when creating the table (see Section 13.1.20.10, “Setting NDB_TABLE Options”).

**Note**

In previous versions of NDB Cluster it was possible to create extra partitions for NDB Cluster tables and thus have more memory available for hash indexes by using the `MAX_ROWS` option for `CREATE TABLE`. While still supported for backward compatibility, using `MAX_ROWS` for this purpose is deprecated; you should use `PARTITION_BALANCE` instead.

You can also use the `MinFreePct` configuration parameter to help avoid problems with node restarts.

The memory space allocated by `DataMemory` consists of 32KB pages, which are allocated to table fragments. Each table is normally partitioned into the same number of fragments as there are data nodes in the cluster. Thus, for each node, there are the same number of fragments as are set in `NoOfReplicas`.

Once a page has been allocated, it is currently not possible to return it to the pool of free pages, except by deleting the table. (This also means that `DataMemory` pages, once allocated to a given table, cannot be used by other tables.) Performing a data node recovery also compresses the partition because all records are inserted into empty partitions from other live nodes.

The `DataMemory` memory space also contains UNDO information: For each update, a copy of the unaltered record is allocated in the `DataMemory`. There is also a reference to each copy in the ordered table indexes. Unique hash indexes are updated only when the unique index columns are updated, in which case a new entry in the index table is inserted and the old entry is deleted upon commit. For this reason, it is also necessary to allocate enough memory to handle the largest transactions performed by applications using the cluster. In any case, performing a few large transactions holds no advantage over using many smaller ones, for the following reasons:

- Large transactions are not any faster than smaller ones
- Large transactions increase the number of operations that are lost and must be repeated in event of transaction failure
- Large transactions use more memory

The default value for `DataMemory` in NDB 8.0 is 98MB. The minimum value is 1MB. There is no maximum size, but in reality the maximum size has to be adapted so that the process does not start swapping when the limit is reached. This limit is determined by the amount of physical RAM available on the machine and by the amount of memory that the operating system may commit to any one process. 32-bit operating systems are generally limited to 2–4GB per process; 64-bit operating systems can use more. For large databases, it may be preferable to use a 64-bit operating system for this reason.

**IndexMemory**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>1M - 1T</td>
</tr>
</tbody>
</table>
### NDB Cluster Configuration Files

The `IndexMemory` parameter is deprecated (and subject to future removal); any memory assigned to `IndexMemory` is allocated instead to the same pool as `DataMemory`, which is solely responsible for all resources needed for storing data and indexes in memory. In NDB 8.0, the use of `IndexMemory` in the cluster configuration file triggers a warning from the management server.

You can estimate the size of a hash index using this formula:

\[
\text{size} = \left( \frac{\text{fragments} \times 32K + \text{rows} \times 18}{\text{fragment_replicas}} \right)
\]

`fragments` is the number of fragments, `fragment_replicas` is the number of fragment replicas (normally 2), and `rows` is the number of rows. If a table has one million rows, eight fragments, and two fragment replicas, the expected index memory usage is calculated as shown here:

\[
\left(\frac{(8 \times 32K) + (1000000 \times 18)}{2}\right) \times 2 = \left(\frac{(8 \times 32768) + (1000000 \times 18)}{2}\right) \times 2
\]

\[
= \left(\frac{262144 + 18000000}{2}\right) 2 = 36524288 \text{ bytes} = \sim 35 \text{MB}
\]

Index statistics for ordered indexes (when these are enabled) are stored in the `mysql.ndb_index_stat_sample` table. Since this table has a hash index, this adds to index memory usage. An upper bound to the number of rows for a given ordered index can be calculated as follows:

\[
\text{sample_size} = \text{key_size} + (\text{key_attributes} + 1) \times 4
\]

\[
\text{sample_rows} = \frac{\text{IndexStatSaveSize} \times (0.01 \times \text{IndexStatSaveScale} \times \log_2(\text{rows} \times \text{sample_size})) + 1}{\text{sample_size}}
\]

In the preceding formula, `key_size` is the size of the ordered index key in bytes, `key_attributes` is the number of attributes in the ordered index key, and `rows` is the number of rows in the base table.

Assume that table `t1` has 1 million rows and an ordered index named `ix1` on two four-byte integers. Assume in addition that `IndexStatSaveSize` and `IndexStatSaveScale` are set to their default values (32K and 100, respectively). Using the previous 2 formulas, we can calculate as follows:

\[
\text{sample_size} = 8 + ((1 + 2) \times 4) = 20 \text{ bytes}
\]

\[
\text{sample_rows} = \frac{32K \times ((0.01 \times 100 \times \log_2(1000000 \times 20)) + 1)}{20}
= 32768 \times \left(\frac{16.811}{20}\right) + 1)
= 32768 \times \sim 17.811 / 20
= \sim 29182 \text{ rows}
\]

The expected index memory usage is thus \(2 \times 18 \times 29182 = \sim 1050550 \text{ bytes}\).

In NDB 8.0, the minimum and default value for this parameter is 0 (zero).

- **StringMemory**

<table>
<thead>
<tr>
<th><strong>Version (or later)</strong></th>
<th><strong>NDB 8.0.13</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Type or units</strong></td>
<td>% or bytes</td>
</tr>
<tr>
<td><strong>Default</strong></td>
<td>25</td>
</tr>
<tr>
<td><strong>Range</strong></td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>
This parameter determines how much memory is allocated for strings such as table names, and is specified in an \[ndbd\] or \[ndbd default\] section of the config.ini file. A value between 0 and 100 inclusive is interpreted as a percent of the maximum default value, which is calculated based on a number of factors including the number of tables, maximum table name size, maximum size of .FRM files, MaxNoOFTriggers, maximum column name size, and maximum default column value.

A value greater than 100 is interpreted as a number of bytes.

The default value is 25—that is, 25 percent of the default maximum.

Under most circumstances, the default value should be sufficient, but when you have a great many NDB tables (1000 or more), it is possible to get Error 773 Out of string memory, please modify StringMemory config parameter: Permanent error: Schema error, in which case you should increase this value. 25 (25 percent) is not excessive, and should prevent this error from recurring in all but the most extreme conditions.

The following example illustrates how memory is used for a table. Consider this table definition:

```sql
CREATE TABLE example (
  a INT NOT NULL,
  b INT NOT NULL,
  c INT NOT NULL,
  PRIMARY KEY(a),
  UNIQUE(b)
) ENGINE=NDBCLUSTER;
```

For each record, there are 12 bytes of data plus 12 bytes overhead. Having no nullable columns saves 4 bytes of overhead. In addition, we have two ordered indexes on columns a and b consuming roughly 10 bytes each per record. There is a primary key hash index on the base table using roughly 29 bytes per record. The unique constraint is implemented by a separate table with b as primary key and a as a column. This other table consumes an additional 29 bytes of index memory per record in the example table as well 8 bytes of record data plus 12 bytes of overhead.

Thus, for one million records, we need 58MB for index memory to handle the hash indexes for the primary key and the unique constraint. We also need 64MB for the records of the base table and the unique index table, plus the two ordered index tables.

You can see that hash indexes takes up a fair amount of memory space; however, they provide very fast access to the data in return. They are also used in NDB Cluster to handle uniqueness constraints.

Currently, the only partitioning algorithm is hashing and ordered indexes are local to each node. Thus, ordered indexes cannot be used to handle uniqueness constraints in the general case.

An important point for both IndexMemory and DataMemory is that the total database size is the sum of all data memory and all index memory for each node group. Each node group is used to store replicated information, so if there are four nodes with two fragment replicas, there are two node groups. Thus, the total data memory available is 2 \times DataMemory for each data node.

It is highly recommended that DataMemory and IndexMemory be set to the same values for all nodes. Data distribution is even over all nodes in the cluster, so the maximum amount of space available for any node can be no greater than that of the smallest node in the cluster.

DataMemory can be changed, but decreasing it can be risky; doing so can easily lead to a node or even an entire NDB Cluster that is unable to restart due to there being insufficient memory space. Increasing these values should be acceptable, but it is recommended that such upgrades are performed in the same
manner as a software upgrade, beginning with an update of the configuration file, and then restarting the management server followed by restarting each data node in turn.

**MinFreePct.** A proportion (5% by default) of data node resources including `DataMemory` is kept in reserve to insure that the data node does not exhaust its memory when performing a restart. This can be adjusted using the `MinFreePct` data node configuration parameter (default 5).

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>5</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 100</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Updates do not increase the amount of index memory used. Inserts take effect immediately; however, rows are not actually deleted until the transaction is committed.

**Transaction parameters.** The next few `ndbd` parameters that we discuss are important because they affect the number of parallel transactions and the sizes of transactions that can be handled by the system. `MaxNoOfConcurrentTransactions` sets the number of parallel transactions possible in a node. `MaxNoOfConcurrentOperations` sets the number of records that can be in update phase or locked simultaneously.

Both of these parameters (especially `MaxNoOfConcurrentOperations`) are likely targets for users setting specific values and not using the default value. The default value is set for systems using small transactions, to ensure that these do not use excessive memory.

`MaxDMLOperationsPerTransaction` sets the maximum number of DML operations that can be performed in a given transaction.

- `MaxNoOfConcurrentTransactions`

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>

<tr>
<td>Deprecated</td>
<td>NDB 8.0.19</td>
</tr>
</tbody>
</table>

Each cluster data node requires a transaction record for each active transaction in the cluster. The task of coordinating transactions is distributed among all of the data nodes. The total number of transaction records in the cluster is the number of transactions in any given node times the number of nodes in the cluster.

Transaction records are allocated to individual MySQL servers. Each connection to a MySQL server requires at least one transaction record, plus an additional transaction object per table accessed by that connection. This means that a reasonable minimum for the total number of transactions in the cluster can be expressed as

\[
\text{TotalNoOfConcurrentTransactions} = (\text{maximum number of tables accessed in any single transaction} + 1) \times \text{number of SQL nodes}
\]
Suppose that there are 10 SQL nodes using the cluster. A single join involving 10 tables requires 11 transaction records; if there are 10 such joins in a transaction, then \(10 \times 11 = 110\) transaction records are required for this transaction, per MySQL server, or \(110 \times 10 = 1100\) transaction records total. Each data node can be expected to handle \(\frac{\text{TotalNoOfConcurrentTransactions}}{\text{number of data nodes}}\). For an NDB Cluster having 4 data nodes, this would mean setting \(\text{MaxNoOfConcurrentTransactions}\) on each data node to \(\frac{1100}{4} = 275\). In addition, you should provide for failure recovery by ensuring that a single node group can accommodate all concurrent transactions; in other words, that each data node's \(\text{MaxNoOfConcurrentTransactions}\) is sufficient to cover a number of transactions equal to \(\frac{\text{TotalNoOfConcurrentTransactions}}{\text{number of node groups}}\). If this cluster has a single node group, then \(\text{MaxNoOfConcurrentTransactions}\) should be set to 1100 (the same as the total number of concurrent transactions for the entire cluster).

In addition, each transaction involves at least one operation; for this reason, the value set for \(\text{MaxNoOfConcurrentTransactions}\) should always be no more than the value of \(\text{MaxNoOfConcurrentOperations}\).

This parameter must be set to the same value for all cluster data nodes. This is due to the fact that, when a data node fails, the oldest surviving node re-creates the transaction state of all transactions that were ongoing in the failed node.

It is possible to change this value using a rolling restart, but the amount of traffic on the cluster must be such that no more transactions occur than the lower of the old and new levels while this is taking place.

The default value is 4096.

- \(\text{MaxNoOfConcurrentOperations}\)

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>32K</td>
</tr>
<tr>
<td>Range</td>
<td>32 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

It is a good idea to adjust the value of this parameter according to the size and number of transactions. When performing transactions which involve only a few operations and records, the default value for this parameter is usually sufficient. Performing large transactions involving many records usually requires that you increase its value.

Records are kept for each transaction updating cluster data, both in the transaction coordinator and in the nodes where the actual updates are performed. These records contain state information needed to find UNDO records for rollback, lock queues, and other purposes.

This parameter should be set at a minimum to the number of records to be updated simultaneously in transactions, divided by the number of cluster data nodes. For example, in a cluster which has four data nodes and which is expected to handle one million concurrent updates using transactions, you should set this value to \(\frac{1000000}{4} = 250000\). To help provide resiliency against failures, it is suggested that you set this parameter to a value that is high enough to permit an individual data node to handle the load for its node group. In other words, you should set the value equal to the total number of concurrent operations.
operations / number of node groups. (In the case where there is a single node group, this is the same as the total number of concurrent operations for the entire cluster.)

Because each transaction always involves at least one operation, the value of **MaxNoOfConcurrentOperations** should always be greater than or equal to the value of **MaxNoOfConcurrentTransactions**.

Read queries which set locks also cause operation records to be created. Some extra space is allocated within individual nodes to accommodate cases where the distribution is not perfect over the nodes.

When queries make use of the unique hash index, there are actually two operation records used per record in the transaction. The first record represents the read in the index table and the second handles the operation on the base table.

The default value is 32768.

This parameter actually handles two values that can be configured separately. The first of these specifies how many operation records are to be placed with the transaction coordinator. The second part specifies how many operation records are to be local to the database.

A very large transaction performed on an eight-node cluster requires as many operation records in the transaction coordinator as there are reads, updates, and deletes involved in the transaction. However, the operation records of the are spread over all eight nodes. Thus, if it is necessary to configure the system for one very large transaction, it is a good idea to configure the two parts separately. **MaxNoOfConcurrentOperations** is always used to calculate the number of operation records in the transaction coordinator portion of the node.

It is also important to have an idea of the memory requirements for operation records. These consume about 1KB per record.

- **MaxNoOfLocalOperations**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>UNDEFINED</td>
</tr>
<tr>
<td>Range</td>
<td>32 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
<tr>
<td>Deprecated</td>
<td>NDB 8.0.19</td>
</tr>
</tbody>
</table>

By default, this parameter is calculated as 1.1 × **MaxNoOfConcurrentOperations**. This fits systems with many simultaneous transactions, none of them being very large. If there is a need to handle one very large transaction at a time and there are many nodes, it is a good idea to override the default value by explicitly specifying this parameter.

This parameter is deprecated as of NDB 8.0.19, and is subject to removal in a future NDB Cluster release. In addition, this parameter is incompatible with the **TransactionMemory** parameter; if you try to set values for both parameters in the cluster configuration file (`config.ini`), the management server refuses to start.

- **MaxDMLOperationsPerTransaction**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>operations (DML)</td>
</tr>
</tbody>
</table>
This parameter limits the size of a transaction. The transaction is aborted if it requires more than this many DML operations. The minimum number of operations per transaction is 32; however, you can set MaxDMLOperationsPerTransaction to 0 to disable any limitation on the number of DML operations per transaction. The maximum (and default) is 4294967295.

The value of this parameter cannot exceed that set for MaxNoOfConcurrentOperations.

Transaction temporary storage. The next set of [ndbd] parameters is used to determine temporary storage when executing a statement that is part of a Cluster transaction. All records are released when the statement is completed and the cluster is waiting for the commit or rollback.

The default values for these parameters are adequate for most situations. However, users with a need to support transactions involving large numbers of rows or operations may need to increase these values to enable better parallelism in the system, whereas users whose applications require relatively small transactions can decrease the values to save memory.

• MaxNoOfConcurrentIndexOperations

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>8K</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
<tr>
<td>Deprecated</td>
<td>NDB 8.0.19</td>
</tr>
</tbody>
</table>

For queries using a unique hash index, another temporary set of operation records is used during a query’s execution phase. This parameter sets the size of that pool of records. Thus, this record is allocated only while executing a part of a query. As soon as this part has been executed, the record is released. The state needed to handle aborts and commits is handled by the normal operation records, where the pool size is set by the parameter MaxNoOfConcurrentOperations.

The default value of this parameter is 8192. Only in rare cases of extremely high parallelism using unique hash indexes should it be necessary to increase this value. Using a smaller value is possible and can save memory if the DBA is certain that a high degree of parallelism is not required for the cluster.

This parameter is deprecated as of NDB 8.0.19, and is subject to removal in a future NDB Cluster release. In addition, this parameter is incompatible with the TransactionMemory parameter; if you try to set values for both parameters in the cluster configuration file (config.ini), the management server refuses to start.

• MaxNoOfFiredTriggers

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>4000</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>
The default value of MaxNoOfFiredTriggers is 4000, which is sufficient for most situations. In some cases it can even be decreased if the DBA feels certain the need for parallelism in the cluster is not high.

A record is created when an operation is performed that affects a unique hash index. Inserting or deleting a record in a table with unique hash indexes or updating a column that is part of a unique hash index fires an insert or a delete in the index table. The resulting record is used to represent this index table operation while waiting for the original operation that fired it to complete. This operation is short-lived but can still require a large number of records in its pool for situations with many parallel write operations on a base table containing a set of unique hash indexes.

This parameter is deprecated as of NDB 8.0.19, and is subject to removal in a future NDB Cluster release. In addition, this parameter is incompatible with the TransactionMemory parameter; if you try to set values for both parameters in the cluster configuration file (config.ini), the management server refuses to start.

- **TransactionBufferMemory**

<table>
<thead>
<tr>
<th>Version (or later)</th>

</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>1M</td>
</tr>
<tr>
<td>Range</td>
<td>1K - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

The memory affected by this parameter is used for tracking operations fired when updating index tables and reading unique indexes. This memory is used to store the key and column information for these operations. It is only very rarely that the value for this parameter needs to be altered from the default.

The default value for TransactionBufferMemory is 1MB.

Normal read and write operations use a similar buffer, whose usage is even more short-lived. The compile-time parameter ZATTRBUF_FILESIZE (found in ndb/src/kernel/blocks/Dbtc/Dbtc.hpp) set to 4000 × 128 bytes (500KB). A similar buffer for key information, ZDATABUF_FILESIZE (also in Dbtc.hpp) contains 4000 × 16 = 62.5KB of buffer space. Dbtc is the module that handles transaction coordination.

**Transaction resource allocation parameters.** The parameters in the following list are used to allocate transaction resources in the transaction coordinator (DBTC). Leaving any one of these set to the default (0) dedicates transaction memory for 25% of estimated total data node usage for the corresponding resource. The actual maximum possible values for these parameters are typically limited by the amount of memory available to the data node; setting them has no impact on the total amount of memory allocated to the data node. In addition, you should keep in mind that they control numbers of reserved internal records for the data node independent of any settings for MaxDMLOperationsPerTransaction, MaxNoOfConcurrentIndexOperations, MaxNoOfConcurrentOperations, MaxNoOfConcurrentScans, MaxNoOfConcurrentTransactions, MaxNoOfFiredTriggers, MaxNoOfLocalScans, or TransactionBufferMemory (see Transaction parameters and Transaction temporary storage).

<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
<tr>
<td>Added</td>
<td>NDB 8.0.19</td>
</tr>
</tbody>
</table>

This parameter determines the memory (in bytes) allocated for transactions on each data node. Setting of transaction memory can be handled in any one of the three ways listed here:

- A number of configuration parameters are incompatible with TransactionMemory. If any of these are set, transaction memory is calculated as it was previous to NDB 8.0.19. You should be aware that it is not possible to set any of these parameters concurrently with TransactionMemory; if you attempt to do so, the management server is unable to start (see Parameters incompatible with TransactionMemory).

- If TransactionMemory is set, this value is used for determining transaction memory.
NDB Cluster Configuration Files

- If neither any incompatible parameters are set nor TransactionMemory is set, transaction memory is set by NDB to 10% of the value of the DataMemory configuration parameter.

**Parameters incompatible with TransactionMemory.** The following parameters cannot be used concurrently with TransactionMemory and are deprecated as of NDB 8.0.19:

- MaxNoOfConcurrentIndexOperations
- MaxNoOfFiredTriggers
- MaxNoOfLocalOperations
- MaxNoOfLocalScans

Explicitly setting any of the parameters just listed when TransactionMemory has also been set in the cluster configuration file (config.ini) keeps the management node from starting.

For more information regarding resource allocation in NDB Cluster data nodes, see Section 22.3.3.13, “Data Node Memory Management”.

**Scans and buffering.** There are additional [ndbd] parameters in the Dblqh module (in ndb/src/kernel/blocks/Dblqh/Dblqh.hpp) that affect reads and updates. These include ZATTRINBUF_FILESIZE, set by default to 10000 × 128 bytes (1250KB) and ZDATABUF_FILE_SIZE, set by default to 10000*16 bytes (roughly 156KB) of buffer space. To date, there have been neither any reports from users nor any results from our own extensive tests suggesting that either of these compile-time limits should be increased.

- **BatchSizePerLocalScan**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>256</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 992</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>N</td>
</tr>
<tr>
<td><strong>Deprecated</strong></td>
<td>NDB 8.0.19</td>
</tr>
</tbody>
</table>

This parameter is used to calculate the number of lock records used to handle concurrent scan operations.

*BatchSizePerLocalScan* has a strong connection to the BatchSize defined in the SQL nodes.

Depreciated as of NDB 8.0.19.

- **LongMessageBuffer**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>64M</td>
</tr>
<tr>
<td>Range</td>
<td>512K - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>N</td>
</tr>
</tbody>
</table>
This is an internal buffer used for passing messages within individual nodes and between nodes. The default is 64MB.

This parameter seldom needs to be changed from the default.

- **MaxFKBuildBatchSize**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>64</td>
</tr>
<tr>
<td>Range</td>
<td>16 - 512</td>
</tr>
<tr>
<td>Restart Type</td>
<td>S</td>
</tr>
</tbody>
</table>

Maximum scan batch size used for building foreign keys. Increasing the value set for this parameter may speed up building of foreign key builds at the expense of greater impact to ongoing traffic.

- **MaxNoOfConcurrentScans**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>256</td>
</tr>
<tr>
<td>Range</td>
<td>2 - 500</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter is used to control the number of parallel scans that can be performed in the cluster. Each transaction coordinator can handle the number of parallel scans defined for this parameter. Each scan query is performed by scanning all partitions in parallel. Each partition scan uses a scan record in the node where the partition is located, the number of records being the value of this parameter times the number of nodes. The cluster should be able to sustain $\text{MaxNoOfConcurrentScans}$ scans concurrently from all nodes in the cluster.

Scans are actually performed in two cases. The first of these cases occurs when no hash or ordered indexes exists to handle the query, in which case the query is executed by performing a full table scan. The second case is encountered when there is no hash index to support the query but there is an ordered index. Using the ordered index means executing a parallel range scan. The order is kept on the local partitions only, so it is necessary to perform the index scan on all partitions.

The default value of $\text{MaxNoOfConcurrentScans}$ is 256. The maximum value is 500.

- **MaxNoOfLocalScans**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>$4 \times \text{MaxNoOfConcurrentScans} \times # \text{of data nodes} + 2$</td>
</tr>
<tr>
<td>Range</td>
<td>32 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>
NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>Deprecated</th>
<th>NDB 8.0.19</th>
</tr>
</thead>
</table>

Specifies the number of local scan records if many scans are not fully parallelized. When the number of local scan records is not provided, it is calculated as shown here:

\[ 4 \times \text{MaxNoOfConcurrentScans} \times [\# \text{data nodes}] + 2 \]

This parameter is deprecated as of NDB 8.0.19, and is subject to removal in a future NDB Cluster release. In addition, this parameter is incompatible with the `TransactionMemory` parameter; if you try to set values for both parameters in the cluster configuration file (`config.ini`), the management server refuses to start.

- **MaxParallelCopyInstances**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 64</td>
</tr>
</tbody>
</table>

This parameter sets the parallelization used in the copy phase of a node restart or system restart, when a node that is currently just starting is synchronised with a node that already has current data by copying over any changed records from the node that is up to date. Because full parallelism in such cases can lead to overload situations, `MaxParallelCopyInstances` provides a means to decrease it. This parameter's default value 0. This value means that the effective parallelism is equal to the number of LDM instances in the node just starting as well as the node updating it.

- **MaxParallelScansPerFragment**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>256</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

It is possible to configure the maximum number of parallel scans (`TUP` scans and `TUX` scans) allowed before they begin queuing for serial handling. You can increase this to take advantage of any unused CPU when performing large number of scans in parallel and improve their performance.

The default value for this parameter is 256.

- **MaxReorgBuildBatchSize**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>64</td>
</tr>
<tr>
<td>Range</td>
<td>16 - 512</td>
</tr>
</tbody>
</table>
NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>Restart Type</th>
<th>S</th>
</tr>
</thead>
</table>

Maximum scan batch size used for reorganization of table partitions. Increasing the value set for this parameter may speed up reorganization at the expense of greater impact to ongoing traffic.

- **MaxUIBuildBatchSize**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>64</td>
</tr>
<tr>
<td>Range</td>
<td>16 - 512</td>
</tr>
<tr>
<td>Restart Type</td>
<td>S</td>
</tr>
</tbody>
</table>

Maximum scan batch size used for building unique keys. Increasing the value set for this parameter may speed up such builds at the expense of greater impact to ongoing traffic.

**Memory Allocation**

- **MaxAllocate**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>32M</td>
</tr>
<tr>
<td>Range</td>
<td>1M - 1G</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This is the maximum size of the memory unit to use when allocating memory for tables. In cases where NDB gives Out of memory errors, but it is evident by examining the cluster logs or the output of DUMP 1000 that all available memory has not yet been used, you can increase the value of this parameter (or MaxNoOfTables, or both) to cause NDB to make sufficient memory available.

**Multiple Transporters**

Beginning with version 8.0.20, NDB allocates multiple transporters for communication between pairs of data nodes. The number of transporters so allocated can be influenced by setting an appropriate value for the NodeGroupTransporters parameter introduced in that release.

- **NodeGroupTransporters**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.20</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 32</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
<tr>
<td>Added</td>
<td>NDB 8.0.20</td>
</tr>
</tbody>
</table>

This parameter determines the number of transporters used between nodes in the same node group. The default value (0) means that the number of transporters used is the same as the number of LDMs in the node group.
node. This should be sufficient for most use cases; thus it should seldom be necessary to change this value from its default.

Setting `NodeGroupTransporters` to a number greater than the number of LDM threads or the number of TC threads, whichever is higher, causes NDB to use the maximum of these two numbers of threads. This means that a value greater than this is effectively ignored.

**Hash Map Size**

**DefaultHashMapSize**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>LDM threads</td>
</tr>
<tr>
<td>Default</td>
<td>240</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 3840</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>N</td>
</tr>
</tbody>
</table>

The original intended use for this parameter was to facilitate upgrades and especially downgrades to and from very old releases with differing default hash map sizes. This is not an issue when upgrading from NDB Cluster 7.3 (or later) to later versions.

Decreasing this parameter online after any tables have been created or modified with `DefaultHashMapSize` equal to 3840 is not currently supported.

**Logging and checkpointing.** The following `[ndbd]` parameters control log and checkpoint behavior.

- **FragmentLogFileSize**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>16M</td>
</tr>
<tr>
<td>Range</td>
<td>4M - 1G</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>IN</td>
</tr>
</tbody>
</table>

Setting this parameter enables you to control directly the size of redo log files. This can be useful in situations when NDB Cluster is operating under a high load and it is unable to close fragment log files quickly enough before attempting to open new ones (only 2 fragment log files can be open at one time); increasing the size of the fragment log files gives the cluster more time before having to open each new fragment log file. The default value for this parameter is 16M.

For more information about fragment log files, see the description for `NoOfFragmentLogFiles`.

- **InitialNoOfOpenFiles**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>files</td>
</tr>
<tr>
<td>Default</td>
<td>27</td>
</tr>
<tr>
<td>Range</td>
<td>20 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter sets the initial number of internal threads to allocate for open files.
The default value is 27.

- **InitFragmentLogFiles**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>[see values]</td>
</tr>
<tr>
<td>Default</td>
<td>SPARSE</td>
</tr>
<tr>
<td>Range</td>
<td>SPARSE, FULL</td>
</tr>
<tr>
<td>Restart Type</td>
<td>IN</td>
</tr>
</tbody>
</table>

By default, fragment log files are created sparsely when performing an initial start of a data node—that is, depending on the operating system and file system in use, not all bytes are necessarily written to disk. However, it is possible to override this behavior and force all bytes to be written, regardless of the platform and file system type being used, by means of this parameter. **InitFragmentLogFiles** takes either of two values:

- **SPARSE.** Fragment log files are created sparsely. This is the default value.
- **FULL.** Force all bytes of the fragment log file to be written to disk.

Depending on your operating system and file system, setting `InitFragmentLogFiles=FULL` may help eliminate I/O errors on writes to the REDO log.

- **EnablePartialLcp**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>true</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

When `true`, enable partial local checkpoints: This means that each LCP records only part of the full database, plus any records containing rows changed since the last LCP; if no rows have changed, the LCP updates only the LCP control file and does not update any data files.

If **EnablePartialLcp** is disabled (`false`), each LCP uses only a single file and writes a full checkpoint; this requires the least amount of disk space for LCPs, but increases the write load for each LCP. The default value is enabled (`true`). The proportion of space used by partial LCPS can be modified by the setting for the **RecoveryWork** configuration parameter.

For more information about files and directories used for full and partial LCPs, see [NDB Cluster Data Node File System Directory](#).

Setting this parameter to `false` also disables the calculation of disk write speed used by the adaptive LCP control mechanism.

- **LcpScanProgressTimeout**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>second</td>
</tr>
<tr>
<td>Default</td>
<td>60</td>
</tr>
</tbody>
</table>

3988
NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>N</td>
</tr>
<tr>
<td><strong>Version (or later)</strong></td>
<td>NDB 8.0.19</td>
</tr>
<tr>
<td><strong>Type or units</strong></td>
<td>second</td>
</tr>
<tr>
<td><strong>Default</strong></td>
<td>180</td>
</tr>
<tr>
<td><strong>Range</strong></td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>N</td>
</tr>
</tbody>
</table>

A local checkpoint fragment scan watchdog checks periodically for no progress in each fragment scan performed as part of a local checkpoint, and shuts down the node if there is no progress after a given amount of time has elapsed. This interval can be set using the `LcpScanProgressTimeout` data node configuration parameter, which sets the maximum time for which the local checkpoint can be stalled before the LCP fragment scan watchdog shuts down the node.

The default value is 60 seconds (providing compatibility with previous releases). Setting this parameter to 0 disables the LCP fragment scan watchdog altogether.

- **MaxNoOfOpenFiles**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Version (or later)</strong></td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td><strong>Type or units</strong></td>
<td>unsigned</td>
</tr>
<tr>
<td><strong>Default</strong></td>
<td>0</td>
</tr>
<tr>
<td><strong>Range</strong></td>
<td>20 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter sets a ceiling on how many internal threads to allocate for open files. *Any situation requiring a change in this parameter should be reported as a bug.*

The default value is 0. However, the minimum value to which this parameter can be set is 20.

- **MaxNoOfSavedMessages**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Version (or later)</strong></td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td><strong>Type or units</strong></td>
<td>integer</td>
</tr>
<tr>
<td><strong>Default</strong></td>
<td>25</td>
</tr>
<tr>
<td><strong>Range</strong></td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter sets the maximum number of errors written in the error log as well as the maximum number of trace files that are kept before overwriting the existing ones. Trace files are generated when, for whatever reason, the node crashes.

The default is 25, which sets these maximums to 25 error messages and 25 trace files.

- **MaxLCPStartDelay**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Version (or later)</strong></td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td><strong>Type or units</strong></td>
<td>seconds</td>
</tr>
<tr>
<td><strong>Default</strong></td>
<td>0</td>
</tr>
</tbody>
</table>
In parallel data node recovery, only table data is actually copied and synchronized in parallel; synchronization of metadata such as dictionary and checkpoint information is done in a serial fashion. In addition, recovery of dictionary and checkpoint information cannot be executed in parallel with performing of local checkpoints. This means that, when starting or restarting many data nodes concurrently, data nodes may be forced to wait while a local checkpoint is performed, which can result in longer node recovery times.

It is possible to force a delay in the local checkpoint to permit more (and possibly all) data nodes to complete metadata synchronization; once each data node's metadata synchronization is complete, all of the data nodes can recover table data in parallel, even while the local checkpoint is being executed. To force such a delay, set `MaxLCPStartDelay`, which determines the number of seconds the cluster can wait to begin a local checkpoint while data nodes continue to synchronize metadata. This parameter should be set in the `[ndbd default]` section of the `config.ini` file, so that it is the same for all data nodes. The maximum value is 600; the default is 0.

- **NoOfFragmentLogFiles**

This parameter sets the number of REDO log files for the node, and thus the amount of space allocated to REDO logging. Because the REDO log files are organized in a ring, it is extremely important that the first and last log files in the set (sometimes referred to as the “head” and “tail” log files, respectively) do not meet. When these approach one another too closely, the node begins aborting all transactions encompassing updates due to a lack of room for new log records.

A REDO log record is not removed until both required local checkpoints have been completed since that log record was inserted. Checkpointing frequency is determined by its own set of configuration parameters discussed elsewhere in this chapter.

The default parameter value is 16, which by default means 16 sets of 4 16MB files for a total of 1024MB. The size of the individual log files is configurable using the `FragmentLogFileSize` parameter. In scenarios requiring a great many updates, the value for `NoOfFragmentLogFiles` may need to be set as high as 300 or even higher to provide sufficient space for REDO logs.

If the checkpointing is slow and there are so many writes to the database that the log files are full and the log tail cannot be cut without jeopardizing recovery, all updating transactions are aborted with internal error code 410 (Out of log file space temporarily). This condition prevails until a checkpoint has completed and the log tail can be moved forward.

**Important**

This parameter cannot be changed “on the fly”; you must restart the node using `--initial`. If you wish to change this value for all data nodes in a running cluster, you can do so using a rolling node restart (using `--initial` when starting each data node).
**RecoveryWork**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>60</td>
</tr>
<tr>
<td>Range</td>
<td>25 - 100</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Percentage of storage overhead for LCP files. This parameter has an effect only when `EnablePartialLcp` is true, that is, only when partial local checkpoints are enabled. A higher value means:

- Fewer records are written for each LCP, LCPs use more space
- More work is needed during restarts

A lower value for `RecoveryWork` means:

- More records are written during each LCP, but LCPs require less space on disk.
- Less work during restart and thus faster restarts, at the expense of more work during normal operations

For example, setting `RecoveryWork` to 60 means that the total size of an LCP is roughly \( 1 + 0.6 = 1.6 \) times the size of the data to be checkpointed. This means that 60% more work is required during the restore phase of a restart compared to the work done during a restart that uses full checkpoints. (This is more than compensated for during other phases of the restart such that the restart as a whole is still faster when using partial LCPs than when using full LCPs.) In order not to fill up the redo log, it is necessary to write at \( 1 + \left(\frac{1}{RecoveryWork}\right) \) times the rate of data changes during checkpoints—thus, when `RecoveryWork` = 60, it is necessary to write at approximately \( 1 + \left(\frac{1}{0.6}\right) = 2.67 \) times the change rate. In other words, if changes are being written at 10 MByte per second, the checkpoint needs to be written at roughly 26.7 MByte per second.

Setting `RecoveryWork` = 40 means that only 1.4 times the total LCP size is needed (and thus the restore phase takes 10 to 15 percent less time. In this case, the checkpoint write rate is 3.5 times the rate of change.

The NDB source distribution includes a test program for simulating LCPs. `lcp_simulator.cc` can be found in `storage/ndb/src/kernel/blocks/backup/`. To compile and run it on Unix platforms, execute the commands shown here:

```
shell> gcc lcp_simulator.cc
shell> ./a.out
```

This program has no dependencies other than `stdio.h`, and does not require a connection to an NDB cluster or a MySQL server. By default, it simulates 300 LCPs (three sets of 100 LCPs, each consisting of inserts, updates, and deletes, in turn), reporting the size of the LCP after each one. You can alter the simulation by changing the values of `recovery_work`, `insert_work`, and `delete_work` in the source and recompiling. For more information, see the source of the program.

**InsertRecoveryWork**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td></td>
<td>3991</td>
</tr>
</tbody>
</table>
NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>Default</th>
<th>40</th>
</tr>
</thead>
<tbody>
<tr>
<td>Range</td>
<td>0 - 70</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Percentage of `RecoveryWork` used for inserted rows. A higher value increases the number of writes during a local checkpoint, and decreases the total size of the LCP. A lower value decreases the number of writes during an LCP, but results in more space being used for the LCP, which means that recovery takes longer. This parameter has an effect only when `EnablePartialLcp` is true, that is, only when partial local checkpoints are enabled.

- **EnableRedoControl**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Enable adaptive checkpointing speed for controlling redo log usage. Set to `false` to disable (the default). Setting `EnablePartialLcp` to `false` also disables the adaptive calculation.

When enabled, `EnableRedoControl` allows the data nodes greater flexibility with regard to the rate at which they write LCPs to disk. More specifically, enabling this parameter means that higher write rates can be employed, so that LCPs can complete and Redo logs be trimmed more quickly, thereby reducing recovery time and disk space requirements. This functionality allows data nodes to make better use of the higher rate of I/O and greater bandwidth available from modern solid-state storage devices and protocols, such as solid-state drives (SSDs) using Non-Volatile Memory Express (NVMe).

The parameter currently defaults to `false` (disabled) due to the fact that NDB is still deployed widely on systems whose I/O or bandwidth is constrained relative to those employing solid-state technology, such as those using conventional hard disks (HDDs). In settings such as these, the `EnableRedoControl` mechanism can easily cause the I/O subsystem to become saturated, increasing wait times for data node input and output. In particular, this can cause issues with NDB Disk Data tables which have table spaces or log file groups sharing a constrained IO subsystem with data node LCP and redo log files; such problems potentially include node or cluster failure due to GCP stop errors.

**Metadata objects.** The next set of `[ndbd]` parameters defines pool sizes for metadata objects, used to define the maximum number of attributes, tables, indexes, and trigger objects used by indexes, events, and replication between clusters.

- **MaxNoOfAttributes**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>1000</td>
</tr>
<tr>
<td>Range</td>
<td>32 - 4294967039 (0xFFFFFFFF)</td>
</tr>
</tbody>
</table>
### NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th><strong>Restart Type</strong></th>
<th><strong>N</strong></th>
</tr>
</thead>
</table>

This parameter sets a suggested maximum number of attributes that can be defined in the cluster; like `MaxNoOfAttributes`, it is not intended to function as a hard upper limit.

(In older NDB Cluster releases, this parameter was sometimes treated as a hard limit for certain operations. This caused problems with NDB Cluster Replication, when it was possible to create more tables than could be replicated, and sometimes led to confusion when it was possible [or not possible, depending on the circumstances] to create more than `MaxNoOfAttributes` attributes.)

The default value is 1000, with the minimum possible value being 32. The maximum is 4294967039. Each attribute consumes around 200 bytes of storage per node due to the fact that all metadata is fully replicated on the servers.

When setting `MaxNoOfAttributes`, it is important to prepare in advance for any `ALTER TABLE` statements that you might want to perform in the future. This is due to the fact, during the execution of `ALTER TABLE` on a Cluster table, 3 times the number of attributes as in the original table are used, and a good practice is to permit double this amount. For example, if the NDB Cluster table having the greatest number of attributes (`greatest_number_of_attributes`) has 100 attributes, a good starting point for the value of `MaxNoOfAttributes` would be $6 \times greatest_number_of_attributes = 600$.

You should also estimate the average number of attributes per table and multiply this by `MaxNoOfAttributes`. If this value is larger than the value obtained in the previous paragraph, you should use the larger value instead.

Assuming that you can create all desired tables without any problems, you should also verify that this number is sufficient by trying an actual `ALTER TABLE` after configuring the parameter. If this is not successful, increase `MaxNoOfAttributes` by another multiple of `MaxNoOfTables` and test it again.

**MaxNoOfTables**

<table>
<thead>
<tr>
<th><strong>Version (or later)</strong></th>
<th><strong>NDB 8.0.13</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Type or units</strong></td>
<td>integer</td>
</tr>
<tr>
<td><strong>Default</strong></td>
<td>128</td>
</tr>
<tr>
<td><strong>Range</strong></td>
<td>8 - 20320</td>
</tr>
</tbody>
</table>

A table object is allocated for each table and for each unique hash index in the cluster. This parameter sets a suggested maximum number of table objects for the cluster as a whole; like `MaxNoOfAttributes`, it is not intended to function as a hard upper limit.

(In older NDB Cluster releases, this parameter was sometimes treated as a hard limit for certain operations. This caused problems with NDB Cluster Replication, when it was possible to create more...
tables than could be replicated, and sometimes led to confusion when it was possible [or not possible, depending on the circumstances] to create more than MaxNoOfTables tables.)

For each attribute that has a BLOB data type an extra table is used to store most of the BLOB data. These tables also must be taken into account when defining the total number of tables.

The default value of this parameter is 128. The minimum is 8 and the maximum is 20320. Each table object consumes approximately 20KB per node.

Note
The sum of MaxNoOfTables, MaxNoOfOrderedIndexes, and MaxNoOfUniqueHashIndexes must not exceed $2^{32} - 2$ (4294967294).

• MaxNoOfOrderedIndexes

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>128</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

For each ordered index in the cluster, an object is allocated describing what is being indexed and its storage segments. By default, each index so defined also defines an ordered index. Each unique index and primary key has both an ordered index and a hash index. MaxNoOfOrderedIndexes sets the total number of ordered indexes that can be in use in the system at any one time.

The default value of this parameter is 128. Each index object consumes approximately 10KB of data per node.

Note
The sum of MaxNoOfTables, MaxNoOfOrderedIndexes, and MaxNoOfUniqueHashIndexes must not exceed $2^{32} - 2$ (4294967294).

• MaxNoOfUniqueHashIndexes

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>64</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

For each unique index that is not a primary key, a special table is allocated that maps the unique key to the primary key of the indexed table. By default, an ordered index is also defined for each unique index. To prevent this, you must specify the USING HASH option when defining the unique index.

The default value is 64. Each index consumes approximately 15KB per node.

Note
The sum of MaxNoOfTables, MaxNoOfOrderedIndexes, and MaxNoOfUniqueHashIndexes must not exceed $2^{32} - 2$ (4294967294).
- **MaxNoOfTriggers**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>768</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Internal update, insert, and delete triggers are allocated for each unique hash index. (This means that three triggers are created for each unique hash index.) However, an ordered index requires only a single trigger object. Backups also use three trigger objects for each normal table in the cluster.

Replication between clusters also makes use of internal triggers.

This parameter sets the maximum number of trigger objects in the cluster.

The default value is 768.

- **MaxNoOfSubscriptions**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Each NDB table in an NDB Cluster requires a subscription in the NDB kernel. For some NDB API applications, it may be necessary or desirable to change this parameter. However, for normal usage with MySQL servers acting as SQL nodes, there is not any need to do so.

The default value for MaxNoOfSubscriptions is 0, which is treated as equal to MaxNoOfTables. Each subscription consumes 108 bytes.

- **MaxNoOfSubscribers**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter is of interest only when using NDB Cluster Replication. The default value is 0, which is treated as \(2 \times \) MaxNoOfTables; that is, there is one subscription per NDB table for each of two MySQL servers (one acting as the replication source and the other as the replica). Each subscriber uses 16 bytes of memory.

When using circular replication, multi-source replication, and other replication setups involving more than 2 MySQL servers, you should increase this parameter to the number of mysqld processes included in replication (this is often, but not always, the same as the number of clusters). For example, if you have a circular replication setup using three NDB Clusters, with one mysqld attached to each cluster, and each
of these `mysqld` processes acts as a source and as a replica, you should set `MaxNoOfSubscribers` equal to `3 * MaxNoOfTables`.

For more information, see Section 22.6, “NDB Cluster Replication”.

- `MaxNoOfConcurrentSubOperations`

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>256</td>
</tr>
<tr>
<td>Range</td>
<td><code>0 - 4294967039 (0xFFFFFFFF)</code></td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter sets a ceiling on the number of operations that can be performed by all API nodes in the cluster at one time. The default value (256) is sufficient for normal operations, and might need to be adjusted only in scenarios where there are a great many API nodes each performing a high volume of operations concurrently.

**Boolean parameters.** The behavior of data nodes is also affected by a set of `[ndbd]` parameters taking on boolean values. These parameters can each be specified as `TRUE` by setting them equal to `1` or `Y`, and as `FALSE` by setting them equal to `0` or `N`.

- `CompressedLCP`

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td><code>true, false</code></td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Setting this parameter to `1` causes local checkpoint files to be compressed. The compression used is equivalent to `gzip --fast`, and can save 50% or more of the space required on the data node to store uncompressed checkpoint files. Compressed LCPs can be enabled for individual data nodes, or for all data nodes (by setting this parameter in the `[ndbd default]` section of the `config.ini` file).

**Important**

You cannot restore a compressed local checkpoint to a cluster running a MySQL version that does not support this feature.

The default value is `0` (disabled).

- `CrashOnCorruptedTuple`

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>true</td>
</tr>
<tr>
<td>Range</td>
<td><code>true, false</code></td>
</tr>
<tr>
<td>Restart Type</td>
<td>S</td>
</tr>
</tbody>
</table>
NDB Cluster Configuration Files

When this parameter is enabled (the default), it forces a data node to shut down whenever it encounters a corrupted tuple.

- **Diskless**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>true/false (1</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td>Restart Type</td>
<td>IS</td>
</tr>
</tbody>
</table>

It is possible to specify NDB Cluster tables as **diskless**, meaning that tables are not checkpointed to disk and that no logging occurs. Such tables exist only in main memory. A consequence of using diskless tables is that neither the tables nor the records in those tables survive a crash. However, when operating in diskless mode, it is possible to run **ndbd** on a diskless computer.

⚠️ **Important**

This feature causes the **entire** cluster to operate in diskless mode.

When this feature is enabled, Cluster online backup is disabled. In addition, a partial start of the cluster is not possible.

**Diskless** is disabled by default.

- **LateAlloc**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>1</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 1</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Allocate memory for this data node after a connection to the management server has been established. Enabled by default.

- **LockPagesInMainMemory**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 2</td>
</tr>
</tbody>
</table>
NDB Cluster Configuration Files

**Restart Type** | N
---|---

For a number of operating systems, including Solaris and Linux, it is possible to lock a process into memory and so avoid any swapping to disk. This can be used to help guarantee the cluster’s real-time characteristics.

This parameter takes one of the integer values 0, 1, or 2, which act as shown in the following list:

- **0**: Disables locking. This is the default value.
- **1**: Performs the lock after allocating memory for the process.
- **2**: Performs the lock before memory for the process is allocated.

If the operating system is not configured to permit unprivileged users to lock pages, then the data node process making use of this parameter may have to be run as system root. *(LockPagesInMainMemory uses the mlockall function. From Linux kernel 2.6.9, unprivileged users can lock memory as limited by max locked memory. For more information, see ulimit -l and http://linux.die.net/man/2/mlock).*

---

**Note**

In older NDB Cluster releases, this parameter was a Boolean. 0 or false was the default setting, and disabled locking. 1 or true enabled locking of the process after its memory was allocated. NDB Cluster 8.0 treats true or false for the value of this parameter as an error.

---

**Important**

Beginning with glibc 2.10, glibc uses per-thread arenas to reduce lock contention on a shared pool, which consumes real memory. In general, a data node process does not need per-thread arenas, since it does not perform any memory allocation after startup. (This difference in allocators does not appear to affect performance significantly.)

The glibc behavior is intended to be configurable via the MALLOC_ARENA_MAX environment variable, but a bug in this mechanism prior to glibc 2.16 meant that this variable could not be set to less than 8, so that the wasted memory could not be reclaimed. (Bug #15907219; see also http://sourceware.org/bugzilla/show_bug.cgi?id=13137 for more information concerning this issue.)

One possible workaround for this problem is to use the LD_PRELOAD environment variable to preload a jemalloc memory allocation library to take the place of that supplied with glibc.

---

**ODirect**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
</tbody>
</table>
Enabling this parameter causes NDB to attempt using `O_DIRECT` writes for LCP, backups, and redo logs, often lowering `kswapd` and CPU usage. When using NDB Cluster on Linux, enable `ODirect` if you are using a 2.6 or later kernel.

`ODirect` is disabled by default.

**ODirectSyncFlag**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
</tbody>
</table>

When this parameter is enabled, redo log writes are performed such that each completed file system write is handled as a call to `fsync`. The setting for this parameter is ignored if at least one of the following conditions is true:

- `ODirect` is not enabled.
- `InitFragmentLogFiles` is set to `SPARSE`.

Disabled by default.

**RestartOnErrorInsert**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>error code</td>
</tr>
<tr>
<td>Default</td>
<td>2</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4</td>
</tr>
</tbody>
</table>

This feature is accessible only when building the debug version where it is possible to insert errors in the execution of individual blocks of code as part of testing.

This feature is disabled by default.

**StopOnError**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>1</td>
</tr>
<tr>
<td>Range</td>
<td>0, 1</td>
</tr>
</tbody>
</table>
The parameter `Restart Type` specifies whether a data node process should exit or perform an automatic restart when an error condition is encountered.

This parameter's default value is 1; this means that, by default, an error causes the data node process to halt.

When an error is encountered and `StopOnError` is 0, the data node process is restarted.

Users of MySQL Cluster Manager should note that, when `StopOnError` equals 1, this prevents the MySQL Cluster Manager agent from restarting any data nodes after it has performed its own restart and recovery. See Starting and Stopping the Agent on Linux, for more information.

**UseShm**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
</tbody>
</table>

Enable a shared memory connection between this data node and the API node also running on this host. Set to 1 to enable.

### Controlling Timeouts, Intervals, and Disk Paging

There are a number of `ndbd` parameters specifying timeouts and intervals between various actions in Cluster data nodes. Most of the timeout values are specified in milliseconds. Any exceptions to this are mentioned where applicable.

**TimeBetweenWatchDogCheck**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>6000</td>
</tr>
<tr>
<td>Range</td>
<td>70 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

To prevent the main thread from getting stuck in an endless loop at some point, a “watchdog” thread checks the main thread. This parameter specifies the number of milliseconds between checks. If the process remains in the same state after three checks, the watchdog thread terminates it.

This parameter can easily be changed for purposes of experimentation or to adapt to local conditions. It can be specified on a per-node basis although there seems to be little reason for doing so.

The default timeout is 6000 milliseconds (6 seconds).
This is similar to the TimeBetweenWatchDogCheck parameter, except that TimeBetweenWatchDogCheckInitial controls the amount of time that passes between execution checks inside a storage node in the early start phases during which memory is allocated.

The default timeout is 6000 milliseconds (6 seconds).

**StartPartialTimeout**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>30000</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter specifies how long the Cluster waits for all data nodes to come up before the cluster initialization routine is invoked. This timeout is used to avoid a partial Cluster startup whenever possible.

This parameter is overridden when performing an initial start or initial restart of the cluster.

The default value is 30000 milliseconds (30 seconds). 0 disables the timeout, in which case the cluster may start only if all nodes are available.

**StartPartitionedTimeout**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

If the cluster is ready to start after waiting for StartPartialTimeout milliseconds but is still possibly in a partitioned state, the cluster waits until this timeout has also passed. If StartPartitionedTimeout is set to 0, the cluster waits indefinitely (2^{32}−1 ms, or approximately 49.71 days).

This parameter is overridden when performing an initial start or initial restart of the cluster.

**StartFailureTimeout**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>
If a data node has not completed its startup sequence within the time specified by this parameter, the node startup fails. Setting this parameter to 0 (the default value) means that no data node timeout is applied.

For nonzero values, this parameter is measured in milliseconds. For data nodes containing extremely large amounts of data, this parameter should be increased. For example, in the case of a data node containing several gigabytes of data, a period as long as 10–15 minutes (that is, 600000 to 1000000 milliseconds) might be required to perform a node restart.

• **StartNoNodeGroupTimeout**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>15000</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

When a data node is configured with `Nodegroup = 65536`, is regarded as not being assigned to any node group. When that is done, the cluster waits `StartNoNodeGroupTimeout` milliseconds, then treats such nodes as though they had been added to the list passed to the `--nowait-nodes` option, and starts. The default value is 15000 (that is, the management server waits 15 seconds). Setting this parameter equal to 0 means that the cluster waits indefinitely.

*StartNoNodeGroupTimeout* must be the same for all data nodes in the cluster; for this reason, you should always set it in the `[ndbd default]` section of the `config.ini` file, rather than for individual data nodes.

See Section 22.5.7, “Adding NDB Cluster Data Nodes Online”, for more information.

• **HeartbeatIntervalDbDb**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>5000</td>
</tr>
<tr>
<td>Range</td>
<td>10 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

One of the primary methods of discovering failed nodes is by the use of heartbeats. This parameter states how often heartbeat signals are sent and how often to expect to receive them. Heartbeats cannot be disabled.

After missing four heartbeat intervals in a row, the node is declared dead. Thus, the maximum time for discovering a failure through the heartbeat mechanism is five times the heartbeat interval.

The default heartbeat interval is 5000 milliseconds (5 seconds). This parameter must not be changed drastically and should not vary widely between nodes. If one node uses 5000 milliseconds and the node
watching it uses 1000 milliseconds, obviously the node is declared dead very quickly. This parameter can be changed during an online software upgrade, but only in small increments.

See also Network communication and latency, as well as the description of the ConnectCheckIntervalDelay configuration parameter.

• **HeartbeatIntervalDbApi**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>1500</td>
</tr>
<tr>
<td>Range</td>
<td>100 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Each data node sends heartbeat signals to each MySQL server (SQL node) to ensure that it remains in contact. If a MySQL server fails to send a heartbeat in time it is declared “dead,” in which case all ongoing transactions are completed and all resources released. The SQL node cannot reconnect until all activities initiated by the previous MySQL instance have been completed. The three-heartbeat criteria for this determination are the same as described for HeartbeatIntervalDbDb.

The default interval is 1500 milliseconds (1.5 seconds). This interval can vary between individual data nodes because each data node watches the MySQL servers connected to it, independently of all other data nodes.

For more information, see Network communication and latency.

• **HeartbeatOrder**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 65535</td>
</tr>
<tr>
<td>Restart Type</td>
<td>S</td>
</tr>
</tbody>
</table>

Data nodes send heartbeats to one another in a circular fashion whereby each data node monitors the previous one. If a heartbeat is not detected by a given data node, this node declares the previous data node in the circle “dead” (that is, no longer accessible by the cluster). The determination that a data node is dead is done globally; in other words; once a data node is declared dead, it is regarded as such by all nodes in the cluster.

It is possible for heartbeats between data nodes residing on different hosts to be too slow compared to heartbeats between other pairs of nodes (for example, due to a very low heartbeat interval or temporary connection problem), such that a data node is declared dead, even though the node can still function as part of the cluster.

In this type of situation, it may be that the order in which heartbeats are transmitted between data nodes makes a difference as to whether or not a particular data node is declared dead. If this declaration
occurs unnecessarily, this can in turn lead to the unnecessary loss of a node group and as thus to a failure of the cluster.

Consider a setup where there are 4 data nodes A, B, C, and D running on 2 host computers host1 and host2, and that these data nodes make up 2 node groups, as shown in the following table:

<table>
<thead>
<tr>
<th>Node Group</th>
<th>Nodes Running on host1</th>
<th>Nodes Running on host2</th>
</tr>
</thead>
<tbody>
<tr>
<td>Node Group 0:</td>
<td>Node A</td>
<td>Node B</td>
</tr>
<tr>
<td>Node Group 1:</td>
<td>Node C</td>
<td>Node D</td>
</tr>
</tbody>
</table>

Suppose the heartbeats are transmitted in the order A->B->C->D->A. In this case, the loss of the heartbeat between the hosts causes node B to declare node A dead and node C to declare node B dead. This results in loss of Node Group 0, and so the cluster fails. On the other hand, if the order of transmission is A->B->D->C->A (and all other conditions remain as previously stated), the loss of the heartbeat causes nodes A and D to be declared dead; in this case, each node group has one surviving node, and the cluster survives.

The `HeartbeatOrder` configuration parameter makes the order of heartbeat transmission user-configurable. The default value for `HeartbeatOrder` is zero; allowing the default value to be used on all data nodes causes the order of heartbeat transmission to be determined by NDB. If this parameter is used, it must be set to a nonzero value (maximum 65535) for every data node in the cluster, and this value must be unique for each data node; this causes the heartbeat transmission to proceed from data node to data node in the order of their `HeartbeatOrder` values from lowest to highest (and then directly from the data node having the highest `HeartbeatOrder` to the data node having the lowest value, to complete the circle). The values need not be consecutive. For example, to force the heartbeat transmission order A->B->D->C->A in the scenario outlined previously, you could set the `HeartbeatOrder` values as shown here:

<table>
<thead>
<tr>
<th>Node</th>
<th><code>HeartbeatOrder</code> Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>10</td>
</tr>
<tr>
<td>B</td>
<td>20</td>
</tr>
<tr>
<td>C</td>
<td>30</td>
</tr>
<tr>
<td>D</td>
<td>25</td>
</tr>
</tbody>
</table>

To use this parameter to change the heartbeat transmission order in a running NDB Cluster, you must first set `HeartbeatOrder` for each data node in the cluster in the global configuration (`config.ini`) file (or files). To cause the change to take effect, you must perform either of the following:

- A complete shutdown and restart of the entire cluster.
- 2 rolling restarts of the cluster in succession. *All nodes must be restarted in the same order in both rolling restarts.*

You can use `DUMP 908` to observe the effect of this parameter in the data node logs.
### NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type or units</th>
<th>Default</th>
<th>Range</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>ConnectCheckIntervalDelay</td>
<td>milliseconds</td>
<td>0</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter enables connection checking between data nodes after one of them has failed heartbeat checks for 5 intervals of up to `HeartbeatIntervalDbDb` milliseconds.

Such a data node that further fails to respond within an interval of `ConnectCheckIntervalDelay` milliseconds is considered suspect, and is considered dead after two such intervals. This can be useful in setups with known latency issues.

The default value for this parameter is 0 (disabled).

**TimeBetweenLocalCheckpoints**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Version (or later)</th>
<th>Type or units</th>
<th>Default</th>
<th>Range</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>NDB 8.0.13</td>
<td>number of 4-byte words, as a base-2 logarithm</td>
<td>20</td>
<td>0 - 31</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter is an exception in that it does not specify a time to wait before starting a new local checkpoint; rather, it is used to ensure that local checkpoints are not performed in a cluster where relatively few updates are taking place. In most clusters with high update rates, it is likely that a new local checkpoint is started immediately after the previous one has been completed.

The size of all write operations executed since the start of the previous local checkpoints is added. This parameter is also exceptional in that it is specified as the base-2 logarithm of the number of 4-byte words, so that the default value 20 means 4MB ($4 \times 2^{20}$) of write operations, 21 would mean 8MB, and so on up to a maximum value of 31, which equates to 8GB of write operations.

All the write operations in the cluster are added together. Setting `TimeBetweenLocalCheckpoints` to 6 or less means that local checkpoints are executed continuously without pause, independent of the cluster's workload.

**TimeBetweenGlobalCheckpoints**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Version (or later)</th>
<th>Type or units</th>
<th>Default</th>
<th>Range</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>NDB 8.0.13</td>
<td>milliseconds</td>
<td>2000</td>
<td>20 - 32000</td>
<td>N</td>
</tr>
</tbody>
</table>

When a transaction is committed, it is committed in main memory in all nodes on which the data is mirrored. However, transaction log records are not flushed to disk as part of the commit. The reasoning behind this behavior is that having the transaction safely committed on at least two autonomous host machines should meet reasonable standards for durability.

It is also important to ensure that even the worst of cases—a complete crash of the cluster—is handled properly. To guarantee that this happens, all transactions taking place within a given interval are put into
NDB Cluster Configuration Files

A global checkpoint, which can be thought of as a set of committed transactions that has been flushed to disk. In other words, as part of the commit process, a transaction is placed in a global checkpoint group. Later, this group's log records are flushed to disk, and then the entire group of transactions is safely committed to disk on all computers in the cluster.

In NDB 8.0.19 and later, it recommended when using solid-state disks (especially those employing NVMe) with Disk Data tables that you reduce this value. In such cases, you should also ensure that MaxDiskDataLatency is set to a proper level.

This parameter defines the interval between global checkpoints. The default is 2000 milliseconds.

- **TimeBetweenGlobalCheckpointsTimeout**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>120000</td>
</tr>
<tr>
<td>Range</td>
<td>10 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter defines the minimum timeout between global checkpoints. The default is 120000 milliseconds.

- **TimeBetweenEpochs**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>100</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 32000</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter defines the interval between synchronization epochs for NDB Cluster Replication. The default value is 100 milliseconds.

**TimeBetweenEpochs** is part of the implementation of “micro-GCPs”, which can be used to improve the performance of NDB Cluster Replication.

- **TimeBetweenEpochsTimeout**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 256000</td>
</tr>
</tbody>
</table>
The parameter defines a timeout for synchronization epochs for NDB Cluster Replication. If a node fails to participate in a global checkpoint within the time determined by this parameter, the node is shut down. The default value is 0; in other words, the timeout is disabled.

_TimeBetweenEpochsTimeout_ is part of the implementation of “micro-GCPs”, which can be used to improve the performance of NDB Cluster Replication.

The current value of this parameter and a warning are written to the cluster log whenever a GCP save takes longer than 1 minute or a GCP commit takes longer than 10 seconds.

Setting this parameter to zero has the effect of disabling GCP stops caused by save timeouts, commit timeouts, or both. The maximum possible value for this parameter is 256000 milliseconds.

**MaxBufferedEpochs**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>epochs</td>
</tr>
<tr>
<td>Default</td>
<td>100</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 100000</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

The number of unprocessed epochs by which a subscribing node can lag behind. Exceeding this number causes a lagging subscriber to be disconnected.

The default value of 100 is sufficient for most normal operations. If a subscribing node does lag enough to cause disconnections, it is usually due to network or scheduling issues with regard to processes or threads. (In rare circumstances, the problem may be due to a bug in the NDB client.) It may be desirable to set the value lower than the default when epochs are longer.

Disconnection prevents client issues from affecting the data node service, running out of memory to buffer data, and eventually shutting down. Instead, only the client is affected as a result of the disconnect (by, for example gap events in the binary log), forcing the client to reconnect or restart the process.

**MaxBufferedEpochBytes**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>26214400</td>
</tr>
<tr>
<td>Range</td>
<td>26214400 (0x01900000) - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

The total number of bytes allocated for buffering epochs by this node.

**TimeBetweenInactiveTransactionAbortCheck**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>1000</td>
</tr>
<tr>
<td></td>
<td>4007</td>
</tr>
</tbody>
</table>
Timeout handling is performed by checking a timer on each transaction once for every interval specified by this parameter. Thus, if this parameter is set to 1000 milliseconds, every transaction is checked for timing out once per second.

The default value is 1000 milliseconds (1 second).

- **TransactionInactiveTimeout**

<table>
<thead>
<tr>
<th>Range</th>
<th>1000 - 4294967039 (0xFFFFFEFF)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter states the maximum time that is permitted to lapse between operations in the same transaction before the transaction is aborted.

The default for this parameter is 4G (also the maximum). For a real-time database that needs to ensure that no transaction keeps locks for too long, this parameter should be set to a relatively small value. Setting it to 0 means that the application never times out. The unit is milliseconds.

- **TransactionDeadlockDetectionTimeout**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

When a node executes a query involving a transaction, the node waits for the other nodes in the cluster to respond before continuing. This parameter sets the amount of time that the transaction can spend executing within a data node, that is, the time that the transaction coordinator waits for each data node participating in the transaction to execute a request.

A failure to respond can occur for any of the following reasons:

- The node is “dead”
- The operation has entered a lock queue
- The node requested to perform the action could be heavily overloaded.

This timeout parameter states how long the transaction coordinator waits for query execution by another node before aborting the transaction, and is important for both node failure handling and deadlock detection.

The default timeout value is 1200 milliseconds (1.2 seconds).

The minimum for this parameter is 50 milliseconds.
NDB Cluster Configuration Files

- **DiskSyncSize**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>4M</td>
</tr>
<tr>
<td>Range</td>
<td>32K - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

  This is the maximum number of bytes to store before flushing data to a local checkpoint file. This is done to prevent write buffering, which can impede performance significantly. This parameter is *not* intended to take the place of `TimeBetweenLocalCheckpoints`.

  **Note**

  When `ODirect` is enabled, it is not necessary to set `DiskSyncSize`; in fact, in such cases its value is simply ignored.

  The default value is 4M (4 megabytes).

- **MaxDiskWriteSpeed**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>20M</td>
</tr>
<tr>
<td>Range</td>
<td>1M - 1024G</td>
</tr>
<tr>
<td>Restart Type</td>
<td>S</td>
</tr>
</tbody>
</table>

  Set the maximum rate for writing to disk, in bytes per second, by local checkpoints and backup operations when no restarts (by this data node or any other data node) are taking place in this NDB Cluster.

  For setting the maximum rate of disk writes allowed while this data node is restarting, use `MaxDiskWriteSpeedOwnRestart`. For setting the maximum rate of disk writes allowed while other data nodes are restarting, use `MaxDiskWriteSpeedOtherNodeRestart`. The minimum speed for disk writes by all LCPs and backup operations can be adjusted by setting `MinDiskWriteSpeed`.

- **MaxDiskWriteSpeedOtherNodeRestart**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>50M</td>
</tr>
<tr>
<td>Range</td>
<td>1M - 1024G</td>
</tr>
<tr>
<td>Restart Type</td>
<td>S</td>
</tr>
</tbody>
</table>

  Set the maximum rate for writing to disk, in bytes per second, by local checkpoints and backup operations when one or more data nodes in this NDB Cluster are restarting, other than this node.

  For setting the maximum rate of disk writes allowed while this data node is restarting, use `MaxDiskWriteSpeedOwnRestart`. For setting the maximum rate of disk writes allowed when no data
nodes are restarting anywhere in the cluster, use `MaxDiskWriteSpeed`. The minimum speed for disk writes by all LCPs and backup operations can be adjusted by setting `MinDiskWriteSpeed`.

- **MaxDiskWriteSpeedOwnRestart**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>200M</td>
</tr>
<tr>
<td>Range</td>
<td>1M - 1024G</td>
</tr>
<tr>
<td>Restart Type</td>
<td>S</td>
</tr>
</tbody>
</table>

Set the maximum rate for writing to disk, in bytes per second, by local checkpoints and backup operations while this data node is restarting.

For setting the maximum rate of disk writes allowed while other data nodes are restarting, use `MaxDiskWriteSpeedOtherNodeRestart`. For setting the maximum rate of disk writes allowed when no data nodes are restarting anywhere in the cluster, use `MaxDiskWriteSpeed`. The minimum speed for disk writes by all LCPs and backup operations can be adjusted by setting `MinDiskWriteSpeed`.

- **MinDiskWriteSpeed**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>10M</td>
</tr>
<tr>
<td>Range</td>
<td>1M - 1024G</td>
</tr>
<tr>
<td>Restart Type</td>
<td>S</td>
</tr>
</tbody>
</table>

Set the minimum rate for writing to disk, in bytes per second, by local checkpoints and backup operations.

The maximum rates of disk writes allowed for LCPs and backups under various conditions are adjustable using the parameters `MaxDiskWriteSpeed`, `MaxDiskWriteSpeedOwnRestart`, and `MaxDiskWriteSpeedOtherNodeRestart`. See the descriptions of these parameters for more information.

- **ArbitrationTimeout**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>7500</td>
</tr>
<tr>
<td>Range</td>
<td>10 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter specifies how long data nodes wait for a response from the arbitrator to an arbitration message. If this is exceeded, the network is assumed to have split.

The default value is 7500 milliseconds (7.5 seconds).

- **Arbitration**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
</table>
The **Arbitration** parameter enables a choice of arbitration schemes, corresponding to one of 3 possible values for this parameter:

- **Default.** This enables arbitration to proceed normally, as determined by the `ArbitrationRank` settings for the management and API nodes. This is the default value.

- **Disabled.** Setting `Arbitration = Disabled` in the `[ndbd default]` section of the `config.ini` file accomplishes the same task as setting `ArbitrationRank` to 0 on all management and API nodes. When `Arbitration` is set in this way, any `ArbitrationRank` settings are ignored.

- **WaitExternal.** The `Arbitration` parameter also makes it possible to configure arbitration in such a way that the cluster waits until after the time determined by `ArbitrationTimeout` has passed for an external cluster manager application to perform arbitration instead of handling arbitration internally. This can be done by setting `Arbitration = WaitExternal` in the `[ndbd default]` section of the `config.ini` file. For best results with the `WaitExternal` setting, it is recommended that `ArbitrationTimeout` be 2 times as long as the interval required by the external cluster manager to perform arbitration.

### Important

This parameter should be used only in the `[ndbd default]` section of the cluster configuration file. The behavior of the cluster is unspecified when `Arbitration` is set to different values for individual data nodes.

- **RestartSubscriberConnectTimeout**

### Version (or later)

<table>
<thead>
<tr>
<th>Type or units</th>
<th>Default</th>
<th>Range</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>ms</td>
<td>12000</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
<td>S</td>
</tr>
</tbody>
</table>

This parameter determines the time that a data node waits for subscribing API nodes to connect. Once this timeout expires, any “missing” API nodes are disconnected from the cluster. To disable this timeout, set `RestartSubscriberConnectTimeout` to 0.

While this parameter is specified in milliseconds, the timeout itself is resolved to the next-greatest whole second.

**Buffering and logging.** Several `[ndbd]` configuration parameters enable the advanced user to have more control over the resources used by node processes and to adjust various buffer sizes at need.

These buffers are used as front ends to the file system when writing log records to disk. If the node is running in diskless mode, these parameters can be set to their minimum values without penalty due to the fact that disk writes are “faked” by the NDB storage engine’s file system abstraction layer.

- **UndoIndexBuffer**
The UNDO index buffer, whose size is set by this parameter, is used during local checkpoints. The NDB storage engine uses a recovery scheme based on checkpoint consistency in conjunction with an operational REDO log. To produce a consistent checkpoint without blocking the entire system for writes, UNDO logging is done while performing the local checkpoint. UNDO logging is activated on a single table fragment at a time. This optimization is possible because tables are stored entirely in main memory.

The UNDO index buffer is used for the updates on the primary key hash index. Inserts and deletes rearrange the hash index; the NDB storage engine writes UNDO log records that map all physical changes to an index page so that they can be undone at system restart. It also logs all active insert operations for each fragment at the start of a local checkpoint.

Reads and updates set lock bits and update a header in the hash index entry. These changes are handled by the page-writing algorithm to ensure that these operations need no UNDO logging.

This buffer is 2MB by default. The minimum value is 1MB, which is sufficient for most applications. For applications doing extremely large or numerous inserts and deletes together with large transactions and large primary keys, it may be necessary to increase the size of this buffer. If this buffer is too small, the NDB storage engine issues internal error code 677 (Index UNDO buffers overloaded).

---

### Important

It is not safe to decrease the value of this parameter during a rolling restart.

- **UndoDataBuffer**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>16M</td>
</tr>
<tr>
<td>Range</td>
<td>1M - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter sets the size of the UNDO data buffer, which performs a function similar to that of the UNDO index buffer, except the UNDO data buffer is used with regard to data memory rather than index
memory. This buffer is used during the local checkpoint phase of a fragment for inserts, deletes, and updates.

Because UNDO log entries tend to grow larger as more operations are logged, this buffer is also larger than its index memory counterpart, with a default value of 16MB.

This amount of memory may be unnecessarily large for some applications. In such cases, it is possible to decrease this size to a minimum of 1MB.

It is rarely necessary to increase the size of this buffer. If there is such a need, it is a good idea to check whether the disks can actually handle the load caused by database update activity. A lack of sufficient disk space cannot be overcome by increasing the size of this buffer.

If this buffer is too small and gets congested, the NDB storage engine issues internal error code 891 (Data UNDO buffers overloaded).

---

Important
It is not safe to decrease the value of this parameter during a rolling restart.

• RedoBuffer

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>32M</td>
</tr>
<tr>
<td>Range</td>
<td>1M - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

All update activities also need to be logged. The REDO log makes it possible to replay these updates whenever the system is restarted. The NDB recovery algorithm uses a “fuzzy” checkpoint of the data together with the UNDO log, and then applies the REDO log to play back all changes up to the restoration point.

RedoBuffer sets the size of the buffer in which the REDO log is written. The default value is 32MB; the minimum value is 1MB.

If this buffer is too small, the NDB storage engine issues error code 1221 (REDO log buffers overloaded). For this reason, you should exercise care if you attempt to decrease the value of RedoBuffer as part of an online change in the cluster’s configuration.

ndbmtd allocates a separate buffer for each LDM thread (see ThreadConfig). For example, with 4 LDM threads, an ndbmtd data node actually has 4 buffers and allocates RedoBuffer bytes to each one, for a total of 4 * RedoBuffer bytes.

• EventLogBufferSize

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>8192</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 64K</td>
</tr>
</tbody>
</table>
## NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>Restart Type</th>
<th>S</th>
</tr>
</thead>
</table>

Controls the size of the circular buffer used for NDB log events within data nodes.

**Controlling log messages.** In managing the cluster, it is very important to be able to control the number of log messages sent for various event types to `stdout`. For each event category, there are 16 possible event levels (numbered 0 through 15). Setting event reporting for a given event category to level 15 means all event reports in that category are sent to `stdout`; setting it to 0 means that no event reports in that category are made.

By default, only the startup message is sent to `stdout`, with the remaining event reporting level defaults being set to 0. The reason for this is that these messages are also sent to the management server's cluster log.

An analogous set of levels can be set for the management client to determine which event levels to record in the cluster log.

- **LogLevelStartup**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>1</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 15</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

The reporting level for events generated during startup of the process.

The default level is 1.

- **LogLevelShutdown**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 15</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

The reporting level for events generated as part of graceful shutdown of a node.

The default level is 0.

- **LogLevelStatistic**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 15</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

The reporting level for statistical events such as number of primary key reads, number of updates, number of inserts, information relating to buffer usage, and so on.
The default level is 0.

- **LogLevelCheckpoint**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>log level</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 15</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>N</td>
</tr>
</tbody>
</table>

The reporting level for events generated by local and global checkpoints.

The default level is 0.

- **LogLevelNodeRestart**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 15</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>N</td>
</tr>
</tbody>
</table>

The reporting level for events generated during node restart.

The default level is 0.

- **LogLevelConnection**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 15</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>N</td>
</tr>
</tbody>
</table>

The reporting level for events generated by connections between cluster nodes.

The default level is 0.

- **LogLevelError**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 15</td>
</tr>
</tbody>
</table>
NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>Restart Type</th>
<th>N</th>
</tr>
</thead>
</table>

The reporting level for events generated by errors and warnings by the cluster as a whole. These errors do not cause any node failure but are still considered worth reporting.

The default level is 0.

- **LogLevelCongestion**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>level</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 15</td>
</tr>
</tbody>
</table>

The reporting level for events generated by congestion. These errors do not cause node failure but are still considered worth reporting.

The default level is 0.

- **LogLevelInfo**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 15</td>
</tr>
</tbody>
</table>

The reporting level for events generated for information about the general state of the cluster.

The default level is 0.

- **MemReportFrequency**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

This parameter controls how often data node memory usage reports are recorded in the cluster log; it is an integer value representing the number of seconds between reports.

Each data node's data memory and index memory usage is logged as both a percentage and a number of 32 KB pages of **DataMemory**, as set in the **config.ini** file. For example, if **DataMemory** is equal
to 100 MB, and a given data node is using 50 MB for data memory storage, the corresponding line in the cluster log might look like this:

```
2006-12-24 01:18:16 [MgmSrvr] INFO -- Node 2: Data usage is 50% (1280 32K pages of total 2560)
```

`MemReportFrequency` is not a required parameter. If used, it can be set for all cluster data nodes in the `[ndbd default]` section of `config.ini`, and can also be set or overridden for individual data nodes in the corresponding `[ndbd]` sections of the configuration file. The minimum value—which is also the default value—is 0, in which case memory reports are logged only when memory usage reaches certain percentages (80%, 90%, and 100%), as mentioned in the discussion of statistics events in Section 22.5.3.2, “NDB Cluster Log Events”.

- **StartupStatusReportFrequency**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>seconds</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

When a data node is started with the `--initial`, it initializes the redo log file during Start Phase 4 (see Section 22.5.4, “Summary of NDB Cluster Start Phases”). When very large values are set for `NoOfFragmentLogFiles`, `FragmentLogFileSize`, or both, this initialization can take a long time. You can force reports on the progress of this process to be logged periodically, by means of the `StartupStatusReportFrequency` configuration parameter. In this case, progress is reported in the cluster log, in terms of both the number of files and the amount of space that have been initialized, as shown here:

```
```

These reports are logged each `StartupStatusReportFrequency` seconds during Start Phase 4. If `StartupStatusReportFrequency` is 0 (the default), then reports are written to the cluster log only when at the beginning and at the completion of the redo log file initialization process.

### Data Node Debugging Parameters

The following parameters are intended for use during testing or debugging of data nodes, and not for use in production.

- **DictTrace**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>undefined</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 100</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

It is possible to cause logging of traces for events generated by creating and dropping tables using `DictTrace`. This parameter is useful only in debugging NDB kernel code. `DictTrace` takes an integer
value. 0 is the default, and means no logging is performed; 1 enables trace logging, and 2 enables logging of additional DBDICT debugging output.

- **WatchdogImmediateKill**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td>Restart Type</td>
<td>S</td>
</tr>
</tbody>
</table>

You can cause threads to be killed immediately whenever watchdog issues occur by enabling the WatchdogImmediateKill data node configuration parameter. This parameter should be used only when debugging or troubleshooting, to obtain trace files reporting exactly what was occurring the instant that execution ceased.

**Backup parameters.** The [ndbd] parameters discussed in this section define memory buffers set aside for execution of online backups.

- **BackupDataBufferSize**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>16M</td>
</tr>
<tr>
<td>Range</td>
<td>512K - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
<tr>
<td>Deprecated</td>
<td>Yes (in NDB 7.6)</td>
</tr>
</tbody>
</table>

In creating a backup, there are two buffers used for sending data to the disk. The backup data buffer is used to fill in data recorded by scanning a node’s tables. Once this buffer has been filled to the level specified as BackupWriteSize, the pages are sent to disk. While flushing data to disk, the backup process can continue filling this buffer until it runs out of space. When this happens, the backup process pauses the scan and waits until some disk writes have completed freeing up memory so that scanning may continue.

The default value for this parameter is 16MB. The minimum is 512K.

- **BackupDiskWriteSpeedPct**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>percent</td>
</tr>
<tr>
<td>Default</td>
<td>50</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 90</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

During normal operation, data nodes attempt to maximize the disk write speed used for local checkpoints and backups while remaining within the bounds set by MinDiskWriteSpeed and MaxDiskWriteSpeed. Disk write throttling gives each LDM thread an equal share of the total budget. This allows parallel LCPs to take place without exceeding the disk I/O budget. Because a backup is executed by only one LDM thread, this effectively caused a budget cut, resulting in longer backup
completion times, and—if the rate of change is sufficiently high—in failure to complete the backup when the backup log buffer fill rate is higher than the achievable write rate.

This problem can be addressed by using the `BackupDiskWriteSpeedPct` configuration parameter, which takes a value in the range 0-90 (inclusive) which is interpreted as the percentage of the node's maximum write rate budget that is reserved prior to sharing out the remainder of the budget among LDM threads for LCPs. The LDM thread running the backup receives the whole write rate budget for the backup, plus its (reduced) share of the write rate budget for local checkpoints.

The default value for this parameter is 50 (interpreted as 50%).

- **BackupLogBufferSize**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>16M</td>
</tr>
<tr>
<td>Range</td>
<td>2M - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

The backup log buffer fulfills a role similar to that played by the backup data buffer, except that it is used for generating a log of all table writes made during execution of the backup. The same principles apply for writing these pages as with the backup data buffer, except that when there is no more space in the backup log buffer, the backup fails. For that reason, the size of the backup log buffer must be large enough to handle the load caused by write activities while the backup is being made. See Section 22.5.8.3, “Configuration for NDB Cluster Backups”.

The default value for this parameter should be sufficient for most applications. In fact, it is more likely for a backup failure to be caused by insufficient disk write speed than it is for the backup log buffer to become full. If the disk subsystem is not configured for the write load caused by applications, the cluster is unlikely to be able to perform the desired operations.

It is preferable to configure cluster nodes in such a manner that the processor becomes the bottleneck rather than the disks or the network connections.

The default value for this parameter is 16MB.

- **BackupMemory**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>32M</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
<tr>
<td>Deprecated</td>
<td>Yes (in NDB 7.4)</td>
</tr>
</tbody>
</table>

This parameter is deprecated, and subject to removal in a future version of NDB Cluster. Any setting made for it is ignored.

- **BackupReportFrequency**
NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type or units</th>
<th>Default</th>
<th>Range</th>
<th>Restart Type</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>BackupReportFrequency</td>
<td>seconds</td>
<td>0</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
<td>This parameter controls how often backup status reports are issued in the management client during a backup, as well as how often such reports are written to the cluster log (provided cluster event logging is configured to permit it—see Logging and checkpointing). BackupReportFrequency represents the time in seconds between backup status reports. The default value is 0.</td>
</tr>
<tr>
<td>BackupWriteSize</td>
<td>bytes</td>
<td>256K</td>
<td>32K - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
<td>This parameter specifies the default size of messages written to disk by the backup log and backup data buffers. The default value for this parameter is 256KB.</td>
</tr>
<tr>
<td>BackupMaxWriteSize</td>
<td>bytes</td>
<td>1M</td>
<td>256K - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
<td>This parameter specifies the maximum size of messages written to disk by the backup log and backup data buffers. The default value for this parameter is 1MB.</td>
</tr>
<tr>
<td>CompressedBackup</td>
<td>boolean</td>
<td>false</td>
<td>true, false</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
NDB Cluster Configuration Files

| Restart Type | N |

Enabling this parameter causes backup files to be compressed. The compression used is equivalent to `gzip --fast`, and can save 50% or more of the space required on the data node to store uncompressed backup files. Compressed backups can be enabled for individual data nodes, or for all data nodes (by setting this parameter in the `[ndbd default]` section of the `config.ini` file).

**Important**

You cannot restore a compressed backup to a cluster running a MySQL version that does not support this feature.

The default value is 0 (disabled).

- **RequireEncryptedBackup**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.22</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 1</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
<tr>
<td>Added</td>
<td>NDB 8.0.22</td>
</tr>
</tbody>
</table>

If set to 1, backups must be encrypted. While it is possible to set this parameter for each data node individually, it is recommended that you set it in the `[ndbd default]` section of the `config.ini` global configuration file. For more information about performing encrypted backups, see Section 22.5.8.2, “Using The NDB Cluster Management Client to Create a Backup”.

Added in NDB 8.0.22.

**Note**

The location of the backup files is determined by the `BackupDataDir` data node configuration parameter.

**Additional requirements.** When specifying these parameters, the following relationships must hold true. Otherwise, the data node cannot start.

- `BackupDataBufferSize >= BackupWriteSize + 188KB`
- `BackupLogBufferSize >= BackupWriteSize + 16KB`
- `BackupMaxWriteSize >= BackupWriteSize`

**NDB Cluster Realtime Performance Parameters**

The `[ndbd]` parameters discussed in this section are used in scheduling and locking of threads to specific CPUs on multiprocessor data node hosts.

**Note**

To make use of these parameters, the data node process must be run as system root.

- `BuildIndexThreads`
### NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>128</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 128</td>
</tr>
<tr>
<td>Restart Type</td>
<td>S</td>
</tr>
</tbody>
</table>

This parameter determines the number of threads to create when rebuilding ordered indexes during a system or node start, as well as when running `ndb_restore --rebuild-indexes`. It is supported only when there is more than one fragment for the table per data node (for example, when `COMMENT="NDB_TABLE=PARTITION_BALANCE=FOR_RA_BY_LDM_X_2"` is used with `CREATE TABLE`).

Setting this parameter to 0 (the default) disables multithreaded building of ordered indexes.

This parameter is supported when using `ndbd` or `ndbmtd`.

You can enable multithreaded builds during data node initial restarts by setting the `TwoPassInitialNodeRestartCopy` data node configuration parameter to `TRUE`.

- **LockExecuteThreadToCPU**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>set of CPU IDs</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

When used with `ndbd`, this parameter (now a string) specifies the ID of the CPU assigned to handle the `NDBCLUSTER` execution thread. When used with `ndbmtd`, the value of this parameter is a comma-separated list of CPU IDs assigned to handle execution threads. Each CPU ID in the list should be an integer in the range 0 to 65535 (inclusive).

The number of IDs specified should match the number of execution threads determined by `MaxNoOfExecutionThreads`. However, there is no guarantee that threads are assigned to CPUs in any given order when using this parameter. You can obtain more finely-grained control of this type using `ThreadConfig`.

`LockExecuteThreadToCPU` has no default value.

- **LockMaintThreadsToCPU**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>CPU ID</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 64K</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter specifies the ID of the CPU assigned to handle `NDBCLUSTER` maintenance threads.

The value of this parameter is an integer in the range 0 to 65535 (inclusive). **There is no default value.**
• **Numa**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>1</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter determines whether Non-Uniform Memory Access (NUMA) is controlled by the operating system or by the data node process, whether the data node uses `ndbd` or `ndbmd`. By default, NDB attempts to use an interleaved NUMA memory allocation policy on any data node where the host operating system provides NUMA support.

Setting **Numa = 0** means that the datanode process does not itself attempt to set a policy for memory allocation, and permits this behavior to be determined by the operating system, which may be further guided by the separate `numactl` tool. That is, **Numa = 0** yields the system default behavior, which can be customised by `numactl`. For many Linux systems, the system default behavior is to allocate socket-local memory to any given process at allocation time. This can be problematic when using `nbdmt`, this is because `nbdmt` allocates all memory at startup, leading to an imbalance, giving different access speeds for different sockets, especially when locking pages in main memory.

Setting **Numa = 1** means that the data node process uses `libnuma` to request interleaved memory allocation. (This can also be accomplished manually, on the operating system level, using `numactl`.) Using interleaved allocation in effect tells the data node process to ignore non-uniform memory access but does not attempt to take any advantage of fast local memory; instead, the data node process tries to avoid imbalances due to slow remote memory. If interleaved allocation is not desired, set **Numa** to 0 so that the desired behavior can be determined on the operating system level.

The **Numa** configuration parameter is supported only on Linux systems where `libnuma.so` is available.

• **RealtimeScheduler**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Setting this parameter to 1 enables real-time scheduling of data node threads.

The default is 0 (scheduling disabled).

• **SchedulerExecutionTimer**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>µs</td>
</tr>
<tr>
<td>Default</td>
<td>50</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 11000</td>
</tr>
</tbody>
</table>
**Restart Type**

This parameter specifies the time in microseconds for threads to be executed in the scheduler before being sent. Setting it to 0 minimizes the response time; to achieve higher throughput, you can increase the value at the expense of longer response times.

The default is 50 μsec, which our testing shows to increase throughput slightly in high-load cases without materially delaying requests.

- **SchedulerResponsiveness**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>5</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 10</td>
</tr>
</tbody>
</table>

Set the balance in the NDB scheduler between speed and throughput. This parameter takes an integer whose value is in the range 0-10 inclusive, with 5 as the default. Higher values provide better response times relative to throughput. Lower values provide increased throughput at the expense of longer response times.

- **SchedulerSpinTimer**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>µs</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 500</td>
</tr>
</tbody>
</table>

This parameter specifies the time in microseconds for threads to be executed in the scheduler before sleeping.

Starting with NDB 8.0.20, if SpinMethod is set, any setting for this parameter is ignored.

- **SpinMethod**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.20</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>enumeration</td>
</tr>
<tr>
<td>Default</td>
<td>StaticSpinning</td>
</tr>
<tr>
<td>Range</td>
<td>CostBasedSpinning, LatencyOptimisedSpinning, DatabaseMachineSpinning, StaticSpinning</td>
</tr>
</tbody>
</table>

This parameter provides a simple interface to control adaptive spinning on data nodes, with four possible values furnishing presets for spin parameter values, as shown in the following list:

1. **StaticSpinning** (default): Sets EnableAdaptiveSpinning to false and SchedulerSpinTimer to 0. (SetAllowedSpinOverhead is not relevant in this case.)
2. **CostBasedSpinning**: Sets `EnableAdaptiveSpinning` to `true`, `SchedulerSpinTimer` to `100`, and `SetAllowedSpinOverhead` to `200`.

3. **LatencyOptimisedSpinning**: Sets `EnableAdaptiveSpinning` to `true`, `SchedulerSpinTimer` to `200`, and `SetAllowedSpinOverhead` to `1000`.

4. **DatabaseMachineSpinning**: Sets `EnableAdaptiveSpinning` to `true`, `SchedulerSpinTimer` to `500`, and `SetAllowedSpinOverhead` to `10000`. This is intended for use in cases where threads own their own CPUs.

The spin parameters modified by SpinMethod are described in the following list:

- **SchedulerSpinTimer**: This is the same as the data node configuration parameter of that name. The setting applied to this parameter by SpinMethod overrides any value set in the `config.ini` file.

- **EnableAdaptiveSpinning**: Enables or disables adaptive spinning. Disabling it causes spinning to be performed without making any checks for CPU resources. This parameter cannot be set directly in the cluster configuration file, and under most circumstances should not need to be, but can be enabled directly using `DUMP 104004 1` or disabled with `DUMP 104004 0` in the `ndb_mgm` management client.

- **SetAllowedSpinOverhead**: Sets the amount of CPU time to allow for gaining latency. This parameter cannot be set directly in the `config.ini` file. In most cases, the setting applied by SpinMethod should be satisfactory, but if it is necessary to change it directly, you can use `DUMP 104002 overhead` to do so, where `overhead` is a value ranging from 0 to 10000, inclusive; see the description of the indicated `DUMP` command for details.

On platforms lacking usable spin instructions, such as PowerPC and some SPARC platforms, spin time is set to 0 in all situations, and values for SpinMethod other than StaticSpinning are ignored.

- **TwoPassInitialNodeRestartCopy**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>true</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Multithreaded building of ordered indexes can be enabled for initial restarts of data nodes by setting this configuration parameter to `true` (the default value), which enables two-pass copying of data during initial node restarts.

You must also set `BuildIndexThreads` to a nonzero value.

**Multi-Threading Configuration Parameters (ndbmtd)**. `ndbmtd` runs by default as a single-threaded process and must be configured to use multiple threads, using either of two methods, both of which require setting configuration parameters in the `config.ini` file. The first method is simply to set an appropriate value for the `MaxNoOfExecutionThreads` configuration parameter. A second method, makes it possible to set up more complex rules for `ndbmtd` multithreading using `ThreadConfig`. The next few paragraphs provide information about these parameters and their use with multithreaded data nodes.
A backup using parallelism on the data nodes requires that multiple LDMs are in use on all data nodes in the cluster prior to taking the backup. For more information, see Section 22.5.8.5, “Taking an NDB Backup with Parallel Data Nodes”, as well as Section 22.4.23.2, “Restoring from a backup taken in parallel”.

This parameter directly controls the number of execution threads used by `ndbmtd`, up to a maximum of 72. Although this parameter is set in `[ndbd]` or `[ndbd default]` sections of the `config.ini` file, it is exclusive to `ndbmtd` and does not apply to `ndbd`.

Setting `MaxNoOfExecutionThreads` sets the number of threads for each type as determined by a matrix in the file `storage/ndb/src/kernel/vm/mt_thr_config.cpp`. This table shows these numbers of threads for possible values of `MaxNoOfExecutionThreads`.

### Table 22.11 MaxNoOfExecutionThreads values and the corresponding number of threads by thread type (LQH, TC, Send, Receive).

</table>
There is always one SUMA (replication) thread.

NoOfFragmentLogParts should be set equal to the number of LDM threads used by ndbmtd, as determined by the setting for this parameter. This ratio should not be any greater than 4:1; a configuration in which this is the case is specifically disallowed.

The number of LDM threads also determines the number of partitions used by an NDB table that is not explicitly partitioned; this is the number of LDM threads times the number of data nodes in the cluster. (If ndbd is used on the data nodes rather than ndbmtd, then there is always a single LDM thread; in this case, the number of partitions created automatically is simply equal to the number of data nodes. See Section 22.1.2, “NDB Cluster Nodes, Node Groups, Fragment Replicas, and Partitions”, for more information.

Adding large tablespaces for Disk Data tables when using more than the default number of LDM threads may cause issues with resource and CPU usage if the disk page buffer is insufficiently large; see the description of the DiskPageBufferMemory configuration parameter, for more information.

The thread types are described later in this section (see ThreadConfig).

Setting this parameter outside the permitted range of values causes the management server to abort on startup with the error Error line number: Illegal value value for parameter MaxNoOfExecutionThreads.

For MaxNoOfExecutionThreads, a value of 0 or 1 is rounded up internally by NDB to 2, so that 2 is considered this parameter's default and minimum value.

MaxNoOfExecutionThreads is generally intended to be set equal to the number of CPU threads available, and to allocate a number of threads of each type suitable to typical workloads. It does not assign particular threads to specified CPUs. For cases where it is desirable to vary from the settings provided, or to bind threads to CPUs, you should use ThreadConfig instead, which allows you to allocate each thread directly to a desired type, CPU, or both.

The multithreaded data node process always spawns, at a minimum, the threads listed here:

- 1 local query handler (LDM) thread

NDB Cluster Configuration Files

- 1 receive thread
- 1 subscription manager (SUMA or replication) thread

For a `MaxNoOfExecutionThreads` value of 8 or less, no TC threads are created, and TC handling is instead performed by the main thread.

Changing the number of LDM threads normally requires a system restart, whether it is changed using this parameter or `ThreadConfig`, but it is possible to effect the change using a node initial restart (N) provided the following two conditions are met:

- Each LDM thread handles a maximum of 8 fragments, and
- The total number of table fragments is an integer multiple of the number of LDM threads.

In NDB 8.0, an initial restart is *not* required to effect a change in this parameter, as it was in some older versions of NDB Cluster.

### NoOfFragmentLogParts

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>4</td>
</tr>
<tr>
<td>Range</td>
<td>4, 6, 8, 10, 12, 16, 20, 24, 32</td>
</tr>
<tr>
<td>Restart Type</td>
<td>IN</td>
</tr>
</tbody>
</table>

Set the number of log file groups for redo logs belonging to this `ndbmtd`. The value of this parameter should be set equal to the number of LDM threads used by `ndbmtd` as determined by the setting for `MaxNoOfExecutionThreads`. A configuration using more than 4 redo log parts per LDM is disallowed.

See the description of `MaxNoOfExecutionThreads` for more information.

### ThreadConfig

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>string</td>
</tr>
<tr>
<td>Default</td>
<td>&quot;</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>IS</td>
</tr>
</tbody>
</table>

This parameter is used with `ndbmtd` to assign threads of different types to different CPUs. Its value is a string whose format has the following syntax:

```
ThreadConfig := entry[,entry[,...]]
entry := type={param[,param[,...]]}
type := ldm | main | recv | send | rep | io | tc | watchdog | idxbld
param := count=number
     | cpubind=cpu_list
     | cpuset=cpu_list
     | spintime=number
     | realtime={0|1}
```
A param (parameter) specifies any or all of the following information:

- The number of threads of the given type (count).
- The set of CPUs to which the threads of the given type are to be nonexclusively bound. This is determined by either one of cpubind or cpuset. cpubind causes each thread to be bound (nonexclusively) to a CPU in the set; cpuset means that each thread is bound (nonexclusively) to the set of CPUs specified.

On Solaris, you can instead specify a set of CPUs to which the threads of the given type are to be bound exclusively. cpubind_exclusive causes each thread to be bound exclusively to a CPU in the set; cpuset_exclusive means that each thread is bound exclusively to the set of CPUs specified.

Only one of cpubind, cpuset, cpubind_exclusive, or cpuset_exclusive can be provided in a single configuration.

- spintime determines the wait time in microseconds the thread spins before going to sleep.

The default value for spintime is the value of the SchedulerSpinTimer data node configuration parameter.

spintime does not apply to I/O threads, watchdog, or offline index build threads, and so cannot be set for these thread types.

- realtime can be set to 0 or 1. If it is set to 1, the threads run with real-time priority. This also means that thread_prio cannot be set.

The realtime parameter is set by default to the value of the RealtimeScheduler data node configuration parameter.

realtime cannot be set for offline index build threads.

- By setting nosend to 1, you can prevent a main, ldm, rep, or tc thread from assisting the send threads. This parameter is 0 by default, and cannot be used with other types of threads.
thread_prio is a thread priority level that can be set from 0 to 10, with 10 representing the greatest priority. The default is 5. The precise effects of this parameter are platform-specific, and are described later in this section.

The thread priority level cannot be set for offline index build threads.

**thread_prio settings and effects by platform.** The implementation of thread_prio differs between Linux/FreeBSD, Solaris, and Windows. In the following list, we discuss its effects on each of these platforms in turn:

- **Linux and FreeBSD:** We map thread_prio to a value to be supplied to the nice system call. Since a lower niceness value for a process indicates a higher process priority, increasing thread_prio has the effect of lowering the nice value.

Table 22.12 Mapping of thread_prio to nice values on Linux and FreeBSD

<table>
<thead>
<tr>
<th>thread_prio value</th>
<th>nice value</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>19</td>
</tr>
<tr>
<td>1</td>
<td>16</td>
</tr>
<tr>
<td>2</td>
<td>12</td>
</tr>
<tr>
<td>3</td>
<td>8</td>
</tr>
<tr>
<td>4</td>
<td>4</td>
</tr>
<tr>
<td>5</td>
<td>0</td>
</tr>
<tr>
<td>6</td>
<td>-4</td>
</tr>
<tr>
<td>7</td>
<td>-8</td>
</tr>
<tr>
<td>8</td>
<td>-12</td>
</tr>
<tr>
<td>9</td>
<td>-16</td>
</tr>
<tr>
<td>10</td>
<td>-20</td>
</tr>
</tbody>
</table>

Some operating systems may provide for a maximum process niceness level of 20, but this is not supported by all targeted versions; for this reason, we choose 19 as the maximum nice value that can be set.

- **Solaris:** Setting thread_prio on Solaris sets the Solaris FX priority, with mappings as shown in the following table:

Table 22.13 Mapping of thread_prio to FX priority on Solaris

<table>
<thead>
<tr>
<th>thread_prio value</th>
<th>Solaris FX priority</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>15</td>
</tr>
<tr>
<td>1</td>
<td>20</td>
</tr>
<tr>
<td>2</td>
<td>25</td>
</tr>
<tr>
<td>3</td>
<td>30</td>
</tr>
<tr>
<td>4</td>
<td>35</td>
</tr>
<tr>
<td>5</td>
<td>40</td>
</tr>
<tr>
<td>6</td>
<td>45</td>
</tr>
<tr>
<td>7</td>
<td>50</td>
</tr>
</tbody>
</table>
A thread_prio setting of 9 is mapped on Solaris to the special FX priority value 59, which means that the operating system also attempts to force the thread to run alone on its own CPU core.

- **Windows**: We map thread_prio to a Windows thread priority value passed to the Windows API SetThreadPriority() function. This mapping is shown in the following table:

<table>
<thead>
<tr>
<th>thread_prio value</th>
<th>Solaris FX priority</th>
</tr>
</thead>
<tbody>
<tr>
<td>8</td>
<td>55</td>
</tr>
<tr>
<td>9</td>
<td>59</td>
</tr>
<tr>
<td>10</td>
<td>60</td>
</tr>
</tbody>
</table>

### Table 22.14 Mapping of thread_prio to Windows thread priority

<table>
<thead>
<tr>
<th>thread_prio value</th>

<td>THREAD_PRIORITY_ABOVE_NORMAL</td>
</tr>
<tr>
<td>8 - 10</td>
<td>THREAD_PRIORITY_HIGHEST</td>
</tr>
</tbody>
</table>

The `type` attribute represents an NDB thread type. The thread types supported, and the range of permitted count values for each, are provided in the following list:

- **ldm**: Local query handler (DBLQH kernel block) that handles data. The more LDM threads that are used, the more highly partitioned the data becomes. Each LDM thread maintains its own sets of data and index partitions, as well as its own redo log. The value set for ldm must be one of the values 1, 2, 4, 6, 8, 12, 16, 24, or 32.

Changing the number of LDM threads normally requires a system restart to be effective and safe for cluster operations, this requirement is relaxed in certain cases, as explained later in this section. This is also true when this is done using MaxNoOfExecutionThreads.

Adding large tablespaces (hundreds of gigabytes or more) for Disk Data tables when using more than the default number of LDMs may cause issues with resource and CPU usage if DiskPageBufferMemory is not sufficiently large.

- **tc**: Transaction coordinator thread (DBTC kernel block) containing the state of an ongoing transaction. The maximum number of TC threads is 32.

Optimally, every new transaction can be assigned to a new TC thread. In most cases 1 TC thread per 2 LDM threads is sufficient to guarantee that this can happen. In cases where the number of writes is relatively small when compared to the number of reads, it is possible that only 1 TC thread per 4 LQH threads is required to maintain transaction states. Conversely, in applications that perform a great many updates, it may be necessary for the ratio of TC threads to LDM threads to approach 1 (for example, 3 TC threads to 4 LDM threads).

Setting tc to 0 causes TC handling to be done by the main thread. In most cases, this is effectively the same as setting it to 1.

Range: 0 - 32
• **main**: Data dictionary and transaction coordinator (**DBDIH** and **DBTC** kernel blocks), providing schema management. This is always handled by a single dedicated thread.
  
  Range: 1 only.

• **recv**: Receive thread (**CMVMI** kernel block). Each receive thread handles one or more sockets for communicating with other nodes in an NDB Cluster, with one socket per node. NDB Cluster supports multiple receive threads; the maximum is 16 such threads.
  
  Range: 1 - 16

• **send**: Send thread (**CMVMI** kernel block). To increase throughput, it is possible to perform sends from one or more separate, dedicated threads (maximum 8).

  In NDB 8.0.20 and later, due to changes in the multithreading implementation, using many send threads can have an adverse effect on scalability.

  Previously, all threads handled their own sending directly; this can still be made to happen by setting the number of send threads to 0 (this also happens when **MaxNoOfExecutionThreads** is set less than 10). While doing so can have an adverse impact on throughput, it can also in some cases provide decreased latency.

  Range: 0 - 16

• **rep**: Replication thread (**SUMA** kernel block). Asynchronous replication operations are always handled by a single, dedicated thread.

  Range: 1 only.

• **io**: File system and other miscellaneous operations. These are not demanding tasks, and are always handled as a group by a single, dedicated I/O thread.

  Range: 1 only.

• **watchdog**: Parameters settings associated with this type are actually applied to several threads, each having a specific use. These threads include the **SocketServer** thread, which receives connection setups from other nodes; the **SocketClient** thread, which attempts to set up connections to other nodes; and the thread watchdog thread that checks that threads are progressing.

  Range: 1 only.

• **idxbld**: Offline index build threads. Unlike the other thread types listed previously, which are permanent, these are temporary threads which are created and used only during node or system
restarts, or when running `ndb_restore --rebuild-indexes`. They may be bound to CPU sets which overlap with CPU sets bound to permanent thread types.

`thread_prio`, `realtime`, and `spintime` values cannot be set for offline index build threads. In addition, `count` is ignored for this type of thread.

If `idxbld` is not specified, the default behavior is as follows:

- Offline index build threads are not bound if the I/O thread is also not bound, and these threads use any available cores.
- If the I/O thread is bound, then the offline index build threads are bound to the entire set of bound threads, due to the fact that there should be no other tasks for these threads to perform.

Range: 0 - 1.

Changing `ThreadConfig` normally requires a system initial restart, but this requirement can be relaxed under certain circumstances:

- If, following the change, the number of LDM threads remains the same as before, nothing more than a simple node restart (rolling restart, or `N`) is required to implement the change.
- Otherwise (that is, if the number of LDM threads changes), it is still possible to effect the change using a node initial restart (NI) provided the following two conditions are met:
  a. Each LDM thread handles a maximum of 8 fragments, and
  b. The total number of table fragments is an integer multiple of the number of LDM threads.

In any other case, a system initial restart is needed to change this parameter.

**NDB** can distinguish between thread types by both of the following criteria:

- Whether the thread is an execution thread. Threads of type `main`, `ldm`, `recv`, `rep`, `tc`, and `send` are execution threads; `io`, `watchdog`, and `idxbld` threads are not considered execution threads.
- Whether the allocation of threads to a given task is permanent or temporary. Currently all thread types except `idxbld` are considered permanent; `idxbld` threads are regarded as temporary threads.

Simple examples:

```
# Example 1.
ThreadConfig=ldm={count=2,cpubind=1,2},main={cpubind=12},rep={cpubind=11}
# Example 2.
Threadconfig=main={cpubind=0},ldm={count=4,cpubind=1,2,5,6},io={cpubind=3}
```

It is usually desirable when configuring thread usage for a data node host to reserve one or more number of CPUs for operating system and other tasks. Thus, for a host machine with 24 CPUs, you might want to use 20 CPU threads (leaving 4 for other uses), with 8 LDM threads, 4 TC threads (half the number of LDM threads), 3 send threads, 3 receive threads, and 1 thread each for schema management, asynchronous replication, and I/O operations. (This is almost the same distribution of threads used when `MaxNoOfExecutionThreads` is set equal to 20.) The following `ThreadConfig` setting performs these assignments, additionally binding all of these threads to specific CPUs:

```
ThreadConfig=ldm{count=8,cpubind=1,2,3,4,5,6,7,8},main={cpubind=9},io={cpubind=9}, \
rep={cpubind=10},tc{count=4,cpubind=11,12,13,14},recv={count=3,cpubind=15,16,17}, \
```
It should be possible in most cases to bind the main (schema management) thread and the I/O thread to the same CPU, as we have done in the example just shown.

The following example incorporates groups of CPUs defined using both `cpuset` and `cpubind`, as well as use of thread prioritization.

```plaintext
ThreadConfig=ldm={count=4,cpuset=0-3,thread_prio=8,spintime=200}, \  ldm={count=4,cpubind=4-7,thread_prio=8,spintime=200}, \  tc={count=4,cpuset=8-9,thread_prio=6,send={count=2,thread_prio=10,cpubind=10-11}, \  main={count=1,cpubind=10},rep={count=1,cpubind=11}
```

In this case we create two LDM groups; the first uses `cpubind` and the second uses `cpuset`. `thread_prio` and `spintime` are set to the same values for each group. This means there are eight LDM threads in total. (You should ensure that `NoOfFragmentLogParts` is also set to 8.) The four TC threads use only two CPUs; it is possible when using `cpuset` to specify fewer CPUs than threads in the group. (This is not true for `cpubind`.) The send threads use two threads using `cpubind` to bind these threads to CPUs 10 and 11. The main and rep threads can reuse these CPUs.

This example shows how `ThreadConfig` and `NoOfFragmentLogParts` might be set up for a 24-CPU host with hyperthreading, leaving CPUs 10, 11, 22, and 23 available for operating system functions and interrupts:

```plaintext
NoOfFragmentLogParts=10
ThreadConfig=ldm={count=10,cpubind=0-4,12-16,thread_prio=9,spintime=200}, \  tc={count=4,cpubind=6-7,18-19,thread_prio=8},send={count=1,cpubind=8}, \  recv={count=1,cpubind=20},main={count=1,cpubind=9,thread_prio=8},rep={count=1,cpubind=9,21}, \  io={count=1,cpubind=9,21,thread_prio=8},watchdog={count=1,cpubind=9,21,thread_prio=9}
```

The next few examples include settings for `idxbld`. The first two of these demonstrate how a CPU set defined for `idxbld` can overlap those specified for other (permanent) thread types, the first using `cpuset` and the second using `cpubind`:

```plaintext
ThreadConfig=main,ldm={count=4,cpubind=1-4},tc={count=4,cpubind=5,6,7}, \  io={cpubind=8},idxbld={count=1,cpubind=1}
ThreadConfig=main,ldm={count=1,cpubind=1},idxbld={count=1,cpubind=1}
```

The next example specifies a CPU for the I/O thread, but not for the index build threads:

```plaintext
ThreadConfig=main,ldm={count=4,cpubind=1-4},tc={count=4,cpubind=5,6,7}, \  io={cpubind=8}
```

Since the `ThreadConfig` setting just shown locks threads to eight cores numbered 1 through 8, it is equivalent to the setting shown here:

```plaintext
ThreadConfig=main,ldm={count=4,cpubind=1-4},tc={count=4,cpubind=5,6,7}, \  io={cpubind=8},idxbld={cpuset=1,2,3,4,5,6,7,8}
```

In order to take advantage of the enhanced stability that the use of `ThreadConfig` offers, it is necessary to insure that CPUs are isolated, and that they not subject to interrupts, or to being scheduled for other tasks by the operating system. On many Linux systems, you can do this by setting `IRQBALANCE_BANNED_CPUS` in `/etc/sysconfig/irqbalance` to `0xFFFFF0`, and by using the `isolcpus` boot option in `grub.conf`. For specific information, see your operating system or platform documentation.

**Disk Data Configuration Parameters.** Configuration parameters affecting Disk Data behavior include the following:

- `DiskPageBufferEntries`
### DiskPageBufferMemory

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>64M</td>
</tr>
<tr>
<td>Range</td>
<td>4M - 1T</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This determines the amount of space used for caching pages on disk, and is set in the [ndbd] or [ndbd default] section of the config.ini file.

**Note**

Previously, this parameter was specified as a number of 32 KB pages. Beginning with NDB 8.0.19, it is specified as a number of bytes.

If the value for DiskPageBufferMemory is set too low in conjunction with using more than the default number of LDM threads in ThreadConfig (for example {ldm=6...}), problems can arise when trying to add a large (for example 500G) data file to a disk-based NDB table, wherein the process takes indefinitely long while occupying one of the CPU cores.

This is due to the fact that, as part of adding a data file to a tablespace, extent pages are locked into memory in an extra PGMAN worker thread, for quick metadata access. When adding a large file, this worker has insufficient memory for all of the data file metadata. In such cases, you should either increase DiskPageBufferMemory, or add smaller tablespace files. You may also need to adjust DiskPageBufferEntries.
You can query the `ndbinfo.diskpagebuffer` table to help determine whether the value for this parameter should be increased to minimize unnecessary disk seeks. See Section 22.5.14.20, “The ndbinfo diskpagebuffer Table”, for more information.

**SharedGlobalMemory**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>128M</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 64T</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter determines the amount of memory that is used for log buffers, disk operations (such as page requests and wait queues), and metadata for table spaces, log file groups, UNDO files, and data files. The shared global memory pool also provides memory used for satisfying the memory requirements of the `UNDO_BUFFER_SIZE` option used with `CREATE LOGFILE GROUP` and `ALTER LOGFILE GROUP` statements, including any default value implied for this option by the setting of the `InitialLogFileGroup` data node configuration parameter. `SharedGlobalMemory` can be set in the `[ndbd]` or `[ndbd default]` section of the `config.ini` configuration file, and is measured in bytes.

The default value is 128M.

**DiskIOThreadPool**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>threads</td>
</tr>
<tr>
<td>Default</td>
<td>2</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter determines the number of unbound threads used for Disk Data file access. Before `DiskIOThreadPool` was introduced, exactly one thread was spawned for each Disk Data file, which could lead to performance issues, particularly when using very large data files. With `DiskIOThreadPool`, you can—for example—access a single large data file using several threads working in parallel.

This parameter applies to Disk Data I/O threads only.

The optimum value for this parameter depends on your hardware and configuration, and includes these factors:

- **Physical distribution of Disk Data files.** You can obtain better performance by placing data files, undo log files, and the data node file system on separate physical disks. If you do this with some or all
of these sets of files, then you can (and should) set DiskIOThreadPool higher to enable separate threads to handle the files on each disk.

In NDB 8.0.19 and later, you should also disable DiskDataUsingSameDisk when using a separate disk or disks for Disk Data files; this increases the rate at which checkpoints of Disk Data tablespaces can be performed.

• **Disk performance and types.** The number of threads that can be accommodated for Disk Data file handling is also dependent on the speed and throughput of the disks. Faster disks and higher throughput allow for more disk I/O threads. Our test results indicate that solid-state disk drives can handle many more disk I/O threads than conventional disks, and thus higher values for DiskIOThreadPool.

Decreasing TimeBetweenGlobalCheckpoints is also recommended when using solid-state disk drives, in particular those using NVMe. See also Disk Data latency parameters.

The default value for this parameter is 2.

• **Disk Data file system parameters.** The parameters in the following list make it possible to place NDB Cluster Disk Data files in specific directories without the need for using symbolic links.

  • **FileSystemPathDD**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>filename</td>
</tr>
<tr>
<td>Default</td>
<td>FileSystemPath</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>IN</td>
</tr>
</tbody>
</table>

If this parameter is specified, then NDB Cluster Disk Data data files and undo log files are placed in the indicated directory. This can be overridden for data files, undo log files, or both, by specifying values for FileSystemPathDataFiles, FileSystemPathUndoFiles, or both, as explained for these parameters. It can also be overridden for data files by specifying a path in the ADD DATAFILE clause of a CREATE TABLESPACE or ALTER TABLESPACE statement, and for undo log files by specifying a path in the ADD UNDOFILE clause of a CREATE LOGFILE GROUP or ALTER LOGFILE GROUP statement. If FileSystemPathDD is not specified, then FileSystemPath is used.

If a FileSystemPathDD directory is specified for a given data node (including the case where the parameter is specified in the [ndbd default] section of the config.ini file), then starting that data node with --initial causes all files in the directory to be deleted.

• **FileSystemPathDataFiles**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>filename</td>
</tr>
<tr>
<td>Default</td>
<td>FileSystemPathDD</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>IN</td>
</tr>
</tbody>
</table>

If this parameter is specified, then NDB Cluster Disk Data data files are placed in the indicated directory. This overrides any value set for FileSystemPathDD. This parameter can be overridden for a given data file by specifying a path in the ADD DATAFILE clause of a CREATE TABLESPACE or...
The `ALTER TABLESPACE` statement used to create that data file. If `FileSystemPathDataFiles` is not specified, then `FileSystemPathDD` is used (or `FileSystemPath`, if `FileSystemPathDD` has also not been set).

If a `FileSystemPathDataFiles` directory is specified for a given data node (including the case where the parameter is specified in the `[ndbd default]` section of the `config.ini` file), then starting that data node with `--initial` causes all files in the directory to be deleted.

- `FileSystemPathUndoFiles`

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>filename</td>
</tr>
<tr>
<td>Default</td>
<td>FileSystemPathDD</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>IN</td>
</tr>
</tbody>
</table>

If this parameter is specified, then NDB Cluster Disk Data undo log files are placed in the indicated directory. This overrides any value set for `FileSystemPathDD`. This parameter can be overridden for a given data file by specifying a path in the ADD UNDO clause of a `CREATE LOGFILE GROUP` or `ALTER LOGFILE GROUP` statement used to create that data file. If `FileSystemPathUndoFiles` is not specified, then `FileSystemPathDD` is used (or `FileSystemPath`, if `FileSystemPathDD` has also not been set).

If a `FileSystemPathUndoFiles` directory is specified for a given data node (including the case where the parameter is specified in the `[ndbd default]` section of the `config.ini` file), then starting that data node with `--initial` causes all files in the directory to be deleted.

For more information, see Section 22.5.10.1, “NDB Cluster Disk Data Objects”.

- Disk Data object creation parameters. The next two parameters enable you—when starting the cluster for the first time—to cause a Disk Data log file group, tablespace, or both, to be created without the use of SQL statements.

- InitialLogFileGroup

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>string</td>
</tr>
<tr>
<td>Default</td>
<td>[see documentation]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>S</td>
</tr>
</tbody>
</table>

This parameter can be used to specify a log file group that is created when performing an initial start of the cluster. `InitialLogFileGroup` is specified as shown here:

```
InitialLogFileGroup = [name=name;] [undo_buffer_size=size;] file-specification-list
file-specification-list:  
  file-specification[; file-specification[; ...]]
file-specification:
```

4039
The name of the log file group is optional and defaults to DEFAULT-LG. The undo_buffer_size is also optional; if omitted, it defaults to 64M. Each file-specification corresponds to an undo log file, and at least one must be specified in the file-specification-list. Undo log files are placed according to any values that have been set for FileSystemPath, FileSystemPathDD, and FileSystemPathUndoFiles, just as if they had been created as the result of a CREATE LOGFILE GROUP or ALTER LOGFILE GROUP statement.

Consider the following:

```
InitialLogFileGroup = name=LG1; undo_buffer_size=128M; undo1.log:250M; undo2.log:150M
```

This is equivalent to the following SQL statements:

```
CREATE LOGFILE GROUP LG1
  ADD UNDOFILE 'undo1.log'
  INITIAL_SIZE 250M
  UNDO_BUFFER_SIZE 128M
  ENGINE NDBCLUSTER;

ALTER LOGFILE GROUP LG1
  ADD UNDOFILE 'undo2.log'
  INITIAL_SIZE 150M
  ENGINE NDBCLUSTER;
```

This logfile group is created when the data nodes are started with `--initial`.

Resources for the initial log file group are added to the global memory pool along with those indicated by the value of `SharedGlobalMemory`.

This parameter, if used, should always be set in the [ndbd default] section of the `config.ini` file. The behavior of an NDB Cluster when different values are set on different data nodes is not defined.

• InitialTablespace

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>string</td>
</tr>
<tr>
<td>Default</td>
<td>[see documentation]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>S</td>
</tr>
</tbody>
</table>

This parameter can be used to specify an NDB Cluster Disk Data tablespace that is created when performing an initial start of the cluster. InitialTablespace is specified as shown here:

```
InitialTablespace = [name=name;] [extent_size=size;] file-specification-list
```

The name of the tablespace is optional and defaults to DEFAULT-TS. The extent_size is also optional; it defaults to 1M. The file-specification-list uses the same syntax as shown with the InitialLogfileGroup parameter, the only difference being that each file-specification used with InitialTablespace corresponds to a data file. At least one must be specified in the file-specification-list. Data files are placed according to any values that have been set for
FilesystemPath, FilesystemPathDD, and FilesystemPathDataFiles, just as if they had been created as the result of a `CREATE TABLESPACE` or `ALTER TABLESPACE` statement.

For example, consider the following line specifying `InitialTablespace` in the `[ndbd default]` section of the `config.ini` file (as with `InitialLogfileGroup`, this parameter should always be set in the `[ndbd default]` section, as the behavior of an NDB Cluster when different values are set on different data nodes is not defined):

```
InitialTablespace = name=TS1; extent_size=8M; data1.dat:2G; data2.dat:4G
```

This is equivalent to the following SQL statements:

```
CREATE TABLESPACE TS1
  ADD DATAFILE 'data1.dat'
  EXTENT_SIZE 8M
  INITIAL_SIZE 2G
  ENGINE NDBCLUSTER;

ALTER TABLESPACE TS1
  ADD DATAFILE 'data2.dat'
  INITIAL_SIZE 4G
  ENGINE NDBCLUSTER;
```

This tablespace is created when the data nodes are started with `--initial`, and can be used whenever creating NDB Cluster Disk Data tables thereafter.

- **Disk Data latency parameters.** The two parameters listed here can be used to improve handling of latency issues with NDB Cluster Disk Data tables.

  - **MaxDiskDataLatency**

    | Version (or later) | NDB 8.0.19 |
    |-------------------|------------|
    | Type or units     | ms         |
    | Default           | 0          |
    | Range             | 0 - 8000   |
    | Restart Type      | N          |
    | Added             | NDB 8.0.19 |

  This parameter controls the maximum allowed mean latency for disk access (maximum 8000 milliseconds). When this limit is reached, NDB begins to abort transactions in order to decrease pressure on the Disk Data I/O subsystem. Use 0 to disable the latency check.

  - **DiskDataUsingSameDisk**

    | Version (or later) | NDB 8.0.19 |
    |-------------------|------------|
    | Type or units     | boolean    |
    | Default           | true       |
    | Range             | ...        |
    | Restart Type      | N          |
Set this parameter to `false` if your Disk Data tablespaces use one or more separate disks. Doing so allows checkpoints to tablespaces to be executed at a higher rate than normally used for when disks are shared.

When `DiskDataUsingSameDisk` is `true`, NDB decreases the rate of Disk Data checkpointing whenever an in-memory checkpoint is in progress to help ensure that disk load remains constant.

**Disk Data and GCP Stop errors.**  Errors encountered when using Disk Data tables such as `Node nodeid killed this node because GCP stop was detected (error 2303)` are often referred to as “GCP stop errors”. Such errors occur when the redo log is not flushed to disk quickly enough; this is usually due to slow disks and insufficient disk throughput.

You can help prevent these errors from occurring by using faster disks, and by placing Disk Data files on a separate disk from the data node file system. Reducing the value of `TimeBetweenGlobalCheckpoints` tends to decrease the amount of data to be written for each global checkpoint, and so may provide some protection against redo log buffer overflows when trying to write a global checkpoint; however, reducing this value also permits less time in which to write the GCP, so this must be done with caution.

In addition to the considerations given for `DiskPageBufferMemory` as explained previously, it is also very important that the `DiskIOThreadPool` configuration parameter be set correctly; having `DiskIOThreadPool` set too high is very likely to cause GCP stop errors (Bug #37227).

GCP stops can be caused by save or commit timeouts; the `TimeBetweenEpochsTimeout` data node configuration parameter determines the timeout for commits. However, it is possible to disable both types of timeouts by setting this parameter to 0.

**Parameters for configuring send buffer memory allocation.**  Send buffer memory is allocated dynamically from a memory pool shared between all transporters, which means that the size of the send buffer can be adjusted as necessary. (Previously, the NDB kernel used a fixed-size send buffer for every node in the cluster, which was allocated when the node started and could not be changed while the node was running.) The `TotalSendBufferMemory` and `OverLoadLimit` data node configuration parameters permit the setting of limits on this memory allocation. For more information about the use of these parameters (as well as `SendBufferMemory`), see Section 22.3.3.14, “Configuring NDB Cluster Send Buffer Parameters”.

- `ExtraSendBufferMemory`

  This parameter specifies the amount of transporter send buffer memory to allocate in addition to any set using `TotalSendBufferMemory`, `SendBufferMemory`, or both.

- `TotalSendBufferMemory`

  This parameter is used to determine the total amount of memory to allocate on this node for shared send buffer memory among all configured transporters.

  If this parameter is set, its minimum permitted value is 256KB; 0 indicates that the parameter has not been set. For more detailed information, see Section 22.3.3.14, “Configuring NDB Cluster Send Buffer Parameters”.

See also Section 22.5.7, “Adding NDB Cluster Data Nodes Online”.

**Redo log over-commit handling.**  It is possible to control a data node’s handling of operations when too much time is taken flushing redo logs to disk. This occurs when a given redo log flush takes longer than `RedoOverCommitLimit` seconds, more than `RedoOverCommitCounter` times, causing any pending transactions to be aborted. When this happens, the API node that sent the transaction can handle
the operations that should have been committed either by queuing the operations and re-trying them, or by aborting them, as determined by DefaultOperationRedoProblemAction. The data node configuration parameters for setting the timeout and number of times it may be exceeded before the API node takes this action are described in the following list:

- **RedoOverCommitCounter**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>3</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

- **RedoOverCommitLimit**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>seconds</td>
</tr>
<tr>
<td>Default</td>
<td>20</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

When RedoOverCommitLimit is exceeded when trying to write a given redo log to disk this many times or more, any transactions that were not committed as a result are aborted, and an API node where any of these transactions originated handles the operations making up those transactions according to its value for DefaultOperationRedoProblemAction (by either queuing the operations to be re-tried, or aborting them).

- **RedoOverCommitLimit**

This parameter sets an upper limit in seconds for trying to write a given redo log to disk before timing out. The number of times the data node tries to flush this redo log, but takes longer than RedoOverCommitLimit, is kept and compared with RedoOverCommitCounter, and when flushing takes too long more times than the value of that parameter, any transactions that were not committed as a result of the flush timeout are aborted. When this occurs, the API node where any of these transactions originated handles the operations making up those transactions according to its DefaultOperationRedoProblemAction setting (it either queues the operations to be re-tried, or aborts them).
Controlling restart attempts.  It is possible to exercise finely-grained control over restart attempts by data nodes when they fail to start using the MaxStartFailRetries and StartFailRetryDelay data node configuration parameters.

MaxStartFailRetries limits the total number of retries made before giving up on starting the data node, StartFailRetryDelay sets the number of seconds between retry attempts. These parameters are listed here:

- **StartFailRetryDelay**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Use this parameter to set the number of seconds between restart attempts by the data node in the event on failure on startup. The default is 0 (no delay).

Both this parameter and MaxStartFailRetries are ignored unless StopOnError is equal to 0.

- **MaxStartFailRetries**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>3</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Use this parameter to limit the number restart attempts made by the data node in the event that it fails on startup. The default is 3 attempts.

Both this parameter and StartFailRetryDelay are ignored unless StopOnError is equal to 0.

**NDB index statistics parameters.** The parameters in the following list relate to NDB index statistics generation.

- **IndexStatAutoCreate**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0, 1</td>
</tr>
<tr>
<td>Restart Type</td>
<td>S</td>
</tr>
</tbody>
</table>

Enable (set equal to 1) or disable (set equal to 0) automatic statistics collection when indexes are created. Disabled by default.
Enable (set equal to 1) or disable (set equal to 0) monitoring of indexes for changes and trigger automatic statistics updates these are detected. The amount and degree of change needed to trigger the updates are determined by the settings for the `IndexStatTriggerPct` and `IndexStatTriggerScale` options.

- **IndexStatSaveSize**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>32768</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFEEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>IN</td>
</tr>
</tbody>
</table>

Maximum space in bytes allowed for the saved statistics of any given index in the NDB system tables and in the mysqld memory cache.

At least one sample is always produced, regardless of any size limit. This size is scaled by `IndexStatSaveScale`.

The size specified by `IndexStatSaveSize` is scaled by the value of `IndexStatTriggerPct` for a large index, times 0.01. This is further multiplied by the logarithm to the base 2 of the index size. Setting `IndexStatTriggerPct` equal to 0 disables the scaling effect.

- **IndexStatSaveScale**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>percentage</td>
</tr>
<tr>
<td>Default</td>
<td>100</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFEEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>IN</td>
</tr>
</tbody>
</table>

The size specified by `IndexStatSaveSize` is scaled by the value of `IndexStatTriggerPct` for a large index, times 0.01. This is further multiplied by the logarithm to the base 2 of the index size. Setting `IndexStatTriggerPct` equal to 0 disables the scaling effect.

- **IndexStatTriggerPct**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>percentage</td>
</tr>
<tr>
<td>Default</td>
<td>100</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFEEFF)</td>
</tr>
</tbody>
</table>
Percentage change in updates that triggers an index statistics update. The value is scaled by \textit{IndexStatTriggerScale}. You can disable this trigger altogether by setting \textit{IndexStatTriggerPct} to 0.

- \textbf{IndexStatTriggerScale}

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>percentage</td>
</tr>
<tr>
<td>Default</td>
<td>100</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

Scale \textit{IndexStatTriggerPct} by this amount times 0.01 for a large index. A value of 0 disables scaling.

- \textbf{IndexStatUpdateDelay}

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>seconds</td>
</tr>
<tr>
<td>Default</td>
<td>60</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

Minimum delay in seconds between automatic index statistics updates for a given index. Setting this variable to 0 disables any delay. The default is 60 seconds.

\textbf{Restart types.} Information about the restart types used by the parameter descriptions in this section is shown in the following table:

\begin{center}
\begin{tabular}{|c|c|}
\hline
\textbf{Symbol} & \textbf{Restart Type} & \textbf{Description} \\
\hline
N & Node & The parameter can be updated using a rolling restart (see Section 22.5.5, “Performing a Rolling Restart of an NDB Cluster”) \\
\hline
S & System & All cluster nodes must be shut down completely, then restarted, to effect a change in this parameter \\
\hline
I & Initial & Data nodes must be restarted using the \texttt{--initial} option \\
\hline
\end{tabular}
\end{center}

\textbf{22.3.3.7 Defining SQL and Other API Nodes in an NDB Cluster}

The [mysqld] and [api] sections in the config.ini file define the behavior of the MySQL servers (SQL nodes) and other applications (API nodes) used to access cluster data. None of the parameters shown is required. If no computer or host name is provided, any host can use this SQL or API node.

Generally speaking, a [mysqld] section is used to indicate a MySQL server providing an SQL interface to the cluster, and an [api] section is used for applications other than mysqld processes accessing cluster data, but the two designations are actually synonymous; you can, for instance, list parameters for a MySQL server acting as an SQL node in an [api] section.
Note

For a discussion of MySQL server options for NDB Cluster, see MySQL Server Options for NDB Cluster. For information about MySQL server system variables relating to NDB Cluster, see NDB Cluster System Variables.

- **Id**

<table>
<thead>

<td>1 - 255</td>
</tr>
<tr>
<td>Restart Type</td>
<td>IS</td>
</tr>
</tbody>
</table>

The **Id** is an integer value used to identify the node in all cluster internal messages. The permitted range of values is 1 to 255 inclusive. This value must be unique for each node in the cluster, regardless of the type of node.

Note

In NDB 8.0.18 and later, data node IDs must be less than 145. If you plan to deploy a large number of data nodes, it is a good idea to limit the node IDs for API nodes (and management nodes) to values greater than 144. (Previous to NDB 8.0.18, the maximum supported value for a data node ID was 48.)

**NodeId** is the preferred parameter name to use when identifying API nodes. (**Id** continues to be supported for backward compatibility, but is now deprecated and generates a warning when used. It is also subject to future removal.)

- **ConnectionMap**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>string</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Specifies which data nodes to connect.

- **NodeId**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 255</td>
</tr>
</tbody>
</table>
The **NodeId** is an integer value used to identify the node in all cluster internal messages. The permitted range of values is 1 to 255 inclusive. This value must be unique for each node in the cluster, regardless of the type of node.

**Note**

In NDB 8.0.18 and later, data node IDs must be less than 145. If you plan to deploy a large number of data nodes, it is a good idea to limit the node IDs for API nodes (and management nodes) to values greater than 144. (Previous to NDB 8.0.18, the maximum supported value for a data node ID was 48.)

**NodeId** is the preferred parameter name to use when identifying management nodes. An alias, **Id**, was used for this purpose in very old versions of NDB Cluster, and continues to be supported for backward compatibility; it is now deprecated and generates a warning when used, and is subject to removal in a future release of NDB Cluster.

- **ExecuteOnComputer**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>name</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>S</td>
</tr>
<tr>
<td>Deprecated</td>
<td>Yes (in NDB 7.5)</td>
</tr>
</tbody>
</table>

This refers to the **Id** set for one of the computers (hosts) defined in a *[computer]* section of the configuration file.

**Important**

This parameter is deprecated, and is subject to removal in a future release. Use the **HostName** parameter instead.

- **HostName**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>name or IP address</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>N</td>
</tr>
</tbody>
</table>

Specifying this parameter defines the hostname of the computer on which the SQL node (API node) is to reside. To specify a hostname, either this parameter or **ExecuteOnComputer** is required.
If no HostName or ExecuteOnComputer is specified in a given [mysql] or [api] section of the config.ini file, then an SQL or API node may connect using the corresponding "slot" from any host which can establish a network connection to the management server host machine. This differs from the default behavior for data nodes, where localhost is assumed for HostName unless otherwise specified.

• LocationDomainId

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 16</td>
</tr>
<tr>
<td>Restart Type</td>
<td>S</td>
</tr>
</tbody>
</table>

Assigns an SQL or other API node to a specific availability domain (also known as an availability zone) within a cloud. By informing NDB which nodes are in which availability domains, performance can be improved in a cloud environment in the following ways:

• If requested data is not found on the same node, reads can be directed to another node in the same availability domain.

• Communication between nodes in different availability domains are guaranteed to use NDB transporters' WAN support without any further manual intervention.

• The transporter’s group number can be based on which availability domain is used, such that also SQL and other API nodes communicate with local data nodes in the same availability domain whenever possible.

• The arbitrator can be selected from an availability domain in which no data nodes are present, or, if no such availability domain can be found, from a third availability domain.

LocationDomainId takes an integer value between 0 and 16 inclusive, with 0 being the default; using 0 is the same as leaving the parameter unset.

• ArbitrationRank

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>0-2</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 2</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter defines which nodes can act as arbitrators. Both management nodes and SQL nodes can be arbitrators. A value of 0 means that the given node is never used as an arbitrator, a value of 1 gives the node high priority as an arbitrator, and a value of 2 gives it low priority. A normal configuration uses the management server as arbitrator, setting its ArbitrationRank to 1 (the default for management nodes) and those for all SQL nodes to 0 (the default for SQL nodes).

By setting ArbitrationRank to 0 on all management and SQL nodes, you can disable arbitration completely. You can also control arbitration by overriding this parameter; to do so, set the Arbitration parameter in the [ndbd default] section of the config.ini global configuration file.
• **ArbitrationDelay**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Setting this parameter to any other value than 0 (the default) means that responses by the arbitrator to arbitration requests are delayed by the stated number of milliseconds. It is usually not necessary to change this value.

• **BatchByteSize**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>16K</td>
</tr>
<tr>
<td>Range</td>
<td>1K - 1M</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

For queries that are translated into full table scans or range scans on indexes, it is important for best performance to fetch records in properly sized batches. It is possible to set the proper size both in terms of number of records (**BatchSize**) and in terms of bytes (**BatchByteSize**). The actual batch size is limited by both parameters.

The speed at which queries are performed can vary by more than 40% depending upon how this parameter is set.

This parameter is measured in bytes. The default value is 16K.

• **BatchSize**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>records</td>
</tr>
<tr>
<td>Default</td>
<td>256</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 992</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter is measured in number of records and is by default set to 256. The maximum size is 992.

• **ExtraSendBufferMemory**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>
This parameter specifies the amount of transporter send buffer memory to allocate in addition to any that has been set using `TotalSendBufferMemory`, `SendBufferMemory`, or both.

- **HeartbeatThreadPriority**

  ```
  HeartbeatThreadPriority = policy[, priority]
  
  policy: {FIFO | RR}
  ```

  When setting this parameter, you must specify a policy. This is one of FIFO (first in, first in) or RR (round robin). This followed optionally by the priority (an integer).

- **MaxScanBatchSize**

  The batch size is the size of each batch sent from each data node. Most scans are performed in parallel to protect the MySQL Server from receiving too much data from many nodes in parallel; this parameter sets a limit to the total batch size over all nodes.

  The default value of this parameter is set to 256KB. Its maximum size is 16MB.

- **TotalSendBufferMemory**
### Restart Type

| Restart Type | N |

This parameter is used to determine the total amount of memory to allocate on this node for shared send buffer memory among all configured transporters.

If this parameter is set, its minimum permitted value is 256KB; 0 indicates that the parameter has not been set. For more detailed information, see Section 22.3.3.14, "Configuring NDB Cluster Send Buffer Parameters".

- **AutoReconnect**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
</tbody>
</table>

This parameter is *false* by default. This forces disconnected API nodes (including MySQL Servers acting as SQL nodes) to use a new connection to the cluster rather than attempting to re-use an existing one, as re-use of connections can cause problems when using dynamically_allocated node IDs. (Bug #45921)

**Note**

This parameter can be overridden using the NDB API. For more information, see `Ndb_cluster_connection::set_auto_reconnect()` and `Ndb_cluster_connection::get_auto_reconnect()`.

- **DefaultOperationRedoProblemAction**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>enumeration</td>
</tr>
<tr>
<td>Default</td>
<td>QUEUE</td>
</tr>
<tr>
<td>Range</td>
<td>ABORT, QUEUE</td>
</tr>
</tbody>
</table>

This parameter (along with `RedoOverCommitLimit` and `RedoOverCommitCounter`) controls the data node’s handling of operations when too much time is taken flushing redo logs to disk. This occurs when a given redo log flush takes longer than `RedoOverCommitLimit` seconds, more than `RedoOverCommitCounter` times, causing any pending transactions to be aborted.

When this happens, the node can respond in either of two ways, according to the value of `DefaultOperationRedoProblemAction`, listed here:

- **ABORT**: Any pending operations from aborted transactions are also aborted.
- **QUEUE**: Pending operations from transactions that were aborted are queued up to be re-tried. This is the default. Pending operations are still aborted when the redo log runs out of space—that is, when `P_TAIL_PROBLEM` errors occur.
NDB Cluster Configuration Files

- **DefaultHashMapSize**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>buckets</td>
</tr>
<tr>
<td>Default</td>
<td>3840</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 3840</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

The size of the table hash maps used by NDB is configurable using this parameter. 
**DefaultHashMapSize** can take any of three possible values (0, 240, 3840). These values and their effects are described in the following table.

**Table 22.16 DefaultHashMapSize parameter values**

<table>
<thead>
<tr>
<th>Value</th>
<th>Description / Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Use the lowest value set, if any, for this parameter among all data nodes and API nodes in the cluster; if it is not set on any data or API node, use the default value.</td>
</tr>
<tr>
<td>240</td>
<td>Old default hash map size</td>
</tr>
<tr>
<td>3840</td>
<td>Hash map size used by default in NDB 8.0</td>
</tr>
</tbody>
</table>

The original intended use for this parameter was to facilitate upgrades and downgrades to and from older NDB Cluster versions, in which the hash map size differed, due to the fact that this change was not otherwise backward compatible. This is not an issue when upgrading to or downgrading from NDB Cluster 8.0.

- **Wan**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Use WAN TCP setting as default.

- **ConnectBackoffMaxTime**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

In an NDB Cluster with many unstarted data nodes, the value of this parameter can be raised to circumvent connection attempts to data nodes which have not yet begun to function in the cluster, as well as moderate high traffic to management nodes. As long as the API node is not connected to any new data nodes, the value of the **StartConnectBackoffMaxTime** parameter is applied; otherwise,
ConnectBackoffMaxTime is used to determine the length of time in milliseconds to wait between connection attempts.

Time elapsed during node connection attempts is not taken into account when calculating elapsed time for this parameter. The timeout is applied with approximately 100 ms resolution, starting with a 100 ms delay; for each subsequent attempt, the length of this period is doubled until it reaches ConnectBackoffMaxTime milliseconds, up to a maximum of 100000 ms (100s).

Once the API node is connected to a data node and that node reports (in a heartbeat message) that it has connected to other data nodes, connection attempts to those data nodes are no longer affected by this parameter, and are made every 100 ms thereafter until connected. Once a data node has started, it can take up HeartbeatIntervalDbApi for the API node to be notified that this has occurred.

- **StartConnectBackoffMaxTime**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

In an NDB Cluster with many unstarted data nodes, the value of this parameter can be raised to circumvent connection attempts to data nodes which have not yet begun to function in the cluster, as well as moderate high traffic to management nodes. As long as the API node is not connected to any new data nodes, the value of the StartConnectBackoffMaxTime parameter is applied; otherwise, ConnectBackoffMaxTime is used to determine the length of time in milliseconds to wait between connection attempts.

Time elapsed during node connection attempts is not taken into account when calculating elapsed time for this parameter. The timeout is applied with approximately 100 ms resolution, starting with a 100 ms delay; for each subsequent attempt, the length of this period is doubled until it reaches StartConnectBackoffMaxTime milliseconds, up to a maximum of 100000 ms (100s).

Once the API node is connected to a data node and that node reports (in a heartbeat message) that it has connected to other data nodes, connection attempts to those data nodes are no longer affected by this parameter, and are made every 100 ms thereafter until connected. Once a data node has started, it can take up HeartbeatIntervalDbApi for the API node to be notified that this has occurred.

**API Node Debugging Parameters.** You can use the ApiVerbose configuration parameter to enable debugging output from a given API node. This parameter takes an integer value. 0 is the default, and disables such debugging; 1 enables debugging output to the cluster log; 2 adds DBDICT debugging output as well. (Bug #20638450) See also DUMP 1229.

You can also obtain information from a MySQL server running as an NDB Cluster SQL node using SHOW STATUS in the mysql client, as shown here:

```sql
mysql> SHOW STATUS LIKE 'ndb%';
+-----------------------------+----------------+
| Variable_name               | Value          |
+-----------------------------+----------------+
| Ndb_cluster_node_id         | 5              |
| Ndb_config_from_host        | 198.51.100.112 |
| Ndb_config_from_port        | 1186           |
| Ndb_number_of_storage_nodes | 4              |
+-----------------------------+----------------+
4 rows in set (0.02 sec)
```
For information about the status variables appearing in the output from this statement, see NDB Cluster Status Variables.

### Note

To add new SQL or API nodes to the configuration of a running NDB Cluster, it is necessary to perform a rolling restart of all cluster nodes after adding new [mysqld] or [api] sections to the config.ini file (or files, if you are using more than one management server). This must be done before the new SQL or API nodes can connect to the cluster.

It is *not* necessary to perform any restart of the cluster if new SQL or API nodes can employ previously unused API slots in the cluster configuration to connect to the cluster.

### Restart types

Information about the restart types used by the parameter descriptions in this section is shown in the following table:

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Restart Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>N</td>
<td>Node</td>
<td>The parameter can be updated using a rolling restart (see Section 22.5.5, “Performing a Rolling Restart of an NDB Cluster”)</td>
</tr>
<tr>
<td>S</td>
<td>System</td>
<td>All cluster nodes must be shut down completely, then restarted, to effect a change in this parameter</td>
</tr>
<tr>
<td>I</td>
<td>Initial</td>
<td>Data nodes must be restarted using the <code>--initial</code> option</td>
</tr>
</tbody>
</table>

### 22.3.3.8 Defining the System

The [system] section is used for parameters applying to the cluster as a whole. The Name system parameter is used with MySQL Enterprise Monitor; ConfigGenerationNumber and PrimaryMGMNode are not used in production environments. Except when using NDB Cluster with MySQL Enterprise Monitor, is not necessary to have a [system] section in the config.ini file.

More information about these parameters can be found in the following list:

- **ConfigGenerationNumber**
  
<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFFFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Configuration generation number. This parameter is currently unused.

- **Name**
  
<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>string</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
</tbody>
</table>
NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>Restart Type</th>
<th>N</th>
</tr>
</thead>
</table>

Set a name for the cluster. This parameter is required for deployments with MySQL Enterprise Monitor; it is otherwise unused.

You can obtain the value of this parameter by checking the `Ndb_system_name` status variable. In NDB API applications, you can also retrieve it using `get_system_name()`.

- **PrimaryMGMNode**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Node ID of the primary management node. This parameter is currently unused.

**Restart types.** Information about the restart types used by the parameter descriptions in this section is shown in the following table:

**Table 22.18 NDB Cluster restart types**

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Restart Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>N</td>
<td>Node</td>
<td>The parameter can be updated using a rolling restart (see Section 22.5.5, “Performing a Rolling Restart of an NDB Cluster”)</td>
</tr>
<tr>
<td>S</td>
<td>System</td>
<td>All cluster nodes must be shut down completely, then restarted, to effect a change in this parameter</td>
</tr>
<tr>
<td>I</td>
<td>Initial</td>
<td>Data nodes must be restarted using the <code>--initial</code> option</td>
</tr>
</tbody>
</table>

**22.3.3.9 MySQL Server Options and Variables for NDB Cluster**

This section provides information about MySQL server options, server and status variables that are specific to NDB Cluster. For general information on using these, and for other options and variables not specific to NDB Cluster, see Section 5.1, “The MySQL Server”.

For NDB Cluster configuration parameters used in the cluster configuration file (usually named `config.ini`), see Section 22.3, “Configuration of NDB Cluster”.

**MySQL Server Options for NDB Cluster**

This section provides descriptions of `mysqld` server options relating to NDB Cluster. For information about `mysqld` options not specific to NDB Cluster, and for general information about the use of options with `mysqld`, see Section 5.1.7, “Server Command Options”.

For information about command-line options used with other NDB Cluster processes (`ndbd`, `ndb_mgmd`, and `ndb_mgm`), see Section 22.4.32, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”. For information about command-line options used with NDB utility programs (such as `ndb_desc`, `ndb_size.pl`, and `ndb_show_tables`), see Section 22.4, “NDB Cluster Programs”.

- `--ndbcluster`

**Command-Line Format**

`--ndbcluster [=value]`
The `ndbcluster` storage engine is necessary for using NDB Cluster. If a `mysqld` binary includes support for the `ndbcluster` storage engine, the engine is disabled by default. Use the `--ndbcluster` option to enable it. Use `--skip-ndbcluster` to explicitly disable the engine.

The `--ndbcluster` option is ignored (and the NDB storage engine is not enabled) if `--initialize` is also used. (It is neither necessary nor desirable to use this option together with `--initialize`.)

- `--ndb-allow-copying-alter-table=[ON|OFF]`

Let `ALTER TABLE` and other DDL statements use copying operations on NDB tables. Set to `OFF` to keep this from happening; doing so may improve performance of critical applications.

- `--ndb-batch-size=#`

This sets the size in bytes that is used for NDB transaction batches.

- `--ndb-cluster-connection-pool=#`
By setting this option to a value greater than 1 (the default), a `mysqld` process can use multiple connections to the cluster, effectively mimicking several SQL nodes. Each connection requires its own [api] or [mysqld] section in the cluster configuration (config.ini) file, and counts against the maximum number of API connections supported by the cluster.

Suppose that you have 2 cluster host computers, each running an SQL node whose `mysqld` process was started with `--ndb-cluster-connection-pool=4`; this means that the cluster must have 8 API slots available for these connections (instead of 2). All of these connections are set up when the SQL node connects to the cluster, and are allocated to threads in a round-robin fashion.

This option is useful only when running `mysqld` on host machines having multiple CPUs, multiple cores, or both. For best results, the value should be smaller than the total number of cores available on the host machine. Setting it to a value greater than this is likely to degrade performance severely.

![Important]

**Important**

Because each SQL node using connection pooling occupies multiple API node slots—each slot having its own node ID in the cluster—you must not use a node ID as part of the cluster connection string when starting any `mysqld` process that employs connection pooling.

Setting a node ID in the connection string when using the `--ndb-cluster-connection-pool` option causes node ID allocation errors when the SQL node attempts to connect to the cluster.

- `--ndb-cluster-connection-pool-nodeids=list`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--ndb-cluster-connection-pool-nodeids</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>ndb_cluster_connection_pool_nodeids</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Set</td>
</tr>
<tr>
<td>Default Value</td>
<td></td>
</tr>
</tbody>
</table>

Specifies a comma-separated list of node IDs for connections to the cluster used by an SQL node. The number of nodes in this list must be the same as the value set for the `--ndb-cluster-connection-pool` option.

- `--ndb-blob-read-batch-bytes=bytes`
This option can be used to set the size (in bytes) for batching of BLOB data reads in NDB Cluster applications. When this batch size is exceeded by the amount of BLOB data to be read within the current transaction, any pending BLOB read operations are immediately executed.

The maximum value for this option is 4294967295; the default is 65536. Setting it to 0 has the effect of disabling BLOB read batching.

Note

In NDB API applications, you can control BLOB write batching with the `setMaxPendingBlobWriteBytes()` and `getMaxPendingBlobWriteBytes()` methods.

```
--ndb-blob-write-batch-bytes=bytes
```

This option can be used to set the size (in bytes) for batching of BLOB data writes in NDB Cluster applications. When this batch size is exceeded by the amount of BLOB data to be written within the current transaction, any pending BLOB write operations are immediately executed.

The maximum value for this option is 4294967295; the default is 65536. Setting it to 0 has the effect of disabling BLOB write batching.

Note

In NDB API applications, you can control BLOB write batching with the `setMaxPendingBlobWriteBytes()` and `getMaxPendingBlobWriteBytes()` methods.
- **--ndb-connectstring=** connection_string

  **Command-Line Format**
  --ndb-connectstring

  **Type**
  String

  When using the NDBCLUSTER storage engine, this option specifies the management server that distributes cluster configuration data. See Section 22.3.3.3, “NDB Cluster Connection Strings”, for syntax.

- **--ndb-default-column-format=** [FIXED|DYNAMIC]

  **Command-Line Format**
  --ndb-default-column-format={FIXED|DYNAMIC}

  **System Variable**
  ndb_default_column_format

  **Scope**
  Global

  **Dynamic**
  Yes

  **SET_VAR**
  No

  **Type**
  Enumeration

  **Default Value**
  FIXED

  **Valid Values**
  FIXED

  DYNAMIC

  Sets the default COLUMN_FORMAT and ROW_FORMAT for new tables (see Section 13.1.20, “CREATE TABLE Statement”). The default is FIXED.

- **--ndb-deferred-constraints=** [0|1]

  **Command-Line Format**
  --ndb-deferred-constraints

  **System Variable**
  ndb_deferred_constraints

  **Scope**
  Global, Session

  **Dynamic**
  Yes

  **SET_VAR**
  No

  **Type**
  Integer

  **Default Value**
  0

  **Minimum Value**
  0

  **Maximum Value**
  1

  Controls whether or not constraint checks on unique indexes are deferred until commit time, where such checks are supported. 0 is the default.

  This option is not normally needed for operation of NDB Cluster or NDB Cluster Replication, and is intended primarily for use in testing.

- **--ndb-schema-dist-timeout=#**

  **Command-Line Format**
  --ndb-schema-dist-timeout=#

  **Introduced**
  8.0.17-ndb-8.0.17

  **System Variable**
  ndb_schema_dist_timeout
NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>Scope</th>

<td>seconds</td>
</tr>
</tbody>
</table>

Specifies the maximum time in seconds that this `mysqld` waits for a schema operation to complete before marking it as having timed out.

- `--ndb-distribution=[KEYHASH|LINHASH]`

    **Command-Line Format**

    `--ndb-distribution=(KEYHASH|LINHASH)`

    **System Variable**

    `ndb_distribution`

    **Scope**

    Global

    **Dynamic**

    Yes

    **SET_VAR** Hint Applies

    No

    **Type**

    Enumeration

    **Default Value**

    KEYHASH

    **Valid Values**

    LINHASH

    KEYHASH

Controls the default distribution method for NDB tables. Can be set to either of KEYHASH (key hashing) or LINHASH (linear hashing). KEYHASH is the default.

- `--ndb-log-apply-status`

    **Command-Line Format**

    `--ndb-log-apply-status=[OFF|ON]`

    **System Variable**

    `ndb_log_apply_status`

    **Scope**

    Global

    **Dynamic**

    No

    **SET_VAR** Hint Applies

    No

    **Type**

    Boolean

    **Default Value**

    OFF

Causes a replica `mysqld` to log any updates received from its immediate source to the `mysql.ndb_apply_status` table in its own binary log using its own server ID rather than the server ID of the source. In a circular or chain replication setting, this allows such updates to propagate to
the `mysql.ndb_apply_status` tables of any MySQL servers configured as replicas of the current `mysqld`.

In a chain replication setup, using this option allows downstream (replica) clusters to be aware of their positions relative to all of their upstream contributors (sources).

In a circular replication setup, this option causes changes to `ndb_apply_status` tables to complete the entire circuit, eventually propagating back to the originating NDB Cluster. This also allows a cluster acting as a replication source to see when its changes (epochs) have been applied to the other clusters in the circle.

This option has no effect unless the MySQL server is started with the `--ndbcluster` option.

- `--ndb-log-empty-epochs=[ON|OFF]`

| Command-Line Format          | `--ndb-log-empty-epochs=[OFF|ON]` |
|------------------------------|----------------------------------|
| System Variable              | `ndb_log_empty_epochs`           |
| Scope                        | Global                           |
| Dynamic                      | Yes                              |
| `SET_VAR` Hint Applies       | No                               |
| Type                         | Boolean                          |
| Default Value                | OFF                              |

Causes epochs during which there were no changes to be written to the `ndb_apply_status` and `ndb_binlog_index` tables, even when `log_slave_updates` is enabled.

By default this option is disabled. Disabling `--ndb-log-empty-epochs` causes epoch transactions with no changes not to be written to the binary log, although a row is still written even for an empty epoch in `ndb_binlog_index`.

Because `--ndb-log-empty-epochs=1` causes the size of the `ndb_binlog_index` table to increase independently of the size of the binary log, users should be prepared to manage the growth of this table, even if they expect the cluster to be idle a large part of the time.

- `--ndb-log-empty-update=[ON|OFF]`

| Command-Line Format          | `--ndb-log-empty-update=[OFF|ON]` |
|------------------------------|----------------------------------|
| System Variable              | `ndb_log_empty_update`           |
| Scope                        | Global                           |
| Dynamic                      | Yes                              |
| `SET_VAR` Hint Applies       | No                               |
| Type                         | Boolean                          |
| Default Value                | OFF                              |

Causes updates that produced no changes to be written to the `ndb_apply_status` and `ndb_binlog_index` tables, when when `log_slave_updates` is enabled.

By default this option is disabled (OFF). Disabling `--ndb-log-empty-update` causes updates with no changes not to be written to the binary log.

- `--ndb-log-exclusive-reads=[0|1]`
Starting the server with this option causes primary key reads to be logged with exclusive locks, which allows for NDB Cluster Replication conflict detection and resolution based on read conflicts. You can also enable and disable these locks at runtime by setting the value of the `ndb_log_exclusive_reads` system variable to 1 or 0, respectively. 0 (disable locking) is the default.

For more information, see Read conflict detection and resolution.

### `--ndb-log-fail-terminate`

When this option is specified, and complete logging of all found row events is not possible, the `mysqld` process is terminated.

### `--ndb-log-orig`

Log the originating server ID and epoch in the `ndb_binlog_index` table.

**Note**

This makes it possible for a given epoch to have multiple rows in `ndb_binlog_index`, one for each originating epoch.

For more information, see Section 22.6.4, "NDB Cluster Replication Schema and Tables".
NDB Cluster Configuration Files

- **--ndb-log-transaction-id**

  | Command-Line Format | --ndb-log-transaction-id[={OFF|ON}] |
  |--------------------|----------------------------------|
  | System Variable    | ndb_log_transaction_id           |
  | Scope              | Global                           |
  | Dynamic            | No                               |
  | SET_VAR Hint Applies | No                              |
  | Type               | Boolean                          |
  | Default Value      | OFF                              |

Causes a replica `mysqld` to write the NDB transaction ID in each row of the binary log. The default value is `FALSE`.

This option is not supported in mainline MySQL Server 8.0. It is required to enable NDB Cluster Replication conflict detection and resolution using the `NDB$EPOCH_TRANS()` function (see `NDB$EPOCH_TRANS()`). For more information, see Section 22.6.11, “NDB Cluster Replication Conflict Resolution”.

The deprecated `log_bin_use_v1_row_events` system variable, which defaults to `OFF`, must not be set to `ON` when you use `--ndb-log-transaction-id`.

- **--ndb-log-update-minimal**

  | Command-Line Format | --ndb-log-update-minimal[={OFF|ON}] |
  |--------------------|----------------------------------|
  | System Variable    | ndb_log_update_minimal           |
  | Scope              | Global                           |
  | Dynamic            | Yes                              |
  | SET_VAR Hint Applies | No                              |
  | Type               | Boolean                          |
  | Default Value      | OFF                              |

Log updates in a minimal fashion, by writing only the primary key values in the before image, and only the changed columns in the after image. This may cause compatibility problems if replicating to storage engines other than `NDB`.

- **--ndb-mgmd-host=host[:port]**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ndb-mgmd-host=host_name[:port_num]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>localhost:1186</td>
</tr>
</tbody>
</table>

Can be used to set the host and port number of a single management server for the program to connect to. If the program requires node IDs or references to multiple management servers (or both) in its connection information, use the `--ndb-connectstring` option instead.

- **--ndb-nodeid=#**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ndb-nodeid=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Status Variable</td>
<td>Ndb_cluster_node_id</td>
</tr>
</tbody>
</table>

NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>Scope</th>
<th>Global</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>255</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>63</td>
</tr>
</tbody>
</table>

Set this MySQL server's node ID in an NDB Cluster.

The `--ndb-nodeid` option overrides any node ID set with `--ndb-connectstring`, regardless of the order in which the two options are used.

In addition, if `--ndb-nodeid` is used, then either a matching node ID must be found in a `[mysqld]` or `[api]` section of `config.ini`, or there must be an “open” [mysqld] or [api] section in the file (that is, a section without a `NodeId` or `Id` parameter specified). This is also true if the node ID is specified as part of the connection string.

Regardless of how the node ID is determined, its is shown as the value of the global status variable `Ndb_cluster_node_id` in the output of `SHOW STATUS`, and as `cluster_node_id` in the connection row of the output of `SHOW ENGINE NDBCLUSTER STATUS`.

For more information about node IDs for NDB Cluster SQL nodes, see Section 22.3.3.7, “Defining SQL and Other API Nodes in an NDB Cluster”.

- `--ndbinfo={ON|OFF|FORCE}`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--ndbinfo[=value]</code> (≥ 8.0.13-ndb-8.0.13)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.13-ndb-8.0.13</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>ON</td>
</tr>
<tr>
<td>Valid Values</td>
<td>OFF, FORCE</td>
</tr>
</tbody>
</table>

Enables the plugin for the `ndbinfo` information database. By default this is ON whenever `NDBCLUSTER` is enabled.

- `--ndb-optimization-delay=milliseconds`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--ndb-optimization-delay=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>ndb_optimization_delay</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>10</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
</tbody>
</table>
Maximum Value | 100000

Set the number of milliseconds to wait between sets of rows by OPTIMIZE TABLE statements on NDB tables. The default is 10.

• `--ndb-transid-mysql-connection-map=state`

Command-Line Format: `--ndb-transid-mysql-connection-map[=state]`

<table>
<thead>
<tr>
<th>Type</th>
<th>Enumeration</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>ON</td>
</tr>
<tr>
<td>Valid Values</td>
<td>ON, OFF, FORCE</td>
</tr>
</tbody>
</table>

Enables or disables the plugin that handles the `ndb_transid_mysql_connection_map` table in the INFORMATION_SCHEMA database. Takes one of the values ON, OFF, or FORCE. ON (the default) enables the plugin. OFF disables the plugin, which makes `ndb_transid_mysql_connection_map` inaccessible. FORCE keeps the MySQL Server from starting if the plugin fails to load and start.

You can see whether the `ndb_transid_mysql_connection_map` table plugin is running by checking the output of `SHOW PLUGINS`.

• `--ndb-wait-connected=seconds`

Command-Line Format: `--ndb-wait-connected=#`

<table>
<thead>
<tr>
<th>System Variable</th>
<th>ndb_wait_connected</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>30</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>31536000</td>
</tr>
</tbody>
</table>

This option sets the period of time that the MySQL server waits for connections to NDB Cluster management and data nodes to be established before accepting MySQL client connections. The time is specified in seconds. The default value is 30.

• `--ndb-wait-setup=seconds`

Command-Line Format: `--ndb-wait-setup=#`

<table>
<thead>
<tr>
<th>System Variable</th>
<th>ndb_wait_setup</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td></td>
</tr>
<tr>
<td>Minimum Value</td>
<td></td>
</tr>
<tr>
<td>Maximum Value</td>
<td></td>
</tr>
</tbody>
</table>
This variable shows the period of time that the MySQL server waits for the NDB storage engine to complete setup before timing out and treating NDB as unavailable. The time is specified in seconds. The default value is 30.

- **--skip-ndbcluster**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--skip-ndbcluster</th>
</tr>
</thead>
</table>

Disable the NDBCLUSTER storage engine. This is the default for binaries that were built with NDBCLUSTER storage engine support; the server allocates memory and other resources for this storage engine only if the --ndbcluster option is given explicitly. See Section 22.3.1, “Quick Test Setup of NDB Cluster”, for an example.

### NDB Cluster System Variables

This section provides detailed information about MySQL server system variables that are specific to NDB Cluster and the NDB storage engine. For system variables not specific to NDB Cluster, see Section 5.1.8, “Server System Variables”. For general information on using system variables, see Section 5.1.9, “Using System Variables”.

- **ndb_autoincrement_prefetch_sz**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ndb-autoincrement-prefetch-sz=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>ndb_autoincrement_prefetch_sz</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value (≥ 8.0.19-ndb-8.0.19)</td>
<td>512</td>
</tr>
<tr>
<td>Default Value (≤ 8.0.18-ndb-8.0.18)</td>
<td>1</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>65536</td>
</tr>
</tbody>
</table>

Determines the probability of gaps in an autoincremented column. Set it to 1 to minimize this. Setting it to a high value for optimization makes inserts faster, but decreases the likelihood of consecutive autoincrement numbers being used in a batch of inserts.

This variable affects only the number of AUTO_INCREMENT IDs that are fetched between statements; within a given statement, at least 32 IDs are obtained at a time.
NDB Cluster Configuration Files

Important
This variable does not affect inserts performed using INSERT ... SELECT.

- **ndb_cache_check_time**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ndb-cache-check-time=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Deprecated</td>
<td>Yes</td>
</tr>
<tr>
<td>System Variable</td>
<td>ndb_cache_check_time</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
</tbody>
</table>

The number of milliseconds that elapse between checks of NDB Cluster SQL nodes by the MySQL query cache. Setting this to 0 (the default and minimum value) means that the query cache checks for validation on every query.

The recommended maximum value for this variable is 1000, which means that the check is performed once per second. A larger value means that the check is performed and possibly invalidated due to updates on different SQL nodes less often. It is generally not desirable to set this to a value greater than 2000.

Note
The query cache ndb_cache_check_time are deprecated in MySQL 5.7; the query cache was removed in MySQL 8.0.

- **ndb_clear_apply_status**

| Command-Line Format | --ndb-clear-apply-status=[{OFF|ON}] |
|---------------------|------------------------------------|
| System Variable     | ndb_clear_apply_status             |
| Scope               | Global                             |
| Dynamic             | Yes                                |
| SET_VAR Hint Applies| No                                 |
| Type                | Boolean                            |
| Default Value       | ON                                 |

By the default, executing RESET SLAVE causes an NDB Cluster replica to purge all rows from its ndb_apply_status table. You can disable this by setting ndb_clear_apply_status=OFF.

- **ndb_data_node_neighbour**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ndb-data-node-neighbour=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>ndb_data_node_neighbour</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
</tbody>
</table>
Sets the ID of a “nearest” data node—that is, a preferred nonlocal data node is chosen to execute the transaction, rather than one running on the same host as the SQL or API node. This used to ensure that when a fully replicated table is accessed, we access it on this data node, to ensure that the local copy of the table is always used whenever possible. This can also be used for providing hints for transactions.

This can improve data access times in the case of a node that is physically closer than and thus has higher network throughput than others on the same host.

Note

An equivalent method `set_data_node_neighbour()` is provided for use in NDB API applications.

• ndb_dbg_check_shares

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ndb-db-g-check-shares=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.13-ndb-8.0.13</td>
</tr>
<tr>
<td>System Variable</td>
<td>ndb_dbg_check_shares</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1</td>
</tr>
</tbody>
</table>

When set to 1, check that no shares are lingering. Available in debug builds only.

Added in NDB 8.0.13.

• ndb_default_column_format

| Command-Line Format | --ndb-default-column-format={FIXED|DYNAMIC} |
|---------------------|-------------------------------------------|
| System Variable     | ndb_default_column_format                 |
| Scope               | Global                                    |
| Dynamic             | Yes                                       |
| SET_VAR Hint Applies| No                                        |
| Type                | Enumeration                               |
### NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>Default Value</th>
<th>FIXED</th>
</tr>
</thead>
<tbody>
<tr>
<td>Valid Values</td>
<td>FIXED</td>
</tr>
<tr>
<td></td>
<td>DYNAMIC</td>
</tr>
</tbody>
</table>

Sets the default `COLUMN_FORMAT` and `ROW_FORMAT` for new tables (see Section 13.1.20, “CREATE TABLE Statement”). The default is FIXED.

- **ndb_deferred_constraints**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--ndb-deferred-constraints=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>ndb_deferred_constraints</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1</td>
</tr>
</tbody>
</table>

Controls whether or not constraint checks are deferred, where these are supported. 0 is the default.

This variable is not normally needed for operation of NDB Cluster or NDB Cluster Replication, and is intended primarily for use in testing.

- **ndb_distribution**

  | Command-Line Format | `--ndb-distribution={KEYHASH|LINHASH}` |
|---------------------|---------------------------------------|
| System Variable     | `ndb_distribution`                    |
| Scope               | Global                                |
| Dynamic             | Yes                                   |
| `SET_VAR` Hint Applies | No                               |
| Type                | Enumeration                           |
| Default Value       | KEYHASH                               |
| Valid Values        | LINHASH, KEYHASH                      |

Controls the default distribution method for NDB tables. Can be set to either of `KEYHASH` (key hashing) or `LINHASH` (linear hashing). KEYHASH is the default.

- **ndb_eventbuffer_free_percent**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--ndb-eventbuffer-free-percent=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>ndb_eventbuffer_free_percent</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
</tbody>
</table>

4070
NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>SET_VAR Hint Applies</th>
<th>No</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>20</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>99</td>
</tr>
</tbody>
</table>

Sets the percentage of the maximum memory allocated to the event buffer (`ndb_eventbuffer_max_alloc`) that should be available in event buffer after reaching the maximum, before starting to buffer again.

- **ndb_eventbuffer_max_alloc**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--ndb-eventbuffer-max-alloc=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>ndb_eventbuffer_max_alloc</code></td>

<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

Sets the maximum amount memory (in bytes) that can be allocated for buffering events by the NDB API. 0 means that no limit is imposed, and is the default.

- **ndb_extra_logging**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>ndb_extra_logging=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>ndb_extra_logging</code></td>
</tr>
<tr>

</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
</tbody>
</table>

This variable enables recording in the MySQL error log of information specific to the NDB storage engine.

When this variable is set to 0, the only information specific to NDB that is written to the MySQL error log relates to transaction handling. If it set to a value greater than 0 but less than 10, NDB table schema and connection events are also logged, as well as whether or not conflict resolution is in use, and other NDB errors and information. If the value is set to 10 or more, information about NDB internals, such as the progress of data distribution among cluster nodes, is also written to the MySQL error log. The default is 1.

- **ndb_force_send**

  | Command-Line Format | `--ndb-force-send[={OFF|ON}]` |
|---------------------|------------------------------|
| System Variable     | `ndb_force_send`             | 4071 |
NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>Scope</th>
<th>Global, Session</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>ON</td>
</tr>
</tbody>
</table>

Forces sending of buffers to NDB immediately, without waiting for other threads. Defaults to ON.

- **ndb_fully_replicated**

  Command-Line Format  
  `--ndb-fully-replicated=[{OFF|ON}]`

  System Variable  
  `ndb_fully_replicated`

  Scope  
  Global, Session

  Dynamic  
  Yes

  SET_VAR Hint Applies  
  No

  Type  
  Boolean

  Default Value  
  OFF

Determines whether new NDB tables are fully replicated. This setting can be overridden for an individual table using `COMMENT="NDB_TABLE=FULLY_REPLICATED=..."` in a `CREATE TABLE` or `ALTER TABLE` statement; see Section 13.1.20.10, “Setting NDB_TABLE Options”, for syntax and other information.

- **ndb_index_stat_enable**

  Command-Line Format  
  `--ndb-index-stat-enable=[{OFF|ON}]`

  System Variable  
  `ndb_index_stat_enable`

  Scope  
  Global, Session

  Dynamic  
  Yes

  SET_VAR Hint Applies  
  No

  Type  
  Boolean

  Default Value  
  ON

Use NDB index statistics in query optimization. The default is ON.

- **ndb_index_stat_option**

  Command-Line Format  
  `--ndb-index-stat-option=value`

  System Variable  
  `ndb_index_stat_option`

  Scope  
  Global, Session

  Dynamic  
  Yes

  SET_VAR Hint Applies  
  No

  Type  
  String

  Default Value  
  `loop_checkon=1000ms,loop_idle=1000ms,loop_busy=100ms,update_batch=1,read_batch=4,idle_batch=32,check_batch=32,check_delay=1m,delete_batch=8,clean_delay=0,error_batch=4,`
This variable is used for providing tuning options for NDB index statistics generation. The list consist of comma-separated name-value pairs of option names and values, and this list must not contain any space characters.

Options not used when setting `ndb_index_stat_option` are not changed from their default values. For example, you can set `ndb_index_stat_option = 'loop_idle=1000ms,cache_limit=32M'`.

Time values can be optionally suffixed with h (hours), m (minutes), or s (seconds). Millisecond values can optionally be specified using ms; millisecond values cannot be specified using h, m, or s.) Integer values can be suffixed with K, M, or G.

The names of the options that can be set using this variable are shown in the table that follows. The table also provides brief descriptions of the options, their default values, and (where applicable) their minimum and maximum values.

### Table 22.19 ndb_index_stat_option options and values

#### ndb_join_pushdown

- **System Variable**: ndb_join_pushdown
- **Scope**: Global, Session
- **Dynamic**: Yes
- **SET_VAR Hint Applies**: No
- **Type**: Boolean
- **Default Value**: ON

This variable controls whether joins on NDB tables are pushed down to the NDB kernel (data nodes). Previously, a join was handled using multiple accesses of NDB by the SQL node; however, when ndb_join_pushdown is enabled, a pushable join is sent in its entirety to the data nodes, where it can be distributed among the data nodes and executed in parallel on multiple copies of the data, with a single, merged result being returned to mysql. This can reduce greatly the number of round trips between an SQL node and the data nodes required to handle such a join.

By default, ndb_join_pushdown is enabled.

**Conditions for NDB pushdown joins.** In order for a join to be pushable, it must meet the following conditions:

1. Only columns can be compared, and all columns to be joined must use exactly the same data type. This means that (for example) a join on an INT column and a BIGINT column also cannot be pushed down.

   Previously, expressions such as `t1.a = t2.a + constant` could not be pushed down. This restriction is lifted in NDB 8.0.18 and later. The result of any operations on any column to be compared must yield the same type as the column itself.

   Also beginning with NDB 8.0.18, expressions comparing columns from the same table can be pushed down. The columns (or the result of any operations on those columns) must be of exactly the
same type, including the same signedness, length, character set and collation, precision, and scale, where these are applicable.

2. Queries referencing BLOB or TEXT columns are not supported.

3. Explicit locking is not supported; however, the NDB storage engine's characteristic implicit row-based locking is enforced.

This means that a join using FOR UPDATE cannot be pushed down.

4. In order for a join to be pushed down, child tables in the join must be accessed using one of the ref, eq_ref, or const access methods, or some combination of these methods.

Outer joined child tables can only be pushed using eq_ref.

If the root of the pushed join is an eq_ref or const, only child tables joined by eq_ref can be appended. (A table joined by ref is likely to become the root of another pushed join.)

If the query optimizer decides on Using join cache for a candidate child table, that table cannot be pushed as a child. However, it may be the root of another set of pushed tables.

5. Joins referencing tables explicitly partitioned by [LINEAR] HASH, LIST, or RANGE currently cannot be pushed down.

You can see whether a given join can be pushed down by checking it with EXPLAIN; when the join can be pushed down, you can see references to the pushed join in the Extra column of the output, as shown in this example:

```sql
mysql> EXPLAIN
    -> SELECT e.first_name, e.last_name, t.title, d.dept_name
    -> FROM employees e
    -> JOIN dept_emp de ON e.emp_no=de.emp_no
    -> JOIN departments d ON d.dept_no=de.dept_no
    -> JOIN titles t ON e.emp_no=t.emp_no

4 rows in set (0.00 sec)

---

**Note**

If inner joined child tables are joined by `ref`, and the result is ordered or grouped by a sorted index, this index cannot provide sorted rows, which forces writing to a sorted tempfile.

Two additional sources of information about pushed join performance are available:

1. The status variables `Ndb_pushed_queries_defined`, `Ndb_pushed_queries_dropped`, `Ndb_pushed_queries_executed`, and `Ndb_pushed_reads`.

2. The counters in the `ndbinfo.counters` table that belong to the DBSPJ kernel block. See Section 22.5.14.10, “The ndbinfo counters Table”, for information about these counters. See also The DBSPJ Block, in the NDB Cluster API Developer Guide.

---

- **ndb_log_apply_status**

| Command-Line Format | --ndb-log-apply-status={OFF|ON} |
|---------------------|----------------------------------|
| System Variable     | ndb_log_apply_status             |
| Scope               | Global                           |
| Dynamic             | No                               |
| SET_VAR Hint Applies| No                               |
| Type                | Boolean                          |
| Default Value       | OFF                              |

A read-only variable which shows whether the server was started with the `--ndb-log-apply-status` option.

- **ndb_log_bin**

| Command-Line Format | --ndb-log-bin={OFF|ON} |
|---------------------|------------------------|
| System Variable     | ndb_log_bin            |
| Scope               | Global, Session        |
| Dynamic             | Yes                    |
| SET_VAR Hint Applies| No                     |
| Type                | Boolean                |

---
### NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>Default Value (≥ 8.0.16-ndb-8.0.16)</th>
<th>OFF</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value (≤ 8.0.15-ndb-8.0.15)</td>
<td>ON</td>
</tr>
</tbody>
</table>

Causes updates to NDB tables to be written to the binary log. The setting for this variable has no effect if binary logging is not already enabled on the server using `log_bin`. In NDB 8.0.16 and later, `ndb_log_bin` defaults to 0 (FALSE).

- **ndb_log_binlog_index**

| Command-Line Format | --ndb-log-binlog-index[={OFF|ON}] |
|---------------------|----------------------------------|
| System Variable     | ndb_log_binlog_index             |
| Scope               | Global                           |
| Dynamic             | Yes                              |
| SET_VAR Hint Applies| No                               |
| Type                | Boolean                          |
| Default Value       | ON                               |

Causes a mapping of epochs to positions in the binary log to be inserted into the `ndb_binlog_index` table. Setting this variable has no effect if binary logging is not already enabled for the server using `log_bin`. (In addition, `ndb_log_bin` must not be disabled.) `ndb_log_binlog_index` defaults to 1 (ON); normally, there is never any need to change this value in a production environment.

- **ndb_log_empty_epochs**

| Command-Line Format | --ndb-log-empty-epochs[={OFF|ON}] |
|---------------------|----------------------------------|
| System Variable     | ndb_log_empty_epochs             |
| Scope               | Global                           |
| Dynamic             | Yes                              |
| SET_VAR Hint Applies| No                               |
| Type                | Boolean                          |
| Default Value       | OFF                              |

When this variable is set to 0, epoch transactions with no changes are not written to the binary log, although a row is still written even for an empty epoch in `ndb_binlog_index`.

- **ndb_log_empty_update**

| Command-Line Format | --ndb-log-empty-update[={OFF|ON}] |
|---------------------|----------------------------------|
| System Variable     | ndb_log_empty_update             |
| Scope               | Global                           |
| Dynamic             | Yes                              |
| SET_VAR Hint Applies| No                               |
| Type                | Boolean                          |
When this variable is set to `ON`, update transactions with no changes are written to the binary log, even when `log_slave_updates` is enabled.

- **ndb_log_exclusive_reads**

| Command-Line Format       | --ndb-log-exclusive-reads[={OFF|ON}] |
|---------------------------|--------------------------------------|
| System Variable           | `ndb_log_exclusive_reads`             |
| Scope                     | Global, Session                      |
| Dynamic                   | Yes                                  |
| `SET_VAR` Hint Applies    | No                                   |
| Type                      | Boolean                              |
| Default Value             | 0                                    |

This variable determines whether primary key reads are logged with exclusive locks, which allows for NDB Cluster Replication conflict detection and resolution based on read conflicts. To enable these locks, set the value of `ndb_log_exclusive_reads` to 1. 0, which disables such locking, is the default.

For more information, see Read conflict detection and resolution.

- **ndb_log_orig**

| Command-Line Format       | --ndb-log-orig[={OFF|ON}] |
|---------------------------|---------------------------|
| System Variable           | `ndb_log_orig`             |
| Scope                     | Global                    |
| Dynamic                   | No                        |
| `SET_VAR` Hint Applies    | No                        |
| Type                      | Boolean                   |
| Default Value             | OFF                       |

Shows whether the originating server ID and epoch are logged in the `ndb_binlog_index` table. Set using the `--ndb-log-orig` server option.

- **ndb_log_transaction_id**

<table>
<thead>
<tr>
<th>System Variable</th>
<th><code>ndb_log_transaction_id</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
</tbody>
</table>
This read-only, Boolean system variable shows whether a replica mysql writes NDB transaction IDs in the binary log (required to use “active-active” NDB Cluster Replication with \texttt{NDB\$EPOCH\_TRANS()} conflict detection). To change the setting, use the \texttt{--ndb-log-transaction-id} option.

\texttt{ndb\_log\_transaction\_id} is not supported in mainline MySQL Server 8.0.

For more information, see Section 22.6.11, “NDB Cluster Replication Conflict Resolution”.

\begin{table}
\begin{tabular}{|l|l|}
\hline
\textbf{Default Value} & \texttt{OFF} \\
\hline
\end{tabular}
\end{table}

\begin{table}
\begin{tabular}{|l|l|}
\hline
\textbf{Command-Line Format} & \texttt{--ndb\_metadata\_check=[\{OFF|ON\}]} \\
\hline
\textbf{Introduced} & 8.0.16-ndb-8.0.16 \\
\hline
\textbf{System Variable} & \texttt{ndb\_metadata\_check} \\
\hline
\textbf{Scope} & Global \\
\hline
\textbf{Dynamic} & Yes \\
\hline
\textbf{SET\_VAR} Hint Applies & No \\
\hline
\textbf{Type} & Boolean \\
\hline
\textbf{Default Value} & \texttt{ON} \\
\hline
\end{tabular}
\end{table}

Beginning with NDB 8.0.16, NDB uses a background thread to check for metadata changes each \texttt{ndb\_metadata\_check\_interval} seconds as compared with the MySQL data dictionary. This metadata change detection thread can be disabled by setting \texttt{ndb\_metadata\_check} to \texttt{OFF}. The thread is enabled by default.

\begin{table}
\begin{tabular}{|l|l|}
\hline
\textbf{Command-Line Format} & \texttt{--ndb\_metadata\_check\_interval=\#} \\
\hline
\textbf{Introduced} & 8.0.16-ndb-8.0.16 \\
\hline
\textbf{System Variable} & \texttt{ndb\_metadata\_check\_interval} \\
\hline
\textbf{Scope} & Global \\
\hline
\textbf{Dynamic} & Yes \\
\hline
\textbf{SET\_VAR} Hint Applies & No \\
\hline
\textbf{Type} & Integer \\
\hline
\textbf{Default Value} & 60 \\
\hline
\textbf{Minimum Value} & 0 \\
\hline
\textbf{Maximum Value} & 31536000 \\
\hline
\textbf{Unit} & \texttt{seconds} \\
\hline
\end{tabular}
\end{table}

In NDB 8.0.16 and later, NDB runs a metadata change detection thread in the background to determine when the NDB dictionary has changed with respect to the MySQL data dictionary. By default, the interval between such checks is 60 seconds; this can be adjusted by setting the value of \texttt{ndb\_metadata\_check\_interval}. To enable or disable the thread, use \texttt{ndb\_metadata\_check}.

\begin{table}
\begin{tabular}{|l|l|}
\hline
\textbf{Introduced} & 8.0.19-ndb-8.0.19 \\
\hline
\end{tabular}
\end{table}
NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>System Variable</th>
<th>ndb_metadata_sync</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>false</td>
</tr>
</tbody>
</table>

Setting this variable causes the change monitor thread to override any values set for `ndb_metadata_check` or `ndb_metadata_check_interval`, and to enter a period of continuous change detection. When the thread ascertains that there are no more changes to be detected, it stalls until the binary logging thread has finished synchronization of all detected objects. `ndb_metadata_sync` is then set to `false`, and the change monitor thread reverts to the behavior determined by the settings for `ndb_metadata_check` and `ndb_metadata_check_interval`.

In NDB 8.0.22 and later, setting this variable to `true` causes the list of excluded objects to be cleared, and setting it to `false` clears the list of objects to be retried.

- `ndb_optimized_node_selection`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ndb-optimized-node-selection=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>ndb_optimized_node_selection</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>3</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>3</td>
</tr>
</tbody>
</table>

There are two forms of optimized node selection, described here:

1. The SQL node uses *promixity* to determine the transaction coordinator; that is, the “closest” data node to the SQL node is chosen as the transaction coordinator. For this purpose, a data node having a shared memory connection with the SQL node is considered to be “closest” to the SQL node; the next closest (in order of decreasing proximity) are: TCP connection to `localhost`, followed by TCP connection from a host other than `localhost`.

2. The SQL thread uses *distribution awareness* to select the data node. That is, the data node housing the cluster partition accessed by the first statement of a given transaction is used as the transaction coordinator for the entire transaction. (This is effective only if the first statement of the transaction accesses no more than one cluster partition.)

This option takes one of the integer values 0, 1, 2, or 3. 3 is the default. These values affect node selection as follows:

- **0**: Node selection is not optimized. Each data node is employed as the transaction coordinator 8 times before the SQL thread proceeds to the next data node.

- **1**: Proximity to the SQL node is used to determine the transaction coordinator.
• **2**: Distribution awareness is used to select the transaction coordinator. However, if the first statement of the transaction accesses more than one cluster partition, the SQL node reverts to the round-robin behavior seen when this option is set to 0.

• **3**: If distribution awareness can be employed to determine the transaction coordinator, then it is used; otherwise proximity is used to select the transaction coordinator. (This is the default behavior.)

Proximity is determined as follows:

1. Start with the value set for the `Group` parameter (default 55).

2. For an API node sharing the same host with other API nodes, decrement the value by 1. Assuming the default value for `Group`, the effective value for data nodes on same host as the API node is 54, and for remote data nodes 55.

3. Setting `ndb_data_node_neighbour` further decreases the effective `Group` value by 50, causing this node to be regarded as the nearest node. This is needed only when all data nodes are on hosts other than that hosts the API node and it is desirable to dedicate one of them to the API node. In normal cases, the default adjustment described previously is sufficient.

Frequent changes in `ndb_data_node_neighbour` are not advisable, since this changes the state of the cluster connection and thus may disrupt the selection algorithm for new transactions from each thread until it stabilizes.

• **ndb_read_backup**

| Command-Line Format | `--ndb-read-backup[={OFF|ON}]` |
|---------------------|---------------------------------|
| System Variable     | `ndb_read_backup`               |
| Scope               | Global                          |
| Dynamic             | Yes                             |
| `SET_VAR` Hint Applies | No                               |
| Type                | Boolean                         |
| Default Value (≥ 8.0.19-ndb-8.0.19) | ON                         |
| Default Value (≤ 8.0.18-ndb-8.0.18) | OFF                         |

Enable read from any fragment replica for any **NDB** table subsequently created; doing so greatly improves the table read performance at a relatively small cost to writes.

To enable or disable read from any fragment replica for an individual table, you can set the **NDB_TABLE** option `READ_BACKUP` for the table accordingly, in a **CREATE TABLE** or **ALTER TABLE** statement; see Section 13.1.20.10, “Setting NDB_TABLE Options”, for more information.

• **ndb_recv_thread_activation_threshold**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--ndb-recv-thread-activation-threshold=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>ndb_recv_thread_activation_threshold</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
</tbody>
</table>
NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>SET_VAR Hint Applies</th>
<th>No</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>8</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0 (MIN_ACTIVATION_THRESHOLD)</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>16 (MAX_ACTIVATION_THRESHOLD)</td>
</tr>
</tbody>
</table>

When this number of concurrently active threads is reached, the receive thread takes over polling of the cluster connection.

This variable is global in scope. It can also be set at startup.

- `ndb_recv_thread_cpu_mask`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ndb-recv-thread-cpu-mask=mask</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>ndb_recv_thread_cpu_mask</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Bitmap</td>
</tr>
<tr>
<td>Default Value</td>
<td>[empty]</td>
</tr>
</tbody>
</table>

CPU mask for locking receiver threads to specific CPUs. This is specified as a hexadecimal bitmask. For example, 0x33 means that one CPU is used per receiver thread. An empty string is the default; setting `ndb_recv_thread_cpu_mask` to this value removes any receiver thread locks previously set.

This variable is global in scope. It can also be set at startup.

- `ndb_report_thresh_binlog_epoch_slip`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ndb-report-thresh-binlog-epoch-slip=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>ndb_report_thresh_binlog_epoch_slip</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>10</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>256</td>
</tr>
</tbody>
</table>

This represents the threshold for the number of epochs completely buffered in the event buffer, but not yet consumed by the binlog injector thread. When this degree of slippage (lag) is exceeded, an event buffer status message is reported, with BUFFERED_EPOCHS_OVER_THRESHOLD supplied as the reason (see Section 22.5.2.3, “Event Buffer Reporting in the Cluster Log”). Slip is increased when an epoch is received from data nodes and buffered completely in the event buffer; it is decreased when an epoch is consumed by the binlog injector thread, it is reduced. Empty epochs are buffered and queued, and so included in this calculation only when this is enabled using the Ndb::setEventBufferQueueEmptyEpoch() method from the NDB API.
• **ndb_report_thresh_binlog_mem_usage**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ndb-report-thresh-binlog-mem-usage=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>ndb_report_thresh_binlog_mem_usage</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>10</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>10</td>
</tr>
</tbody>
</table>

This is a threshold on the percentage of free memory remaining before reporting binary log status. For example, a value of 10 (the default) means that if the amount of available memory for receiving binary log data from the data nodes falls below 10%, a status message is sent to the cluster log.

• **ndb_row_checksum**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>ndb_row_checksum</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1</td>
</tr>
</tbody>
</table>

Traditionally, NDB has created tables with row checksums, which checks for hardware issues at the expense of performance. Setting `ndb_row_checksum` to 0 means that row checksums are *not* used for new or altered tables, which has a significant impact on performance for all types of queries. This variable is set to 1 by default, to provide backward-compatible behavior.

• **ndb_schema_dist_lock_wait_timeout**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ndb-schema-dist-lock-wait-timeout=value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.18-ndb-8.0.18</td>
</tr>
<tr>
<td>System Variable</td>
<td>ndb_schema_dist_lock_wait_timeout</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>30</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1200</td>
</tr>
<tr>
<td>Unit</td>
<td>seconds</td>
</tr>
</tbody>
</table>
Number of seconds to wait during schema distribution for the metadata lock taken on each SQL node in order to change its local data dictionary to reflect the DDL statement change. After this time has elapsed, a warning is returned to the effect that a given SQL node's data dictionary was not updated with the change. This avoids having the binary logging thread wait an excessive length of time while handling schema operations.

- **ndb_schema_dist_timeout**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ndb-schema-dist-timeout=value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.16-ndb-8.0.16</td>
</tr>
<tr>
<td>System Variable</td>
<td>ndb_schema_dist_timeout</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>120</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>5</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1200</td>
</tr>
<tr>
<td>Unit</td>
<td>seconds</td>
</tr>
</tbody>
</table>

Number of seconds to wait before detecting a timeout during schema distribution. This can indicate that other SQL nodes are experiencing excessive activity, or that they are somehow being prevented from acquiring necessary resources at this time.

- **ndb_schema_dist_upgrade_allowed**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ndb-schema-dist-upgrade-allowed=value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.17-ndb-8.0.17</td>
</tr>
<tr>
<td>System Variable</td>
<td>ndb_schema_dist_upgrade_allowed</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>true</td>
</tr>
</tbody>
</table>

Allow upgrading of the schema distribution table when connecting to NDB. When true (the default), this change is deferred until all SQL nodes have been upgraded to the same version of the NDB Cluster software.

**Note**

The performance of the schema distribution may be somewhat degraded until the upgrade has been performed.

- **ndb_show_foreign_key_mock_tables**

| Command-Line Format     | --ndb-show-foreign-key-mock-tables[={OFF|ON}] |
NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>System Variable</th>
<th>ndb_show_foreign_key_mock_tables</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Show the mock tables used by NDB to support foreign_key_checks=0. When this is enabled, extra warnings are shown when creating and dropping the tables. The real (internal) name of the table can be seen in the output of SHOW CREATE TABLE.

- **ndb_slave_conflict_role**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ndb-slave-conflict-role=value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>ndb_slave_conflict_role</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>NONE</td>
</tr>
<tr>
<td>Valid Values</td>
<td>NONE, PRIMARY, SECONDARY, PASS</td>
</tr>
</tbody>
</table>

Determine the role of this SQL node (and NDB Cluster) in a circular (“active-active”) replication setup. *ndb_slave_conflict_role* can take any one of the values PRIMARY, SECONDARY, PASS, or NULL (the default). The replica SQL thread must be stopped before you can change *ndb_slave_conflict_role*. In addition, it is not possible to change directly between PASS and either of PRIMARY or SECONDARY directly; in such cases, you must ensure that the SQL thread is stopped, then execute SET @@GLOBAL.ndb_slave_conflict_role = 'NONE' first.

For more information, see Section 22.6.11, “NDB Cluster Replication Conflict Resolution”.

- **ndb_table_no_logging**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>ndb_table_no_logging</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

When this variable is set to ON or 1, it causes NDB tables not to be checkpointed to disk. More specifically, this setting applies to tables which are created or altered using ENGINE NDB when
**ndb_table_no_logging** is enabled, and continues to apply for the lifetime of the table, even if **ndb_table_no_logging** is later changed. Suppose that A, B, C, and D are tables that we create (and perhaps also alter), and that we also change the setting for **ndb_table_no_logging** as shown here:

```sql
SET @@ndb_table_no_logging = 1;
CREATE TABLE A ... ENGINE NDB;
CREATE TABLE B ... ENGINE MYISAM;
CREATE TABLE C ... ENGINE MYISAM;
ALTER TABLE B ENGINE NDB;
SET @@ndb_table_no_logging = 0;
CREATE TABLE D ... ENGINE NDB;
ALTER TABLE C ENGINE NDB;
SET @@ndb_table_no_logging = 1;
```

After the previous sequence of events, tables A and B are not checkpointed; A was created with **ENGINE NDB** and B was altered to use **NDB**, both while **ndb_table_no_logging** was enabled. However, tables C and D are logged; C was altered to use **NDB** and D was created using **ENGINE NDB**, both while **ndb_table_no_logging** was disabled. Setting **ndb_table_no_logging** back to 1 or ON does **not** cause table C or D to be checkpointed.

**Note**

**ndb_table_no_logging** has no effect on the creation of **NDB** table schema files; to suppress these, use **ndb_table_temporary** instead.

**ndb_table_temporary**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>ndb_table_temporary</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

When set to ON or 1, this variable causes **NDB** tables not to be written to disk: This means that no table schema files are created, and that the tables are not logged.

**Note**

Setting this variable currently has no effect. This is a known issue; see Bug #34036.

**ndb_use_copying_alter_table**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>ndb_use_copying_alter_table</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
</tbody>
</table>
NDB Cluster Configuration Files

| SET_VAR | Hint Applies | No |

Forces NDB to use copying of tables in the event of problems with online `ALTER TABLE` operations. The default value is `OFF`.

- **ndb_use_exact_count**

  System Variable: `ndb_use_exact_count`
  Scope: Global, Session
  Dynamic: Yes
  SET_VAR Hint Applies: No
  Type: Boolean
  Default Value: `OFF`

Forces NDB to use a count of records during `SELECT COUNT(*)` query planning to speed up this type of query. The default value is `OFF`, which allows for faster queries overall.

- **ndb_use_transactions**

  Command-Line Format: `--ndb-use-transactions={OFF|ON}`
  System Variable: `ndb_use_transactions`
  Scope: Global, Session
  Dynamic: Yes
  SET_VAR Hint Applies: No
  Type: Boolean
  Default Value: `ON`

You can disable NDB transaction support by setting this variable's values to `OFF` (not recommended). The default is `ON`.

- **ndb_version**

  System Variable: `ndb_version`
  Scope: Global
  Dynamic: No
  SET_VAR Hint Applies: No
  Type: String
  Default Value: 

  NDB engine version, as a composite integer.

- **ndb_version_string**

  System Variable: `ndb_version_string`
  Scope: Global
  Dynamic: No
  SET_VAR Hint Applies: No
NDB engine version in ndb-<i>x.y.z</i> format.

- **server_id_bits**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--server-id-bits=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>server_id_bits</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>32</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>7</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>32</td>
</tr>
</tbody>
</table>

This variable indicates the number of least significant bits within the 32-bit <i>server_id</i> which actually identify the server. Indicating that the server is actually identified by fewer than 32 bits makes it possible for some of the remaining bits to be used for other purposes, such as storing user data generated by applications using the NDB API's Event API within the AnyValue of an OperationOptions structure (NDB Cluster uses the AnyValue to store the server ID).

When extracting the effective server ID from <i>server_id</i> for purposes such as detection of replication loops, the server ignores the remaining bits. The <i>server_id_bits</i> variable is used to mask out any irrelevant bits of <i>server_id</i> in the I/O and SQL threads when deciding whether an event should be ignored based on the server ID.

This data can be read from the binary log by mysqlbinlog, provided that it is run with its own <i>server_id_bits</i> variable set to 32 (the default).

If the value of <i>server_id</i> greater than or equal to 2 to the power of <i>server_id_bits</i>; otherwise, mysqld refuses to start.

This system variable is supported only by NDB Cluster. It is not supported in the standard MySQL 8.0 Server.

- **slave_allow_batching**

  | Command-Line Format       | --slave-allow-batching[={OFF|ON}]          |
  |----------------------------|---------------------------------------------|
  | System Variable            | slave_allow_batching                        |
  | Scope                      | Global                                      |
  | Dynamic                    | Yes                                         |
  | SET_VAR Hint Applies       | No                                          |
  | Type                       | Boolean                                     |
NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>Default Value</th>
<th>OFF</th>
</tr>
</thead>
</table>

Whether or not batched updates are enabled on NDB Cluster replicas.

Setting this variable has an effect only when using replication with the NDB storage engine; in MySQL Server 8.0, it is present but does nothing. For more information, see Section 22.6.6, “Starting NDB Cluster Replication (Single Replication Channel)”.

- **transaction_allow_batching**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>transaction_allow_batching</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

When set to 1 or ON, this variable enables batching of statements within the same transaction. To use this variable, autocommit must first be disabled by setting it to 0 or OFF; otherwise, setting transaction_allow_batching has no effect.

It is safe to use this variable with transactions that performs writes only, as having it enabled can lead to reads from the “before” image. You should ensure that any pending transactions are committed (using an explicit COMMIT if desired) before issuing a SELECT.

⚠️ **Important**

transaction_allow_batching should not be used whenever there is the possibility that the effects of a given statement depend on the outcome of a previous statement within the same transaction.

This variable is currently supported for NDB Cluster only.

The system variables in the following list all relate to the ndbinfo information database.

- **ndbinfo_database**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>ndbinfo_database</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>ndbinfo</td>
</tr>
</tbody>
</table>

Shows the name used for the NDB information database; the default is ndbinfo. This is a read-only variable whose value is determined at compile time; you can set it by starting the server using -- ndbinfo-database=name, which sets the value shown for this variable but does not actually change the name used for the NDB information database.

- **ndbinfo_max_bytes**

4089
NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ndbinfo-max-bytes=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>ndbinfo_max_bytes</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
</tbody>
</table>

Used in testing and debugging only.

- **ndbinfo_max_rows**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ndbinfo-max-rows=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>ndbinfo_max_rows</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>10</td>
</tr>
</tbody>
</table>

Used in testing and debugging only.

- **ndbinfo_offline**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>ndbinfo_offline</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Place the `ndbinfo` database into offline mode, in which tables and views can be opened even when they do not actually exist, or when they exist but have different definitions in NDB. No rows are returned from such tables (or views).

- **ndbinfo_show_hidden**

| Command-Line Format | --ndbinfo-show-hidden[={OFF|ON}] |
|---------------------|----------------------------------|
| System Variable     | ndbinfo_show_hidden              |
| Scope               | Global, Session                  |
| Dynamic             | Yes                              |
| SET_VAR Hint Applies| No                               |
| Type                | Boolean                          |

4090
NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>Default Value</th>
<th>OFF</th>
</tr>
</thead>
</table>

Whether or not the `ndbinfo` database’s underlying internal tables are shown in the `mysql` client. The default is **OFF**.

- **ndbinfo_table_prefix**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--ndbinfo-table-prefix=name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>ndbinfo_table_prefix</code></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Scope</th>
<th>Global, Session</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>Dynamic</th>
<th>Yes</th>
</tr>
</thead>
</table>

| SET_VAR Hint Applies | No |

<table>
<thead>
<tr>
<th>Type</th>
<th>String</th>
</tr>
</thead>
</table>

| Default Value | `ndb$` |

The prefix used in naming the `ndbinfo` database’s base tables (normally hidden, unless exposed by setting `ndbinfo_show_hidden`). This is a read-only variable whose default value is `ndb$`. You can start the server with the `--ndbinfo-table-prefix` option, but this merely sets the variable and does not change the actual prefix used to name the hidden base tables; the prefix itself is determined at compile time.

- **ndbinfo_version**

<table>
<thead>
<tr>
<th>System Variable</th>
<th><code>ndbinfo_version</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Type</th>
<th>String</th>
</tr>
</thead>
</table>

| Default Value |            |

Shows the version of the `ndbinfo` engine in use; read-only.

**NDB Cluster Status Variables**

This section provides detailed information about MySQL server status variables that relate to NDB Cluster and the NDB storage engine. For status variables not specific to NDB Cluster, and for general information on using status variables, see Section 5.1.10, “Server Status Variables”.

- **Handler_discover**

  The MySQL server can ask the NDBCLUSTER storage engine if it knows about a table with a given name. This is called discovery. `Handler_discover` indicates the number of times that tables have been discovered using this mechanism.

- **Ndb_api_bytes_sent_count_session**

  Amount of data (in bytes) sent to the data nodes in this client session.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 22.5.13, “NDB API Statistics Counters and Variables”.

4091
NDB Cluster Configuration Files

- **Ndb_api_bytes_sent_count_slave**
  Amount of data (in bytes) sent to the data nodes by this replica.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

  For more information, see Section 22.5.13, “NDB API Statistics Counters and Variables”.

- **Ndb_api_bytes_sent_count**
  Amount of data (in bytes) sent to the data nodes by this MySQL Server (SQL node).

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 22.5.13, “NDB API Statistics Counters and Variables”.

- **Ndb_api_bytes_received_count_session**
  Amount of data (in bytes) received from the data nodes in this client session.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 22.5.13, “NDB API Statistics Counters and Variables”.

- **Ndb_api_bytes_received_count_slave**
  Amount of data (in bytes) received from the data nodes by this replica.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

  For more information, see Section 22.5.13, “NDB API Statistics Counters and Variables”.

- **Ndb_api_bytes_received_count**
  Amount of data (in bytes) received from the data nodes by this MySQL Server (SQL node).

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 22.5.13, “NDB API Statistics Counters and Variables”.

- **Ndb_api_event_data_count_injector**
  The number of row change events received by the NDB binlog injector thread.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 22.5.13, “NDB API Statistics Counters and Variables”.

- **Ndb_api_event_data_count**
  The number of row change events received by this MySQL Server (SQL node).
Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see Section 22.5.13, “NDB API Statistics Counters and Variables”.

- **Ndb_api_event_nondata_count_injector**
  
  The number of events received, other than row change events, by the NDB binary log injector thread.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 22.5.13, “NDB API Statistics Counters and Variables”.

- **Ndb_api_event_nondata_count**
  
  The number of events received, other than row change events, by this MySQL Server (SQL node).

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 22.5.13, “NDB API Statistics Counters and Variables”.

- **Ndb_api_event_bytes_count_injector**
  
  The number of bytes of events received by the NDB binlog injector thread.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 22.5.13, “NDB API Statistics Counters and Variables”.

- **Ndb_api_event_bytes_count**
  
  The number of bytes of events received by this MySQL Server (SQL node).

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 22.5.13, “NDB API Statistics Counters and Variables”.

- **Ndb_api_pk_op_count_session**
  
  The number of operations in this client session based on or using primary keys. This includes operations on blob tables, implicit unlock operations, and auto-increment operations, as well as user-visible primary key operations.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 22.5.13, “NDB API Statistics Counters and Variables”.

- **Ndb_api_pk_op_count_slave**
  
  The number of operations by this replica based on or using primary keys. This includes operations on blob tables, implicit unlock operations, and auto-increment operations, as well as user-visible primary key operations.
Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see Section 22.5.13, “NDB API Statistics Counters and Variables”.

- **Ndb_api_pk_op_count**

The number of operations by this MySQL Server (SQL node) based on or using primary keys. This includes operations on blob tables, implicit unlock operations, and auto-increment operations, as well as user-visible primary key operations.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see Section 22.5.13, “NDB API Statistics Counters and Variables”.

- **Ndb_api_pruned_scan_count_session**

The number of scans in this client session that have been pruned to a single partition.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see Section 22.5.13, “NDB API Statistics Counters and Variables”.

- **Ndb_api_pruned_scan_count_slave**

The number of scans by this replica that have been pruned to a single partition.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see Section 22.5.13, “NDB API Statistics Counters and Variables”.

- **Ndb_api_pruned_scan_count**

The number of scans by this MySQL Server (SQL node) that have been pruned to a single partition.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see Section 22.5.13, “NDB API Statistics Counters and Variables”.

- **Ndb_api_range_scan_count_session**

The number of range scans that have been started in this client session.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see Section 22.5.13, “NDB API Statistics Counters and Variables”.

- **Ndb_api_range_scan_count_slave**

The number of range scans that have been started by this replica.
Although this variable can be read using either \texttt{SHOW GLOBAL STATUS} or \texttt{SHOW SESSION STATUS}, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see \textit{Section 22.5.13, “NDB API Statistics Counters and Variables”}.

- \texttt{Ndb_api_range_scan_count}

  The number of range scans that have been started by this MySQL Server (SQL node).

  Although this variable can be read using either \texttt{SHOW GLOBAL STATUS} or \texttt{SHOW SESSION STATUS}, it is effectively global in scope.

  For more information, see \textit{Section 22.5.13, “NDB API Statistics Counters and Variables”}.

- \texttt{Ndb_api_read_row_count_session}

  The total number of rows that have been read in this client session. This includes all rows read by any primary key, unique key, or scan operation made in this client session.

  Although this variable can be read using either \texttt{SHOW GLOBAL STATUS} or \texttt{SHOW SESSION STATUS}, it relates to the current session only, and is not affected by any other clients of this \texttt{mysqld}.

  For more information, see \textit{Section 22.5.13, “NDB API Statistics Counters and Variables”}.

- \texttt{Ndb_api_read_row_count_slave}

  The total number of rows that have been read by this replica. This includes all rows read by any primary key, unique key, or scan operation made by this replica.

  Although this variable can be read using either \texttt{SHOW GLOBAL STATUS} or \texttt{SHOW SESSION STATUS}, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

  For more information, see \textit{Section 22.5.13, “NDB API Statistics Counters and Variables”}.

- \texttt{Ndb_api_read_row_count}

  The total number of rows that have been read by this MySQL Server (SQL node). This includes all rows read by any primary key, unique key, or scan operation made by this MySQL Server (SQL node).

  You should be aware that this value may not be completely accurate with regard to rows read by \texttt{SELECT COUNT(*)} queries, due to the fact that, in this case, the MySQL server actually reads pseudo-rows in the form \texttt{[table fragment ID]:[number of rows in fragment]} and sums the rows per fragment for all fragments in the table to derive an estimated count for all rows. \texttt{Ndb_api_read_row_count} uses this estimate and not the actual number of rows in the table.

  Although this variable can be read using either \texttt{SHOW GLOBAL STATUS} or \texttt{SHOW SESSION STATUS}, it is effectively global in scope.

  For more information, see \textit{Section 22.5.13, “NDB API Statistics Counters and Variables”}.
- **Ndb_api_scan_batch_count_session**
  The number of batches of rows received in this client session. 1 batch is defined as 1 set of scan results from a single fragment.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 22.5.13, “NDB API Statistics Counters and Variables”.

- **Ndb_api_scan_batch_count_slave**
  The number of batches of rows received by this replica. 1 batch is defined as 1 set of scan results from a single fragment.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

  For more information, see Section 22.5.13, “NDB API Statistics Counters and Variables”.

- **Ndb_api_scan_batch_count**
  The number of batches of rows received by this MySQL Server (SQL node). 1 batch is defined as 1 set of scan results from a single fragment.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 22.5.13, “NDB API Statistics Counters and Variables”.

- **Ndb_api_table_scan_count_session**
  The number of table scans that have been started in this client session, including scans of internal tables.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 22.5.13, “NDB API Statistics Counters and Variables”.

- **Ndb_api_table_scan_count_slave**
  The number of table scans that have been started by this replica, including scans of internal tables.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

  For more information, see Section 22.5.13, “NDB API Statistics Counters and Variables”.

- **Ndb_api_table_scan_count**
  The number of table scans that have been started by this MySQL Server (SQL node), including scans of internal tables.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.
For more information, see Section 22.5.13, “NDB API Statistics Counters and Variables”.

• **Ndb_api_trans_abort_count_session**

The number of transactions aborted in this client session.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this mysqld.

For more information, see Section 22.5.13, “NDB API Statistics Counters and Variables”.

• **Ndb_api_trans_abort_count_slave**

The number of transactions aborted by this replica.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see Section 22.5.13, “NDB API Statistics Counters and Variables”.

• **Ndb_api_trans_abort_count**

The number of transactions aborted by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see Section 22.5.13, “NDB API Statistics Counters and Variables”.

• **Ndb_api_trans_close_count_session**

The number of transactions closed in this client session. This value may be greater than the sum of `Ndb_api_trans_commit_count_session` and `Ndb_api_trans_abort_count_session`, since some transactions may have been rolled back.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this mysqld.

For more information, see Section 22.5.13, “NDB API Statistics Counters and Variables”.

• **Ndb_api_trans_close_count_slave**

The number of transactions closed by this replica. This value may be greater than the sum of `Ndb_api_trans_commit_count_slave` and `Ndb_api_trans_abort_count_slave`, since some transactions may have been rolled back.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see Section 22.5.13, “NDB API Statistics Counters and Variables”.
NDB Cluster Configuration Files

• **Ndb_api_trans_close_count**

  The number of transactions closed by this MySQL Server (SQL node). This value may be greater than the sum of **Ndb_api_trans_commit_count** and **Ndb_api_trans_abort_count**, since some transactions may have been rolled back.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see [Section 22.5.13, “NDB API Statistics Counters and Variables”](#).

• **Ndb_api_trans_commit_count_session**

  The number of transactions committed in this client session.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see [Section 22.5.13, “NDB API Statistics Counters and Variables”](#).

• **Ndb_api_trans_commit_count_slave**

  The number of transactions committed by this replica.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

  For more information, see [Section 22.5.13, “NDB API Statistics Counters and Variables”](#).

• **Ndb_api_trans_commit_count**

  The number of transactions committed by this MySQL Server (SQL node).

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see [Section 22.5.13, “NDB API Statistics Counters and Variables”](#).

• **Ndb_api_trans_local_read_row_count_session**

  The total number of rows that have been read in this client session. This includes all rows read by any primary key, unique key, or scan operation made in this client session.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see [Section 22.5.13, “NDB API Statistics Counters and Variables”](#).
• **Ndb_api_trans_local_read_row_count_slave**

  The total number of rows that have been read by this replica. This includes all rows read by any primary key, unique key, or scan operation made by this replica.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

  For more information, see [Section 22.5.13, “NDB API Statistics Counters and Variables”](#).

• **Ndb_api_trans_local_read_row_count**

  The total number of rows that have been read by this MySQL Server (SQL node). This includes all rows read by any primary key, unique key, or scan operation made by this MySQL Server (SQL node).

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see [Section 22.5.13, “NDB API Statistics Counters and Variables”](#).

• **Ndb_api_trans_start_count_session**

  The number of transactions started in this client session.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see [Section 22.5.13, “NDB API Statistics Counters and Variables”](#).

• **Ndb_api_trans_start_count_slave**

  The number of transactions started by this replica.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

  For more information, see [Section 22.5.13, “NDB API Statistics Counters and Variables”](#).

• **Ndb_api_trans_start_count**

  The number of transactions started by this MySQL Server (SQL node).

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see [Section 22.5.13, “NDB API Statistics Counters and Variables”](#).

• **Ndb_api_uk_op_count_session**

  The number of operations in this client session based on or using unique keys.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see [Section 22.5.13, “NDB API Statistics Counters and Variables”](#).

• **Ndb_api_uk_op_count_slave**

  4099
The number of operations by this replica based on or using unique keys.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see Section 22.5.13, “NDB API Statistics Counters and Variables”.

- **Ndb_api_uk_op_count**

  The number of operations by this MySQL Server (SQL node) based on or using unique keys.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 22.5.13, “NDB API Statistics Counters and Variables”.

- **Ndb_api_wait_exec_complete_count_session**

  The number of times a thread has been blocked in this client session while waiting for execution of an operation to complete. This includes all `execute()` calls as well as implicit executes for blob and auto-increment operations not visible to clients.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 22.5.13, “NDB API Statistics Counters and Variables”.

- **Ndb_api_wait_exec_complete_count_slave**

  The number of times a thread has been blocked by this replica while waiting for execution of an operation to complete. This includes all `execute()` calls as well as implicit executes for blob and auto-increment operations not visible to clients.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

  For more information, see Section 22.5.13, “NDB API Statistics Counters and Variables”.

- **Ndb_api_wait_exec_complete_count**

  The number of times a thread has been blocked by this MySQL Server (SQL node) while waiting for execution of an operation to complete. This includes all `execute()` calls as well as implicit executes for blob and auto-increment operations not visible to clients.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 22.5.13, “NDB API Statistics Counters and Variables”.

4100
• **Ndb_api_wait_meta_request_count_session**

The number of times a thread has been blocked in this client session waiting for a metadata-based signal, such as is expected for DDL requests, new epochs, and seizure of transaction records.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see Section 22.5.13, “NDB API Statistics Counters and Variables”.

• **Ndb_api_wait_meta_request_count_slave**

The number of times a thread has been blocked by this replica waiting for a metadata-based signal, such as is expected for DDL requests, new epochs, and seizure of transaction records.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see Section 22.5.13, “NDB API Statistics Counters and Variables”.

• **Ndb_api_wait_meta_request_count**

The number of times a thread has been blocked by this MySQL Server (SQL node) waiting for a metadata-based signal, such as is expected for DDL requests, new epochs, and seizure of transaction records.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see Section 22.5.13, “NDB API Statistics Counters and Variables”.

• **Ndb_api_wait_nanos_count_session**

Total time (in nanoseconds) spent in this client session waiting for any type of signal from the data nodes.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see Section 22.5.13, “NDB API Statistics Counters and Variables”.

• **Ndb_api_wait_nanos_count_slave**

Total time (in nanoseconds) spent by this replica waiting for any type of signal from the data nodes.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see Section 22.5.13, “NDB API Statistics Counters and Variables”.
• **Ndb_api_wait_nanos_count**

  Total time (in nanoseconds) spent by this MySQL Server (SQL node) waiting for any type of signal from the data nodes.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 22.5.13, “NDB API Statistics Counters and Variables”.

• **Ndb_api_wait_scan_result_count_session**

  The number of times a thread has been blocked in this client session while waiting for a scan-based signal, such as when waiting for more results from a scan, or when waiting for a scan to close.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 22.5.13, “NDB API Statistics Counters and Variables”.

• **Ndb_api_wait_scan_result_count_slave**

  The number of times a thread has been blocked by this replica while waiting for a scan-based signal, such as when waiting for more results from a scan, or when waiting for a scan to close.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

  For more information, see Section 22.5.13, “NDB API Statistics Counters and Variables”.

• **Ndb_api_wait_scan_result_count**

  The number of times a thread has been blocked by this MySQL Server (SQL node) while waiting for a scan-based signal, such as when waiting for more results from a scan, or when waiting for a scan to close.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 22.5.13, “NDB API Statistics Counters and Variables”.

• **Ndb_cluster_node_id**

  If the server is acting as an NDB Cluster node, then the value of this variable its node ID in the cluster.

  If the server is not part of an NDB Cluster, then the value of this variable is 0.

• **Ndb_config_from_host**

  If the server is part of an NDB Cluster, the value of this variable is the host name or IP address of the Cluster management server from which it gets its configuration data.

  If the server is not part of an NDB Cluster, then the value of this variable is an empty string.
• **Ndb_config_from_port**

If the server is part of an NDB Cluster, the value of this variable is the number of the port through which it is connected to the Cluster management server from which it gets its configuration data.

If the server is not part of an NDB Cluster, then the value of this variable is 0.

• **Ndb_conflict_fn_max_del_win**

Shows the number of times that a row was rejected on the current SQL node due to NDB Cluster Replication conflict resolution using \texttt{NDB$MAX\_DELETE\_WIN()}, since the last time that this \texttt{mysqld} was started.

For more information, see Section 22.6.11, “NDB Cluster Replication Conflict Resolution”.

• **Ndb_conflict_fn_max**

Used in NDB Cluster Replication conflict resolution, this variable shows the number of times that a row was not applied on the current SQL node due to “greatest timestamp wins” conflict resolution since the last time that this \texttt{mysqld} was started.

For more information, see Section 22.6.11, “NDB Cluster Replication Conflict Resolution”.

• **Ndb_conflict_fn_old**

Used in NDB Cluster Replication conflict resolution, this variable shows the number of times that a row was not applied as the result of “same timestamp wins” conflict resolution on a given \texttt{mysqld} since the last time it was restarted.

For more information, see Section 22.6.11, “NDB Cluster Replication Conflict Resolution”.

• **Ndb_conflict_fn_epoch**

Used in NDB Cluster Replication conflict resolution, this variable shows the number of rows found to be in conflict using \texttt{NDB$EPOCH()} conflict resolution on a given \texttt{mysqld} since the last time it was restarted.

For more information, see Section 22.6.11, “NDB Cluster Replication Conflict Resolution”.

• **Ndb_conflict_fn_epoch2**

Shows the number of rows found to be in conflict in NDB Cluster Replication conflict resolution, when using \texttt{NDB$EPOCH2()}, on the source designated as the primary since the last time it was restarted.

For more information, see \texttt{NDB$EPOCH2()}.

• **Ndb_conflict_fn_epoch_trans**

Used in NDB Cluster Replication conflict resolution, this variable shows the number of rows found to be in conflict using \texttt{NDB$EPOCH\_TRANS()} conflict resolution on a given \texttt{mysqld} since the last time it was restarted.

For more information, see Section 22.6.11, “NDB Cluster Replication Conflict Resolution”.

• **Ndb_conflict_fn_epoch2_trans**

Used in NDB Cluster Replication conflict resolution, this variable shows the number of rows found to be in conflict using \texttt{NDB$EPOCH\_TRANS2()} conflict resolution on a given \texttt{mysqld} since the last time it was restarted.
NDB Cluster Configuration Files

For more information, see `NDB$EPOCH2_TRANS()`.

- **Ndb_conflict_last_conflict_epoch**
  The most recent epoch in which a conflict was detected on this replica. You can compare this value with `Ndb_slave_max_replicated_epoch`; if `Ndb_slave_max_replicated_epoch` is greater than `Ndb_conflict_last_conflict_epoch`, no conflicts have yet been detected.
  
  See Section 22.6.11, “NDB Cluster Replication Conflict Resolution”, for more information.

- **Ndb_conflict_reflected_op_discard_count**
  When using NDB Cluster Replication conflict resolution, this is the number of reflected operations that were not applied on the secondary, due to encountering an error during execution.
  
  See Section 22.6.11, “NDB Cluster Replication Conflict Resolution”, for more information.

- **Ndb_conflict_reflected_op_prepare_count**
  When using conflict resolution with NDB Cluster Replication, this status variable contains the number of reflected operations that have been defined (that is, prepared for execution on the secondary).
  
  See Section 22.6.11, “NDB Cluster Replication Conflict Resolution”.

- **Ndb_conflict_refresh_op_count**
  When using conflict resolution with NDB Cluster Replication, this gives the number of refresh operations that have been prepared for execution on the secondary.
  
  See Section 22.6.11, “NDB Cluster Replication Conflict Resolution”, for more information.

- **Ndb_conflict_last_stable_epoch**
  Number of rows found to be in conflict by a transactional conflict function
  
  See Section 22.6.11, “NDB Cluster Replication Conflict Resolution”, for more information.

- **Ndb_conflict_trans_row_conflict_count**
  Used in NDB Cluster Replication conflict resolution, this status variable shows the number of rows found to be directly in-conflict by a transactional conflict function on a given `mysqld` since the last time it was restarted.
  
  Currently, the only transactional conflict detection function supported by NDB Cluster is `NDB$EPOCH_TRANS()`, so this status variable is effectively the same as `Ndb_conflict_fn_epoch_trans`.
  
  For more information, see Section 22.6.11, “NDB Cluster Replication Conflict Resolution”.

- **Ndb_conflict_trans_row_reject_count**
  Used in NDB Cluster Replication conflict resolution, this status variable shows the total number of rows realigned due to being determined as conflicting by a transactional conflict detection function. This includes not only `Ndb_conflict_trans_row_conflict_count`, but any rows in or dependent on conflicting transactions.
  
  For more information, see Section 22.6.11, “NDB Cluster Replication Conflict Resolution”.
NDB Cluster Configuration Files

- **Ndb_conflict_trans_reject_count**
  Used in NDB Cluster Replication conflict resolution, this status variable shows the number of transactions found to be in conflict by a transactional conflict detection function.
  For more information, see Section 22.6.11, "NDB Cluster Replication Conflict Resolution".

- **Ndb_conflict_trans_detect_iter_count**
  Used in NDB Cluster Replication conflict resolution, this shows the number of internal iterations required to commit an epoch transaction. Should be (slightly) greater than or equal to **Ndb_conflict_trans_conflict_commit_count**.
  For more information, see Section 22.6.11, "NDB Cluster Replication Conflict Resolution".

- **Ndb_conflict_trans_conflict_commit_count**
  Used in NDB Cluster Replication conflict resolution, this shows the number of epoch transactions committed after they required transactional conflict handling.
  For more information, see Section 22.6.11, "NDB Cluster Replication Conflict Resolution".

- **Ndb_epoch_delete_delete_count**
  When using delete-delete conflict detection, this is the number of delete-delete conflicts detected, where a delete operation is applied, but the indicated row does not exist.

- **Ndb_execute_count**
  Provides the number of round trips to the NDB kernel made by operations.

- **Ndb_last_commit_epoch_server**
  The epoch most recently committed by NDB.

- **Ndb_last_commit_epoch_session**
  The epoch most recently committed by this NDB client.

- **Ndb_metadata_detected_count**
  The number of times since this server was last started that the NDB metadata change detection thread has discovered changes with respect to the MySQL data dictionary.
  Added in NDB 8.0.16.

- **Ndb_metadata_excluded_count**
  The number of metadata objects that the NDB binlog thread has been unable to synchronize on this SQL node since it was last restarted.
  Should an object be excluded, it is not again considered for automatic synchronization until the user corrects the mismatch manually. This can be done by attempting to use the table with a statement such as `SHOW CREATE TABLE table, SELECT * FROM table`, or any other statement that would trigger table discovery.
  Added in NDB 8.0.18. Prior to NDB 8.0.22, this variable was named **Ndb_metadata_blacklist_size**.
• **Ndb_metadata_synced_count**

The number of NDB metadata objects which have been synchronized on this SQL node since it was last restarted.

Added in NDB 8.0.18.

• **Ndb_number_of_data_nodes**

If the server is part of an NDB Cluster, the value of this variable is the number of data nodes in the cluster.

If the server is not part of an NDB Cluster, then the value of this variable is 0.

• **Ndb_pushed_queries_defined**

The total number of joins pushed down to the NDB kernel for distributed handling on the data nodes.

**Note**

Joins tested using `EXPLAIN` that can be pushed down contribute to this number.

• **Ndb_pushed_queries_dropped**

The number of joins that were pushed down to the NDB kernel but that could not be handled there.

• **Ndb_pushed_queries_executed**

The number of joins successfully pushed down to NDB and executed there.

• **Ndb_pushed_reads**

The number of rows returned to `mysql` from the NDB kernel by joins that were pushed down.

**Note**

Executing `EXPLAIN` on joins that can be pushed down to NDB does not add to this number.

• **Ndb_pruned_scan_count**

This variable holds a count of the number of scans executed by `NDBCLUSTER` since the NDB Cluster was last started where `NDBCLUSTER` was able to use partition pruning.

Using this variable together with `Ndb_scan_count` can be helpful in schema design to maximize the ability of the server to prune scans to a single table partition, thereby involving only a single data node.

• **Ndb_scan_count**

This variable holds a count of the total number of scans executed by `NDBCLUSTER` since the NDB Cluster was last started.
NDB Cluster Configuration Files

- **Ndb_slave_max_replicated_epoch**

  The most recently committed epoch on this replica. You can compare this value with `Ndb_conflict_last_conflict_epoch`; if `Ndb_slave_max_replicated_epoch` is the greater of the two, no conflicts have yet been detected.

  For more information, see Section 22.6.11, “NDB Cluster Replication Conflict Resolution”.

- **Ndb_system_name**

  If this MySQL Server is connected to an NDB cluster, this read-only variable shows the cluster system name. Otherwise, the value is an empty string.

- **Ndb_trans_hint_count_session**

  The number of transactions using hints that have been started in the current session. Compare with `Ndb_api_trans_start_count_session` to obtain the proportion of all NDB transactions able to use hints. Added in NDB 8.0.17.

### 22.3.3.10 NDB Cluster TCP/IP Connections

TCP/IP is the default transport mechanism for all connections between nodes in an NDB Cluster. Normally it is not necessary to define TCP/IP connections; NDB Cluster automatically sets up such connections for all data nodes, management nodes, and SQL or API nodes.

**Note**

For an exception to this rule, see Section 22.3.3.11, “NDB Cluster TCP/IP Connections Using Direct Connections”.

To override the default connection parameters, it is necessary to define a connection using one or more `[tcp]` sections in the `config.ini` file. Each `[tcp]` section explicitly defines a TCP/IP connection between two NDB Cluster nodes, and must contain at a minimum the parameters `NodeId1` and `NodeId2`, as well as any connection parameters to override.

It is also possible to change the default values for these parameters by setting them in the `[tcp default]` section.

**Important**

Any `[tcp]` sections in the `config.ini` file should be listed *last*, following all other sections in the file. However, this is not required for a `[tcp default]` section. This requirement is a known issue with the way in which the `config.ini` file is read by the NDB Cluster management server.

Connection parameters which can be set in `[tcp]` and `[tcp default]` sections of the `config.ini` file are listed here:

- **AllowUnresolvedHostNames**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.22</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>
By default, when a management node fails to resolve a host name while trying to connect, this results in a fatal error. This behavior can be overridden by setting `AllowUnresolvedHostNames` to `true` in the `[tcp default]` section of the global configuration file (usually named `config.ini`), in which case failure to resolve a host name is treated as a warning and `ndb_mgmd` startup continues uninterrupted.

**Checksum**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter is a boolean parameter (enabled by setting it to `Y` or `1`, disabled by setting it to `N` or `0`). It is disabled by default. When it is enabled, checksums for all messages are calculated before they placed in the send buffer. This feature ensures that messages are not corrupted while waiting in the send buffer, or by the transport mechanism.

**Group**

When `ndb_optimized_node_selection` is enabled, node proximity is used in some cases to select which node to connect to. This parameter can be used to influence proximity by setting it to a lower value, which is interpreted as “closer”. See the description of the system variable for more information.

**HostName1**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>name or IP address</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

The `HostName1` and `HostName2` parameters can be used to specify specific network interfaces to be used for a given TCP connection between two nodes. The values used for these parameters can be host names or IP addresses.

**HostName2**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>name or IP address</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

The `HostName1` and `HostName2` parameters can be used to specify specific network interfaces to be used for a given TCP connection between two nodes. The values used for these parameters can be host names or IP addresses.

**NodeId1**
### NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type or units</th>
<th>Default</th>
<th>Range</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>NodeId1</strong></td>
<td>numeric</td>
<td>[none]</td>
<td>1 - 255</td>
<td>N</td>
</tr>
<tr>
<td><strong>NodeId2</strong></td>
<td>numeric</td>
<td>[none]</td>
<td>1 - 255</td>
<td>N</td>
</tr>
<tr>
<td><strong>OverloadLimit</strong></td>
<td>bytes</td>
<td>0</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
<tr>
<td><strong>PreSendChecksum</strong></td>
<td>boolean</td>
<td>false</td>
<td>true, false</td>
<td>S</td>
</tr>
</tbody>
</table>

To identify a connection between two nodes it is necessary to provide their node IDs in the `[tcp]` section of the configuration file as the values of `NodeId1` and `NodeId2`. These are the same unique `Id` values for each of these nodes as described in Section 22.3.3.7, “Defining SQL and Other API Nodes in an NDB Cluster”.

- **NodeId2**

- **OverloadLimit**

  When more than this many unsent bytes are in the send buffer, the connection is considered overloaded.

  This parameter can be used to determine the amount of unsent data that must be present in the send buffer before the connection is considered overloaded. See Section 22.3.3.14, “Configuring NDB Cluster Send Buffer Parameters”, for more information.

- **PreSendChecksum**

  If this parameter and `Checksum` are both enabled, perform pre-send checksum checks, and check all TCP signals between nodes for errors. Has no effect if `Checksum` is not also enabled.
NDB Cluster Configuration Files

- **ReceiveBufferMemory**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>2M</td>
</tr>
<tr>
<td>Range</td>
<td>16K - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Specifies the size of the buffer used when receiving data from the TCP/IP socket.

The default value of this parameter is 2MB. The minimum possible value is 16KB; the theoretical maximum is 4GB.

- **SendBufferMemory**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>2M</td>
</tr>
<tr>
<td>Range</td>
<td>256K - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

TCP transporters use a buffer to store all messages before performing the send call to the operating system. When this buffer reaches 64KB its contents are sent; these are also sent when a round of messages have been executed. To handle temporary overload situations it is also possible to define a bigger send buffer.

If this parameter is set explicitly, then the memory is not dedicated to each transporter; instead, the value used denotes the hard limit for how much memory (out of the total available memory—that is, TotalSendBufferMemory) that may be used by a single transporter. For more information about configuring dynamic transporter send buffer memory allocation in NDB Cluster, see Section 22.3.3.14, “Configuring NDB Cluster Send Buffer Parameters”.

The default size of the send buffer is 2MB, which is the size recommended in most situations. The minimum size is 64 KB, the theoretical maximum is 4 GB.

- **SendSignalId**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false (debug builds: true)</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

To be able to retrace a distributed message datagram, it is necessary to identify each message. When this parameter is set to Y, message IDs are transported over the network. This feature is disabled by default in production builds, and enabled in -debug builds.

- **TcpBind_INADDR_ANY**

Setting this parameter to TRUE or 1 binds IP_ADDR_ANY so that connections can be made from anywhere (for autogenerated connections). The default is FALSE (0).
### NDB Cluster Configuration Files

- **TcpSpinTime**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.20</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>µsec</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 2000</td>
</tr>
</tbody>
</table>

**Restart Type**: N

**Added**: NDB 8.0.20

Controls spin for a TCP transporter; no enable, set to a nonzero value. This works for both the data node and management or SQL node side of the connection.

- **TCP_MAXSEG_SIZE**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 2G</td>
</tr>
</tbody>
</table>

**Restart Type**: N

Determines the size of the memory set during TCP transporter initialization. The default is recommended for most common usage cases.

- **TCP_RCV_BUF_SIZE**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 2G</td>
</tr>
</tbody>
</table>

**Restart Type**: N

Determines the size of the receive buffer set during TCP transporter initialization. The default and minimum value is 0, which allows the operating system or platform to set this value. The default is recommended for most common usage cases.

- **TCP_SND_BUF_SIZE**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 2G</td>
</tr>
</tbody>
</table>

**Restart Type**: N

Determines the size of the send buffer set during TCP transporter initialization. The default and minimum value is 0, which allows the operating system or platform to set this value. The default is recommended for most common usage cases.
**Restart types.** Information about the restart types used by the parameter descriptions in this section is shown in the following table:

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Restart Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>N</td>
<td>Node</td>
<td>The parameter can be updated using a rolling restart (see Section 22.5.5, “Performing a Rolling Restart of an NDB Cluster”)</td>
</tr>
<tr>
<td>S</td>
<td>System</td>
<td>All cluster nodes must be shut down completely, then restarted, to effect a change in this parameter</td>
</tr>
<tr>
<td>I</td>
<td>Initial</td>
<td>Data nodes must be restarted using the <code>--initial</code> option</td>
</tr>
</tbody>
</table>

### 22.3.3.11 NDB Cluster TCP/IP Connections Using Direct Connections

Setting up a cluster using direct connections between data nodes requires specifying explicitly the crossover IP addresses of the data nodes so connected in the [tcp] section of the cluster `config.ini` file.

In the following example, we envision a cluster with at least four hosts, one each for a management server, an SQL node, and two data nodes. The cluster as a whole resides on the `172.23.72.*` subnet of a LAN. In addition to the usual network connections, the two data nodes are connected directly using a standard crossover cable, and communicate with one another directly using IP addresses in the `1.1.0.*` address range as shown:

```ini
# Management Server
[ndb_mgmd]
Id=1
HostName=172.23.72.20

# SQL Node
[mysqld]
Id=2
HostName=172.23.72.21

# Data Nodes
[ndbd]
Id=3
HostName=172.23.72.22
[ndbd]
Id=4
HostName=172.23.72.23

# TCP/IP Connections
[tcp]
NodeId1=3
NodeId2=4
HostName1=1.1.0.1
HostName2=1.1.0.2
```

The `HostName1` and `HostName2` parameters are used only when specifying direct connections.

The use of direct TCP connections between data nodes can improve the cluster's overall efficiency by enabling the data nodes to bypass an Ethernet device such as a switch, hub, or router, thus cutting down on the cluster's latency.
Note
To take the best advantage of direct connections in this fashion with more than two
data nodes, you must have a direct connection between each data node and every
other data node in the same node group.

22.3.3.12 NDB Cluster Shared-Memory Connections

Communications between NDB cluster nodes are normally handled using TCP/IP. The shared memory
(SHM) transporter is distinguished by the fact that signals are transmitted by writing in memory rather than
on a socket. The shared-memory transporter (SHM) can improve performance by negating up to 20% of
the overhead required by a TCP connection when running an API node (usually an SQL node) and a data
node together on the same host. You can enable a shared memory connection in either of the two ways
listed here:

• By setting the UseShm data node configuration parameter to 1, and setting HostName for the data node
  and HostName for the API node to the same value.

• By using [shm] sections in the cluster configuration file, each containing settings for NodeId1 and
  NodeId2. This method is described in more detail later in this section.

Suppose a cluster is running a data node which has node ID 1 and an SQL node having node ID 51 on
the same host computer at 10.0.0.1. To enable an SHM connection between these two nodes, all that is
necessary is to insure that the following entries are included in the cluster configuration file:

```
[ndbd]
NodeId=1
HostName=10.0.0.1
UseShm=1

[mysqld]
NodeId=51
HostName=10.0.0.1
```

Important
The two entries just shown are in addition to any other entries and parameter
settings needed by the cluster. A more complete example is shown later in this
section.

Before starting data nodes that use SHM connections, it is also necessary to make sure that the operating
system on each computer hosting such a data node has sufficient memory allocated to shared memory
segments. See the documentation for your operating platform for information regarding this. In setups
where multiple hosts are each running a data node and an API node, it is possible to enable shared
memory on all such hosts by setting UseShm in the [ndbd default] section of the configuration file.
This is shown in the example later in this section.

While not strictly required, tuning for all SHM connections in the cluster can be done by setting one or more
of the following parameters in the [shm default] section of the cluster configuration (config.ini) file:

• ShmSize: Shared memory size

• ShmSpinTime: Time in µs to spin before sleeping

• SendBufferMemory: Size of buffer for signals sent from this node, in bytes.

• SendSignalId: Indicates that a signal ID is included in each signal sent through the transporter.

• Checksum: Indicates that a checksum is included in each signal sent through the transporter.
• **PreSendChecksum**: Checks of the checksum are made prior to sending the signal; Checksum must also be enabled for this to work

This example shows a simple setup with SHM connections defined on multiple hosts, in an NDB Cluster using 3 computers listed here by host name, hosting the node types shown:

1. **10.0.0.0**: The management server
2. **10.0.0.1**: A data node and an SQL node
3. **10.0.0.2**: A data node and an SQL node

In this scenario, each data node communicates with both the management server and the other data node using TCP transporters; each SQL node uses a shared memory transporter to communicate with the data nodes that is local to it, and a TCP transporter to communicate with the remote data node. A basic configuration reflecting this setup is enabled by the config.ini file whose contents are shown here:

```
[nbdb default]
DataDir=/path/to/datadir
UseShm=1

[shm default]
ShmSize=8M
ShmSpintime=200
SendBufferMemory=4M

[tcp default]
SendBufferMemory=8M

[nbdb_mgmd]
NodeId=49
Hostname=10.0.0.0
DataDir=/path/to/datadir

[nbdb]
NodeId=1
Hostname=10.0.0.1
DataDir=/path/to/datadir

[nbdb]
NodeId=2
Hostname=10.0.0.2
DataDir=/path/to/datadir

[mysqld]
NodeId=51
Hostname=10.0.0.1

[mysqld]
NodeId=52
Hostname=10.0.0.2

[api]
[api]
```

Parameters affecting all shared memory transporters are set in the **[shm default]** section; these can be overridden on a per-connection basis in one or more **[shm]** sections. Each such section must be associated with a given SHM connection using `NodeId1` and `NodeId2`; the values required for these parameters are the node IDs of the two nodes connected by the transporter. You can also identify the nodes by host name using `HostName1` and `HostName2`, but these parameters are not required.

The API nodes for which no host names are set use the TCP transporter to communicate with data nodes independent of the hosts on which they are started; the parameters and values set in the **[tcp default]** section of the configuration file apply to all TCP transporters in the cluster.
For optimum performance, you can define a spin time for the SHM transporter (ShmSpinTime parameter); this affects both the data node receiver thread and the poll owner (receive thread or user thread) in NDB.

- **Checksum**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>true</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter is a boolean (Y/N) parameter which is disabled by default. When it is enabled, checksums for all messages are calculated before being placed in the send buffer.

This feature prevents messages from being corrupted while waiting in the send buffer. It also serves as a check against data being corrupted during transport.

- **Group**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>35</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 200</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Determines the group proximity; a smaller value is interpreted as being closer. The default value is sufficient for most conditions.

- **HostName1**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>name or IP address</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

The HostName1 and HostName2 parameters can be used to specify specific network interfaces to be used for a given SHM connection between two nodes. The values used for these parameters can be host names or IP addresses.

- **HostName2**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>name or IP address</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
</tbody>
</table>
The `HostName1` and `HostName2` parameters can be used to specify specific network interfaces to be used for a given SHM connection between two nodes. The values used for these parameters can be host names or IP addresses.

- **NodeId1**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 255</td>
</tr>
</tbody>
</table>

To identify a connection between two nodes it is necessary to provide node identifiers for each of them, as `NodeId1` and `NodeId2`.

- **NodeId2**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 255</td>
</tr>
</tbody>
</table>

To identify a connection between two nodes it is necessary to provide node identifiers for each of them, as `NodeId1` and `NodeId2`.

- **NodeIdServer**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 63</td>
</tr>
</tbody>
</table>

Identify the server end of a shared memory connection. By default, this is the node ID of the data node.

- **OverloadLimit**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>
NDB Cluster Configuration Files

| Restart Type | N |

When more than this many unsent bytes are in the send buffer, the connection is considered overloaded. See Section 22.3.3.14, “Configuring NDB Cluster Send Buffer Parameters”, and Section 22.5.14.47, “The ndbinfo transporters Table”, for more information.

- **PreSendChecksum**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td>Restart Type</td>
<td>S</td>
</tr>
</tbody>
</table>

If this parameter and **Checksum** are both enabled, perform pre-send checksum checks, and check all SHM signals between nodes for errors. Has no effect if **Checksum** is not also enabled.

- **SendBufferMemory**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>2M</td>
</tr>
<tr>
<td>Range</td>
<td>256K - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Size (in bytes) of the shared memory buffer for signals sent from this node using a shared memory connection.

- **SendSignalId**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

To retrace the path of a distributed message, it is necessary to provide each message with a unique identifier. Setting this parameter to `Y` causes these message IDs to be transported over the network as well. This feature is disabled by default in production builds, and enabled in `-debug` builds.

- **ShmKey**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>
When setting up shared memory segments, a node ID, expressed as an integer, is used to identify uniquely the shared memory segment to use for the communication. There is no default value. If `UseShm` is enabled, the shared memory key is calculated automatically by NDB.

• **ShmSize**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>

<td>The parameter can be updated using a rolling restart (see Section 22.5.5, “Performing a Rolling Restart of an NDB Cluster”)</td>
</tr>
</tbody>
</table>
### Symbol | Restart Type | Description
---|---|---
S | System | All cluster nodes must be shut down completely, then restarted, to effect a change in this parameter
I | Initial | Data nodes must be restarted using the `--initial` option

#### 22.3.3.13 Data Node Memory Management

All memory allocation for a data node is performed when the node is started. This ensures that the data node can run in a stable manner without using swap memory, so that NDB can be used for latency-sensitive (realtime) applications. The following types of memory are allocated on data node startup:

- Data memory
- Shared global memory
- Redo log buffers
- Job buffers
- Send buffers
- Page cache for disk data records
- Schema transaction memory
- Transaction memory
- Undo log buffer
- Query memory
- Block objects
- Schema memory
- Block data structures
- Long signal memory
- Shared memory communication buffers

The NDB memory manager, which regulates most data node memory, handles the following memory resources:

- Data Memory (`DataMemory`)
- Redo log buffers (`RedoBuffer`)
- Job buffers
- Send buffers (`SendBufferMemory, TotalSendBufferMemory, ExtraSendBufferMemory, ReservedSendBufferMemory`)
- Disk Data record page cache (`DiskPageBufferMemory, DiskPageBufferEntries`)
- Transaction memory (`TransactionMemory`)
- Query memory
• Disk access records

• File buffers

Each of these resources is set up with a reserved memory area and a maximum memory area. The reserved memory area can be used only by the resource for which it is reserved and cannot be shared with other resources; a given resource can never allocate more than the maximum memory allowed for the resource. A resource that has no maximum memory can expand to use all the shared memory in the memory manager.

The size of the global shared memory for these resources is controlled by the `SharedGlobalMemory` configuration parameter (default: 128 MB).

Data memory is always reserved and never acquires any memory from shared memory. It is controlled using the `DataMemory` configuration parameter, whose maximum is 16384 GB. `DataMemory` is where records are stored, including hash indexes (approximately 15 bytes per row), ordered indexes (10-12 bytes per row per index), and row headers (16-32 bytes per row).

Redo log buffers also use reserved memory only; this is controlled by the `RedoBuffer` configuration parameter, which sets the size of the redo log buffer per LDM thread. This means that the actual amount of memory used is the value of this parameter multiplied by the number of LDM threads in the data node.

Job buffers use reserved memory only; the size of this memory is calculated by NDB, based on the numbers of threads of various types.

Send buffers have a reserved part but can also allocate an additional 25% of shared global memory. The send buffer reserved size is calculated in two steps:

1. Use the value of the `TotalSendBufferMemory` configuration parameter (no default value) or the sum of the individual send buffers used by all individual connections to the data node. A data node is connected to all other data nodes, to all API nodes, and to all management nodes. This means that, in a cluster with 2 data nodes, 2 management nodes, and 10 API nodes each data node has 13 node connections. Since the default value for `SendBufferMemory` for a data node connection is 2 MByte, this works out to 26 MB total.

2. To obtain the total reserved size for the send buffer, the value of the `ExtraSendBufferMemory` configuration parameter, if any (default value 0), is added to the value obtained in the previous step.

In other words, if `TotalSendBufferMemory` has been set, the send buffer size is `TotalSendBufferMemory + ExtraSendBufferMemory`; otherwise, the size of the send buffer is equal to `([number of node connections] * SendBufferMemory) + ExtraSendBufferMemory`.

The page cache for disk data records uses a reserved resource only; the size of this resource is controlled by the `DiskPageBufferMemory` configuration parameter (default 64 MB). Memory for 32 KB disk page entries is also allocated; the number of these is determined by the `DiskPageBufferEntries` configuration parameter (default 10).

Transaction memory has a reserved part that either is calculated by NDB, or is set explicitly using the `TransactionMemory` configuration parameter introduced in NDB 8.0.19 (in previous releases, this value was always calculated by NDB); transaction memory can also use an unlimited amount of shared global memory. Transaction memory is used for all operational resources handling transactions, scans, locks, scan buffers, and trigger operations. It also holds table rows as they are updated, before the next commit writes them to data memory.

In NDB 8.0.16 and earlier, operational records used dedicated resources whose sizes were controlled by a number of configuration parameters. Beginning with NDB 8.0.17, these are all allocated from a common
transaction memory resource and can also use resources from global shared memory. In NDB 8.0.19 and later, the size of this resource can be controlled using a single `TransactionMemory` configuration parameter.

Reserved memory for undo log buffers can be set using the `InitialLogFileGroup` configuration parameter. If an undo log buffer is created as part of a `CREATE LOGFILE GROUP` SQL statement, the memory is taken from the transaction memory.

A number of resources relating to metadata for Disk Data resources also have no reserved part, and use shared global memory only. Shared global shared memory is thus shared between send buffers, transaction memory, and Disk Data metadata.

If `TransactionMemory` is not set, it is calculated based on the following parameters:

- `MaxNoOfConcurrentOperations`
- `MaxNoOfConcurrentTransactions`
- `MaxNoOfFiredTriggers`
- `MaxNoOfLocalOperations`
- `MaxNoOfConcurrentIndexOperations`
- `MaxNoOfConcurrentScans`
- `MaxNoOfLocalScans`
- `BatchSizePerLocalScan`
- `TransactionBufferMemory`

When `TransactionMemory` is set explicitly, none of the configuration parameters just listed are used to calculate memory size. In addition, the parameters `MaxNoOfConcurrentIndexOperations`, `MaxNoOfFiredTriggers`, `MaxNoOfLocalOperations`, and `MaxNoOfLocalScans` are incompatible with `TransactionMemory` and cannot be set concurrently with it; if `TransactionMemory` is set and any of these four parameters are also set in the `config.ini` configuration file, the management server cannot start. These four parameters are deprecated in NDB 8.0.19; expect them to be removed from a future release of MySQL NDB Cluster.

The transaction memory resource contains a large number of memory pools. Each memory pool represents an object type and contains a set of objects; each pool includes a reserved part allocated to the pool at startup; this reserved memory is never returned to shared global memory. Reserved records are found using a data structure having only a single level for fast retrieval, which means that a number of records in each pool should be reserved. The number of reserved records in each pool has some impact on performance and reserved memory allocation, but is generally necessary only in certain very advanced use cases to set the reserved sizes explicitly.

The size of the reserved part of the pool can be controlled by setting the following configuration parameters:

- `ReservedConcurrentIndexOperations`
- `ReservedFiredTriggers`
- `ReservedConcurrentOperations`
ReservedLocalScans
ReservedConcurrentTransactions
ReservedConcurrentScans
ReservedTransactionBufferMemory

If the parameters just listed are not set, the reserved setting is 25% of transaction memory. The number of reserved records is per data node; these records are split among the threads handling them (LDM and TC threads) on each node. In most cases, it is sufficient to set TransactionMemory alone, and to allow the number of records in pools to be governed by its value.

MaxNoOfConcurrentScans limits the number of concurrent scans that can be active in each TC thread. This is important in guarding against cluster overload.

MaxNoOfConcurrentOperations limits the number of operations that can be active at any one time in updating transactions. (Simple reads are not affected by this parameter.) This number needs to be limited because it is necessary to preallocate memory for node failure handling, and a resource must be available for handling the maximum number of active operations in one TC thread when contending with node failures. It is imperative that MaxNoOfConcurrentOperations be set to the same number on all nodes (this can be done most easily by setting a value for it once, in the [ndbd default] section of the config.ini global configuration file). While its value can be increased using a rolling restart (see Section 22.5.5, “Performing a Rolling Restart of an NDB Cluster”), decreasing it in this way is not considered safe due to the possibility of a node failure occurring during the rolling restart.

It is possible to limit the size of a single transaction in NDB Cluster through the MaxDMLOperationsPerTransaction parameter. If this is not set, the size of one transaction is limited by MaxNoOfConcurrentOperations since this parameter limits the total number of concurrent operations per TC thread.

Schema memory size is controlled by the following set of configuration parameters:

• MaxNoOfSubscriptions
• MaxNoOfSubscribers
• MaxNoOfConcurrentSubOperations
• MaxNoOfAttributes
• MaxNoOfTables
• MaxNoOfOrderedIndexes
• MaxNoOfUniqueHashIndexes
• MaxNoOfTriggers

The number of nodes and the number of LDM threads also have a major impact on the size of schema memory since the number of partitions in each table and each partition (and its fragment replicas) have to be represented in schema memory.

In addition, a number of other records are allocated during startup. These are relatively small. Each block in each thread contains block objects that use memory. This memory size is also normally quite small compared to the other data node memory structures.
22.3.3.14 Configuring NDB Cluster Send Buffer Parameters

The NDB kernel employs a unified send buffer whose memory is allocated dynamically from a pool shared by all transporters. This means that the size of the send buffer can be adjusted as necessary. Configuration of the unified send buffer can accomplished by setting the following parameters:

- **TotalSendBufferMemory.** This parameter can be set for all types of NDB Cluster nodes—that is, it can be set in the [ndbd], [mgm], and [api] (or [mysql]) sections of the config.ini file. It represents the total amount of memory (in bytes) to be allocated by each node for which it is set for use among all configured transporters. If set, its minimum is 256KB; the maximum is 4294967039.

To be backward-compatible with existing configurations, this parameter takes as its default value the sum of the maximum send buffer sizes of all configured transporters, plus an additional 32KB (one page) per transporter. The maximum depends on the type of transporter, as shown in the following table:

**Table 22.22 Transporter types with maximum send buffer sizes**

<table>
<thead>
<tr>
<th>Transporter</th>
<th>Maximum Send Buffer Size (bytes)</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCP</td>
<td>SendBufferMemory (default = 2M)</td>
</tr>
<tr>
<td>SHM</td>
<td>20K</td>
</tr>
</tbody>
</table>

This enables existing configurations to function in close to the same way as they did with NDB Cluster 6.3 and earlier, with the same amount of memory and send buffer space available to each transporter. However, memory that is unused by one transporter is not available to other transporters.

- **OverloadLimit.** This parameter is used in the config.ini file [tcp] section, and denotes the amount of unsent data (in bytes) that must be present in the send buffer before the connection is considered overloaded. When such an overload condition occurs, transactions that affect the overloaded connection fail with NDB API Error 1218 (*Send Buffers overloaded in NDB kernel*) until the overload status passes. The default value is 0, in which case the effective overload limit is calculated as SendBufferMemory * 0.8 for a given connection. The maximum value for this parameter is 4G.

- **SendBufferMemory.** This value denotes a hard limit for the amount of memory that may be used by a single transporter out of the entire pool specified by TotalSendBufferMemory. However, the sum of SendBufferMemory for all configured transporters may be greater than the TotalSendBufferMemory that is set for a given node. This is a way to save memory when many nodes are in use, as long as the maximum amount of memory is never required by all transporters at the same time.

You can use the ndbinfo.transporters table to monitor send buffer memory usage, and to detect slowdown and overload conditions that can adversely affect performance.

22.3.4 Using High-Speed Interconnects with NDB Cluster

Even before design of NDBCLUSTER began in 1996, it was evident that one of the major problems to be encountered in building parallel databases would be communication between the nodes in the network. For this reason, NDBCLUSTER was designed from the very beginning to permit the use of a number of different data transport mechanisms. In this Manual, we use the term transporter for these.

The NDB Cluster codebase provides for four different transporters:

- **TCP/IP using 100 Mbps or gigabit Ethernet,** as discussed in Section 22.3.3.10, “NDB Cluster TCP/IP Connections”.

- **Direct (machine-to-machine) TCP/IP,** although this transporter uses the same TCP/IP protocol as mentioned in the previous item, it requires setting up the hardware differently and is configured
NDB Cluster Programs

differently as well. For this reason, it is considered a separate transport mechanism for NDB Cluster. See Section 22.3.3.11, “NDB Cluster TCP/IP Connections Using Direct Connections”, for details.

- *Shared memory (SHM).* For more information about SHM, see Section 22.3.3.12, “NDB Cluster Shared-Memory Connections”.

- *Scalable Coherent Interface (SCI).*

  Note
  Using SCI transporters in NDB Cluster requires specialized hardware, software, and MySQL binaries not available with NDB 8.0.

Most users today employ TCP/IP over Ethernet because it is ubiquitous. TCP/IP is also by far the best-tested transporter for use with NDB Cluster.

Regardless of the transporter used, NDB attempts to make sure that communication with data node processes is done using chunks that are as large as possible since this benefits all types of data transmission.

22.4 NDB Cluster Programs

Using and managing an NDB Cluster requires several specialized programs, which we describe in this chapter. We discuss the purposes of these programs in an NDB Cluster, how to use the programs, and what startup options are available for each of them.

These programs include the NDB Cluster data, management, and SQL node processes (*ndbd*, *ndbmtd*, *ndb_mgmd*, and *mysqld*) and the management client (*ndb_mgm*).

Information about the program *ndb_setup.py* (now deprecated), used to start the NDB Cluster Auto-Installer, is also included in this section. You should be aware that Section 22.4.26, "*ndb_setup.py — Start browser-based Auto-Installer for NDB Cluster (DEPRECATED)"", contains information about the command-line client only; for information about using the GUI installer spawned by this program to configure and deploy an NDB Cluster, see The NDB Cluster Auto-Installer (NDB 7.5) (DEPRECATED).

For information about using *mysqld* as an NDB Cluster process, see Section 22.5.9, “MySQL Server Usage for NDB Cluster”.

Other NDB utility, diagnostic, and example programs are included with the NDB Cluster distribution. These include *ndb_restore, ndb_show_tables*, and *ndb_config*. These programs are also covered in this section.

The final portion of this section contains tables of options that are common to all the various NDB Cluster programs.

22.4.1 *ndbd — The NDB Cluster Data Node Daemon*

*ndbd* is the process that is used to handle all the data in tables using the NDB Cluster storage engine. This is the process that empowers a data node to accomplish distributed transaction handling, node recovery, checkpointing to disk, online backup, and related tasks.

In an NDB Cluster, a set of *ndbd* processes cooperate in handling data. These processes can execute on the same computer (host) or on different computers. The correspondences between data nodes and Cluster hosts is completely configurable.

The following table includes command options specific to the NDB Cluster data node program *ndbd*. Additional descriptions follow the table. For options common to most NDB Cluster programs (including
**ndbd** — The NDB Cluster Data Node Daemon

ndbd, see Section 22.4.32, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

Table 22.23 Command-line options for the ndbd program

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--bind-address=name</td>
<td>Local bind address</td>
<td>(Supported in all MySQL 8.0 based releases)</td>

</tbody>
</table>
### ndbd — The NDB Cluster Data Node Daemon

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--verbose, -v</td>
<td>Windows service; does not apply on other platforms</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--connect-delay=</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--connect-retries=</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--connect-retry-delay=</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

#### Note
All of these options also apply to the multithreaded version of this program (ndbmttd) and you may substitute “ndbmttd” for “ndbd” wherever the latter occurs in this section.

- **--bind-address**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--bind-address=name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>Causes ndbd to bind to a specific network interface (host name or IP address). This option has no default value.</td>
</tr>
</tbody>
</table>

- **--connect-delay=**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--connect-delay=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Deprecated</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>5</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>3600</td>
</tr>
</tbody>
</table>

  Determines the time to wait between attempts to contact a management server when starting (the number of attempts is controlled by the --connect-retries option). The default is 5 seconds.

  This option is deprecated, and is subject to removal in a future release of NDB Cluster. Use --connect-retry-delay instead.

- **--connect-retries=**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--connect-retries=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>12</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>65535</td>
</tr>
</tbody>
</table>

  Set the number of times to retry a connection before giving up; 0 means 1 attempt only (and no retries). The default is 12 attempts. The time to wait between attempts is controlled by the --connect-retry-delay option.

- **--connect-retry-delay=#**
### ndbd — The NDB Cluster Data Node Daemon

#### Command-Line Format

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>--connect-retry-delay=#</td>
<td>Determines the time to wait between attempts to contact a management server when starting (the time between attempts is controlled by the --connect-retries option). The default is 5 seconds. This option takes the place of the --connect-delay option, which is now deprecated and subject to removal in a future release of NDB Cluster.</td>
</tr>
</tbody>
</table>

#### --daemon, -d

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>--daemon</td>
<td>Instructs ndbd or ndbmtd to execute as a daemon process. This is the default behavior. --nodaemon can be used to prevent the process from running as a daemon.</td>
</tr>
</tbody>
</table>

This option has no effect when running ndbd or ndbmtd on Windows platforms.

#### --foreground

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>--foreground</td>
<td>Causes ndbd or ndbmtd to execute as a foreground process, primarily for debugging purposes. This option implies the --nodaemon option.</td>
</tr>
</tbody>
</table>

This option has no effect when running ndbd or ndbmtd on Windows platforms.

#### --initial

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
</table>
| --initial               | Instructs ndbd to perform an initial start. An initial start erases any files created for recovery purposes by earlier instances of ndbd. It also re-creates recovery log files. On some operating systems, this process can take a substantial amount of time. An --initial start is to be used only when starting the ndbd process under very special circumstances; this is because this option causes all files to be removed from the NDB Cluster file system and all redo log files to be re-created. These circumstances are listed here:  
  - When performing a software upgrade which has changed the contents of any files.  
  - When restarting the node with a new version of ndbd. |
| **Default Value**       | **FALSE**                                                                   |

<table>
<thead>
<tr>
<th>Type</th>
<th>Numeric</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>5</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>
• As a measure of last resort when for some reason the node restart or system restart repeatedly fails. In this case, be aware that this node can no longer be used to restore data due to the destruction of the data files.

**Warning**

To avoid the possibility of eventual data loss, it is recommended that you *not* use the `--initial` option together with `StopOnError = 0`. Instead, set `StopOnError` to 0 in `config.ini` only after the cluster has been started, then restart the data nodes normally—that is, without the `--initial` option. See the description of the `StopOnError` parameter for a detailed explanation of this issue. (Bug #24945638)

Use of this option prevents the `StartPartialTimeout` and `StartPartitionedTimeout` configuration parameters from having any effect.

**Important**

This option does *not* affect backup files that have already been created by the affected node.

Prior to NDB 8.0.21, the `--initial` option also did not affect any Disk Data files. In NDB 8.0.21 and later, when used to perform an initial restart of the cluster, the option causes the removal of all data files associated with Disk Data tablespaces and undo log files associated with log file groups that existed previously on this data node (see Section 22.5.10, “NDB Cluster Disk Data Tables”).

This option also has no effect on recovery of data by a data node that is just starting (or restarting) from data nodes that are already running (unless they also were started with `--initial`, as part of an initial restart). This recovery of data occurs automatically, and requires no user intervention in an NDB Cluster that is running normally.

It is permissible to use this option when starting the cluster for the very first time (that is, before any data node files have been created); however, it is *not* necessary to do so.

• `--initial-start`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--initial-start</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

This option is used when performing a partial initial start of the cluster. Each node should be started with this option, as well as `--nowait-nodes`.

Suppose that you have a 4-node cluster whose data nodes have the IDs 2, 3, 4, and 5, and you wish to perform a partial initial start using only nodes 2, 4, and 5—that is, omitting node 3:

```bash
shell> ndbd --ndb-nodeid=2 --nowait-nodes=3 --initial-start
shell> ndbd --ndb-nodeid=4 --nowait-nodes=3 --initial-start
shell> ndbd --ndb-nodeid=5 --nowait-nodes=3 --initial-start
```

When using this option, you must also specify the node ID for the data node being started with the `--ndb-nodeid` option.
Important
Do not confuse this option with the \texttt{--nowait-nodes} option for \texttt{ndb_mgmd}, which can be used to enable a cluster configured with multiple management servers to be started without all management servers being online.

- \texttt{--install[=name]}

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>\texttt{--install[=name]}</th>
</tr>
</thead>
<tbody>
<tr>
<td>Platform Specific</td>
<td>Windows</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>ndbd</td>
</tr>
</tbody>
</table>

Causes \texttt{ndbd} to be installed as a Windows service. Optionally, you can specify a name for the service; if not set, the service name defaults to \texttt{ndbd}. Although it is preferable to specify other \texttt{ndbd} program options in a \texttt{my.ini} or \texttt{my.cnf} configuration file, it is possible to use together with \texttt{--install}. However, in such cases, the \texttt{--install} option must be specified first, before any other options are given, for the Windows service installation to succeed.

It is generally not advisable to use this option together with the \texttt{--initial} option, since this causes the data node file system to be wiped and rebuilt every time the service is stopped and started. Extreme care should also be taken if you intend to use any of the other \texttt{ndbd} options that affect the starting of data nodes—including \texttt{--initial-start}, \texttt{--nostart}, and \texttt{--nowait-nodes}—together with \texttt{--install}, and you should make absolutely certain you fully understand and allow for any possible consequences of doing so.

The \texttt{--install} option has no effect on non-Windows platforms.

- \texttt{--logbuffer-size=#}

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>\texttt{--logbuffer-size=#}</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>32768</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>2048</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

Sets the size of the data node log buffer. When debugging with high amounts of extra logging, it is possible for the log buffer to run out of space if there are too many log messages, in which case some log messages can be lost. This should not occur during normal operations.

- \texttt{--nodaemon}

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>\texttt{--nodaemon}</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Prevents \texttt{ndbd} or \texttt{ndbmtd} from executing as a daemon process. This option overrides the \texttt{--daemon} option. This is useful for redirecting output to the screen when debugging the binary.

The default behavior for \texttt{ndbd} and \texttt{ndbmtd} on Windows is to run in the foreground, making this option unnecessary on Windows platforms, where it has no effect.
- **--nostart, -n**

  **Command-Line Format**  
  `--nostart`

  **Type**  
  Boolean

  **Default Value**  
  FALSE

Instructs ndbd not to start automatically. When this option is used, ndbd connects to the management server, obtains configuration data from it, and initializes communication objects. However, it does not actually start the execution engine until specifically requested to do so by the management server. This can be accomplished by issuing the proper START command in the management client (see Section 22.5.1, “Commands in the NDB Cluster Management Client”).

- **--nowait-nodes=node_id_1[, node_id_2[, ...]]**

  **Command-Line Format**  
  `--nowait-nodes=list`

  **Type**  
  String

  **Default Value**

  This option takes a list of data nodes for which the cluster does not wait, prior to starting.

  This can be used to start the cluster in a partitioned state. For example, to start the cluster with only half of the data nodes (nodes 2, 3, 4, and 5) running in a 4-node cluster, you can start each ndbd process with `--nowait-nodes=3,5`. In this case, the cluster starts as soon as nodes 2 and 4 connect, and does not wait `StartPartitionedTimeout` milliseconds for nodes 3 and 5 to connect as it would otherwise.

  If you wanted to start up the same cluster as in the previous example without one ndbd (say, for example, that the host machine for node 3 has suffered a hardware failure) then start nodes 2, 4, and 5 with `--nowait-nodes=3`. Then the cluster starts as soon as nodes 2, 4, and 5 connect, and does not wait for node 3 to start.

- **--remove[=name]**

  **Command-Line Format**  
  `--remove[=name]`

  **Platform Specific**  
  Windows

  **Type**  
  String

  **Default Value**  
  ndbd

  Causes an ndbd process that was previously installed as a Windows service to be removed. Optionally, you can specify a name for the service to be uninstalled; if not set, the service name defaults to ndbd.

  The `--remove` option has no effect on non-Windows platforms.

- **--verbose, -v**

  Causes extra debug output to be written to the node log.

  You can also use `NODELOG DEBUG ON` and `NODELOG DEBUG OFF` to enable and disable this extra logging while the data node is running.

  ndbd generates a set of log files which are placed in the directory specified by DataDir in the config.ini configuration file.
These log files are listed below. \textit{node\_id} is and represents the node's unique identifier. For example, \texttt{ndb\_2\_error.log} is the error log generated by the data node whose node ID is \texttt{2}.

- \texttt{ndb\_node\_id\_error.log} is a file containing records of all crashes which the referenced \texttt{ndbd} process has encountered. Each record in this file contains a brief error string and a reference to a trace file for this crash. A typical entry in this file might appear as shown here:

  Date/Time: Saturday 30 July 2004 - 00:20:01  
  Type of error: error  
  Message: Internal program error (failed ndbrequire)  
  Fault ID: 2341  
  Problem data: DbtupFixAlloc.cpp  
  Object of reference: DBTUP (Line: 173)  
  ProgramName: NDB Kernel  
  ProcessID: 14909  
  TraceFile: ndb\_2\_trace.log.2  

**EOM**

Listings of possible \texttt{ndbd} exit codes and messages generated when a data node process shuts down prematurely can be found in \textit{Data Node Error Messages}.

\textbf{Important}

\textit{The last entry in the error log file is not necessarily the newest one} (nor is it likely to be). Entries in the error log are \textit{not} listed in chronological order; rather, they correspond to the order of the trace files as determined in the \texttt{ndb\_node\_id\_trace.log.next} file (see below). Error log entries are thus overwritten in a cyclical and not sequential fashion.

- \texttt{ndb\_node\_id\_trace.log.trace\_id} is a trace file describing exactly what happened just before the error occurred. This information is useful for analysis by the NDB Cluster development team.

  It is possible to configure the number of these trace files that are created before old files are overwritten. \texttt{trace\_id} is a number which is incremented for each successive trace file.

- \texttt{ndb\_node\_id\_trace.log.next} is the file that keeps track of the next trace file number to be assigned.

- \texttt{ndb\_node\_id\_out.log} is a file containing any data output by the \texttt{ndbd} process. This file is created only if \texttt{ndbd} is started as a daemon, which is the default behavior.

- \texttt{ndb\_node\_id.pid} is a file containing the process ID of the \texttt{ndbd} process when started as a daemon. It also functions as a lock file to avoid the starting of nodes with the same identifier.

- \texttt{ndb\_node\_id\_signal.log} is a file used only in debug versions of \texttt{ndbd}, where it is possible to trace all incoming, outgoing, and internal messages with their data in the \texttt{ndbd} process.

  It is recommended not to use a directory mounted through NFS because in some environments this can cause problems whereby the lock on the \texttt{.pid} file remains in effect even after the process has terminated.

  To start \texttt{ndbd}, it may also be necessary to specify the host name of the management server and the port on which it is listening. Optionally, one may also specify the node ID that the process is to use.

  \texttt{shell> ndbd --connect-string="nodeid=2;host=ndb\_mgmd.mysql.com:1186"}

See Section 22.3.3.3, “NDB Cluster Connection Strings”, for additional information about this issue. Section 22.4.32, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”, describes other command-line options which can be used with \texttt{ndbd}. For information about data node configuration parameters, see Section 22.3.3.6, “Defining NDB Cluster Data Nodes”.
When \texttt{ndbd} starts, it actually initiates two processes. The first of these is called the “angel process”; its only job is to discover when the execution process has been completed, and then to restart the \texttt{ndbd} process if it is configured to do so. Thus, if you attempt to kill \texttt{ndbd} using the Unix \texttt{kill} command, it is necessary to kill both processes, beginning with the angel process. The preferred method of terminating an \texttt{ndbd} process is to use the management client and stop the process from there.

The execution process uses one thread for reading, writing, and scanning data, as well as all other activities. This thread is implemented asynchronously so that it can easily handle thousands of concurrent actions. In addition, a watch-dog thread supervises the execution thread to make sure that it does not hang in an endless loop. A pool of threads handles file I/O, with each thread able to handle one open file. Threads can also be used for transporter connections by the transporters in the \texttt{ndbd} process. In a multi-processor system performing a large number of operations (including updates), the \texttt{ndbd} process can consume up to 2 CPUs if permitted to do so.

For a machine with many CPUs it is possible to use several \texttt{ndbd} processes which belong to different node groups; however, such a configuration is still considered experimental and is not supported for MySQL 8.0 in a production setting. See Section 22.1.7, “Known Limitations of NDB Cluster”.

\begin{verbatim}
22.4.2 \texttt{ndbinfo_select_all} — Select From ndbinfo Tables

\texttt{ndbinfo_select_all} is a client program that selects all rows and columns from one or more tables in the \texttt{ndbinfo} database.

Not all \texttt{ndbinfo} tables available in the \texttt{mysql} client can be read by this program. In addition, \texttt{ndbinfo_select_all} can show information about some tables internal to \texttt{ndbinfo} which cannot be accessed using SQL, including the \texttt{tables} and \texttt{columns} metadata tables.

To select from one or more \texttt{ndbinfo} tables using \texttt{ndbinfo_select_all}, it is necessary to supply the names of the tables when invoking the program as shown here:

\verbatim{shell}
shell> \texttt{ndbinfo_select_all table_name1 [table_name2] [...]}
\endverbatim

For example:

\verbatim{shell}
shell> \texttt{ndbinfo_select_all logbuffers logspaces}
== logbuffers ==
   node_id log_type  log_id  log_part  total  used  high
   5        0       0       0     33554432  262144  0
   6        0       0       0     33554432  262144  0
   7        0       0       0     33554432  262144  0
   8        0       0       0     33554432  262144  0

== logspaces ==
   node_id log_type  log_id  log_part  total  used  high
   5        0       0       0     268435456    0      0
   5        0       0       1     268435456    0      0
   5        0       0       2     268435456    0      0
   5        0       0       3     268435456    0      0
   6        0       0       0     268435456    0      0
   6        0       0       1     268435456    0      0
   6        0       0       2     268435456    0      0
   6        0       0       3     268435456    0      0
   7        0       0       0     268435456    0      0
   7        0       0       1     268435456    0      0
   7        0       0       2     268435456    0      0
   7        0       0       3     268435456    0      0
   8        0       0       0     268435456    0      0
   8        0       0       1     268435456    0      0
   8        0       0       2     268435456    0      0
   8        0       0       3     268435456    0      0
shell>
\end{verbatim}
\end{verbatim}
The following table includes options that are specific to `ndbinfo_select_all`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndbinfo_select_all`), see Section 22.4.32, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

**Table 22.24 Command-line options for the ndbinfo_select_all program**

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--delay=#</code></td>
<td>Set delay in seconds between</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td></td>
<td>loops</td>
<td></td>
</tr>
<tr>
<td><code>--loops=</code>,</td>
<td>Set number of times to perform</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>-l</code></td>
<td>select</td>
<td></td>
</tr>
<tr>
<td><code>--database=db_name</code>,</td>
<td>Name of database where table is</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>-d</code></td>
<td>located</td>
<td></td>
</tr>
<tr>
<td><code>--parallelism=</code>,</td>
<td>Set degree of parallelism</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>-p</code></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

* `--delay=seconds`

Command-Line Format | `--delay=#`
--- | ---
Type             | Numeric
Default Value    | 5
Minimum Value     | 0
Maximum Value     | MAX_INT

This option sets the number of seconds to wait between executing loops. Has no effect if `--loops` is set to 0 or 1.

* `--loops=number, -l number`

Command-Line Format | `--loops=#`
--- | ---
Type             | Numeric
Default Value    | 1
Minimum Value     | 0
Maximum Value     | MAX_INT

This option sets the number of times to execute the select. Use `--delay` to set the time between loops.

### 22.4.3 ndbmtd — The NDB Cluster Data Node Daemon (Multi-Threaded)

`ndbmtd` is a multithreaded version of `ndbd`, the process that is used to handle all the data in tables using the `NDBCLUSTER` storage engine. `ndbmtd` is intended for use on host computers having multiple CPU cores. Except where otherwise noted, `ndbmtd` functions in the same way as `ndbd`; therefore, in this section, we concentrate on the ways in which `ndbmtd` differs from `ndbd`, and you should consult Section 22.4.1, “ndbd — The NDB Cluster Data Node Daemon”, for additional information about running

4133
NDB Cluster data nodes that apply to both the single-threaded and multithreaded versions of the data node process.

Command-line options and configuration parameters used with `ndbd` also apply to `ndbmtd`. For more information about these options and parameters, see Section 22.4.1, “`ndbd` — The NDB Cluster Data Node Daemon”, and Section 22.3.3.6, “Defining NDB Cluster Data Nodes”, respectively.

`ndbmtd` is also file system-compatible with `ndbd`. In other words, a data node running `ndbd` can be stopped, the binary replaced with `ndbmtd`, and then restarted without any loss of data. (However, when doing this, you must make sure that `MaxNoOfExecutionThreads` is set to an appropriate value before restarting the node if you wish for `ndbmtd` to run in multithreaded fashion.) Similarly, an `ndbmtd` binary can be replaced with `ndbd` simply by stopping the node and then starting `ndbd` in place of the multithreaded binary. It is not necessary when switching between the two to start the data node binary using `--initial`.

Using `ndbmtd` differs from using `ndbd` in two key respects:

1. Because `ndbmtd` runs by default in single-threaded mode (that is, it behaves like `ndbd`), you must configure it to use multiple threads. This can be done by setting an appropriate value in the `config.ini` file for the `MaxNoOfExecutionThreads` configuration parameter or the `ThreadConfig` configuration parameter. Using `MaxNoOfExecutionThreads` is simpler, but `ThreadConfig` offers more flexibility. For more information about these configuration parameters and their use, see Multi-Threading Configuration Parameters (`ndbmtd`).

2. Trace files are generated by critical errors in `ndbmtd` processes in a somewhat different fashion from how these are generated by `ndbd` failures. These differences are discussed in more detail in the next few paragraphs.

Like `ndbd`, `ndbmtd` generates a set of log files which are placed in the directory specified by `DataDir` in the `config.ini` configuration file. Except for trace files, these are generated in the same way and have the same names as those generated by `ndbd`.

In the event of a critical error, `ndbmtd` generates trace files describing what happened just prior to the error occurrence. These files, which can be found in the data node's `DataDir`, are useful for analysis of problems by the NDB Cluster Development and Support teams. One trace file is generated for each `ndbmtd` thread. The names of these files have the following pattern:

```
ndb_node_id_trace.log.trace_id_tthread_id,
```

In this pattern, `node_id` stands for the data node's unique node ID in the cluster, `trace_id` is a trace sequence number, and `thread_id` is the thread ID. For example, in the event of the failure of an `ndbmtd` process running as an NDB Cluster data node having the node ID 3 and with `MaxNoOfExecutionThreads` equal to 4, four trace files are generated in the data node's data directory. If the is the first time this node has failed, then these files are named `ndb_3_trace.log.1_t1`, `ndb_3_trace.log.1_t2`, `ndb_3_trace.log.1_t3`, and `ndb_3_trace.log.1_t4`. Internally, these trace files follow the same format as `ndbd` trace files.

The `ndbd` exit codes and messages that are generated when a data node process shuts down prematurely are also used by `ndbmtd`. See Data Node Error Messages, for a listing of these.

Note

It is possible to use `ndbd` and `ndbmtd` concurrently on different data nodes in the same NDB Cluster. However, such configurations have not been tested extensively; thus, we cannot recommend doing so in a production setting at this time.
# ndb_mgmd — The NDB Cluster Management Server Daemon

The management server is the process that reads the cluster configuration file and distributes this information to all nodes in the cluster that request it. It also maintains a log of cluster activities. Management clients can connect to the management server and check the cluster's status.

The following table includes options that are specific to the NDB Cluster management server program `ndb_mgmd`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndb_mgmd`), see Section 22.4.32, "Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs".

### Table 22.25 Command-line options for the `ndb_mgmd` program

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--bind-address=host</code></td>
<td>Local bind address</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>`--config-cache[=TRUE</td>
<td>FALSE]`</td>
<td>Enable management server configuration cache; true by default</td>
</tr>
<tr>
<td><code>--config-file=file, -f</code></td>
<td>Specify cluster configuration file; also specify <code>--reload</code> or <code>--initial</code> to override configuration cache if present</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--configdir=directory</code></td>
<td>Specify cluster management server configuration cache directory</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--daemon, -d</code></td>
<td>Run ndb_mgmd in daemon mode (default)</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--initial</code></td>
<td>Causes management server to reload configuration data from configuration file, bypassing configuration cache</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--install[=name]</code></td>
<td>Used to install management server process as Windows service; does not apply on other platforms</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--interactive</code></td>
<td>Run ndb_mgmd in interactive mode (not officially supported in production; for testing purposes only)</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--log-name=name</code></td>
<td>Name to use when writing cluster log messages applying to this node</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--mycnf</code></td>
<td>Read cluster configuration data from my.cnf file</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--no-nodeid-checks</code></td>
<td>Do not provide any node ID checks</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--nodaemon</code></td>
<td>Do not run ndb_mgmd as a daemon</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--nowait-nodes=list</code></td>
<td>Do not wait for management nodes specified when starting this</td>
<td>(Supported in all MySQL 8.0 based releases)</td>

</thead>
<tbody>
<tr>
<td>--print-full-config, -P</td>
<td>management server; requires --ndb-nodeid option</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--reload</td>
<td>Causes management server to compare configuration file with configuration cache</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--remove[=name]</td>
<td>Used to remove management server process that was previously installed as Windows service, optionally specifying name of service to be removed; does not apply on other platforms</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--verbose, -v</td>
<td>Write additional information to log</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
</tbody>
</table>

---

#### --bind-address=host

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--bind-address=host</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Causes the management server to bind to a specific network interface (host name or IP address). This option has no default value.

---

#### --config-cache

| Command-Line Format       | --config-cache[=TRUE|FALSE]                                     |
|---------------------------|-----------------------------------------------------------------|
| Type                      | Boolean                                                         |
| Default Value             | TRUE                                                            |

This option, whose default value is 1 (or TRUE, or ON), can be used to disable the management server's configuration cache, so that it reads its configuration from config.ini every time it starts (see Section 22.3.3, "NDB Cluster Configuration Files"). You can do this by starting the ndb_mgmd process with any one of the following options:

- --config-cache=0
- --config-cache=FALSE
- --config-cache=OFF
- --skip-config-cache

Using one of the options just listed is effective only if the management server has no stored configuration at the time it is started. If the management server finds any configuration cache files, then the --config-cache option or the --skip-config-cache option is ignored. Therefore, to disable configuration caching, the option should be used the first time that the management server is started.
Otherwise—that is, if you wish to disable configuration caching for a management server that has already created a configuration cache—you must stop the management server, delete any existing configuration cache files manually, then restart the management server with `--skip-config-cache` (or with `--config-cache` set equal to 0, OFF, or FALSE).

Configuration cache files are normally created in a directory named `mysql-cluster` under the installation directory (unless this location has been overridden using the `--configdir` option). Each time the management server updates its configuration data, it writes a new cache file. The files are named sequentially in order of creation using the following format:

```
ndb_node-id_config.bin.seq-number
```

`node-id` is the management server’s node ID; `seq-number` is a sequence number, beginning with 1. For example, if the management server’s node ID is 5, then the first three configuration cache files would, when they are created, be named `ndb_5_config.bin.1`, `ndb_5_config.bin.2`, and `ndb_5_config.bin.3`.

If your intent is to purge or reload the configuration cache without actually disabling caching, you should start `ndb_mgmd` with one of the options `--reload` or `--initial` instead of `--skip-config-cache`.

To re-enable the configuration cache, simply restart the management server, but without the `--config-cache` or `--skip-config-cache` option that was used previously to disable the configuration cache.

`ndb_mgmd` does not check for the configuration directory (`--configdir`) or attempts to create one when `--skip-config-cache` is used. (Bug #13428853)

- `--config-file=filename, -f filename`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--config-file=file</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Instructs the management server as to which file it should use for its configuration file. By default, the management server looks for a file named `config.ini` in the same directory as the `ndb_mgmd` executable; otherwise the file name and location must be specified explicitly.

This option has no default value, and is ignored unless the management server is forced to read the configuration file, either because `ndb_mgmd` was started with the `--reload` or `--initial` option, or because the management server could not find any configuration cache. This option is also read if `ndb_mgmd` was started with `--config-cache=OFF`. See Section 22.3.3, “NDB Cluster Configuration Files”, for more information.

- `--configdir=dir_name`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--configdir=directory</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td>$INSTALLDIR/mysql-cluster</td>
</tr>
</tbody>
</table>

Specifies the cluster management server’s configuration cache directory. `--config-dir` is an alias for this option.
**ndb_mgmd** — The NDB Cluster Management Server Daemon

- **--daemon, -d**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--daemon</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>TRUE</td>
</tr>
</tbody>
</table>

Instructs **ndb_mgmd** to start as a daemon process. This is the default behavior.

This option has no effect when running **ndb_mgmd** on Windows platforms.

- **--initial**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--initial</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Configuration data is cached internally, rather than being read from the cluster global configuration file each time the management server is started (see Section 22.3.3, “NDB Cluster Configuration Files”). Using the **--initial** option overrides this behavior, by forcing the management server to delete any existing cache files, and then to re-read the configuration data from the cluster configuration file and to build a new cache.

This differs in two ways from the **--reload** option. First, **--reload** forces the server to check the configuration file against the cache and reload its data only if the contents of the file are different from the cache. Second, **--reload** does not delete any existing cache files.

If **ndb_mgmd** is invoked with **--initial** but cannot find a global configuration file, the management server cannot start.

When a management server starts, it checks for another management server in the same NDB Cluster and tries to use the other management server's configuration data. This behavior has implications when performing a rolling restart of an NDB Cluster with multiple management nodes. See Section 22.5.5, “Performing a Rolling Restart of an NDB Cluster”, for more information.

When used together with the **--config-file** option, the cache is cleared only if the configuration file is actually found.

- **--install [=name]**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--install [=name]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Platform Specific</td>
<td>Windows</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>ndb_mgmd</td>
</tr>
</tbody>
</table>

Causes **ndb_mgmd** to be installed as a Windows service. Optionally, you can specify a name for the service; if not set, the service name defaults to **ndb_mgmd**. Although it is preferable to specify other **ndb_mgmd** program options in a **my.ini** or **my.cnf** configuration file, it is possible to use them together with **--install**. However, in such cases, the **--install** option must be specified first, before any other options are given, for the Windows service installation to succeed.

It is generally not advisable to use this option together with the **--initial** option, since this causes the configuration cache to be wiped and rebuilt every time the service is stopped and started. Care
should also be taken if you intend to use any other `ndb_mgmd` options that affect the starting of the management server, and you should make absolutely certain you fully understand and allow for any possible consequences of doing so.

The `--install` option has no effect on non-Windows platforms.

- **--interactive**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--interactive</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

  Starts `ndb_mgmd` in interactive mode; that is, an `ndb_mgm` client session is started as soon as the management server is running. This option does not start any other NDB Cluster nodes.

- **--log-name=name**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--log-name=name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>MgmtSrvr</td>
</tr>
</tbody>
</table>

  Provides a name to be used for this node in the cluster log.

- **--mycnf**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--mycnf</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

  Read configuration data from the `my.cnf` file.

- **--no-nodeid-checks**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--no-nodeid-checks</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

  Do not perform any checks of node IDs.

- **--nodaemon**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--nodaemon</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

  Instructs `ndb_mgmd` not to start as a daemon process.

  The default behavior for `ndb_mgmd` on Windows is to run in the foreground, making this option unnecessary on Windows platforms.
--nowait-nodes

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--nowait-nodes=list</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td></td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>255</td>
</tr>
</tbody>
</table>

When starting an NDB Cluster is configured with two management nodes, each management server normally checks to see whether the other ndb_mgmd is also operational and whether the other management server’s configuration is identical to its own. However, it is sometimes desirable to start the cluster with only one management node (and perhaps to allow the other ndb_mgmd to be started later). This option causes the management node to bypass any checks for any other management nodes whose node IDs are passed to this option, permitting the cluster to start as though configured to use only the management node that was started.

For purposes of illustration, consider the following portion of a config.ini file (where we have omitted most of the configuration parameters that are not relevant to this example):

```
[ndbd]
NodeId = 1
HostName = 198.51.100.101

[ndbd]
NodeId = 2
HostName = 198.51.100.102

[ndbd]
NodeId = 3
HostName = 198.51.100.103

[ndbd]
NodeId = 4
HostName = 198.51.100.104

[ndb_mgmd]
NodeId = 10
HostName = 198.51.100.150

[ndb_mgmd]
NodeId = 11
HostName = 198.51.100.151

[api]
NodeId = 20
HostName = 198.51.100.200

[api]
NodeId = 21
HostName = 198.51.100.201
```

Assume that you wish to start this cluster using only the management server having node ID 10 and running on the host having the IP address 198.51.100.150. (Suppose, for example, that the host computer on which you intend to the other management server is temporarily unavailable due to
a hardware failure, and you are waiting for it to be repaired.) To start the cluster in this way, use a
command line on the machine at 198.51.100.150 to enter the following command:

```shell
ndb_mgmd --ndb-nodeid=10 --nowait-nodes=11
```

As shown in the preceding example, when using `--nowait-nodes`, you must also use the `--ndb-nodeid` option to specify the node ID of this `ndb_mgmd` process.

You can then start each of the cluster's data nodes in the usual way. If you wish to start and use the second management server in addition to the first management server at a later time without restarting the data nodes, you must start each data node with a connection string that references both management servers, like this:

```shell
ndbd -c 198.51.100.150,198.51.100.151
```

The same is true with regard to the connection string used with any `mysqld` processes that you wish to start as NDB Cluster SQL nodes connected to this cluster. See Section 22.3.3.3, “NDB Cluster Connection Strings”, for more information.

When used with `ndb_mgmd`, this option affects the behavior of the management node with regard to other management nodes only. Do not confuse it with the `--nowait-nodes` option used with `ndbd` or `ndbmtd` to permit a cluster to start with fewer than its full complement of data nodes; when used with data nodes, this option affects their behavior only with regard to other data nodes.

Multiple management node IDs may be passed to this option as a comma-separated list. Each node ID must be no less than 1 and no greater than 255. In practice, it is quite rare to use more than two management servers for the same NDB Cluster (or to have any need for doing so); in most cases you need to pass to this option only the single node ID for the one management server that you do not wish to use when starting the cluster.

![Note]

When you later start the “missing” management server, its configuration must match that of the management server that is already in use by the cluster. Otherwise, it fails the configuration check performed by the existing management server, and does not start.

- `--print-full-config`, `-P`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--print-full-config</code></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Type</strong></td>
<td>Boolean</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Shows extended information regarding the configuration of the cluster. With this option on the command line the `ndb_mgmd` process prints information about the cluster setup including an extensive list of the cluster configuration sections as well as parameters and their values. Normally used together with the `--config-file (-f)` option.

- `--reload`
**ndb_mgmd** — The NDB Cluster Management Server Daemon

<table>
<thead>
<tr>
<th>Default Value</th>
<th>FALSE</th>
</tr>
</thead>
</table>

NDB Cluster configuration data is stored internally rather than being read from the cluster global configuration file each time the management server is started (see Section 22.3.3, “NDB Cluster Configuration Files”). Using this option forces the management server to check its internal data store against the cluster configuration file and to reload the configuration if it finds that the configuration file does not match the cache. Existing configuration cache files are preserved, but not used.

This differs in two ways from the **--initial** option. First, **--initial** causes all cache files to be deleted. Second, **--initial** forces the management server to re-read the global configuration file and construct a new cache.

If the management server cannot find a global configuration file, then the **--reload** option is ignored.

When **--reload** is used, the management server must be able to communicate with data nodes and any other management servers in the cluster before it attempts to read the global configuration file; otherwise, the management server fails to start. This can happen due to changes in the networking environment, such as new IP addresses for nodes or an altered firewall configuration. In such cases, you must use **--initial** instead to force the existing cached configuration to be discarded and reloaded from the file. See Section 22.5.5, “Performing a Rolling Restart of an NDB Cluster”, for additional information.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>--remove</strong>{=name}</td>
<td>Remove a management server process that has been installed as a Windows service, optionally specifying the name of the service to be removed. Applies only to Windows platforms.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><strong>--remove</strong>{=name}</th>
</tr>
</thead>
<tbody>
<tr>
<td>Platform Specific</td>
<td>Windows</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>ndb_mgmd</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>--verbose</strong>, <strong>-v</strong></td>
<td>Remove a management server process that has been installed as a Windows service, optionally specifying the name of the service to be removed. Applies only to Windows platforms.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><strong>--verbose</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

It is not strictly necessary to specify a connection string when starting the management server. However, if you are using more than one management server, a connection string should be provided and each node in the cluster should specify its node ID explicitly.

See Section 22.3.3.3, “NDB Cluster Connection Strings”, for information about using connection strings. Section 22.4.4, “ndb_mgmd — The NDB Cluster Management Server Daemon”, describes other options for ndb_mgmd.

The following files are created or used by ndb_mgmd in its starting directory, and are placed in the **DataDir** as specified in the **config.ini** configuration file. In the list that follows, **node_id** is the unique node identifier.
• **config.ini** is the configuration file for the cluster as a whole. This file is created by the user and read by the management server. Section 22.3, “Configuration of NDB Cluster”, discusses how to set up this file.

• **ndb_node_id_cluster.log** is the cluster events log file. Examples of such events include checkpoint startup and completion, node startup events, node failures, and levels of memory usage. A complete listing of cluster events with descriptions may be found in Section 22.5, “Management of NDB Cluster”.

By default, when the size of the cluster log reaches one million bytes, the file is renamed to **ndb_node_id_cluster.log.seq_id**, where *seq_id* is the sequence number of the cluster log file. (For example: If files with the sequence numbers 1, 2, and 3 already exist, the next log file is named using the number 4.) You can change the size and number of files, and other characteristics of the cluster log, using the LogDestination configuration parameter.

• **ndb_node_id_out.log** is the file used for stdout and stderr when running the management server as a daemon.

• **ndb_node_id.pid** is the process ID file used when running the management server as a daemon.

### 22.4.5 ndb_mgm — The NDB Cluster Management Client

The **ndb_mgm** management client process is actually not needed to run the cluster. Its value lies in providing a set of commands for checking the cluster’s status, starting backups, and performing other administrative functions. The management client accesses the management server using a C API. Advanced users can also employ this API for programming dedicated management processes to perform tasks similar to those performed by **ndb_mgm**.

To start the management client, it is necessary to supply the host name and port number of the management server:

```
shell> ndb_mgm [host_name [port_num]]
```

For example:

```
shell> ndb_mgm ndb_mgmd.mysql.com 1186
```

The default host name and port number are **localhost** and 1186, respectively.

The following table includes options that are specific to the NDB Cluster management client program **ndb_mgm**. Additional descriptions follow the table. For options common to most NDB Cluster programs (including **ndb_mgm**), see Section 22.4.32, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--connect-retries=#</td>
<td>Set number of times to retry connection before giving up; 0 means 1 attempt only (and no retries)</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--try-reconnect=#, -t</td>
<td>Set number of times to retry connection before giving up; synonym for --connect-retries</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--execute=name, -e</td>
<td>Execute command and exit</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
</tbody>
</table>
• **--connect-retries=#**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--connect-retries=#</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Type</strong></td>
<td>Numeric</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>3</td>
</tr>
<tr>
<td><strong>Minimum Value</strong></td>
<td>0</td>
</tr>
<tr>
<td><strong>Maximum Value</strong></td>
<td>4294967295</td>
</tr>
</tbody>
</table>

This option specifies the number of times following the first attempt to retry a connection before giving up (the client always tries the connection at least once). The length of time to wait per attempt is set using **--connect-retry-delay**.

This option is synonymous with the **--try-reconnect** option, which is now deprecated.

The default for this option this option differs from its default when used with other NDB programs. See Section 22.4.32, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”, for more information.

• **--execute=command, -e command**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--execute=name</th>
</tr>
</thead>
</table>

This option can be used to send a command to the NDB Cluster management client from the system shell. For example, either of the following is equivalent to executing **SHOW** in the management client:

```shell
shell> ndb_mgm -e "SHOW"
shell> ndb_mgm --execute="SHOW"
```

This is analogous to how the **--execute** or **-e** option works with the **mysql** command-line client. See Section 4.2.2.1, “Using Options on the Command Line”.

**Note**

If the management client command to be passed using this option contains any space characters, then the command **must** be enclosed in quotation marks. Either single or double quotation marks may be used. If the management client command contains no space characters, the quotation marks are optional.

• **--try-reconnect=number**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--try-reconnect=#</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Deprecated</strong></td>
<td>Yes</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Numeric</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>12</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>3</td>
</tr>
<tr>
<td><strong>Minimum Value</strong></td>
<td>0</td>
</tr>
</tbody>
</table>
**ndb_blob_tool** — Check and Repair BLOB and TEXT columns of NDB Cluster Tables

| Maximum Value | 4294967295 |

If the connection to the management server is broken, the node tries to reconnect to it every 5 seconds until it succeeds. By using this option, it is possible to limit the number of attempts to *number* before giving up and reporting an error instead.

This option is deprecated and subject to removal in a future release. Use **--connect-retries**, instead.

Additional information about using **ndb_mgm** can be found in Section 22.5.1, “Commands in the NDB Cluster Management Client”.

### 22.4.6 ndb_blob_tool — Check and Repair BLOB and TEXT columns of NDB Cluster Tables

This tool can be used to check for and remove orphaned BLOB column parts from **NDB** tables, as well as to generate a file listing any orphaned parts. It is sometimes useful in diagnosing and repairing corrupted or damaged **NDB** tables containing **BLOB** or **TEXT** columns.

The basic syntax for **ndb_blob_tool** is shown here:

```
ndb_blob_tool [options] table [column, ...]
```

Unless you use the **--help** option, you must specify an action to be performed by including one or more of the options **--check-orphans**, **--delete-orphans**, or **--dump-file**. These options cause **ndb_blob_tool** to check for orphaned BLOB parts, remove any orphaned BLOB parts, and generate a dump file listing orphaned BLOB parts, respectively, and are described in more detail later in this section.

You must also specify the name of a table when invoking **ndb_blob_tool**. In addition, you can optionally follow the table name with the (comma-separated) names of one or more **BLOB** or **TEXT** columns from that table. If no columns are listed, the tool works on all of the table’s **BLOB** and **TEXT** columns. If you need to specify a database, use the **--database (-d)** option.

The **--verbose** option provides additional information in the output about the tool's progress.

The following table includes options that are specific to **ndb_blob_tool**. Additional descriptions follow the table. For options common to most NDB Cluster programs (including **ndb_blob_tool**), see Section 22.4.32, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

#### Table 22.27 Command-line options for the ndb_blob_tool program

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>--add-missing</strong></td>
<td>Write dummy blob parts to take place of those which are missing</td>
<td>ADDED: NDB 8.0.20</td>
</tr>
<tr>
<td><strong>--check-missing</strong></td>
<td>Check for blobs having inline parts but missing one or more parts from parts table</td>
<td>ADDED: NDB 8.0.20</td>
</tr>
<tr>
<td><strong>--check-orphans</strong></td>
<td>Check for blob parts having no corresponding inline parts</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><strong>--database=db_name, -d</strong></td>
<td>Database to find the table in</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
</tbody>
</table>
ndb_blob_tool — Check and Repair BLOB and TEXT columns of NDB Cluster Tables

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--delete-orphans</td>
<td>Delete blob parts having no corresponding inline parts</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--dump-file=file</td>
<td>Write orphan keys to specified file</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--verbose, -v</td>
<td>Verbose output</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
</tbody>
</table>

• --add-missing

Command-Line Format      --add-missing
Introduced               8.0.20-ndb-8.0.20
Type                     Boolean
Default Value            FALSE

For each inline part in NDB Cluster tables which has no corresponding BLOB part, write a dummy BLOB part of the required length, consisting of spaces.

• --check-missing

Command-Line Format      --check-missing
Introduced               8.0.20-ndb-8.0.20
Type                     Boolean
Default Value            FALSE

Check for inline parts in NDB Cluster tables which have no corresponding BLOB parts.

• --check-orphans

Command-Line Format      --check-orphans
Type                     Boolean
Default Value            FALSE

Check for BLOB parts in NDB Cluster tables which have no corresponding inline parts.

• --database=db_name, -d

Command-Line Format      --database=db_name
Type                     String
Default Value            [none]

Specify the database to find the table in.

• --delete-orphans

Command-Line Format      --delete-orphans
Type                     Boolean
**ndb_blob_tool** — Check and Repair BLOB and TEXT columns of NDB Cluster Tables

<table>
<thead>
<tr>
<th>Default Value</th>
<th>FALSE</th>
</tr>
</thead>
</table>

Remove BLOB parts from NDB Cluster tables which have no corresponding inline parts.

- **--dump-file=file**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--dump-file=file</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Writes a list of orphaned BLOB column parts to `file`. The information written to the file includes the table key and BLOB part number for each orphaned BLOB part.

- **--verbose**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--verbose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Provide extra information in the tool's output regarding its progress.

**Example**

First we create an **NDB** table in the **test** database, using the **CREATE TABLE** statement shown here:

```sql
USE test;
CREATE TABLE btest (  
c0 BIGINT UNSIGNED NOT NULL AUTO_INCREMENT PRIMARY KEY,  
c1 TEXT,  
c2 BLOB  
) ENGINE=NDB;
```

Then we insert a few rows into this table, using a series of statements similar to this one:

```sql
INSERT INTO btest VALUES (NULL, 'x', REPEAT('x', 1000));
```

When run with **--check-orphans** against this table, **ndb_blob_tool** generates the following output:

```
shell> ndb_blob_tool --check-orphans --verbose --d test btest  
connected  
processing 2 blobs  
processing blob #0 c1 NDB$BLOB_19_1  	NDB$BLOB_19_1: nextResult: res=1  
total parts: 0  
orphan parts: 0  
total parts: 10  
orphan parts: 0
```
The tool reports that there are no NDB BLOB column parts associated with column cl, even though cl is a TEXT column. This is due to the fact that, in an NDB table, only the first 256 bytes of a BLOB or TEXT column value are stored inline, and only the excess, if any, is stored separately; thus, if there are no values using more than 256 bytes in a given column of one of these types, no BLOB column parts are created by NDB for this column. See Section 11.7, “Data Type Storage Requirements”, for more information.

22.4.7 ndb_config — Extract NDB Cluster Configuration Information

This tool extracts current configuration information for data nodes, SQL nodes, and API nodes from one of a number of sources: an NDB Cluster management node, or its config.ini or my.cnf file. By default, the management node is the source for the configuration data; to override the default, execute ndb_config with the --config-file or --mycnf option. It is also possible to use a data node as the source by specifying its node ID with --config_from_node=node_id.

ndb_config can also provide an offline dump of all configuration parameters which can be used, along with their default, maximum, and minimum values and other information. The dump can be produced in either text or XML format; for more information, see the discussion of the --configinfo and --xml options later in this section).

You can filter the results by section (DB, SYSTEM, or CONNECTIONS) using one of the options --nodes, --system, or --connections.

The following table includes options that are specific to ndb_config. Additional descriptions follow the table. For options common to most NDB Cluster programs (including ndb_config), see Section 22.4.32, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

Table 22.28 Command-line options for the ndb_config program

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--config-file=file_name</td>
<td>Set the path to config.ini file</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--config-from-node=</td>
<td>Obtain configuration data from the node having this ID (must be a data node)</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--configinfo</td>
<td>Dumps information about all NDB configuration parameters in text format with default, maximum, and minimum values. Use with --xml to obtain XML output</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--connections</td>
<td>Print connections information ([tcp], [tcp default], [sci], [sci default], [shm], or [shm default] sections of cluster configuration file) only. Cannot be used with --system or --nodes</td>
<td>(Supported in all MySQL 8.0 based releases)</td>

</tr>
</tbody>
</table>
• **--configinfo**

The **--configinfo** option causes **ndb_config** to dump a list of each NDB Cluster configuration parameter supported by the NDB Cluster distribution of which **ndb_config** is a part, including the following information:

• A brief description of each parameter’s purpose, effects, and usage
• The section of the config.ini file where the parameter may be used
• The parameter’s data type or unit of measurement
• Where applicable, the parameter’s default, minimum, and maximum values
• NDB Cluster release version and build information

By default, this output is in text format. Part of this output is shown here:

```bash
shell> ndb_config --configinfo

****** SYSTEM ******
Name (String)
Name of system (NDB Cluster)
MANDATORY
PrimaryMGMNode (Non-negative Integer)
Node id of Primary ndb_mgmd(MGM) node
Default: 0 (Min: 0, Max: 4294967039)
ConfigGenerationNumber (Non-negative Integer)
Configuration generation number
Default: 0 (Min: 0, Max: 4294967039)

****** DB ******
MaxNoOfSubscriptions (Non-negative Integer)
Max no of subscriptions (default 0 == MaxNoOfTables)
Default: 0 (Min: 0, Max: 4294967039)
MaxNoOfSubscribers (Non-negative Integer)
Max no of subscribers (default 0 == 2 * MaxNoOfTables)
Default: 0 (Min: 0, Max: 4294967039)
```

Use this option together with the **--xml** option to obtain output in XML format.

• **--config-file=path-to-file**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--config-file=file_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td></td>
</tr>
</tbody>
</table>

Gives the path to the management server’s configuration file (**config.ini**). This may be a relative or absolute path. If the management node resides on a different host from the one on which **ndb_config** is invoked, then an absolute path must be used.
• **--config-from-node=**#

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--config-from-node=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>none</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>48</td>
</tr>
</tbody>
</table>

Obtain the cluster's configuration data from the data node that has this ID.

If the node having this ID is not a data node, `ndb_config` fails with an error. (To obtain configuration data from the management node instead, simply omit this option.)

• **--connections**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--connections</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Tells `ndb_config` to print CONNECTIONS information only—that is, information about parameters found in the [tcp], [tcp default], [shm], or [shm default] sections of the cluster configuration file (see Section 22.3.3.10, “NDB Cluster TCP/IP Connections”, and Section 22.3.3.12, “NDB Cluster Shared-Memory Connections”, for more information).

This option is mutually exclusive with **--nodes** and **--system**; only one of these 3 options can be used.

• **--diff-default**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--diff-default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Print only configuration parameters that have non-default values.

• **--fields=delimiter,-f delimiter**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--fields=string</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td></td>
</tr>
</tbody>
</table>

Specifies a `delimiter` string used to separate the fields in the result. The default is ``, (the comma character).

*Note*

If the `delimiter` contains spaces or escapes (such as `\n` for the linefeed character), then it must be quoted.

• **--host=hostname**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--host=name</th>
</tr>
</thead>
</table>
ndb_config — Extract NDB Cluster Configuration Information

<table>
<thead>
<tr>
<th>Type</th>
<th>String</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td></td>
</tr>
</tbody>
</table>

Specifies the host name of the node for which configuration information is to be obtained.

**Note**

While the hostname `localhost` usually resolves to the IP address `127.0.0.1`, this may not necessarily be true for all operating platforms and configurations. This means that it is possible, when `localhost` is used in `config.ini`, for `ndb_config --host=localhost` to fail if `ndb_config` is run on a different host where `localhost` resolves to a different address (for example, on some versions of SUSE Linux, this is `127.0.0.2`). In general, for best results, you should use numeric IP addresses for all NDB Cluster configuration values relating to hosts, or verify that all NDB Cluster hosts handle `localhost` in the same fashion.

• **--mycnf**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--mycnf</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Read configuration data from the `my.cnf` file.

• **--ndb-connectstring=connection_string, --connect-string=connectstring**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ndb-connectstring=connectstring</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>--connect-string=connectstring</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>localhost:1186</td>
</tr>
</tbody>
</table>

Specifies the connection string to use in connecting to the management server. The format for the connection string is the same as described in Section 22.3.3.3, “NDB Cluster Connection Strings”, and defaults to `localhost:1186`.

• **--nodeid=node_id**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ndb-nodeid=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
</tbody>
</table>

Specify the node ID of the node for which configuration information is to be obtained.

• **--nodes**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--nodes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
</tbody>
</table>
### ndb_config — Extract NDB Cluster Configuration Information

<table>
<thead>
<tr>
<th>Default Value</th>
<th>FALSE</th>
</tr>
</thead>
</table>

Tells `ndb_config` to print information relating only to parameters defined in an `[ndbd]` or `[ndbd default]` section of the cluster configuration file (see Section 22.3.3.6, “Defining NDB Cluster Data Nodes”).

This option is mutually exclusive with `--connections` and `--system`; only one of these 3 options can be used.

- **`--query=query-options`, `-q query-options`**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--query=string</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td></td>
</tr>
</tbody>
</table>

  This is a comma-delimited list of *query options*—that is, a list of one or more node attributes to be returned. These include `nodeid` (node ID), type (node type—that is, `ndbd`, `mysqld`, or `ndb_mgmd`), and any configuration parameters whose values are to be obtained.

  For example, `--query=nodeid,type,datamemory,datadir` returns the node ID, node type, `DataMemory`, and `DataDir` for each node.

  **Note**
  
  If a given parameter is not applicable to a certain type of node, than an empty string is returned for the corresponding value. See the examples later in this section for more information.

- **`--query-all`, `-a`**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--query-all</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td></td>
</tr>
</tbody>
</table>

  Returns a comma-delimited list of all query options (node attributes; note that this list is a single string.

- **`--rows=separator`, `-r separator`**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--rows=string</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td></td>
</tr>
</tbody>
</table>

  Specifies a `separator` string used to separate the rows in the result. The default is a space character.

  **Note**
  
  If the `separator` contains spaces or escapes (such as `\n` for the linefeed character), then it must be quoted.

- **`--system`**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--system</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
</tbody>
</table>
ndb_config — Extract NDB Cluster Configuration Information

<table>
<thead>
<tr>
<th>Default Value</th>
<th>FALSE</th>
</tr>
</thead>
</table>

Tells ndb_config to print SYSTEM information only. This consists of system variables that cannot be changed at run time; thus, there is no corresponding section of the cluster configuration file for them. They can be seen (prefixed with ****** SYSTEM ******) in the output of ndb_config --configinfo.

This option is mutually exclusive with --nodes and --connections; only one of these 3 options can be used.

• --type=node_type

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--type=name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
<tr>
<td>Valid Values</td>
<td>ndbd</td>
</tr>
<tr>
<td></td>
<td>mysqlld</td>
</tr>
<tr>
<td></td>
<td>ndb_mgmd</td>
</tr>
</tbody>
</table>

Filters results so that only configuration values applying to nodes of the specified node_type (ndbd, mysqlld, or ndb_mgmd) are returned.

• --usage, --help, or -?

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--help</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>--usage</td>
</tr>
</tbody>
</table>

Causes ndb_config to print a list of available options, and then exit.

• --version, -V

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--version</th>
</tr>
</thead>
</table>

Causes ndb_config to print a version information string, and then exit.

• --configinfo --xml

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--configinfo --xml</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>false</td>
</tr>
</tbody>
</table>

Cause ndb_config --configinfo to provide output as XML by adding this option. A portion of such output is shown in this example:

```
shell> ndb_config --configinfo --xml
<configvariables protocolversion="1" ndbversionstring="5.7.32-ndb-7.5.20"
  ndbversion="460032" ndbversionmajor="7" ndbversionminor="5" ndbversionbuild="0">
  <section name="SYSTEM">
    <param name="Name" comment="Name of system (NDB Cluster)" type="string"
      mandatory="true"/>
```
<param name="PrimaryMGMNode" comment="Node id of Primary ndb_mgmd(MGM) node" type="unsigned" default="0" min="0" max="4294967039"/>
<param name="ConfigGenerationNumber" comment="Configuration generation number" type="unsigned" default="0" min="0" max="4294967039"/>
</section>
</section name="MYSQLD" primarykeys="NodeId">
<param name="wan" comment="Use WAN TCP setting as default" type="bool" default="false"/>
<param name="HostName" comment="Name of computer for this node" type="string" default=""/>
<param name="Id" comment="NodeId" type="unsigned" mandatory="true" min="1" max="255" deprecated="true"/>
<param name="NodeId" comment="Number identifying application node (mysqld(API))" type="unsigned" mandatory="true" min="1" max="255"/>
<param name="ExecuteOnComputer" comment="HostName" type="string" deprecated="true"/>
...
</section>
...
</configvariables>

**Note**

Normally, the XML output produced by **ndb_config --configinfo --xml** is formatted using one line per element; we have added extra whitespace in the previous example, as well as the next one, for reasons of legibility. This should not make any difference to applications using this output, since most XML processors either ignore nonessential whitespace as a matter of course, or can be instructed to do so.

The XML output also indicates when changing a given parameter requires that data nodes be restarted using the **--initial** option. This is shown by the presence of an **initial="true"** attribute in the corresponding **<param>** element. In addition, the restart type (**system** or **node**) is also shown; if a given parameter requires a system restart, this is indicated by the presence of a **restart="system"** attribute in the corresponding **<param>** element. For example, changing the value set for the Diskless parameter requires a system initial restart, as shown here (with the **restart** and **initial** attributes highlighted for visibility):

```xml
<param name="Diskless" comment="Run wo/ disk" type="bool" default="false" restart="system" initial="true"/>
```

Currently, no **initial** attribute is included in the XML output for **<param>** elements corresponding to parameters which do not require initial restarts; in other words, **initial="false"** is the default, and the value **false** should be assumed if the attribute is not present. Similarly, the default restart type is **node** (that is, an online or “rolling” restart of the cluster), but the **restart** attribute is included only if the restart type is **system** (meaning that all cluster nodes must be shut down at the same time, then restarted).

Deprecated parameters are indicated in the XML output by the **deprecated** attribute, as shown here:

```xml
<param name="NoOfDiskPagesToDiskAfterRestartACC" comment="DiskCheckpointSpeed" type="unsigned" default="20" min="1" max="4294967039" deprecated="true"/>
```

In such cases, the **comment** refers to one or more parameters that supersede the deprecated parameter. Similarly to **initial**, the **deprecated** attribute is indicated only when the parameter
is deprecated, with `deprecated="true"`, and does not appear at all for parameters which are not deprecated. (Bug #21127135)

Beginning with NDB 7.5.0, parameters that are required are indicated with `mandatory="true"`, as shown here:

```xml
<param name="NodeId"
    comment="Number identifying application node (mysqld(API))"
    type="unsigned" mandatory="true" min="1" max="255"/>
```

In much the same way that the initial or deprecated attribute is displayed only for a parameter that requires an intial restart or that is deprecated, the mandatory attribute is included only if the given parameter is actually required.

**Important**

The `--xml` option can be used only with the `--configinfo` option. Using `--xml` without `--configinfo` fails with an error.

Unlike the options used with this program to obtain current configuration data, `--configinfo` and `--xml` use information obtained from the NDB Cluster sources when `ndb_config` was compiled. For this reason, no connection to a running NDB Cluster or access to a `config.ini` or `my.cnf` file is required for these two options.

Combining other `ndb_config` options (such as `--query` or `--type`) with `--configinfo` (with or without the `--xml` option is not supported. Currently, if you attempt to do so, the usual result is that all other options besides `--configinfo` and `--xml` are simply ignored. However, this behavior is not guaranteed and is subject to change at any time. In addition, since `ndb_config`, when used with the `--configinfo` option, does not access the NDB Cluster or read any files, trying to specify additional options such as `--ndb-connectstring` or `--config-file` with `--configinfo` serves no purpose.

**Examples**

1. To obtain the node ID and type of each node in the cluster:

   ```shell
   ./ndb_config --query=nodeid,type --fields=':' --rows='\n'
   1:ndbd
   2:ndbd
   3:ndbd
   4:ndbd
   5:ndb_mgmd
   6:mysql
   7:mysql
   8:mysql
   9:mysql
   ```

   In this example, we used the `--fields` options to separate the ID and type of each node with a colon character (:`), and the `--rows` options to place the values for each node on a new line in the output.

2. To produce a connection string that can be used by data, SQL, and API nodes to connect to the management server:

   ```shell
   ./ndb_config --config-file=usr/local/mysql/cluster-data/config.ini \
   --query=hostname,portnumber --fields=: --rows=, --type=ndb_mgmd
   198.51.100.179:1186
   ```

3. This invocation of `ndb_config` checks only data nodes (using the `--type` option), and shows the values for each node's ID and host name, as well as the values set for its `DataMemory` and `DataDir` parameters:
### ndb_delete_all — Delete All Rows from an NDB Table

**ndb_delete_all** deletes all rows from the given NDB table. In some cases, this can be much faster than `DELETE` or even `TRUNCATE TABLE`.

#### Usage

```
ndb_delete_all -c connection_string tbl_name -d db_name
```

This deletes all rows from the table named `tbl_name` in the database named `db_name`. It is exactly equivalent to executing `TRUNCATE db_name.tbl_name` in MySQL.

The following table includes options that are specific to `ndb_delete_all`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndb_delete_all`), see Section 22.4.32, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--database=dbname</code></td>
<td>Name of the database in which the table is found</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>-d</code></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--transactional</code></td>
<td>Perform the delete in a single transaction (may run out of operations)</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>-t</code></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--tupscan</code></td>
<td>Run tup scan</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--diskscan</code></td>
<td>Run disk scan</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
</tbody>
</table>

- **`--transactional`, `-t`**

  Use of this option causes the delete operation to be performed as a single transaction.

---

In this example, we used the short options `-f` and `-r` for setting the field delimiter and row separator, respectively, as well as the short option `-q` to pass a list of parameters to be obtained.

4. To exclude results from any host except one in particular, use the `--host` option:

```
shell> ./ndb_config --host=198.51.100.176 -f : -r '
' -q id,type
```

In this example, we also used the short form `-q` to determine the attributes to be queried.

Similarly, you can limit results to a node with a specific ID using the `--nodeid` option.

22.4.8 **ndb_delete_all — Delete All Rows from an NDB Table**

**ndb_delete_all** deletes all rows from the given NDB table. In some cases, this can be much faster than `DELETE` or even `TRUNCATE TABLE`.
Warning
With very large tables, using this option may cause the number of operations available to the cluster to be exceeded.

Prior to NDB 8.0.18, this program printed `NDBT_ProgramExit - status` upon completion of its run, due to an unnecessary dependency on the `NDBT` testing library. This dependency has been removed, eliminating the extraneous output.

22.4.9 ndb_desc — Describe NDB Tables

`ndb_desc` provides a detailed description of one or more NDB tables.

Usage

```
ndb_desc -c connection_string tbl_name -d db_name [options]
ndb_desc -c connection_string index_name -d db_name -t tbl_name
```

Additional options that can be used with `ndb_desc` are listed later in this section.

Sample Output

MySQL table creation and population statements:

```
USE test;

CREATE TABLE fish (  
    id INT NOT NULL AUTO_INCREMENT,
    name VARCHAR(20) NOT NULL,
    length_mm INT NOT NULL,
    weight_gm INT NOT NULL,

    PRIMARY KEY pk (id),
    UNIQUE KEY uk (name)
) ENGINE=NDB;

INSERT INTO fish VALUES
    (NULL, 'guppy', 35, 2), (NULL, 'tuna', 2500, 150000),
    (NULL, 'shark', 3000, 110000), (NULL, 'manta ray', 1500, 50000),
    (NULL, 'grouper', 900, 125000), (NULL, 'puffer', 250, 2500);
```

Output from `ndb_desc`:

```
shell> ./ndb_desc -c localhost fish -d test -p
-- fish --
Version: 2
Fragment type: HashMapPartition
K Value: 6
Min load factor: 78
Max load factor: 80
Temporary table: no
Number of attributes: 4
Number of primary keys: 1
Length of frm data: 337
Max Rows: 0
Row Checksum: 1
Row GCI: 1
SingleUserMode: 0
ForceVarPart: 1
PartitionCount: 2
FragmentCount: 2
```
Information about multiple tables can be obtained in a single invocation of `ndb_desc` by using their names, separated by spaces. All of the tables must be in the same database.

You can obtain additional information about a specific index using the `--table` (short form: `-t`) option and supplying the name of the index as the first argument to `ndb_desc`, as shown here:

```sh
cshell> ./ndb_desc uk -d test -t fish
```

```
--- uk ---
Version: 2
Base table: fish
Number of attributes: 1
Logging: 0
Index type: OrderedIndex
Index status: Retrieved
--- Attributes ---
name Varchar(20;latin1_swedish_ci) NOT NULL AT=SHORT_VAR ST=MEMORY
--- IndexTable 10/uk ---
Version: 2
Fragment type: FragUndefined
K Value: 6
Min load factor: 78
Max load factor: 80
Temporary table: yes
Number of attributes: 2
Number of primary keys: 1
Length of frm data: 0
Max Rows: 0
Row Checksum: 1
Row GCI: 1
SingleUserMode: 2
ForceVarPart: 0
PartitionCount: 2
FragmentCount: 2
FragmentCountType: ONE_PER_LDM_PER_NODE
ExtraRowGciBits: 0
ExtraRowAuthorBits: 0
TableStatus: Retrieved
Table options:
--- Attributes ---
nname Varchar(20;latin1_swedish_ci) NOT NULL AT=SHORT_VAR ST=MEMORY
NDB$TNODE Unsigned [64] PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY
--- Indexes ---
```
When an index is specified in this way, the **--extra-partition-info** and **--extra-node-info** options have no effect.

The **Version** column in the output contains the table’s schema object version. For information about interpreting this value, see **NDB Schema Object Versions**.

Three of the table properties that can be set using **NDB_TABLE** comments embedded in **CREATE TABLE** and **ALTER TABLE** statements are also visible in **ndb_desc** output. The table’s **FRAGMENT_COUNT_TYPE** is always shown in the FragmentCountType column. **READ_ONLY** and **FULLY_REPLICATED**, if set to 1, are shown in the Table options column. You can see this after executing the following **ALTER TABLE** statement in the **mysql** client:

```sql
mysql> ALTER TABLE fish COMMENT='NDB_TABLE=READ_ONLY=1,FULLY_REPLICATED=1';
1 row in set, 1 warning (0.00 sec)
```

```sql
mysql> SHOW WARNINGS\G
+---------+------+---------------------------------------------------------------------------------------------------------+
| Level   | Code | Message                                                                                                 |
+---------+------+---------------------------------------------------------------------------------------------------------+
| Warning | 1296 | Got error 4503 'Table property is FRAGMENT_COUNT_TYPE=ONE_PER_LDM_PER_NODE but not in comment' from NDB |
+---------+------+---------------------------------------------------------------------------------------------------------+
1 row in set (0.00 sec)
```

The warning is issued because **READ_ONLY=1** requires that the table’s fragment count type is (or be set to) **ONE_PER_LDM_PER_NODE_GROUP**; NDB sets this automatically in such cases. You can check that the **ALTER TABLE** statement has the desired effect using **SHOW CREATE TABLE**:

```sql
mysql> SHOW CREATE TABLE fish\G
*************************** 1. row ***************************
Table: fish
Create Table: CREATE TABLE `fish` (
  `id` int(11) NOT NULL AUTO_INCREMENT,
  `name` varchar(20) NOT NULL,
  `length_mm` int(11) NOT NULL,
  `weight_gm` int(11) NOT NULL,
  PRIMARY KEY (`id`),
  UNIQUE KEY `uk` (`name`) ) ENGINE=ndbcluster DEFAULT CHARSET=latin1
COMMENT='NDB_TABLE=READ_BACKUP=1,FULLY_REPLICATED=1'
1 row in set (0.01 sec)
```

Because **FRAGMENT_COUNT_TYPE** was not set explicitly, its value is not shown in the comment text printed by **SHOW CREATE TABLE**. **ndb_desc**, however, displays the updated value for this attribute. The Table options column shows the binary properties just enabled. You can see this in the output shown here (emphasized text):

```bash
shell> ./ndb_desc -c localhost fish -d test -p
-- fish --
Version: 4
Fragment type: HashMapPartition

-- Per partition info --
Partition    Row count    Commit count    Frag fixed memory    Frag varsized memory    Extent_space    Free extent_space

NDBT_ProgramExit: 0 - OK

For more information about these table properties, see Section 13.1.20.10, “Setting NDB_TABLE Options”.

The Extent_space and Free extent_space columns are applicable only to NDB tables having columns on disk; for tables having only in-memory columns, these columns always contain the value 0.

To illustrate their use, we modify the previous example. First, we must create the necessary Disk Data objects, as shown here:

CREATE LOGFILE GROUP lg_1
   ADD UNDOFILE 'undo_1.log'
   INITIAL_SIZE 16M
   UNDO_BUFFER_SIZE 2M
   ENGINE NDB;

ALTER LOGFILE GROUP lg_1
   ADD UNDOFILE 'undo_2.log'
   INITIAL_SIZE 12M
   ENGINE NDB;

CREATE TABLESPACE ts_1
   ADD DATAFILE 'data_1.dat'
   USE LOGFILE GROUP lg_1
   INITIAL_SIZE 32M
   ENGINE NDB;

ALTER TABLESPACE ts_1
   ADD DATAFILE 'data_2.dat'
   INITIAL_SIZE 48M
   ENGINE NDB;

(For more information on the statements just shown and the objects created by them, see Section 22.5.10.1, “NDB Cluster Disk Data Objects”, as well as Section 13.1.16, “CREATE LOGFILE GROUP Statement”, and Section 13.1.21, “CREATE TABLESPACE Statement”.)

Now we can create and populate a version of the fish table that stores 2 of its columns on disk (deleting the previous version of the table first, if it already exists):

DROP TABLE IF EXISTS fish;

CREATE TABLE fish (}
When run against this version of the table, `ndb_desc` displays the following output:

```
shell> ./ndb_desc -c localhost fish -d test -p
-- fish --
Version: 1
Fragment type: HashMapPartition
K Value: 6
Min load factor: 78
Max load factor: 80
Temporary table: no
Number of attributes: 4
Number of primary keys: 1
Length of frm data: 1001
Max Rows: 0
Row Checksum: 1
Row GCI: 1
SingleUserMode: 0
ForceVarPart: 1
PartitionCount: 2
FragmentCount: 2
PartitionBalance: FOR_RP_BY_LDM
ExtraRowGciBits: 0
ExtraRowAuthorBits: 0
TableStatus: Retrieved
Table options: readbackup
HashMap: DEFAULT-HASHMAP-3840-2
Tablespace id: 16
Tablespace: ts_1
-- Attributes --
id Int PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY AUTO_INCR
name Varchar(80;utf8mb4_0900_ai_ci) NOT NULL AT=SHORT_VAR ST=MEMORY
length_mm Int NOT NULL AT=FIXED ST=DISK
weight_gm Int NOT NULL AT=FIXED ST=DISK
-- Indexes --
PRIMARY KEY(id) - UniqueHashIndex
PRIMARY(id) - OrderedIndex
uk(name) - OrderedIndex
uk$unique(name) - UniqueHashIndex
-- Per partition info --
Partition Row count Commit count Frag fixed memory Frag varsized memory Extent_space
 0   2       2       32768       32768       1048576
 1   4       4       32768       32768       1048576
```

This means that 1048576 bytes are allocated from the tablespace for this table on each partition, of which 1044440 bytes remain free for additional storage. In other words, 1048576 - 1044440 = 4136 bytes per partition is currently being used to store the data from this table's disk-based columns. The number of bytes shown as `Free extent_space` is available for storing on-disk column data from the `fish` table only; for this reason, it is not visible when selecting from the `INFORMATION_SCHEMA.FILES` table.
**ndb_desc** — Describe NDB Tables

Tablespace id and Tablespace are displayed for Disk Data tables beginning with NDB 8.0.21.

For fully replicated tables, `ndb_desc` shows only the nodes holding primary partition fragment replicas; nodes with copy fragment replicas (only) are ignored. You can obtain such information, using the `mysql` client, from the `table_distribution_status`, `table_fragments`, `table_info`, and `table_replicas` tables in the `ndbinfo` database.

The following table includes options that are specific to `ndb_desc`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndb_desc`), see Section 22.4.32, "Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs".

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--auto-inc</code>, <code>-a</code></td>
<td>Show next value for AUTO_INCREMENT column if table has one</td>
<td>ADDED: NDB 8.0.21</td>
</tr>
<tr>
<td><code>--blob-info</code>, <code>-b</code></td>
<td>Include partition information for BLOB tables in output. Requires that the -p option also be used</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--context</code>, <code>-x</code></td>
<td>Show extra information for table such as database, schema, name, internal ID</td>
<td>ADDED: NDB 8.0.21</td>
</tr>
<tr>
<td><code>--database=dbname</code>, <code>-d</code></td>
<td>Name of database containing table</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--extra-node-info</code>, <code>-n</code></td>
<td>Include partition-to-data-node mappings in output. Requires that the -p option also be used</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--extra-partition-info</code>, <code>-p</code></td>
<td>Display information about partitions</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--retries=#</code>, <code>-r</code></td>
<td>Number of times to retry the connection (once per second)</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--table=tbl_name</code>, <code>-t</code></td>
<td>Specify the table in which to find an index. When this option is used, -p and -n have no effect and are ignored</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--unqualified</code>, <code>-u</code></td>
<td>Use unqualified table names</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
</tbody>
</table>

- `--auto-inc`, `-a`
  
  Show the next value for a table’s AUTO_INCREMENT column, if it has one.

- `--blob-info`, `-b`
  
  Include information about subordinate BLOB and TEXT columns.
  
  Use of this option also requires the use of the `--extra-partition-info` (-p) option.
ndb_drop_index — Drop Index from an NDB Table

- --context, -x
  Show additional contextual information for the table such as schema, database name, table name, and the table's internal ID.

- --database=db_name, -d
  Specify the database in which the table should be found.

- --extra-node-info, -n
  Include information about the mappings between table partitions and the data nodes upon which they reside. This information can be useful for verifying distribution awareness mechanisms and supporting more efficient application access to the data stored in NDB Cluster.

  Use of this option also requires the use of the --extra-partition-info (-p) option.

- --extra-partition-info, -p
  Print additional information about the table’s partitions.

- --retries=#, -r
  Try to connect this many times before giving up. One connect attempt is made per second.

- --table=tbl_name, -t
  Specify the table in which to look for an index.

- --unqualified, -u
  Use unqualified table names.

Table indexes listed in the output are ordered by ID.

22.4.10 ndb_drop_index — Drop Index from an NDB Table

ndb_drop_index drops the specified index from an NDB table. It is recommended that you use this utility only as an example for writing NDB API applications—see the Warning later in this section for details.

Usage

```bash
ndb_drop_index -c connection_string table_name index -d db_name
```

The statement shown above drops the index named `index` from the `table` in the `database`.

The following table includes options that are specific to ndb_drop_index. Additional descriptions follow the table. For options common to most NDB Cluster programs (including ndb_drop_index), see Section 22.4.32, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--database=db_name,</td>
<td>Name of database in which table is found</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
</tbody>
</table>
### ndb_drop_table — Drop an NDB Table

**Format**

<table>
<thead>
<tr>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>-d</td>
<td></td>
</tr>
</tbody>
</table>

**Warning**

Operations performed on Cluster table indexes using the NDB API are not visible to MySQL and make the table unusable by a MySQL server. If you use this program to drop an index, then try to access the table from an SQL node, an error results, as shown here:

```shell
./ndb_drop_index -c localhost dogs ix -d ctest1
Dropping index dogs/idx...OK
NDBT_ProgramExit: 0 - OK
```

```shell
./mysql -u jon -p ctest1
Enter password: *******
Welcome to the MySQL monitor. Commands end with ; or \g.
Your MySQL connection id is 7 to server version: 5.7.32-ndb-7.5.20
You can turn off this feature to get a quicker startup with -A
Type 'help;' or '\h' for help. Type '\c' to clear the buffer.
```

```sql
SHOW TABLES;
+------------------+
<table>
<thead>
<tr>
<th>Tables_in_ctest1</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
</tr>
<tr>
<td>bt1</td>
</tr>
<tr>
<td>bt2</td>
</tr>
<tr>
<td>dogs</td>
</tr>
<tr>
<td>employees</td>
</tr>
<tr>
<td>fish</td>
</tr>
</tbody>
</table>
+------------------+
6 rows in set (0.00 sec)
```

```sql
SELECT * FROM dogs;
ERROR 1296 (HY000): Got error 4243 'Index not found' from NDBCLUSTER
```

In such a case, your only option for making the table available to MySQL again is to drop the table and re-create it. You can use either the SQL statement `DROP TABLE` or the `ndb_drop_table` utility (see Section 22.4.11, “ndb_drop_table — Drop an NDB Table”) to drop the table.

### 22.4.11 ndb_drop_table — Drop an NDB Table

`ndb_drop_table` drops the specified NDB table. (If you try to use this on a table created with a storage engine other than NDB, the attempt fails with the error 723: No such table exists.) This operation is extremely fast; in some cases, it can be an order of magnitude faster than using a MySQL `DROP TABLE` statement on an NDB table.

**Usage**

```
ndb_drop_table -c connection_string tbl_name -d db_name
```

The following table includes options that are specific to `ndb_drop_table`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndb_drop_table`), see Section 22.4.32, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

---

### Table 22.32 Command-line options for the ndb_drop_table program

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--database=dbname, -d</td>
<td>Name of database in which table is found</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
</tbody>
</table>

Prior to NDB 8.0.17, an NDB table dropped using this utility persisted in the MySQL data dictionary but could not be dropped using `DROP TABLE` in the `mysql` client. In NDB 8.0.17 and later, such “orphan” tables can be dropped using `DROP TABLE`. (Bug #29125206, Bug #93672)

### 22.4.12 ndb_error_reporter — NDB Error-Reporting Utility

`ndb_error_reporter` creates an archive from data node and management node log files that can be used to help diagnose bugs or other problems with a cluster. *It is highly recommended that you make use of this utility when filing reports of bugs in NDB Cluster.*

The following table includes command options specific to the NDB Cluster program `ndb_error_reporter`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndb_error_reporter`), see Section 22.4.32, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

### Table 22.33 Command-line options for the ndb_error_reporter program

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--connection-timeout=timeout</td>
<td>Number of seconds to wait when connecting to nodes before timing out</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--dry-scp</td>
<td>Disable scp with remote hosts; used only for testing</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--fs</td>
<td>Include file system data in error report; can use a large amount of disk space</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--skip-nodegroup=nodegroup_id</td>
<td>Skip all nodes in the node group having this ID</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
</tbody>
</table>

### Usage

```
ndb_error_reporter path/to/config-file [username] [options]
```

This utility is intended for use on a management node host, and requires the path to the management host configuration file (usually named `config.ini`). Optionally, you can supply the name of a user that is able to access the cluster's data nodes using SSH, to copy the data node log files. `ndb_error_reporter` then includes all of these files in archive that is created in the same directory in which it is run. The archive is named `ndb_error_report_YYYYMMDDhhmms.tar.bz2`, where `YYYYMMDDhhmms` is a datetime string.

`ndb_error_reporter` also accepts the options listed here:

- `--connection-timeout=timeout`

#### Command-Line Format

<table>
<thead>
<tr>
<th>Type</th>
<th><code>--connection-timeout=timeout</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
</tbody>
</table>

---

4166
ndb_import — Import CSV Data Into NDB

<table>
<thead>
<tr>
<th>Default Value</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Wait this many seconds when trying to connect to nodes before timing out.</td>
<td></td>
</tr>
</tbody>
</table>

- **--dry-scp**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--dry-scp</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>TRUE</td>
</tr>
</tbody>
</table>

  Run ndb_error_reporter without using scp from remote hosts. Used for testing only.

- **--fs**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--fs</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

  Copy the data node file systems to the management host and include them in the archive.

  Because data node file systems can be extremely large, even after being compressed, we ask that you please do not send archives created using this option to Oracle unless you are specifically requested to do so.

- **--skip-nodegroup=nodegroup_id**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--connection-timeout=timeout</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
</tbody>
</table>

  Skip all nodes belong to the node group having the supplied node group ID.

**22.4.13 ndb_import — Import CSV Data Into NDB**

ndb_import imports CSV-formatted data, such as that produced by mysqldump --tab, directly into NDB using the NDB API. ndb_import requires a connection to an NDB management server (ndb_mgmd) to function; it does not require a connection to a MySQL Server.

**Usage**

```
ndb_import db_name file_name options
```

ndb_import requires two arguments. db_name is the name of the database where the table into which to import the data is found; file_name is the name of the CSV file from which to read the data; this must include the path to this file if it is not in the current directory. The name of the file must match that of the table; the file’s extension, if any, is not taken into consideration. Options supported by ndb_import include those for specifying field separators, escapes, and line terminators, and are described later in this section. ndb_import must be able to connect to an NDB Cluster management server; for this reason, there must be an unused [api] slot in the cluster config.ini file.

To duplicate an existing table that uses a different storage engine, such as InnoDB, as an NDB table, use the mysql client to perform a SELECT INTO OUTFILE statement to export the existing table to a CSV file, then to execute a CREATE TABLE LIKE statement to create a new table having the same structure as the existing table, then perform ALTER TABLE ... ENGINE=NDB on the new table; after this, from
the system shell, invoke ndb_import to load the data into the new NDB table. For example, an existing InnoDB table named myinnodb_table in a database named myinnodb can be exported into an NDB table named myndb_table in a database named myndb as shown here, assuming that you are already logged in as a MySQL user with the appropriate privileges:

1. In the mysql client:

```sql
mysql> USE myinnodb;
mysql> SELECT * INTO OUTFILE '/tmp/myndb_table.csv'
    > FIELDS TERMINATED BY ',' OPTIONALLY ENCLOSED BY '"' ESCAPED BY '\'
    > LINES TERMINATED BY '
    > FROM myinnodb_table;

mysql> CREATE DATABASE myndb;
mysql> USE myndb;
mysql> CREATE TABLE myndb_table LIKE myinnodb.myinnodb_table;
mysql> ALTER TABLE myndb_table ENGINE=NDB;
```

Once the target database and table have been created, a running mysqld is no longer required. You can stop it using mysqladmin shutdown or another method before proceeding, if you wish.

2. In the system shell:

```bash
# if you are not already in the MySQL bin directory:
shell> cd path-to-mysql-bin-dir
shell> ndb_import myndb /tmp/myndb_table.csv --fields-optionally-enclosed-by="" \
\n--fields-terminated-by="" --fields-escaped-by='\'
```

The output should resemble what is shown here:

```
job-1 import myndb.myndb_table from /tmp/myndb_table.csv
job-1 [running] import myndb.myndb_table from /tmp/myndb_table.csv
job-1 [success] import myndb.myndb_table from /tmp/myndb_table.csv
job-1 imported 19984 rows in 0h0m9s at 2277 rows/s
jobs summary: defined: 1 run: 1 with success: 1 with failure: 0
```

The following table includes options that are specific to ndb_import. Additional descriptions follow the table. For options common to most NDB Cluster programs (including ndb_import), see Section 22.4.32, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

### Table 22.34 Command-line options for the ndb_import program

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--abort-on-error</td>
<td>Dump core on any fatal error; used for debugging</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--ai-increment=#</td>
<td>For table with hidden PK, specify autoincrement increment. See mysqld</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--ai-offset=#</td>
<td>For table with hidden PK, specify autoincrement offset. See mysqld</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>Format</td>
<td>Description</td>
<td>Added, Deprecated, or Removed</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>--------------------------------------------------------</td>
</tr>
<tr>
<td>--ai-prefetch-sz=#</td>
<td>For table with hidden PK, specify number of autoincrement values that are prefetched. See mysqld</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--connections=#</td>
<td>Number of cluster connections to create</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--continue</td>
<td>When job fails, continue to next job</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--db-workers=#</td>
<td>Number of threads, per data node, executing database operations</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--errins-type=name</td>
<td>Error insert type, for testing purposes; use &quot;list&quot; to obtain all possible values</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--errins-delay=#</td>
<td>Error insert delay in milliseconds; random variation is added</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--fields-enclosed-by=char</td>
<td>Same as FIELDS ENCLOSED BY option for LOAD DATA statements. For CSV input this is same as using --fields-optionally-enclosed-by</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--fields-escaped-by=name</td>
<td>Same as FIELDS ESCAPED BY option for LOAD DATA statements</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--fields-optionally-enclosed-by=char</td>
<td>Same as FIELDS OPTIONALLY ENCLOSED BY option for LOAD DATA statements</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--fields-terminated-by=char</td>
<td>Same as FIELDS TERMINATED BY option for LOAD DATA statements</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--idlesleep=#</td>
<td>Number of milliseconds to sleep waiting for more to do</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--idlespin=#</td>
<td>Number of times to re-try before idlesleep</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--ignore-lines=#</td>
<td>Ignore first # lines in input file. Used to skip a non-data header</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--input-type=name</td>
<td>Input type: random or csv</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--input-workers=#</td>
<td>Number of threads processing input. Must be 2 or more if --input-type is csv</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--keep-state</td>
<td>State files (except non-empty *.rej files) are normally removed on job completion. Using this option causes all state files to be preserved instead</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--lines-terminated-by=name</td>
<td>Same as LINES TERMINATED BY option for LOAD DATA statements</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
</tbody>
</table>
## ndb_import — Import CSV Data Into NDB

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--max-rows=#</td>
<td>Import only this number of input data rows; default is 0, which imports all rows.</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--monitor=#</td>
<td>Periodically print status of running job if something has changed (status, rejected rows, temporary errors). Value 0 disables. Value 1 prints any change seen. Higher values reduce status printing exponentially up to some pre-defined limit</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--no-asynch</td>
<td>Run database operations as batches, in single transactions</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--no-hint</td>
<td>Do not use distribution key hint to select data node (TC)</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--opbatch=#</td>
<td>A db execution batch is a set of transactions and operations sent to NDB kernel. This option limits NDB operations (including blob operations) in a db execution batch. Therefore it also limits number of async transactions. Value 0 is not valid</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--opbytes=#</td>
<td>Limit bytes in execution batch (default 0 = no limit)</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--output-type=name</td>
<td>Output type: ndb is default, null used for testing</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--output-workers=#</td>
<td>Number of threads processing output or relaying database operations</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--pagesize=#</td>
<td>Align I/O buffers to given size</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--pagecnt=#</td>
<td>Size of I/O buffers as multiple of page size. CSV input worker allocates a double-sized buffer</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--polltimeout=#</td>
<td>Timeout per poll for completed asynchronous transactions; polling continues until all polls are completed, or error occurs</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--rejects=#</td>
<td>Limit number of rejected rows (rows with permanent error) in data load. Default is 0 which means that any rejected row causes a fatal error. The row exceeding the limit is also added to *.rej</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
</tbody>
</table>
### ndb_import — Import CSV Data Into NDB

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--resume</td>
<td>If job aborted (temporary error, user interrupt), resume with rows not yet processed</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--rowbatch=#</td>
<td>Limit rows in row queues (default 0 = no limit); must be 1 or more if --input-type is random</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--rowbytes=#</td>
<td>Limit bytes in row queues (0 = no limit)</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--state-dir=name</td>
<td>Where to write state files; current directory is default</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--stats</td>
<td>Save performance related options and internal statistics in *.sto and *.stt files. These files are kept on successful completion even if --keep-state is not used</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--tempdelay=#</td>
<td>Number of milliseconds to sleep between temporary errors</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--temperrors=#</td>
<td>Number of times a transaction can fail due to a temporary error, per execution batch; 0 means any temporary error is fatal. Such errors do not cause any rows to be written to .rej file</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--verbose, -v</td>
<td>Enable verbose output</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
</tbody>
</table>

- **--abort-on-error**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--abort-on-error</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Dump core on any fatal error; used for debugging only.

- **--ai-increment=#**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ai-increment=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

For a table with a hidden primary key, specify the autoincrement increment, like the auto_increment_increment system variable does in the MySQL Server.
- **--ai-offset=#**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ai-offset=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

  For a table with hidden primary key, specify the autoincrement offset. Similar to the `auto_increment_offset` system variable.

- **--ai-prefetch-sz=#**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ai-prefetch-sz=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1024</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

  For a table with a hidden primary key, specify the number of autoincrement values that are prefetched. Behaves like the `ndb_autoincrement_prefetch_sz` system variable does in the MySQL Server.

- **--connections=#**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--connections=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

  Number of cluster connections to create.

- **--continue**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--continue</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

  When a job fails, continue to the next job.

- **--db-workers=#**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--db-workers=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>4</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
</tbody>
</table>
ndb_import — Import CSV Data Into NDB

<table>
<thead>
<tr>
<th>Maximum Value</th>
<th>4294967295</th>
</tr>
</thead>
</table>

Number of threads, per data node, executing database operations.

- **--errins-type=name**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--errins-type=name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
<tr>
<td>Valid Values</td>
<td>stopjob</td>
</tr>
<tr>
<td></td>
<td>stopall</td>
</tr>
<tr>
<td></td>
<td>sighup</td>
</tr>
<tr>
<td></td>
<td>sigint</td>
</tr>
<tr>
<td></td>
<td>list</td>
</tr>
</tbody>
</table>

Error insert type; use `list` as the `name` value to obtain all possible values. This option is used for testing purposes only.

- **--errins-delay=#**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--errins-delay=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1000</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
<tr>
<td>Unit</td>
<td>ms</td>
</tr>
</tbody>
</table>

Error insert delay in milliseconds; random variation is added. This option is used for testing purposes only.

- **--fields-enclosed-by=char**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--fields-enclosed-by=char</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

This works in the same way as the `FIELDS ENCLOSED BY` option does for the `LOAD DATA` statement, specifying a character to be interpreted as quoting field values. For CSV input, this is the same as `--fields-optionally-enclosed-by`.

- **--fields-escaped-by=name**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--fields-escaped-by=name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

4173
### ndb_import — Import CSV Data Into NDB

#### Default Value
```
\n```

Specify an escape character in the same way as the `FIELDS ESCAPED BY` option does for the SQL `LOAD DATA` statement.

- **--fields-optionally-enclosed-by=char**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--fields-optionally-enclosed-by=char</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

  This works in the same way as the `FIELDS OPTIONALLY ENCLOSED BY` option does for the `LOAD DATA` statement, specifying a character to be interpreted as optionally quoting field values. For CSV input, this is the same as `--fields-enclosed-by`.

- **--fields-terminated-by=char**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--fields-terminated-by=char</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>\t</td>
</tr>
</tbody>
</table>

  This works in the same way as the `FIELDS TERMINATED BY` option does for the `LOAD DATA` statement, specifying a character to be interpreted as the field separator.

- **--idlesleep=#**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--idlesleep=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
<tr>
<td>Unit</td>
<td>ms</td>
</tr>
</tbody>
</table>

  Number of milliseconds to sleep waiting for more work to perform.

- **--idlespin=#**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--idlespin=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

  Number of times to retry before sleeping.

- **--ignore-lines=#**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ignore-lines=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
</tbody>
</table>

**ndb_import** — Import CSV Data Into NDB

<table>
<thead>
<tr>
<th>Default Value</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

Cause ndb_import to ignore the first `#` lines of the input file. This can be employed to skip a file header that does not contain any data.

* --input-type=name

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--input-type=name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>csv</td>
</tr>
<tr>
<td>Valid Values</td>
<td>random</td>
</tr>
<tr>
<td></td>
<td>csv</td>
</tr>
</tbody>
</table>

Set the type of input type. The default is `csv`; `random` is intended for testing purposes only.

* --input-workers=#

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--input-workers=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>4</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

Set the number of threads processing input.

* --keep-state

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--keep-state</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>false</td>
</tr>
</tbody>
</table>

By default, ndb_import removes all state files (except non-empty `*.rej` files) when it completes a job. Specify this option (no argument is required) to force the program to retain all state files instead.

* --lines-terminated-by=name

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--lines-terminated-by=name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>\n</td>
</tr>
</tbody>
</table>

This works in the same way as the `LINES TERMINATED BY` option does for the `LOAD DATA` statement, specifying a character to be interpreted as end-of-line.

* --log-level=#

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--log-level=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
</tbody>
</table>
Performs internal logging at the given level. This option is intended primarily for internal and development use.

In debug builds of NDB only, the logging level can be set using this option to a maximum of 4.

- **--max-rows=**#

Import only this number of input data rows; the default is 0, which imports all rows.

- **--monitor=**#

Periodically print the status of a running job if something has changed (status, rejected rows, temporary errors). Set to 0 to disable this reporting. Setting to 1 prints any change that is seen. Higher values reduce the frequency of this status reporting.

- **--no-asynch**

Run database operations as batches, in single transactions.

- **--no-hint**

Do not use distribution key hinting to select a data node.
### --opbatch=

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--opbatch=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>256</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
<tr>
<td>Unit</td>
<td>bytes</td>
</tr>
</tbody>
</table>

Set a limit on the number of operations (including blob operations), and thus the number of asynchronous transactions, per execution batch.

### --opbytes=

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--opbytes=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
<tr>
<td>Unit</td>
<td>bytes</td>
</tr>
</tbody>
</table>

Set a limit on the number of bytes per execution batch. Use 0 for no limit.

### --output-type=*

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--output-type=name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>ndb</td>
</tr>
<tr>
<td>Valid Values</td>
<td>null</td>
</tr>
</tbody>
</table>

Set the output type. `ndb` is the default. `null` is used only for testing.

### --output-workers=

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--output-workers=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>2</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

Set the number of threads processing output or relaying database operations.

### --pagesize=

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--pagesize=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>4096</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>4177</td>
</tr>
</tbody>
</table>

Set the page size.
Minimum Value 1
Maximum Value 4294967295
Unit bytes

Align I/O buffers to the given size.

- **--pagecnt=**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--pagecnt=</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>64</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

Set the size of I/O buffers as multiple of page size. The CSV input worker allocates buffer that is doubled in size.

- **--polltimeout=**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--polltimeout=</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1000</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
<tr>
<td>Unit</td>
<td>ms</td>
</tr>
</tbody>
</table>

Set a timeout per poll for completed asynchronous transactions; polling continues until all polls are completed, or until an error occurs.

- **--rejects=**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--rejects=</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

Limit the number of rejected rows (rows with permanent errors) in the data load. The default is 0, which means that any rejected row causes a fatal error. Any rows causing the limit to be exceeded are added to the .rej file.

The limit imposed by this option is effective for the duration of the current run. A run restarted using **--resume** is considered a “new” run for this purpose.

- **--resume**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--resume</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
</tbody>
</table>
Default Value | FALSE
---|---
If a job is aborted (due to a temporary db error or when interrupted by the user), resume with any rows not yet processed.

- **--rowbatch=#**

  | Command-Line Format | --rowbatch=#
  | Type | Integer
  | Default Value | 0
  | Minimum Value | 0
  | Maximum Value | 4294967295
  | Unit | rows

Set a limit on the number of rows per row queue. Use 0 for no limit.

- **--rowbytes=#**

  | Command-Line Format | --rowbytes=#
  | Type | Integer
  | Default Value | 262144
  | Minimum Value | 0
  | Maximum Value | 4294967295
  | Unit | bytes

Set a limit on the number of bytes per row queue. Use 0 for no limit.

- **--stats**

  | Command-Line Format | --stats
  | Type | Boolean
  | Default Value | false

Save information about options related to performance and other internal statistics in files named *.sto and *.stt. These files are always kept on successful completion (even if --keep-state is not also specified).

- **--state-dir=name**

  | Command-Line Format | --state-dir=name
  | Type | String
  | Default Value | .

Where to write the state files (tbl_name.map, tbl_name.rej, tbl_name.res, and tbl_name.stt) produced by a run of the program; the default is the current directory.

- **--tempdelay=#**

  | Command-Line Format | --tempdelay=#
**ndb_index_stat** — NDB Index Statistics Utility

<table>
<thead>
<tr>
<th>Type</th>
<th>Integer</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>10</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
<tr>
<td>Unit</td>
<td>ms</td>
</tr>
</tbody>
</table>

Number of milliseconds to sleep between temporary errors.

- **--temperrors=*/

| Command-Line Format | --temperrors=*
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

Number of times a transaction can fail due to a temporary error, per execution batch. The default is 0, which means that any temporary error is fatal. Temporary errors do not cause any rows to be added to the `.rej` file.

- **--verbose,-v**

| Command-Line Format | --verbose
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>false</td>
</tr>
</tbody>
</table>

Enable verbose output.

As with LOAD DATA, options for field and line formatting much match those used to create the CSV file, whether this was done using SELECT INTO ... OUTFILE, or by some other means. There is no equivalent to the LOAD DATA statement STARTING WITH option.

**ndb_import** was added in NDB 7.6.2.

### 22.4.14 ndb_index_stat — NDB Index Statistics Utility

*ndb_index_stat* provides per-fragment statistical information about indexes on *NDB* tables. This includes cache version and age, number of index entries per partition, and memory consumption by indexes.

**Usage**

To obtain basic index statistics about a given *NDB* table, invoke *ndb_index_stat* as shown here, with the name of the table as the first argument and the name of the database containing this table specified immediately following it, using the **--database (−d)** option:

```
ndb_index_stat table -d database
```

In this example, we use *ndb_index_stat* to obtain such information about an *NDB* table named *mytable* in the *test* database:

```
shell> ndb_index_stat -d test mytable
```
sampleVersion is the version number of the cache from which the statistics data is taken. Running ndb_index_stat with the --update option causes sampleVersion to be incremented.

loadTime shows when the cache was last updated. This is expressed as seconds since the Unix Epoch.

sampleCount is the number of index entries found per partition. You can estimate the total number of entries by multiplying this by the number of fragments (shown as fragCount).

sampleCount can be compared with the cardinality of SHOW INDEX or INFORMATION_SCHEMA.STATISTICS, although the latter two provide a view of the table as a whole, while ndb_index_stat provides a per-fragment average.

keyBytes is the number of bytes used by the index. In this example, the primary key is an integer, which requires four bytes for each index, so keyBytes can be calculated in this case as shown here:

\[
\text{keyBytes} = \text{sampleCount} \times (4 \text{ bytes per index}) = 1994 \times 4 = 7976
\]

This information can also be obtained using the corresponding column definitions from INFORMATION_SCHEMA.COLUMNS (this requires a MySQL Server and a MySQL client application).

totalBytes is the total memory consumed by all indexes on the table, in bytes.

Timings shown in the preceding examples are specific to each invocation of ndb_index_stat.

The --verbose option provides some additional output, as shown here:

```
shell> ndb_index_stat -d test mytable --verbose
random seed 1337010518
connected
loop 1 of 1
table:mytable index:PRIMARY fragCount:4
sampleVersion:2 loadTime:1336751773 sampleCount:0 keyBytes:0
read stats
query cache: valid:1 sampleCount:0 totalBytes:0
times in ms: save: 20.766 sort: 0.001
disconnected
NDBT_ProgramExit: 0 - OK
shell>
```

If the only output from the program is NDBT_ProgramExit: 0 - OK, this may indicate that no statistics yet exist. To force them to be created (or updated if they already exist), invoke ndb_index_stat with the --update option, or execute ANALYZE TABLE on the table in the mysql client.

Options

The following table includes options that are specific to the NDB Cluster ndb_index_stat utility. Additional descriptions are listed following the table. For options common to most NDB Cluster programs (including ndb_index_stat), see Section 22.4.32, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”. 

```
### Table 22.35 Command-line options for the ndb_index_stat program

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--database=name,</td>
<td>Name of database containing table</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>-d</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--delete</td>
<td>Delete index statistics for table, stopping any auto-update previously configured</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--update</td>
<td>Update index statistics for table, restarting any auto-update previously configured</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--dump</td>
<td>Print query cache</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--query=#</td>
<td>Perform random range queries on first key attr (must be int unsigned)</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--sys-drop</td>
<td>Drop any statistics tables and events in NDB kernel (all statistics are lost)</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--sys-create</td>
<td>Create all statistics tables and events in NDB kernel (all statistics are lost)</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--sys-create-if-not-exist</td>
<td>Create any statistics tables and events in NDB kernel that do not already exist</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--sys-create-if-not-valid</td>
<td>Create any statistics tables or events that do not already exist in the NDB kernel, after dropping any that are invalid</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--sys-check</td>
<td>Verify that NDB system index statistics and event tables exist</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--sys-skip-tables</td>
<td>Do not apply sys-* options to tables</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--sys-skip-events</td>
<td>Do not apply sys-* options to events</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--verbose,</td>
<td>Turn on verbose output</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>-v</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--loops=#</td>
<td>Set the number of times to perform given command; default is 0</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
</tbody>
</table>

**ndb_index_stat statistics options.** The following options are used to generate index statistics. They work with a given table and database. They cannot be mixed with system options (see ndb_index_stat system options).

- `--database=name, -d name`
<table>
<thead>
<tr>
<th>Default Value</th>
<th>[none]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Minimum Value</td>
<td></td>
</tr>
<tr>
<td>Maximum Value</td>
<td></td>
</tr>
</tbody>
</table>

The name of the database that contains the table being queried.

• **--delete**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--delete</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>false</td>
</tr>
<tr>
<td>Minimum Value</td>
<td></td>
</tr>
<tr>
<td>Maximum Value</td>
<td></td>
</tr>
</tbody>
</table>

Delete the index statistics for the given table, stopping any auto-update that was previously configured.

• **--update**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--update</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>false</td>
</tr>
<tr>
<td>Minimum Value</td>
<td></td>
</tr>
<tr>
<td>Maximum Value</td>
<td></td>
</tr>
</tbody>
</table>

Update the index statistics for the given table, and restart any auto-update that was previously configured.

• **--dump**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--dump</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>false</td>
</tr>
<tr>
<td>Minimum Value</td>
<td></td>
</tr>
<tr>
<td>Maximum Value</td>
<td></td>
</tr>
</tbody>
</table>

Dump the contents of the query cache.

• **--query=#**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--query=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>MAX_INT</td>
</tr>
</tbody>
</table>

Perform random range queries on first key attribute (must be int unsigned).
**ndb_index_stat system options.** The following options are used to generate and update the statistics tables in the NDB kernel. None of these options can be mixed with statistics options (see *ndb_index_stat statistics options*).

- **--sys-drop**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--sys-drop</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>false</td>
</tr>
<tr>
<td>Minimum Value</td>
<td></td>
</tr>
<tr>
<td>Maximum Value</td>
<td></td>
</tr>
</tbody>
</table>

Drop all statistics tables and events in the NDB kernel. *This causes all statistics to be lost.*

- **--sys-create**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--sys-create</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>false</td>
</tr>
<tr>
<td>Minimum Value</td>
<td></td>
</tr>
<tr>
<td>Maximum Value</td>
<td></td>
</tr>
</tbody>
</table>

Create all statistics tables and events in the NDB kernel. This works only if none of them exist previously.

- **sys-create-if-not-exist**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--sys-create-if-not-exist</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>false</td>
</tr>
<tr>
<td>Minimum Value</td>
<td></td>
</tr>
<tr>
<td>Maximum Value</td>
<td></td>
</tr>
</tbody>
</table>

Create any NDB system statistics tables or events (or both) that do not already exist when the program is invoked.

- **--sys-create-if-not-valid**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--sys-create-if-not-valid</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>false</td>
</tr>
<tr>
<td>Minimum Value</td>
<td></td>
</tr>
<tr>
<td>Maximum Value</td>
<td></td>
</tr>
</tbody>
</table>

Create any NDB system statistics tables or events that do not already exist, after dropping any that are invalid.

- **--sys-check**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--sys-check</th>
</tr>
</thead>
</table>
Verify that all required system statistics tables and events exist in the NDB kernel.

- **--sys-skip-tables**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--sys-skip-tables</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>false</td>
</tr>
</tbody>
</table>

Do not apply any **--sys-** options to any statistics tables.

- **--sys-skip-events**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--sys-skip-events</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>false</td>
</tr>
</tbody>
</table>

Do not apply any **--sys-** options to any events.

- **--verbose**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--verbose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>false</td>
</tr>
</tbody>
</table>

Turn on verbose output.

- **--loops=#**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--loops=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>MAX_INT</td>
</tr>
</tbody>
</table>

Repeat commands this number of times (for use in testing).
**22.4.15 ndb_move_data — NDB Data Copy Utility**

`ndb_move_data` copies data from one NDB table to another.

### Usage

The program is invoked with the names of the source and target tables; either or both of these may be qualified optionally with the database name. Both tables must use the NDB storage engine.

```
ndb_move_data options source target
```

The following table includes options that are specific to `ndb_move_data`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndb_move_data`), see Section 22.4.32, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

#### Table 22.36 Command-line options for the ndb_move_data program

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--abort-on-error</code></td>
<td>Dump core on permanent error (debug option)</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--character-sets-dir=name</code></td>
<td>Directory where character sets are</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--database=dbname</code>, <code>-d</code></td>
<td>Name of database in which table is found</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--drop-source</code></td>
<td>Drop source table after all rows have been moved</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--error-insert</code></td>
<td>Insert random temporary errors (testing option)</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--exclude-missing-columns</code></td>
<td>Ignore extra columns in source or target table</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--lossy-conversions</code>, <code>-l</code></td>
<td>Allow attribute data to be truncated when converted to smaller type</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--promote-attributes</code>, <code>-A</code></td>
<td>Allow attribute data to be converted to larger type</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--staging-tries=x[,y[,z]]</code></td>
<td>Specify tries on temporary errors; format is x[,y[,z]] where x=max tries (0=no limit), y=min delay (ms), z=max delay (ms)</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--verbose</code></td>
<td>Enable verbose messages</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
</tbody>
</table>

### Command-Line Format

#### `--abort-on-error`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--abort-on-error</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
</tbody>
</table>
Default Value: FALSE

Dump core on permanent error (debug option).

• \(--\texttt{character-sets-dir}=%\texttt{name}\)

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>(--\texttt{character-sets-dir}=\texttt{name})</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Directory where character sets are.

• \(--\texttt{database}=%\texttt{dbname}, -d\)

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>(--\texttt{database}=\texttt{dbname})</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>TEST_DB</td>
</tr>
</tbody>
</table>

Name of the database in which the table is found.

• \(--\texttt{drop-source}\)

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>(--\texttt{drop-source})</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Drop source table after all rows have been moved.

• \(--\texttt{error-insert}\)

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>(--\texttt{error-insert})</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Insert random temporary errors (testing option).

• \(--\texttt{exclude-missing-columns}\)

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>(--\texttt{exclude-missing-columns})</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Ignore extra columns in source or target table.

• \(--\texttt{lossy-conversions}, -l\)

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>(--\texttt{lossy-conversions})</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Allow attribute data to be truncated when converted to a smaller type.
**ndb_perror** — Obtain NDB Error Message Information

- **--promote-attributes, -A**

  Command-Line Format: `--promote-attributes
  Type: Boolean
  Default Value: FALSE

  Allow attribute data to be converted to a larger type.

- **--staging-tries=x[,y[,z]]**

  Command-Line Format: `--staging-tries=x[,y[,z]]
  Type: String
  Default Value: 0,1000,60000

  Specify tries on temporary errors. Format is x[,y[,z]] where x=max tries (0=no limit), y=min delay (ms), z=max delay (ms).

- **--verbose**

  Command-Line Format: `--verbose
  Type: Boolean
  Default Value: FALSE

  Enable verbose messages.

### 22.4.16 ndb_perror — Obtain NDB Error Message Information

`ndb_perror` shows information about an NDB error, given its error code. This includes the error message, the type of error, and whether the error is permanent or temporary. Added to the MySQL NDB Cluster distribution in NDB 7.6.4, it is intended as a drop-in replacement for `perror --ndb`.

**Usage**

```
ndb_perror [options] error_code
```

`ndb_perror` does not need to access a running NDB Cluster, or any nodes (including SQL nodes). To view information about a given NDB error, invoke the program, using the error code as an argument, like this:

```
shell> ndb_perror 323
NDB error code 323: Invalid nodegroup id, nodegroup already existing: Permanent error: Application error
```

To display only the error message, invoke `ndb_perror` with the `--silent` option (short form `-s`), as shown here:

```
shell> ndb_perror -s 323
Invalid nodegroup id, nodegroup already existing: Permanent error: Application error
```

Like `perror`, `ndb_perror` accepts multiple error codes:

```
shell> ndb_perror 321 1001
NDB error code 321: Invalid nodegroup id: Permanent error: Application error
NDB error code 1001: Illegal connect string
```

Additional program options for `ndb_perror` are described later in this section.
**ndb_perror** replaces *perror --ndb*, which is deprecated as of NDB 7.6.4 and subject to removal in a future release of MySQL NDB Cluster. To make substitution easier in scripts and other applications that might depend on *perror* for obtaining NDB error information, **ndb_perror** supports its own “dummy” **--ndb** option, which does nothing.

The following table includes all options that are specific to the NDB Cluster program **ndb_perror**. Additional descriptions follow the table.

### Table 22.37 Command-line options for the ndb_perror program

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>--help,</strong></td>
<td>Display help text</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>-?</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>--ndb</strong></td>
<td>For compatibility with applications depending on old versions of <em>perror</em>; does nothing</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><strong>--silent,</strong></td>
<td>Show error message only</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>-s</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>--version,</strong></td>
<td>Print program version information and exit</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>-V</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>--verbose,</strong></td>
<td>Verbose output; disable with <strong>--silent</strong></td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>-v</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

#### Additional Options

- **--help,** -?

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><strong>--help</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>TRUE</td>
</tr>
</tbody>
</table>

  Display program help text and exit.

- **--ndb**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><strong>--ndb</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>TRUE</td>
</tr>
</tbody>
</table>

  For compatibility with applications depending on old versions of *perror* that use that program's **--ndb** option. The option when used with **ndb_perror** does nothing, and is ignored by it.

- **--silent,** -s

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><strong>--silent</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>TRUE</td>
</tr>
</tbody>
</table>
ndb_print_backup_file — Print NDB Backup File Contents

Show error message only.

- --version, -V

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--version</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>TRUE</td>
</tr>
</tbody>
</table>

Print program version information and exit.

- --verbose, -v

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--verbose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>TRUE</td>
</tr>
</tbody>
</table>

Verbose output; disable with --silent.

22.4.17 ndb_print_backup_file — Print NDB Backup File Contents

ndb_print_backup_file obtains diagnostic information from a cluster backup file.

Usage

ndb_print_backup_file [-P password] file_name

file_name is the name of a cluster backup file. This can be any of the files (.Data, .ctl, or .log file) found in a cluster backup directory. These files are found in the data node's backup directory under the subdirectory BACKUP-#, where # is the sequence number for the backup. For more information about cluster backup files and their contents, see Section 22.5.8.1, "NDB Cluster Backup Concepts".

Like ndb_print_schema_file and ndb_print_sys_file (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a management server) ndb_print_backup_file must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

In NDB 8.0.17 and later, this program can also be used to read undo log files.

Beginning with NDB 8.0.22, this program can read encrypted backups. To do this, supply the -P option together with the password used to encrypt the backup.

Additional Options

None.

22.4.18 ndb_print_file — Print NDB Disk Data File Contents

ndb_print_file obtains information from an NDB Cluster Disk Data file.

Usage

ndb_print_file [-v] [-q] file_name+

file_name is the name of an NDB Cluster Disk Data file. Multiple filenames are accepted, separated by spaces.
Like `ndb_print_schema_file` and `ndb_print_sys_file` (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a management server)
`ndb_print_file` must be run on an NDB Cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

### Additional Options

`ndb_print_file` supports the following options:

- `--v`: Make output verbose.
- `--q`: Suppress output (quiet mode).
- `--help`, `-h`, `-?`: Print help message.

For more information, see Section 22.5.10, “NDB Cluster Disk Data Tables”.

---

### 22.4.19 ndb_print_frag_file — Print NDB Fragment List File Contents

`ndb_print_frag_file` obtains information from a cluster fragment list file. It is intended for use in helping to diagnose issues with data node restarts.

#### Usage

```
ndb_print_frag_file file_name
```

`file_name` is the name of a cluster fragment list file, which matches the pattern `SX.FragList`, where `X` is a digit in the range 2-9 inclusive, and are found in the data node file system of the data node having the node ID `nodeid`, in directories named `ndb_nodeid_fs/DN/DBDIH/`, where `N` is 1 or 2. Each fragment file contains records of the fragments belonging to each NDB table. For more information about cluster fragment files, see NDB Cluster Data Node File System Directory.

Like `ndb_print_backup_file`, `ndb_print_sys_file`, and `ndb_print_schema_file` (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a management server), `ndb_print_frag_file` must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

#### Additional Options

None.

#### Sample Output

```
shell> ndb_print_frag_file /usr/local/mysqld/data/ndb_3_fs/D1/DBDIH/S2.FragList
Filename: /usr/local/mysqld/data/ndb_3_fs/D1/DBDIH/S2.FragList with size 8192
noOfPages = 1 noOfWords = 182

-------- Stored Replica ----------
```
22.4.20 **ndb_print_schema_file** — Print NDB Schema File Contents

*ndb_print_schema_file* obtains diagnostic information from a cluster schema file.

**Usage**

```
ndb_print_schema_file file_name
```

*file_name* is the name of a cluster schema file. For more information about cluster schema files, see NDB Cluster Data Node File System Directory.

Like *ndb_print_backup_file* and *ndb_print_sys_file* (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a management server) *ndb_print_schema_file* must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

**Additional Options**

None.

22.4.21 **ndb_print_sys_file** — Print NDB System File Contents

*ndb_print_sys_file* obtains diagnostic information from an NDB Cluster system file.

**Usage**

```
ndb_print_sys_file file_name
```

*file_name* is the name of a cluster system file (sysfile). Cluster system files are located in a data node's data directory (`DataDir`); the path under this directory to system files matches the pattern `ndb_#_fs/D#/DBDIH/P#./sysfile`. In each case, the # represents a number (not necessarily the same number). For more information, see NDB Cluster Data Node File System Directory.

Like *ndb_print_backup_file* and *ndb_print_schema_file* (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a management server) *ndb_print_backup_file* must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

**Additional Options**

None.

22.4.22 **ndb_redo_log_reader** — Check and Print Content of Cluster Redo Log
Reads a redo log file, checking it for errors, printing its contents in a human-readable format, or both. *ndb_redo_log_reader* is intended for use primarily by NDB Cluster developers and Support personnel in debugging and diagnosing problems.

This utility remains under development, and its syntax and behavior are subject to change in future NDB Cluster releases.

The C++ source files for *ndb_redo_log_reader* can be found in the directory `/storage/ndb/src/kernel/blocks/dblqh/redoLogReader`.

The following table includes options that are specific to the NDB Cluster program *ndb_redo_log_reader*. Additional descriptions follow the table. For options common to most NDB Cluster programs (including *ndb_redo_log_reader*), see Section 22.4.32, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

<table>
<thead>

<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>-twiddle</td>
<td>Bit-shifted dump</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
</tbody>
</table>

**Usage**

```
ndb_redo_log_reader file_name [options]
```

*file_name* is the name of a cluster redo log file. redo log files are located in the numbered directories under the data node’s data directory (*DataDir*); the path under this directory to the redo log files matches
the pattern \texttt{ndb_nodeid\_fs/D\#/DBLQH/S\#.FragLog.nodeid} is the data node's node ID. The two instances of \# each represent a number (not necessarily the same number); the number following D is in the range 8-39 inclusive; the range of the number following S varies according to the value of the \texttt{NoOffFragmentLogFiles} configuration parameter, whose default value is 16; thus, the default range of the number in the file name is 0-15 inclusive. For more information, see \textit{NDB Cluster Data Node File System Directory}.

The name of the file to be read may be followed by one or more of the options listed here:

- \texttt{--dump} \\
  \begin{tabular}{|l|l|}
  \hline
  Command-Line Format & \texttt{--dump} \\
  Type & Boolean \\
  Default Value & FALSE \\
  \hline
  \end{tabular}
  
  \texttt{--dump}: Print dump info.

- \texttt{--filedescriptors} \\
  \begin{tabular}{|l|l|}
  \hline
  Command-Line Format & \texttt{--filedescriptors} \\
  Type & Boolean \\
  Default Value & FALSE \\
  \hline
  \end{tabular}
  
  \texttt{--filedescriptors}: Print file descriptors only.

- \texttt{--help} \\
  \texttt{--help}: Print usage information.

- \texttt{--lap} \\

  Default Value & FALSE \\
  \hline
  \end{tabular}
  
  \texttt{--lap}: Provide lap info, with max GCI started and completed.

- \texttt{--mbyte \#} \\
  \begin{tabular}{|l|l|l|l|}
  \hline
  Command-Line Format & \texttt{--mbyte \#} \\
  Type & Numeric \\
  Default Value & 0 \\
  Minimum Value & 0 \\
  Maximum Value & 15 \\
  \hline
  \end{tabular}
  
  \texttt{--mbyte \#}: Starting megabyte. \\
  \# is an integer in the range 0 to 15, inclusive.

- \texttt{--mbyteheaders} \\
  \begin{tabular}{|l|l|}
  \hline
  Command-Line Format & \texttt{--mbyteheaders} \\
  Type & Boolean \\
  Default Value & FALSE \\
  \hline
  \end{tabular}
  
  \texttt{--mbyteheaders}: Show only the first page header of every megabyte in the file.
ndb_redo_log_reader — Check and Print Content of Cluster Redo Log

- **noprint**: Do not print the contents of the log file.

- **nocheck**: Do not check the log file for errors.

- **page #**: Start at this page.

  # is an integer in the range 0 to 31, inclusive.

- **pageheaders**: Show page headers only.

- **pageindex #**: Start at this page index.

  # is an integer between 12 and 8191, inclusive.

- **twiddle**: Bit-shifted dump.

Like **ndb_print_backup_file** and **ndb_print_schema_file** (and unlike most of the NDB utilities that are intended to be run on a management server host or to connect to a management server) **ndb_redo_log_reader** must be run on a cluster data node, since it accesses the data node file system.
ndb_restore — Restore an NDB Cluster Backup

directly. Because it does not make use of the management server, this utility can be used when the
management server is not running, and even when the cluster has been completely shut down.

22.4.23 ndb_restore — Restore an NDB Cluster Backup

The NDB Cluster restoration program is implemented as a separate command-line utility ndb_restore,
which can normally be found in the MySQL bin directory. This program reads the files created as a result
of the backup and inserts the stored information into the database.

Note
Beginning with NDB 8.0.17, this program no longer prints
NDBT_ProgramExit: ... when it finishes its run. Applications depending on
this behavior should be modified accordingly when upgrading from NDB 8.0.16 or
earlier to a NDB 8.0 later release.

ndb_restore must be executed once for each of the backup files that were created by the START
BACKUP command used to create the backup (see Section 22.5.8.2, “Using The NDB Cluster Management
Client to Create a Backup”). This is equal to the number of data nodes in the cluster at the time that the
backup was created.

Note
Before using ndb_restore, it is recommended that the cluster be running in
single user mode, unless you are restoring multiple data nodes in parallel. See
Section 22.5.6, “NDB Cluster Single User Mode”, for more information.

The following table includes options that are specific to the NDB Cluster native backup restoration program
ndb_restore. Additional descriptions follow the table. For options common to most NDB Cluster
programs (including ndb_restore), see Section 22.4.32, “Options Common to NDB Cluster Programs —
Options Common to NDB Cluster Programs”.

Table 22.39 Command-line options for the ndb_restore program

<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--verbose=#</td>
<td>Level of verbosity in output</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
</tbody>
</table>

Typical options for this utility are shown here:
ndb_restore — Restore an NDB Cluster Backup

ndb_restore [-c connection_string] -n node_id -b backup_id \
[-m] -r --backup-path=/path/to/backup/files

Normally, when restoring from an NDB Cluster backup, ndb_restore requires at a minimum the --nodeid (short form: -n), --backupid (short form: -b), and --backup-path options.

Prior to NDB 8.0.19, when ndb_restore was used to restore any tables containing unique indexes, it was necessary to include --disable-indexes or --rebuild-indexes. Beginning with NDB 8.0.19, when automatic metadata synchronization is enabled, this is no longer necessary.

The -c option is used to specify a connection string which tells ndb_restore where to locate the cluster management server (see Section 22.3.3.3, “NDB Cluster Connection Strings”). If this option is not used, then ndb_restore attempts to connect to a management server on localhost:1186. This utility acts as a cluster API node, and so requires a free connection “slot” to connect to the cluster management server. This means that there must be at least one [api] or [mysqld] section that can be used by it in the cluster config.ini file. It is a good idea to keep at least one empty [api] or [mysqld] section in config.ini that is not being used for a MySQL server or other application for this reason (see Section 22.3.3.7, “Defining SQL and Other API Nodes in an NDB Cluster”).

In NDB 8.0.22 and later, ndb_restore can decrypt an encrypted backup using --decrypt and --backup-password. Both options must be specified to perform decryption. See the documentation for the START BACKUP management client command for information on creating encrypted backups.

You can verify that ndb_restore is connected to the cluster by using the SHOW command in the ndb_mgm management client. You can also accomplish this from a system shell, as shown here:

shell> ndb_mgm -e "SHOW"

More detailed information about all options used by ndb_restore can be found in the following list:

- **--allow-pk-changes**

| Command-Line Format | --allow-pk-changes[=0|1] |
|---------------------|--------------------------|
| Introduced          | 8.0.21-ndb-8.0.21         |
| Type                | Integer                  |
| Default Value       | 0                        |
| Minimum Value       | 0                        |
| Maximum Value       | 1                        |

When this option is set to 1, ndb_restore allows the primary keys in a table definition to differ from that of the same table in the backup. This may be desirable when backing up and restoring between different schema versions with primary key changes on one or more tables, and it appears that performing the restore operation using ndb_restore is simpler or more efficient than issuing many ALTER TABLE statements after restoring table schemas and data.

The following changes in primary key definitions are supported by **--allow-pk-changes**:

- **Extending the primary key**: A non-nullable column that exists in the table schema in the backup becomes part of the table's primary key in the database.

  **Important**
  
  When extending a table’s primary key, any columns which become part of primary key must not be updated while the backup is being taken; any such updates discovered by ndb_restore cause the restore operation to fail, even...
when no change in value takes place. In some cases, it may be possible to
override this behavior using the `--ignore-extended-pk-updates` option; see
the description of this option for more information.

- **Contracting the primary key (1):** A column that is already part of the table's primary key in the
backup schema is no longer part of the primary key, but remains in the table.

- **Contracting the primary key (2):** A column that is already part of the table's primary key in the
backup schema is removed from the table entirely.

These differences can be combined with other schema differences supported by `ndb_restore`,
including changes to blob and text columns requiring the use of staging tables.

Basic steps in a typical scenario using primary key schema changes are listed here:

1. Restore table schemas using `ndb_restore --restore-meta`
2. Alter schema to that desired, or create it
3. Back up the desired schema
4. Run `ndb_restore --disable-indexes` using the backup from the previous step, to drop indexes
   and constraints
5. Run `ndb_restore --allow-pk-changes` (possibly along with `--ignore-extended-pk-updates`,
   `--disable-indexes`, and possibly other options as needed) to restore all data
6. Run `ndb_restore --rebuild-indexes` using the backup made with the desired schema, to
   rebuild indexes and constraints

When extending the primary key, it may be necessary for `ndb_restore` to use a temporary secondary
unique index during the restore operation to map from the old primary key to the new one. Such an index
is created only when necessary to apply events from the backup log to a table which has an extended
primary key. This index is named `NDB$RESTORE_PK_MAPPING`, and is created on each table requiring
it; it can be shared, if necessary, by multiple instances of `ndb_restore` instances running in parallel.
(Running `ndb_restore --rebuild-indexes` at the end of the restore process causes this index to
be dropped.)

- **--append**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--append</th>
</tr>
</thead>
</table>

When used with the `--tab` and `--print-data` options, this causes the data to be appended to any
existing files having the same names.

- **--backup-path=dir_name**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--backup-path=dir_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Directory name</td>
</tr>
<tr>
<td>Default Value</td>
<td>./</td>
</tr>
</tbody>
</table>

The path to the backup directory is required; this is supplied to `ndb_restore` using the `--backup-path`
option, and must include the subdirectory corresponding to the ID backup of the backup to be
restored. For example, if the data node's `DataDir` is `/var/lib/mysql-cluster`, then the backup
directory is `/var/lib/mysql-cluster/BACKUP`, and the backup files for the backup with the ID 3 can
be found in /var/lib/mysql-cluster/BACKUP/BACKUP-3. The path may be absolute or relative to the directory in which the `ndb_restore` executable is located, and may be optionally prefixed with `backup-path=`.

It is possible to restore a backup to a database with a different configuration than it was created from. For example, suppose that a backup with backup ID 12, created in a cluster with two storage nodes having the node IDs 2 and 3, is to be restored to a cluster with four nodes. Then `ndb_restore` must be run twice—once for each storage node in the cluster where the backup was taken. However, `ndb_restore` cannot always restore backups made from a cluster running one version of MySQL to a cluster running a different MySQL version.

### Important

It is not possible to restore a backup made from a newer version of NDB Cluster using an older version of `ndb_restore`. You can restore a backup made from a newer version of MySQL to an older cluster, but you must use a copy of `ndb_restore` from the newer NDB Cluster version to do so.

For example, to restore a cluster backup taken from a cluster running NDB Cluster 7.5.20 to a cluster running NDB Cluster 7.4.30, you must use the `ndb_restore` that comes with the NDB Cluster 7.5.20 distribution.

For more rapid restoration, the data may be restored in parallel, provided that there is a sufficient number of cluster connections available. That is, when restoring to multiple nodes in parallel, you must have an `[api]` or `[mysqld]` section in the cluster `config.ini` file available for each concurrent `ndb_restore` process. However, the data files must always be applied before the logs.

- `--backup-password=password`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--backup-password=string</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.22-ndb-8.0.22</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

  This option specifies a password to be used when decrypting an encrypted backup with the `--decrypt` option. This must be the same password that was used to encrypt the backup.

  The password can be up to 256 characters in length, and must be enclosed by single or double quotation marks. It can contain any of the ASCII characters having character codes 32, 35, 38, 40-91, 93, 95, and 97-126; in other words, it can use any printable ASCII characters except for !, ', "", $, %, \, and ^.

- `--backupid=#, -b`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--backupid=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>none</td>
</tr>
</tbody>
</table>

  This option is used to specify the ID or sequence number of the backup, and is the same number shown by the management client in the `Backup backup_id completed` message displayed upon
ndb_restore — Restore an NDB Cluster Backup

completion of a backup. (See Section 22.5.8.2, “Using The NDB Cluster Management Client to Create a Backup”.)

Important

When restoring cluster backups, you must be sure to restore all data nodes from backups having the same backup ID. Using files from different backups results at best in restoring the cluster to an inconsistent state, and is likely to fail altogether.

In NDB 8.0.15 and later, this option is required.

- **--connect, -c**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--connect</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>localhost:1186</td>
</tr>
</tbody>
</table>

Alias for **--ndb-connectstring**.

- **--decrypt**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--decrypt</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.22-ndb-8.0.22</td>
</tr>
</tbody>
</table>

Decrypt an encrypted backup using the password supplied by the **--backup-password** option.

- **--disable-indexes**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--disable-indexes</th>
</tr>
</thead>
</table>

Disable restoration of indexes during restoration of the data from a native NDB backup. Afterwards, you can restore indexes for all tables at once with multithreaded building of indexes using **--rebuild-indexes**, which should be faster than rebuilding indexes concurrently for very large tables.

- **--dont-ignore-systab-0, -f**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--dont-ignore-systab-0</th>
</tr>
</thead>
</table>

Normally, when restoring table data and metadata, ndb_restore ignores the copy of the NDB system table that is present in the backup. **--dont-ignore-systab-0** causes the system table to be restored. This option is intended for experimental and development use only, and is not recommended in a production environment.

- **--exclude-databases=db-list**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--exclude-databases=db-list</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>Comma-delimited list of one or more databases which should not be restored.</td>
</tr>
</tbody>
</table>

This option is often used in combination with **--exclude-tables**; see that option's description for further information and examples.
ndb_restore — Restore an NDB Cluster Backup

- **--exclude-intermediate-sql-tables**
  
  **Command-Line Format**
  
  `--exclude-intermediate-sql-tables [=TRUE|FALSE]`

  **Type**
  
  Boolean

  **Default Value**
  
  TRUE

  When performing copying `ALTER TABLE` operations, `mysqld` creates intermediate tables (whose names are prefixed with `#sql-`). When `TRUE`, the `--exclude-intermediate-sql-tables` option keeps `ndb_restore` from restoring such tables that may have been left over from these operations. This option is `TRUE` by default.

- **--exclude-missing-columns**
  
  **Command-Line Format**
  
  `--exclude-missing-columns`

  It is possible to restore only selected table columns using this option, which causes `ndb_restore` to ignore any columns missing from tables being restored as compared to the versions of those tables found in the backup. This option applies to all tables being restored. If you wish to apply this option only to selected tables or databases, you can use it in combination with one or more of the `--include-*` or `--exclude-*` options described elsewhere in this section to do so, then restore data to the remaining tables using a complementary set of these options.

- **--exclude-missing-tables**
  
  **Command-Line Format**
  
  `--exclude-missing-tables`

  It is possible to restore only selected tables using this option, which causes `ndb_restore` to ignore any tables from the backup that are not found in the target database.

- **--exclude-tables=table-list**
  
  **Command-Line Format**
  
  `--exclude-tables=table-list`

  **Type**
  
  String

  **Default Value**
  
  
  List of one or more tables to exclude; each table reference must include the database name. Often used together with `--exclude-databases`.

  When `--exclude-databases` or `--exclude-tables` is used, only those databases or tables named by the option are excluded; all other databases and tables are restored by `ndb_restore`.

  This table shows several invocations of `ndb_restore` using `--exclude-*` options (other options possibly required have been omitted for clarity), and the effects these options have on restoring from an NDB Cluster backup:

  **Table 22.40** Several invocations of `ndb_restore` using `--exclude-*` options, and the effects these options have on restoring from an NDB Cluster backup.

<table>
<thead>
<tr>
<th>Option</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--exclude-databases=db1</code></td>
<td>All tables in all databases except <code>db1</code> are restored; no tables in <code>db1</code> are restored</td>
</tr>
</tbody>
</table>
ndb_restore — Restore an NDB Cluster Backup

<table>
<thead>
<tr>
<th>Option</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--exclude-databases=db1,db2</code> (or <code>--exclude-databases=db1 --exclude-databases=db2</code>)</td>
<td>All tables in all databases except <code>db1</code> and <code>db2</code> are restored; no tables in <code>db1</code> or <code>db2</code> are restored</td>
</tr>
<tr>
<td><code>--exclude-tables=db1.t1</code></td>
<td>All tables except <code>t1</code> in database <code>db1</code> are restored; all other tables in <code>db1</code> are restored; all tables in all other databases are restored</td>
</tr>
<tr>
<td><code>--exclude-tables=db1.t2,db2.t1</code> (or <code>--exclude-tables=db1.t2 --exclude-tables=db2.t1</code>)</td>
<td>All tables in database <code>db1</code> except for <code>t2</code> and all tables in database <code>db2</code> except for table <code>t1</code> are restored; no other tables in <code>db1</code> or <code>db2</code> are restored; all tables in all other databases are restored</td>
</tr>
</tbody>
</table>

You can use these two options together. For example, the following causes all tables in all databases except for databases `db1` and `db2`, and tables `t1` and `t2` in database `db3`, to be restored:

```
shell> ndb_restore [...] --exclude-databases=db1,db2 --exclude-tables=db3.t1,db3.t2
```

(Again, we have omitted other possibly necessary options in the interest of clarity and brevity from the example just shown.)

You can use `--include-*` and `--exclude-*` options together, subject to the following rules:

- The actions of all `--include-*` and `--exclude-*` options are cumulative.
- All `--include-*` and `--exclude-*` options are evaluated in the order passed to ndb_restore, from right to left.
- In the event of conflicting options, the first (rightmost) option takes precedence. In other words, the first option (going from right to left) that matches against a given database or table “wins”.

For example, the following set of options causes `ndb_restore` to restore all tables from database `db1` except `db1.t1`, while restoring no other tables from any other databases:

```
--include-databases=db1 --exclude-tables=db1.t1
```

However, reversing the order of the options just given simply causes all tables from database `db1` to be restored (including `db1.t1`, but no tables from any other database), because the `--include-databases` option, being farthest to the right, is the first match against database `db1` and thus takes precedence over any other option that matches `db1` or any tables in `db1`:

```
--exclude-tables=db1.t1 --include-databases=db1
```

- `--fields-enclosed-by=char`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--fields-enclosed-by=char</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td></td>
</tr>
</tbody>
</table>

Each column value is enclosed by the string passed to this option (regardless of data type; see the description of `--fields-optionally-enclosed-by`).
## ndb_restore — Restore an NDB Cluster Backup

### --fields-optionally-enclosed-by

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--fields-optionally-enclosed-by</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td></td>
</tr>
</tbody>
</table>

The string passed to this option is used to enclose column values containing character data (such as `CHAR`, `VARCHAR`, `BINARY`, `TEXT`, or `ENUM`).

### --fields-terminated-by=char

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--fields-terminated-by=char</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>\t (tab)</td>
</tr>
</tbody>
</table>

The string passed to this option is used to separate column values. The default value is a tab character (\t).

### --hex

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--hex</th>
</tr>
</thead>
</table>

If this option is used, all binary values are output in hexadecimal format.

### --ignore-extended-pk-updates

| Command-Line Format | --ignore-extended-pk-updates[=0|1]   |
|---------------------|-------------------------------------|
| Introduced          | 8.0.21-ndb-8.0.21                    |
| Type                | Integer                              |
| Default Value       | 0                                    |
| Minimum Value       | 0                                    |
| Maximum Value       | 1                                    |

When using `--allow-pk-changes`, columns which become part of a table's primary key must not be updated while the backup is being taken; such columns should keep the same values from the time values are inserted into them until the rows containing the values are deleted. If `ndb_restore` encounters updates to these columns when restoring a backup, the restore fails. Because some applications may set values for all columns when updating a row, even when some column values are not changed, the backup may include log events appearing to update columns which are not in fact modified. In such cases you can set `--ignore-extended-pk-updates` to 1, forcing `ndb_restore` to ignore such updates.

**Important**

When causing these updates to be ignored, the user is responsible for ensuring that there are no updates to the values of any columns that become part of the primary key.

For more information, see the description of `--allow-pk-changes`. 4206
- **--include-databases=db-list**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--include-databases=db-list</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td></td>
</tr>
</tbody>
</table>

Comma-delimited list of one or more databases to restore. Often used together with **--include-tables**; see the description of that option for further information and examples.

- **--include-stored-grants**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--include-stored-grants</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.19-ndb-8.0.19</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

In NDB 8.0.19 and later, `ndb_restore` does not by default restore shared users and grants (see Section 22.5.12, “Distributed MySQL Privileges with NDB_STORED_USER”) to the `ndb_sql_metadata` table. Specifying this option causes it to do so.

- **--include-tables=table-list**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--include-tables=table-list</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td></td>
</tr>
</tbody>
</table>

Comma-delimited list of tables to restore; each table reference must include the database name.

When **--include-databases** or **--include-tables** is used, only those databases or tables named by the option are restored; all other databases and tables are excluded by `ndb_restore`, and are not restored.

The following table shows several invocations of `ndb_restore` using **--include-*** options (other options possibly required have been omitted for clarity), and the effects these have on restoring from an NDB Cluster backup:

**Table 22.41 Several invocations of ndb_restore using --include-* options, and their effects on restoring from an NDB Cluster backup.**

<table>
<thead>
<tr>
<th>Option</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>--include-databases=db1</strong></td>
<td>Only tables in database <code>db1</code> are restored; all tables in all other databases are ignored</td>
</tr>
<tr>
<td><strong>--include-databases=db1,db2</strong> (or <strong>--include-databases=db1 --include-databases=db2</strong>)</td>
<td>Only tables in databases <code>db1</code> and <code>db2</code> are restored; all tables in all other databases are ignored</td>
</tr>
<tr>
<td><strong>--include-tables=db1.t1</strong></td>
<td>Only table <code>t1</code> in database <code>db1</code> is restored; no other tables in <code>db1</code> or in any other database are restored</td>
</tr>
</tbody>
</table>
ndb_restore — Restore an NDB Cluster Backup

<table>
<thead>
<tr>
<th>Option</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>--include-tables=db1.t2,db2.t1 (or</td>
<td>Only the table t2 in database db1 and the table</td>
</tr>
<tr>
<td>--include-tables=db1.t2 --include-</td>
<td>t1 in database db2 are restored; no other tables in db1, db2, or any</td>
</tr>
<tr>
<td>tables=db2.t1)</td>
<td>other database are restored</td>
</tr>
</tbody>
</table>

You can also use these two options together. For example, the following causes all tables in databases db1 and db2, together with the tables t1 and t2 in database db3, to be restored (and no other databases or tables):

```shell
db_restore [...]
```

(Again we have omitted other, possibly required, options in the example just shown.)

It also possible to restore only selected databases, or selected tables from a single database, without any --include-* (or --exclude-*) options, using the syntax shown here:

```
ndb_restore other_options db_name, [db_name[,...] | tbl_name[,tbl_name][,...]]
```

In other words, you can specify either of the following to be restored:

- All tables from one or more databases
- One or more tables from a single database
- --lines-terminated-by=char

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--lines-terminated-by=char</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>\n (linebreak)</td>
</tr>
</tbody>
</table>

Specifies the string used to end each line of output. The default is a linefeed character (\n).

- --lossy-conversions, -L

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--lossy-conversions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE (If option is not used)</td>
</tr>
</tbody>
</table>

This option is intended to complement the --promote-attributes option. Using --lossy-conversions allows lossy conversions of column values (type demotions or changes in sign) when restoring data from backup. With some exceptions, the rules governing demotion are the same as for MySQL replication; see Replication of Columns Having Different Data Types, for information about specific type conversions currently supported by attribute demotion.

ndb_restore reports any truncation of data that it performs during lossy conversions once per attribute and column.

- --no-binlog

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--no-binlog</th>
</tr>
</thead>
</table>

This option prevents any connected SQL nodes from writing data restored by ndb_restore to their binary logs.
**ndb_restore** — Restore an NDB Cluster Backup

### Options

- **--no-restore-disk-objects, -d**
  
  **Command-Line Format**
  
  `--no-restore-disk-objects`

  **Type**
  
  Boolean

  **Default Value**
  
  FALSE

  This option stops `ndb_restore` from restoring any NDB Cluster Disk Data objects, such as tablespaces and log file groups; see Section 22.5.10, "NDB Cluster Disk Data Tables", for more information about these.

- **--no-upgrade, -u**

  **Command-Line Format**
  
  `--no-upgrade`

  When using `ndb_restore` to restore a backup, VARCHAR columns created using the old fixed format are resized and recreated using the variable-width format now employed. This behavior can be overridden by specifying `--no-upgrade`.

- **--ndb-nodegroup-map=map, -z**

  **Command-Line Format**
  
  `--ndb-nodegroup-map=map`

  This option can be used to restore a backup taken from one node group to a different node group. Its argument is a list of the form `source_node_group, target_node_group`.

- **--nodeid=#, -n**

  **Command-Line Format**
  
  `--nodeid=#`

  **Type**
  
  Numeric

  **Default Value**
  
  none

  Specify the node ID of the data node on which the backup was taken.

  When restoring to a cluster with different number of data nodes from that where the backup was taken, this information helps identify the correct set or sets of files to be restored to a given node. (In such cases, multiple files usually need to be restored to a single data node.) See Section 22.4.23.1, "Restoring to a different number of data nodes", for additional information and examples.

  In NDB 8.0.15 and later, this option is required.

- **--num-slices=#**

  **Command-Line Format**
  
  `--num-slices=#`

  **Introduced**
  
  8.0.20-ndb-8.0.20

  **Type**
  
  Integer

  **Default Value**
  
  1

  **Minimum Value**
  
  1

  **Maximum Value**
  
  1024

  When restoring a backup by slices, this option sets the number of slices into which to divide the backup. This allows multiple instances of `ndb_restore` to restore disjoint subsets in parallel, potentially reducing the amount of time required to perform the restore operation.
A slice is a subset of the data in a given backup; that is, it is a set of fragments having the same slice ID, specified using the \(--\)slice-id\(\) option. The two options must always be used together, and the value set by \(--\)slice-id\(\) must always be less than the number of slices.

\texttt{ndb_restore} encounters fragments and assigns each one a fragment counter. When restoring by slices, a slice ID is assigned to each fragment; this slice ID is in the range 0 to 1 less than the number of slices. For a table that is not a BLOB table, the slice to which a given fragment belongs is determined using the formula shown here:

\[
[slice\_ID] = [fragment\_counter] \% [number\_of\_slices]
\]

For a BLOB table, a fragment counter is not used; the fragment number is used instead, along with the ID of the main table for the BLOB table (recall that NDB stores BLOB values in a separate table internally). In this case, the slice ID for a given fragment is calculated as shown here:

\[
[slice\_ID] = ([main\_table\_ID] + [fragment\_ID]) \% [number\_of\_slices]
\]

Thus, restoring by \(N\) slices means running \(N\) instances of \texttt{ndb_restore}, all with \(--\)num-slices=\(N\) (along with any other necessary options) and one each with \(--\)slice-id=1, \(--\)slice-id=2, \(--\)slice-id=3, and so on through \(--\)slice-id=\(N-1\).

**Example.** Assume that you want to restore a backup named \(\text{BACKUP-1}\), found in the default directory \(/var/lib/mysql-cluster/BACKUP/BACKUP-3\) on the node file system on each data node, to a cluster with four data nodes having the node IDs 1, 2, 3, and 4. To perform this operation using five slices, execute the sets of commands shown in the following list:

1. Restore the cluster metadata using \texttt{ndb_restore} as shown here:

   \begin{verbatim}
   shell> ndb_restore -b 1 -n 1 -m --disable-indexes --backup-path=/home/ndbuser/backups
   \end{verbatim}

2. Restore the cluster data to the data nodes invoking \texttt{ndb_restore} as shown here:

   \begin{verbatim}
   shell> ndb_restore -b 1 -n 1 -r --num-slices=5 --slice-id=0 --backup-path=/var/lib/mysql-cluster/BACKUP/BACKUP-1
   shell> ndb_restore -b 1 -n 1 -r --num-slices=5 --slice-id=1 --backup-path=/var/lib/mysql-cluster/BACKUP/BACKUP-1
   shell> ndb_restore -b 1 -n 1 -r --num-slices=5 --slice-id=2 --backup-path=/var/lib/mysql-cluster/BACKUP/BACKUP-1
   shell> ndb_restore -b 1 -n 1 -r --num-slices=5 --slice-id=3 --backup-path=/var/lib/mysql-cluster/BACKUP/BACKUP-1
   shell> ndb_restore -b 1 -n 1 -r --num-slices=5 --slice-id=4 --backup-path=/var/lib/mysql-cluster/BACKUP/BACKUP-1
   \end{verbatim}

   All of the commands just shown in this step can be executed in parallel, provided there are enough slots for connections to the cluster (see the description for the \(--\)backup-path\(\) option).
3. Restore indexes as usual, as shown here:

```bash
shell> ndb_restore -b 1 -n 1 --rebuild-indexes --backup-path=/var/lib/mysql-cluster/BACKUP/BACKUP-1
```

4. Finally, restore the epoch, using the command shown here:

```bash
shell> ndb_restore -b 1 -n 1 --restore-epoch --backup-path=/var/lib/mysql-cluster/BACKUP/BACKUP-1
```

You should use slicing to restore the cluster data only; it is not necessary to employ `--num-slices` or `--slice-id` when restoring the metadata, indexes, or epoch information. If either or both of these options are used with the `ndb_restore` options controlling restoration of these, the program ignores them.

The effects of using the `--parallelism` option on the speed of restoration are independent of those produced by slicing or parallel restoration using multiple instances of `ndb_restore` (`--parallelism` specifies the number of parallel transactions executed by a single `ndb_restore` thread), but it can be used together with either or both of these. You should be aware that increasing `--parallelism` causes `ndb_restore` to impose a greater load on the cluster; if the system can handle this, restoration should complete even more quickly.

The value of `--num-slices` is not directly dependent on values relating to hardware such as number of CPUs or CPU cores, amount of RAM, and so forth, nor does it depend on the number of LDMs.

It is possible to employ different values for this option on different data nodes as part of the same restoration; doing so should not in and of itself produce any ill effects.

- `--parallelism=#, -p`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--parallelism=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>128</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1024</td>
</tr>
</tbody>
</table>

`ndb_restore` uses single-row transactions to apply many rows concurrently. This parameter determines the number of parallel transactions (concurrent rows) that an instance of `ndb_restore` tries to use. By default, this is 128; the minimum is 1, and the maximum is 1024.

The work of performing the inserts is parallelized across the threads in the data nodes involved. This mechanism is employed for restoring bulk data from the `.Data` file—that is, the fuzzy snapshot of the data; it is not used for building or rebuilding indexes. The change log is applied serially; index drops and builds are DDL operations and handled separately. There is no thread-level parallelism on the client side of the restore.

- `--preserve-trailing-spaces, -P`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--preserve-trailing-spaces</code></th>
</tr>
</thead>
</table>

Cause trailing spaces to be preserved when promoting a fixed-width character data type to its variable-width equivalent—that is, when promoting a `CHAR` column value to `VARCHAR`, or a `BINARY` column value.
ndb_restore — Restore an NDB Cluster Backup

to VARBINARY. Otherwise, any trailing spaces are dropped from such column values when they are inserted into the new columns.

Note
Although you can promote CHAR columns to VARCHAR and BINARY columns to VARBINARY, you cannot promote VARCHAR columns to CHAR or VARBINARY columns to BINARY.

• --print

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--print</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Causes ndb_restore to print all data, metadata, and logs to stdout. Equivalent to using the --print-data, --print-meta, and --print-log options together.

Note
Use of --print or any of the --print_* options is in effect performing a dry run. Including one or more of these options causes any output to be redirected to stdout; in such cases, ndb_restore makes no attempt to restore data or metadata to an NDB Cluster.

• --print-data

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--print-data</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Cause ndb_restore to direct its output to stdout. Often used together with one or more of --tab, --fields-enclosed-by, --fields-optionally-enclosed-by, --fields-terminated-by, --hex, and --append.

TEXT and BLOB column values are always truncated. Such values are truncated to the first 256 bytes in the output. This cannot currently be overridden when using --print-data.

• --print-log

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--print-log</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Cause ndb_restore to output its log to stdout.

• --print-meta

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--print-meta</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Print all metadata to stdout.
nbd_restore — Restore an NDB Cluster Backup

- **print-sql-log**
  
  **Command-Line Format**: `--print-sql-log`
  
  **Type**: Boolean
  
  **Default Value**: FALSE
  
  Log SQL statements to stdout. Use the option to enable; normally this behavior is disabled. The option checks before attempting to log whether all the tables being restored have explicitly defined primary keys; queries on a table having only the hidden primary key implemented by NDB cannot be converted to valid SQL.

  This option does not work with tables having BLOB columns.

- **--progress-frequency=N**
  
  **Command-Line Format**: `--progress-frequency=#`
  
  **Type**: Numeric
  
  **Default Value**: 0
  
  **Minimum Value**: 0
  
  **Maximum Value**: 65535
  
  Print a status report each $N$ seconds while the backup is in progress. 0 (the default) causes no status reports to be printed. The maximum is 65535.

- **--promote-attributes, -A**
  
  nbd_restore supports limited attribute promotion in much the same way that it is supported by MySQL replication; that is, data backed up from a column of a given type can generally be restored to a column using a “larger, similar” type. For example, data from a `CHAR(20)` column can be restored to a column declared as `VARCHAR(20)`, `VARCHAR(30)`, or `CHAR(30)`; data from a `MEDIUMINT` column can be restored to a column of type `INT` or `BIGINT`. See Replication of Columns Having Different Data Types, for a table of type conversions currently supported by attribute promotion.

  Attribute promotion by nbd_restore must be enabled explicitly, as follows:

  1. Prepare the table to which the backup is to be restored. nbd_restore cannot be used to re-create the table with a different definition from the original; this means that you must either create the table manually, or alter the columns which you wish to promote using `ALTER TABLE` after restoring the table metadata but before restoring the data.

  2. Invoke nbd_restore with the `--promote-attributes` option (short form `-A`) when restoring the table data. Attribute promotion does not occur if this option is not used; instead, the restore operation fails with an error.

  When converting between character data types and TEXT or BLOB, only conversions between character types (`CHAR` and `VARCHAR`) and binary types (`BINARY` and `VARBINARY`) can be performed at the same time. For example, you cannot promote an INT column to BIGINT while promoting a VARCHAR column to TEXT in the same invocation of nbd_restore.

  Converting between TEXT columns using different character sets is not supported, and is expressly disallowed.
When performing conversions of character or binary types to TEXT or BLOB with ndb_restore, you may notice that it creates and uses one or more staging tables named `table_name$STnode_id`. These tables are not needed afterwards, and are normally deleted by ndb_restore following a successful restoration.

- **--rebuild-indexes**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--rebuild-indexes</th>
</tr>
</thead>
</table>

Enable multithreaded rebuilding of the ordered indexes while restoring a native NDB backup. The number of threads used for building ordered indexes by ndb_restore with this option is controlled by the BuildIndexThreads data node configuration parameter and the number of LDMs.

It is necessary to use this option only for the first run of ndb_restore; this causes all ordered indexes to be rebuilt without using --rebuild-indexes again when restoring subsequent nodes. You should use this option prior to inserting new rows into the database; otherwise, it is possible for a row to be inserted that later causes a unique constraint violation when trying to rebuild the indexes.

Building of ordered indices is parallelized with the number of LDMs by default. Offline index builds performed during node and system restarts can be made faster using the BuildIndexThreads data node configuration parameter; this parameter has no effect on dropping and rebuilding of indexes by ndb_restore, which is performed online.

Rebuilding of unique indexes uses disk write bandwidth for redo logging and local checkpointing. An insufficient amount of this bandwidth can lead to redo buffer overload or log overload errors. In such cases you can run ndb_restore --rebuild-indexes again; the process resumes at the point where the error occurred. You can also do this when you have encountered temporary errors. You can repeat execution of ndb_restore --rebuild-indexes indefinitely; you may be able to stop such errors by reducing the value of --parallelism. If the problem is insufficient space, you can increase the size of the redo log (FragmentLogFileSize node configuration parameter), or you can increase the speed at which LCPs are performed (MaxDiskWriteSpeed and related parameters), in order to free space more quickly.

- **--remap-column=db.tbl.col:fn:args**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--remap-column=[db].[tbl].[col]:[fn]:[args]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.21-ndb-8.0.21</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>
When used together with `--restore-data`, this option applies a function to the value of the indicated column. Values in the argument string are listed here:

- **db**: Database name, following any renames performed by `--rewrite-database`.
- **tbl**: Table name.
- **col**: Name of the column to be updated. This column must be of type INT or BIGINT. The column can also be but is not required to be UNSIGNED.
- **fn**: Function name; currently, the only supported name is `offset`.
- **args**: Arguments supplied to the function. Currently, only a single argument, the size of the offset to be added by the `offset` function, is supported. Negative values are supported. The size of the argument cannot exceed that of the signed variant of the column's type; for example, if `col` is an INT column, then the allowed range of the argument passed to the `offset` function is $[-2^{31}, 2^{31}]$ (see Section 11.1.2, “Integer Types (Exact Value) - INTEGER, INT, SMALLINT, TINYINT, MEDIUMINT, BIGINT”).

If applying the offset value to the column would cause an overflow or underflow, the restore operation fails. This could happen, for example, if the column is a BIGINT, and the option attempts to apply an offset value of 8 on a row in which the column value is 4294967291, since $4294967291 + 8 > 4294967295$.

This option can be useful when you wish to merge data stored in multiple source instances of NDB Cluster (all using the same schema) into a single destination NDB Cluster, using NDB native backup (see Section 22.5.8.2, “Using The NDB Cluster Management Client to Create a Backup”) and `ndb_restore` to merge the data, where primary and unique key values are overlapping between source clusters, and it is necessary as part of the process to remap these values to ranges that do not overlap. It may also be necessary to preserve other relationships between tables. To fulfill such requirements, it is possible to use the option multiple times in the same invocation of `ndb_restore` to remap columns of different tables, as shown here:

```
shell> ndb_restore --restore-data --remap-column=hr.employee.id:offset:1000 \ 
                  --remap-column=hr.manager.id:offset:1000 \ 
                  --remap-column=hr.firstaiders.id:offset:1000
```

(Other options not shown here may also be used.)

`--remap-column` can also be used to update multiple columns of the same table. Combinations of multiple tables and columns are possible. Different offset values can also be used for different columns of the same table, like this:

```
shell> ndb_restore --restore-data --remap-column=hr.employee.salary:offset:10000 \ 
                  --remap-column=hr.employee.hours:offset:-10
```

When source backups contain duplicate tables which should not be merged, you can handle this by using `--exclude-tables`, `--exclude-databases`, or by some other means in your application.

Information about the structure and other characteristics of tables to be merged can obtained using `SHOW CREATE TABLE`; the `ndb_desc` tool; and `MAX()`, `MIN()`, `LAST_INSERT_ID()`, and other MySQL functions.

Replication of changes from merged to unmerged tables, or from unmerged to merged tables, in separate instances of NDB Cluster is not supported.
ndb_restore — Restore an NDB Cluster Backup

- **--restore-data, -r**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--restore-data</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Output **NDB** table data and logs.

- **--restore-epoch, -e**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--restore-epoch</th>
</tr>
</thead>
</table>

Add (or restore) epoch information to the cluster replication status table. This is useful for starting replication on an NDB Cluster replica. When this option is used, the row in the `mysql.ndb_apply_status` having 0 in the `id` column is updated if it already exists; such a row is inserted if it does not already exist. (See Section 22.6.9, “NDB Cluster Backups With NDB Cluster Replication”.)

- **--restore-meta, -m**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--restore-meta</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

This option causes **ndb_restore** to print **NDB** table metadata.

The first time you run the **ndb_restore** restoration program, you also need to restore the metadata. In other words, you must re-create the database tables—this can be done by running it with the **--restore-meta (-m)** option. Restoring the metadata need be done only on a single data node; this is sufficient to restore it to the entire cluster.

In older versions of NDB Cluster, tables whose schemas were restored using this option used the same number of partitions as they did on the original cluster, even if it had a differing number of data nodes from the new cluster. In NDB 8.0, when restoring metadata, this is no longer an issue; **ndb_restore** now uses the default number of partitions for the target cluster, unless the number of local data manager threads is also changed from what it was for data nodes in the original cluster.

When using this option in NDB 8.0.16 or later, it is recommended that auto synchronization be disabled by setting `ndb_metadata_check=OFF` until **ndb_restore** has completed restoring the metadata, after which it can it turned on again to synchronize objects newly created in the NDB dictionary.

---

**Note**

The cluster should have an empty database when starting to restore a backup. (In other words, you should start the data nodes with **--initial** prior to performing the restore.)

- **--restore-privilege-tables**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--restore-privilege-tables</th>
</tr>
</thead>
<tbody>
<tr>
<td>Deprecated</td>
<td>8.0.16-ndb-8.0.16</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
</tbody>
</table>
**ndb_restore** — Restore an NDB Cluster Backup

<table>
<thead>
<tr>
<th>Default Value</th>
<th>FALSE (If option is not used)</th>
</tr>
</thead>
</table>

**ndb_restore** does not by default restore distributed MySQL privilege tables created in releases of NDB Cluster prior to version 8.0, which does not support distributed privileges as implemented in NDB 7.6 and earlier. This option causes **ndb_restore** to restore them.

In NDB 8.0.16 and later, such tables are not used for access control; as part of the MySQL server's upgrade process, the server creates **InnoDB** copies of these tables local to itself. For more information, see Section 22.2.7, "Upgrading and Downgrading NDB Cluster", as well as Section 6.2.3, "Grant Tables".

**--rewrite-database=olddb,newdb**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--rewrite-database=olddb,newdb</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>none</td>
</tr>
</tbody>
</table>

This option makes it possible to restore to a database having a different name from that used in the backup. For example, if a backup is made of a database named products, you can restore the data it contains to a database named inventory, use this option as shown here (omitting any other options that might be required):

shell> ndb_restore --rewrite-database=product,inventory

The option can be employed multiple times in a single invocation of **ndb_restore**. Thus it is possible to restore simultaneously from a database named db1 to a database named db2 and from a database named db3 to one named db4 using --rewrite-database=db1,db2 --rewrite-database=db3,db4. Other **ndb_restore** options may be used between multiple occurrences of --rewrite-database.

In the event of conflicts between multiple --rewrite-database options, the last --rewrite-database option used, reading from left to right, is the one that takes effect. For example, if --rewrite-database=db1,db2 --rewrite-database=db1,db3 is used, only --rewrite-database=db1,db3 is honored, and --rewrite-database=db1,db2 is ignored. It is also possible to restore from multiple databases to a single database, so that --rewrite-database=db1,db3 --rewrite-database=db2,db3 restores all tables and data from databases db1 and db2 into database db3.

**Important**

When restoring from multiple backup databases into a single target database using --rewrite-database, no check is made for collisions between table or other object names, and the order in which rows are restored is not guaranteed. This means that it is possible in such cases for rows to be overwritten and updates to be lost.

**--skip-broken-objects**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--skip-broken-objects</th>
</tr>
</thead>
</table>

This option causes **ndb_restore** to ignore corrupt tables while reading a native NDB backup, and to continue restoring any remaining tables (that are not also corrupted). Currently, the --skip-broken-objects option works only in the case of missing blob parts tables.

**--skip-table-check, -s**
It is possible to restore data without restoring table metadata. By default when doing this, `ndb_restore` fails with an error if a mismatch is found between the table data and the table schema; this option overrides that behavior.

Some of the restrictions on mismatches in column definitions when restoring data using `ndb_restore` are relaxed; when one of these types of mismatches is encountered, `ndb_restore` does not stop with an error as it did previously, but rather accepts the data and inserts it into the target table while issuing a warning to the user that this is being done. This behavior occurs whether or not either of the options `--skip-table-check` or `--promote-attributes` is in use. These differences in column definitions are of the following types:

- Different `COLUMN_FORMAT` settings (`FIXED`, `DYNAMIC`, `DEFAULT`)
- Different `STORAGE` settings (`MEMORY`, `DISK`)
- Different default values
- Different distribution key settings
- `--skip-unknown-objects`

This option causes `ndb_restore` to ignore any schema objects it does not recognize while reading a native NDB backup. This can be used for restoring a backup made from a cluster running (for example) NDB 7.6 to a cluster running NDB Cluster 7.5.

- `--slice-id=#`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--slice-id=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.20-ndb-8.0.20</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1023</td>
</tr>
</tbody>
</table>

When restoring by slices, this is the ID of the slice to restore. This option is always used together with `--num-slices`, and its value must be always less than that of `--num-slices`.

For more information, see the description of the `--num-slices` elsewhere in this section.

- `--tab=dir_name, -T dir_name`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--tab=dir_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Directory name</td>
</tr>
</tbody>
</table>

Causes `--print-data` to create dump files, one per table, each named `tbl_name.txt`. It requires as its argument the path to the directory where the files should be saved; use . for the current directory.
ndb_restore — Restore an NDB Cluster Backup

- --verbose=

| Command-Line Format | --verbose=
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>255</td>
</tr>
</tbody>
</table>

Sets the level for the verbosity of the output. The minimum is 0; the maximum is 255. The default value is 1.

**Error reporting.**

ndb_restore reports both temporary and permanent errors. In the case of temporary errors, it may able to recover from them, and reports *Restore successful, but encountered temporary error, please look at configuration* in such cases.

---

**Important**

After using ndb_restore to initialize an NDB Cluster for use in circular replication, binary logs on the SQL node acting as the replica are not automatically created, and you must cause them to be created manually. To cause the binary logs to be created, issue a *SHOW TABLES* statement on that SQL node before running *START SLAVE*. This is a known issue in NDB Cluster.

**Restoring a backup to a previous version of NDB Cluster.** You may encounter issues when restoring a backup taken from a later version of NDB Cluster to a previous one, due to the use of features which do not exist in the earlier version. For example, tables created in NDB 8.0 by default use the *utf8mb4_ai_ci* character set, which is not available in NDB 7.6 and earlier, and so cannot be read by an ndb_restore binary from one of these earlier versions.

### 22.4.23.1 Restoring to a different number of data nodes

It is possible to restore from an NDB backup to a cluster having a different number of data nodes than the original from which the backup was taken. The following two sections discuss, respectively, the cases where the target cluster has a lesser or greater number of data nodes than the source of the backup.

**Restoring to Fewer Nodes Than the Original**

You can restore to a cluster having fewer data nodes than the original provided that the larger number of nodes is an even multiple of the smaller number. In the following example, we use a backup taken on a cluster having four data nodes to a cluster having two data nodes.

1. The management server for the original cluster is on host host10. The original cluster has four data nodes, with the node IDs and host names shown in the following extract from the management server’s config.ini file:

```
[ndbd]
NodeId=2
HostName=host2

[ndbd]
NodeId=4
HostName=host4

[ndbd]
```
2. Perform a backup in the normal manner. See Section 22.5.8.2, "Using The NDB Cluster Management Client to Create a Backup", for information about how to do this.

3. The files created by the backup on each data node are listed here, where \( N \) is the node ID and \( B \) is the backup ID.

- BACKUP-\( B \)-0.\( N \).Data
- BACKUP-\( B \).\( N \).ctl
- BACKUP-\( B \).\( N \).log

These files are found under BackupDataDir/BACKUP/BACKUP-\( B \), on each data node. For the rest of this example, we assume that the backup ID is 1.

Have all of these files available for later copying to the new data nodes (where they can be accessed on the data node's local file system by \texttt{ndb_restore}). It is simplest to copy them all to a single location; we assume that this is what you have done.

4. The management server for the target cluster is on host \texttt{host20}, and the target has two data nodes, with the node IDs and host names shown, from the management server \texttt{config.ini} file on \texttt{host20}:

- [ndbd] NodeId=3 hostname=host3
- [ndbd] NodeId=5 hostname=host5

Each of the data node processes on \texttt{host3} and \texttt{host5} should be started with \texttt{ndbmtd -c host20 -- initial} or the equivalent, so that the new (target) cluster starts with clean data node file systems.

5. Copy two different sets of two backup files to each of the target data nodes. For this example, copy the backup files from nodes 2 and 4 from the original cluster to node 3 in the target cluster. These files are listed here:

- BACKUP-1-0.2.Data
- BACKUP-1.2.ctl
- BACKUP-1.2.log
- BACKUP-1-0.6.Data
- BACKUP-1.6.ctl
- BACKUP-1.6.log

Then copy the backup files from nodes 6 and 8 to node 5; these files are shown in the following list:
ndb_restore — Restore an NDB Cluster Backup

- BACKUP-1-0.4.Data
- BACKUP-1.4.ctl
- BACKUP-1.4.log
- BACKUP-1-0.8.Data
- BACKUP-1.8.ctl
- BACKUP-1.8.log

For the remainder of this example, we assume that the respective backup files have been saved to the directory /BACKUP-1 on each of nodes 3 and 5.

6. On each of the two target data nodes, you must restore from both sets of backups. First, restore the backups from nodes 2 and 4 to node 3 by invoking `ndb_restore` on `host3` as shown here:

```shell
shell> ndb_restore -c host20 --nodeid=2  --backupid=1  --restore-data  --backup-path=/BACKUP-1
shell> ndb_restore -c host20 --nodeid=4 --backupid=1 --restore-data --backup-path=/BACKUP-1
```

Then restore the backups from nodes 6 and 8 to node 5 by invoking `ndb_restore` on `host5`, like this:

```shell
shell> ndb_restore -c host20 --nodeid=6 --backupid=1 --restore-data --backup-path=/BACKUP-1
shell> ndb_restore -c host20 --nodeid=8 --backupid=1 --restore-data --backup-path=/BACKUP-1
```

Restoring to More Nodes Than The Original

The node ID specified for a given `ndb_restore` command is that of the node in the original backup and not that of the data node to restore it to. When performing a backup using the method described in this section, `ndb_restore` connects to the management server and obtains a list of data nodes in the cluster the backup is being restored to. The restored data is distributed accordingly, so that the number of nodes in the target cluster does not need to be to be known or calculated when performing the backup.

**Note**

When changing the total number of LCP threads or LQH threads per node group, you should recreate the schema from backup created using `mysqldump`.

1. **Create the backup of the data.** You can do this by invoking the `ndb_mgm` client `START BACKUP` command from the system shell, like this:

```shell
shell> ndb_mgm -e "START BACKUP 1"
```

This assumes that the desired backup ID is 1.

2. Create a backup of the schema. This step is necessary only if the total number of LCP threads or LQH threads per node group is changed.

```shell
shell> mysqldump --no-data --routines --events --triggers --databases > myschema.sql
```

**Important**

Once you have created the NDB native backup using `ndb_mgm`, you must not make any schema changes before creating the backup of the schema, if you do so.
3. Copy the backup directory to the new cluster. For example if the backup you want to restore has ID 1 and `BackupDataDir = /backups/node_nodeid`, then the path to the backup on this node is `/backups/node_1/BACKUP/BACKUP-1`. Inside this directory there are three files, listed here:

- `BACKUP-1-0.1.Data`
- `BACKUP-1.1.ctl`
- `BACKUP-1.1.log`

You should copy the entire directory to the new node.

If you needed to create a schema file, copy this to a location on an SQL node where it can be read by `mysqld`.

There is no requirement for the backup to be restored from a specific node or nodes.

To restore from the backup just created, perform the following steps:

1. **Restore the schema.**
   - If you created a separate schema backup file using `mysqldump`, import this file using the `mysql` client, similar to what is shown here:
     ```shell
     shell> mysql < myschema.sql
     ```
     When importing the schema file, you may need to specify the `--user` and `--password` options (and possibly others) in addition to what is shown, in order for the `mysql` client to be able to connect to the MySQL server.
   - If you did not need to create a schema file, you can re-create the schema using `ndb_restore --restore-meta` (short form `-m`), similar to what is shown here:
     ```shell
     shell> ndb_restore --nodeid=1 --backupid=1 --restore-meta --backup-path=/backups/node_1/BACKUP/BACKUP-1
     ```

     `ndb_restore` must be able to contact the management server; add the `--ndb-connectstring` option if and as needed to make this possible.

2. **Restore the data.** This needs to be done once for each data node in the original cluster, each time using that data node's node ID. Assuming that there were 4 data nodes originally, the set of commands required would look something like this:

   ```
   ndb_restore --nodeid=1 --backupid=1 --restore-data --backup-path=/backups/node_1/BACKUP/BACKUP-1 --disable-indexes
   ndb_restore --nodeid=2 --backupid=1 --restore-data --backup-path=/backups/node_2/BACKUP/BACKUP-1 --disable-indexes
   ndb_restore --nodeid=3 --backupid=1 --restore-data --backup-path=/backups/node_3/BACKUP/BACKUP-1 --disable-indexes
   ndb_restore --nodeid=4 --backupid=1 --restore-data --backup-path=/backups/node_4/BACKUP/BACKUP-1 --disable-indexes
   ```

   These can be run in parallel.

   Be sure to add the `--ndb-connectstring` option as needed.

3. **Rebuild the indexes.** These were disabled by the `--disable-indexes` option used in the commands just shown. Recreating the indexes avoids errors due to the restore not being consistent at all points. Rebuilding the indexes can also improve performance in some cases. To rebuild the indexes, execute the following command once, on a single node:

   ```shell
   shell> ndb_restore --nodeid=1 --backupid=1 --backup-path=/backups/node_1/BACKUP/BACKUP-1 --rebuild-indexes
   ```
As mentioned previously, you may need to add the --ndb-connectstring option, so that ndb_restore can contact the management server.

22.4.23.2 Restoring from a backup taken in parallel

Beginning with NDB Cluster 8.0.16, it is possible to take parallel backups on each data node using ndbmtld with multiple LDMs (see Section 22.5.8.5, "Taking an NDB Backup with Parallel Data Nodes"). The next two sections describe how to restore backups that were taken in this fashion.

Restoring a parallel backup in parallel

Restoring a parallel backup in parallel requires an ndb_restore binary from an NDB Cluster distribution version 8.0.16 or later. The process is not substantially different from that outlined in the general usage section under the description of the ndb_restore program, and consists of executing ndb_restore twice, similarly to what is shown here:

```
shell> ndb_restore -n 1 -b 1 -m --backup-path=path/to/backup_dir/BACKUP/BACKUP-backup_id
shell> ndb_restore -n 1 -b 1 -r --backup-path=path/to/backup_dir/BACKUP/BACKUP-backup_id
```

backup_id is the ID of the backup to be restored. In the general case, no additional special arguments are required; ndb_restore always checks for the existence of parallel subdirectories under the directory indicated by the --backup-path option and restores the metadata (serially) and then the table data (in parallel).

Restoring a parallel backup serially

It is possible to restore a backup that was made using parallelism on the data nodes in serial fashion. To do this, invoke ndb_restore with --backup-path pointing to the subdirectories created by each LDM under the main backup directory, once to any one of the subdirectories to restore the metadata (it does not matter which one, since each subdirectory contains a complete copy of the metadata), then to each of the subdirectories in turn to restore the data. Suppose that we want to restore the backup having backup ID 100 that was taken with four LDMs, and that the BackupDataDir is /opt. To restore the metadata in this case, we can invoke ndb_restore like this:

```
shell> ndb_restore -n 1 -b 1 -m --backup-path=/opt/BACKUP/BACKUP-100/BACKUP-100-PART-1-OF-4
```

To restore the table data, execute ndb_restore four times, each time using one of the subdirectories in turn, as shown here:

```
shell> ndb_restore -n 1 -b 1 -r --backup-path=/opt/BACKUP/BACKUP-100/BACKUP-100-PART-1-OF-4
shell> ndb_restore -n 1 -b 1 -r --backup-path=/opt/BACKUP/BACKUP-100/BACKUP-100-PART-2-OF-4
shell> ndb_restore -n 1 -b 1 -r --backup-path=/opt/BACKUP/BACKUP-100/BACKUP-100-PART-3-OF-4
shell> ndb_restore -n 1 -b 1 -r --backup-path=/opt/BACKUP/BACKUP-100/BACKUP-100-PART-4-OF-4
```

You can employ the same technique to restore a parallel backup to an older version of NDB Cluster (prior to NDB 8.0.16) that does not support parallel backups, using the ndb_restore binary supplied with the older version of the NDB Cluster software.

22.4.24 ndb_select_all — Print Rows from an NDB Table

ndb_select_all prints all rows from an NDB table to stdout.

Usage

```
ndb_select_all -c connection_string tbl_name -d db_name [>] file_name
```

The following table includes options that are specific to the NDB Cluster native backup restoration program ndb_select_all. Additional descriptions follow the table. For options common to most NDB
ndb_select_all — Print Rows from an NDB Table

Cluster programs (including ndb_select_all), see Section 22.4.32, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

<td>Include GCI and row epoch in output</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--tupscan,</td>
<td>Scan in tup order</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>-t</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--nodata</td>
<td>Do not print table column data</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
</tbody>
</table>

- **--database=dbname, -d dbname**
  
  Name of the database in which the table is found. The default value is **TEST_DB**.

- **parallelism=#, -p #**
ndb_select_all — Print Rows from an NDB Table

Specifies the degree of parallelism.

- **--lock=lock_type, -l lock_type**
  Employs a lock when reading the table. Possible values for `lock_type` are:
  - 0: Read lock
  - 1: Read lock with hold
  - 2: Exclusive read lock
  There is no default value for this option.

- **--order=index_name, -o index_name**
  Orders the output according to the index named `index_name`.
  
  **Note**
  This is the name of an index, not of a column; the index must have been explicitly named when created.

- **--descending, -z**
  Sorts the output in descending order. This option can be used only in conjunction with the `-o (--order)` option.

- **--header=FALSE**
  Excludes column headers from the output.

- **--useHexFormat -x**
  Causes all numeric values to be displayed in hexadecimal format. This does not affect the output of numerals contained in strings or datetime values.

- **--delimiter=character, -D character**
  Causes the `character` to be used as a column delimiter. Only table data columns are separated by this delimiter.
  
  The default delimiter is the tab character.

- **--disk**
  Adds a disk reference column to the output. The column is nonempty only for Disk Data tables having nonindexed columns.

- **--rowid**
  Adds a ROWID column providing information about the fragments in which rows are stored.

- **--gci**
  Adds a GCI column to the output showing the global checkpoint at which each row was last updated. See Section 22.1, “NDB Cluster Overview”, and Section 22.5.3.2, “NDB Cluster Log Events”, for more information about checkpoints.
• --gci64

Adds a ROW$GCI64 column to the output showing the global checkpoint at which each row was last updated, as well as the number of the epoch in which this update occurred.

• --tupscan, -t

Scan the table in the order of the tuples.

• --nodata

Causes any table data to be omitted.

Sample Output

Output from a MySQL SELECT statement:

```
mysql> SELECT * FROM ctest1.fish;
+----+-----------+
| id | name      |
+----+-----------+
|  3 | shark     |
|  6 | puffer    |
|  2 | tuna      |
|  4 | manta ray |
|  5 | grouper   |
|  1 | guppy     |
+----+-----------+
6 rows in set (0.04 sec)
```

Output from the equivalent invocation of ndb_select_all:

```
shell> ./ndb_select_all -c localhost fish -d ctest1
id      name
3       [shark]
6       [puffer]
2       [tuna]
4       [manta ray]
5       [grouper]
1       [guppy]
6 rows returned
```

All string values are enclosed by square brackets ([...]) in the output of ndb_select_all. For another example, consider the table created and populated as shown here:

```
CREATE TABLE dogs (  
    id INT(11) NOT NULL AUTO_INCREMENT,  
    name VARCHAR(25) NOT NULL,  
    breed VARCHAR(50) NOT NULL,  
    PRIMARY KEY pk (id),  
    KEY ix (name)  
)  
TABLESPACE ts STORAGE DISK  
ENGINE=NDBCLUSTER;

INSERT INTO dogs VALUES  
('', 'Lassie', 'collie'),  
('', 'Scooby-Doo', 'Great Dane'),  
('', 'Rin-Tin-Tin', 'Alsatian'),  
('', 'Rosscoe', 'Mutt');
```

This demonstrates the use of several additional ndb_select_all options:
shell> ./ndb_select_all -d ctest1 dogs -o ix -z --gci --disk
GCI   id name          breed        DISK_REF
  834461  2  [Scooby-Doo]  [Great Dane] [ m_file_no: 0 m_page: 98 m_page_idx: 0 ]
  834878  4  [Rosscoe]     [Mutt]       [ m_file_no: 0 m_page: 98 m_page_idx: 16 ]
  834463  3  [Rin-Tin-Tin] [Alsatian]   [ m_file_no: 0 m_page: 34 m_page_idx: 0 ]
  835657  1  [Lassie]      [Collie]     [ m_file_no: 0 m_page: 66 m_page_idx: 0 ]
4 rows returned
NDBT_ProgramExit: 0 - OK

22.4.25 **ndb_select_count** — Print Row Counts for NDB Tables

**ndb_select_count** prints the number of rows in one or more NDB tables. With a single table, the result is equivalent to that obtained by using the MySQL statement `SELECT COUNT(*) FROM tbl_name`.

### Usage

```
ndb_select_count [-c connection_string] -d db_name tbl_name[, tbl_name2[, ...]]
```

The following table includes options that are specific to the NDB Cluster native backup restoration program **ndb_select_count**. Additional descriptions follow the table. For options common to most NDB Cluster programs (including **ndb_select_count**), see Section 22.4.32, "Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs".

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--database=dbname, -d</td>
<td>Name of database in which table is found</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--parallelism=#, -p</td>
<td>Degree of parallelism</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--lock=#, -l</td>
<td>Lock type</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
</tbody>
</table>

You can obtain row counts from multiple tables in the same database by listing the table names separated by spaces when invoking this command, as shown under **Sample Output**.

### Sample Output

```
shell> ./ndb_select_count -c localhost -d ctest1 fish dogs
6 records in table fish
4 records in table dogs
NDBT_ProgramExit: 0 - OK
```

22.4.26 **ndb_setup.py** — Start browser-based Auto-Installer for NDB Cluster (DEPRECATED)

**Note**

This feature is deprecated and should be avoided. It is subject to removal in a future version of NDB Cluster.

**ndb_setup.py** starts the NDB Cluster Auto-Installer and opens the installer’s Start page in the default Web browser.
ndb_setup.py — Start browser-based Auto-Installer for NDB Cluster (DEPRECATED)

**Important**

This program is intended to be invoked as a normal user, and not with the mysql, system root or other administrative account.

This section describes usage of and program options for the command-line tool only. For information about using the Auto-Installer GUI that is spawned when ndb_setup.py is invoked, see The NDB Cluster Auto-Installer (NDB 7.5) (DEPRECATED).

**Usage**

All platforms:

```
ndb_setup.py [options]
```

Additionally, on Windows platforms only:

```
setup.bat [options]
```

The following table includes all options that are supported by the NDB Cluster installation and configuration program `ndb_setup.py`. Additional descriptions follow the table.

**Table 22.44 Command-line options for the ndb_setup.py program**

<table>
<thead>

### ndb_setup.py — Start browser-based Auto-Installer for NDB Cluster (DEPRECATED)

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--server-name=name,</code> -N</td>
<td>Name of server to connect to</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--use-http,</code> -H</td>
<td>Use unencrypted (HTTP) client/server connection</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--use-https,</code> -S</td>
<td>Use encrypted (HTTPS) client/server connection</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
</tbody>
</table>

- **--browser-start-page=** `file`, `-s`

  Command-Line Format: `--browser-start-page=filename`

<table>
<thead>
<tr>
<th>Type</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td><code>index.html</code></td>
</tr>
</tbody>
</table>

  Specify the file to open in the browser as the installation and configuration Start page. The default is `index.html`.

- **--ca-certs-file=** `file`, `-a`

  Command-Line Format: `--ca-certs-file=filename`

<table>
<thead>
<tr>
<th>Type</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>File name</td>
<td>[none]</td>
</tr>
</tbody>
</table>

  Specify a file containing a list of client certificates which are allowed to connect to the server. The default is an empty string, which means that no client authentication is used.

- **--cert-file=** `file`, `-c`

  Command-Line Format: `--cert-file=filename`

<table>
<thead>
<tr>
<th>Type</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>File name</td>
<td><code>/usr/share/mysql/mcc/cfg.pem</code></td>
</tr>
</tbody>
</table>

  Specify a file containing an X509 certificate which identifies the server. It is possible for the certificate to be self-signed. The default is `cfg.pem`.

- **--debug-level=** `level`, `-d`

  Command-Line Format: `--debug-level=level`

<table>
<thead>
<tr>
<th>Type</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enumeration</td>
<td><code>WARNING</code></td>
</tr>
</tbody>
</table>

  Valid Values:
  - `WARNING`
  - `DEBUG`
  - `INFO`
  - `ERROR`
CRITICAL

Set the Python logging module debug level. This is one of DEBUG, INFO, WARNING, ERROR, or CRITICAL. WARNING is the default.

• --help, -h

Command-Line Format --help

Print a help message.

• --key-file=file, -d

Command-Line Format --key-file=file

Type File name
Default Value [none]

Specify a file containing the private key if this is not included in the X509 certificate file (--cert-file). The default is an empty string, which means that no such file is used.

• --no-browser, -n

Command-Line Format --no-browser

Start the installation and configuration tool, but do not open the Start page in a browser.

• --port=#, -p

Command-Line Format --port=#

Type Numeric
Default Value 8081
Minimum Value 1
Maximum Value 65535

Set the port used by the web server. The default is 8081.

• --server-log-file=file, -o

Command-Line Format --server-log-file=file

Type File name
Default Value ndb_setup.log
Valid Values ndb_setup.log
- (Log to stderr)

Log requests to this file. The default is ndb_setup.log. To specify logging to stderr, rather than to a file, use a - (dash character) for the file name.

• --server-name=host, -N

Command-Line Format --server-name=name
**ndb_show_tables** — Display List of NDB Tables

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--database=string, -d</code></td>
<td>Specifies database in which table is found; database name must be followed by table name</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--loops=#, -l</code></td>
<td>Number of times to repeat output</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--parsable, -p</code></td>
<td>Return output suitable for MySQL LOAD DATA statement</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--show-temp-status</code></td>
<td>Show table temporary flag</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--type=#, -t</code></td>
<td>Limit output to objects of this type</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--unqualified, -u</code></td>
<td>Do not qualify table names</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
</tbody>
</table>

**Usage**

```
ndb_show_tables [-c connection_string]
```
--database, -d

Specifies the name of the database in which the desired table is found. If this option is given, the name of a table must follow the database name.

If this option has not been specified, and no tables are found in the TEST_DB database, ndb_show_tables issues a warning.

--loops, -l

Specifies the number of times the utility should execute. This is 1 when this option is not specified, but if you do use the option, you must supply an integer argument for it.

--parsable, -p

Using this option causes the output to be in a format suitable for use with LOAD DATA.

--show-temp-status

If specified, this causes temporary tables to be displayed.

--type, -t

Can be used to restrict the output to one type of object, specified by an integer type code as shown here:

- 1: System table
- 2: User-created table
- 3: Unique hash index

Any other value causes all NDB database objects to be listed (the default).

--unqualified, -u

If specified, this causes unqualified object names to be displayed.

Note

Only user-created NDB Cluster tables may be accessed from MySQL; system tables such as SYSTAB_0 are not visible to mysql. However, you can examine the contents of system tables using NDB API applications such as ndb_select_all (see Section 22.4.24, “ndb_select_all — Print Rows from an NDB Table”).

Prior to NDB 8.0.20, this program printed NDBT_ProgramExit - status upon completion of its run, due to an unnecessary dependency on the NDBT testing library. This dependency has been removed, eliminating the extraneous output.

22.4.28 ndb_size.pl — NDBCLUSTER Size Requirement Estimator

This is a Perl script that can be used to estimate the amount of space that would be required by a MySQL database if it were converted to use the NDBCLUSTER storage engine. Unlike the other utilities discussed in this section, it does not require access to an NDB Cluster (in fact, there is no reason for it to do so). However, it does need to access the MySQL server on which the database to be tested resides.

Requirements

- A running MySQL server. The server instance does not have to provide support for NDB Cluster.
ndb_size.pl — NDBCLUSTER Size Requirement Estimator

- A working installation of Perl.
- The DBI module, which can be obtained from CPAN if it is not already part of your Perl installation. (Many Linux and other operating system distributions provide their own packages for this library.)
- A MySQL user account having the necessary privileges. If you do not wish to use an existing account, then creating one using `GRANT USAGE ON db_name.*`—where `db_name` is the name of the database to be examined—is sufficient for this purpose.

`ndb_size.pl` can also be found in the MySQL sources in `storage/ndb/tools`.

The following table includes options that are specific to the NDB Cluster program `ndb_size.pl`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndb_size.pl`), see Section 22.4.32, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

**Table 22.46 Command-line options for the ndb_size.pl program**

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--database=dbname</code></td>
<td>Database or databases to examine; a comma-delimited list; default is ALL (use all databases found on server)</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--hostname[:port]</code></td>
<td>Specify host and optional port as <code>host[:port]</code></td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--socket=file_name</code></td>
<td>Specify socket to connect to</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--user=string</code></td>
<td>Specify MySQL user name</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--password=string</code></td>
<td>Specify MySQL user password</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--format=string</code></td>
<td>Set output format (text or HTML)</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--excludetables=tbl_list</code></td>
<td>Skip any tables in comma-separated list</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--excludedbs=db_list</code></td>
<td>Skip any databases in comma-separated list</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--savequeries=file</code></td>
<td>Saves all queries on database into file specified</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--loadqueries=file</code></td>
<td>Loads all queries from file specified; does not connect to database</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--real_table_name=table</code></td>
<td>Designates table to handle unique index size calculations</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
</tbody>
</table>

**Usage**

```bash
perl ndb_size.pl [--database={db_name|ALL}] [--hostname=host[:port]] [--socket=socket] \ 
[--user=user] [--password=password] \ 
[--help|-h] [--format={html|text}] \ 
```
By default, this utility attempts to analyze all databases on the server. You can specify a single database using the `--database` option; the default behavior can be made explicit by using `ALL` for the name of the database. You can also exclude one or more databases by using the `--excludedbs` option with a comma-separated list of the names of the databases to be skipped. Similarly, you can cause specific tables to be skipped by listing their names, separated by commas, following the optional `--excludetables` option. A host name can be specified using `--hostname`; the default is `localhost`. You can specify a port in addition to the host using `host:port` format for the value of `--hostname`. The default port number is 3306. If necessary, you can also specify a socket; the default is `/var/lib/mysql.sock`. A MySQL user name and password can be specified the corresponding options shown.

It also possible to control the format of the output using the `--format` option; this can take either of the values `html` or `text`, with `text` being the default. An example of the text output is shown here:

```bash
shell> ndb_size.pl --database=test --socket=/tmp/mysql.sock
ndb_size.pl report for database: 'test' (1 tables)
----------
Connected to: DBI:mysql:host=localhost;mysql_socket=/tmp/mysql.sock

```
For debugging purposes, the Perl arrays containing the queries run by this script can be read from the file specified using `--savequeries`; a file containing such arrays to be read during script execution can be specified using `--loadqueries`. Neither of these options has a default value.

To produce output in HTML format, use the `--format` option and redirect the output to a file, as shown here:

```
shell> ndb_size.pl --database=test --socket=/tmp/mysql.sock --format=html > ndb_size.html
```

(Without the redirection, the output is sent to `stdout`.)

The output from this script includes the following information:

- Minimum values for the DataMemory, IndexMemory, MaxNoOfTables, MaxNoOfAttributes, MaxNoOfOrderedIndexes, and MaxNoOfTriggers configuration parameters required to accommodate the tables analyzed.
- Memory requirements for all of the tables, attributes, ordered indexes, and unique hash indexes defined in the database.
- The IndexMemory and DataMemory required per table and table row.

### 22.4.29 ndb_top — View CPU usage information for NDB threads

`ndb_top` displays running information in the terminal about CPU usage by NDB threads on an NDB Cluster data node. Each thread is represented by two rows in the output, the first showing system statistics, the second showing the measured statistics for the thread.

`ndb_top` is available beginning with MySQL NDB Cluster 7.6.3.

**Usage**

```
ndb_top [-h hostname] [-t port] [-u user] [-p pass] [-n node_id]
```

`ndb_top` connects to a MySQL Server running as an SQL node of the cluster. By default, it attempts to connect to a `mysql` running on `localhost` and port 3306, as the MySQL `root` user with no password specified. You can override the default host and port using, respectively, `--host (-h)` and `--port (-t)`. To specify a MySQL user and password, use the `--user (-u)` and `--passwd (-p)` options. This user must be able to read tables in the `ndbinfo` database (`ndb_top` uses information from `ndbinfo.cpustat` and related tables).

For more information about MySQL user accounts and passwords, see Section 6.2, “Access Control and Account Management”.
Output is available as plain text or an ASCII graph; you can specify this using the `--text (-x)` and `--graph (-g)` options, respectively. These two display modes provide the same information; they can be used concurrently. At least one display mode must be in use.

Color display of the graph is supported and enabled by default (`--color` or `-c` option). With color support enabled, the graph display shows OS user time in blue, OS system time in green, and idle time as blank. For measured load, blue is used for execution time, yellow for send time, red for time spent in send buffer full waits, and blank spaces for idle time. The percentage shown in the graph display is the sum of percentages for all threads which are not idle. Colors are not currently configurable; you can use grayscale instead by using `--skip-color`.

The sorted view (`--sort, -r`) is based on the maximum of the measured load and the load reported by the OS. Display of these can be enabled and disabled using the `--measured-load (-m)` and `--os-load (-o)` options. Display of at least one of these loads must be enabled.

The program tries to obtain statistics from a data node having the node ID given by the `--node-id` option; if unspecified, this is 1. `ndb_top` cannot provide information about other types of nodes.

The view adjusts itself to the height and width of the terminal window; the minimum supported width is 76 characters.

Once started, `ndb_top` runs continuously until forced to exit; you can quit the program using `Ctrl-C`. The display updates once per second; to set a different delay interval, use `--sleep-time (-s)`.

---

**Note**

*ndb_top* is available on macOS, Linux, and Solaris. It is not currently supported on Windows platforms.

The following table includes all options that are specific to the NDB Cluster program `ndb_top`. Additional descriptions follow the table.

**Table 22.47 Command-line options for the ndb_top program**

</tbody>
</table>

Use the specified socket file for the connection.

Added in NDB 7.6.6. (Bug #86614, Bug #26236298)

- **--sort, -r**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--sort</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>TRUE</td>
</tr>
</tbody>
</table>

Sort threads by usage; use **--skip-sort** to disable.

- **--text, -t**
**ndb_waiter** — Wait for NDB Cluster to Reach a Given Status

<table>
<thead>
<tr>
<th>Type</th>
<th>Boolean</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Display data using text. This option or `--graph` must be true; both options may be true.

The short form for this option was `-x` in previous versions of NDB Cluster, but this is no longer supported.

- `--user=[name], -u`  
  
  **Command-Line Format**  
  
  `--user=[name]`  

  **Type**  
  
  String  

  **Default Value**  
  
  `root`

Connect as this MySQL user.

**Sample Output.** The next figure shows `ndb_top` running in a terminal window on a Linux system with an `ndbmtc` data node under a moderate load. Here, the program has been invoked using `ndb_top -n8 -x` to provide both text and graph output:

**Figure 22.26 ndb_top Running in Terminal**

Beginning with NDB 8.0.20, `ndb_top` also shows spin times for threads, displayed in green.

### 22.4.30 ndb_waiter — Wait for NDB Cluster to Reach a Given Status

`ndb_waiter` repeatedly (each 100 milliseconds) prints out the status of all cluster data nodes until either the cluster reaches a given status or the `--timeout` limit is exceeded, then exits. By default, it waits for the cluster to achieve `STARTED` status, in which all nodes have started and connected to the cluster. This can be overridden using the `--no-contact` and `--not-started` options.

The node states reported by this utility are as follows:

- **NO_CONTACT**: The node cannot be contacted.
- **UNKNOWN**: The node can be contacted, but its status is not yet known. Usually, this means that the node has received a `START` or `RESTART` command from the management server, but has not yet acted on it.
ndb_waiter — Wait for NDB Cluster to Reach a Given Status

- **NOT_STARTED**: The node has stopped, but remains in contact with the cluster. This is seen when restarting the node using the management client's `RESTART` command.
- **STARTING**: The node's `ndbd` process has started, but the node has not yet joined the cluster.
- **STARTED**: The node is operational, and has joined the cluster.
- **SHUTTING_DOWN**: The node is shutting down.
- **SINGLE_USER_MODE**: This is shown for all cluster data nodes when the cluster is in single user mode.

The following table includes options that are specific to the NDB Cluster native backup restoration program `ndb_waiter`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndb_waiter`), see Section 22.4.32, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--no-contact</code>, <code>-n</code></td>
<td>Wait for cluster to reach NO CONTACT state</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--not-started</code></td>
<td>Wait for cluster to reach NOT STARTED state</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--single-user</code></td>
<td>Wait for cluster to enter single user mode</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--timeout=##, -t</code></td>
<td>Wait this many seconds, then exit whether or not cluster has reached desired state</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--nowait-nodes=list</code></td>
<td>List of nodes not to be waited for</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td><code>--wait-nodes=list, -w</code></td>
<td>List of nodes to be waited for</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
</tbody>
</table>

**Usage**

```
ndb_waiter [-c connection_string]
```

**Additional Options**

- `--no-contact, -n`

  Instead of waiting for the `STARTED` state, `ndb_waiter` continues running until the cluster reaches `NO_CONTACT` status before exiting.

- `--not-started`

  Instead of waiting for the `STARTED` state, `ndb_waiter` continues running until the cluster reaches `NOT_STARTED` status before exiting.

- `--timeout=seconds, -t seconds`
Time to wait. The program exits if the desired state is not achieved within this number of seconds. The default is 120 seconds (1200 reporting cycles).

- **--single-user**
  The program waits for the cluster to enter single user mode.

- **--nowait-nodes=list**
  When this option is used, `ndb_waiter` does not wait for the nodes whose IDs are listed. The list is comma-delimited; ranges can be indicated by dashes, as shown here:

  ```shell
  ndb_waiter --nowait-nodes=1,3,7-9
  ```

  **Important**
  Do *not* use this option together with the **--wait-nodes** option.

- **--wait-nodes=list,-w list**
  When this option is used, `ndb_waiter` waits only for the nodes whose IDs are listed. The list is comma-delimited; ranges can be indicated by dashes, as shown here:

  ```shell
  ndb_waiter --wait-nodes=2,4-6,10
  ```

  **Important**
  Do *not* use this option together with the **--nowait-nodes** option.

**Sample Output.** Shown here is the output from `ndb_waiter` when run against a 4-node cluster in which two nodes have been shut down and then started again manually. Duplicate reports (indicated by `...`) are omitted.

```shell
./ndb_waiter -c localhost
```

Connecting to mgmsrv at (localhost)
State node 1 STARTED
State node 2 NO_CONTACT
State node 3 STARTED
State node 4 NO_CONTACT
Waiting for cluster enter state STARTED
...
State node 1 STARTED
State node 2 UNKNOWN
State node 3 STARTED
State node 4 NO_CONTACT
Waiting for cluster enter state STARTED
...
State node 1 STARTED
State node 2 STARTING
State node 3 STARTED
State node 4 NO_CONTACT
Waiting for cluster enter state STARTED
...
State node 1 STARTED
```
Note

If no connection string is specified, then `ndb_waiter` tries to connect to a management on `localhost`, and reports `Connecting to mgmsrv at (null)`.

Prior to NDB 8.0.20, this program printed `NDBT_ProgramExit - status` upon completion of its run, due to an unnecessary dependency on the `NDBT` testing library. This dependency has been removed, eliminating the extraneous output.

22.4.31 ndbxfrm — Compress, Decompress, Encrypt, and Decrypt Files Created by NDB Cluster

The `ndbxfrm` utility, introduced in NDB 8.0.22, can be used to decompress, decrypt, and output information about files created by NDB Cluster that are compressed, encrypted, or both. It can also be used to compress or encrypt files.

### Table 22.49 Command-line options for the ndbxfrm program

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--compress</code>, <code>-c</code></td>
<td>Compress file</td>
<td>ADDED: NDB 8.0.22</td>
</tr>
<tr>
<td><code>--decrypt-password=string</code></td>
<td>Use this password to decrypt file</td>
<td>ADDED: NDB 8.0.22</td>
</tr>
<tr>
<td><code>--encrypt-kdf-iter-count=#</code>, <code>-k</code></td>
<td>Number of iterations used in key definition</td>
<td>ADDED: NDB 8.0.22</td>
</tr>
<tr>
<td><code>--encrypt-password=string</code></td>
<td>Use this password to encrypt file</td>
<td>ADDED: NDB 8.0.22</td>
</tr>
<tr>
<td><code>--help</code>,</td>
<td>Print usage information</td>
<td>ADDED: NDB 8.0.22</td>
</tr>
</tbody>
</table>
Format | Description | Added, Deprecated, or Removed
---|---|---
-? | Print file information | ADDED: NDB 8.0.22
--info, -i | Print file information | ADDED: NDB 8.0.22
--usage, -? | Prints usage information; synonym for --help | ADDED: NDB 8.0.22
--version, -V | Output version information | ADDED: NDB 8.0.22

**Usage**

```
ndbxfrm --info file[ file ...]
ndbxfrm --compress input_file output_file
ndbxfrm --decrypt-password=password input_file output_file
ndbxfrm [--encrypt-ldf-iter-count=#] --encrypt-password=password input_file output_file
```

*input_file* and *output_file* cannot be the same file.

**Options**

- **--compress, -c**

  Compresses the input file, using the same compression method as is used for compressing NDB Cluster backups, and writes the output to an output file. To decompress a compressed NDB backup file that is not encrypted, it is necessary only to invoke *ndbxfrm* using the names of the compressed file and an output file (with no options required).

- **--decrypt-password=password**

  Decrypts a file encrypted by NDB using the password supplied.

- **--encrypt-kdf-iter-count=#, -k #**

  When encrypting a file, specifies the number of iterations to use for the encryption key. Requires the **--encrypt-password** option.

- **--encrypt-password=password**

  Encrypts the backup file using the password supplied by the option. The password must meet the requirements listed here:

  - Uses any of the printable ASCII characters except !, ', " , $, %, \, and ^
  - Is no more than 256 characters in length
  - Is enclosed by single or double quotation marks

  It is possible but not recommended to use an empty password ("" or "").

- **--help, -?**
Prints usage information for the program.

- **--info, -i**
  
  Prints the following information about one or more input files:

  - The name of the file
  - Whether the file is compressed (compress=yes or compression=no)
  - Whether the file is encrypted (encryption=yes or encryption=no)

  Example:

  ```shell
  ndbxfrm -i BACKUP-10-0.5.Data BACKUP-10.5.ctl BACKUP-10.5.log
  File=BACKUP-10-0.5.Data, compression=no, encryption=yes
  File=BACKUP-10.5.ctl, compression=no, encryption=yes
  File=BACKUP-10.5.log, compression=no, encryption=yes
  ```

- **--usage, -?**
  
  Synonym for **--help**.

- **--version, -V**
  
  Prints out version information.

`ndbxfrm` can encrypt backups created by any version of NDB Cluster. The `.Data`, `.ctl`, and `.log` files comprising the backup must be encrypted separately, and these files must be encrypted separately for each data node. Once encrypted, such backups can be decrypted only by `ndbxfrm`, `ndb_restore`, or `ndb_print_backup` from NDB Cluster 8.0.22 or later.

An encrypted file can be re-encrypted with a new password using the **--encrypt-password** and **--decrypt-password** options together, like this:

```shell
ndbxfrm --decrypt-password=old --encrypt-password=new input_file output_file
```

In the example just shown, `old` and `new` are the old and new passwords, respectively; both of these must be quoted. The input file is decrypted and then encrypted as the output file. The input file itself is not changed; if you do not want it to be accessible using the old password, you must remove the input file manually.

`ndbxfrm` does not take any of the options shown in Section 22.4.32, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”, other than those explicitly listed in this section (that is, **--help**, **--usage**, and **--version**).

### 22.4.32 Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs

All NDB Cluster programs accept the options described in this section, with the following exceptions:

- `mysqld`
- `ndb_print_backup_file`
- `ndb_print_schema_file`
- `ndb_print_sys_file`
Note

Users of earlier NDB Cluster versions should note that some of these options have been changed to make them consistent with one another, and also with mysqld. You can use the \texttt{--help} option with any NDB Cluster program—with the exception of \texttt{ndb_print_backup_file}, \texttt{ndb_print_schema_file}, and \texttt{ndb_print_sys_file}—to view a list of the options which the program supports.

The options in the following table are common to all NDB Cluster executables (except those noted previously in this section).

Table 22.50 Command-line options common to all MySQL NDB Cluster programs

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{--character-sets-dir=dir_name}</td>
<td>Directory where character sets are installed</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>\texttt{--connect-retries=#}</td>
<td>Set the number of times to retry a connection before giving up</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>\texttt{--connect-retry-delay=#}</td>
<td>Time to wait between attempts to contact a management server, in seconds</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>\texttt{--core-file}</td>
<td>Write core on errors (defaults to TRUE in debug builds)</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>\texttt{--debug=options}</td>
<td>Enable output from debug calls. Can be used only for versions compiled with debugging enabled</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>\texttt{--defaults-extra-file=filename}</td>
<td>Read this file after global option files are read</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>\texttt{--defaults-file=filename}</td>
<td>Read default options from this file</td>

<tr>
<td>--print-defaults</td>
<td>Print the program argument list and exit</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
<tr>
<td>--version, -V</td>
<td>Output version information and exit</td>
<td>(Supported in all MySQL 8.0 based releases)</td>
</tr>
</tbody>
</table>

For options specific to individual NDB Cluster programs, see Section 22.4, "NDB Cluster Programs".

See MySQL Server Options for NDB Cluster, for mysqld options relating to NDB Cluster.

- **--character-sets-dir=**

  Command-Line Format: `--character-sets-dir=dir_name`

  Type: Directory name

  Default Value

  Tells the program where to find character set information.

- **--connect-retries=#**

  Command-Line Format: `--connect-retries=#`

  Type: Numeric

  Default Value: 12

  Minimum Value: 0

  Maximum Value: 4294967295

  This option specifies the number of times following the first attempt to retry a connection before giving up (the client always tries the connection at least once). The length of time to wait per attempt is set using `--connect-retry-delay`.

  **Note**

  When used with ndb_mgm, this option has 3 as its default. See Section 22.4.5, "ndb_mgm — The NDB Cluster Management Client", for more information.

- **--connect-retry-delay=#**

  Command-Line Format: `--connect-retry-delay=#`

  Type: Numeric

  Default Value: 5

  Minimum Value: 1

  Maximum Value: 0
Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs

| Maximum Value | 4294967295 |

This option specifies the length of time to wait per attempt a connection before giving up. The number of times to try connecting is set by `--connect-retries`.

• `--core-file`

| Command-Line Format | `--core-file` |
| Type | Boolean |
| Default Value | FALSE |

Write a core file if the program dies. The name and location of the core file are system-dependent. (For NDB Cluster programs nodes running on Linux, the default location is the program's working directory—for a data node, this is the node's `DataDir`.) For some systems, there may be restrictions or limitations. For example, it might be necessary to execute `ulimit -c unlimited` before starting the server. Consult your system documentation for detailed information.

If NDB Cluster was built using the `--debug` option for `configure`, then `--core-file` is enabled by default. For regular builds, `--core-file` is disabled by default.

• `--debug[=options]`

| Command-Line Format | `--debug=options` |
| Type | String |
| Default Value | `d:t:o,/tmp/ndb_restore.trace` |

This option can be used only for versions compiled with debugging enabled. It is used to enable output from debug calls in the same manner as for the `mysqld` process.

• `--defaults-extra-file=filename`

| Command-Line Format | `--defaults-extra-file=filename` |
| Type | String |
| Default Value | [none] |

Read this file after global option files are read.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

• `--defaults-file=filename`

| Command-Line Format | `--defaults-file=filename` |
| Type | String |
| Default Value | [none] |

Read default options from this file.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

• `--defaults-group-suffix`
Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--defaults-group-suffix</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Also read groups with names ending in this suffix.

For additional information about this and other option-file options, see Section 4.2.3, “Command-Line Options that Affect Option-File Handling”.

• **--help, --usage, -?**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--help</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>--usage</td>
</tr>
</tbody>
</table>

Prints a short list with descriptions of the available command options.

• **--login-path=path**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--login-path=path</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Read this path from the login file.

For additional information about this and other option-file options, see Section 4.2.3, “Command-Line Options that Affect Option-File Handling”.

• **--ndb-connectstring=connection_string, --connect-string=connection_string, -c connection_string**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ndb-connectstring=connectstring</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>--connect-string=connectstring</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>localhost:1186</td>
</tr>
</tbody>
</table>

This option takes an NDB Cluster connection string that specifies the management server for the application to connect to, as shown here:

```sh
shell> ndbd --ndb-connectstring="nodeid=2;host=ndb_mgmd.mysql.com:1186"
```

For more information, see Section 22.3.3.3, “NDB Cluster Connection Strings”.

• **--ndb-mgmd-host=host[:port]**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ndb-mgmd-host=host[:port]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>
Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs

| Default Value | localhost:1186 |

Can be used to set the host and port number of a single management server for the program to connect to. If the program requires node IDs or references to multiple management servers (or both) in its connection information, use the \(--ndb-connectstring\) option instead.

- \(--ndb-nodeid=\#\)

Command-Line Format: \(--ndb-nodeid=\#

<table>
<thead>
<tr>
<th>Type</th>
<th>Numeric</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
</tbody>
</table>

Sets this node's NDB Cluster node ID. *The range of permitted values depends on the node's type (data, management, or API) and the NDB Cluster software version.* See Section 22.1.7.2, “Limits and Differences of NDB Cluster from Standard MySQL Limits”, for more information.

- \(--no-defaults\)

Command-Line Format: \(--no-defaults\)

<table>
<thead>
<tr>
<th>Type</th>
<th>Boolean</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>TRUE</td>
</tr>
</tbody>
</table>

Do not read default options from any option file other than login file.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- \(--ndb-optimized-node-selection\)

Command-Line Format: \(--ndb-optimized-node-selection\)

<table>
<thead>
<tr>
<th>Type</th>
<th>Boolean</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>TRUE</td>
</tr>
</tbody>
</table>

Optimize selection of nodes for transactions. Enabled by default.

- \(--print-defaults\)

Command-Line Format: \(--print-defaults\)

<table>
<thead>
<tr>
<th>Type</th>
<th>Boolean</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>TRUE</td>
</tr>
</tbody>
</table>

Print the program argument list and exit.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- \(--version, -V\)

Command-Line Format: \(--version\)

Prints the NDB Cluster version number of the executable. The version number is relevant because not all versions can be used together, and the NDB Cluster startup process verifies that the versions of the
binaries being used can co-exist in the same cluster. This is also important when performing an online (rolling) software upgrade or downgrade of NDB Cluster.

See Section 22.5.5, “Performing a Rolling Restart of an NDB Cluster”), for more information.

22.5 Management of NDB Cluster

Managing an NDB Cluster involves a number of tasks, the first of which is to configure and start NDB Cluster. This is covered in Section 22.3, “Configuration of NDB Cluster”, and Section 22.4, “NDB Cluster Programs”.

The next few sections cover the management of a running NDB Cluster.

For information about security issues relating to management and deployment of an NDB Cluster, see Section 22.5.17, “NDB Cluster Security Issues”.

There are essentially two methods of actively managing a running NDB Cluster. The first of these is through the use of commands entered into the management client whereby cluster status can be checked, log levels changed, backups started and stopped, and nodes stopped and started. The second method involves studying the contents of the cluster log `ndb_node_id_cluster.log`; this is usually found in the management server's `DataDir` directory, but this location can be overridden using the `LogDestination` option. (Recall that `node_id` represents the unique identifier of the node whose activity is being logged.) The cluster log contains event reports generated by `ndbd`. It is also possible to send cluster log entries to a Unix system log.

Some aspects of the cluster's operation can be also be monitored from an SQL node using the `SHOW ENGINE NDB STATUS` statement.

More detailed information about NDB Cluster operations is available in real time through an SQL interface using the `ndbinfo` database. For more information, see Section 22.5.14, “ndbinfo: The NDB Cluster Information Database”.

NDB statistics counters provide improved monitoring using the `mysql` client. These counters, implemented in the NDB kernel, relate to operations performed by or affecting `Ndb` objects, such as starting, closing, and aborting transactions; primary key and unique key operations; table, range, and pruned scans; blocked threads waiting for various operations to complete; and data and events sent and received by NDB Cluster. The counters are incremented by the NDB kernel whenever NDB API calls are made or data is sent to or received by the data nodes.

`mysql` exposes the NDB API statistics counters as system status variables, which can be identified from the prefix common to all of their names (`Ndb_api_`). The values of these variables can be read in the `mysql` client from the output of a `SHOW STATUS` statement, or by querying either the Performance Schema `session_status` or `global_status` table. By comparing the values of the status variables before and after the execution of an SQL statement that acts on `NDB` tables, you can observe the actions taken on the NDB API level that correspond to this statement, which can be beneficial for monitoring and performance tuning of NDB Cluster.

MySQL Cluster Manager provides an advanced command-line interface that simplifies many otherwise complex NDB Cluster management tasks, such as starting, stopping, or restarting an NDB Cluster with a large number of nodes. The MySQL Cluster Manager client also supports commands for getting and setting the values of most node configuration parameters as well as `mysql` server options and variables relating to NDB Cluster. MySQL Cluster Manager version 1.4.8 provides experimental support for NDB 8.0. See MySQL™ Cluster Manager 1.4.8 User Manual, for more information.

22.5.1 Commands in the NDB Cluster Management Client
In addition to the central configuration file, a cluster may also be controlled through a command-line interface available through the management client `ndb_mgm`. This is the primary administrative interface to a running cluster.

Commands for the event logs are given in Section 22.5.3, “Event Reports Generated in NDB Cluster”; commands for creating backups and restoring from them are provided in Section 22.5.8, “Online Backup of NDB Cluster”.

**Using ndb_mgm with MySQL Cluster Manager.** MySQL Cluster Manager 1.4.8 provides experimental support for NDB 8.0. MySQL Cluster Manager handles starting and stopping processes and tracks their states internally, so it is not necessary to use `ndb_mgm` for these tasks for an NDB Cluster that is under MySQL Cluster Manager control. It is recommended not to use the `ndb_mgm` command-line client that comes with the NDB Cluster distribution to perform operations that involve starting or stopping nodes. These include but are not limited to the `START`, `STOP`, `RESTART`, and `SHUTDOWN` commands. For more information, see MySQL Cluster Manager Process Commands.

The management client has the following basic commands. In the listing that follows, `node_id` denotes either a data node ID or the keyword `ALL`, which indicates that the command should be applied to all of the cluster's data nodes.

- **HELP**
  - Displays information on all available commands.

- **CONNECT connection-string**
  - Connects to the management server indicated by the connection string. If the client is already connected to this server, the client reconnects.

- **SHOW**
  - Displays information on the cluster's status. Possible node status values include `UNKNOWN`, `NO_CONTACT`, `NOT_STARTED`, `STARTING`, `STARTED`, `SHUTTING_DOWN`, and `RESTARTING`.

  The output from this command also indicates when the cluster is in single user mode (status `SINGLE USER MODE`). In NDB 8.0.17 and later, it also indicates which API or SQL node has exclusive access when this mode is in effect; this works only when all data nodes and management nodes connected to the cluster are version 8.0.17 or later.

- **node_id START**
  - Brings online the data node identified by `node_id` (or all data nodes).

  `ALL START` works on all data nodes only, and does not affect management nodes.

  **Important**
  - To use this command to bring a data node online, the data node must have been started using `--nostart` or `-n`.

- **node_id STOP [-a] [-f]**
  - Stops the data or management node identified by `node_id`.

  `ALL STOP` works to stop all data nodes only, and does not affect management nodes.

  **Note**
A node affected by this command disconnects from the cluster, and its associated `ndbd` or `ndb_mgmd` process terminates.

The `-a` option causes the node to be stopped immediately, without waiting for the completion of any pending transactions.

Normally, `STOP` fails if the result would cause an incomplete cluster. The `-f` option forces the node to shut down without checking for this. If this option is used and the result is an incomplete cluster, the cluster immediately shuts down.

**Warning**

Use of the `-a` option also disables the safety check otherwise performed when `STOP` is invoked to insure that stopping the node does not cause an incomplete cluster. In other words, you should exercise extreme care when using the `-a` option with the `STOP` command, due to the fact that this option makes it possible for the cluster to undergo a forced shutdown because it no longer has a complete copy of all data stored in `NDB`.

• `node_id` `RESTART` `-n` `-i` `-a` `-f`

Restarts the data node identified by `node_id` (or all data nodes).

Using the `-i` option with `RESTART` causes the data node to perform an initial restart; that is, the node's file system is deleted and recreated. The effect is the same as that obtained from stopping the data node process and then starting it again using `ndbd --initial` from the system shell.

**Note**

Backup files and Disk Data files are not removed when this option is used.

Using the `-n` option causes the data node process to be restarted, but the data node is not actually brought online until the appropriate `START` command is issued. The effect of this option is the same as that obtained from stopping the data node and then starting it again using `ndbd --nostart` or `ndbd -n` from the system shell.

Using the `-a` causes all current transactions relying on this node to be aborted. No GCP check is done when the node rejoins the cluster.

Normally, `RESTART` fails if taking the node offline would result in an incomplete cluster. The `-f` option forces the node to restart without checking for this. If this option is used and the result is an incomplete cluster, the entire cluster is restarted.

• `node_id` `STATUS`

Displays status information for the data node identified by `node_id` (or for all data nodes).

The output from this command also indicates when the cluster is in single user mode.
Commands in the NDB Cluster Management Client

- **node_id REPORT report-type**

Displays a report of type `report-type` for the data node identified by `node_id`, or for all data nodes using `ALL`.

Currently, there are three accepted values for `report-type`:

- **BackupStatus** provides a status report on a cluster backup in progress

- **MemoryUsage** displays how much data memory and index memory is being used by each data node as shown in this example:

```
ndb_mgm> ALL REPORT MEMORY
Node 1: Data usage is 5% (17732K pages of total 3200)
Node 1: Index usage is 0% (1088K pages of total 12832)
Node 2: Data usage is 5% (17732K pages of total 3200)
Node 2: Index usage is 0% (1088K pages of total 12832)
```

This information is also available from the `ndbinfo.memoryusage` table.

- **EventLog** reports events from the event log buffers of one or more data nodes.

`report-type` is case-insensitive and “fuzzy”; for `MemoryUsage`, you can use `MEMORY` (as shown in the prior example), `memory`, or even simply `MEM` (or `mem`). You can abbreviate `BackupStatus` in a similar fashion.

- **ENTER SINGLE USER MODE node_id**

Enters single user mode, whereby only the MySQL server identified by the node ID `node_id` is permitted to access the database.

Beginning with NDB 8.0.17, the `ndb_mgm` client provides a clear acknowledgement that this command has been issued and has taken effect, as shown here:

```
ndb_mgm> ENTER SINGLE USER MODE 100
Single user mode entered
Access is granted for API node 100 only.
```

Also in NDB 8.0.17 and later, the API or SQL node having exclusive access when in single user mode is indicated in the output of the `SHOW` command, like this:

```
ndb_mgm> SHOW
Cluster Configuration
------------------------
[ndbd(NDB)] 2 node(s)
id=5 @127.0.0.1 (mysql-8.0.17 ndb-8.0.17, single user mode, Nodegroup: 0, *)
id=6 @127.0.0.1 (mysql-8.0.17 ndb-8.0.17, single user mode, Nodegroup: 0)

[ndb_mgmd(MGM)] 1 node(s)
id=50 @127.0.0.1 (mysql-8.0.17 ndb-8.0.17)

[mysqld(API)] 2 node(s)
id=100 @127.0.0.1 (mysql-8.0.17 ndb-8.0.17, allowed single user)
id=101 (not connected, accepting connect from any host)
```

**Note**

All data and management nodes must be running version 8.0.17 of the NDB Cluster software for this feature to be enabled.
Commands in the NDB Cluster Management Client

- **EXIT SINGLE USER MODE**
  Exits single user mode, enabling all SQL nodes (that is, all running `mysql` processes) to access the database.

  **Note**
  It is possible to use `EXIT SINGLE USER MODE` even when not in single user mode, although the command has no effect in this case.

- **QUIT, EXIT**
  Terminates the management client.
  This command does not affect any nodes connected to the cluster.

- **SHUTDOWN**
  Shuts down all cluster data nodes and management nodes. To exit the management client after this has been done, use `EXIT` or `QUIT`.
  This command does *not* shut down any SQL nodes or API nodes that are connected to the cluster.

- **CREATE NODEGROUP nodeid[, nodeid, ...]**
  Creates a new NDB Cluster node group and causes data nodes to join it.

  This command is used after adding new data nodes online to an NDB Cluster, and causes them to join a new node group and thus to begin participating fully in the cluster. The command takes as its sole parameter a comma-separated list of node IDs—these are the IDs of the nodes just added and started that are to join the new node group. The number of nodes must be the same as the number of nodes in each node group that is already part of the cluster (each NDB Cluster node group must have the same number of nodes). In other words, if the NDB Cluster has 2 node groups of 2 data nodes each, then the new node group must also have 2 data nodes.

  The node group ID of the new node group created by this command is determined automatically, and always the next highest unused node group ID in the cluster; it is not possible to set it manually.

  For more information, see Section 22.5.7, “Adding NDB Cluster Data Nodes Online”.

- **DROP NODEGROUP nodegroup_id**
  Drops the NDB Cluster node group with the given `nodegroup_id`.

  This command can be used to drop a node group from an NDB Cluster. `DROP NODEGROUP` takes as its sole argument the node group ID of the node group to be dropped.

  `DROP NODEGROUP` acts only to remove the data nodes in the effected node group from that node group. It does not stop data nodes, assign them to a different node group, or remove them from the cluster's configuration. A data node that does not belong to a node group is indicated in the output of the management client `SHOW` command with `no nodegroup` in place of the node group ID, like this (indicated using bold text):

  ```
  id=3    @10.100.2.67  (8.0.22-ndb-8.0.22, no nodegroup)
  ```

  `DROP NODEGROUP` works only when all data nodes in the node group to be dropped are completely empty of any table data and table definitions. Since there is currently no way using `ndb_mgm` or the
**Commands in the NDB Cluster Management Client**

`mysql` client to remove all data from a specific data node or node group, this means that the command succeeds only in the two following cases:

1. After issuing `CREATE NODEGROUP` in the `ndb_mgm` client, but before issuing any `ALTER TABLE ... REORGANIZE PARTITION` statements in the `mysql` client.

2. After dropping all `NDBCLUSTER` tables using `DROP TABLE`.

`TRUNCATE TABLE` does not work for this purpose because this removes only the table data; the data nodes continue to store an `NDBCLUSTER` table’s definition until a `DROP TABLE` statement is issued that causes the table metadata to be dropped.

For more information about `DROP NODEGROUP`, see Section 22.5.7, “Adding NDB Cluster Data Nodes Online”.

- **PROMPT [prompt]**

Changes the prompt shown by `ndb_mgm` to the string literal `prompt`.

`prompt` should not be quoted (unless you want the prompt to include the quotation marks). Unlike the case with the `mysql` client, special character sequences and escapes are not recognized. If called without an argument, the command resets the prompt to the default value (`ndb_mgm>`).

Some examples are shown here:

```
ndb_mgm> PROMPT mgm#1:
mgm#1: SHOW
Cluster Configuration
...
mgm#1: PROMPT mymgm >
mymgm > PROMPT 'mymgm:'
'mymgm:' PROMPT
mymgm:
ndb_mgm> EXIT
jon@valhaj:/bin>
```

Note that leading spaces and spaces within the `prompt` string are not trimmed. Trailing spaces are removed.

- **node_id NODELOG DEBUG {ON|OFF}**

Toggles debug logging in the node log, as though the effected data node or nodes had been started with the `--verbose` option. `NODELOG DEBUG ON` starts debug logging; `NODELOG DEBUG OFF` switches debug logging off.

**Additional commands.** A number of other commands available in the `ndb_mgm` client are described elsewhere, as shown in the following list:

- **START BACKUP** is used to perform an online backup in the `ndb_mgm` client; the `ABORT BACKUP` command is used to cancel a backup already in progress. For more information, see Section 22.5.8, “Online Backup of NDB Cluster”.

- The `CLUSTERLOG` command is used to perform various logging functions. See Section 22.5.3, “Event Reports Generated in NDB Cluster”, for more information and examples. `NODELOG DEBUG` activates or deactivates debug printouts in node logs, as described previously in this section.

- For testing and diagnostics work, the client supports a `DUMP` command which can be used to execute internal commands on the cluster. It should never be used in a production setting unless directed to do so by MySQL Support. For more information, see MySQL NDB Cluster Internals Manual.
### 22.5.2 NDB Cluster Log Messages

This section contains information about the messages written to the cluster log in response to different cluster log events. It provides additional, more specific information on NDB transporter errors.

#### 22.5.2.1 NDB Cluster: Messages in the Cluster Log

The following table lists the most common NDB cluster log messages. For information about the cluster log, log events, and event types, see Section 22.5.3, “Event Reports Generated in NDB Cluster”. These log messages also correspond to log event types in the MGM API; see The Ndb_logevent_type Type, for related information of interest to Cluster API developers.

**Table 22.51 Common NDB cluster log messages**

<table>
<thead>
<tr>
<th>Log Message</th>
<th>Description</th>

**22.5.2.2 NDB Cluster Log Startup Messages**

Possible startup messages with descriptions are provided in the following list:

- **Initial start, waiting for %s to connect, nodes [ all: %s connected: %s no-wait: %s ]**

- **Waiting until nodes: %s connects, nodes [ all: %s connected: %s no-wait: %s ]**

- **Waiting %u sec for nodes %s to connect, nodes [ all: %s connected: %s no-wait: %s ]**

- **Waiting for non partitioned start, nodes [ all: %s connected: %s missing: %s no-wait: %s ]**

- **Waiting %u sec for non partitioned start, nodes [ all: %s connected: %s missing: %s no-wait: %s ]**

- **Initial start with nodes %s [ missing: %s no-wait: %s ]**

- **Start with all nodes %s**
22.5.2.3 Event Buffer Reporting in the Cluster Log

**NDB** uses one or more memory buffers for events received from the data nodes. There is one such buffer for each **Ndb** object subscribing to table events, which means that there are usually two buffers for each **mysqld** performing binary logging (one buffer for schema events, and one for data events). Each buffer contains epochs made up of events. These events consist of operation types (insert, update, delete) and row data (before and after images plus metadata).

**NDB** generates messages in the cluster log to describe the state of these buffers. Although these reports appear in the cluster log, they refer to buffers on API nodes (unlike most other cluster log messages, which are generated by data nodes).

Event buffer logging reports in the cluster log use the format shown here:

```
Node node_id: Event buffer status (object_id):
  used=bytes_used (percent_used% of alloc)
  alloc=bytes_allocated (percent_alloc% of max) max=bytes_available
  latest_consumed_epoch=latest_buffered_epoch
  latest_buffered_epoch
  report_reason=report_reason
```

The fields making up this report are listed here, with descriptions:

- **node_id**: ID of the node where the report originated.
- **object_id**: ID of the **Ndb** object where the report originated.
- **bytes_used**: Number of bytes used by the buffer.
- **percent_used**: Percentage of allocated bytes used.
- **bytes_allocated**: Number of bytes allocated to this buffer.
- **percent_alloc**: Percentage of available bytes used; not printed if **ndb_eventbuffer_max_alloc** is equal to 0 (unlimited).
- **bytes_available**: Number of bytes available; this is 0 if **ndb_eventbuffer_max_alloc** is 0 (unlimited).
- **latest_consumed_epoch**: The epoch most recently consumed to completion. (In **NDB** API applications, this is done by calling `nextEvent()`.)
- **latest_buffered_epoch**: The epoch most recently buffered (completely) in the event buffer.
- **report_reason**: The reason for making the report. Possible reasons are shown later in this section.

Possible reasons for reporting are described in the following list:

- **ENOUGH_FREE_EVENTBUFFER**: The event buffer has sufficient space.
- **LOW_FREE_EVENTBUFFER**: The event buffer is running low on free space.

The threshold free percentage level triggering these reports can be adjusted by setting the **ndb_report_thresh_binlog_mem_usage** server variable.
NDB Cluster Log Messages

- **BUFFERED_EPOCHS_OVER_THRESHOLD**: Whether the number of buffered epochs has exceeded the configured threshold. This number is the difference between the latest epoch that has been received in its entirety and the epoch that has most recently been consumed (in NDB API applications, this is done by calling `nextEvent()` or `nextEvent2()`). The report is generated every second until the number of buffered epochs goes below the threshold, which can be adjusted by setting the `ndb_report_thresh_binlog_epoch_slip` server variable. You can also adjust the threshold in NDB API applications by calling `setEventBufferQueueEmptyEpoch()`.

- **PARTIALLY_DISCARDING**: Event buffer memory is exhausted—that is, 100% of `ndb_eventbuffer_max_alloc` has been used. Any partially buffered epoch is buffered to completion even if usage exceeds 100%, but any new epochs received are discarded. This means that a gap has occurred in the event stream.

- **COMPLETELY_DISCARDING**: No epochs are buffered.

- **PARTIALLY_BUFFERING**: The buffer free percentage following the gap has risen to the threshold, which can be set in the `mysql` client using the `ndb_eventbuffer_free_percent` server system variable or in NDB API applications by calling `set_eventbuffer_free_percent()`. New epochs are buffered. Epochs that could not be completed due to the gap are discarded.

- **COMPLETELY_BUFFERING**: All epochs received are being buffered, which means that there is sufficient event buffer memory. The gap in the event stream has been closed.

### 22.5.2.4 NDB Cluster: NDB Transporter Errors

This section lists error codes, names, and messages that are written to the cluster log in the event of transporter errors.

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Error Description</th>

0x15  TE_SIGNAL_LOST  Send failed for unknown reason(signal lost)

0x16  TE_SEND_BUFFER_FULL  The send buffer was full, but sleeping for a while solved

0x21  TE_SHM_IPC_PERMANENT  Shm ipc Permanent error
22.5.3 Event Reports Generated in NDB Cluster

In this section, we discuss the types of event logs provided by NDB Cluster, and the types of events that are logged.

NDB Cluster provides two types of event log:

- **The cluster log**, which includes events generated by all cluster nodes. The cluster log is the log recommended for most uses because it provides logging information for an entire cluster in a single location.

  By default, the cluster log is saved to a file named `ndb_node_id_cluster.log`, (where `node_id` is the node ID of the management server) in the management server's DataDir.

  Cluster logging information can also be sent to stdout or a syslog facility in addition to or instead of being saved to a file, as determined by the values set for the DataDir and LogDestination configuration parameters. See Section 22.3.3.5, “Defining an NDB Cluster Management Server”, for more information about these parameters.

- **Node logs** are local to each node.

  Output generated by node event logging is written to the file `ndb_node_id_out.log` (where `node_id` is the node’s node ID) in the node’s DataDir. Node event logs are generated for both management nodes and data nodes.

  Node logs are intended to be used only during application development, or for debugging application code.

Both types of event logs can be set to log different subsets of events.

Each reportable event can be distinguished according to three different criteria:

- **Category**: This can be any one of the following values: STARTUP, SHUTDOWN, STATISTICS, CHECKPOINT, NODERESTART, CONNECTION, ERROR, or INFO.

- **Priority**: This is represented by one of the numbers from 0 to 15 inclusive, where 0 indicates “most important” and 15 “least important.”

- **Severity Level**: This can be any one of the following values: ALERT, CRITICAL, ERROR, WARNING, INFO, or DEBUG.

Both the cluster log and the node log can be filtered on these properties.

The format used in the cluster log is as shown here:

```
2007-01-26 19:35:55 [MgmSrvr] INFO -- Node 1: Data usage is 2%(60 32K pages of total 2560)
```
Each line in the cluster log contains the following information:

- A timestamp in **YYYY-MM-DD HH:MM:SS** format.
- The type of node which is performing the logging. In the cluster log, this is always **[MgmSvr]**.
- The severity of the event.
- The ID of the node reporting the event.
- A description of the event. The most common types of events to appear in the log are connections and disconnections between different nodes in the cluster, and when checkpoints occur. In some cases, the description may contain status information.

### 22.5.3.1 NDB Cluster Logging Management Commands

**ndb_mgm** supports a number of management commands related to the cluster log and node logs. In the listing that follows, **node_id** denotes either a storage node ID or the keyword **ALL**, which indicates that the command should be applied to all of the cluster’s data nodes.

- **CLUSTERLOG ON**
  Turns the cluster log on.
- **CLUSTERLOG OFF**
  Turns the cluster log off.
- **CLUSTERLOG INFO**
  Provides information about cluster log settings.
- **node_id CLUSTERLOG category=threshold**
  Logs **category** events with priority less than or equal to **threshold** in the cluster log.
- **CLUSTERLOG FILTER severity_level**
  Toggles cluster logging of events of the specified **severity_level**.

The following table describes the default setting (for all data nodes) of the cluster log category threshold. If an event has a priority with a value lower than or equal to the priority threshold, it is reported in the cluster log.
Note
Events are reported per data node, and that the threshold can be set to different values on different nodes.

Table 22.52 Cluster log categories, with default threshold setting

<table>
<thead>
<tr>
<th>Category</th>
<th>Default threshold (All data nodes)</th>
</tr>
</thead>
<tbody>
<tr>
<td>STARTUP</td>
<td>7</td>
</tr>
<tr>
<td>SHUTDOWN</td>
<td>7</td>
</tr>
<tr>
<td>STATISTICS</td>
<td>7</td>
</tr>
<tr>
<td>CHECKPOINT</td>
<td>7</td>
</tr>
<tr>
<td>NODERESTART</td>
<td>7</td>
</tr>
<tr>
<td>CONNECTION</td>
<td>7</td>
</tr>
<tr>
<td>ERROR</td>
<td>15</td>
</tr>
<tr>
<td>INFO</td>
<td>7</td>
</tr>
</tbody>
</table>

The STATISTICS category can provide a great deal of useful data. See Section 22.5.3.3, “Using CLUSTERLOG STATISTICS in the NDB Cluster Management Client“, for more information.

Thresholds are used to filter events within each category. For example, a STARTUP event with a priority of 3 is not logged unless the threshold for STARTUP is set to 3 or higher. Only events with priority 3 or lower are sent if the threshold is 3.

The following table shows the event severity levels.

Note
These correspond to Unix syslog levels, except for LOG_EMERG and LOG_NOTICE, which are not used or mapped.

Table 22.53 Event severity levels

<table>
<thead>
<tr>
<th>Severity Level Value</th>
<th>Severity</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>ALERT</td>
<td>A condition that should be corrected immediately, such as a corrupted system database</td>
</tr>
<tr>
<td>2</td>
<td>CRITICAL</td>
<td>Critical conditions, such as device errors or insufficient resources</td>
</tr>
<tr>
<td>3</td>
<td>ERROR</td>
<td>Conditions that should be corrected, such as configuration errors</td>
</tr>
<tr>
<td>4</td>
<td>WARNING</td>
<td>Conditions that are not errors, but that might require special handling</td>
</tr>
<tr>
<td>5</td>
<td>INFO</td>
<td>Informational messages</td>
</tr>
<tr>
<td>6</td>
<td>DEBUG</td>
<td>Debugging messages used for NDBCLUSTER development</td>
</tr>
</tbody>
</table>

Event severity levels can be turned on or off (using CLUSTERLOG FILTER—see above). If a severity level is turned on, then all events with a priority less than or equal to the category thresholds are logged. If the severity level is turned off then no events belonging to that severity level are logged.
Important

Cluster log levels are set on a per ndb_mgmd, per subscriber basis. This means that, in an NDB Cluster with multiple management servers, using a CLUSTERLOG command in an instance of ndb_mgm connected to one management server affects only logs generated by that management server but not by any of the others. This also means that, should one of the management servers be restarted, only logs generated by that management server are affected by the resetting of log levels caused by the restart.

### 22.5.3.2 NDB Cluster Log Events

An event report reported in the event logs has the following format:

```
datetime [string] severity -- message
```

For example:

```
```

This section discusses all reportable events, ordered by category and severity level within each category.

In the event descriptions, GCP and LCP mean “Global Checkpoint” and “Local Checkpoint”, respectively.

#### CONNECTION Events

These events are associated with connections between Cluster nodes.

**Table 22.54 Events associated with connections between cluster nodes**

<table>
<thead>
<tr>
<th>Event</th>
<th>Priority</th>
<th>Severity Level</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Connected</td>

### 22.5.3.3 Using CLUSTERLOG STATISTICS in the NDB Cluster Management Client

The NDB management client's `CLUSTERLOG STATISTICS` command can provide a number of useful statistics in its output. Counters providing information about the state of the cluster are updated at 5-second reporting intervals by the transaction coordinator (TC) and the local query handler (LQH), and written to the cluster log.

**Transaction coordinator statistics.** Each transaction has one transaction coordinator, which is chosen by one of the following methods:

- In a round-robin fashion
- By communication proximity
- By supplying a data placement hint when the transaction is started

**Note**

You can determine which TC selection method is used for transactions started from a given SQL node using the `ndb_optimized_node_selection` system variable.

All operations within the same transaction use the same transaction coordinator, which reports the following statistics:

- **Trans count.** This is the number transactions started in the last interval using this TC as the transaction coordinator. Any of these transactions may have committed, have been aborted, or remain uncommitted at the end of the reporting interval.

**Note**

Transactions do not migrate between TCs.

- **Commit count.** This is the number of transactions using this TC as the transaction coordinator that were committed in the last reporting interval. Because some transactions committed in this reporting
interval may have started in a previous reporting interval, it is possible for commit count to be greater than trans count.

- **Read count.** This is the number of primary key read operations using this TC as the transaction coordinator that were started in the last reporting interval, including simple reads. This count also includes reads performed as part of unique index operations. A unique index read operation generates 2 primary key read operations—1 for the hidden unique index table, and 1 for the table on which the read takes place.

- **Simple read count.** This is the number of simple read operations using this TC as the transaction coordinator that were started in the last reporting interval. This includes all inserts, updates, writes, and deletes, as well as writes performed as part of unique index operations.

  **Note**

  A unique index update operation can generate multiple PK read and write operations on the index table and on the base table.

- **Write count.** This is the number of primary key write operations using this TC as the transaction coordinator that were started in the last reporting interval. This includes all inserts, updates, writes, and deletes, as well as writes performed as part of unique index operations.

  A unique index operation generates multiple PK operations and so increases this count. However, data words sent to describe the PK operation itself, and the key information sent, are not counted here. Attribute information sent to describe columns to read for scans, or to describe ScanFilters, is also not counted in AttrInfoCount.

- **AttrInfoCount.** This is the number of 32-bit data words received in the last reporting interval for primary key operations using this TC as the transaction coordinator. For reads, this is proportional to the number of columns requested. For inserts and updates, this is proportional to the number of columns written, and the size of their data. For delete operations, this is usually zero.

Unique index operations generate multiple PK operations and so increase this count. However, data words sent to describe the PK operation itself, and the key information sent, are not counted here. Attribute information sent to describe columns to read for scans, or to describe ScanFilters, is also not counted in AttrInfoCount.

- **Concurrent Operations.** This is the number of primary key or scan operations using this TC as the transaction coordinator that were started during the last reporting interval but that were not completed. Operations increment this counter when they are started and decrement it when they are completed; this occurs after the transaction commits. Dirty reads and writes—as well as failed operations—decrement this counter.

  The maximum value that Concurrent Operations can have is the maximum number of operations that a TC block can support; currently, this is \((2 \times \text{MaxNoOfConcurrentOperations}) + 16 + \text{MaxNoOfConcurrentTransactions}\). (For more information about these configuration parameters, see the Transaction Parameters section of Section 22.3.3.6, “Defining NDB Cluster Data Nodes”.)

- **Abort count.** This is the number of transactions using this TC as the transaction coordinator that were aborted during the last reporting interval. Because some transactions that were aborted in the last reporting interval may have started in a previous reporting interval, Abort count can sometimes be greater than Trans count.

- **Scans.** This is the number of table scans using this TC as the transaction coordinator that were started during the last reporting interval. This does not include range scans (that is, ordered index scans).

- **Range scans.** This is the number of ordered index scans using this TC as the transaction coordinator that were started in the last reporting interval.

- **Local reads.** This is the number of primary-key read operations performed using a transaction coordinator on a node that also holds the primary fragment replica of the record. This count can also be obtained from the LOCAL_READS counter in the ndbinfo.counters table.
• **Local writes.** This contains the number of primary-key read operations that were performed using a transaction coordinator on a node that also holds the primary fragment replica of the record. This count can also be obtained from the `LOCAL_WRITES` counter in the `ndbinfo.counters` table.

**Local query handler statistics (Operations).** There is 1 cluster event per local query handler block (that is, 1 per data node process). Operations are recorded in the LQH where the data they are operating on resides.

![Note]

A single transaction may operate on data stored in multiple LQH blocks.

The **Operations** statistic provides the number of local operations performed by this LQH block in the last reporting interval, and includes all types of read and write operations (insert, update, write, and delete operations). This also includes operations used to replicate writes. For example, in a cluster with two fragment replicas, the write to the primary fragment replica is recorded in the primary LQH, and the write to the backup is recorded in the backup LQH. Unique key operations may result in multiple local operations; however, this does not include local operations generated as a result of a table scan or ordered index scan, which are not counted.

**Process scheduler statistics.** In addition to the statistics reported by the transaction coordinator and local query handler, each `ndbd` process has a scheduler which also provides useful metrics relating to the performance of an NDB Cluster. This scheduler runs in an infinite loop; during each loop the scheduler performs the following tasks:

1. Read any incoming messages from sockets into a job buffer.
2. Check whether there are any timed messages to be executed; if so, put these into the job buffer as well.
3. Execute (in a loop) any messages in the job buffer.
4. Send any distributed messages that were generated by executing the messages in the job buffer.
5. Wait for any new incoming messages.

Process scheduler statistics include the following:

- **Mean Loop Counter.** This is the number of loops executed in the third step from the preceding list. This statistic increases in size as the utilization of the TCP/IP buffer improves. You can use this to monitor changes in performance as you add new data node processes.

- **Mean send size and Mean receive size.** These statistics enable you to gauge the efficiency of, respectively writes and reads between nodes. The values are given in bytes. Higher values mean a lower cost per byte sent or received; the maximum value is 64K.

To cause all cluster log statistics to be logged, you can use the following command in the NDB management client:

```
ndb_mgm> ALL CLUSTERLOG STATISTICS=15
```

![Note]

Setting the threshold for `STATISTICS` to 15 causes the cluster log to become very verbose, and to grow quite rapidly in size, in direct proportion to the number of cluster nodes and the amount of activity in the NDB Cluster.

For more information about NDB Cluster management client commands relating to logging and reporting, see Section 22.5.3.1, “NDB Cluster Logging Management Commands”.
22.5.4 Summary of NDB Cluster Start Phases

This section provides a simplified outline of the steps involved when NDB Cluster data nodes are started. More complete information can be found in NDB Cluster Start Phases, in the NDB Internals Guide.

These phases are the same as those reported in the output from the node_id STATUS command in the management client (see Section 22.5.1, “Commands in the NDB Cluster Management Client”). These start phases are also reported in the start_phase column of the ndbinfo.nodes table.

Start types. There are several different startup types and modes, as shown in the following list:

- **Initial start.** The cluster starts with a clean file system on all data nodes. This occurs either when the cluster started for the very first time, or when all data nodes are restarted using the --initial option.

  \[\text{Note}\]
  Disk Data files are not removed when restarting a node using --initial.

- **System restart.** The cluster starts and reads data stored in the data nodes. This occurs when the cluster has been shut down after having been in use, when it is desired for the cluster to resume operations from the point where it left off.

- **Node restart.** This is the online restart of a cluster node while the cluster itself is running.

- **Initial node restart.** This is the same as a node restart, except that the node is reinitialized and started with a clean file system.

**Setup and initialization (phase -1).** Prior to startup, each data node (ndbd process) must be initialized.

Initialization consists of the following steps:

1. Obtain a node ID
2. Fetch configuration data
3. Allocate ports to be used for inter-node communications
4. Allocate memory according to settings obtained from the configuration file

When a data node or SQL node first connects to the management node, it reserves a cluster node ID. To make sure that no other node allocates the same node ID, this ID is retained until the node has managed to connect to the cluster and at least one ndbd reports that this node is connected. This retention of the node ID is guarded by the connection between the node in question and ndb_mgmd.

After each data node has been initialized, the cluster startup process can proceed. The stages which the cluster goes through during this process are listed here:

- **Phase 0.** The NDBFS and NDBCNTR blocks start (see NDB Kernel Blocks). Data node file systems are cleared on those data nodes that were started with --initial option.

- **Phase 1.** In this stage, all remaining NDB kernel blocks are started. NDB Cluster connections are set up, inter-block communications are established, and heartbeats are started. In the case of a node restart, API node connections are also checked.

  \[\text{Note}\]
  When one or more nodes hang in Phase 1 while the remaining node or nodes hang in Phase 2, this often indicates network problems. One possible cause of such issues is one or more cluster hosts having multiple network interfaces.
Performing a Rolling Restart of an NDB Cluster

Another common source of problems causing this condition is the blocking of TCP/IP ports needed for communications between cluster nodes. In the latter case, this is often due to a misconfigured firewall.

• **Phase 2.** The NDBCNT kernel block checks the states of all existing nodes. The master node is chosen, and the cluster schema file is initialized.

• **Phase 3.** The DBLQH and DBTC kernel blocks set up communications between them. The startup type is determined; if this is a restart, the DBDIH block obtains permission to perform the restart.

• **Phase 4.** For an initial start or initial node restart, the redo log files are created. The number of these files is equal to NoOfFragmentLogFiles.

For a system restart:

• Read schema or schemas.

• Read data from the local checkpoint.

• Apply all redo information until the latest restorable global checkpoint has been reached.

For a node restart, find the tail of the redo log.

• **Phase 5.** Most of the database-related portion of a data node start is performed during this phase. For an initial start or system restart, a local checkpoint is executed, followed by a global checkpoint. Periodic checks of memory usage begin during this phase, and any required node takeovers are performed.

• **Phase 6.** In this phase, node groups are defined and set up.

• **Phase 7.** The arbitrator node is selected and begins to function. The next backup ID is set, as is the backup disk write speed. Nodes reaching this start phase are marked as Started. It is now possible for API nodes (including SQL nodes) to connect to the cluster.

• **Phase 8.** If this is a system restart, all indexes are rebuilt (by DBDIH).

• **Phase 9.** The node internal startup variables are reset.

• **Phase 100 (OBSOLETE).** Formerly, it was at this point during a node restart or initial node restart that API nodes could connect to the node and begin to receive events. Currently, this phase is empty.

• **Phase 101.** At this point in a node restart or initial node restart, event delivery is handed over to the node joining the cluster. The newly-joined node takes over responsibility for delivering its primary data to subscribers. This phase is also referred to as SUMA handover phase.

After this process is completed for an initial start or system restart, transaction handling is enabled. For a node restart or initial node restart, completion of the startup process means that the node may now act as a transaction coordinator.

### 22.5.5 Performing a Rolling Restart of an NDB Cluster

This section discusses how to perform a rolling restart of an NDB Cluster installation, so called because it involves stopping and starting (or restarting) each node in turn, so that the cluster itself remains operational. This is often done as part of a rolling upgrade or rolling downgrade, where high availability of the cluster is mandatory and no downtime of the cluster as a whole is permissible. Where we refer to upgrades, the information provided here also generally applies to downgrades as well.

There are a number of reasons why a rolling restart might be desirable. These are described in the next few paragraphs.
Configuration change.  
To make a change in the cluster’s configuration, such as adding an SQL node to the cluster, or setting a configuration parameter to a new value.

NDB Cluster software upgrade or downgrade.  
To upgrade the cluster to a newer version of the NDB Cluster software (or to downgrade it to an older version). This is usually referred to as a “rolling upgrade” (or “rolling downgrade”, when reverting to an older version of NDB Cluster).

Change on node host.  
To make changes in the hardware or operating system on which one or more NDB Cluster node processes are running.

System reset (cluster reset).  
To reset the cluster because it has reached an undesirable state. In such cases it is often desirable to reload the data and metadata of one or more data nodes. This can be done in any of three ways:

- Start each data node process (ndbd or possibly ndbmtd) with the --initial option, which forces the data node to clear its file system and to reload all NDB Cluster data and metadata from the other data nodes.

  Beginning with NDB 8.0.21, this also forces the removal of all Disk Data objects and files associated with those objects.

- Create a backup using the ndb_mgm client START_BACKUP command prior to performing the restart. Following the upgrade, restore the node or nodes using ndb_restore.

  See Section 22.5.8, “Online Backup of NDB Cluster”, and Section 22.4.23, “ndb_restore — Restore an NDB Cluster Backup”, for more information.

- Use mysqldump to create a backup prior to the upgrade; afterward, restore the dump using LOAD DATA.

Resource Recovery.  
To free memory previously allocated to a table by successive INSERT and DELETE operations, for re-use by other NDB Cluster tables.

The process for performing a rolling restart may be generalized as follows:

1. Stop all cluster management nodes (ndb_mgmd processes), reconfigure them, then restart them. (See Rolling restarts with multiple management servers.)

2. Stop, reconfigure, then restart each cluster data node (ndbd process) in turn.

Some node configuration parameters can be updated by issuing RESTART for each of the data nodes in the ndb_mgm client following the previous step. Other parameters require that the data node be stopped completely using the management client STOP command, then started again from a system shell by invoking the ndbd or ndbmtd executable as appropriate. (A shell command such as kill can also be used on most Unix systems to stop a data node process, but the STOP command is preferred and usually simpler.)

Note
On Windows, you can also use SC STOP and SC START commands, NET STOP and NET START commands, or the Windows Service Manager to stop and start nodes which have been installed as Windows services (see Section 22.2.2.4, “Installing NDB Cluster Processes as Windows Services”).

The type of restart required is indicated in the documentation for each node configuration parameter. See Section 22.3.3, “NDB Cluster Configuration Files”.

4286
3. Stop, reconfigure, then restart each cluster SQL node (mysqld process) in turn.

NDB Cluster supports a somewhat flexible order for upgrading nodes. When upgrading an NDB Cluster, you may upgrade API nodes (including SQL nodes) before upgrading the management nodes, data nodes, or both. In other words, you are permitted to upgrade the API and SQL nodes in any order. This is subject to the following provisions:

- This functionality is intended for use as part of an online upgrade only. A mix of node binaries from different NDB Cluster releases is neither intended nor supported for continuous, long-term use in a production setting.

- All management nodes must be upgraded before any data nodes are upgraded. This remains true regardless of the order in which you upgrade the cluster’s API and SQL nodes.

- Features specific to the “new” version must not be used until all management nodes and data nodes have been upgraded.

  This also applies to any MySQL Server version change that may apply, in addition to the NDB engine version change, so do not forget to take this into account when planning the upgrade. (This is true for online upgrades of NDB Cluster in general.)

It is not possible for any API node to perform schema operations (such as data definition statements) during a node restart. Due in part to this limitation, schema operations are also not supported during an online upgrade or downgrade.

**Rolling restarts with multiple management servers.** When performing a rolling restart of an NDB Cluster with multiple management nodes, you should keep in mind that ndb_mgmd checks to see if any other management node is running, and, if so, tries to use that node’s configuration data. To keep this from occurring, and to force ndb_mgmd to reread its configuration file, perform the following steps:

1. Stop all NDB Cluster ndb_mgmd processes.
2. Update all config.ini files.
3. Start a single ndb_mgmd with --reload, --initial, or both options as desired.
4. If you started the first ndb_mgmd with the --initial option, you must also start any remaining ndb_mgmd processes using --initial.

   Regardless of any other options used when starting the first ndb_mgmd, you should not start any remaining ndb_mgmd processes after the first one using --reload.
5. Complete the rolling restarts of the data nodes and API nodes as normal.

When performing a rolling restart to update the cluster’s configuration, you can use the config_generation column of the ndbinfo.nodes table to keep track of which data nodes have been successfully restarted with the new configuration. See Section 22.5.14.30, “The ndbinfo nodes Table”.

### 22.5.6 NDB Cluster Single User Mode

**Single user mode** enables the database administrator to restrict access to the database system to a single API node, such as a MySQL server (SQL node) or an instance of ndb_restore. When entering single user mode, connections to all other API nodes are closed gracefully and all running transactions are aborted. No new transactions are permitted to start.

Once the cluster has entered single user mode, only the designated API node is granted access to the database.
Adding NDB Cluster Data Nodes Online

You can use the `ALL STATUS` command in the `ndb_mgm` client to see when the cluster has entered single user mode. You can also check the `status` column of the `ndbinfo.nodes` table (see Section 22.5.14.30, “The ndbinfo nodes Table”, for more information).

Example:

```
ndb_mgm> ENTER SINGLE USER MODE 5
```

After this command has executed and the cluster has entered single user mode, the API node whose node ID is 5 becomes the cluster's only permitted user.

The node specified in the preceding command must be an API node; attempting to specify any other type of node is rejected.

**Note**

When the preceding command is invoked, all transactions running on the designated node are aborted, the connection is closed, and the server must be restarted.

The command `EXIT SINGLE USER MODE` changes the state of the cluster's data nodes from single user mode to normal mode. API nodes—such as MySQL Servers—waiting for a connection (that is, waiting for the cluster to become ready and available), are again permitted to connect. The API node denoted as the single-user node continues to run (if still connected) during and after the state change.

Example:

```
ndb_mgm> EXIT SINGLE USER MODE
```

There are two recommended ways to handle a node failure when running in single user mode:

- **Method 1:**
  1. Finish all single user mode transactions
  2. Issue the `EXIT SINGLE USER MODE` command
  3. Restart the cluster's data nodes

- **Method 2:**
  Restart storage nodes prior to entering single user mode.

### 22.5.7 Adding NDB Cluster Data Nodes Online

This section describes how to add NDB Cluster data nodes “online”—that is, without needing to shut down the cluster completely and restart it as part of the process.

**Important**

Currently, you must add new data nodes to an NDB Cluster as part of a new node group. In addition, it is not possible to change the number of fragment replicas (or the number of nodes per node group) online.

### 22.5.7.1 Adding NDB Cluster Data Nodes Online: General Issues

This section provides general information about the behavior of and current limitations in adding NDB Cluster nodes online.
Adding NDB Cluster Data Nodes Online

Redistribution of Data. The ability to add new nodes online includes a means to reorganize NDBCLUSTER table data and indexes so that they are distributed across all data nodes, including the new ones, by means of the ALTER TABLE ... REORGANIZE PARTITION statement. Table reorganization of both in-memory and Disk Data tables is supported. This redistribution does not currently include unique indexes (only ordered indexes are redistributed).

The redistribution for NDBCLUSTER tables already existing before the new data nodes were added is not automatic, but can be accomplished using simple SQL statements in mysql or another MySQL client application. However, all data and indexes added to tables created after a new node group has been added are distributed automatically among all cluster data nodes, including those added as part of the new node group.

Partial starts. It is possible to add a new node group without all of the new data nodes being started. It is also possible to add a new node group to a degraded cluster—that is, a cluster that is only partially started, or where one or more data nodes are not running. In the latter case, the cluster must have enough nodes running to be viable before the new node group can be added.

Effects on ongoing operations. Normal DML operations using NDB Cluster data are not prevented by the creation or addition of a new node group, or by table reorganization. However, it is not possible to perform DDL concurrently with table reorganization—that is, no other DDL statements can be issued while an ALTER TABLE ... REORGANIZE PARTITION statement is executing. In addition, during the execution of ALTER TABLE ... REORGANIZE PARTITION (or the execution of any other DDL statement), it is not possible to restart cluster data nodes.

Failure handling. Failures of data nodes during node group creation and table reorganization are handled as shown in the following table:

| Table 22.64 Data node failure handling during node group creation and table reorganization |
|---|---|---|---|
| Failure during | Failure in “Old” data node | Failure in “New” data node | System Failure |
| Node group creation | • If a node other than the master fails: The creation of the node group is always rolled forward. | • If a node other than the master fails: The creation of the node group is always rolled forward. | • If the execution of CREATE NODEGROUP has reached the internal commit point: When restarted, the cluster includes the new node group. Otherwise it without. |
| | • If the master fails: | • If the master fails: | • If the execution of CREATE NODEGROUP has not yet reached the internal commit point: When restarted, the cluster does not include the new node group. |
| | • If the internal commit point has been reached: The creation of the node group is rolled forward. | • If the internal commit point has been reached: The creation of the node group is rolled forward. | |
| | • If the internal commit point has not yet been reached: The creation of the node group is rolled back. | • If the internal commit point has not yet been reached: The creation of the node group is rolled back. | |
| Table reorganization | • If a node other than the master fails: The table | • If a node other than the master fails: The table | • If the execution of an ALTER TABLE ... REORGANIZE PARTITION statement |
Adding NDB Cluster Data Nodes Online

<table>
<thead>
<tr>
<th>Failure during</th>
<th>Failure in “Old” data node</th>
<th>Failure in “New” data node</th>
<th>System Failure</th>
</tr>
</thead>
<tbody>
<tr>
<td>reorganization is always rolled forward.</td>
<td>reorganization is always rolled forward.</td>
<td>reorganization is always rolled forward.</td>
<td>has reached the internal commit point: When the cluster is restarted, the data and indexes belonging to table are distributed using the “new” data nodes.</td>
</tr>
<tr>
<td>• If the master fails:</td>
<td>• If the master fails:</td>
<td>• If the master fails:</td>

<td>• If the internal commit point has not yet been reached. The table reorganization is rolled back.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Dropping node groups. The ndb_mgm client supports a DROP NODEGROUP command, but it is possible to drop a node group only when no data nodes in the node group contain any data. Since there is currently no way to “empty” a specific data node or node group, this command works only the following two cases:

1. After issuing CREATE NODEGROUP in the ndb_mgm client, but before issuing any ALTER TABLE ... REORGANIZE PARTITION statements in the mysql client.

2. After dropping all NDBCLUSTER tables using DROP TABLE. TRUNCATE TABLE does not work for this purpose because the data nodes continue to store the table definitions.

22.5.7.2 Adding NDB Cluster Data Nodes Online: Basic procedure

In this section, we list the basic steps required to add new data nodes to an NDB Cluster. This procedure applies whether you are using ndbd or ndbmt.d binaries for the data node processes. For a more detailed example, see Section 22.5.7.3, “Adding NDB Cluster Data Nodes Online: Detailed Example”.

Assuming that you already have a running NDB Cluster, adding data nodes online requires the following steps:

1. Edit the cluster configuration config.ini file, adding new [ndbd] sections corresponding to the nodes to be added. In the case where the cluster uses multiple management servers, these changes need to be made to all config.ini files used by the management servers.

   You must be careful that node IDs for any new data nodes added in the config.ini file do not overlap node IDs used by existing nodes. In the event that you have API nodes using dynamically allocated node IDs and these IDs match node IDs that you want to use for new data nodes, it is possible to force any such API nodes to “migrate”, as described later in this procedure.

2. Perform a rolling restart of all NDB Cluster management servers.
Adding NDB Cluster Data Nodes Online

Important

All management servers must be restarted with the `--reload` or `--initial` option to force the reading of the new configuration.

3. Perform a rolling restart of all existing NDB Cluster data nodes. It is not necessary (or usually even desirable) to use `--initial` when restarting the existing data nodes.

If you are using API nodes with dynamically allocated IDs matching any node IDs that you wish to assign to new data nodes, you must restart all API nodes (including SQL nodes) before restarting any of the data nodes processes in this step. This causes any API nodes with node IDs that were previously not explicitly assigned to relinquish those node IDs and acquire new ones.

4. Perform a rolling restart of any SQL or API nodes connected to the NDB Cluster.

5. Start the new data nodes.

The new data nodes may be started in any order. They can also be started concurrently, as long as they are started after the rolling restarts of all existing data nodes have been completed, and before proceeding to the next step.

6. Execute one or more `CREATE NODEGROUP` commands in the NDB Cluster management client to create the new node group or node groups to which the new data nodes belong.

7. Redistribute the cluster’s data among all data nodes, including the new ones. Normally this is done by issuing an `ALTER TABLE ... ALGORITHM=INPLACE, REORGANIZE PARTITION` statement in the `mysql` client for each `NDBCLUSTER` table.

   Exception: For tables created using the `MAX_ROWS` option, this statement does not work; instead, use `ALTER TABLE ... ALGORITHM=INPLACE MAX_ROWS=...` to reorganize such tables. You should also bear in mind that using `MAX_ROWS` to set the number of partitions in this fashion is deprecated, and you should use `PARTITION_BALANCE` instead; see Section 13.1.20.10, “Setting NDB_TABLE Options”, for more information.

Note

This needs to be done only for tables already existing at the time the new node group is added. Data in tables created after the new node group is added is distributed automatically; however, data added to any given table `tbl` that existed before the new nodes were added is not distributed using the new nodes until that table has been reorganized.

8. `ALTER TABLE ... REORGANIZE PARTITION ALGORITHM=INPLACE` reorganizes partitions but does not reclaim the space freed on the “old” nodes. You can do this by issuing, for each `NDBCLUSTER` table, an `OPTIMIZE TABLE` statement in the `mysql` client.

   This works for space used by variable-width columns of in-memory NDB tables. `OPTIMIZE TABLE` is not supported for fixed-width columns of in-memory tables; it is also not supported for Disk Data tables.

You can add all the nodes desired, then issue several `CREATE NODEGROUP` commands in succession to add the new node groups to the cluster.

22.5.7.3 Adding NDB Cluster Data Nodes Online: Detailed Example

In this section we provide a detailed example illustrating how to add new NDB Cluster data nodes online, starting with an NDB Cluster having 2 data nodes in a single node group and concluding with a cluster having 4 data nodes in 2 node groups.
Starting configuration. For purposes of illustration, we assume a minimal configuration, and that the cluster uses a `config.ini` file containing only the following information:

```
[ndbd default]
DataMemory = 100M
IndexMemory = 100M
NoOfReplicas = 2
DataDir = /usr/local/mysql/var/mysql-cluster

[ndbd]
Id = 1
HostName = 198.51.100.1

[ndbd]
Id = 2
HostName = 198.51.100.2

[mgm]
HostName = 198.51.100.10
Id = 10

[api]
Id=20
HostName = 198.51.100.20

[api]
Id=21
HostName = 198.51.100.21
```

Note

We have left a gap in the sequence between data node IDs and other nodes. This make it easier later to assign node IDs that are not already in use to data nodes which are newly added.

We also assume that you have already started the cluster using the appropriate command line or `my.cnf` options, and that running `SHOW` in the management client produces output similar to what is shown here:

```
-- NDB Cluster -- Management Client --
db_mgm> SHOW
Connected to Management Server at: 198.51.100.10:1186
Cluster Configuration
---------------------
[ndbd(NDB)] 2 node(s)
id=1  @198.51.100.1 (8.0.22-ndb-8.0.22, Nodegroup: 0, *)
id=2  @198.51.100.2 (8.0.22-ndb-8.0.22, Nodegroup: 0)

[nbd_mgm(MGM)] 1 node(s)
id=10  @198.51.100.10 (8.0.22-ndb-8.0.22)

[mysqld(API)] 2 node(s)
id=20  @198.51.100.20 (8.0.22-ndb-8.0.22)
id=21  @198.51.100.21 (8.0.22-ndb-8.0.22)
```

Finally, we assume that the cluster contains a single `NDBCluster` table created as shown here:

```
USE n;
CREATE TABLE ips (
    id BIGINT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    country_code CHAR(2) NOT NULL,
    type CHAR(4) NOT NULL,
    ip_address VARCHAR(15) NOT NULL,
    addresses BIGINT UNSIGNED DEFAULT NULL,
    date BIGINT UNSIGNED DEFAULT NULL
) 
```
Adding NDB Cluster Data Nodes Online

The memory usage and related information shown later in this section was generated after inserting approximately 50000 rows into this table.

**Note**
In this example, we show the single-threaded `ndbd` being used for the data node processes. You can also apply this example, if you are using the multithreaded `ndbmtd` by substituting `ndbmtd` for `ndbd` wherever it appears in the steps that follow.

**Step 1: Update configuration file.** Open the cluster global configuration file in a text editor and add `ndbd` sections corresponding to the 2 new data nodes. (We give these data nodes IDs 3 and 4, and assume that they are to be run on host machines at addresses 198.51.100.3 and 198.51.100.4, respectively.) After you have added the new sections, the contents of the `config.ini` file should look like what is shown here, where the additions to the file are shown in bold type:

```
[nbdb default]
DataMemory = 100M
IndexMemory = 100M
NoOfReplicas = 2
DataDir = /usr/local/mysql/var/mysql-cluster

[nbdb]
Id = 1
HostName = 198.51.100.1

[nbdb]
Id = 2
HostName = 198.51.100.2

[nbdb]
Id = 3
HostName = 198.51.100.3

[nbdb]
Id = 4
HostName = 198.51.100.4

[mgm]
HostName = 198.51.100.10
Id = 10

[api]
Id=20
HostName = 198.51.100.20

[api]
Id=21
HostName = 198.51.100.21
```

Once you have made the necessary changes, save the file.

**Step 2: Restart the management server.** Restarting the cluster management server requires that you issue separate commands to stop the management server and then to start it again, as follows:

1. Stop the management server using the management client `STOP` command, as shown here:

```
ndb_mgm> 10 STOP
Node 10 has shut down.
Disconnecting to allow Management Server to shutdown
```
2. Because shutting down the management server causes the management client to terminate, you must start the management server from the system shell. For simplicity, we assume that `config.ini` is in the same directory as the management server binary, but in practice, you must supply the correct path to the configuration file. You must also supply the `--reload` or `--initial` option so that the management server reads the new configuration from the file rather than its configuration cache. If your shell's current directory is also the same as the directory where the management server binary is located, then you can invoke the management server as shown here:

```
shell> ndb_mgmd -f config.ini --reload
2008-12-08 17:29:23 [MgmSrvr] INFO     -- Reading cluster configuration from 'config.ini'
```

If you check the output of `SHOW` in the management client after restarting the `ndb_mgm` process, you should now see something like this:

```
-- NDB Cluster -- Management Client --
ndb_mgm> SHOW
Connected to Management Server at: 198.51.100.10:1186
Cluster Configuration
----------------------
[ndbd(NDB)]  2 node(s)
id=1  @198.51.100.1  (8.0.22-ndb-8.0.22, Nodegroup: 0, *)
id=2  @198.51.100.2  (8.0.22-ndb-8.0.22, Nodegroup: 0)
id=3 (not connected, accepting connect from 198.51.100.3)
id=4 (not connected, accepting connect from 198.51.100.4)

[ndb_mgmd(MGM)]  1 node(s)
id=10  @198.51.100.10  (8.0.22-ndb-8.0.22)

[mysqld(API)]  2 node(s)
id=20  @198.51.100.20  (8.0.22-ndb-8.0.22)
id=21  @198.51.100.21  (8.0.22-ndb-8.0.22)
```

**Step 3: Perform a rolling restart of the existing data nodes.**  
This step can be accomplished entirely within the cluster management client using the `RESTART` command, as shown here:

```
ndb_mgm> 1 RESTART
Node 1: Node shutdown initiated
Node 1: Node shutdown completed, restarting, no start.
Node 1 is being restarted

ndb_mgm> Node 1: Start initiated (version 8.0.22)
Node 1: Started (version 8.0.22)

ndb_mgm> 2 RESTART
Node 2: Node shutdown initiated
Node 2: Node shutdown completed, restarting, no start.
Node 2 is being restarted

ndb_mgm> Node 2: Start initiated (version 8.0.22)
ndb_mgm> Node 2: Started (version 8.0.22)
```

**Important**

After issuing each `X RESTART` command, wait until the management client reports `Node X: Started (version ...)` before proceeding any further.

You can verify that all existing data nodes were restarted using the updated configuration by checking the `ndbinfo.nodes` table in the `mysql` client.

**Step 4: Perform a rolling restart of all cluster API nodes.**  
Shut down and restart each MySQL server acting as an SQL node in the cluster using `mysqladmin shutdown` followed by `mysqld_safe` (or
Adding NDB Cluster Data Nodes Online

another startup script). This should be similar to what is shown here, where `password` is the MySQL root password for a given MySQL server instance:

```bash
shell> mysqladmin -uroot -p password shutdown
081208 20:19:56 mysqlld_safe mysqld from pid file
/usr/local/mysql/var/tonfisk.pid ended
shell> mysqld_safe --ndbcluster --ndb-connectstring=198.51.100.10 &
081208 20:20:06 mysqld_safe Logging to '/usr/local/mysql/var/tonfisk.err'.
081208 20:20:06 mysqld_safe Starting mysqld daemon with databases
from /usr/local/mysql/var
```

Of course, the exact input and output depend on how and where MySQL is installed on the system, as well as which options you choose to start it (and whether or not some or all of these options are specified in a `my.cnf` file).

**Step 5: Perform an initial start of the new data nodes.** From a system shell on each of the hosts for the new data nodes, start the data nodes as shown here, using the `--initial` option:

```bash
shell> ndbd -c 198.51.100.10 --initial
```

**Note**

Unlike the case with restarting the existing data nodes, you can start the new data nodes concurrently; you do not need to wait for one to finish starting before starting the other.

*Wait until both of the new data nodes have started before proceeding with the next step. Once the new data nodes have started, you can see in the output of the management client `SHOW` command that they do not yet belong to any node group (as indicated with bold type here):*

```javascript
ndb_mgm> SHOW
Connected to Management Server at: 198.51.100.10:1186
Cluster Configuration
---------------------
[ndbd(NDB)] 2 node(s)
id=1 @198.51.100.1 (8.0.22-ndb-8.0.22, Nodegroup: 0, *)
id=2 @198.51.100.2 (8.0.22-ndb-8.0.22, Nodegroup: 0)
id=3 @198.51.100.3 (8.0.22-ndb-8.0.22, no nodegroup)
id=4 @198.51.100.4 (8.0.22-ndb-8.0.22, no nodegroup)
[ndbd_mgmd(MGM)] 1 node(s)
id=10 @198.51.100.10 (8.0.22-ndb-8.0.22)
[mysqld(API)] 2 node(s)
id=20 @198.51.100.20 (8.0.22-ndb-8.0.22)
id=21 @198.51.100.21 (8.0.22-ndb-8.0.22)
```

**Step 6: Create a new node group.** You can do this by issuing a `CREATE NODEGROUP` command in the cluster management client. This command takes as its argument a comma-separated list of the node IDs of the data nodes to be included in the new node group, as shown here:

```bash
ndb_mgm> CREATE NODEGROUP 3,4
Nodegroup 1 created
```

By issuing `SHOW` again, you can verify that data nodes 3 and 4 have joined the new node group (again indicated in bold type):
Adding NDB Cluster Data Nodes Online

Step 7: Redistribute cluster data. When a node group is created, existing data and indexes are not automatically distributed to the new node group’s data nodes, as you can see by issuing the appropriate REPORT command in the management client:

```sql
ndb_mgm> ALL REPORT MEMORY
```

By using `ndb_desc` with the `-p` option, which causes the output to include partitioning information, you can see that the table still uses only 2 partitions (in the Per partition info section of the output, shown here in bold text):

```bash
shell> ndb_desc -c 198.51.100.10 -d ips -p
```

```
-- Attributes --
id Bigint PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY AUTO_INCR
country_code Char(2;latin1_swedish_ci) NOT NULL AT=FIXED ST=MEMORY
type Char(4;latin1_swedish_ci) NOT NULL AT=FIXED ST=MEMORY
ip_address Varchar(15;latin1_swedish_ci) NOT NULL AT=SHORT_VAR ST=MEMORY
addresses Bigunsigned NULL AT=FIXED ST=MEMORY
date Bigunsigned NULL AT=FIXED ST=MEMORY

-- Indexes --
PRIMARY KEY(id) - UniqueHashIndex
PRIMARY(id) - OrderedIndex

-- Per partition info --
Partition | Row count | Commit count | Frag fixed memory | Frag varsized memory
----------|-----------|--------------|-------------------|-------------------
0         | 26106     | 26106        | 1572864           | 557056
1         | 26329     | 26329        | 1605632           | 557056
```

NDBT_ProgramExit: 0 - OK
You can cause the data to be redistributed among all of the data nodes by performing, for each NDB table, an `ALTER TABLE ... ALGORITHM=INPLACE, REORGANIZE PARTITION` statement in the `mysql` client.

**Important**

`ALTER TABLE ... ALGORITHM=INPLACE, REORGANIZE PARTITION` does not work on tables that were created with the `MAX_ROWS` option. Instead, use `ALTER TABLE ... ALGORITHM=INPLACE, MAX_ROWS=...` to reorganize such tables.

Keep in mind that using `MAX_ROWS` to set the number of partitions per table is deprecated, and you should use `PARTITION_BALANCE` instead; see Section 13.1.20.10, “Setting NDB_TABLE Options”, for more information.

After issuing the statement `ALTER TABLE ips ALGORITHM=INPLACE, REORGANIZE PARTITION`, you can see using `ndb_desc` that the data for this table is now stored using 4 partitions, as shown here (with the relevant portions of the output in bold type):

```
shell> ndb_desc -c 198.51.100.10 -d n ips -p
-- ips --

<td>13093</td>
<td>819200</td>
<td>294912</td>
</tr>
</tbody>
</table>

NDBT_ProgramExit: 0 - OK
```

**Note**

Normally, `ALTER TABLE table_name [ALGORITHM=INPLACE,] REORGANIZE PARTITION` is used with a list of partition identifiers and a set of partition definitions to create a new partitioning scheme for a table that has already been explicitly partitioned. Its use here to redistribute data onto a new NDB Cluster node group is
Adding NDB Cluster Data Nodes Online

An exception in this regard; when used in this way, no other keywords or identifiers follow `REORGANIZE PARTITION`.

For more information, see Section 13.1.9, “ALTER TABLE Statement”.

In addition, for each table, the `ALTER TABLE` statement should be followed by an `OPTIMIZE TABLE` to reclaim wasted space. You can obtain a list of all NDBCLUSTER tables using the following query against the `INFORMATION_SCHEMA.TABLES` table:

```sql
SELECT TABLE_SCHEMA, TABLE_NAME
FROM INFORMATION_SCHEMA.TABLES
WHERE ENGINE = 'NDBCLUSTER';
```

**Note**

The `INFORMATION_SCHEMA.TABLES.ENGINE` value for an NDB Cluster table is always `NDBCLUSTER`, regardless of whether the `CREATE TABLE` statement used to create the table (or `ALTER TABLE` statement used to convert an existing table from a different storage engine) used `NDB` or `NDBCLUSTER` in its `ENGINE` option.

You can see after performing these statements in the output of `ALL REPORT MEMORY` that the data and indexes are now redistributed between all cluster data nodes, as shown here:

```
ndb_mgm> ALL REPORT MEMORY
Node 1: Data usage is 5%(176 32K pages of total 3200)
Node 1: Index usage is 0%(76 8K pages of total 12832)
Node 2: Data usage is 5%(176 32K pages of total 3200)
Node 2: Index usage is 0%(76 8K pages of total 12832)
Node 3: Data usage is 2%(80 32K pages of total 3200)
Node 3: Index usage is 0%(51 8K pages of total 12832)
Node 4: Data usage is 2%(80 32K pages of total 3200)
Node 4: Index usage is 0%(50 8K pages of total 12832)
```

**Note**

Since only one DDL operation on NDBCLUSTER tables can be executed at a time, you must wait for each `ALTER TABLE ... REORGANIZE PARTITION` statement to finish before issuing the next one.

It is not necessary to issue `ALTER TABLE ... REORGANIZE PARTITION` statements for NDBCLUSTER tables created after the new data nodes have been added; data added to such tables is distributed among all data nodes automatically. However, in NDBCLUSTER tables that existed prior to the addition of the new nodes, neither existing nor new data is distributed using the new nodes until these tables have been reorganized using `ALTER TABLE ... REORGANIZE PARTITION`.

**Alternative procedure, without rolling restart.**

It is possible to avoid the need for a rolling restart by configuring the extra data nodes, but not starting them, when first starting the cluster. We assume, as before, that you wish to start with two data nodes—nodes 1 and 2—in one node group and later to expand the cluster to four data nodes, by adding a second node group consisting of nodes 3 and 4:

```
[nbdb default]
DataMemory = 100M
IndexMemory = 100M
NoOfReplicas = 2
DataDir = /usr/local/mysql/var/mysql-cluster

[nbdb]
Id = 1
HostName = 198.51.100.1

[nbdb]
```
The data nodes to be brought online at a later time (nodes 3 and 4) can be configured with `NodeGroup = 65536`, in which case nodes 1 and 2 can each be started as shown here:

```
shell> ndbd -c 198.51.100.10 --initial
```

The data nodes configured with `NodeGroup = 65536` are treated by the management server as though you had started nodes 1 and 2 using `--nowait-nodes=3,4` after waiting for a period of time determined by the setting for the `StartNoNodeGroupTimeout` data node configuration parameter. By default, this is 15 seconds (15000 milliseconds).

**Note**

`StartNoNodeGroupTimeout` must be the same for all data nodes in the cluster; for this reason, you should always set it in the `[ndbd default]` section of the `config.ini` file, rather than for individual data nodes.

When you are ready to add the second node group, you need only perform the following additional steps:

1. Start data nodes 3 and 4, invoking the data node process once for each new node:

```
shell> ndbd -c 198.51.100.10 --initial
```

2. Issue the appropriate `CREATE NODEGROUP` command in the management client:

```
ndb_mgm> CREATE NODEGROUP 3,4
```

3. In the `mysql` client, issue `ALTER TABLE ... REORGANIZE PARTITION` and `OPTIMIZE TABLE` statements for each existing `NDBCLUSTER` table. (As noted elsewhere in this section, existing NDB Cluster tables cannot use the new nodes for data distribution until this has been done.)

### 22.5.8 Online Backup of NDB Cluster

The next few sections describe how to prepare for and then to create an NDB Cluster backup using the functionality for this purpose found in the `ndb_mgm` management client. To distinguish this type of backup from a backup made using `mysqldump`, we sometimes refer to it as a "native" NDB Cluster backup. (For information about the creation of backups with `mysqldump`, see Section 4.5.4, "mysqldump — A Database Backup Program"). Restoration of NDB Cluster backups is done using the `ndb_restore` utility.
provided with the NDB Cluster distribution; for information about `ndb_restore` and its use in restoring NDB Cluster backups, see Section 22.4.23, "ndb_restore — Restore an NDB Cluster Backup".

Starting with NDB 8.0.16, it is possible to create backups using multiple LDMs to achieve parallelism on the data nodes. See Section 22.5.8.5, "Taking an NDB Backup with Parallel Data Nodes".

### 22.5.8.1 NDB Cluster Backup Concepts

A backup is a snapshot of the database at a given time. The backup consists of three main parts:

- **Metadata.** The names and definitions of all database tables
- **Table records.** The data actually stored in the database tables at the time that the backup was made
- **Transaction log.** A sequential record telling how and when data was stored in the database

Each of these parts is saved on all nodes participating in the backup. During backup, each node saves these three parts into three files on disk:

- **BACKUP-`backup_id`.node_id.ctl**
  - A control file containing control information and metadata. Each node saves the same table definitions (for all tables in the cluster) to its own version of this file.

- **BACKUP-`backup_id`-0.node_id.data**
  - A data file containing the table records, which are saved on a per-fragment basis. That is, different nodes save different fragments during the backup. The file saved by each node starts with a header that states the tables to which the records belong. Following the list of records there is a footer containing a checksum for all records.

- **BACKUP-`backup_id`.node_id.log**
  - A log file containing records of committed transactions. Only transactions on tables stored in the backup are stored in the log. Nodes involved in the backup save different records because different nodes host different database fragments.

In the listing just shown, `backup_id` stands for the backup identifier and `node_id` is the unique identifier for the node creating the file.

The location of the backup files is determined by the `BackupDataDir` parameter.

### 22.5.8.2 Using The NDB Cluster Management Client to Create a Backup

Before starting a backup, make sure that the cluster is properly configured for performing one. (See Section 22.5.8.3, "Configuration for NDB Cluster Backups").

The `START BACKUP` command is used to create a backup:

```
START BACKUP [`backup_id`]
[encryption_option]
[wait_option]
[ snapshot_option]
```

**encryption_option:**

```
ENCRYPT PASSWORD=`password`
```

**password:**

```
{"password_string"} | "password_string"
```

**wait_option:**

```
Online Backup of NDB Cluster

**Wait Option**

 WAIT {STARTED | COMPLETED} | NOWAIT

**Snapshot Option**

 SNAPSHOTSTART | SNAPSHOTEND

Successive backups are automatically identified sequentially, so the `backup_id`, an integer greater than or equal to 1, is optional; if it is omitted, the next available value is used. If an existing `backup_id` value is used, the backup fails with the error *Backup failed: file already exists*. If used, the `backup_id` must follow *START BACKUP* immediately, before any other options are used.

NDB 8.0.22 and later supports the creation of encrypted backups using `ENCRIPT PASSWORD=password`; the `password` must meet all of the following requirements:

- Uses any of the printable ASCII characters except !, ', " , $, %, \ , and ^
- Is no more than 256 characters in length
- Is enclosed by single or double quotation marks

It is possible to use an empty password ("" or ""), but this is not recommended.

An encrypted backup can be decrypted using any of the following commands:

- `ndb_restore --decrypt --backup-password=password`
- `ndbxfrm --decrypt-password=password input_file output_file`
- `ndb_print_backup_file -P password file_name`

See the descriptions of these programs for more information, such as additional options that may be required.

The `wait_option` can be used to determine when control is returned to the management client after a *START BACKUP* command is issued, as shown in the following list:

- If *NOWAIT* is specified, the management client displays a prompt immediately, as seen here:

  ```
  ndb_mgm> START BACKUP NOWAIT
  ndb_mgm>
  ```

  In this case, the management client can be used even while it prints progress information from the backup process.

- With *WAIT STARTED* the management client waits until the backup has started before returning control to the user, as shown here:

  ```
  ndb_mgm> START BACKUP WAIT STARTED
  Waiting for started, this may take several minutes
  Node 2: Backup 3 started from node 1
  ndb_mgm>
  ```

- **WAIT COMPLETED** causes the management client to wait until the backup process is complete before returning control to the user.

  **WAIT COMPLETED** is the default.

A `snapshot_option` can be used to determine whether the backup matches the state of the cluster when *START BACKUP* was issued, or when it was completed. `SNAPSHOTSTART` causes the backup to match the state of the cluster when the backup began; `SNAPSHOTEND` causes the backup to reflect the state of the cluster when the backup was finished. `SNAPSHOTEND` is the default, and matches the behavior found in previous NDB Cluster releases.
Online Backup of NDB Cluster

Note

If you use the `SNAPSHOTSTART` option with `START BACKUP`, and the `CompressedBackup` parameter is enabled, only the data and control files are compressed—the log file is not compressed.

If both a `wait_option` and a `snapshot_option` are used, they may be specified in either order. For example, all of the following commands are valid, assuming that there is no existing backup having 4 as its ID:

```
START BACKUP WAIT STARTED SNAPSHOTSTART
START BACKUP SNAPSHOTSTART WAIT STARTED
START BACKUP 4 WAIT COMPLETED SNAPSHOTSTART
START BACKUP SNAPSHOTEND WAIT COMPLETED
START BACKUP 4 NOWAIT SNAPSHOTSTART
```

The procedure for creating a backup consists of the following steps:

1. Execute the `START BACKUP` command. This produces several lines of output indicating the progress of the backup, as shown here:

   ```
   ndb_mgm> START BACKUP
   Waiting for completed, this may take several minutes
   Node 2: Backup 1 started from node 1
   Node 2: Backup 1 started from node 1 completed
   StartGCP: 177 StopGCP: 180
   #Records: 7362 #LogRecords: 0
   Data: 453648 bytes Log: 0 bytes
   ndb_mgm>
   ```

2. When the backup has started the management client displays this message:

   ```
   Backup backup_id started from node node_id
   ```

   `backup_id` is the unique identifier for this particular backup. This identifier is saved in the cluster log, if it has not been configured otherwise. `node_id` is the identifier of the management server that is coordinating the backup with the data nodes. At this point in the backup process the cluster has received and processed the backup request. It does not mean that the backup has finished. An example of this statement is shown here:

   ```
   Node 2: Backup 1 started from node 1
   ```

3. The management client indicates with a message like this one that the backup has started:

   ```
   Backup backup_id started from node node_id completed
   ```

   As is the case for the notification that the backup has started, `backup_id` is the unique identifier for this particular backup, and `node_id` is the node ID of the management server that is coordinating the backup with the data nodes. This output is accompanied by additional information including relevant global checkpoints, the number of records backed up, and the size of the data, as shown here:

   ```
   Node 2: Backup 1 started from node 1 completed
   StartGCP: 177 StopGCP: 180
   #Records: 7362 #LogRecords: 0
   Data: 453648 bytes Log: 0 bytes
   ndb_mgm>
   ```

4. It is also possible to perform a backup from the system shell by invoking `ndb_mgm` with the `-e` or `--execute` option, as shown in this example:

   ```
   shell> ndb_mgm -e "START BACKUP 6 WAIT COMPLETED SNAPSHOTSTART"
   ```
When using `START BACKUP` in this way, you must specify the backup ID.

Cluster backups are created by default in the `BACKUP` subdirectory of the `DataDir` on each data node. This can be overridden for one or more data nodes individually, or for all cluster data nodes in the `config.ini` file using the `BackupDataDir` configuration parameter. The backup files created for a backup with a given `backup_id` are stored in a subdirectory named `BACKUP-backup_id` in the backup directory.

**Cancelling backups.** To cancel or abort a backup that is already in progress, perform the following steps:

1. Start the management client.
2. Execute this command:

   ```
   ndb_mgm> ABORT BACKUP backup_id
   ```

   The number `backup_id` is the identifier of the backup that was included in the response of the management client when the backup was started (in the message `Backup backup_id started from node management_node_id`).

3. The management client acknowledges the abort request with `Abort of backup backup_id ordered`.

   **Note**

   At this point, the management client has not yet received a response from the cluster data nodes to this request, and the backup has not yet actually been aborted.

4. After the backup has been aborted, the management client reports this fact in a manner similar to what is shown here:

   ```
   Node 1: Backup 3 started from 5 has been aborted.
   Error: 1321 - Backup aborted by user request: Permanent error: User defined error
   Node 3: Backup 3 started from 5 has been aborted.
   Error: 1323 - 1323: Permanent error: Internal error
   Node 2: Backup 3 started from 5 has been aborted.
   Error: 1323 - 1323: Permanent error: Internal error
   Node 4: Backup 3 started from 5 has been aborted.
   Error: 1323 - 1323: Permanent error: Internal error
   ```

   In this example, we have shown sample output for a cluster with 4 data nodes, where the sequence number of the backup to be aborted is `3`, and the management node to which the cluster management client is connected has the node ID `5`. The first node to complete its part in aborting the backup reports that the reason for the abort was due to a request by the user. (The remaining nodes report that the backup was aborted due to an unspecified internal error.)

   **Note**

   There is no guarantee that the cluster nodes respond to an `ABORT BACKUP` command in any particular order.

   The `Backup backup_id started from node management_node_id has been aborted` messages mean that the backup has been terminated and that all files relating to this backup have been removed from the cluster file system.

It is also possible to abort a backup in progress from a system shell using this command:

```shell
shell> ndb_mgm --e "ABORT BACKUP backup_id"
```
Online Backup of NDB Cluster

22.5.8.3 Configuration for NDB Cluster Backups

Five configuration parameters are essential for backup:

- **BackupDataBufferSize**
  The amount of memory used to buffer data before it is written to disk.

- **BackupLogBufferSize**
  The amount of memory used to buffer log records before these are written to disk.

- **BackupMemory**
  The total memory allocated in a data node for backups. This should be the sum of the memory allocated for the backup data buffer and the backup log buffer.

- **BackupWriteSize**
  The default size of blocks written to disk. This applies for both the backup data buffer and the backup log buffer.

- **BackupMaxWriteSize**
  The maximum size of blocks written to disk. This applies for both the backup data buffer and the backup log buffer.

In addition, **CompressedBackup** causes **NDB** to use compression when creating and writing to backup files.

More detailed information about these parameters can be found in Backup Parameters.

You can also set a location for the backup files using the **BackupDataDir** configuration parameter. The default is **FileSystemPath /BACKUP/BACKUP-backup_id**.

In NDB 8.0.22 and later, you can enforce encryption of backup files by enabling **RequireEncryptedBackup**. When this parameter is set to 1, backups cannot be created without specifying **ENCRYPT PASSWORD=password** as part of a **START BACKUP** command.

22.5.8.4 NDB Cluster Backup Troubleshooting

If an error code is returned when issuing a backup request, the most likely cause is insufficient memory or disk space. You should check that there is enough memory allocated for the backup.

**Important**

If you have set **BackupDataBufferSize** and **BackupLogBufferSize** and their sum is greater than 4MB, then you must also set **BackupMemory** as well.

You should also make sure that there is sufficient space on the hard drive partition of the backup target.

**NDB** does not support repeatable reads, which can cause problems with the restoration process. Although the backup process is “hot”, restoring an NDB Cluster from backup is not a 100% “hot” process. This is due
to the fact that, for the duration of the restore process, running transactions get nonrepeatable reads from the restored data. This means that the state of the data is inconsistent while the restore is in progress.

### 22.5.8.5 Taking an NDB Backup with Parallel Data Nodes

Beginning with NDB 8.0.16, it is possible to take a backup with multiple local data managers (LDMs) acting in parallel on the data nodes. For this to work, all data nodes in the cluster must use multiple LDMs, and each data node must use the same number of LDMs. This means that all data nodes must run ndbmtd (`ndbd` is single-threaded and thus always has only one LDM) and they must be configured to use multiple LDMs before taking the backup; ndbmtd by default runs in single-threaded mode. You can cause them to use multiple LDMs this by choosing an appropriate setting for one of the multi-threaded data node configuration parameters `MaxNoOfExecutionThreads` or `ThreadConfig`. Keep in mind that changing these parameters requires a restart of the cluster; this can be a rolling restart.

Depending on the number of LDMs and other factors, you may also need to increase `NoOfFragmentLogParts`. If you are using large Disk Data tables, you may also need to increase `DiskPageBufferMemory`. As with single-threaded backups, you also want or need to make adjustments to settings for `BackupDataBufferSize`, `BackupMemory`, and other configuration parameters relating to backups (see Backup parameters).

Once all data nodes are using multiple LDMs, you can take the parallel backup using the `START BACKUP` command in the NDB management client just as you would if the data nodes were running `ndbd` (or `ndbmtd` in single-threaded mode); no additional or special syntax is required, and you can specify a backup ID, wait option, or snapshot option in any combination as needed or desired.

Backups using multiple LDMs create subdirectories, one per LDM, under the directory `BACKUP/BACKUP-`\{backup_id\}/ (which in turn resides under the `BackupDataDir`) on each data node; these subdirectories are named `BACKUP-backup_id-PART-1-OF-N/`, `BACKUP-backup_id-PART-2-OF-N/`, and so on, up to `BACKUP-backup_id-PART-N-OF-N/`, where `backup_id` is the backup ID used for this backup and `N` is the number of LDMs per data node. Each of these subdirectories contains the usual backup files `BACKUP-backup_id-node_id.Data`, `BACKUP-backup_id.node_id.ctl`, and `BACKUP-backup_id.node_id.log`, where `node_id` is the node ID of this data node.

In NDB 8.0.16 and later, `ndb_restore` automatically checks for the presence of the subdirectories just described; if it finds them, it attempts to restore the backup in parallel. For information about restoring backups taken with multiple LDMs, see Section 22.4.23.2, “Restoring from a backup taken in parallel”.

### 22.5.9 MySQL Server Usage for NDB Cluster

`mysqld` is the traditional MySQL server process. To be used with NDB Cluster, `mysqld` needs to be built with support for the NDB storage engine, as it is in the precompiled binaries available from [https://dev.mysql.com/downloads/](https://dev.mysql.com/downloads/). If you build MySQL from source, you must invoke `CMake` with the `-DWITH_NDBCLUSTER=1` option to include support for NDB.

For more information about compiling NDB Cluster from source, see Section 22.2.1.4, “Building NDB Cluster from Source on Linux”, and Section 22.2.2.2, “Compiling and Installing NDB Cluster from Source on Windows”.

(For information about `mysqld` options and variables, in addition to those discussed in this section, which are relevant to NDB Cluster, see Section 22.3.3.9, “MySQL Server Options and Variables for NDB Cluster”.)

If the `mysqld` binary has been built with Cluster support, the `NDBCLUSTER` storage engine is still disabled by default. You can use either of two possible options to enable this engine:

- Use `--ndbcluster` as a startup option on the command line when starting `mysqld`.
• Insert a line containing ndbcluster in the [mysqld] section of your my.cnf file.

An easy way to verify that your server is running with the NDBCLUSTER storage engine enabled is to issue the SHOW ENGINES statement in the MySQL Monitor (mysql). You should see the value YES as the Support value in the row for NDBCLUSTER. If you see NO in this row or if there is no such row displayed in the output, you are not running an NDB-enabled version of MySQL. If you see DISABLED in this row, you need to enable it in either one of the two ways just described.

To read cluster configuration data, the MySQL server requires at a minimum three pieces of information:

• The MySQL server's own cluster node ID
• The host name or IP address for the management server
• The number of the TCP/IP port on which it can connect to the management server

Node IDs can be allocated dynamically, so it is not strictly necessary to specify them explicitly.

The mysqld parameter ndb-connectstring is used to specify the connection string either on the command line when starting mysqld or in my.cnf. The connection string contains the host name or IP address where the management server can be found, as well as the TCP/IP port it uses.

In the following example, ndb_mgmd.mysql.com is the host where the management server resides, and the management server listens for cluster messages on port 1186:

shell> mysqld --ndbcluster --ndb-connectstring=ndb_mgmd.mysql.com:1186

See Section 22.3.3.3, “NDB Cluster Connection Strings”, for more information on connection strings.

Given this information, the MySQL server can act as a full participant in the cluster. (We often refer to a mysqld process running in this manner as an SQL node.) It is fully aware of all cluster data nodes as well as their status, and establishes connections to all data nodes. In this case, it is able to use any data node as a transaction coordinator and to read and update node data.

You can see in the mysql client whether a MySQL server is connected to the cluster using SHOW PROCESSLIST. If the MySQL server is connected to the cluster, and you have the PROCESS privilege, then the first row of the output is as shown here:

mysql> SHOW PROCESSLIST \G
*************************** 1. row ***************************
     Id: 1
   User: system user
    Host: 
db: 
   Command: Daemon
    Time: 1
   State: Waiting for event from ndbcluster
   Info: NULL

Important

To participate in an NDB Cluster, the mysqld process must be started with both the options --ndbcluster and --ndb-connectstring (or their equivalents in my.cnf). If mysqld is started with only the --ndbcluster option, or if it is unable to contact the cluster, it is not possible to work with NDB tables, nor is it possible to create any new tables regardless of storage engine. The latter restriction is a safety measure intended to prevent the creation of tables having the same names as NDB tables while the SQL node is not connected to the cluster. If you wish to create tables using a different storage engine while the mysqld process is not participating in an NDB Cluster, you must restart the server without the --ndbcluster option.
22.5.10 NDB Cluster Disk Data Tables

NDB Cluster supports storing nonindexed columns of NDB tables on disk, rather than in RAM. Column data and logging metadata are kept in data files and undo log files, conceptualized as tablespaces and log file groups, as described in the next section—see Section 22.5.10.1, “NDB Cluster Disk Data Objects”.

NDB Cluster Disk Data performance can be influenced by a number of configuration parameters. For information about these parameters and their effects, see Disk Data Configuration Parameters, and Disk Data and GCP Stop errors.

Beginning with NDB 8.0.19, you should also set the DiskDataUsingSameDisk data node configuration parameter to false when using separate disks for Disk Data files.

See also Disk Data file system parameters.

NDB 8.0.19 (and later) provides improved support when using Disk Data tables with solid-state drives, in particular those using NVMe. See the following documentation for more information:

- Disk Data latency parameters
- Section 22.5.14.21, “The ndbinfo diskstat Table”
- Section 22.5.14.22, “The ndbinfo diskstats_1sec Table”
- Section 22.5.14.32, “The ndbinfo pgman_time_track_stats Table”

22.5.10.1 NDB Cluster Disk Data Objects

NDB Cluster Disk Data storage is implemented using the following objects:

- **Tablespace**: Acts as containers for other Disk Data objects. A tablespace contains one or more data files and one or more undo log file groups.

- **Data file**: Stores column data. A data file is assigned directly to a tablespace.

- **Undo log file**: Contains undo information required for rolling back transactions. Assigned to an undo log file group.

- **log file group**: Contains one or more undo log files. Assigned to a tablespace.

Undo log files and data files are actual files in the file system of each data node; by default they are placed in ndb_node_id_fs in the DataDir specified in the NDB Cluster config.ini file, and where node_id is the data node’s node ID. It is possible to place these elsewhere by specifying either an absolute or relative path as part of the filename when creating the undo log or data file. Statements that create these files are shown later in this section.

Undo log files are used only by Disk Data tables, and are not needed or used by NDB tables that are stored in memory only.

NDB Cluster tablespaces and log file groups are not implemented as files.

Although not all Disk Data objects are implemented as files, they all share the same namespace. This means that each Disk Data object must be uniquely named (and not merely each Disk Data object of a given type). For example, you cannot have a tablespace and a log file group both named dd1.

Assuming that you have already set up an NDB Cluster with all nodes (including management and SQL nodes), the basic steps for creating an NDB Cluster table on disk are as follows:
1. Create a log file group, and assign one or more undo log files to it (an undo log file is also sometimes referred to as an undofile).

2. Create a tablespace; assign the log file group, as well as one or more data files, to the tablespace.

3. Create a Disk Data table that uses this tablespace for data storage.

Each of these tasks can be accomplished using SQL statements in the mysql client or other MySQL client application, as shown in the example that follows.

1. We create a log file group named **lg_1** using **CREATE LOGFILE GROUP**. This log file group is to be made up of two undo log files, which we name **undo_1.log** and **undo_2.log**, whose initial sizes are 16 MB and 12 MB, respectively. (The default initial size for an undo log file is 128 MB.) Optionally, you can also specify a size for the log file group's undo buffer, or permit it to assume the default value of 8 MB. In this example, we set the UNDO buffer's size at 2 MB. A log file group must be created with an undo log file; so we add **undo_1.log** to **lg_1** in this CREATE LOGFILE GROUP statement:

```sql
CREATE LOGFILE GROUP lg_1
  ADD UNDOFILE 'undo_1.log'
  INITIAL_SIZE 16M
  UNDO_BUFFER_SIZE 2M
  ENGINE NDBCLUSTER;
```

To add **undo_2.log** to the log file group, use the following **ALTER LOGFILE GROUP** statement:

```sql
ALTER LOGFILE GROUP lg_1
  ADD UNDOFILE 'undo_2.log'
  INITIAL_SIZE 12M
  ENGINE NDBCLUSTER;
```

Some items of note:

- The .log file extension used here is not required. We employ it merely to make the log files easily recognizable.

- Every **CREATE LOGFILE GROUP** and **ALTER LOGFILE GROUP** statement must include an ENGINE option. The only permitted values for this option are NDBCLUSTER and NDB.

**Important**

There can exist at most one log file group in the same NDB Cluster at any given time.

- When you add an undo log file to a log file group using **ADD UNDOFILE 'filename'**, a file with the name **filename** is created in the **ndb_node_id_fs** directory within the **DataDir** of each data node in the cluster, where **node_id** is the node ID of the data node. Each undo log file is of the size specified in the SQL statement. For example, if an NDB Cluster has 4 data nodes, then the **ALTER LOGFILE GROUP** statement just shown creates 4 undo log files, 1 each on in the data directory of each of the 4 data nodes; each of these files is named **undo_2.log** and each file is 12 MB in size.

- **UNDO_BUFFER_SIZE** is limited by the amount of system memory available.

- See Section 13.1.16, “CREATE LOGFILE GROUP Statement”, and Section 13.1.6, “ALTER LOGFILE GROUP Statement”, for more information about these statements.

2. Now we can create a tablescape—an abstract container for files used by Disk Data tables to store data. A tablespace is associated with a particular log file group; when creating a new tablespace, you must specify the log file group it uses for undo logging. You must also specify at least one data file; you
can add more data files to the tablespace after the tablespace is created. It is also possible to drop data files from a tablespace (see example later in this section).

Assume that we wish to create a tablespace named ts_1 which uses lg_1 as its log file group. We want the tablespace to contain two data files, named data_1.dat and data_2.dat, whose initial sizes are 32 MB and 48 MB, respectively. (The default value for INITIAL_SIZE is 128 MB.) We can do this using two SQL statements, as shown here:

```sql
CREATE TABLESPACE ts_1
  ADD DATAFILE 'data_1.dat'
  USE LOGFILE GROUP lg_1
  INITIAL_SIZE 32M
  ENGINE NDBCLUSTER;

ALTER TABLESPACE ts_1
  ADD DATAFILE 'data_2.dat'
  INITIAL_SIZE 48M;
```

The `CREATE TABLESPACE` statement creates a tablespace ts_1 with the data file data_1.dat, and associates ts_1 with log file group lg_1. The `ALTER TABLESPACE` adds the second data file (data_2.dat).

Some items of note:

- As is the case with the `.log` file extension used in this example for undo log files, there is no special significance for the `.dat` file extension; it is used merely for easy recognition.

- When you add a data file to a tablespace using `ADD DATAFILE 'filename'`, a file with the name `filename` is created in the `ndb_node_id_fs` directory within the `DataDir` of each data node in the cluster, where `node_id` is the node ID of the data node. Each data file is of the size specified in the SQL statement. For example, if an NDB Cluster has 4 data nodes, then the `ALTER TABLESPACE` statement just shown creates 4 data files, 1 each in the data directory of each of the 4 data nodes; each of these files is named `data_2.dat` and each file is 48 MB in size.

- **NDB** reserves 4% of each tablespace for use during data node restarts. This space is not available for storing data.

- `CREATE TABLESPACE` statements must contain an `ENGINE` clause; only tables using the same storage engine as the tablespace can be created in the tablespace. For `ALTER TABLESPACE`, an `ENGINE` clause is accepted but is deprecated and subject to removal in a future release. For NDB tablespaces, the only permitted values for this option are `NDBCLUSTER` and `NDB`.

- In NDB 8.0.20 and later, allocation of extents is performed in round-robin fashion among all data files used by a given tablespace.

- For more information about the `CREATE TABLESPACE` and `ALTER TABLESPACE` statements, see Section 13.1.21, “CREATE TABLESPACE Statement”, and Section 13.1.10, “ALTER TABLESPACE Statement”.

3. Now it is possible to create a table whose unindexed columns are stored on disk using files in tablespace ts_1:

```sql
CREATE TABLE dt_1 (
  member_id INT UNSIGNED NOT NULL AUTO_INCREMENT PRIMARY KEY,
  last_name VARCHAR(50) NOT NULL,
  first_name VARCHAR(50) NOT NULL,
  dob DATE NOT NULL,
  joined DATE NOT NULL,
  INDEX(last_name, first_name)
)
```
TABLESPACE ts_1 STORAGE DISK ENGINE NDBCLUSTER;

TABLESPACE ts_1 STORAGE DISK tells the NDB storage engine to use tablespace ts_1 for data storage on disk.

Once table ts_1 has been created as shown, you can perform INSERT, SELECT, UPDATE, and DELETE statements on it just as you would with any other MySQL table.

It is also possible to specify whether an individual column is stored on disk or in memory by using a STORAGE clause as part of the column's definition in a CREATE TABLE or ALTER TABLE statement. STORAGE DISK causes the column to be stored on disk, and STORAGE MEMORY causes in-memory storage to be used. See Section 13.1.20, “CREATE TABLE Statement”, for more information.

You can obtain information about the NDB disk data files and undo log files just created by querying the FILES table in the INFORMATION_SCHEMA database, as shown here:

```
mysql> SELECT
    -> FILE_NAME AS File, FILE_TYPE AS Type,
    -> TABLESPACE_NAME AS Tablespace, TABLE_NAME AS Name,
    -> LOGFILE_GROUP_NAME AS 'File group',
    -> FREE_EXTENTS AS Free, TOTAL_EXTENTS AS Total
    -> FROM INFORMATION_SCHEMA.FILES
    -> WHERE ENGINE='ndbcluster';
```

```
+--------------+----------+------------+------+------------+------+---------+
| File         | Type     | Tablespace | Name | File group | Free | Total   |
+--------------+----------+------------+------+------------+------+---------+
| ./undo_1.log | UNDO LOG | lg_1       | NULL | lg_1       |    0 | 4194304 |
| ./undo_2.log | UNDO LOG | lg_1       | NULL | lg_1       |    0 | 3145728 |
| ./data_1.dat | DATAFILE | ts_1       | NULL | lg_1       |   32 |      32 |
| ./data_2.dat | DATAFILE | ts_1       | NULL | lg_1       |   48 |      48 |
+--------------+----------+------------+------+------------+------+---------+
4 rows in set (0.00 sec)
```

For more information and examples, see Section 25.15, “The INFORMATION_SCHEMA FILES Table”.

Indexing of columns implicitly stored on disk. For table dt_1 as defined in the example just shown, only the dob and joined columns are stored on disk. This is because there are indexes on the id, last_name, and first_name columns, and so data belonging to these columns is stored in RAM. Only nonindexed columns can be held on disk; indexes and indexed column data continue to be stored in memory. This tradeoff between the use of indexes and conservation of RAM is something you must keep in mind as you design Disk Data tables.

You cannot add an index to a column that has been explicitly declared STORAGE DISK, without first changing its storage type to MEMORY; any attempt to do so fails with an error. A column which implicitly uses disk storage can be indexed; when this is done, the column's storage type is changed to MEMORY automatically. By “implicitly”, we mean a column whose storage type is not declared, but which is which inherited from the parent table. In the following CREATE TABLE statement (using the tablespace ts_1 defined previously), columns c2 and c3 use disk storage implicitly:

```
mysql> CREATE TABLE ti {
    -> c1 INT PRIMARY KEY,
    -> c2 INT,
    -> c3 INT,
    -> c4 INT
    -> }
    -> STORAGE DISK
    -> TABLESPACE ts_1
    -> ENGINE NDBCLUSTER;
```

Query OK, 0 rows affected (1.31 sec)
Because \(c_2\), \(c_3\), and \(c_4\) are themselves not declared with \texttt{STORAGE DISK}, it is possible to index them. Here, we add indexes to \(c_2\) and \(c_3\), using, respectively, \texttt{CREATE Index} and \texttt{ALTER TABLE}:

```sql
mysql> CREATE INDEX i1 ON ti(c2);
Query OK, 0 rows affected (2.72 sec)
Records: 0  Duplicates: 0  Warnings: 0

mysql> ALTER TABLE ti ADD INDEX i2(c3);
Query OK, 0 rows affected (0.92 sec)
Records: 0  Duplicates: 0  Warnings: 0
```

\texttt{SHOW CREATE TABLE} confirms that the indexes were added.

```sql
mysql> SHOW CREATE TABLE ti\G
*************************** 1. row ***************************
Table: ti
Create Table: CREATE TABLE `ti` (
  `c1` int(11) NOT NULL,
  `c2` int(11) DEFAULT NULL,
  `c3` int(11) DEFAULT NULL,
  `c4` int(11) DEFAULT NULL,
  PRIMARY KEY (`c1`),
  KEY `i1` (`c2`),
  KEY `i2` (`c3`)
) /*!50100 TABLESPACE `ts_1` STORAGE DISK */ ENGINE=ndbcluster DEFAULT CHARSET=latin1
1 row in set (0.00 sec)
```

You can see using \texttt{ndb_desc} that the indexed columns (emphasized text) now use in-memory rather than on-disk storage:

```bash
shell> ./ndb_desc -d test t1
-- t1 --
Version: 33554433

c1 Int PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY
c2 Int NULL AT=FIXED ST=MEMORY
c3 Int NULL AT=FIXED ST=MEMORY
c4 Int NULL AT=FIXED ST=DISK
-- Indexes --
  PRIMARY KEY(c1) - UniqueHashIndex
  i2(c3) - OrderedIndex
  PRIMARY(c1) - OrderedIndex
  i1(c2) - OrderedIndex
NDBT_ProgramExit: 0 - OK
```
**Performance note.** The performance of a cluster using Disk Data storage is greatly improved if Disk Data files are kept on a separate physical disk from the data node file system. This must be done for each data node in the cluster to derive any noticeable benefit.

You can use absolute and relative file system paths with `ADD UNDOFILE` and `ADD DATAFILE`; relative paths are calculated with respect to the data node’s data directory.

A log file group, a tablespace, and any Disk Data tables using these must be created in a particular order. This is also true for dropping these objects, subject to the following constraints:

- A log file group cannot be dropped as long as any tablespaces use it.
- A tablespace cannot be dropped as long as it contains any data files.
- You cannot drop any data files from a tablespace as long as there remain any tables which are using the tablespace.
- It is not possible to drop files created in association with a different tablespace other than the one with which the files were created.

For example, to drop all the objects created so far in this section, you can use the following statements:

```sql
mysql> DROP TABLE dt_1;
mysql> ALTER TABLESPACE ts_1
   -> DROP DATAFILE 'data_2.dat'
   -> ENGINE NDBCLUSTER;
mysql> ALTER TABLESPACE ts_1
   -> DROP DATAFILE 'data_1.dat'
   -> ENGINE NDBCLUSTER;
mysql> DROP TABLESPACE ts_1
   -> ENGINE NDBCLUSTER;
mysql> DROP LOGFILE GROUP lg_1
   -> ENGINE NDBCLUSTER;
```

These statements must be performed in the order shown, except that the two `ALTER TABLESPACE ... DROP DATAFILE` statements may be executed in either order.

### 22.5.10.2 NDB Cluster Disk Data Storage Requirements

The following items apply to Disk Data storage requirements:

- Variable-length columns of Disk Data tables take up a fixed amount of space. For each row, this is equal to the space required to store the largest possible value for that column.

For general information about calculating these values, see Section 11.7, “Data Type Storage Requirements”.

You can obtain an estimate the amount of space available in data files and undo log files by querying the `INFORMATION_SCHEMA.FILES` table. For more information and examples, see Section 25.15, “The INFORMATION_SCHEMA FILES Table”.

**Note**

The `OPTIMIZE TABLE` statement does not have any effect on Disk Data tables.

- In a Disk Data table, the first 256 bytes of a `TEXT` or `BLOB` column are stored in memory; only the remainder is stored on disk.
Each row in a Disk Data table uses 8 bytes in memory to point to the data stored on disk. This means that, in some cases, converting an in-memory column to the disk-based format can actually result in greater memory usage. For example, converting a `CHAR(4)` column from memory-based to disk-based format increases the amount of `DataMemory` used per row from 4 to 8 bytes.

**Important**

Starting the cluster with the `--initial` option does not remove Disk Data files. You must remove these manually prior to performing an initial restart of the cluster.

Performance of Disk Data tables can be improved by minimizing the number of disk seeks by making sure that `DiskPageBufferMemory` is of sufficient size. You can query the `diskpagebuffer` table to help determine whether the value for this parameter needs to be increased.

### 22.5.11 Online Operations with ALTER TABLE in NDB Cluster

MySQL NDB Cluster 8.0 supports online table schema changes using the standard `ALTER TABLE` syntax employed by the MySQL Server (`ALGORITHM=DEFAULT|INPLACE|COPY`), and described elsewhere.

**Note**

Some older releases of NDB Cluster used a syntax specific to NDB for online `ALTER TABLE` operations. That syntax has since been removed.

Operations that add and drop indexes on variable-width columns of NDB tables occur online. Online operations are noncopying; that is, they do not require that indexes be re-created. They do not lock the table being altered from access by other API nodes in an NDB Cluster (but see Limitations of NDB online operations, later in this section). Such operations do not require single user mode for NDB table alterations made in an NDB cluster with multiple API nodes; transactions can continue uninterrupted during online DDL operations.

`ALGORITHM=INPLACE` can be used to perform online `ADD COLUMN`, `ADD INDEX` (including `CREATE INDEX` statements), and `DROP INDEX` operations on NDB tables. Online renaming of NDB tables is also supported.

Previously, columns of NDB tables could not be renamed online; this limitation is removed in NDB 8.0.18.

Currently you cannot add disk-based columns to NDB tables online. This means that, if you wish to add an in-memory column to an NDB table that uses a table-level `STORAGE DISK` option, you must declare the new column as using memory-based storage explicitly. For example—assuming that you have already created tablespace `ts1`—suppose that you create table `t1` as follows:

```sql
mysql> CREATE TABLE t1 (  
  >   c1 INT NOT NULL PRIMARY KEY,  
  >   c2 VARCHAR(30)  
  > )  
  >   TABLESPACE ts1 STORAGE DISK  
  >   ENGINE NDB;
Query OK, 0 rows affected (1.73 sec)
Records: 0  Duplicates: 0  Warnings: 0
```

You can add a new in-memory column to this table online as shown here:

```sql
mysql> ALTER TABLE t1  
  >   ADD COLUMN c3 INT COLUMN_FORMAT DYNAMIC STORAGE MEMORY,  
  >   ALGORITHM=INPLACE;
Query OK, 0 rows affected (1.25 sec)
Records: 0  Duplicates: 0  Warnings: 0
```

This statement fails if the `STORAGE MEMORY` option is omitted:
Online Operations with ALTER TABLE in NDB Cluster

mysql> ALTER TABLE t1
    > ADD COLUMN c4 INT COLUMN_FORMAT DYNAMIC,
    > ALGORITHM=INPLACE;
ERROR 1846 (0A000): ALGORITHM=INPLACE is not supported. Reason:
Adding column(s) or add/reorganize partition not supported online. Try
ALGORITHM=COPY.

If you omit the COLUMN_FORMAT DYNAMIC option, the dynamic column format is employed automatically, but a warning is issued, as shown here:

mysql> ALTER ONLINE TABLE t1 ADD COLUMN c4 INT STORAGE MEMORY;
Query OK, 0 rows affected, 1 warning (1.17 sec)
Records: 0  Duplicates: 0  Warnings: 0

mysql> SHOW WARNINGS\G
*************************** 1. row ***************************
  Level: Warning
  Code: 1478
  Message: DYNAMIC column c4 with STORAGE DISK is not supported, column will
  become FIXED

mysql> SHOW CREATE TABLE t1\G
*************************** 1. row ****************************
  Table: t1
Create Table: CREATE TABLE `t1` (  
  `c1` int(11) NOT NULL,
  `c2` varchar(30) DEFAULT NULL,
  `c3` int(11) /*!50606 STORAGE MEMORY */ /*!50606 COLUMN_FORMAT DYNAMIC */,/!
  DEFAULT NULL,
  `c4` int(11) /*!50606 STORAGE MEMORY */ DEFAULT NULL,
  PRIMARY KEY (`c1`)  
) /*!50606 TABLESPACE ts_1 STORAGE DISK */ ENGINE=ndbcluster DEFAULT CHARSET=latin1

Note

The STORAGE and COLUMN_FORMAT keywords are supported only in NDB Cluster; in any other version of MySQL, attempting to use either of these keywords in a CREATE TABLE or ALTER TABLE statement results in an error.

It is also possible to use the statement ALTER TABLE ... REORGANIZE PARTITION, ALGORITHM=INPLACE with no partition_names INTO (partition_definitions) option on NDB tables. This can be used to redistribute NDB Cluster data among new data nodes that have been added to the cluster online. This does not perform any defragmentation, which requires an OPTIMIZE TABLE or null ALTER TABLE statement. For more information, see Section 22.5.7, “Adding NDB Cluster Data Nodes Online”.

Limitations of NDB online operations

Online DROP COLUMN operations are not supported.

Online ALTER TABLE, CREATE INDEX, or DROP INDEX statements that add columns or add or drop indexes are subject to the following limitations:

- A given online ALTER TABLE can use only one of ADD COLUMN, ADD INDEX, or DROP INDEX. One or more columns can be added online in a single statement; only one index may be created or dropped online in a single statement.

- The table being altered is not locked with respect to API nodes other than the one on which an online ALTER TABLE ADD COLUMN, ADD INDEX, or DROP INDEX operation (or CREATE INDEX or DROP INDEX statement) is run. However, the table is locked against any other operations originating on the same API node while the online operation is being executed.
Online Operations with ALTER TABLE in NDB Cluster

• The table to be altered must have an explicit primary key; the hidden primary key created by the NDB storage engine is not sufficient for this purpose.

• The storage engine used by the table cannot be changed online.

• The tablespace used by the table cannot be changed online. Beginning with NDB 8.0.21, a statement such as `ALTER TABLE ndb_table ... ALGORITHM=INPLACE, TABLESPACE=new_tablespace` is specifically disallowed. (Bug #99269, Bug #31180526)

• When used with NDB Cluster Disk Data tables, it is not possible to change the storage type (DISK or MEMORY) of a column online. This means, that when you add or drop an index in such a way that the operation would be performed online, and you want the storage type of the column or columns to be changed, you must use `ALGORITHM=COPY` in the statement that adds or drops the index.

Columns to be added online cannot use the BLOB or TEXT type, and must meet the following criteria:

• The columns must be dynamic; that is, it must be possible to create them using COLUMN_FORMAT DYNAMIC. If you omit the COLUMN_FORMAT DYNAMIC option, the dynamic column format is employed automatically.

• The columns must permit NULL values and not have any explicit default value other than NULL. Columns added online are automatically created as DEFAULT NULL, as can be seen here:

```sql
mysql> CREATE TABLE t2 (
   >   c1 INT NOT NULL AUTO_INCREMENT PRIMARY KEY
   > ) ENGINE=NDB;
Query OK, 0 rows affected (1.44 sec)

mysql> ALTER TABLE t2
   > ADD COLUMN c2 INT,
   > ADD COLUMN c3 INT,
   > ALGORITHM=INPLACE;
Query OK, 0 rows affected, 2 warnings (0.93 sec)

mysql> SHOW CREATE TABLE t1;
*************************** 1. row ***************************
Table: t1
Create Table: CREATE TABLE `t2` (
   `c1` int(11) NOT NULL AUTO_INCREMENT,
   `c2` int(11) DEFAULT NULL,
   `c3` int(11) DEFAULT NULL,
   PRIMARY KEY (`c1`) ) ENGINE=ndbcluster DEFAULT CHARSET=latin1
1 row in set (0.00 sec)
```

• The columns must be added following any existing columns. If you attempt to add a column online before any existing columns or using the FIRST keyword, the statement fails with an error.

• Existing table columns cannot be reordered online.

For online ALTER TABLE operations on NDB tables, fixed-format columns are converted to dynamic when they are added online, or when indexes are created or dropped online, as shown here (repeating the CREATE TABLE and ALTER TABLE statements just shown for the sake of clarity):

```sql
mysql> CREATE TABLE t2 (
   >   c1 INT NOT NULL AUTO_INCREMENT PRIMARY KEY
   > ) ENGINE=NDB;
Query OK, 0 rows affected (1.44 sec)

mysql> ALTER TABLE t2
   > ADD COLUMN c2 INT,
   > ADD COLUMN c3 INT,
   > ALGORITHM=INPLACE;
```

4315
Only the column or columns to be added online must be dynamic. Existing columns need not be; this includes the table's primary key, which may also be FIXED, as shown here:

```sql
mysql> CREATE TABLE t3 (
    > c1 INT NOT NULL AUTO_INCREMENT PRIMARY KEY COLUMN_FORMAT FIXED
    > ) ENGINE=NDB;
Query OK, 0 rows affected (2.10 sec)
```

```sql
mysql> ALTER TABLE t3 ADD COLUMN c2 INT, ALGORITHM=INPLACE;
Query OK, 0 rows affected, 1 warning (0.78 sec)
Records: 0  Duplicates: 0  Warnings: 0
```

```sql
mysql> SHOW WARNINGS;
*************************** 1. row ***************************
Level: Warning
Code: 1478
Message: Converted FIXED field 'c2' to DYNAMIC to enable online ADD COLUMN
```

Columns are not converted from FIXED to DYNAMIC column format by renaming operations. For more information about COLUMN_FORMAT, see Section 13.1.20, "CREATE TABLE Statement".

The KEY, CONSTRAINT, and IGNORE keywords are supported in ALTER TABLE statements using ALGORITHM=INPLACE.

Setting MAX_ROWS to 0 using an online ALTER TABLE statement is disallowed. You must use a copying ALTER TABLE to perform this operation. (Bug #21960004)

### 22.5.12 Distributed MySQL Privileges with NDB_STORED_USER

NDB 8.0.18 introduces a new mechanism for sharing and synchronizing users, roles, and privileges between SQL nodes connected to an NDB Cluster. This can be enabled by granting the NDB_STORED_USER privilege. See the description of the privilege for usage information.

NDB_STORED_USER is printed in the output of SHOW GRANTS as with any other privilege. To verify that privileges are shared, use the ndb_select_all utility supplied with the NDB Cluster distribution, as shown here (some output wrapped to preserve formatting):

```bash
shell> ndb_select_all -d mysql ndb_sql_metadata
```

<table>
<thead>
<tr>
<th>type</th>
<th>name</th>
<th>seq</th>
<th>note</th>
<th>sql_ddl_text</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>&quot;jon'@'localhost&quot;</td>
<td>0</td>
<td>4</td>
<td>&quot;CREATE USER 'jon'@'localhost' IDENTIFIED WITH 'caching_sha2_password' AS 'SA80058{Bj}3!7t&quot;.EFy%A5K5QHwiBuRNYT1Me00YeBlPpZofFRpJvTYzTA5b0' REQUIRE NONE PASSWORD EXPIRE DEFAULT ACCOUNT UNLOCK PASSWORD HISTORY DEFAULT PASSWORD REUSE INTERVAL DEFAULT PASSWORD REQUIRE CURRENT DEFAULT&quot;</td>
</tr>
<tr>
<td>12</td>
<td>&quot;jon'@'localhost&quot;</td>
<td>0</td>
<td>[NULL]</td>
<td>&quot;GRANT USAGE ON <em>.</em> TO 'jon'@'localhost'&quot;</td>
</tr>
<tr>
<td>12</td>
<td>&quot;jon'@'localhost&quot;</td>
<td>3</td>
<td>[NULL]</td>
<td>&quot;GRANT ALL PRIVILEGES ON 'test'.* TO 'jon'@'localhost'&quot;</td>
</tr>
<tr>
<td>12</td>
<td>&quot;jon'@'localhost&quot;</td>
<td>2</td>
<td>[NULL]</td>
<td>&quot;GRANT ALL PRIVILEGES ON 'mydb'.* TO 'jon'@'localhost'&quot;</td>
</tr>
<tr>
<td>12</td>
<td>&quot;jon'@'localhost&quot;</td>
<td>1</td>
<td>[NULL]</td>
<td>&quot;GRANT NDB_STORED_USER ON <em>.</em> TO 'jon'@'localhost'&quot;</td>
</tr>
</tbody>
</table>

5 rows returned
ndb_sql_metadata is a special NDB table that is not visible using the mysql or other MySQL client.

A statement granting the NDB_STORED_USER privilege, such as GRANT NDB_STORED_USER ON *.* TO 'cluster_app_user'@'localhost', works by directing NDB to create a snapshot using the queries SHOW CREATE USER cluster_app_user@localhost and SHOW GRANTS FOR cluster_app_user@localhost, then storing the results in ndb_sql_metadata. Any other SQL nodes are then requested to read and apply the snapshot. Whenever a MySQL server starts up and joins the cluster as an SQL node it executes these stored CREATE USER and GRANT statements as part of the cluster schema synchronization process.

Whenever an SQL statement is executed on an SQL node other than the one where it originated, the statement is run in a utility thread of the NDBCLUSTER storage engine; this is done within a security environment equivalent to that of the MySQL replication replica applier thread.

You should be aware that changes to users with NDB_STORED_USER are distributed asynchronously. Because distributed schema change operations are performed synchronously, the next distributed schema change following a change to any distributed user or users serves as a synchronization point. Any pending user changes run to completion before the schema change distribution can begin; after this the schema change itself runs synchronously. For example, if a DROP DATABASE statement follows a DROP USER of a distributed user, the drop of the database cannot take place until the drop of the user has completed on all SQL nodes.

In the event that multiple GRANT, REVOKE, or other user administration statements from multiple SQL nodes cause privileges for a given user to diverge on different SQL nodes, you can fix this problem by issuing GRANT NDB_STORED_USER for this user on an SQL node where the privileges are known to be correct; this causes a new snapshot of the privileges to be taken and synchronized to the other SQL nodes.

NDB Cluster 8.0 does not support distribution of MySQL users and privileges across SQL nodes in an NDB Cluster by converting the MySQL privilege tables to use the NDB storage engine, as implemented in NDB 7.6 and earlier releases (see Distributed Privileges Using Shared Grant Tables). For information about the impact of this change on upgrades to NDB 8.0 from a previous release, see Section 22.2.7, “Upgrading and Downgrading NDB Cluster”.

### 22.5.13 NDB API Statistics Counters and Variables

A number of types of statistical counters relating to actions performed by or affecting Ndb objects are available. Such actions include starting and closing (or aborting) transactions; primary key and unique key operations; table, range, and pruned scans; threads blocked while waiting for the completion of various operations; and data and events sent and received by NDBCLUSTER. The counters are incremented inside the NDB kernel whenever NDB API calls are made or data is sent to or received by the data nodes. mysqld exposes these counters as system status variables; their values can be read in the output of SHOW STATUS, or by querying the Performance Schema session_status or global_status table. By comparing the values before and after statements operating on NDB tables, you can observe the corresponding actions taken on the API level, and thus the cost of performing the statement.

You can list all of these status variables using the following SHOW STATUS statement:

```sql
mysql> SHOW STATUS LIKE 'ndb_api%';
+-----------------------------+----------+
<table>
<thead>
<tr>
<th>Variable_name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ndb_api_wait_exec_complete_count_session</td>
<td>0</td>
</tr>
<tr>
<td>Ndb_api_wait_scan_result_count_session</td>
<td>0</td>
</tr>
<tr>
<td>Ndb_api_wait_meta_request_count_session</td>
<td>0</td>
</tr>
<tr>
<td>Ndb_api_wait_nanos_count_session</td>
<td>0</td>
</tr>
<tr>
<td>Ndb_api_bytes_sent_count_session</td>
<td>0</td>
</tr>
<tr>
<td>Ndb_api_bytes_received_count_session</td>
<td>0</td>
</tr>
</tbody>
</table>
```
These status variables are also available from the Performance Schema `session_status` and `global_status` tables, as shown here:

mysql> SELECT * FROM performance_schema.session_status
    -> WHERE VARIABLE_NAME LIKE 'ndb_api%';
+--------------------------------------------+----------------+
<table>
<thead>
<tr>
<th>VARIABLE_NAME</th>
<th>VARIABLE_VALUE</th>
</tr>
</thead>

</table>

60 rows in set (0.00 sec)

Each Ndb object has its own counters. NDB API applications can read the values of the counters for use in optimization or monitoring. For multithreaded clients which use more than one Ndb object...
concurrently, it is also possible to obtain a summed view of counters from all Ndb objects belonging to a given Ndb_cluster_connection.

Four sets of these counters are exposed. One set applies to the current session only; the other 3 are global. This is in spite of the fact that their values can be obtained as either session or global status variables in the mysql client. This means that specifying the SESSION or GLOBAL keyword with SHOW STATUS has no effect on the values reported for NDB API statistics status variables, and the value for each of these variables is the same whether the value is obtained from the equivalent column of the session_status or the global_status table.

• Session counters (session specific)

Session counters relate to the Ndb objects in use by (only) the current session. Use of such objects by other MySQL clients does not influence these counts.

In order to minimize confusion with standard MySQL session variables, we refer to the variables that correspond to these NDB API session counters as "_session variables", with a leading underscore.

• Replica counters (global)

This set of counters relates to the Ndb objects used by the replica SQL thread, if any. If this mysql does not act as a replica, or does not use NDB tables, then all of these counts are 0.

We refer to the related status variables as "_slave variables" (with a leading underscore).

• Injector counters (global)

Injector counters relate to the Ndb object used to listen to cluster events by the binary log injector thread. Even when not writing a binary log, mysql processes attached to an NDB Cluster continue to listen for some events, such as schema changes.

We refer to the status variables that correspond to NDB API injector counters as "_injector variables" (with a leading underscore).

• Server (Global) counters (global)

This set of counters relates to all Ndb objects currently used by this mysql. This includes all MySQL client applications, the replica SQL thread (if any), the binary log injector, and the NDB utility thread.

We refer to the status variables that correspond to these counters as "global variables" or "mysql-level variables".

You can obtain values for a particular set of variables by additionally filtering for the substring session, slave, or injector in the variable name (along with the common prefix Ndb_api). For _session variables, this can be done as shown here:

```sql
mysql> SHOW STATUS LIKE 'ndb_api%session';
+-----------------------------------------------+---------+
| Variable_name                               | Value   |
+-----------------------------------------------+---------+
| Ndb_api_wait_exec_complete_count_session     | 2       |
| Ndb_api_wait_scan_result_count_session       | 0       |
| Ndb_api_wait_meta_request_count_session      | 1       |
| Ndb_api_wait_nanos_count_session             | 8144375 |
| Ndb_api_bytes_sent_count_session             | 68      |
| Ndb_api_bytes_received_count_session         | 84      |
| Ndb_api_trans_start_count_session            | 1       |
| Ndb_api_trans_commit_count_session           | 1       |
| Ndb_api_trans_abort_count_session            | 0       |
| Ndb_api_trans_close_count_session            | 1       |
```
NDB API Statistics Counters and Variables

| Ndb_api_pk_op_count_session                | 1       |
| Ndb_api_uk_op_count_session                | 0       |
| Ndb_api_table_scan_count_session           | 0       |
| Ndb_api_range_scan_count_session           | 0       |
| Ndb_api_pruned_scan_count_session          | 0       |
| Ndb_api_scan_batch_count_session           | 0       |
| Ndb_api_read_row_count_session             | 1       |
| Ndb_api_trans_local_read_row_count_session | 1       |

18 rows in set (0.50 sec)

To obtain a listing of the NDB API `mysqld`-level status variables, filter for variable names beginning with `ndb_api` and ending in `_count`, like this:

```
mysql> SELECT * FROM performance_schema.session_status
WHERE VARIABLE_NAME LIKE 'ndb_api%count';
```

```
+------------------------------------+----------------+
| VARIABLE_NAME                      | VARIABLE_VALUE |
+------------------------------------+----------------+
| NDB_API_WAIT_EXEC_COMPLETE_COUNT   | 4              |
| NDB_API_WAIT_SCAN_RESULT_COUNT     | 3              |
| NDB_API_WAIT_META_REQUEST_COUNT    | 28             |
| NDB_API_WAIT_NANOS_COUNT           | 53756398       |
| NDB_API_BYTES_SENT_COUNT           | 1060           |
| NDB_API_BYTES_RECEIVED_COUNT       | 9724           |
| NDB_API_TRANS_START_COUNT          | 3              |
| NDB_API_TRANS_COMMIT_COUNT         | 2              |
| NDB_API_TRANS_ABORT_COUNT          | 0              |
| NDB_API_TRANS_CLOSE_COUNT          | 3              |
| NDB_API_PK_OP_COUNT                | 2              |
| NDB_API_UK_OP_COUNT                | 0              |
| NDB_API_TABLE_SCAN_COUNT           | 1              |
| NDB_API_RANGE_SCAN_COUNT           | 0              |
| NDB_API_PRUNED_SCAN_COUNT          | 0              |
| NDB_API_SCAN_BATCH_COUNT           | 0              |
| NDB_API_READ_ROW_COUNT             | 2              |
| NDB_API_TRANS_LOCAL_READ_ROW_COUNT | 2              |
| NDB_API_EVENT_DATA_COUNT           | 0              |
| NDB_API_EVENT_NONDATA_COUNT        | 0              |
| NDB_API_EVENT_BYTES_COUNT          | 0              |
+------------------------------------+----------------+
21 rows in set (0.09 sec)

Not all counters are reflected in all 4 sets of status variables. For the event counters `DataEventsRecvdCount`, `NondataEventsRecvdCount`, and `EventBytesRecvdCount`, only `_injector` and `mysqld`-level NDB API status variables are available:

```
mysql> SHOW STATUS LIKE 'ndb_api%event%';
```

```
+--------------------------------------+-------+
| Variable_name                        | Value |
+--------------------------------------+-------+
| Ndb_api_event_data_count_injector    | 0     |
| Ndb_api_event_nondata_count_injector | 0     |
| Ndb_api_event_bytes_count_injector   | 0     |
| Ndb_api_event_data_count             | 0     |
| Ndb_api_event_nondata_count          | 0     |
| Ndb_api_event_bytes_count            | 0     |
+--------------------------------------+-------+
6 rows in set (0.00 sec)

_injector status variables are not implemented for any other NDB API counters, as shown here:

```
mysql> SHOW STATUS LIKE 'ndb_api%injector%';
```

```
+--------------------------------------+-------+
| Variable_name                        | Value |
+--------------------------------------+-------+
| Ndb_api_event_data_count_injector    | 0     |
| Ndb_api_event_nondata_count_injector | 0     |
| Ndb_api_event_bytes_count_injector   | 0     |
| Ndb_api_event_data_count             | 0     |
| Ndb_api_event_nondata_count          | 0     |
| Ndb_api_event_bytes_count            | 0     |
+--------------------------------------+-------+
6 rows in set (0.00 sec)

4322
The names of the status variables can easily be associated with the names of the corresponding counters. Each NDB API statistics counter is listed in the following table with a description as well as the names of any MySQL server status variables corresponding to this counter.

### Table 22.65 NDB API statistics counters

<table>
<thead>
<tr>
<th>Counter Name</th>
<th>Description</th>
<th>Status Variables (by statistic type):</th>
</tr>
</thead>
</table>
| WaitExecCompleteCount      | Number of times thread has been blocked while waiting for execution of an operation to complete. Includes all `execute()` calls as well as implicit executes for blob operations and auto-increment not visible to clients. | • Ndb_api_wait_exec_complete_count_Session  
• Ndb_api_wait_exec_complete_count_Slave  
• [none]  
• Ndb_api_wait_exec_complete_count_Server |
| WaitScanResultCount        | Number of times thread has been blocked while waiting for a scan-based signal, such waiting for additional results, or for a scan to close. | • Ndb_api_wait_scan_result_count_Session  
• Ndb_api_wait_scan_result_count_Slave  
• [none]  
• Ndb_api_wait_scan_result_count_Server |
| WaitMetaRequestCount       | Number of times thread has been blocked waiting for a metadata-based signal; this can occur when waiting for a DDL operation or for an epoch to be started (or ended). | • Ndb_api_wait_meta_request_count_Session  
• Ndb_api_wait_meta_request_count_Slave  
• [none]  
• Ndb_api_wait_meta_request_count_Server |
| WaitNanosCount             | Total time (in nanoseconds) spent waiting for some type of signal from the data nodes. | • Ndb_api_wait_nanos_count_Session  
• Ndb_api_wait_nanos_count_Slave  
• [none]  
• Ndb_api_wait_nanos_count_Server |
| BytesSentCount             | Amount of data (in bytes) sent to the data nodes | • Ndb_api_bytes_sent_count_Session  
• Ndb_api_bytes_sent_count_Slave  
• [none]  
• Ndb_api_bytes_sent_count_Server |

<td></td>
<td>• [none]</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Ndb_api_trans_local_read_row_count</td>
</tr>
</tbody>
</table>
To see all counts of committed transactions—that is, all `TransCommitCount` counter status variables—you can filter the results of `SHOW STATUS` for the substring `trans_commit_count`, like this:

```
mysql> SHOW STATUS LIKE '%trans_commit_count%';
+------------------------------------+-------+
| Variable_name                      | Value |
+------------------------------------+-------+
| Ndb_api_trans_commit_count_session | 1     |
| Ndb_api_trans_commit_count_slave   | 0     |
| Ndb_api_trans_commit_count         | 2     |
+------------------------------------+-------+
3 rows in set (0.00 sec)
```

From this you can determine that 1 transaction has been committed in the current `mysql` client session, and 2 transactions have been committed on this `mysqld` since it was last restarted.

You can see how various NDB API counters are incremented by a given SQL statement by comparing the values of the corresponding `_session` status variables immediately before and after performing the statement. In this example, after getting the initial values from `SHOW STATUS`, we create in the `test` database an `NDB` table, named `t`, that has a single column:

```
mysql> SHOW STATUS LIKE 'ndb_api%session%';
+--------------------------------------------+--------+
| Variable_name                              | Value  |
+--------------------------------------------+--------+
| Ndb_api_wait_exec_complete_count_session   | 2      |
| Ndb_api_wait_scan_result_count_session     | 0      |
| Ndb_api_wait_meta_request_count_session    | 3      |
+--------------------------------------------+--------+
3 rows in set (0.00 sec)
```
## NDB API Statistics Counters and Variables

<table>
<thead>
<tr>
<th>Variable_name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ndb_api_wait_nanos_count_session</td>
<td>820705</td>
</tr>
<tr>
<td>Ndb_api_bytes_sent_count_session</td>
<td>132</td>
</tr>
<tr>
<td>Ndb_api_bytes_received_count_session</td>
<td>372</td>
</tr>
<tr>
<td>Ndb_api_trans_start_count_session</td>
<td>1</td>
</tr>
<tr>
<td>Ndb_api_trans_commit_count_session</td>
<td>1</td>
</tr>
<tr>
<td>Ndb_api_trans_abort_count_session</td>
<td>0</td>
</tr>
<tr>
<td>Ndb_api_trans_close_count_session</td>
<td>1</td>
</tr>
<tr>
<td>Ndb_api_pk_op_count_session</td>
<td>1</td>
</tr>
<tr>
<td>Ndb_api_uk_op_count_session</td>
<td>0</td>
</tr>
<tr>
<td>Ndb_api_table_scan_count_session</td>
<td>0</td>
</tr>
<tr>
<td>Ndb_api_range_scan_count_session</td>
<td>0</td>
</tr>
<tr>
<td>Ndb_api_pruned_scan_count_session</td>
<td>0</td>
</tr>
<tr>
<td>Ndb_api_scan_batch_count_session</td>
<td>0</td>
</tr>
<tr>
<td>Ndb_api_read_row_count_session</td>
<td>1</td>
</tr>
<tr>
<td>Ndb_api_trans_local_read_row_count_session</td>
<td>1</td>
</tr>
</tbody>
</table>

18 rows in set (0.00 sec)

mysql> USE test;
Database changed
mysql> CREATE TABLE t (c INT) ENGINE NDBCLUSTER;
Query OK, 0 rows affected (0.85 sec)

Now you can execute a new **SHOW STATUS** statement and observe the changes, as shown here (with the changed rows highlighted in the output):

```
mysql> SHOW STATUS LIKE 'ndb_api%session%';
```

<table>
<thead>
<tr>
<th>Variable_name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ndb_api_wait_exec_complete_count_session</td>
<td>8</td>
</tr>
<tr>
<td>Ndb_api_wait_scan_result_count_session</td>
<td>0</td>
</tr>
<tr>
<td>Ndb_api_wait_meta_request_count_session</td>
<td>17</td>
</tr>
<tr>
<td>Ndb_api_wait_nanos_count_session</td>
<td>706871709</td>
</tr>
<tr>
<td>Ndb_api_bytes_sent_count_session</td>
<td>2376</td>
</tr>
<tr>
<td>Ndb_api_bytes_received_count_session</td>
<td>3844</td>
</tr>
<tr>
<td>Ndb_api_trans_start_count_session</td>
<td>4</td>
</tr>
<tr>
<td>Ndb_api_trans_commit_count_session</td>
<td>4</td>
</tr>
<tr>
<td>Ndb_api_trans_abort_count_session</td>
<td>0</td>
</tr>
<tr>
<td>Ndb_api_trans_close_count_session</td>
<td>4</td>
</tr>
<tr>
<td>Ndb_api_pk_op_count_session</td>
<td>6</td>
</tr>
<tr>
<td>Ndb_api_uk_op_count_session</td>
<td>0</td>
</tr>
<tr>
<td>Ndb_api_table_scan_count_session</td>
<td>0</td>
</tr>
<tr>
<td>Ndb_api_range_scan_count_session</td>
<td>0</td>
</tr>
<tr>
<td>Ndb_api_pruned_scan_count_session</td>
<td>0</td>
</tr>
<tr>
<td>Ndb_api_scan_batch_count_session</td>
<td>0</td>
</tr>
<tr>
<td>Ndb_api_read_row_count_session</td>
<td>2</td>
</tr>
<tr>
<td>Ndb_api_trans_local_read_row_count_session</td>
<td>1</td>
</tr>
</tbody>
</table>

18 rows in set (0.00 sec)

Similarly, you can see the changes in the NDB API statistics counters caused by inserting a row into `t`:

Insert the row, then run the same **SHOW STATUS** statement used in the previous example, as shown here:

```
mysql> INSERT INTO t VALUES (100);
Query OK, 1 row affected (0.00 sec)
```

```
mysql> SHOW STATUS LIKE 'ndb_api%session%';
```

<table>
<thead>
<tr>
<th>Variable_name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ndb_api_wait_exec_complete_count_session</td>
<td>11</td>
</tr>
<tr>
<td>Ndb_api_wait_scan_result_count_session</td>
<td>6</td>
</tr>
<tr>
<td>Ndb_api_wait_meta_request_count_session</td>
<td>20</td>
</tr>
<tr>
<td>Ndb_api_wait_nanos_count_session</td>
<td>707370418</td>
</tr>
<tr>
<td>Ndb_api_bytes_sent_count_session</td>
<td>2724</td>
</tr>
</tbody>
</table>

18 rows in set (0.00 sec)
We can make a number of observations from these results:

- Although we created t with no explicit primary key, 5 primary key operations were performed in doing so (the difference in the “before” and “after” values of Ndb_api_pk_op_count_session, or 6 minus 1). This reflects the creation of the hidden primary key that is a feature of all tables using the NDB storage engine.

- By comparing successive values for Ndb_api_wait_nanos_count_session, we can see that the NDB API operations implementing the CREATE TABLE statement waited much longer (706871709 - 820705 = 706051004 nanoseconds, or approximately 0.7 second) for responses from the data nodes than those executed by the INSERT (707370418 - 706871709 = 498709 ns or roughly .0005 second). The execution times reported for these statements in the mysql client correlate roughly with these figures.

  On platforms without sufficient (nanosecond) time resolution, small changes in the value of the WaitNanosCount NDB API counter due to SQL statements that execute very quickly may not always be visible in the values of Ndb_api_wait_nanos_count_session, Ndb_api_wait_nanos_count_slave, or Ndb_api_wait_nanos_count.

- The INSERT statement incremented both the ReadRowCount and TransLocalReadRowCount NDB API statistics counters, as reflected by the increased values of Ndb_api_read_row_count_session and Ndb_api_trans_local_read_row_count_session.

### 22.5.14 ndbinfo: The NDB Cluster Information Database

*ndbinfo* is a database containing information specific to NDB Cluster.

This database contains a number of tables, each providing a different sort of data about NDB Cluster node status, resource usage, and operations. You can find more detailed information about each of these tables in the next several sections.

*ndbinfo* is included with NDB Cluster support in the MySQL Server; no special compilation or configuration steps are required; the tables are created by the MySQL Server when it connects to the cluster. You can verify that *ndbinfo* support is active in a given MySQL Server instance using `SHOW PLUGINS`; if *ndbinfo* support is enabled, you should see a row containing *ndbinfo* in the Name column and ACTIVE in the Status column, as shown here (emphasized text):

```
mysql> SHOW PLUGINS;
+----------+--------+--------------------+---------+---------+
| Name     | Status | Type               | Library | License |
+----------+--------+--------------------+---------+---------+
| binlog   | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| mysql_native_password | ACTIVE | AUTHENTICATION     | NULL    | GPL     |
| sha256_password | ACTIVE | AUTHENTICATION     | NULL    | GPL     |
+----------+--------+--------------------+---------+---------+
```
### ndbinfo: The NDB Cluster Information Database

</tbody>
</table>

If `ndbinfo` support is enabled, then you can access `ndbinfo` using SQL statements in `mysql` or another MySQL client. For example, you can see `ndbinfo` listed in the output of `SHOW DATABASES`, as shown here (emphasized text):

```
mysql> SHOW DATABASES;
+---------------------+
| Database            |
+---------------------+
| information_schema  |
| mysql               |
| ndbinfo             |
| performance_schema  |
+---------------------+
```

4330
If the `mysqld` process was not started with the `--ndbcluster` option, `ndbinfo` is not available and is not displayed by `SHOW DATABASES`. If `mysqld` was formerly connected to an NDB Cluster but the cluster becomes unavailable (due to events such as cluster shutdown, loss of network connectivity, and so forth), `ndbinfo` and its tables remain visible, but an attempt to access any tables (other than `blocks` or `config_params`) fails with `Got error 157 'Connection to NDB failed' from NDBINFO`.

With the exception of the `blocks` and `config_params` tables, what we refer to as `ndbinfo` “tables” are actually views generated from internal NDB tables not normally visible to the MySQL Server.

All `ndbinfo` tables are read-only, and are generated on demand when queried. Because many of them are generated in parallel by the data nodes while other are specific to a given SQL node, they are not guaranteed to provide a consistent snapshot.

In addition, pushing down of joins is not supported on `ndbinfo` tables; so joining large `ndbinfo` tables can require transfer of a large amount of data to the requesting API node, even when the query makes use of a `WHERE` clause.

`ndbinfo` tables are not included in the query cache. (Bug #59831)

You can select the `ndbinfo` database with a `USE` statement, and then issue a `SHOW TABLES` statement to obtain a list of tables, just as for any other database, like this:

```sql
mysql> USE ndbinfo;
Database changed
mysql> SHOW TABLES;
+---------------------------------+
| Tables_in_ndbinfo               |
+---------------------------------+
| arbitrator_validity_detail      |
| arbitrator_validity_summary     |
| blocks                          |
| cluster_locks                   |
| cluster_operations              |
| cluster_transactions           |
| config_nodes                    |
| config_params                   |
| config_values                   |
| counters                        |
| cpustat                         |
| cpustat_1sec                    |
| cpustat_20sec                   |
| cpustat_50ms                    |
| dict_obj_info                   |
| dict_obj_types                  |
| disk_write_speed_aggregate      |
| disk_write_speed_aggregate_node |
| disk_write_speed_base           |
| diskpagebuffer                  |
| error_messages                  |
| locks_per_fragment              |
| logbuffers                      |
| logspaces                       |
| membership                      |
| memory_per_fragment             |
| memoryusage                     |
| nodes                           |
| operations_per_fragment         |
| processes                       |
```
In NDB 8.0, all \texttt{ndbinfo} tables use the \texttt{NDB} storage engine; however, an \texttt{ndbinfo} entry still appears in the output of \texttt{SHOW ENGINES} and \texttt{SHOW PLUGINS} as described previously.

You can execute \texttt{SELECT} statements against these tables, just as you would normally expect:

```sql
mysql> SELECT * FROM memoryusage;
```

| node_id | memory_type         | used   | used_pages | total      | total_pages |
|---------|---------------------+--------+------------+------------+-------------|
| 5       | Data memory         | 753664 | 23         | 1073741824 | 32768       |
| 5       | Index memory        | 163840 | 20         | 1074003968 | 131104      |
| 5       | Long message buffer | 2304   | 9          | 67108864   | 262144      |
| 6       | Data memory         | 753664 | 23         | 1073741824 | 32768       |
| 6       | Index memory        | 163840 | 20         | 1074003968 | 131104      |
| 6       | Long message buffer | 2304   | 9          | 67108864   | 262144      |

6 rows in set (0.02 sec)

More complex queries, such as the two following \texttt{SELECT} statements using the \texttt{memoryusage} table, are possible:

```sql
mysql> SELECT SUM(used) as 'Data Memory Used, All Nodes'
    > FROM memoryusage
    > WHERE memory_type = 'Data memory';
```

```
<table>
<thead>
<tr>
<th>Data Memory Used, All Nodes</th>
</tr>
</thead>
<tbody>
<tr>
<td>6460</td>
</tr>
</tbody>
</table>
```

1 row in set (0.37 sec)

```sql
mysql> SELECT SUM(max) as 'Total IndexMemory Available'
    > FROM memoryusage
    > WHERE memory_type = 'Index memory';
```

```
<table>
<thead>
<tr>
<th>Total IndexMemory Available</th>
</tr>
</thead>
<tbody>
<tr>
<td>25664</td>
</tr>
</tbody>
</table>
```

1 row in set (0.33 sec)

\texttt{ndbinfo} table and column names are case sensitive (as is the name of the \texttt{ndbinfo} database itself). These identifiers are in lowercase. Trying to use the wrong lettercase results in an error, as shown in this example:

```sql
mysql> SELECT * FROM nodes;
```

```
| node_id | uptime | status | start_phase |
```

| 4332 |

4332
The NDB Cluster also maintains tables in the INFORMATION_SCHEMA information database, including the FILES table which contains information about files used for NDB Cluster Disk Data storage, and the ndb_transid_mysql_connection_map table, which shows the relationships between transactions, transaction coordinators, and NDB Cluster API nodes. For more information, see the descriptions of the tables or Section 22.5.15, "INFORMATION_SCHEMA Tables for NDB Cluster".

### 22.5.14.1 The ndbinfo arbitrator_validity_detail Table

The arbitrator_validity_detail table shows the view that each data node in the cluster has of the arbitrator. It is a subset of the membership table.

The arbitrator_validity_detail table contains the following columns:

- **node_id**
  
  This node's node ID

- **arbitrator**
  
  Node ID of arbitrator

- **arb_ticket**
  
  Internal identifier used to track arbitration

- **arb_connected**
  
  Whether this node is connected to the arbitrator; either of Yes or No

- **arb_state**
  
  Arbitration state

**Notes**

The node ID is the same as that reported by ndb_mgm -e "SHOW".

All nodes should show the same arbitrator and arb_ticket values as well as the same arb_state value. Possible arb_state values are ARBIT_NULL, ARBIT_INIT, ARBIT_FIND, ARBIT_PREP1, ARBIT_PREP2, ARBIT_START, ARBIT_RUN, ARBIT_CHOOSE, ARBIT_CRASH, and UNKNOWN.

arb_connected shows whether the current node is connected to the arbitrator.

### 22.5.14.2 The ndbinfo arbitrator_validity_summary Table

The arbitrator_validity_summary table provides a composite view of the arbitrator with regard to the cluster's data nodes.
The **arbitrator_validity_summary** table contains the following columns:

- **arbitrator**
  Node ID of arbitrator
- **arb_ticket**
  Internal identifier used to track arbitration
- **arb_connected**
  Whether this arbitrator is connected to the cluster
- **consensus_count**
  Number of data nodes that see this node as arbitrator; either of Yes or No

### Notes

In normal operations, this table should have only 1 row for any appreciable length of time. If it has more than 1 row for longer than a few moments, then either not all nodes are connected to the arbitrator, or all nodes are connected, but do not agree on the same arbitrator.

The **arbitrator** column shows the arbitrator's node ID.

**arb_ticket** is the internal identifier used by this arbitrator.

**arb_connected** shows whether this node is connected to the cluster as an arbitrator.

### 22.5.14.3 The ndbinfo blocks Table

The **blocks** table is a static table which simply contains the names and internal IDs of all NDB kernel blocks (see NDB Kernel Blocks). It is for use by the other **ndbinfo** tables (most of which are actually views) in mapping block numbers to block names for producing human-readable output.

The **blocks** table contains the following columns:

- **block_number**
  Block number
- **block_name**
  Block name

### Notes

To obtain a list of all block names, simply execute `SELECT block_name FROM ndbinfo.blocks`. Although this is a static table, its content can vary between different NDB Cluster releases.

### 22.5.14.4 The ndbinfo cluster_locks Table

The **cluster_locks** table provides information about current lock requests holding and waiting for locks on NDB tables in an NDB Cluster, and is intended as a companion table to **cluster_operations**. Information obtain from the **cluster_locks** table may be useful in investigating stalls and deadlocks.

The **cluster_locks** table contains the following columns:
ndbinf: The NDB Cluster Information Database

- **node_id**
  ID of reporting node

- **block_instance**
  ID of reporting LDM instance

- **tableid**
  ID of table containing this row

- **fragmentid**
  ID of fragment containing locked row

- **rowid**
  ID of locked row

- **transid**
  Transaction ID

- **mode**
  Lock request mode

- **state**
  Lock state

- **detail**
  Whether this is first holding lock in row lock queue

- **op**
  Operation type

- **duration_millis**
  Milliseconds spent waiting or holding lock

- **lock_num**
  ID of lock object

- **waiting_for**
  Waiting for lock with this ID

**Notes**

The table ID (**tableid** column) is assigned internally, and is the same as that used in other **ndbinf** tables. It is also shown in the output of **ndb_show_tables**.

The transaction ID (**transid** column) is the identifier generated by the NDB API for the transaction requesting or holding the current lock.
The **mode** column shows the lock mode; this is always one of **S** (indicating a shared lock) or **X** (an exclusive lock). If a transaction holds an exclusive lock on a given row, all other locks on that row have the same transaction ID.

The **state** column shows the lock state. Its value is always one of **H** (holding) or **W** (waiting). A waiting lock request waits for a lock held by a different transaction.

When the **detail** column contains a * (asterisk character), this means that this lock is the first holding lock in the affected row's lock queue; otherwise, this column is empty. This information can be used to help identify the unique entries in a list of lock requests.

The **op** column shows the type of operation requesting the lock. This is always one of the values **READ**, **INSERT**, **UPDATE**, **DELETE**, **SCAN**, or **REFRESH**.

The **duration_millis** column shows the number of milliseconds for which this lock request has been waiting or holding the lock. This is reset to 0 when a lock is granted for a waiting request.

The lock ID (**lockid** column) is unique to this node and block instance.

The lock state is shown in the **lock_state** column; if this is **W**, the lock is waiting to be granted, and the **waiting_for** column shows the lock ID of the lock object this request is waiting for. Otherwise, the **waiting_for** column is empty. **waiting_for** can refer only to locks on the same row, as identified by **node_id**, **block_instance**, **tableid**, **fragmentid**, and **rowid**.

### 22.5.14.5 The ndbinfo cluster_operations Table

The **cluster_operations** table provides a per-operation (stateful primary key op) view of all activity in the NDB Cluster from the point of view of the local data management (LQH) blocks (see The DBLQH Block).

The **cluster_operations** table contains the following columns:

- **node_id**
  
  Node ID of reporting LQH block

- **block_instance**
  
  LQH block instance

- **transid**
  
  Transaction ID

- **operation_type**
  
  Operation type (see text for possible values)

- **state**
  
  Operation state (see text for possible values)

- **tableid**
  
  Table ID

- **fragmentid**
Fragment ID

- **client_node_id**
  
  Client node ID

- **client_block_ref**
  
  Client block reference

- **tc_node_id**
  
  Transaction coordinator node ID

- **tc_block_no**
  
  Transaction coordinator block number

- **tc_block_instance**
  
  Transaction coordinator block instance

**Notes**

The transaction ID is a unique 64-bit number which can be obtained using the NDB API's `getTransactionId()` method. (Currently, the MySQL Server does not expose the NDB API transaction ID of an ongoing transaction.)

The `operation_type` column can take any one of the values `READ`, `READ-SH`, `READ-EX`, `INSERT`, `UPDATE`, `DELETE`, `WRITE`, `UNLOCK`, `REFRESH`, `SCAN`, `SCAN-SH`, `SCAN-EX`, or `<unknown>`.

(If the MySQL Server is running with `ndbinfo_show_hidden` enabled, you can view this list of states by selecting from the `ndb_info.Show_hidden` table, which is normally hidden.)

You can obtain the name of an NDB table from its table ID by checking the output of `ndb_show_tables`.

The `fragid` is the same as the partition number seen in the output of `ndb_desc --extra-partition-info` (short form `-p`).

In `client_node_id` and `client_block_ref`, `client` refers to an NDB Cluster API or SQL node (that is, an NDB API client or a MySQL Server attached to the cluster).

The `block_instance` and `tc_block_instance` column provide, respectively, the DBLQH and DBTC block instance numbers. You can use these along with the block names to obtain information about specific threads from the `threadblocks` table.

### 22.5.14.6 The ndbinfo cluster_transactions Table
The `cluster_transactions` table shows information about all ongoing transactions in an NDB Cluster.

The `cluster_transactions` table contains the following columns:

- **node_id**
  Node ID of transaction coordinator

- **block_instance**
  TC block instance

- **transid**
  Transaction ID

- **state**
  Operation state (see text for possible values)

- **count_operations**
  Number of stateful primary key operations in transaction (includes reads with locks, as well as DML operations)

- **outstanding_operations**
  Operations still being executed in local data management blocks

- **inactive_seconds**
  Time spent waiting for API

- **client_node_id**
  Client node ID

- **client_block_ref**
  Client block reference

**Notes**

The transaction ID is a unique 64-bit number which can be obtained using the NDB API's `getTransactionId()` method. (Currently, the MySQL Server does not expose the NDB API transaction ID of an ongoing transaction.)

Block instance refers to an instance of a kernel block. Together with the block name, this number can be used to look up a given instance in the `threadblocks` table.

The `state` column can have any one of the values `CS_ABORTING`, `CS_COMMITTING`, `CS_COMMIT_SENT`, `CS_COMPLETE_SENT`, `CS_COMPLETING`, `CS_DISCONNECTED`, `CS_FAIL_ABORTED`, `CS_FAIL_ABORTING`, `CS_FAIL_COMMITTED`, `CS_FAIL_COMMITTING`, `CS_FAIL_COMPLETED`, `CS_FAIL_PREPARED`, `CS_PREPARE_TO_COMMIT`, `CS_RECEIVING`, `CS_REC_COMMITTING`, `CS_RESTART`, `CS_SEND_FIRE_TRIG_REQ`, `CS_STARTED`, `CS_START_COMMITTING`, `CS_START_SCAN`, `CS_WAIT_ABORT_CONF`, `CS_WAIT_COMMIT_CONF`, `CS_WAIT_COMPLETE_CONF`, `CS_WAIT_FIRE_TRIG_REQ`. (If the MySQL Server is running with `ndbinfo_show_hidden` enabled, you can view this list of states by selecting from the `ndb$dbtc_apiconnect_state` table, which is normally hidden.)
In `client_node_id` and `client_block_ref`, `client` refers to an NDB Cluster API or SQL node (that is, an NDB API client or a MySQL Server attached to the cluster).

The `tc_block_instance` column provides the DBTC block instance number. You can use this along with the block name to obtain information about specific threads from the `threadblocks` table.

### 22.5.14.7 The ndbinfo config_nodes Table

The `config_nodes` table shows nodes configured in an NDB Cluster `config.ini` file. For each node, the table displays a row containing the node ID, the type of node (management node, data node, or API node), and the name or IP address of the host on which the node is configured to run.

This table does not indicate whether a given node is actually running, or whether it is currently connected to the cluster. Information about nodes connected to an NDB Cluster can be obtained from the `nodes` and `processes` table.

The `config_nodes` table contains the following columns:

- `node_id`
  The node's ID
- `node_type`
  The type of node
- `node_hostname`
  The name or IP address of the host on which the node resides

#### Notes

The `node_id` column shows the node ID used in the `config.ini` file for this node; if none is specified, the node ID that would be assigned automatically to this node is displayed.

The `node_type` column displays one of the following three values:

- **MGM**: Management node.
- **NDB**: Data node.
- **API**: API node; this includes SQL nodes.

The `node_hostname` column shows the node host as specified in the `config.ini` file. This can be empty for an API node, if `HostName` has not been set in the cluster configuration file. If `HostName` has not been set for a data node in the configuration file, `localhost` is used here. `localhost` is also used if `HostName` has not been specified for a management node.

### 22.5.14.8 The ndbinfo config_params Table

The `config_params` table is a static table which provides the names and internal ID numbers of and other information about NDB Cluster configuration parameters. This table can also be used in conjunction with the `config_values` table for obtaining realtime information about node configuration parameters.

The `config_params` table contains the following columns:

- `param_number`
The parameter's internal ID number

- **param_name**
The name of the parameter

- **param_description**
A brief description of the parameter

- **param_type**
The parameter's data type

- **param_default**
The parameter's default value, if any

- **param_min**
The parameter's maximum value, if any

- **param_max**
The parameter's minimum value, if any

- **param_mandatory**
This is 1 if the parameter is required, otherwise 0

- **param_status**
Currently unused

**Notes**

This table is read-only.

Although this is a static table, its content can vary between NDB Cluster installations, since supported parameters can vary due to differences between software releases, cluster hardware configurations, and other factors.

**22.5.14.9 The ndbinfo config_values Table**

The **config_values** table provides information about the current state of node configuration parameter values. Each row in the table corresponds to the current value of a parameter on a given node.

The **config_values** table contains the following columns:

- **node_id**
  ID of the node in the cluster

- **config_param**
The parameter's internal ID number

- **config_value**
Current value of the parameter

Notes

This table's `config_param` column and the `config_params` table's `param_number` column use the same parameter identifiers. By joining the two tables on these columns, you can obtain detailed information about desired node configuration parameters. The query shown here provides the current values for all parameters on each data node in the cluster, ordered by node ID and parameter name:

```
SELECT    v.node_id AS 'Node Id',
          p.param_name AS 'Parameter',
          v.config_value AS 'Value'
FROM      config_values v
JOIN      config_params p
ON        v.config_param=p.param_number
WHERE     p.param_name NOT LIKE '__%'
ORDER BY  v.node_id, p.param_name;
```

Partial output from the previous query when run on a small example cluster used for simple testing:

<table>
<thead>
<tr>
<th>Node Id</th>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>Arbitration</td>
<td>1</td>
</tr>

</tr>
</tbody>
</table>

`248 rows in set (0.02 sec)`

The `WHERE` clause filters out parameters whose names begin with a double underscore (`__`); these parameters are reserved for testing and other internal uses by the NDB developers, and are not intended for use in a production NDB Cluster.

You can obtain output that is more specific, more detailed, or both by issuing the proper queries. This example provides all types of available information about the `NodeId`, `NoOfReplicas`, `HostName`, `DataMemory`, `IndexMemory`, and `TotalSendBufferMemory` parameters as currently set for all data nodes in the cluster:

```
SELECT  p.param_name AS Name,
        v.node_id AS Node,
        p.param_type AS Type,
        p.param_default AS 'Default',
        p.param_min AS Minimum,
        p.param_max AS Maximum,
        CASE p.param_mandatory WHEN 1 THEN 'Y' ELSE 'N' END AS 'Required',
        v.config_value AS Current
FROM    config_params p
JOIN    config_values v
ON      p.param_number = v.config_param
WHERE   p.param_name
```
The output from this query when run on a small NDB Cluster with 2 data nodes used for simple testing is shown here (NDB 8.0.18 and later):

</table>
22.5.14.10 The ndbinfo counters Table

The counters table provides running totals of events such as reads and writes for specific kernel blocks and data nodes. Counts are kept from the most recent node start or restart; a node start or restart resets all counters on that node. Not all kernel blocks have all types of counters.

The counters table contains the following columns:

- **node_id**
  The data node ID

- **block_name**
  Name of the associated NDB kernel block (see NDB Kernel Blocks).

- **block_instance**
  Block instance

- **counter_id**
  The counter's internal ID number; normally an integer between 1 and 10, inclusive.

- **counter_name**
  The name of the counter. See text for names of individual counters and the NDB kernel block with which each counter is associated.

- **val**
  The counter's value
Each counter is associated with a particular NDB kernel block.

The `OPERATIONS` counter is associated with the `DBLQH` (local query handler) kernel block. A primary-key read counts as one operation, as does a primary-key update. For reads, there is one operation in `DBLQH` per operation in `DBTC`. For writes, there is one operation counted per fragment replica.

The `ATTRINFO`, `TRANSACTIONS`, `COMMITS`, `READS`, `LOCAL_READS`, `SIMPLE_READS`, `WRITES`, `LOCAL_WRITES`, `ABORTS`, `TABLE_SCANS`, and `RANGE_SCANS` counters are associated with the `DBTC` (transaction co-ordinator) kernel block.

`LOCAL_WRITES` and `LOCAL_READS` are primary-key operations using a transaction coordinator in a node that also holds the primary fragment replica of the record.

The `READS` counter includes all reads. `LOCAL_READS` includes only those reads of the primary fragment replica on the same node as this transaction coordinator. `SIMPLE_READS` includes only those reads in which the read operation is the beginning and ending operation for a given transaction. Simple reads do not hold locks but are part of a transaction, in that they observe uncommitted changes made by the transaction containing them but not of any other uncommitted transactions. Such reads are “simple” from the point of view of the TC block; since they hold no locks they are not durable, and once `DBTC` has routed them to the relevant LQH block, it holds no state for them.

`ATTRINFO` keeps a count of the number of times an interpreted program is sent to the data node. See NDB Protocol Messages, for more information about `ATTRINFO` messages in the NDB kernel.

The `LOCAL_TABLE_SCANS_SENT`, `READS_RECEIVED`, `PRUNED_RANGE_SCANS_RECEIVED`, `RANGE_SCANS_RECEIVED`, `LOCAL_READS_SENT`, `CONST_PRUNED_RANGE_SCANS_RECEIVED`, `LOCAL_RANGE_SCANS_SENT`, `REMOTE_READS_SENT`, `REMOTE_RANGE_SCANS_SENT`, `READS_NOT_FOUND`, `SCAN_BATCHES_RETURNED`, `TABLE_SCANS_RECEIVED`, and `SCAN_ROWS_RETURNED` counters are associated with the `DBSPJ` (select push-down join) kernel block.

The block_name and block_instance columns provide, respectively, the applicable NDB kernel block name and instance number. You can use these to obtain information about specific threads from the threadblocks table.

A number of counters provide information about transporter overload and send buffer sizing when troubleshooting such issues. For each LQH instance, there is one instance of each counter in the following list:

- `LQHKEY_OVERLOAD`: Number of primary key requests rejected at the LQH block instance due to transporter overload
- `LQHKEY_OVERLOAD_TC`: Count of instances of `LQHKEY_OVERLOAD` where the TC node transporter was overloaded
- `LQHKEY_OVERLOAD_READER`: Count of instances of `LQHKEY_OVERLOAD` where the API reader (reads only) node was overloaded.
- `LQHKEY_OVERLOAD_NODE_PEER`: Count of instances of `LQHKEY_OVERLOAD` where the next backup data node (writes only) was overloaded.
- `LQHKEY_OVERLOAD_SUBSCRIBER`: Count of instances of `LQHKEY_OVERLOAD` where a event subscriber (writes only) was overloaded.
- `LQHSCAN_SLOWDOWNS`: Count of instances where a fragment scan batch size was reduced due to scanning API transporter overload.
22.5.14.11 The ndbinfo cpustat Table

The cpustat table provides per-thread CPU statistics gathered each second, for each thread running in the NDB kernel.

The cpustat table contains the following columns:

- node_id
  ID of the node where the thread is running
- thr_no
  Thread ID (specific to this node)
- OS_user
  OS user time
- OS_system
  OS system time
- OS_idle
  OS idle time
- thread_exec
  Thread execution time
- thread.sleeping
  Thread sleep time
- thread_spinning
  Thread spin time
- thread_send
  Thread send time
- thread_buffer_full
  Thread buffer full time
- elapsed_time
  Elapsed time

22.5.14.12 The ndbinfo cpustat_50ms Table

The cpustat_50ms table provides raw, per-thread CPU data obtained each 50 milliseconds for each thread running in the NDB kernel.

Like cpustat_1sec and cpustat_20sec, this table shows 20 measurement sets per thread, each referencing a period of the named duration. Thus, cpustat_50ms provides 1 second of history.
The `cpustat_50ms` table contains the following columns:

- **node_id**
  ID of the node where the thread is running

- **thr_no**
  Thread ID (specific to this node)

- **OS_user_time**
  OS user time

- **OS_system_time**
  OS system time

- **OS_idle_time**
  OS idle time

- **exec_time**
  Thread execution time

- **sleep_time**
  Thread sleep time

- **spin_time**
  Thread spin time

- **send_time**
  Thread send time

- **buffer_full_time**
  Thread buffer full time

- **elapsed_time**
  Elapsed time

### 22.5.14.13 The ndbinfo cpustat_1sec Table

The `cpustat-1sec` table provides raw, per-thread CPU data obtained each second for each thread running in the NDB kernel.

Like `cpustat_50ms` and `cpustat_20sec`, this table shows 20 measurement sets per thread, each referencing a period of the named duration. Thus, `cpsustat_1sec` provides 20 seconds of history.

The `cpustat_1sec` table contains the following columns:

- **node_id**
  ID of the node where the thread is running
ndbinfo: The NDB Cluster Information Database

- **thr_no**
  Thread ID (specific to this node)

- **OS_user_time**
  OS user time

- **OS_system_time**
  OS system time

- **OS_idle_time**
  OS idle time

- **exec_time**
  Thread execution time

- **sleep_time**
  Thread sleep time

- **spin_time**
  Thread spin time

- **send_time**
  Thread send time

- **buffer_full_time**
  Thread buffer full time

- **elapsed_time**
  Elapsed time

### 22.5.14.14 The ndbinfo cpustat_20sec Table

The **cpustat_20sec** table provides raw, per-thread CPU data obtained each 20 seconds, for each thread running in the NDB kernel.

Like **cpustat_50ms** and **cpustat_1sec**, this table shows 20 measurement sets per thread, each referencing a period of the named duration. Thus, **cpustat_20sec** provides 400 seconds of history.

The **cpustat_20sec** table contains the following columns:

- **node_id**
  ID of the node where the thread is running

- **thr_no**
  Thread ID (specific to this node)

- **OS_user_time**
OS user time
• **OS_system_time**
  OS system time
• **OS_idle_time**
  OS idle time
• **exec_time**
  Thread execution time
• **sleep_time**
  Thread sleep time
• **spin_time**
  Thread spin time
• **send_time**
  Thread send time
• **buffer_full_time**
  Thread buffer full time
• **elapsed_time**
  Elapsed time

### 22.5.14.15 The ndbinfo dict_obj_info Table

The `dict_obj_info` table provides information about NDB data dictionary (DICT) objects such as tables and indexes. (The `dict_obj_types` table can be queried for a list of all the types.) This information includes the object's type, state, parent object (if any), and fully qualified name.

The `dict_obj_info` table contains the following columns:

• **type**
  Type of DICT object; join on `dict_obj_types` to obtain the name

• **id**
  Object identifier; for Disk Data undo log files and data files, this is the same as the value shown in the `LOGFILE_GROUP_NUMBER` column of the `INFORMATION_SCHEMA.FILES` table; for undo log files, it also the same as the value shown for the `log_id` column in the `ndbinfo logbuffers` and `logspaces` tables

• **version**
  Object version

• **state**
Object state

- **parent_obj_type**
  Parent object's type (a `dict_obj_types` type ID); 0 indicates that the object has no parent

- **parent_obj_id**
  Parent object ID (such as a base table); 0 indicates that the object has no parent

- **fq_name**
  Fully qualified object name; for a table, this has the form `database_name/def/table_name`, for a primary key, the form is `sys/def/table_id/PRIMARY`, and for a unique key it is `sys/def/table_id/uk_name$unique`
Number of bytes written to REDO log during this period

- `target_disk_write_speed`

Actual speed of disk writes per LDM thread (base data)

### 22.5.14.18 The ndbinfo `disk_write_speed_aggregate` Table

The `disk_write_speed_aggregate` table provides aggregated information about the speed of disk writes during LCP, backup, and restore operations.

The `disk_write_speed_aggregate` table contains the following columns:

- `node_id`
  
  Node ID of this node

- `thr_no`
  
  Thread ID of this LDM thread

- `backup_lcp_speed_last_sec`
  
  Number of bytes written to disk by backup and LCP processes in the last second

- `redo_speed_last_sec`
  
  Number of bytes written to REDO log in the last second

- `backup_lcp_speed_last_10sec`
  
  Number of bytes written to disk by backup and LCP processes per second, averaged over the last 10 seconds

- `redo_speed_last_10sec`
  
  Number of bytes written to REDO log per second, averaged over the last 10 seconds

- `std_dev_backup_lcp_speed_last_10sec`
  
  Standard deviation in number of bytes written to disk by backup and LCP processes per second, averaged over the last 10 seconds

- `std_dev_redo_speed_last_10sec`
  
  Standard deviation in number of bytes written to REDO log per second, averaged over the last 10 seconds

- `backup_lcp_speed_last_60sec`
  
  Number of bytes written to disk by backup and LCP processes per second, averaged over the last 60 seconds

- `redo_speed_last_60sec`
  
  Number of bytes written to REDO log per second, averaged over the last 10 seconds

- `std_dev_backup_lcp_speed_last_60sec`
Standard deviation in number of bytes written to disk by backup and LCP processes per second, averaged over the last 60 seconds

- std_dev_redo_speed_last_60sec

Standard deviation in number of bytes written to REDO log per second, averaged over the last 60 seconds

- slowdowns_due_to_io_lag
  Number of seconds since last node start that disk writes were slowed due to REDO log I/O lag

- slowdowns_due_to_high_cpu
  Number of seconds since last node start that disk writes were slowed due to high CPU usage

- disk_write_speed_set_to_min
  Number of seconds since last node start that disk write speed was set to minimum

- current_target_disk_write_speed
  Actual speed of disk writes per LDM thread (aggregated)

### 22.5.14.19 The ndbinfo disk_write_speed_aggregate_node Table

The `disk_write_speed_aggregate_node` table provides aggregated information per node about the speed of disk writes during LCP, backup, and restore operations.

The `disk_write_speed_aggregate_node` table contains the following columns:

- node_id
  Node ID of this node

- backup_lcp_speed_last_sec
  Number of bytes written to disk by backup and LCP processes in the last second

- redo_speed_last_sec
  Number of bytes written to REDO log in the last second

- backup_lcp_speed_last_10sec
  Number of bytes written to disk by backup and LCP processes per second, averaged over the last 10 seconds

- redo_speed_last_10sec
  Number of bytes written to REDO log per second, averaged over the last 10 seconds

- backup_lcp_speed_last_60sec
  Number of bytes written to disk by backup and LCP processes per second, averaged over the last 60 seconds

- redo_speed_last_60sec
Number of bytes written to disk by backup and LCP processes per second, averaged over the last 60 seconds

22.5.14.20 The ndbinfo diskpagebuffer Table

The `diskpagebuffer` table provides statistics about disk page buffer usage by NDB Cluster Disk Data tables.

The `diskpagebuffer` table contains the following columns:

- **node_id**
  The data node ID
- **block_instance**
  Block instance
- **pages_written**
  Number of pages written to disk.
- **pages_written_lcp**
  Number of pages written by local checkpoints.
- **pages_read**
  Number of pages read from disk.
- **log_waits**
  Number of page writes waiting for log to be written to disk
- **page_requests_direct_return**
  Number of requests for pages that were available in buffer
- **page_requests_wait_queue**
  Number of requests that had to wait for pages to become available in buffer
- **page_requests_wait_io**
  Number of requests that had to be read from pages on disk (pages were unavailable in buffer)

Notes

You can use this table with NDB Cluster Disk Data tables to determine whether `DiskPageBufferMemory` is sufficiently large to allow data to be read from the buffer rather than disk; minimizing disk seeks can help improve performance of such tables.

You can determine the proportion of reads from `DiskPageBufferMemory` to the total number of reads using a query such as this one, which obtains this ratio as a percentage:

```sql
SELECT node_id, 
100 * page_requests_direct_return /
(page_requests_direct_return + page_requests_wait_io)
```
AS hit_ratio
FROM ndbinfo.diskpagebuffer;

The result from this query should be similar to what is shown here, with one row for each data node in the cluster (in this example, the cluster has 4 data nodes):

```
+---------+-----------+
<table>
<thead>
<tr>
<th>node_id</th>
<th>hit_ratio</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>97.6744</td>
</tr>
<tr>
<td>6</td>
<td>97.6879</td>
</tr>
<tr>
<td>7</td>
<td>98.1776</td>
</tr>
<tr>
<td>8</td>
<td>98.1343</td>
</tr>
</tbody>
</table>
+---------+-----------+
```

4 rows in set (0.00 sec)

hit_ratio values approaching 100% indicate that only a very small number of reads are being made from disk rather than from the buffer, which means that Disk Data read performance is approaching an optimum level. If any of these values are less than 95%, this is a strong indicator that the setting for DiskPageBufferMemory needs to be increased in the config.ini file.

**Note**

A change in DiskPageBufferMemory requires a rolling restart of all of the cluster’s data nodes before it takes effect.

block_instance refers to an instance of a kernel block. Together with the block name, this number can be used to look up a given instance in the threadblocks table. Using this information, you can obtain information about disk page buffer metrics relating to individual threads; an example query using LIMIT 1 to limit the output to a single thread is shown here:

```
mysql> SELECT
    > node_id, thr_no, block_name, thread_name, pages_written,
    > pages_written_lcp, pages_read, log_waits,
    > page_requests_direct_return, page_requests_wait_queue,
    > page_requests_wait_io
    > FROM ndbinfo.diskpagebuffer
    > INNER JOIN ndbinfo.threadblocks USING (node_id, block_instance)
    > INNER JOIN ndbinfo.threads USING (node_id, thr_no)
    > WHERE block_name = 'PGMAN' LIMIT 1
```

```
*************************** 1. row ***************************
node_id: 1
thr_no: 1
block_name: PGMAN
thread_name: rep
pages_written: 0
pages_written_lcp: 0
pages_read: 1
log_waits: 0
page_requests_direct_return: 4
page_requests_wait_queue: 0
page_requests_wait_io: 1
1 row in set (0.01 sec)
```

**22.5.14.21 The ndbinfo diskstat Table**

The diskstat table provides information about writes to Disk Data tablespaces during the past 1 second.

The diskstat table contains the following columns:

- **node_id**
  
  Node ID of this node
• **block_instance**
  ID of reporting instance of **PGMAN**

• **pages_made_dirty**
  Number of pages made dirty during the past second

• **reads_issued**
  Reads issued during the past second

• **reads_completed**
  Reads completed during the past second

• **writes_issued**
  Writes issued during the past second

• **writes_completed**
  Writes completed during the past second

• **log_writes_issued**
  Number of times a page write has required a log write during the past second

• **log_writes_completed**
  Number of log writes completed during the last second

• **get_page_calls_issued**
  Number of **get_page()** calls issued during the past second

• **get_page_reqs_issued**
  Number of times that a **get_page()** call has resulted in a wait for I/O or completion of I/O already begun during the past second

• **get_page_reqs_completed**
  Number of **get_page()** calls waiting for I/O or I/O completion that have completed during the past second

**Notes**

Each row in this table corresponds to an instance of **PGMAN**; there is one such instance per LDM thread plus an additional instance for each data node.

The **diskstat** table was added in NDB 8.0.19.

**22.5.14.22 The ndbinfo diskstats_1sec Table**

The **diskstats_1sec** table provides information about writes to Disk Data tablespaces over the past 20 seconds.

The **diskstat** table contains the following columns:
• **node_id**
  Node ID of this node

• **block_instance**
  ID of reporting instance of *PGMAN*

• **pages_made_dirty**
  Pages made dirty during the designated 1-second interval

• **reads_issued**
  Reads issued during the designated 1-second interval

• **reads_completed**
  Reads completed during the designated 1-second interval

• **writes_issued**
  Writes issued during the designated 1-second interval

• **writes_completed**
  Writes completed during the designated 1-second interval

• **log_writes_issued**
  Number of times a page write has required a log write during the designated 1-second interval

• **log_writes_completed**
  Number of log writes completed during the designated 1-second interval

• **get_page_calls_issued**
  Number of `get_page()` calls issued during the designated 1-second interval

• **get_page_reqs_issued**
  Number of times that a `get_page()` call has resulted in a wait for I/O or completion of I/O already begun during the designated 1-second interval

• **get_page_reqs_completed**
  Number of `get_page()` calls waiting for I/O or I/O completion that have completed during the designated 1-second interval

• **seconds_ago**
  Number of 1-second intervals in the past of the interval to which this row applies

**Notes**

Each row in this table corresponds to an instance of *PGMAN* during a 1-second interval occurring from 0 to 19 seconds ago; there is one such instance per LDM thread plus an additional instance for each data node.
The diskstats_1sec table was added in NDB 8.0.19.

22.5.14.23 The ndbinfo error_messages Table

The error_messages table provides information about

The error_messages table contains the following columns:

• error_code
  Numeric error code
• error_description
  Description of error
• error_status
  Error status code
• error_classification
  Error classification code

Notes

error_code is a numeric NDB error code. This is the same error code that can be supplied to ndb_perror (or, prior to NDB 8.0.13, to perror --ndb).

error_description provides a basic description of the condition causing the error.

The error_status column provides status information relating to the error. Possible values for this column are listed here:

• No error
• Illegal connect string
• Illegal server handle
• Illegal reply from server
• Illegal number of nodes
• Illegal node status
• Out of memory
• Management server not connected
• Could not connect to socket
• Start failed
• Stop failed
• Restart failed
• Could not start backup
ndbinfo: The NDB Cluster Information Database

- Could not abort backup
- Could not enter single user mode
- Could not exit single user mode
- Failed to complete configuration change
- Failed to get configuration
- Usage error
- Success
- Permanent error
- Temporary error
- Unknown result
- Temporary error, restart node
- Permanent error, external action needed
- Ndbd file system error, restart node initial
- Unknown

The error_classification column shows the error classification. See NDB Error Classifications, for information about classification codes and their meanings.

22.5.14.24 The ndbinfo locks_per_fragment Table

The locks_per_fragment table provides information about counts of lock claim requests, and the outcomes of these requests on a per-fragment basis, serving as a companion table to operations_per_fragment and memory_per_fragment. This table also shows the total time spent waiting for locks successfully and unsuccessfully since fragment or table creation, or since the most recent restart.

The locks_per_fragment table contains the following columns:

- fq_name
  Fully qualified table name
- parent fq_name
  Fully qualified name of parent object
- type
  Table type; see text for possible values
- table_id
  Table ID
- node_id
Reporting node ID

- block_instance
  LDM instance ID
- fragment_num
  Fragment identifier
- ex_req
  Exclusive lock requests started
- ex_imm_ok
  Exclusive lock requests immediately granted
- ex_wait_ok
  Exclusive lock requests granted following wait
- ex_wait_fail
  Exclusive lock requests not granted
- sh_req
  Shared lock requests started
- sh_imm_ok
  Shared lock requests immediately granted
- sh_wait_ok
  Shared lock requests granted following wait
- sh_wait_fail
  Shared lock requests not granted
- wait_ok_millis
  Time spent waiting for lock requests that were granted, in milliseconds
- wait_fail_millis
  Time spent waiting for lock requests that failed, in milliseconds

Notes

block_instance refers to an instance of a kernel block. Together with the block name, this number can be used to look up a given instance in the threadblocks table.

fq_name is a fully qualified database object name in database/schemaname format, such as test/def/t1 or sys/def/10/b$unique.

parent_fq_name is the fully qualified name of this object's parent object (table).
**ndbinfo: The NDB Cluster Information Database**

**table_id** is the table's internal ID generated by NDB. This is the same internal table ID shown in other ndbinfo tables; it is also visible in the output of ndb_show_tables.

The **type** column shows the type of table. This is always one of: System table, User table, Unique hash index, Hash index, Unique ordered index, Ordered index, Hash index trigger, Subscription trigger, Read only constraint, Index trigger, Reorganize trigger, Tablespace, Log file group, Data file, Undo file, Hash map, Foreign key definition, Foreign key parent trigger, Foreign key child trigger, or Schema transaction.

The values shown in all of the columns ex_req, ex_req_imm_ok, ex_wait_ok, ex_wait_fail, sh_req, sh_req_imm_ok, sh_wait_ok, and sh_wait_fail represent cumulative numbers of requests since the table or fragment was created, or since the last restart of this node, whichever of these occurred later. This is also true for the time values shown in the wait_ok_millis and wait_fail_millis columns.

Every lock request is considered either to be in progress, or to have completed in some way (that is, to have succeeded or failed). This means that the following relationships are true:

\[
\begin{align*}
\text{ex_req} & \geq (\text{ex_req_imm_ok} + \text{ex_wait_ok} + \text{ex_wait_fail}) \\
\text{sh_req} & \geq (\text{sh_req_imm_ok} + \text{sh_wait_ok} + \text{sh_wait_fail})
\end{align*}
\]

The number of requests currently in progress is the current number of incomplete requests, which can be found as shown here:

\[
\begin{align*}
\text{[exclusive lock requests in progress]} & = \text{ex_req} - (\text{ex_req_imm_ok} + \text{ex_wait_ok} + \text{ex_wait_fail}) \\
\text{[shared lock requests in progress]} & = \text{sh_req} - (\text{sh_req_imm_ok} + \text{sh_wait_ok} + \text{sh_wait_fail})
\end{align*}
\]

A failed wait indicates an aborted transaction, but the abort may or may not be caused by a lock wait timeout. You can obtain the total number of aborts while waiting for locks as shown here:

\[
\text{[aborts while waiting for locks]} = \text{ex_wait_fail} + \text{sh_wait_fail}
\]

### 22.5.14.25 The ndbinfo logbuffers Table

The **logbuffer** table provides information on NDB Cluster log buffer usage.

The **logbuffers** table contains the following columns:

- **node_id**
  
  The ID of this data node.

- **log_type**
  
  Type of log. One of: REDO, DD-UNDO, BACKUP-DATA, or BACKUP-LOG.

- **log_id**
  
  The log ID; for Disk Data undo log files, this is the same as the value shown in the LOGFILE_GROUP_NUMBER column of the INFORMATION_SCHEMA.FILES table as well as the value shown for the log_id column of the ndbinfo logspaces table.

- **log_part**
  
  The component identifier for this log partition.
The log part number

- **total**
  Total space available for this log
- **used**
  Space used by this log

**Notes**

The `logbuffers` table rows reflecting two additional log types are available when performing an NDB backup. One of these rows has the log type `BACKUP-DATA`, which shows the amount of data buffer used during backup to copy fragments to backup files. The other row has the log type `BACKUP-LOG`, which displays the amount of log buffer used during the backup to record changes made after the backup has started. One each of these `log_type` rows is shown in the `logbuffers` table for each data node in the cluster. These rows are not present unless an NDB backup is currently being performed.

**22.5.14.26 The ndbinfo logspaces Table**

This table provides information about NDB Cluster log space usage.

The `logspaces` table contains the following columns:

- **node_id**
  The ID of this data node.
- **log_type**
  Type of log; one of: **REDO** or **DD-UNDO**.
- **node_id**
  The log ID; for Disk Data undo log files, this is the same as the value shown in the `LOGFILE_GROUP_NUMBER` column of the `INFORMATION_SCHEMA.FILES` table, as well as the value shown for the `log_id` column of the `ndbinfo logbuffers` table.
- **log_part**
  The log part number.
- **total**
  Total space available for this log.
- **used**
  Space used by this log.

**22.5.14.27 The ndbinfo membership Table**

The `membership` table describes the view that each data node has of all the others in the cluster, including node group membership, president node, arbitrator, arbitrator successor, arbitrator connection states, and other information.

The `membership` table contains the following columns:
• node_id
  This node's node ID
• group_id
  Node group to which this node belongs
• left_node
  Node ID of the previous node
• right_node
  Node ID of the next node
• president
  President's node ID
• successor
  Node ID of successor to president
• succession_order
  Order in which this node succeeds to presidency
• Conf_HB_order
  
• arbitrator
  Node ID of arbitrator
• arb_ticket
  Internal identifier used to track arbitration
• arb_state
  Arbitration state
• arb_connected
  Whether this node is connected to the arbitrator; either of Yes or No
• connected_rank1_arbs
  Connected arbitrators of rank 1
• connected_rank2_arbs
  Connected arbitrators of rank 1

Notes

The node ID and node group ID are the same as reported by ndb_mgm -e "SHOW".
left\_node and right\_node are defined in terms of a model that connects all data nodes in a circle, in order of their node IDs, similar to the ordering of the numbers on a clock dial, as shown here:

**Figure 22.27 Circular Arrangement of NDB Cluster Nodes**

In this example, we have 8 data nodes, numbered 5, 6, 7, 8, 12, 13, 14, and 15, ordered clockwise in a circle. We determine "left" and "right" from the interior of the circle. The node to the left of node 5 is node 15, and the node to the right of node 5 is node 6. You can see all these relationships by running the following query and observing the output:

```
mysql> SELECT node_id, left_node, right_node
    > FROM ndbinfo.membership;
```

<table>
<thead>
<tr>
<th>node_id</th>
<th>left_node</th>
<th>right_node</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>15</td>
<td>6</td>
</tr>
<tr>
<td>6</td>
<td>5</td>
<td>7</td>
</tr>
<tr>
<td>7</td>
<td>6</td>
<td>8</td>
</tr>
<tr>
<td>8</td>
<td>7</td>
<td>12</td>
</tr>
<tr>
<td>12</td>
<td>8</td>
<td>13</td>
</tr>
<tr>
<td>13</td>
<td>12</td>
<td>14</td>
</tr>
<tr>
<td>14</td>
<td>13</td>
<td>15</td>
</tr>
<tr>
<td>15</td>
<td>14</td>
<td>5</td>
</tr>
</tbody>
</table>

8 rows in set (0.00 sec)

The designations “left” and “right” are used in the event log in the same way.

The president node is the node viewed by the current node as responsible for setting an arbitrator (see NDB Cluster Start Phases). If the president fails or becomes disconnected, the current node expects the node whose ID is shown in the successor column to become the new president. The succession_order column shows the place in the succession queue that the current node views itself as having.

In a normal NDB Cluster, all data nodes should see the same node as president, and the same node (other than the president) as its successor. In addition, the current president should see itself as 1 in the order of succession, the successor node should see itself as 2, and so on.

All nodes should show the same arb\_ticket values as well as the same arb\_state values. Possible arb\_state values are ARBIT_NULL, ARBIT_INIT, ARBIT_FIND, ARBIT_PREP1, ARBIT_PREP2, ARBIT_START, ARBIT_RUN, ARBIT_CHOOSE, ARBIT_CRASH, and UNKNOWN.

arb\_connected shows whether this node is connected to the node shown as this node's arbitrator.

The connected\_rank1\_arbs and connected\_rank2\_arbs columns each display a list of 0 or more arbitrators having an ArbitrationRank equal to 1, or to 2, respectively.
Note
Both management nodes and API nodes are eligible to become arbitrators.

22.5.14.28 The ndbinfo memoryusage Table

Querying this table provides information similar to that provided by the ALL REPORT MemoryUsage command in the ndb_mgm client, or logged by ALL DUMP 1000.

The memoryusage table contains the following columns:

• node_id
  The node ID of this data node.

• memory_type
  One of Data memory, Index memory, or Long message buffer.

• used
  Number of bytes currently used for data memory or index memory by this data node.

• used_pages
  Number of pages currently used for data memory or index memory by this data node; see text.

• total
  Total number of bytes of data memory or index memory available for this data node; see text.

• total_pages
  Total number of memory pages available for data memory or index memory on this data node; see text.

Notes

The total column represents the total amount of memory in bytes available for the given resource (data memory or index memory) on a particular data node. This number should be approximately equal to the setting of the corresponding configuration parameter in the config.ini file.

Suppose that the cluster has 2 data nodes having node IDs 5 and 6, and the config.ini file contains the following:

```
[nbd default]
DataMemory = 1G
IndexMemory = 1G
```

Suppose also that the value of the LongMessageBuffer configuration parameter is allowed to assume its default (64 MB).

The following query shows approximately the same values:

```
mysql> SELECT node_id, memory_type, total
> FROM ndbinfo.memoryusage;
```

```
+---------+---------------------+------------+
| node_id | memory_type         | total      |
|---------+---------------------+------------|
|        5 | Data memory         | 1073741824 |
```
In this case, the total column values for index memory are slightly higher than the value set of IndexMemory due to internal rounding.

For the used_pages and total_pages columns, resources are measured in pages, which are 32K in size for DataMemory and 8K for IndexMemory. For long message buffer memory, the page size is 256 bytes.

**22.5.14.29 The ndbinfo memory_per_fragment Table**

The memory_per_fragment table provides information about the usage of memory by individual fragments.

The memory_per_fragment table contains the following columns:

- **fq_name**
  Name of this fragment

- **parent fq_name**
  Name of this fragment's parent

- **type**
  Type of object; see text for possible values

- **table_id**
  Table ID for this table

- **node_id**
  Node ID for this node

- **block_instance**
  Kernel block instance ID

- **fragment_num**
  Fragment ID (number)

- **fixed_elem_alloc_bytes**
  Number of bytes allocated for fixed-sized elements

- **fixed_elem_free_bytes**
  Free bytes remaining in pages allocated to fixed-size elements

- **fixed_elem_size_bytes**
Length of each fixed-size element in bytes

• **fixed_elem_count**
  Number of fixed-size elements

• **fixed_elem_free_count**
  Number of free rows for fixed-size elements

• **var_elem_alloc_bytes**
  Number of bytes allocated for variable-size elements

• **var_elem_free_bytes**
  Free bytes remaining in pages allocated to variable-size elements

• **var_elem_count**
  Number of variable-size elements

• **hash_index_alloc_bytes**
  Number of bytes allocated to hash indexes

**Notes**

The **type** column from this table shows the dictionary object type used for this fragment (**Object::Type**, in the NDB API), and can take any one of the values shown in the following list:

• System table
• User table
• Unique hash index
• Hash index
• Unique ordered index
• Ordered index
• Hash index trigger
• Subscription trigger
• Read only constraint
• Index trigger
• Reorganize trigger
• Tablespace
• Log file group
• Data file
ndbinfo: The NDB Cluster Information Database

- Undo file
- Hash map
- Foreign key definition
- Foreign key parent trigger
- Foreign key child trigger
- Schema transaction

You can also obtain this list by executing `SELECT * FROM ndbinfo.dict_obj_types` in the `mysql` client.

The `block_instance` column provides the NDB kernel block instance number. You can use this to obtain information about specific threads from the `threadblocks` table.

### 22.5.14.30 The ndbinfo nodes Table

This table contains information on the status of data nodes. For each data node that is running in the cluster, a corresponding row in this table provides the node's node ID, status, and uptime. For nodes that are starting, it also shows the current start phase.

The `nodes` table contains the following columns:

- **node_id**
  - The data node's unique node ID in the cluster.
- **uptime**
  - Time since the node was last started, in seconds.
- **status**
  - Current status of the data node; see text for possible values.
- **start_phase**
  - If the data node is starting, the current start phase.
- **config_generation**
  - The version of the cluster configuration file in use on this data node.

**Notes**

The `uptime` column shows the time in seconds that this node has been running since it was last started or restarted. This is a BIGINT value. This figure includes the time actually needed to start the node; in other words, this counter starts running the moment that `ndbd` or `ndbmtd` is first invoked; thus, even for a node that has not yet finished starting, `uptime` may show a nonzero value.

The `status` column shows the node's current status. This is one of: NOTHING, CMVMI, STARTING, STARTED, SINGLEUSER, STOPPING_1, STOPPING_2, STOPPING_3, or STOPPING_4. When the status is STARTING, you can see the current start phase in the `start_phase` column (see later in this section). SINGLEUSER is displayed in the `status` column for all data nodes when the cluster is in single user mode.
(see Section 22.5.6, “NDB Cluster Single User Mode”). Seeing one of the STOPPING states does not necessarily mean that the node is shutting down but can mean rather that it is entering a new state. For example, if you put the cluster in single user mode, you can sometimes see data nodes report their state briefly as STOPPING_2 before the status changes to SINGLEUSER.

The start_phase column uses the same range of values as those used in the output of the ndb_mgm client node_id STATUS command (see Section 22.5.1, “Commands in the NDB Cluster Management Client”). If the node is not currently starting, then this column shows 0. For a listing of NDB Cluster start phases with descriptions, see Section 22.5.4, “Summary of NDB Cluster Start Phases”.

The config_generation column shows which version of the cluster configuration is in effect on each data node. This can be useful when performing a rolling restart of the cluster in order to make changes in configuration parameters. For example, from the output of the following SELECT statement, you can see that node 3 is not yet using the latest version of the cluster configuration (6) although nodes 1, 2, and 4 are doing so:

```
mysql> USE ndbinfo;
```
```
Database changed
```
```
mysql> SELECT * FROM nodes;
```
```
+---------+--------+---------+-------------+-------------------+
| node_id | uptime | status  | start_phase | config_generation |
+---------+--------+---------+-------------+-------------------+
|       1 |  10462 | STARTED |           0 |                 6 |
|       2 |  10460 | STARTED |           0 |                 6 |
|       3 |  10457 | STARTED |           0 |                 5 |
|       4 |  10455 | STARTED |           0 |                 6 |
+---------+--------+---------+-------------+-------------------+
2 rows in set (0.04 sec)
```

Therefore, for the case just shown, you should restart node 3 to complete the rolling restart of the cluster.

Nodes that are stopped are not accounted for in this table. Suppose that you have an NDB Cluster with 4 data nodes (node IDs 1, 2, 3 and 4), and all nodes are running normally, then this table contains 4 rows, 1 for each data node:

```
mysql> USE ndbinfo;
```
```
Database changed
```
```
mysql> SELECT * FROM nodes;
```
```
+---------+--------+---------+-------------+-------------------+
| node_id | uptime | status  | start_phase | config_generation |
+---------+--------+---------+-------------+-------------------+
|       1 |  11776 | STARTED |           0 |                 6 |
|       2 |  11774 | STARTED |           0 |                 6 |
|       3 |  11771 | STARTED |           0 |                 6 |
|       4 |  11769 | STARTED |           0 |                 6 |
+---------+--------+---------+-------------+-------------------+
4 rows in set (0.04 sec)
```

If you shut down one of the nodes, only the nodes that are still running are represented in the output of this SELECT statement, as shown here:

```
ndb_mgm> 2 STOP
```
```
Node 2: Node shutdown initiated
Node 2: Node shutdown completed.
Node 2 has shutdown.
```
```
mysql> SELECT * FROM nodes;
```
```
+---------+--------+---------+-------------+-------------------+
| node_id | uptime | status  | start_phase | config_generation |
+---------+--------+---------+-------------+-------------------+
|       1 |  11807 | STARTED |           0 |                 6 |
|       3 |  11802 | STARTED |           0 |                 6 |
|       4 |  11800 | STARTED |           0 |                 6 |
+---------+--------+---------+-------------+-------------------+
3 rows in set (0.04 sec)
```
22.5.14.31 The ndbinfo operations_per_fragment Table

The operations_per_fragment table provides information about the operations performed on individual fragments and fragment replicas, as well as about some of the results from these operations.

The operations_per_fragment table contains the following columns:

- fq_name
  Name of this fragment
- parent_fq_name
  Name of this fragment's parent
- type
  Type of object; see text for possible values
- table_id
  Table ID for this table
- node_id
  Node ID for this node
- block_instance
  Kernel block instance ID
- fragment_num
  Fragment ID (number)
- tot_key_reads
  Total number of key reads for this fragment replica
- tot_key Inserts
  Total number of key inserts for this fragment replica
- tot_key_updates
  Total number of key updates for this fragment replica
- tot_key_writes
  Total number of key writes for this fragment replica
- tot_key_deletes
  Total number of key deletes for this fragment replica
- tot_key_refs
  Total number of key refs
Number of key operations refused

- **tot_key_attrinfo_bytes**
  Total size of all attrinfo attributes

- **tot_key_keyinfo_bytes**
  Total size of all keyinfo attributes

- **tot_key_prog_bytes**
  Total size of all interpreted programs carried by attrinfo attributes

- **tot_key_inst_exec**
  Total number of instructions executed by interpreted programs for key operations

- **tot_key_bytes Returned**
  Total size of all data and metadata returned from key read operations

- **tot_frag_scans**
  Total number of scans performed on this fragment replica

- **tot_scan_rows_examined**
  Total number of rows examined by scans

- **tot_scan_rows_returned**
  Total number of rows returned to client

- **tot_scan_bytes_returned**
  Total size of data and metadata returned to the client

- **tot_scan_prog_bytes**
  Total size of interpreted programs for scan operations

- **tot_scan_bound_bytes**
  Total size of all bounds used in ordered index scans

- **tot_scan_inst_exec**
  Total number of instructions executed for scans

- **tot_qd_frag_scans**
  Number of times that scans of this fragment replica have been queued

- **conc_frag_scans**
  Number of scans currently active on this fragment replica (excluding queued scans)

- **conc_qd_frag_scans**
Number of scans currently queued for this fragment replica

- tot_commits

Total number of row changes committed to this fragment replica

**Notes**

The *fq_name* contains the fully qualified name of the schema object to which this fragment replica belongs. This currently has the following formats:

- **Base table:** `DbName/def/TblName`
- **BLOB table:** `DbName/def/NDB$BLOB_BaseTblId_ColNo`
- **Ordered index:** `sys/def/BaseTblId/IndexName`
- **Unique index:** `sys/def/BaseTblId/IndexName$unique`

The `$unique` suffix shown for unique indexes is added by `mysqld`; for an index created by a different NDB API client application, this may differ, or not be present.

The syntax just shown for fully qualified object names is an internal interface which is subject to change in future releases.

Consider a table `t1` created and modified by the following SQL statements:

```sql
CREATE DATABASE mydb;

USE mydb;

CREATE TABLE t1 {
  a INT NOT NULL,
  b INT NOT NULL,
  t TEXT NOT NULL,
  PRIMARY KEY (b)
} ENGINE=ndbcluster;

CREATE UNIQUE INDEX ix1 ON t1(b) USING HASH;
```

If `t1` is assigned table ID 11, this yields the *fq_name* values shown here:

- **Base table:** `mydb/def/t1`
- **BLOB table:** `mydb/def/NDB$BLOB_11_2`
- **Ordered index (primary key):** `sys/def/11/PRIMARY`
- **Unique index:** `sys/def/11/ix1$unique`

For indexes or BLOB tables, the `parent_fq_name` column contains the *fq_name* of the corresponding base table. For base tables, this column is always `NULL`.

The *type* column shows the schema object type used for this fragment, which can take any one of the values `System table`, `User table`, `Unique hash index`, or `Ordered index`. BLOB tables are shown as `User table`.

The *table_id* column value is unique at any given time, but can be reused if the corresponding object has been deleted. The same ID can be seen using the `ndb_show_tables` utility.
The block_instance column shows which LDM instance this fragment replica belongs to. You can use this to obtain information about specific threads from the threadblocks table. The first such instance is always numbered 0.

Since there are typically two fragment replicas, and assuming that this is so, each fragment_num value should appear twice in the table, on two different data nodes from the same node group.

Since NDB does not use single-key access for ordered indexes, the counts for tot_key_reads, tot_key_inserts, tot_key_updates, tot_key_writes, and tot_key_deletes are not incremented by ordered index operations.

Note

When using tot_key_writes, you should keep in mind that a write operation in this context updates the row if the key exists, and inserts a new row otherwise. (One use of this is in the NDB implementation of the REPLACE SQL statement.)

The tot_key_refs column shows the number of key operations refused by the LDM. Generally, such a refusal is due to duplicate keys (inserts), Key not found errors (updates, deletes, and reads), or the operation was rejected by an interpreted program used as a predicate on the row matching the key.

The attrinfo and keyinfo attributes counted by the tot_key_attrinfo_bytes and tot_key_keyinfo_bytes columns are attributes of an LQHKEYREQ signal (see The NDB Communication Protocol) used to initiate a key operation by the LDM. An attrinfo typically contains tuple field values (inserts and updates) or projection specifications (for reads); keyinfo contains the primary or unique key needed to locate a given tuple in this schema object.

The value shown by tot_frag_scans includes both full scans (that examine every row) and scans of subsets. Unique indexes and BLOB tables are never scanned, so this value, like other scan-related counts, is 0 for fragment replicas of these.

tot_scan_rows_examined may display less than the total number of rows in a given fragment replica, since ordered index scans can limited by bounds. In addition, a client may choose to end a scan before all potentially matching rows have been examined; this occurs when using an SQL statement containing a LIMIT or EXISTS clause, for example. tot_scan_rows_returned is always less than or equal to tot_scan_rows_examined.

tot_scan_bytes_returned includes, in the case of pushed joins, projections returned to the DBSPJ block in the NDB kernel.

tot_qd_frag_scans can be effected by the setting for the MaxParallelScansPerFragment data node configuration parameter, which limits the number of scans that may execute concurrently on a single fragment replica.

22.5.14.32 The ndbinfo pgman_time_track_stats Table

This table provides information regarding the latency of disk operations for NDB Cluster Disk Data tablespaces.

The pgman_time_track_stats table contains the following columns:

- **node_id**
  
  Unique node ID of this node in the cluster

- **block_number**
  
  Block number (from blocks table)
- **block_instance**
  Block instance number
- **upper_bound**
  Upper bound
- **page_reads**
  Page read latency (ms)
- **page_writes**
  Page write latency (ms)
- **log_waits**
  Log wait latency (ms)
- **get_page**
  Latency of `get_page()` calls (ms)

**Notes**

The read latency (*page_reads* column) measures the time from when the read request is sent to the file system thread until the read is complete and has been reported back to the execution thread. The write latency (*page_writes*) is calculated in a similar fashion. The size of the page read to or written from a Disk Data tablespace is always 32 KB.

Log wait latency (*log_waits* column) is the length of time a page write must wait for the undo log to be flushed, which must be done prior to each page write.

The *pgman_time_track_stats* table was added in NDB 8.0.19.

### 22.5.14.33 The ndbinfo processes Table

This table contains information about NDB Cluster node processes; each node is represented by the row in the table. Only nodes that are connected to the cluster are shown in this table. You can obtain information about nodes that are configured but not connected to the cluster from the *nodes* and *config_nodes* tables.

The *processes* table contains the following columns:

- **node_id**
  The node's unique node ID in the cluster
- **node_type**
  Type of node (management, data, or API node; see text)
- **node_version**
  Version of the NDB software program running on this node.
This node's process ID

• **angel_process_id**
  Process ID of this node's angel process

• **process_name**
  Name of the executable

• **service_URI**
  Service URI of this node (see text)

**Notes**

**node_id** is the ID assigned to this node in the cluster.

The **node_type** column displays one of the following three values:

• **MGM**: Management node.
• **NDB**: Data node.
• **API**: API or SQL node.

For an executable shipped with the NDB Cluster distribution, **node_version** shows the software Cluster version string, such as `8.0.22-ndb-8.0.22`.

**process_id** is the node executable's process ID as shown by the host operating system using a process display application such as `top` on Linux, or the Task Manager on Windows platforms.

**angel_process_id** is the system process ID for the node's angel process, which ensures that a data node or SQL is automatically restarted in cases of failures. For management nodes and API nodes other than SQL nodes, the value of this column is **NULL**.

The **process_name** column shows the name of the running executable. For management nodes, this is `ndb_mgmd`. For data nodes, this is `ndbd` (single-threaded) or `ndbmtd` (multithreaded). For SQL nodes, this is `mysqld`. For other types of API nodes, it is the name of the executable program connected to the cluster; NDB API applications can set a custom value for this using `Ndb_cluster_connection::set_name()`.

**service_URI** shows the service network address. For management nodes and data nodes, the scheme used is `ndb://`. For SQL nodes, this is `mysql://`. By default, API nodes other than SQL nodes use `ndb://` for the scheme; NDB API applications can set this to a custom value using `Ndb_cluster_connection::set_service_uri()`. regardless of the node type, the scheme is followed by the IP address used by the NDB transporter for the node in question. For management nodes and SQL nodes, this address includes the port number (usually 1186 for management nodes and 3306 for SQL nodes). If the SQL node was started with the `bind_address` system variable set, this address is used instead of the transporter address, unless the bind address is set to `*`, `0.0.0.0`, or `::`.

Additional path information may be included in the **service_URI** value for an SQL node reflecting various configuration options. For example, `mysql://198.51.100.3/tmp/mysql.sock` indicates that the SQL node was started with the `skip_networking` system variable enabled, and `mysql://198.51.100.3:3306/?server-id=1` shows that replication is enabled for this SQL node.
This table provides information about data node resource availability and usage.

These resources are sometimes known as *super-pools*.

The *resources* table contains the following columns:

- **node_id**
  The unique node ID of this data node.

- **resource_name**
  Name of the resource; see text.

- **reserved**
  The amount reserved for this resource.

- **used**
  The amount actually used by this resource.

- **max**
  The maximum amount of this resource used, since the node was last started.

**Notes**

The *resource_name* can be any one of the names shown in the following table:

- **RESERVED**: Reserved by the system; cannot be overridden.

- **DISK_OPERATIONS**: If a log file group is allocated, the size of the undo log buffer is used to set the size of this resource. This resource is used only to allocate the undo log buffer for an undo log file group; there can only be one such group. Overallocation occurs as needed by `CREATE LOGFILE GROUP`.

- **DISK_RECORDS**: Records allocated for Disk Data operations.

- **DATA_MEMORY**: Used for main memory tuples, indexes, and hash indexes. Sum of DataMemory and IndexMemory, plus 8 pages of 32 KB each if IndexMemory has been set. Cannot be overallocated.

- **JOBBUFFER**: Used for allocating job buffers by the NDB scheduler; cannot be overallocated. This is approximately 2 MB per thread plus a 1 MB buffer in both directions for all threads that can communicate. For large configurations this consume several GB.

- **FILE_BUFFERS**: Used by the redo log handler in the DBLQH kernel block; cannot be overallocated. Size is `NoOfFragmentLogParts * RedoBuffer`, plus 1 MB per log file part.

- **TRANSPORTER_BUFFERS**: Used for send buffers by `ndbmd`; the sum of `TotalSendBufferMemory` and `ExtraSendBufferMemory`. This resource that can be overallocated by up to 25 percent. `TotalSendBufferMemory` is calculated by summing the send buffer memory per node, the default value of which is 2 MB. Thus, in a system having four data nodes and eight API nodes, the data nodes have 12 * 2 MB send buffer memory. `ExtraSendBufferMemory` is used by `ndbmd` and amounts to 2 MB extra memory per thread. Thus, with 4 LDM threads, 2 TC threads, 1 main thread, 1 replication thread, and 2 receive threads, `ExtraSendBufferMemory` is 10 * 2 MB. Overallocation of this resource can be performed by setting the `SharedGlobalMemory` data node configuration parameter.

- **DISK_PAGE_BUFFER**: Used for the disk page buffer; determined by the `DiskPageBufferMemory` configuration parameter. Cannot be overallocated.
**22.5.14.35 The ndbinfo restart_info Table**

The **restart_info** table contains information about node restart operations. Each entry in the table corresponds to a node restart status report in real time from a data node with the given node ID. Only the most recent report for any given node is shown.

The **restart_info** table contains the following columns:

- **node_id**
  
  Node ID in the cluster

- **node_restart_status**
  
  Node status; see text for values. Each of these corresponds to a possible value of **node_restart_status_int**.

- **node_restart_status_int**
  
  Node status code; see text for values.

- **secs_to_complete_node_failure**
  
  Time in seconds to complete node failure handling

- **secs_to_allocate_node_id**
  
  Time in seconds from node failure completion to allocation of node ID

- **secs_to_include_in_heartbeat_protocol**
  
  Time in seconds from allocation of node ID to inclusion in heartbeat protocol

- **secs_until_wait_for_ndbcntr_master**
  
  Time in seconds from being included in heartbeat protocol until waiting for **NDBCNTR** master began

- **secs_wait_for_ndbcntr_master**
  
  Time in seconds spent waiting to be accepted by **NDBCNTR** master for starting

- **secs_to_get_start_permitted**
  
  Time in seconds elapsed from receiving of permission for start from master until all nodes have accepted start of this node

- **secs_to_wait_for_lcp_for_copy_meta_data**
  
  Time in seconds spent waiting for LCP completion before copying meta data

- **secs_to_copy_meta_data**
  
  Time in seconds required to copy metadata from master to newly starting node
• **secs_to_include_node**
  Time in seconds waited for GCP and inclusion of all nodes into protocols

• **secs_starting_node_to_request_local_recovery**
  Time in seconds that the node just starting spent waiting to request local recovery

• **secs_for_local_recovery**
  Time in seconds required for local recovery by node just starting

• **secs_restore_fragments**
  Time in seconds required to restore fragments from LCP files

• **secs_undo_disk_data**
  Time in seconds required to execute undo log on disk data part of records

• **secs_exec_redo_log**
  Time in seconds required to execute redo log on all restored fragments

• **secs_index_rebuild**
  Time in seconds required to rebuild indexes on restored fragments

• **secs_to_synchronize_starting_node**
  Time in seconds required to synchronize starting node from live nodes

• **secs_wait_lcp_for_restart**
  Time in seconds required for LCP start and completion before restart was completed

• **secs_wait_subscription_handover**
  Time in seconds spent waiting for handover of replication subscriptions

• **total_restart_secs**
  Total number of seconds from node failure until node is started again

**Notes**

The following list contains values defined for the `node_restart_status_int` column with their internal status names (in parentheses), and the corresponding messages shown in the `node_restart_status` column:

• **0 (ALLOCATED_NODE_ID)**
  Allocated node id

• **1 (INCLUDED_IN_HB_PROTOCOL)**
  Included in heartbeat protocol

• **2 (NDBCNTR_START_WAIT)**
  Start wait for node to restart
Wait for NDBCNTR master to permit us to start

• 3 (NDBCNTR_STARTED)
  
  NDBCNTR master permitted us to start

• 4 (START_PERMITTED)
  
  All nodes permitted us to start

• 5 (WAIT_LCP_TO_COPY_DICT)
  
  Wait for LCP completion to start copying metadata

• 6 (COPY_DICT_TO_STARTING_NODE)
  
  Copying metadata to starting node

• 7 (INCLUDE_NODE_IN_LCP_AND_GCP)
  
  Include node in LCP and GCP protocols

• 8 (LOCAL_RECOVERY_STARTED)
  
  Restore fragments ongoing

• 9 (COPY_FRAGMENTS_STARTED)
  
  Synchronizing starting node with live nodes

• 10 (WAIT_LCP_FOR_RESTART)
  
  Wait for LCP to ensure durability

• 11 (WAIT_SUMA_HANOVER)
  
  Wait for handover of subscriptions

• 12 (RESTART_COMPLETED)
  
  Restart completed

• 13 (NODE_FAILED)
  
  Node failed, failure handling in progress

• 14 (NODE_FAILURE_COMPLETED)
  
  Node failure handling completed

• 15 (NODE_GETTING_PERMIT)
  
  All nodes permitted us to start

• 16 (NODE_GETTING_INCLUDED)
  
  Include node in LCP and GCP protocols

• 17 (NODE_GETTING_SYNCHED)
Synchronizing starting node with live nodes

- 18 (NODE_GETTING_LCP_WAITED)
  [none]

- 19 (NODE_ACTIVE)
  Restart completed

- 20 (NOT_DEFINED_IN_CLUSTER)
  [none]

- 21 (NODE_NOT_RESTARTED_YET)
  Initial state

Status numbers 0 through 12 apply on master nodes only; the remainder of those shown in the table apply to all restarting data nodes. Status numbers 13 and 14 define node failure states; 20 and 21 occur when no information about the restart of a given node is available.

See also Section 22.5.4, “Summary of NDB Cluster Start Phases”.

22.5.14.36 The ndbinfo server_locks Table

The server_locks table is similar in structure to the cluster_locks table, and provides a subset of the information found in the latter table, but which is specific to the SQL node (MySQL server) where it resides. (The cluster_locks table provides information about all locks in the cluster.) More precisely, server_locks contains information about locks requested by threads belonging to the current mysql instance, and serves as a companion table to server_operations. This may be useful for correlating locking patterns with specific MySQL user sessions, queries, or use cases.

The server_locks table contains the following columns:

- mysql_connection_id
  MySQL connection ID

- node_id
  ID of reporting node

- block_instance
  ID of reporting LDM instance

- tableid
  ID of table containing this row

- fragmentid
  ID of fragment containing locked row

- rowid
  ID of locked row
• **transid**
  Transaction ID
• **mode**
  Lock request mode
• **state**
  Lock state
• **detail**
  Whether this is first holding lock in row lock queue
• **op**
  Operation type
• **duration_millis**
  Milliseconds spent waiting or holding lock
• **lock_num**
  ID of lock object
• **waiting_for**
  Waiting for lock with this ID

**Notes**

The `mysql_connection_id` column shows the MySQL connection or thread ID as shown by `SHOW PROCESSLIST`.

`block_instance` refers to an instance of a kernel block. Together with the block name, this number can be used to look up a given instance in the `threadblocks` table.

The `tableid` is assigned to the table by NDB; the same ID is used for this table in other `ndbinfo` tables, as well as in the output of `ndb_show_tables`.

The transaction ID shown in the `transid` column is the identifier generated by the NDB API for the transaction requesting or holding the current lock.

The `mode` column shows the lock mode, which is always one of `S` (shared lock) or `X` (exclusive lock). If a transaction has an exclusive lock on a given row, all other locks on that row have the same transaction ID.

The `state` column shows the lock state. Its value is always one of `H` (holding) or `W` (waiting). A waiting lock request waits for a lock held by a different transaction.

The `detail` column indicates whether this lock is the first holding lock in the affected row's lock queue, in which case it contains an `*` (asterisk character); otherwise, this column is empty. This information can be used to help identify the unique entries in a list of lock requests.

The `op` column shows the type of operation requesting the lock. This is always one of the values `READ`, `INSERT`, `UPDATE`, `DELETE`, `SCAN`, or `REFRESH`. 
The `duration_millis` column shows the number of milliseconds for which this lock request has been waiting or holding the lock. This is reset to 0 when a lock is granted for a waiting request.

The lock ID (`lockid` column) is unique to this node and block instance.

If the `lock_state` column's value is `W`, this lock is waiting to be granted, and the `waiting_for` column shows the lock ID of the lock object this request is waiting for. Otherwise, `waiting_for` is empty. `waiting_for` can refer only to locks on the same row (as identified by `node_id`, `block_instance`, `tableid`, `fragmentid`, and `rowid`).

### 22.5.14.37 The ndbinfo server_operations Table

The `server_operations` table contains entries for all ongoing NDB operations that the current SQL node (MySQL Server) is currently involved in. It effectively is a subset of the `cluster_operations` table, in which operations for other SQL and API nodes are not shown.

The `server_operations` table contains the following columns:

- **mysql_connection_id**
  MySQL Server connection ID

- **node_id**
  Node ID

- **block_instance**
  Block instance

- **transid**
  Transaction ID

- **operation_type**
  Operation type (see text for possible values)

- **state**
  Operation state (see text for possible values)

- **tableid**
  Table ID

- **fragmentid**
  Fragment ID

- **client_node_id**
  Client node ID

- **client_block_ref**
  Client block reference

- **tc_node_id**
 
Transaction coordinator node ID

- tc_block_no

Transaction coordinator block number

- tc_block_instance

Transaction coordinator block instance

Notes

The mysql_connection_id is the same as the connection or session ID shown in the output of SHOW PROCESSLIST. It is obtained from the INFORMATION_SCHEMA table NDB_TRANSID_MYSQL_CONNECTION_MAP.

block_instance refers to an instance of a kernel block. Together with the block name, this number can be used to look up a given instance in the threadblocks table.

The transaction ID (transid) is a unique 64-bit number which can be obtained using the NDB API's getTransactionId() method. (Currently, the MySQL Server does not expose the NDB API transaction ID of an ongoing transaction.)

The operation_type column can take any one of the values READ, READ-SH, READ-EX, INSERT, UPDATE, DELETE, WRITE, UNLOCK, REFRESH, SCAN, SCAN-SH, SCAN-EX, or <unknown>.

The state column can have any one of the values ABORT_QUEUED, ABORT_STOPPED, COMMITTED, COMMIT_QUEUED, COMMIT_STOPPED, COPY_CLOSE_STOPPED, COPY_FIRST_STOPPED, COPY_STOPPED, COPY_TUPKEY, IDLE, LOG_ABORT_QUEUED, LOG_COMMIT_QUEUED, LOG_COMMIT_QUEUE_WAIT_SIGNAL, LOG_COMMIT_WRITTEN, LOG_COMMIT_WRITTEN_WAIT_SIGNAL, LOG_QUEUED, PREPARED, PREPARED_RECEIVED_COMMIT, SCAN_CHECK_STOPPED, SCAN_CLOSE_STOPPED, SCAN_FIRST_STOPPED, SCAN_RELEASE_STOPPED, SCAN_STATE_USED, SCAN_STOPPED, SCAN_TUPKEY, STOPPED, TC_NOT_CONNECTED, WAIT_ACC, WAIT_ACC_ABORT, WAIT_AI_AFT_ABORT, WAIT_ATTR, WAIT_SCAN_AI, WAIT_TUP, WAIT_TUPKEYINFO, WAIT_TUP_COMMIT, or WAIT_TUP_TO_ABORT. (If the MySQL Server is running with ndbinfo_show_hidden enabled, you can view this list of states by selecting from the ndb $dbtqh_tcconnect_state table, which is normally hidden.)

You can obtain the name of an NDB table from its table ID by checking the output of ndb_show_tables.

The fragid is the same as the partition number seen in the output of ndb_desc --extra-partition-info (short form -p).

In client_node_id and client_block_ref, client refers to an NDB Cluster API or SQL node (that is, an NDB API client or a MySQL Server attached to the cluster).

The block_instance and tc_block_instance column provide NDB kernel block instance numbers. You can use these to obtain information about specific threads from the threadblocks table.

22.5.14.38 The ndbinfo server_transactions Table

The server_transactions table is subset of the cluster_transactions table, but includes only those transactions in which the current SQL node (MySQL Server) is a participant, while including the relevant connection IDs.

The server_transactions table contains the following columns:
ndbinfo: The NDB Cluster Information Database

- **mysql_connection_id**
  MySQL Server connection ID

- **node_id**
  Transaction coordinator node ID

- **block_instance**
  Transaction coordinator block instance

- **transid**
  Transaction ID

- **state**
  Operation state (see text for possible values)

- **count_operations**
  Number of stateful operations in the transaction

- **outstanding_operations**
  Operations still being executed by local data management layer (LQH blocks)

- **inactive_seconds**
  Time spent waiting for API

- **client_node_id**
  Client node ID

- **client_block_ref**
  Client block reference

**Notes**

The **mysql_connection_id** is the same as the connection or session ID shown in the output of `SHOW PROCESSLIST`. It is obtained from the **INFORMATION_SCHEMA** table `NDB_TRANSID_MYSQL_CONNECTION_MAP`.

**block_instance** refers to an instance of a kernel block. Together with the block name, this number can be used to look up a given instance in the `threadblocks` table.

The transaction ID (**transid**) is a unique 64-bit number which can be obtained using the NDB API's `getTransactionId()` method. (Currently, the MySQL Server does not expose the NDB API transaction ID of an ongoing transaction.)

The **state** column can have any one of the values `CS_ABORTING, CS_COMMITTING, CS_COMMIT_SENT, CS_COMPLETE_SENT, CS_COMPLETING, CS_CONNECTED, CS_DISCONNECTED, CS_FAIL_ABORTED, CS_FAIL_ABORTING, CS_FAIL_COMMITTED, CS_FAIL_COMMITTING, CS_FAIL_COMPLETED, CS_FAIL_PREPARED, CS_PREPARE_TO_COMMIT, CS_RECEIVING, CS_REC_COMMITTING, CS_RESTART, CS_SEND_FIRE_TRIG_REQ, CS_STARTED, CS_START_COMMITTING`. 
CS_START_SCAN, CS_WAIT_ABORT_CONF, CS_WAIT_COMMIT_CONF, CS_WAIT_COMPLETE_CONF, CS_WAIT_FIRE_TRIG_REQ. (If the MySQL Server is running with ndbinfo_show_hidden enabled, you can view this list of states by selecting from the ndb$dtc_apiconnect_state table, which is normally hidden.)

In client_node_id and client_block_ref, client refers to an NDB Cluster API or SQL node (that is, an NDB API client or a MySQL Server attached to the cluster).

The block_instance column provides the DBTC kernel block instance number. You can use this to obtain information about specific threads from the threadblocks table.

22.5.14.39 The ndbinfo table_distribution_status Table

The table_distribution_status table provides information about the progress of table distribution for NDB tables.

The table_distribution_status table contains the following columns:

- node_id
  Node id
- table_id
  Table ID
- tab_copy_status
  Status of copying of table distribution data to disk; one of IDLE, SR_PHASE1_READ_PAGES, SR_PHASE2_READ_TABLE, SR_PHASE3_COPY_TABLE, REMOVE_NODE, LCP_READ_TABLE, COPY_TAB_REQ, COPY_NODE_STATE, ADD_TABLE_MASTER, ADD_TABLE_SLAVE, INVALIDATE_NODE_LCP, ALTER_TABLE, COPY_TO_SAVE, or GET_TABINFO
- tab_update_status
  Status of updating of table distribution data; one of IDLE, LOCAL_CHECKPOINT, LOCAL_CHECKPOINT_QUEUED, REMOVE_NODE, COPY_TAB_REQ, ADD_TABLE_MASTER, ADD_TABLE_SLAVE, INVALIDATE_NODE_LCP, or CALLBACK
- tab_lcp_status
  Status of table LCP; one of ACTIVE (waiting for local checkpoint to be performed), WRITING_TO_FILE (checkpoint performed but not yet written to disk), or COMPLETED (checkpoint performed and persisted to disk)
- tab_status
  Table internal status; one of ACTIVE (table exists), CREATING (table is being created), or DROPPING (table is being dropped)
- tab_storage
  Table recoverability; one of NORMAL (fully recoverable with redo logging and checkpointing), NOLOGGING (recoverable from node crash, empty following cluster crash), or TEMPORARY (not recoverable)
- tab_partitions
  Number of partitions in table
• **tab_fragments**

  Number of fragments in table; normally same as **tab_partitions**; for fully replicated tables equal to **tab_partitions** * [number of node groups]

• **current_scan_count**

  Current number of active scans

• **scan_count_wait**

  Current number of scans waiting to be performed before `ALTER TABLE` can complete.

• **is_reorg_ongoing**

  Whether the table is currently being reorganized (1 if true)

### 22.5.14.40 The ndbinfo table_fragments Table

The `table_fragments` table provides information about the fragmentation, partitioning, distribution, and (internal) replication of **NDB** tables.

The `table_fragments` table contains the following columns:

• **node_id**

  Node ID (**DIH master**)

• **table_id**

  Table ID

• **partition_id**

  Partition ID

• **fragment_id**

  Fragment ID (same as partition ID unless table is fully replicated)

• **partition_order**

  Order of fragment in partition

• **log_part_id**

  Log part ID of fragment

• **no_of_replicas**

  Number of fragment replicas

• **current_primary**

  Current primary node ID

• **preferred_primary**

  Preferred primary node ID
• **current_first_backup**
  Current first backup node ID
• **current_second_backup**
  Current second backup node ID
• **current_third_backup**
  Current third backup node ID
• **num_alive_replicas**
  Current number of live fragment replicas
• **num_dead_replicas**
  Current number of dead fragment replicas
• **num_lcp_replicas**
  Number of fragment replicas remaining to be checkpointed

### 22.5.14.41 The ndbinfo table_info Table

The **table_info** table provides information about logging, checkpointing, distribution, and storage options in effect for individual NDB tables.

The **table_info** table contains the following columns:

- **table_id**
  
  Table ID

- **logged_table**
  
  Whether table is logged (1) or not (0)

- **row_contains_gci**
  
  Whether table rows contain GCI (1 true, 0 false)

- **row_contains_checksum**
  
  Whether table rows contain checksum (1 true, 0 false)

- **read_backup**
  
  If backup fragment replicas are read this is 1, otherwise 0

- **fully_replicated**
  
  If table is fully replicated this is 1, otherwise 0

- **storage_type**
  
  Table storage type; one of MEMORY or DISK

- **hashmap_id**
Hashmap ID

- **partition_balance**
  
  Partition balance (fragment count type) used for table; one of `FOR_RP_BY_NODE`, `FOR_RA_BY_NODE`, `FOR_RP_BY_LDM`, or `FOR_RA_BY_LDM`

- **create_gci**
  
  GCI in which table was created

### 22.5.14.42 The ndbinfo table_replicas Table

The **table_replicas** table provides information about the copying, distribution, and checkpointing of NDB table fragments and fragment replicas.

The **table_replicas** table contains the following columns:

- **node_id**
  
  ID of the node from which data is fetched (DIH master)

- **table_id**
  
  Table ID

- **fragment_id**
  
  Fragment ID

- **initial_gci**
  
  Initial GCI for table

- **replica_node_id**
  
  ID of node where fragment replica is stored

- **is_lcp_ongoing**
  
  Is 1 if LCP is ongoing on this fragment, 0 otherwise

- **num_crashed_replicas**
  
  Number of crashed fragment replica instances

- **last_max_gci_started**
  
  Highest GCI started in most recent LCP

- **last_max_gci_completed**
  
  Highest GCI completed in most recent LCP

- **last_lcp_id**
  
  ID of most recent LCP

- **prev_lcp_id**
  
  ID of previous LCP
ID of previous LCP

- **prev_max_gci_started**
  Highest GCI started in previous LCP

- **prev_max_gci_completed**
  Highest GCI completed in previous LCP

- **last_create_gci**
  Last Create GCI of last crashed fragment replica instance

- **last_replica_gci**
  Last GCI of last crashed fragment replica instance

- **is_replica_alive**
  1 if this fragment replica is alive, 0 otherwise

### 22.5.14.43 The ndbinfo tc_time_track_stats Table

The **tc_time_track_stats** table provides time-tracking information obtained from the DBTC block (TC) instances in the data nodes, through API nodes access NDB. Each TC instance tracks latencies for a set of activities it undertakes on behalf of API nodes or other data nodes; these activities include transactions, transaction errors, key reads, key writes, unique index operations, failed key operations of any type, scans, failed scans, fragment scans, and failed fragment scans.

A set of counters is maintained for each activity, each counter covering a range of latencies less than or equal to an upper bound. At the conclusion of each activity, its latency is determined and the appropriate counter incremented. **tc_time_track_stats** presents this information as rows, with a row for each instance of the following:

- Data node, using its ID
- TC block instance
- Other communicating data node or API node, using its ID
- Upper bound value

Each row contains a value for each activity type. This is the number of times that this activity occurred with a latency within the range specified by the row (that is, where the latency does not exceed the upper bound).

The **tc_time_track_stats** table contains the following columns:

- **node_id**
  Requesting node ID

- **block_number**
  TC block number

- **block_instance**
TC block instance number

• **comm_node_id**
  Node ID of communicating API or data node

• **upper_bound**
  Upper bound of interval (in microseconds)

• **scans**
  Based on duration of successful scans from opening to closing, tracked against the API or data nodes requesting them.

• **scan_errors**
  Based on duration of failed scans from opening to closing, tracked against the API or data nodes requesting them.

• **scan.fragments**
  Based on duration of successful fragment scans from opening to closing, tracked against the data nodes executing them

• **scan.fragment.errors**
  Based on duration of failed fragment scans from opening to closing, tracked against the data nodes executing them

• **transactions**
  Based on duration of successful transactions from beginning until sending of commit ACK, tracked against the API or data nodes requesting them. Stateless transactions are not included.

• **transaction.errors**
  Based on duration of failing transactions from start to point of failure, tracked against the API or data nodes requesting them.

• **read_key.ops**
  Based on duration of successful primary key reads with locks. Tracked against both the API or data node requesting them and the data node executing them.

• **write_key.ops**
  Based on duration of successful primary key writes, tracked against both the API or data node requesting them and the data node executing them.

• **index_key.ops**
  Based on duration of successful unique index key operations, tracked against both the API or data node requesting them and the data node executing reads of base tables.

• **key_op.errors**
  Based on duration of all unsuccessful key read or write operations, tracked against both the API or data node requesting them and the data node executing them.
Notes

The `block_instance` column provides the DBTC kernel block instance number. You can use this together with the block name to obtain information about specific threads from the `threadblocks` table.

22.5.14.44 The ndbinfo threadblocks Table

The `threadblocks` table associates data nodes, threads, and instances of NDB kernel blocks.

The `threadblocks` table contains the following columns:

- `node_id`
  Node ID
- `thr_no`
  Thread ID
- `block_name`
  Block name
- `block_instance`
  Block instance number

Notes

The value of the `block_name` in this table is one of the values found in the `block_name` column when selecting from the `ndbinfo.blocks` table. Although the list of possible values is static for a given NDB Cluster release, the list may vary between releases.

The `block_instance` column provides the kernel block instance number.

22.5.14.45 The ndbinfo threads Table

The `threads` table provides information about threads running in the NDB kernel.

The `threads` table contains the following columns:

- `node_id`
  ID of the node where the thread is running
- `thr_no`
  Thread ID (specific to this node)
- `thread_name`
  Thread name (type of thread)
- `thread_description`
  Thread (type) description

Notes

Sample output from a 2-node example cluster, including thread descriptions, is shown here:
SELECT * FROM threads;

<table>
<thead>
<tr>
<th>node_id</th>
<th>thr_no</th>
<th>thread_name</th>
<th>thread_description</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>0</td>
<td>main</td>
<td>main thread, schema and distribution handling</td>
</tr>
<tr>

<td>receive thread, performing receive and polling for new receives</td>
</tr>
</tbody>
</table>

8 rows in set (0.01 sec)

The ndbinfo threadstat Table

The `threadstat` table provides a rough snapshot of statistics for threads running in the NDB kernel.

The `threadstat` table contains the following columns:

- **node_id**
  Node ID
- **thr_no**
  Thread ID
- **thr_nm**
  Thread name
- **c_loop**
  Number of loops in main loop
- **c_exec**
  Number of signals executed
- **c_wait**
  Number of times waiting for additional input
- **c_l_sent_prioa**
  Number of priority A signals sent to own node
- **c_l_sent_priob**
  Number of priority B signals sent to own node
- **c_r_sent_prioa**
  Number of priority A signals sent to remote node
- **c_r_sent_priob**
  Number of priority B signals sent to remote node
ndbinfo: The NDB Cluster Information Database

- **os_tid**
  OS thread ID
- **os_now**
  OS time (ms)
- **os_ru_utime**
  OS user CPU time (µs)
- **os_ru_stime**
  OS system CPU time (µs)
- **os_ru_minflt**
  OS page reclaims (soft page faults)
- **os_ru_majflt**
  OS page faults (hard page faults)
- **os_ru_nvcsw**
  OS voluntary context switches
- **os_ru_nivcsw**
  OS involuntary context switches

**Notes**

`os_time` uses the system `gettimeofday()` call.

The values of the `os_ru_utime`, `os_ru_stime`, `os_ru_minflt`, `os_ru_majflt`, `os_ru_nvcsw`, and `os_ru_nivcsw` columns are obtained using the system `getrusage()` call, or the equivalent.

Since this table contains counts taken at a given point in time, for best results it is necessary to query this table periodically and store the results in an intermediate table or tables. The MySQL Server’s Event Scheduler can be employed to automate such monitoring. For more information, see Section 24.4, “Using the Event Scheduler”.

### 22.5.14.47 The ndbinfo transporters Table

This table contains information about NDB transporters.

The `transporters` table contains the following columns:

- **node_id**
  This data node’s unique node ID in the cluster
- **remote_node_id**
  The remote data node’s node ID
- **status**
Status of the connection

- **remote_address**
  Name or IP address of the remote host

- **bytes_sent**
  Number of bytes sent using this connection

- **bytes_received**
  Number of bytes received using this connection

- **connect_count**
  Number of times connection established on this transporter

- **overloaded**
  1 if this transporter is currently overloaded, otherwise 0

- **overload_count**
  Number of times this transporter has entered overload state since connecting

- **slowdown**
  1 if this transporter is in slowdown state, otherwise 0

- **slowdown_count**
  Number of times this transporter has entered slowdown state since connecting

**Notes**

For each running data node in the cluster, the `transporters` table displays a row showing the status of each of that node’s connections with all nodes in the cluster, including itself. This information is shown in the table’s `status` column, which can have any one of the following values: `CONNECTING`, `CONNECTED`, `DISCONNECTING`, or `DISCONNECTED`.

Connections to API and management nodes which are configured but not currently connected to the cluster are shown with status `DISCONNECTED`. Rows where the `node_id` is that of a data node which is not currently connected are not shown in this table. (This is similar omission of disconnected nodes in the `ndbinfo.nodes` table.

The `remote_address` is the host name or address for the node whose ID is shown in the `remote_node_id` column. The `bytes_sent` from this node and `bytes_received` by this node are the numbers, respectively, of bytes sent and received by the node using this connection since it was established. For nodes whose status is `CONNECTING` or `DISCONNECTED`, these columns always display 0.

Assume you have a 5-node cluster consisting of 2 data nodes, 2 SQL nodes, and 1 management node, as shown in the output of the `SHOW` command in the `ndb_mgm` client:

```
ndb_mgm> SHOW
Connected to Management Server at: localhost:1186
Cluster Configuration
--------------------------
[ndbd(NDB)]   2 node(s)
```
There are 10 rows in the `transporters` table—5 for the first data node, and 5 for the second—assuming that all data nodes are running, as shown here:

```
mysql> SELECT node_id, remote_node_id, status
    -> FROM ndbinfo.transporters;
```

```
<table>
<thead>
<tr>
<th>node_id</th>
<th>remote_node_id</th>
<th>status</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>DISCONNECTED</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>CONNECTED</td>
</tr>
<tr>
<td>1</td>
<td>10</td>
<td>CONNECTED</td>
</tr>
<tr>
<td>1</td>
<td>20</td>
<td>CONNECTED</td>
</tr>
<tr>
<td>1</td>
<td>21</td>
<td>CONNECTED</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
<td>CONNECTED</td>
</tr>
<tr>
<td>2</td>
<td>2</td>
<td>DISCONNECTED</td>
</tr>
<tr>
<td>2</td>
<td>10</td>
<td>CONNECTED</td>
</tr>
<tr>
<td>2</td>
<td>20</td>
<td>CONNECTED</td>
</tr>
<tr>
<td>2</td>
<td>21</td>
<td>CONNECTED</td>
</tr>
</tbody>
</table>
```

10 rows in set (0.04 sec)

If you shut down one of the data nodes in this cluster using the command `STOP` in the `ndb_mgm` client, then repeat the previous query (again using the `mysql` client), this table now shows only 5 rows—1 row for each connection from the remaining management node to another node, including both itself and the data node that is currently offline—and displays `CONNECTING` for the status of each remaining connection to the data node that is currently offline, as shown here:

```
mysql> SELECT node_id, remote_node_id, status
    -> FROM ndbinfo.transporters;
```

```
<table>
<thead>
<tr>
<th>node_id</th>
<th>remote_node_id</th>
<th>status</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>DISCONNECTED</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>CONNECTING</td>
</tr>
<tr>
<td>1</td>
<td>10</td>
<td>CONNECTED</td>
</tr>
<tr>
<td>1</td>
<td>20</td>
<td>CONNECTED</td>
</tr>
<tr>
<td>1</td>
<td>21</td>
<td>CONNECTED</td>
</tr>
</tbody>
</table>
```

5 rows in set (0.02 sec)

The `connect_count`, `overloaded`, `overload_count`, `slowdown`, and `slowdown_count` counters are reset on connection, and retain their values after the remote node disconnects. The `bytes_sent` and `bytes_received` counters are also reset on connection, and so retain their values following disconnection (until the next connection resets them).

The `overload` state referred to by the `overloaded` and `overload_count` columns occurs when this transporter's send buffer contains more than `OverLoadLimit` bytes (default is 80% of `SendBufferMemory`, that is, 0.8 * 2097152 = 1677721 bytes). When a given transporter is in a state of overload, any new transaction that tries to use this transporter fails with Error 1218 (`Send Buffers overloaded in NDB kernel`). This affects both scans and primary key operations.

The `slowdown` state referenced by the `slowdown` and `slowdown_count` columns of this table occurs when the transporter’s send buffer contains more than 60% of the overload limit (equal to 0.6 * 2097152 =
INFORMATION_SCHEMA Tables for NDB Cluster

1258291 bytes by default). In this state, any new scan using this transporter has its batch size reduced to minimize the load on the transporter.

Common causes of send buffer slowdown or overloading include the following:

- Data size, in particular the quantity of data stored in `TEXT` columns or `BLOB` columns (or both types of columns)
- Having a data node (ndbd or ndbmtd) on the same host as an SQL node that is engaged in binary logging
- Large number of rows per transaction or transaction batch
- Configuration issues such as insufficient `SendBufferMemory`
- Hardware issues such as insufficient RAM or poor network connectivity

See also Section 22.3.3.14, “Configuring NDB Cluster Send Buffer Parameters”.

22.5.15 INFORMATION_SCHEMA Tables for NDB Cluster

Two `INFORMATION_SCHEMA` tables provide information that is of particular use when managing an NDB Cluster. The `FILES` table provides information about NDB Cluster Disk Data files (see Section 22.5.10.1, “NDB Cluster Disk Data Objects”). The `ndb_transid_mysql_connection_map` table provides a mapping between transactions, transaction coordinators, and API nodes.

Additional statistical and other data about NDB Cluster transactions, operations, threads, blocks, and other aspects of performance can be obtained from the tables in the `ndbinfo` database. For information about these tables, see Section 22.5.14, “ndbinfo: The NDB Cluster Information Database”.

22.5.16 Quick Reference: NDB Cluster SQL Statements

This section discusses several SQL statements that can prove useful in managing and monitoring a MySQL server that is connected to an NDB Cluster, and in some cases provide information about the cluster itself.

- **SHOW ENGINE NDB STATUS, SHOW ENGINE NDBCLUSTER STATUS**

  The output of this statement contains information about the server's connection to the cluster, creation and usage of NDB Cluster objects, and binary logging for NDB Cluster replication.

  See Section 13.7.7.15, “SHOW ENGINE Statement”, for a usage example and more detailed information.

- **SHOW ENGINES**

  This statement can be used to determine whether or not clustering support is enabled in the MySQL server, and if so, whether it is active.

  See Section 13.7.7.16, “SHOW ENGINES Statement”, for more detailed information.

  **Note**

  This statement does not support a `LIKE` clause. However, you can use `LIKE` to filter queries against the `INFORMATION_SCHEMA.ENGINES` table, as discussed in the next item.

- **SELECT * FROM INFORMATION_SCHEMA.ENGINES [WHERE ENGINE LIKE 'NDB%']**
This is the equivalent of `SHOW ENGINES`, but uses the `ENGINES` table of the `INFORMATION_SCHEMA` database. Unlike the case with the `SHOW ENGINES` statement, it is possible to filter the results using a `LIKE` clause, and to select specific columns to obtain information that may be of use in scripts. For example, the following query shows whether the server was built with NDB support and, if so, whether it is enabled:

```sql
mysql> SELECT ENGINE, SUPPORT FROM INFORMATION_SCHEMA.ENGINES
    -> WHERE ENGINE LIKE 'NDB%';
+------------+---------+
| ENGINE     | SUPPORT |
+------------+---------+
| ndbcluster | YES     |
| ndbinfo    | YES     |
+------------+---------+
```

If NDB support is not enabled, the preceding query returns an empty set. See Section 25.13, "The INFORMATION_SCHEMA ENGINES Table", for more information.

- `SHOW VARIABLES LIKE 'NDB%'`

This statement provides a list of most server system variables relating to the NDB storage engine, and their values, as shown here:

```sql
mysql> SHOW VARIABLES LIKE 'NDB%';
+-------------------------------+--------------------------+
<table>
<thead>
<tr>
<th>Variable_name</th>

</tr>
</tbody>
</table>

See Section 5.1.8, “Server System Variables”, for more information.

- `SELECT * FROM performance_schema.global_variables WHERE VARIABLE_NAME LIKE 'NDB%';`

This statement is the equivalent of the `SHOW VARIABLES` statement described in the previous item, and provides almost identical output, as shown here:

```
mysql> SELECT * FROM performance_schema.global_variables
    -> WHERE VARIABLE_NAME LIKE 'NDB%';
```

<table>
<thead>
<tr>
<th>VARIABLE_NAME</th>
<th>VARIABLE_VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>ndb_allow_copying_alter_table</td>
<td>ON</td>
</tr>
<tr>
<td>ndb_autoincrement_prefetch_sz</td>
<td>512</td>
</tr>
<tr>
<td>ndb_blob_read_batch_bytes</td>
<td>65536</td>
</tr>
<tr>
<td>ndb_blob_write_batch_bytes</td>
<td>65536</td>
</tr>
<tr>
<td>ndb_clear_apply_status</td>
<td>ON</td>
</tr>
<tr>
<td>ndb_cluster_connection_pool</td>
<td>1</td>
</tr>
<tr>
<td>ndb_cluster_connection_pool_nodeids</td>
<td></td>
</tr>
<tr>
<td>ndb_connectstring</td>
<td>127.0.0.1</td>
</tr>
<tr>
<td>ndb_data_node_neighbour</td>
<td>0</td>
</tr>
<tr>
<td>ndb_default_column_format</td>
<td>FIXED</td>
</tr>
<tr>
<td>ndb_deferred_constraints</td>
<td>0</td>
</tr>
<tr>
<td>ndb_distribution</td>
<td>KEYHASH</td>
</tr>
<tr>
<td>ndb_eventbuffer_free_percent</td>
<td>20</td>
</tr>
<tr>
<td>ndb_eventbuffer_max_alloc</td>
<td>0</td>
</tr>
<tr>
<td>ndb_extra_logging</td>
<td>1</td>
</tr>
<tr>
<td>ndb_force_send</td>
<td>ON</td>
</tr>
<tr>
<td>ndb_fully_replicated</td>
<td>OFF</td>
</tr>
<tr>
<td>ndb_index_stat_enable</td>
<td>ON</td>
</tr>
</tbody>
</table>
Unlike the case with the SHOW VARIABLES statement, it is possible to select individual columns. For example:

```sql
mysql> SELECT VARIABLE_VALUE
    -> FROM performance_schema.global_variables
    -> WHERE VARIABLE_NAME = 'ndb_force_send';
+----------------+
| VARIABLE_VALUE |
+----------------+
| ON             |
```
Quick Reference: NDB Cluster SQL Statements

A more useful query is shown here:

```sql
mysql> SELECT VARIABLE_NAME AS Name, VARIABLE_VALUE AS Value
FROM performance_schema.global_variables
WHERE VARIABLE_NAME
IN ('version', 'ndb_version',
'vend_version_string', 'ndbinfo_version');
```

<table>
<thead>
<tr>
<th>Name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>ndb_version</td>
<td>524308</td>
</tr>
<tr>
<td>ndb_version_string</td>
<td>ndb-8.0.20</td>
</tr>
<tr>
<td>ndbinfo_version</td>
<td>524308</td>
</tr>
<tr>
<td>version</td>
<td>8.0.20-cluster</td>
</tr>
</tbody>
</table>

4 rows in set (0.00 sec)

For more information, see Section 26.12.15, “Performance Schema Status Variable Tables”, and Section 5.1.8, “Server System Variables”.

• `SHOW STATUS LIKE 'NDB%'`

This statement shows at a glance whether or not the MySQL server is acting as a cluster SQL node, and if so, it provides the MySQL server's cluster node ID, the host name and port for the cluster management server to which it is connected, and the number of data nodes in the cluster, as shown here:

```sql
mysql> SHOW STATUS LIKE 'NDB%';
```

<table>
<thead>

Quick Reference: NDB Cluster SQL Statements
If the MySQL server was built with NDB support, but it is not currently connected to a cluster, every row in the output of this statement contains a zero or an empty string for the Value column.

See also Section 13.7.7.37, “SHOW STATUS Statement”.

- SELECT * FROM performance_schema.global_status WHERE VARIABLE_NAME LIKE 'NDB %'

This statement provides similar output to the SHOW STATUS statement discussed in the previous item. Unlike the case with SHOW STATUS, it is possible using SELECT statements to extract values in SQL for use in scripts for monitoring and automation purposes.

For more information, see Section 26.12.15, “Performance Schema Status Variable Tables”.

- SELECT * FROM INFORMATION_SCHEMA.PLUGINS WHERE PLUGIN_NAME LIKE 'NDB%'

This statement displays information from the INFORMATION_SCHEMA.PLUGINS table about plugins associated with NDB Cluster, such as version, author, and license, as shown here:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.PLUGINS WHERE PLUGIN_NAME LIKE 'NDB%'

### NDB Cluster Security Issues

You can also use the `SHOW PLUGINS` statement to display this information, but the output from that statement cannot easily be filtered. See also The MySQL Plugin API, which describes where and how the information in the `PLUGINS` table is obtained.

You can also query the tables in the `ndbinfo` information database for real-time data about many NDB Cluster operations. See Section 22.5.14, “ndbinfo: The NDB Cluster Information Database”.

#### 22.5.17 NDB Cluster Security Issues

This section discusses security considerations to take into account when setting up and running NDB Cluster.

Topics covered in this section include the following:

- NDB Cluster and network security issues
- Configuration issues relating to running NDB Cluster securely
- NDB Cluster and the MySQL privilege system
- MySQL standard security procedures as applicable to NDB Cluster

#### 22.5.17.1 NDB Cluster Security and Networking Issues

In this section, we discuss basic network security issues as they relate to NDB Cluster. It is extremely important to remember that NDB Cluster “out of the box” is not secure; you or your network administrator must take the proper steps to ensure that your cluster cannot be compromised over the network.

Cluster communication protocols are inherently insecure, and no encryption or similar security measures are used in communications between nodes in the cluster. Because network speed and latency have a direct impact on the cluster's efficiency, it is also not advisable to employ SSL or other encryption to network connections between nodes, as such schemes cause slow communications.

It is also true that no authentication is used for controlling API node access to an NDB Cluster. As with encryption, the overhead of imposing authentication requirements would have an adverse impact on Cluster performance.

In addition, there is no checking of the source IP address for either of the following when accessing the cluster:

- **SQL or API nodes using “free slots” created by empty `[mysqld]` or `[api]` sections in the `config.ini` file**

This means that, if there are any empty `[mysqld]` or `[api]` sections in the `config.ini` file, then any API nodes (including SQL nodes) that know the management server’s host name (or IP address) and
NDB Cluster Security Issues

port can connect to the cluster and access its data without restriction. (See Section 22.5.17.2, “NDB Cluster and MySQL Privileges”, for more information about this and related issues.)

Note

You can exercise some control over SQL and API node access to the cluster by specifying a HostName parameter for all [mysqld] and [api] sections in the config.ini file. However, this also means that, should you wish to connect an API node to the cluster from a previously unused host, you need to add an [api] section containing its host name to the config.ini file.

More information is available elsewhere in this chapter about the HostName parameter. Also see Section 22.3.1, “Quick Test Setup of NDB Cluster”, for configuration examples using HostName with API nodes.

• Any ndb_mgm client

This means that any cluster management client that is given the management server’s host name (or IP address) and port (if not the standard port) can connect to the cluster and execute any management client command. This includes commands such as ALL STOP and SHUTDOWN.

For these reasons, it is necessary to protect the cluster on the network level. The safest network configuration for Cluster is one which isolates connections between Cluster nodes from any other network communications. This can be accomplished by any of the following methods:

1. Keeping Cluster nodes on a network that is physically separate from any public networks. This option is the most dependable; however, it is the most expensive to implement.

We show an example of an NDB Cluster setup using such a physically segregated network here:

Figure 22.28 NDB Cluster with Hardware Firewall

This setup has two networks, one private (solid box) for the Cluster management servers and data nodes, and one public (dotted box) where the SQL nodes reside. (We show the management and data nodes connected using a gigabit switch since this provides the best performance.) Both networks are protected from the outside by a hardware firewall, sometimes also known as a network-based firewall.
NDB Cluster Security Issues

This network setup is safest because no packets can reach the cluster’s management or data nodes from outside the network—and none of the cluster’s internal communications can reach the outside—without going through the SQL nodes, as long as the SQL nodes do not permit any packets to be forwarded. This means, of course, that all SQL nodes must be secured against hacking attempts.

![Important]

With regard to potential security vulnerabilities, an SQL node is no different from any other MySQL server. See Section 6.1.3, “Making MySQL Secure Against Attackers”, for a description of techniques you can use to secure MySQL servers.

2. Using one or more software firewalls (also known as host-based firewalls) to control which packets pass through to the cluster from portions of the network that do not require access to it. In this type of setup, a software firewall must be installed on every host in the cluster which might otherwise be accessible from outside the local network.

The host-based option is the least expensive to implement, but relies purely on software to provide protection and so is the most difficult to keep secure.

This type of network setup for NDB Cluster is illustrated here:

**Figure 22.29 NDB Cluster with Software Firewalls**

Using this type of network setup means that there are two zones of NDB Cluster hosts. Each cluster host must be able to communicate with all of the other machines in the cluster, but only those hosting SQL nodes (dotted box) can be permitted to have any contact with the outside, while those in the zone containing the data nodes and management nodes (solid box) must be isolated from any machines that
NDB Cluster Security Issues

are not part of the cluster. Applications using the cluster and user of those applications must *not* be permitted to have direct access to the management and data node hosts.

To accomplish this, you must set up software firewalls that limit the traffic to the type or types shown in the following table, according to the type of node that is running on each cluster host computer:

**Table 22.66 Node types in a host-based firewall cluster configuration**

<table>
<thead>
<tr>
<th>Node Type</th>
<th>Permitted Traffic</th>
</tr>
</thead>
</table>
| SQL or API node            | • It originates from the IP address of a management or data node (using any TCP or UDP port).<br>  
• It originates from within the network in which the cluster resides and is on the port that your application is using. |
| Data node or Management node | • It originates from the IP address of a management or data node (using any TCP or UDP port).<br>  
• It originates from the IP address of an SQL or API node. |

Any traffic other than that shown in the table for a given node type should be denied.

The specifics of configuring a firewall vary from firewall application to firewall application, and are beyond the scope of this Manual. *iptables* is a very common and reliable firewall application, which is often used with *APF* as a front end to make configuration easier. You can (and should) consult the documentation for the software firewall that you employ, should you choose to implement an NDB Cluster network setup of this type, or of a “mixed” type as discussed under the next item.

3. It is also possible to employ a combination of the first two methods, using both hardware and software to secure the cluster—that is, using both network-based and host-based firewalls. This is between the first two schemes in terms of both security level and cost. This type of network setup keeps the cluster
behind the hardware firewall, but permits incoming packets to travel beyond the router connecting all cluster hosts to reach the SQL nodes.

One possible network deployment of an NDB Cluster using hardware and software firewalls in combination is shown here:

**Figure 22.30 NDB Cluster with a Combination of Hardware and Software Firewalls**

In this case, you can set the rules in the hardware firewall to deny any external traffic except to SQL nodes and API nodes, and then permit traffic to them only on the ports required by your application.

Whatever network configuration you use, remember that your objective from the viewpoint of keeping the cluster secure remains the same—to prevent any unessential traffic from reaching the cluster while ensuring the most efficient communication between the nodes in the cluster.

Because NDB Cluster requires large numbers of ports to be open for communications between nodes, the recommended option is to use a segregated network. This represents the simplest way to prevent unwanted traffic from reaching the cluster.

---

**Note**

If you wish to administer an NDB Cluster remotely (that is, from outside the local network), the recommended way to do this is to use `ssh` or another secure login shell to access an SQL node host. From this host, you can then run the management client to access the management server safely, from within the cluster's own local network.

Even though it is possible to do so in theory, it is *not* recommended to use `ndb_mgm` to manage a Cluster directly from outside the local network on which the Cluster is running. Since neither authentication nor encryption takes place between the management client and the management server, this represents an extremely insecure means of managing the cluster, and is almost certain to be compromised sooner or later.

### 22.5.17.2 NDB Cluster and MySQL Privileges
In this section, we discuss how the MySQL privilege system works in relation to NDB Cluster and the implications of this for keeping an NDB Cluster secure.

Standard MySQL privileges apply to NDB Cluster tables. This includes all MySQL privilege types (SELECT privilege, UPDATE privilege, DELETE privilege, and so on) granted on the database, table, and column level. As with any other MySQL Server, user and privilege information is stored in the mysql system database. The SQL statements used to grant and revoke privileges on NDB tables, databases containing such tables, and columns within such tables are identical in all respects with the GRANT and REVOKE statements used in connection with database objects involving any (other) MySQL storage engine. The same thing is true with respect to the CREATE USER and DROP USER statements.

It is important to keep in mind that, by default, the MySQL grant tables use the MyISAM storage engine. Because of this, those tables are not normally duplicated or shared among MySQL servers acting as SQL nodes in an NDB Cluster. In other words, changes in users and their privileges do not automatically propagate between SQL nodes by default. If you wish, you can enable automatic distribution of MySQL users and privileges across NDB Cluster SQL nodes; see Section 22.5.12, “Distributed MySQL Privileges with NDB_STORED_USER”, for details.

Conversely, because there is no way in MySQL to deny privileges (privileges can either be revoked or not granted in the first place, but not denied as such), there is no special protection for NDB tables on one SQL node from users that have privileges on another SQL node; (This is true even if you are not using automatic distribution of user privileges. The definitive example of this is the MySQL root account, which can perform any action on any database object. In combination with empty [mysqld] or [api] sections of the config.ini file, this account can be especially dangerous. To understand why, consider the following scenario:

- The config.ini file contains at least one empty [mysqld] or [api] section. This means that the NDB Cluster management server performs no checking of the host from which a MySQL Server (or other API node) accesses the NDB Cluster.
- There is no firewall, or the firewall fails to protect against access to the NDB Cluster from hosts external to the network.
- The host name or IP address of the NDB Cluster management server is known or can be determined from outside the network.

If these conditions are true, then anyone, anywhere can start a MySQL Server with --ndbcluster --ndb-connectstring=management_host and access this NDB Cluster. Using the MySQL root account, this person can then perform the following actions:

- Execute metadata statements such as SHOW DATABASES statement (to obtain a list of all NDB databases on the server) or SHOW TABLES FROM some_ndb_database statement to obtain a list of all NDB tables in a given database
- Run any legal MySQL statements on any of the discovered tables, such as:
  - SELECT * FROM some_table to read all the data from any table
  - DELETE FROM some_table to delete all the data from a table
  - DESCRIBE some_table or SHOW CREATE TABLE some_table to determine the table schema
  - UPDATE some_table SET column1 = some_value to fill a table column with “garbage” data; this could actually cause much greater damage than simply deleting all the data

More insidious variations might include statements like these:
NDB Cluster Security Issues

```sql
UPDATE some_table SET an_int_column = an_int_column + 1
```

or

```sql
UPDATE some_table SET a_varchar_column = REVERSE(a_varchar_column)
```

Such malicious statements are limited only by the imagination of the attacker.

The only tables that would be safe from this sort of mayhem would be those tables that were created using storage engines other than NDB, and so not visible to a “rogue” SQL node.

A user who can log in as root can also access the INFORMATION_SCHEMA database and its tables, and so obtain information about databases, tables, stored routines, scheduled events, and any other database objects for which metadata is stored in INFORMATION_SCHEMA.

It is also a very good idea to use different passwords for the root accounts on different NDB Cluster SQL nodes unless you are using distributed privileges.

In sum, you cannot have a safe NDB Cluster if it is directly accessible from outside your local network.

### Important

*Never leave the MySQL root account password empty.* This is just as true when running MySQL as an NDB Cluster SQL node as it is when running it as a standalone (non-Cluster) MySQL Server, and should be done as part of the MySQL installation process before configuring the MySQL Server as an SQL node in an NDB Cluster.

If you wish to employ NDB Cluster’s distributed privilege capabilities, you should not simply convert the system tables in the mysql database to use the NDB storage engine manually. Use the stored procedure provided for this purpose instead; see Section 22.5.12, “Distributed MySQL Privileges with NDB_STORED_USER”.

Otherwise, if you need to synchronize mysql system tables between SQL nodes, you can use standard MySQL replication to do so, or employ a script to copy table entries between the MySQL servers.

**Summary.** The most important points to remember regarding the MySQL privilege system with regard to NDB Cluster are listed here:

1. Users and privileges established on one SQL node do not automatically exist or take effect on other SQL nodes in the cluster. Conversely, removing a user or privilege on one SQL node in the cluster does not remove the user or privilege from any other SQL nodes.

2. You can distribute MySQL users and privileges among SQL nodes using the SQL script, and the stored procedures it contains, that are supplied for this purpose in the NDB Cluster distribution.

3. Once a MySQL user is granted privileges on an NDB table from one SQL node in an NDB Cluster, that user can “see” any data in that table regardless of the SQL node from which the data originated, even if you are not using privilege distribution.

### 22.5.17.3 NDB Cluster and MySQL Security Procedures

In this section, we discuss MySQL standard security procedures as they apply to running NDB Cluster.

In general, any standard procedure for running MySQL securely also applies to running a MySQL Server as part of an NDB Cluster. First and foremost, you should always run a MySQL Server as the mysql...
operating system user; this is no different from running MySQL in a standard (non-Cluster) environment.

The `mysql` system account should be uniquely and clearly defined. Fortunately, this is the default behavior for a new MySQL installation. You can verify that the `mysqld` process is running as the `mysql` operating system user by using the system command such as the one shown here:

```
shell> ps aux | grep mysql
root   10467  0.0  0.1   3616  1380 pts/3    S    11:53   0:00 /
    /bin/sh ./mysqld_safe --ndbcluster --ndb-connectstring=localhost:1186
mysqld 10512  0.2  2.5  58528 26636 pts/3  Sl  11:53   0:00 /usr/local/mysql/libexec/mysqld --basedir=/usr/local/mysql
    --datadir=/usr/local/mysql/var --user=mysql --ndbcluster
    --ndb-connectstring=localhost:1186 --pid-file=/usr/local/mysql/var/mothra.pid
    --log-error=/usr/local/mysql/var/mothra.err
jon    10579  0.0  0.0   2736   688 pts/0    S+   11:54   0:00 grep mysql
```

If the `mysqld` process is running as any other user than `mysql`, you should immediately shut it down and restart it as the `mysql` user. If this user does not exist on the system, the `mysql` user account should be created, and this user should be part of the `mysql` user group; in this case, you should also make sure that the MySQL data directory on this system (as set using the `--datadir` option for `mysqld`) is owned by the `mysql` user, and that the SQL node’s `my.cnf` file includes `user=mysql` in the `[mysqld]` section. Alternatively, you can start the MySQL server process with `--user=mysql` on the command line, but it is preferable to use the `my.cnf` option, since you might forget to use the command-line option and so have `mysqld` running as another user unintentionally. The `mysqld_safe` startup script forces MySQL to run as the `mysql` user.

---

**Important**

Never run `mysqld` as the system root user. Doing so means that potentially any file on the system can be read by MySQL, and thus—should MySQL be compromised—by an attacker.

As mentioned in the previous section (see Section 22.5.17.2, “NDB Cluster and MySQL Privileges”), you should always set a root password for the MySQL Server as soon as you have it running. You should also delete the anonymous user account that is installed by default. You can accomplish these tasks using the following statements:

```
shell> mysql -u root
mysql> UPDATE mysql.user
    -> SET Password=PASSWORD('secure_password')
    -> WHERE User='root';
mysql> DELETE FROM mysql.user
    -> WHERE User='';
mysql> FLUSH PRIVILEGES;
```

Be very careful when executing the `DELETE` statement not to omit the `WHERE` clause, or you risk deleting all MySQL users. Be sure to run the `FLUSH PRIVILEGES` statement as soon as you have modified the `mysql.user` table, so that the changes take immediate effect. Without `FLUSH PRIVILEGES`, the changes do not take effect until the next time that the server is restarted.

---

**Note**

Many of the NDB Cluster utilities such as `ndb_show_tables`, `ndb_desc`, and `ndb_select_all` also work without authentication and can reveal table names, schemas, and data. By default these are installed on Unix-style systems with the permissions `w+x-r-x` (755), which means they can be executed by any user that can access the `mysql/bin` directory.
See Section 22.4, “NDB Cluster Programs”, for more information about these utilities.

## 22.6 NDB Cluster Replication

NDB Cluster supports asynchronous replication, more usually referred to simply as “replication”. This section explains how to set up and manage a configuration in which one group of computers operating as an NDB Cluster replicates to a second computer or group of computers. We assume some familiarity on the part of the reader with standard MySQL replication as discussed elsewhere in this Manual. (See Chapter 17, Replication).

**Note**

NDB Cluster does not support replication using GTIDs; semisynchronous replication and group replication are also not supported by the NDB storage engine.

Normal (non-clustered) replication involves a source server and a replica server, the source being so named because operations and data to be replicated originate with it, and the replica being the recipient of these. In NDB Cluster, replication is conceptually very similar but can be more complex in practice, as it may be extended to cover a number of different configurations including replicating between two complete clusters. Although an NDB Cluster itself depends on the NDB storage engine for clustering functionality, it is not necessary to use NDB as the storage engine for the replica’s copies of the replicated tables (see Replication from NDB to other storage engines). However, for maximum availability, it is possible (and preferable) to replicate from one NDB Cluster to another, and it is this scenario that we discuss, as shown in the following figure:

**Figure 22.31 NDB Cluster-to-Cluster Replication Layout**

In this scenario, the replication process is one in which successive states of a source cluster are logged and saved to a replica cluster. This process is accomplished by a special thread known as the NDB binary log injector thread, which runs on each MySQL server and produces a binary log (binlog). This thread
ensures that all changes in the cluster producing the binary log—and not just those changes that are
effected through the MySQL Server—are inserted into the binary log with the correct serialization order.
We refer to the MySQL source and replica servers as replication servers or replication nodes, and the data
flow or line of communication between them as a replication channel.

For information about performing point-in-time recovery with NDB Cluster and NDB Cluster Replication,
see Section 22.6.9.2, “Point-In-Time Recovery Using NDB Cluster Replication”.

**NDB API replica status variables.** NDB API counters can provide enhanced monitoring capabilities
on replica clusters. These counters are implemented as NDB statistics _slave status variables, as
seen in the output of SHOW STATUS, or in the results of queries against the Performance Schema
session_status or global_status table in a mysql client session connected to a MySQL Server that
is acting as a replica in NDB Cluster Replication. By comparing the values of these status variables before
and after the execution of statements affecting replicated NDB tables, you can observe the corresponding
actions taken on the NDB API level by the replica, which can be useful when monitoring or troubleshooting
NDB Cluster Replication. Section 22.5.13, “NDB API Statistics Counters and Variables”, provides
additional information.

**Replication from NDB to non-NDB tables.** It is possible to replicate NDB tables from an NDB Cluster
acting as the replication source to tables using other MySQL storage engines such as InnoDB or MyISAM
on a replica mysql. This is subject to a number of conditions; see Replication from NDB to other storage
engines, and Replication from NDB to a nontransactional storage engine, for more information.

### 22.6.1 NDB Cluster Replication: Abbreviations and Symbols

Throughout this section, we use the following abbreviations or symbols for referring to the source and
replica clusters, and to processes and commands run on the clusters or cluster nodes:

<table>
<thead>
<tr>
<th>Symbol or Abbreviation</th>
<th>Description (Refers to...)</th>
</tr>
</thead>
<tbody>
<tr>
<td>S</td>
<td>The cluster serving as the (primary) replication source</td>
</tr>
<tr>
<td>R</td>
<td>The cluster acting as the (primary) replica</td>
</tr>
<tr>
<td>shellS&gt;</td>
<td>Shell command to be issued on the source cluster</td>
</tr>
<tr>
<td>mysqlS&gt;</td>
<td>MySQL client command issued on a single MySQL server running as an SQL node on the source cluster</td>
</tr>
<tr>
<td>mysqlS&gt;*</td>
<td>MySQL client command to be issued on all SQL nodes participating in the replication source cluster</td>
</tr>
<tr>
<td>shellR&gt;</td>
<td>Shell command to be issued on the replica cluster</td>
</tr>
<tr>
<td>mysqlR&gt;</td>
<td>MySQL client command issued on a single MySQL server running as an SQL node on the replica cluster</td>
</tr>
<tr>
<td>mysqlR&gt;*</td>
<td>MySQL client command to be issued on all SQL nodes participating in the replica cluster</td>
</tr>
<tr>
<td>C</td>
<td>Primary replication channel</td>
</tr>
<tr>
<td>C’</td>
<td>Secondary replication channel</td>
</tr>
<tr>
<td>S’</td>
<td>Secondary replication source</td>
</tr>
<tr>
<td>R’</td>
<td>Secondary replica</td>
</tr>
</tbody>
</table>

### 22.6.2 General Requirements for NDB Cluster Replication
A replication channel requires two MySQL servers acting as replication servers (one each for the source and replica). For example, this means that in the case of a replication setup with two replication channels (to provide an extra channel for redundancy), there are a total of four replication nodes, two per cluster.

Replication of an NDB Cluster as described in this section and those following is dependent on row-based replication. This means that the replication source MySQL server must be running with `--binlog-format=ROW` or `--binlog-format=MIXED`, as described in Section 22.6.6, “Starting NDB Cluster Replication (Single Replication Channel)”. For general information about row-based replication, see Section 17.2.1, “Replication Formats”.

**Important**

If you attempt to use NDB Cluster Replication with `--binlog-format=STATEMENT`, replication fails to work properly because the `ndb_binlog_index` table on the source cluster and the `epoch` column of the `ndb_apply_status` table on the replica cluster are not updated (see Section 22.6.4, “NDB Cluster Replication Schema and Tables”). Instead, only updates on the MySQL server acting as the replication source propagate to the replica, and no updates from any other SQL nodes in the source cluster are replicated.

The default value for the `--binlog-format` option is `MIXED`.

Each MySQL server used for replication in either cluster must be uniquely identified among all the MySQL replication servers participating in either cluster (you cannot have replication servers on both the source and replica clusters sharing the same ID). This can be done by starting each SQL node using the `--server-id=id` option, where `id` is a unique integer. Although it is not strictly necessary, we assume for purposes of this discussion that all NDB Cluster binaries are of the same release version.

It is generally true in MySQL Replication that both MySQL servers (`mysqld` processes) involved must be compatible with one another with respect to both the version of the replication protocol used and the SQL feature sets which they support (see Section 17.5.2, “Replication Compatibility Between MySQL Versions”). It is due to such differences between the binaries in the NDB Cluster and MySQL Server 8.0 distributions that NDB Cluster Replication has the additional requirement that both `mysqld` binaries come from an NDB Cluster distribution. The simplest and easiest way to assure that the `mysqld` servers are compatible is to use the same NDB Cluster distribution for all source and replica `mysqld` binaries.

We assume that the replica server or cluster is dedicated to replication of the source cluster, and that no other data is being stored on it.

All NDB tables being replicated must be created using a MySQL server and client. Tables and other database objects created using the NDB API (with, for example, `Dictionary::createTable()`) are not visible to a MySQL server and so are not replicated. Updates by NDB API applications to existing tables that were created using a MySQL server can be replicated.

**Note**

It is possible to replicate an NDB Cluster using statement-based replication. However, in this case, the following restrictions apply:

- All updates to data rows on the cluster acting as the source must be directed to a single MySQL server.
- It is not possible to replicate a cluster using multiple simultaneous MySQL replication processes.
Known Issues in NDB Cluster Replication

• Only changes made at the SQL level are replicated.

These are in addition to the other limitations of statement-based replication as opposed to row-based replication; see Section 17.2.1.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”, for more specific information concerning the differences between the two replication formats.

### 22.6.3 Known Issues in NDB Cluster Replication

This section discusses known problems or issues when using replication with NDB Cluster.

**Loss of connection between source and replica.** A loss of connection can occur either between the source cluster SQL node and the replica cluster SQL node, or between the source SQL node and the data nodes of the source cluster. In the latter case, this can occur not only as a result of loss of physical connection (for example, a broken network cable), but due to the overflow of data node event buffers; if the SQL node is too slow to respond, it may be dropped by the cluster (this is controllable to some degree by adjusting the `MaxBufferedEpochs` and `TimeBetweenEpochs` configuration parameters). If this occurs, it is entirely possible for new data to be inserted into the source cluster without being recorded in the source SQL node's binary log. For this reason, to guarantee high availability, it is extremely important to maintain a backup replication channel, to monitor the primary channel, and to fail over to the secondary replication channel when necessary to keep the replica cluster synchronized with the source. NDB Cluster is not designed to perform such monitoring on its own; for this, an external application is required.

The source SQL node issues a “gap” event when connecting or reconnecting to the source cluster. (A gap event is a type of “incident event,” which indicates an incident that occurs that affects the contents of the database but that cannot easily be represented as a set of changes. Examples of incidents are server failures, database resynchronization, some software updates, and some hardware changes.) When the replica encounters a gap in the replication log, it stops with an error message. This message is available in the output of `SHOW REPLICA | SLAVE STATUS`, and indicates that the SQL thread has stopped due to an incident registered in the replication stream, and that manual intervention is required. See Section 22.6.8, “Implementing Failover with NDB Cluster Replication”, for more information about what to do in such circumstances.

**Important**

Because NDB Cluster is not designed on its own to monitor replication status or provide failover, if high availability is a requirement for the replica server or cluster, then you must set up multiple replication lines, monitor the source `mysqld` on the primary replication line, and be prepared fail over to a secondary line if and as necessary. This must be done manually, or possibly by means of a third-party application. For information about implementing this type of setup, see Section 22.6.7, “Using Two Replication Channels for NDB Cluster Replication”, and Section 22.6.8, “Implementing Failover with NDB Cluster Replication”.

If you are replicating from a standalone MySQL server to an NDB Cluster, one channel is usually sufficient.

**Circular replication.** NDB Cluster Replication supports circular replication, as shown in the next example. The replication setup involves three NDB Clusters numbered 1, 2, and 3, in which Cluster 1 acts as the replication source for Cluster 2, Cluster 2 acts as the source for Cluster 3, and Cluster 3 acts as the source for Cluster 1, thus completing the circle. Each NDB Cluster has two SQL nodes, with SQL nodes A and B belonging to Cluster 1, SQL nodes C and D belonging to Cluster 2, and SQL nodes E and F belonging to Cluster 3.

Circular replication using these clusters is supported as long as the following conditions are met:
Known Issues in NDB Cluster Replication

- The SQL nodes on all source and replica clusters are the same.
- All SQL nodes acting as sources and replicas are started with the `log_slave_updates` system variable enabled.

This type of circular replication setup is shown in the following diagram:

**Figure 22.32 NDB Cluster Circular Replication With All Sources As Replicas**

In this scenario, SQL node A in Cluster 1 replicates to SQL node C in Cluster 2; SQL node C replicates to SQL node E in Cluster 3; SQL node E replicates to SQL node A. In other words, the replication line (indicated by the curved arrows in the diagram) directly connects all SQL nodes used as sources and replicas.

It should also be possible to set up circular replication in which not all source SQL nodes are also replicas, as shown here:
In this case, different SQL nodes in each cluster are used as sources and replicas. However, you must not start any of the SQL nodes with the `log_slave_updates` system variable enabled. This type of circular replication scheme for NDB Cluster, in which the line of replication (again indicated by the curved arrows in the diagram) is discontinuous, should be possible, but it should be noted that it has not yet been thoroughly tested and must therefore still be considered experimental.

**Note**

The NDB storage engine uses *idempotent execution mode*, which suppresses duplicate-key and other errors that otherwise break circular replication of NDB Cluster. This is equivalent to setting the global `slave_exec_mode` system variable to `IDEMPOTENT`, although this is not necessary in NDB Cluster replication, since NDB Cluster sets this variable automatically and ignores any attempts to set it explicitly.

**NDB Cluster replication and primary keys.** In the event of a node failure, errors in replication of NDB tables without primary keys can still occur, due to the possibility of duplicate rows being inserted in such cases. For this reason, it is highly recommended that all NDB tables being replicated have explicit primary keys.
Known Issues in NDB Cluster Replication

**NDB Cluster Replication and Unique Keys.** In older versions of NDB Cluster, operations that updated values of unique key columns of NDB tables could result in duplicate-key errors when replicated. This issue is solved for replication between NDB tables by deferring unique key checks until after all table row updates have been performed.

Deferring constraints in this way is currently supported only by NDB. Thus, updates of unique keys when replicating from NDB to a different storage engine such as InnoDB or MyISAM are still not supported.

The problem encountered when replicating without deferred checking of unique key updates can be illustrated using NDB table such as `t`, is created and populated on the source (and transmitted to a replica that does not support deferred unique key updates) as shown here:

```sql
CREATE TABLE t (  
    p INT PRIMARY KEY,  
    c INT,  
    UNIQUE KEY u (c) 
) ENGINE NDB;

INSERT INTO t  
VALUES (1,1), (2,2), (3,3), (4,4), (5,5);
```

The following `UPDATE` statement on `t` succeeds on the source, since the rows affected are processed in the order determined by the `ORDER BY` option, performed over the entire table:

```sql
UPDATE t SET c = c - 1 ORDER BY p;
```

The same statement fails with a duplicate key error or other constraint violation on the replica, because the ordering of the row updates is performed for one partition at a time, rather than for the table as a whole.

**Note**

Every NDB table is implicitly partitioned by key when it is created. See Section 23.2.5, “KEY Partitioning”, for more information.

**GTIDs not supported.** Replication using global transaction IDs is not compatible with the NDB storage engine, and is not supported. Enabling GTIDs is likely to cause NDB Cluster Replication to fail.

**Multithreaded replicas not supported.** NDB Cluster does not support multithreaded replicas, and setting related system variables such as `slave_parallel_workers`, `slave_checkpoint_group`, and `slave_checkpoint_group` (or the equivalent `mysqld` startup options) has no effect.

This is because the replica may not be able to separate transactions occurring in one database from those in another if they are written within the same epoch. In addition, every transaction handled by the NDB storage engine involves at least two databases—the target database and the mysql system database—due to the requirement for updating the `mysql.ndb_apply_status` table (see Section 22.6.4, “NDB Cluster Replication Schema and Tables”). This in turn breaks the requirement for multithreading that the transaction is specific to a given database.

**Restarting with --initial.** Restarting the cluster with the `--initial` option causes the sequence of GCI and epoch numbers to start over from 0. (This is generally true of NDB Cluster and not limited to replication scenarios involving Cluster.) The MySQL servers involved in replication should in this case be restarted. After this, you should use the `RESET MASTER` and `RESET REPLICA | SLAVE` statements to clear the invalid `ndb_binlog_index` and `ndb_apply_status` tables, respectively.

**Replication from NDB to other storage engines.** It is possible to replicate an NDB table on the source to a table using a different storage engine on the replica, taking into account the restrictions listed here:

- Multi-source and circular replication are not supported (tables on both the source and the replica must use the NDB storage engine for this to work).
Known Issues in NDB Cluster Replication

- Using a storage engine which does not perform binary logging for tables on the replica requires special handling.

- Use of a nontransactional storage engine for tables on the replica also requires special handling.

- The source mysql must be started with \texttt{--ndb-log-update-as-write=0} or \texttt{--ndb-log-update-as-write=OFF}.

The next few paragraphs provide additional information about each of the issues just described.

**Multiple sources not supported when replicating NDB to other storage engines.** For replication from NDB to a different storage engine, the relationship between the two databases must be one-to-one. This means that bidirectional or circular replication is not supported between NDB Cluster and other storage engines.

In addition, it is not possible to configure more than one replication channel when replicating between NDB and a different storage engine. (An NDB Cluster database can simultaneously replicate to multiple NDB Cluster databases.) If the source uses NDB tables, it is still possible to have more than one MySQL Server maintain a binary log of all changes, but for the replica to change sources (fail over), the new source-replica relationship must be explicitly defined on the replica.

**Replicating NDB tables to a storage engine that does not perform binary logging.** If you attempt to replicate from an NDB Cluster to a replica that uses a storage engine that does not handle its own binary logging, the replication process aborts with the error \texttt{Binary logging not possible ... Statement cannot be written atomically since more than one engine involved and at least one engine is self-logging} (Error 1595). It is possible to work around this issue in one of the following ways:

- **Turn off binary logging on the replica.** This can be accomplished by setting \texttt{sql_log_bin = 0}.

- **Change the storage engine used for the mysql.ndb_apply_status table.** Causing this table to use an engine that does not handle its own binary logging can also eliminate the conflict. This can be done by issuing a statement such as \texttt{ALTER TABLE mysql.ndb_apply_status ENGINE=MyISAM} on the replica. It is safe to do this when using a storage engine other than NDB on the replica, since you do not need to worry about keeping multiple replicas synchronized.

- **Filter out changes to the mysql.ndb_apply_status table on the replica.** This can be done by starting the replica with \texttt{--replicate-ignore-table=mysql.ndb_apply_status}. If you need for other tables to be ignored by replication, you might wish to use an appropriate \texttt{--replicate-wildignore-table} option instead.

**Important**

You should not disable replication or binary logging of \texttt{mysql.ndb_apply_status} or change the storage engine used for this table when replicating from one NDB Cluster to another. See Replication and binary log filtering rules with replication between NDB Clusters, for details.

**Replication from NDB to a nontransactional storage engine.** When replicating from NDB to a nontransactional storage engine such as MyISAM, you may encounter unnecessary duplicate key errors when replicating \texttt{INSERT ... ON DUPLICATE KEY UPDATE} statements. You can suppress these by using \texttt{--ndb-log-update-as-write=0}, which forces updates to be logged as writes, rather than as updates.

**Replication and binary log filtering rules with replication between NDB Clusters.** If you are using any of the options \texttt{--replicate-do-*}, \texttt{--replicate-ignore-*}, \texttt{--binlog-do-db}, or \texttt{--binlog-}
ignore-db to filter databases or tables being replicated, you must take care not to block replication or
binary logging of the mysql.ndb_apply_status, which is required for replication between NDB Clusters
to operate properly. In particular, you must keep in mind the following:

1. Using --replicate-do-db=db_name (and no other --replicate-do-* or --replicate-
ignore-* options) means that only tables in database db_name are replicated. In this case, you
should also use --replicate-do-db=mysql,--binlog-do-db=mysql, or --replicate-do-
table=mysql.ndb_apply_status to ensure that mysql.ndb_apply_status is populated on
replicas.

Using --binlog-do-db=db_name (and no other --binlog-do-db options) means that
changes only to tables in database db_name are written to the binary log. In this case, you should
also use --replicate-do-db=mysql,--binlog-do-db=mysql, or --replicate-do-
table=mysql.ndb_apply_status to ensure that mysql.ndb_apply_status is populated on
replicas.

2. Using --replicate-ignore-db=mysql means that no tables in the mysql database are replicated.
In this case, you should also use --replicate-do-table=mysql.ndb_apply_status to ensure
that mysql.ndb_apply_status is replicated.

Using --binlog-ignore-db=mysql means that no changes to tables in the mysql
database are written to the binary log. In this case, you should also use --replicate-do-
table=mysql.ndb_apply_status to ensure that mysql.ndb_apply_status is replicated.

You should also remember that each replication rule requires the following:

1. Its own --replicate-do-* or --replicate-ignore-* option, and that multiple rules cannot be
expressed in a single replication filtering option. For information about these rules, see Section 17.1.6,
"Replication and Binary Logging Options and Variables".

2. Its own --binlog-do-db or --binlog-ignore-db option, and that multiple rules cannot be
expressed in a single binary log filtering option. For information about these rules, see Section 5.4.4,
"The Binary Log".

If you are replicating an NDB Cluster to a replica that uses a storage engine other than NDB, the
considerations just given previously may not apply, as discussed elsewhere in this section.

NDB Cluster Replication and IPv6. Beginning with NDB 8.0.22, all types of NDB Cluster nodes
support IPv6; this includes management nodes, data nodes, and API or SQL nodes.

Prior to NDB 8.0.22, the NDB API and MGM API (and thus data nodes and management nodes) do not
support IPv6, although MySQL Servers—including those acting as SQL nodes in an NDB Cluster —can
use IPv6 to contact other MySQL Servers. In versions of NDB Cluster prior to 8.0.22, you can replicate
between clusters using IPv6 to connect the SQL nodes acting as source and replica as shown by the
dotted arrow in the following diagram:
Prior to NDB 8.0.22, all connections originating within the NDB Cluster —represented in the preceding diagram by solid arrows—must use IPv4. In other words, all NDB Cluster data nodes, management servers, and management clients must be accessible from one another using IPv4. In addition, SQL nodes must use IPv4 to communicate with the cluster. In NDB 8.0.22 and later, these restrictions no longer apply; in addition, any applications written using the NDB and MGM APIs can be written and deployed assuming an IPv6-only environment.

**Attribute promotion and demotion.** NDB Cluster Replication includes support for attribute promotion and demotion. The implementation of the latter distinguishes between lossy and non-lossy type conversions, and their use on the replica can be controlled by setting the `slave_type_conversions` global server system variable.

For more information about attribute promotion and demotion in NDB Cluster, see [Row-based replication: attribute promotion and demotion](#).

NDB, unlike InnoDB or MyISAM, does not write changes to virtual columns to the binary log; however, this has no detrimental effects on NDB Cluster Replication or replication between NDB and other storage engines. Changes to stored generated columns are logged.

### 22.6.4 NDB Cluster Replication Schema and Tables

Replication in NDB Cluster makes use of a number of dedicated tables in the `mysql` database on each MySQL Server instance acting as an SQL node in both the cluster being replicated and in the replica. This is true regardless of whether the replica is a single server or a cluster. These tables are created during the MySQL installation process, and include a table for storing the binary log’s indexing data. Since the `ndb_binlog_index` table is local to each MySQL server and does not participate in clustering, it uses the InnoDB storage engine. This means that it must be created separately on each `mysqld` participating in the source cluster. (The binary log itself contains updates from all MySQL servers in the cluster to be replicated.) This table is defined as follows:

```sql
CREATE TABLE `ndb_binlog_index` (
    `Position` BIGINT(20) UNSIGNED NOT NULL,
    `File` VARCHAR(255) NOT NULL,
    ..
);```
NDB Cluster Replication Schema and Tables

Note

If you are upgrading from an older release (prior to NDB 7.5.2), perform the MySQL upgrade procedure and ensure that the system tables are upgraded. (As of MySQL 8.0.16, start the server with the `--upgrade=FORCE` option. Prior to MySQL 8.0.16, invoke `mysql_upgrade` with the `--force` and `--upgrade-system-tables` options after starting the server.) The system table upgrade causes an `ALTER TABLE` statement to be executed for this table. Use of the MyISAM storage engine for this table continues to be supported for backward compatibility.

`ndb_binlog_index` may require additional disk space after being converted to InnoDB. If this becomes an issue, you may be able to conserve space by using an InnoDB tablespace for this table, changing its `ROW_FORMAT` to `COMPRESSED`, or both. For more information, see Section 13.1.21, “CREATE TABLESPACE Statement”, and Section 13.1.20, “CREATE TABLE Statement”, as well as Section 15.6.3, “Tablespaces”.

The size of the `ndb_binlog_index` table is dependent on the number of epochs per binary log file and the number of binary log files. The number of epochs per binary log file normally depends on the amount of binary log generated per epoch and the size of the binary log file, with smaller epochs resulting in more epochs per file. You should be aware that empty epochs produce inserts to the `ndb_binlog_index` table, even when the `--ndb-log-empty-epochs` option is `OFF`, meaning that the number of entries per file depends on the length of time that the file is in use; this relationship can be represented by the formula shown here:

\[
\text{[number of epochs per file]} = \frac{\text{[time spent per file]}}{\text{TimeBetweenEpochs}}
\]

A busy NDB Cluster writes to the binary log regularly and presumably rotates binary log files more quickly than a quiet one. This means that a “quiet” NDB Cluster with `--ndb-log-empty-epochs=ON` can actually have a much higher number of `ndb_binlog_index` rows per file than one with a great deal of activity.

When `mysqld` is started with the `--ndb-log-orig` option, the `orig_server_id` and `orig_epoch` columns store, respectively, the ID of the server on which the event originated and the epoch in which the event took place on the originating server, which is useful in NDB Cluster replication setups employing multiple sources. The `SELECT` statement used to find the closest binary log position to the highest applied epoch on the replica in a multi-source setup (see Section 22.6.10, “NDB Cluster Replication: Bidirectional and Circular Replication”) employs these two columns, which are not indexed. This can lead to performance issues when trying to fail over, since the query must perform a table scan, especially when the source has been running with `--ndb-log-empty-epochs=ON`. You can improve multi-source failover times by adding an index to these columns, as shown here:

```
ALTER TABLE mysql.ndb_binlog_index
    ADD INDEX orig_lookup USING BTREE (orig_server_id, orig_epoch);
```
Adding this index provides no benefit when replicating from a single source to a single replica, since the query used to get the binary log position in such cases makes no use of `orig_server_id` or `orig_epoch`.

See Section 22.6.8, “Implementing Failover with NDB Cluster Replication”, for more information about using the `next_position` and `next_file` columns.

The following figure shows the relationship of the NDB Cluster replication source server, its binary log injector thread, and the `mysql.ndb_binlog_index` table.

**Figure 22.35 The Replication Source Cluster**

MySQL Replication Between Clusters, Injecting into Binlog

![MySQL Replication Diagram]

An additional table, named `ndb_apply_status`, is used to keep a record of the operations that have been replicated from the source to the replica. Unlike the case with `ndb_binlog_index`, the data in this table is not specific to any one SQL node in the (replica) cluster, and so `ndb_apply_status` can use the NDBCLUSTER storage engine, as shown here:

```sql
CREATE TABLE `ndb_apply_status` (
  `server_id`   INT(10) UNSIGNED NOT NULL,
  `epoch`       BIGINT(20) UNSIGNED NOT NULL,
  `log_name`    VARCHAR(255) CHARACTER SET latin1 COLLATE latin1_bin NOT NULL,
  `start_pos`   BIGINT(20) UNSIGNED NOT NULL,
  `end_pos`     BIGINT(20) UNSIGNED NOT NULL,
  PRIMARY KEY (`server_id`) USING HASH
) ENGINE=NDBCLUSTER   DEFAULT CHARSET=latin1;
```

The `ndb_apply_status` table is populated only on replicas, which means that, on the source, this table never contains any rows; thus, there is no need to allot any DataMemory to `ndb_apply_status` there.

Because this table is populated from data originating on the source, it should be allowed to replicate; any replication filtering or binary log filtering rules that inadvertently prevent the replica from updating `ndb_apply_status`, or that prevent the source from writing into the binary log may prevent replication...
between clusters from operating properly. For more information about potential problems arising from such filtering rules, see Replication and binary log filtering rules with replication between NDB Clusters.

The `ndb_binlog_index` and `ndb_apply_status` tables are created in the `mysql` database because they should not be explicitly replicated by the user. User intervention is normally not required to create or maintain either of these tables, since both are maintained by the NDB binary log (binlog) injector thread. This keeps the source `mysqld` process updated to changes performed by the NDB storage engine. The NDB binlog injector thread receives events directly from the NDB storage engine. The NDB injector is responsible for capturing all the data events within the cluster, and ensures that all events which change, insert, or delete data are recorded in the `ndb_binlog_index` table. The replica I/O thread transfers the events from the source's binary log to the replica's relay log.

Even though `ndb_binlog_index` and `ndb_apply_status` are created and maintained automatically, it is advisable to check for the existence and integrity of these tables as an initial step in preparing an NDB Cluster for replication. It is possible to view event data recorded in the binary log by querying the `mysql.ndb_binlog_index` table directly on the source. This can be also be accomplished using the `SHOW BINLOG EVENTS` statement on either the source or replica SQL node. (See Section 13.7.7.2, “SHOW BINLOG EVENTS Statement”.)

You can also obtain useful information from the output of `SHOW ENGINE NDB STATUS`.

\[\text{Note}\]
When performing schema changes on NDB tables, applications should wait until the `ALTER TABLE` statement has returned in the MySQL client connection that issued the statement before attempting to use the updated definition of the table.

If the `ndb_apply_status` table does not exist on the replica, `ndb_restore` re-creates it.

Conflict resolution for NDB Cluster Replication requires the presence of an additional `mysql.ndb_replication` table. Currently, this table must be created manually. For information about how to do this, see Section 22.6.11, “NDB Cluster Replication Conflict Resolution”.

### 22.6.5 Preparing the NDB Cluster for Replication

Preparing the NDB Cluster for replication consists of the following steps:

1. Check all MySQL servers for version compatibility (see Section 22.6.2, “General Requirements for NDB Cluster Replication”).

2. Create a replication account on the source Cluster with the appropriate privileges, using the following two SQL statements:

   ```sql
   mysql> CREATE USER 'replica_user'@'replica_host'
   -> IDENTIFIED BY 'replica_password';
   mysql> GRANT REPLICATION SLAVE ON *.*
   -> TO 'replica_user'@'replica_host';
   ```

   In the previous statement, `replica_user` is the replication account user name, `replica_host` is the host name or IP address of the replica, and `replica_password` is the password to assign to this account.

   For example, to create a replica user account with the name `myreplica`, logging in from the host named `replica-host`, and using the password `53cr37`, use the following `CREATE USER` and `GRANT` statements:

   ```sql
   mysql> CREATE USER 'myreplica'@'replica-host'
   -> IDENTIFIED BY '53cr37';
   ```
Preparing the NDB Cluster for Replication

For security reasons, it is preferable to use a unique user account—not employed for any other purpose—for the replication account.

3. Set up the replica to use the source. Using the mysql client, this can be accomplished with the the following CHANGE MASTER TO statement:

```
mysql> CHANGE MASTER TO
    > MASTER_HOST='source_host',
    > MASTER_PORT=source_port,
    > MASTER_USER='replica_user',
    > MASTER_PASSWORD='replica_password';
```

In the previous statement, source_host is the host name or IP address of the replication source, source_port is the port for the replica to use when connecting to the source, replica_user is the user name set up for the replica on the source, and replica_password is the password set for that user account in the previous step.

For example, to tell the replica to use the MySQL server whose host name is rep-source with the replication account created in the previous step, use the following statement:

```
mysql> CHANGE MASTER TO
    > MASTER_HOST='rep-source',
    > MASTER_PORT=3306,
    > MASTER_USER='myreplica',
    > MASTER_PASSWORD='53cr37';
```

For a complete list of options that can be used with this statement, see Section 13.4.2.1, “CHANGE MASTER TO Statement”.

To provide replication backup capability, you also need to add an --ndb-connectstring option to the replica’s my.cnf file prior to starting the replication process. See Section 22.6.9, “NDB Cluster Backups With NDB Cluster Replication”, for details.

For additional options that can be set in my.cnf for replicas, see Section 17.1.6, “Replication and Binary Logging Options and Variables”.

4. If the source cluster is already in use, you can create a backup of the source and load this onto the replica to cut down on the amount of time required for the replica to synchronize itself with the source. If the replica is also running NDB Cluster, this can be accomplished using the backup and restore procedure described in Section 22.6.9, “NDB Cluster Backups With NDB Cluster Replication”.

```
ndb-connectstring=management_host[:port]
```

In the event that you are not using NDB Cluster on the replica, you can create a backup with this command on the source:

```
shell> mysqldump --master-data=1
```

Then import the resulting data dump onto the replica by copying the dump file over to it. After this, you can use the mysql client to import the data from the dumpfile into the replica database as shown here,
where `dump_file` is the name of the file that was generated using `mysqldump` on the source, and `db_name` is the name of the database to be replicated:

```bash
shell> mysql -u root -p db_name < dump_file
```

For a complete list of options to use with `mysqldump`, see Section 4.5.4, “`mysqldump` — A Database Backup Program”.

**Note**

If you copy the data to the replica in this fashion, you should make sure that the replica is started with the `--skip-slave-start` option on the command line, or else include `skip-slave-start` in the replica’s `my.cnf` file to keep it from trying to connect to the source to begin replicating before all the data has been loaded. Once the data loading has completed, follow the additional steps outlined in the next two sections.

5. Ensure that each MySQL server acting as a replication source is assigned a unique server ID, and has binary logging enabled, using the row-based format. (See Section 17.2.1, “Replication Formats”.) In addition, we recommend enabling the `slave_allow_batching` system variable, and possibly increasing the values used with the `--ndb-batch-size` and `--ndb-blob-write-batch-bytes` options as well. All of these options can be set either in the source server’s `my.cnf` file, or on the command line when starting the source `mysql` process. See Section 22.6.6, “Starting NDB Cluster Replication (Single Replication Channel)”, for more information.

### 22.6.6 Starting NDB Cluster Replication (Single Replication Channel)

This section outlines the procedure for starting NDB Cluster replication using a single replication channel.

1. Start the MySQL replication source server by issuing this command:

```bash
shell> mysql --ndbcluster --server-id=id --log-bin --ndb-log-bin &
```

In the previous statement, `id` is this server’s unique ID (see Section 22.6.2, “General Requirements for NDB Cluster Replication”). This starts the server's `mysql` process with binary logging enabled using the proper logging format. It is also necessary in NDB 8.0 to enable logging of updates to NDB tables explicitly, using the `--ndb-log-bin` option; this is a change from previous versions of NDB Cluster, in which this option was enabled by default.

**Note**

You can also start the source with `--binlog-format=MIXED`, in which case row-based replication is used automatically when replicating between clusters. Statement-based binary logging is not supported for NDB Cluster Replication (see Section 22.6.2, “General Requirements for NDB Cluster Replication”).

2. Start the MySQL replica server as shown here:

```bash
shell> mysql --ndbcluster --server-id=id &
```

In the command just shown, `id` is the replica server's unique ID. It is not necessary to enable logging on the replica.

**Note**

You should use the `--skip-slave-start` option with this command or else you should include `skip-slave-start` in the replica server's `my.cnf` file,
Starting NDB Cluster Replication (Single Replication Channel)

unless you want replication to begin immediately. With the use of this option, the start of replication is delayed until the appropriate `START REPLICA | SLAVE` statement has been issued, as explained in Step 4 below.

3. It is necessary to synchronize the replica server with the source server's replication binary log. If binary logging has not previously been running on the source, run the following statement on the replica:

```sql
mysqlR> CHANGE MASTER TO
                -> MASTER_LOG_FILE='',
                -> MASTER_LOG_POS=4;
```

This instructs the replica to begin reading the source server's binary log from the log's starting point. Otherwise—that is, if you are loading data from the source using a backup—see Section 22.6.8, “Implementing Failover with NDB Cluster Replication”, for information on how to obtain the correct values to use for `MASTER_LOG_FILE` and `MASTER_LOG_POS` in such cases.

4. Finally, instruct the replica to begin applying replication by issuing this command from the `mysql` client on the replica:

```sql
mysqlR> START SLAVE;
Or from MySQL 8.0.22:
mysqlR> START REPLICA;
```

This also initiates the transmission of data and changes from the source to the replica.

It is also possible to use two replication channels, in a manner similar to the procedure described in the next section; the differences between this and using a single replication channel are covered in Section 22.6.7, "Using Two Replication Channels for NDB Cluster Replication".

It is also possible to improve cluster replication performance by enabling batched updates. This can be accomplished by setting the `slave_allow_batching` system variable on the replicas' `mysqld` processes. Normally, updates are applied as soon as they are received. However, the use of batching causes updates to be applied in batches of 32 KB each; this can result in higher throughput and less CPU usage, particularly where individual updates are relatively small.

**Note**

Batching works on a per-epoch basis; updates belonging to more than one transaction can be sent as part of the same batch.

All outstanding updates are applied when the end of an epoch is reached, even if the updates total less than 32 KB.

Batching can be turned on and off at runtime. To activate it at runtime, you can use either of these two statements:

```sql
SET GLOBAL slave_allow_batching = 1;
SET GLOBAL slave_allow_batching = ON;
```

If a particular batch causes problems (such as a statement whose effects do not appear to be replicated correctly), batching can be deactivated using either of the following statements:

```sql
SET GLOBAL slave_allow_batching = 0;
SET GLOBAL slave_allow_batching = OFF;
```

You can check whether batching is currently being used by means of an appropriate `SHOW VARIABLES` statement, like this one:

```sql
mysql> SHOW VARIABLES LIKE 'slave\%';
```
22.6.7 Using Two Replication Channels for NDB Cluster Replication

In a more complete example scenario, we envision two replication channels to provide redundancy and thereby guard against possible failure of a single replication channel. This requires a total of four replication servers, two source servers on the source cluster and two replica servers on the replica cluster. For purposes of the discussion that follows, we assume that unique identifiers are assigned as shown here:

<table>
<thead>
<tr>
<th>Server ID</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Source - primary replication channel (S)</td>
</tr>
<tr>
<td>2</td>
<td>Source - secondary replication channel (S')</td>
</tr>
<tr>
<td>3</td>
<td>Replica - primary replication channel (R)</td>
</tr>
<tr>
<td>4</td>
<td>replica - secondary replication channel (R')</td>
</tr>
</tbody>
</table>

Setting up replication with two channels is not radically different from setting up a single replication channel. First, the `mysqld` processes for the primary and secondary replication source servers must be started, followed by those for the primary and secondary replicas. The replication processes can be initiated by issuing the `START REPLICA | SLAVE` statement on each of the replicas. The commands and the order in which they need to be issued are shown here:

1. Start the primary replication source:
   
   ```shell
   S> mysql --ndbcluster --server-id=1 --log-bin &
   ```

2. Start the secondary replication source:
   
   ```shell
   S'> mysql --ndbcluster --server-id=2 --log-bin &
   ```

3. Start the primary replica server:
   
   ```shell
   R> mysql --ndbcluster --server-id=3 --skip-slave-start &
   ```

4. Start the secondary replica server:
   
   ```shell
   R'> mysql --ndbcluster --server-id=4 --skip-slave-start &
   ```

5. Finally, initiate replication on the primary channel by executing the `START REPLICA | SLAVE` statement on the primary replica as shown here:

   ```mysql
   R> START SLAVE;
   ```
   Or from MySQL 8.0.22:
   ```mysql
   R> START REPLICA;
   ```
Warning
Only the primary channel must be started at this point. The secondary replication channel needs to be started only in the event that the primary replication channel fails, as described in Section 22.6.8, “Implementing Failover with NDB Cluster Replication”. Running multiple replication channels simultaneously can result in unwanted duplicate records being created on the replicas.

As mentioned previously, it is not necessary to enable binary logging on the replicas.

22.6.8 Implementing Failover with NDB Cluster Replication

In the event that the primary Cluster replication process fails, it is possible to switch over to the secondary replication channel. The following procedure describes the steps required to accomplish this.

1. Obtain the time of the most recent global checkpoint (GCP). That is, you need to determine the most recent epoch from the ndb_apply_status table on the replica cluster, which can be found using the following query:

```sql
SELECT @latest:=MAX(epoch) FROM mysql.ndb_apply_status;
```

In a circular replication topology, with a source and a replica running on each host, when you are using ndb_log_apply_status=1, NDB Cluster epochs are written in the replicas' binary logs. This means that the ndb_apply_status table contains information for the replica on this host as well as for any other host which acts as a replica of the replication source server running on this host.

In this case, you need to determine the latest epoch on this replica to the exclusion of any epochs from any other replicas in this replica's binary log that were not listed in the IGNORE_SERVER_IDS options of the CHANGE MASTER TO statement used to set up this replica. The reason for excluding such epochs is that rows in the mysql.ndb_apply_status table whose server IDs have a match in the IGNORE_SERVER_IDS list from the CHANGE MASTER TO statement used to prepare this replicas's source are also considered to be from local servers, in addition to those having the replica's own server ID. You can retrieve this list as Replicate_Ignore_Server_Ids from the output of SHOW REPLICA | SLAVE STATUS. We assume that you have obtained this list and are substituting it for ignore_server_ids in the query shown here, which like the previous version of the query, selects the greatest epoch into a variable named @latest:

```sql
SELECT @latest:=MAX(epoch)
   FROM mysql.ndb_apply_status
   WHERE server_id NOT IN (ignore_server_ids);
```

In some cases, it may be simpler or more efficient (or both) to use a list of the server IDs to be included and server_id IN server_id_list in the WHERE condition of the preceding query.

2. Using the information obtained from the query shown in Step 1, obtain the corresponding records from the ndb_binlog_index table on the source cluster.

You can use the following query to obtain the needed records from the ndb_binlog_index table on the source:

```sql
SELECT @file:=SUBSTRING_INDEX(next_file, '/', -1),
       @pos:=next_position
FROM mysql.ndb_binlog_index
WHERE epoch >= @latest;
```
These are the records saved on the source since the failure of the primary replication channel. We have employed a user variable `@latest` here to represent the value obtained in Step 1. Of course, it is not possible for one `mysqld` instance to access user variables set on another server instance directly. These values must be "plugged in" to the second query manually or by an application.

### Important

You must ensure that the replica `mysqld` is started with `--slave-skip-errors=ddl_exist_errors` before executing `START REPLICA | SLAVE`. Otherwise, replication may stop with duplicate DDL errors.

5. Now it is possible to synchronize the secondary channel by running the following query on the secondary replica server:

```sql
mysqlR'> CHANGE MASTER TO
-> MASTER_LOG_FILE='@file',
-> MASTER_LOG_POS=@pos;
```

Again we have employed user variables (in this case `@file` and `@pos`) to represent the values obtained in Step 2 and applied in Step 3; in practice these values must be inserted manually or using an application that can access both of the servers involved.

### Note

@file is a string value such as `'/var/log/mysql/replication-source-bin.00001'`, and so must be quoted when used in SQL or application code. However, the value represented by @pos must not be quoted. Although MySQL normally attempts to convert strings to numbers, this case is an exception.

4. You can now initiate replication on the secondary channel by issuing the appropriate command on the secondary replica `mysqld`:

```sql
mysqlR'> START SLAVE;
```

Or from MySQL 8.0.22:

```sql
mysqlR'> START REPLICA;
```

Once the secondary replication channel is active, you can investigate the failure of the primary and effect repairs. The precise actions required to do this depend upon the reasons for which the primary channel failed.

### Warning

The secondary replication channel is to be started only if and when the primary replication channel has failed. Running multiple replication channels simultaneously can result in unwanted duplicate records being created on the replicas.

If the failure is limited to a single server, it should in theory be possible to replicate from `S` to `R'`, or from `S'` to `R`.

### 22.6.9 NDB Cluster Backups With NDB Cluster Replication

This section discusses making backups and restoring from them using NDB Cluster replication. We assume that the replication servers have already been configured as covered previously (see Section 22.6.5, "Preparing the NDB Cluster for Replication", and the sections immediately following). This having been done, the procedure for making a backup and then restoring from it is as follows:

1. There are two different methods by which the backup may be started.
NDB Cluster Backups With NDB Cluster Replication

- **Method A.** This method requires that the cluster backup process was previously enabled on the source server, prior to starting the replication process. This can be done by including the following line in a `[mysql_cluster]` section in the `my.cnf` file, where `management_host` is the IP address or host name of the NDB management server for the source cluster, and `port` is the management server's port number:

  ```
  ndb-connectstring=management_host[:port]
  ```

  **Note**
  
  The port number needs to be specified only if the default port (1186) is not being used. See Section 22.2.3, “Initial Configuration of NDB Cluster”, for more information about ports and port allocation in NDB Cluster.

  In this case, the backup can be started by executing this statement on the replication source:

  ```
  nbd_mgm -e "START BACKUP"
  ```

- **Method B.** If the `my.cnf` file does not specify where to find the management host, you can start the backup process by passing this information to the NDB management client as part of the `START BACKUP` command. This can be done as shown here, where `management_host` and `port` are the host name and port number of the management server:

  ```
  nbd_mgm management_host:port -e "START BACKUP"
  ```

  In our scenario as outlined earlier (see Section 22.6.5, “Preparing the NDB Cluster for Replication”), this would be executed as follows:

  ```
  nbd_mgm rep-source:1186 -e "START BACKUP"
  ```

2. Copy the cluster backup files to the replica that is being brought on line. Each system running an `ndbd` process for the source cluster has cluster backup files located on it, and all of these files must be copied to the replica to ensure a successful restore. The backup files can be copied into any directory on the computer where the replica's management host resides, as long as the MySQL and NDB binaries have read permissions in that directory. In this case, we assume that these files have been copied into the directory `/var/BACKUPS/BACKUP-1`.

   While it is not necessary that the replica cluster have the same number of `ndbd` processes (data nodes) as the source, it is highly recommended this number be the same. It is necessary that the replica be started with the `--skip-slave-start` option, to prevent premature startup of the replication process.

3. Create any databases on the replica cluster that are present on the source cluster and that are to be replicated.

   **Important**
   
   A `CREATE DATABASE` (or `CREATE SCHEMA`) statement corresponding to each database to be replicated must be executed on each SQL node in the replica cluster.

4. Reset the replica cluster using this statement in the `mysql` client:

   ```
   mysql> RESET SLAVE;
   Or from MySQL 8.0.22:
   mysql> RESET REPLICA;
   ```
5. You can now start the cluster restoration process on the replica using the `ndb_restore` command for each backup file in turn. For the first of these, it is necessary to include the `-m` option to restore the cluster metadata, as shown here:

```
shellR> ndb_restore -c replica_host:port -n node-id \
    -b backup-id -m -r dir
```

`dir` is the path to the directory where the backup files have been placed on the replica. For the `ndb_restore` commands corresponding to the remaining backup files, the `-m` option should *not* be used.

For restoring from a source cluster with four data nodes (as shown in the figure in Section 22.6, “NDB Cluster Replication”) where the backup files have been copied to the directory `/var/BACKUPS/BACKUP-1`, the proper sequence of commands to be executed on the replica might look like this:

```
shellR> ndb_restore -c replica-host:1186 -n 2 -b 1 -m \
    -r ./var/BACKUPS/BACKUP-1
shellR> ndb_restore -c replica-host:1186 -n 3 -b 1 \n    -r ./var/BACKUPS/BACKUP-1
shellR> ndb_restore -c replica-host:1186 -n 4 -b 1 \n    -r ./var/BACKUPS/BACKUP-1
shellR> ndb_restore -c replica-host:1186 -n 5 -b 1 -e \n    -r ./var/BACKUPS/BACKUP-1
```

**Important**

The `-e` (or `--restore-epoch`) option in the final invocation of `ndb_restore` in this example is required to make sure that the epoch is written to the replica's `mysql.ndb_apply_status` table. Without this information, the replica cannot synchronize properly with the source. (See Section 22.4.23, "ndb_restore — Restore an NDB Cluster Backup").

6. Now you need to obtain the most recent epoch from the `ndb_apply_status` table on the replica (as discussed in Section 22.6.8, “Implementing Failover with NDB Cluster Replication”):

```
mysqlR> SELECT @latest:=MAX(epoch) 
    FROM mysql.ndb_apply_status;
```

7. Using `@latest` as the epoch value obtained in the previous step, you can obtain the correct starting position `@pos` in the correct binary log file `@file` from the `mysql.ndb_binlog_index` table on the source using the query shown here:

```
mysqlR> SELECT @file:=SUBSTRING_INDEX(File, '/', -1), 
    @pos:=Position 
    FROM mysql.ndb_binlog_index 
    WHERE epoch >= @latest 
    ORDER BY epoch ASC LIMIT 1;
```

In the event that there is currently no replication traffic, you can get this information by running `SHOW MASTER STATUS` on the source and using the value shown in the `Position` column of the output for the file whose name has the suffix with the greatest value for all files shown in the `File` column. In this case, you must determine which file this is and supply the name in the next step manually or by parsing the output with a script.

8. Using the values obtained in the previous step, you can now issue the appropriate `CHANGE MASTER TO` statement in the replica's `mysql` client:

```
mysqlR> CHANGE MASTER TO 
    MASTER_LOG_FILE='@file',
```
Now that the replica knows from what point in which binary log file to start reading data from the source, you can cause the replica to begin replicating with this statement:

```sql
> START SLAVE;
Or from MySQL 8.0.22:
> START REPLICA;
```

To perform a backup and restore on a second replication channel, it is necessary only to repeat these steps, substituting the host names and IDs of the secondary source and replica for those of the primary source and replica servers where appropriate, and running the preceding statements on them.

For additional information on performing Cluster backups and restoring Cluster from backups, see Section 22.5.8, “Online Backup of NDB Cluster”.

### 22.6.9.1 NDB Cluster Replication: Automating Synchronization of the Replica to the Source Binary Log

It is possible to automate much of the process described in the previous section (see Section 22.6.9, “NDB Cluster Backups With NDB Cluster Replication”). The following Perl script `reset-replica.pl` serves as an example of how you can do this.

```perl
#!/usr/bin/perl -w
# file: reset-replica.pl

```
### Sub Prototypes ###

```perl
sub CollectCommandPromptInfo;
sub ConnectToDatabases;
sub DisconnectFromDatabases;
sub GetReplicaEpoch;
sub GetSourceInfo;
sub UpdateReplica;
```

### Program Main ###

```perl
CollectCommandPromptInfo;
ConnectToDatabases;
GetReplicaEpoch;
GetSourceInfo;
UpdateReplica;
DisconnectFromDatabases;
```

### Collect Command Prompt Info ###

```perl
sub CollectCommandPromptInfo
{
    ### Check that user has supplied correct number of command line args
    die "Usage:
    reset-replica >source MySQL host< >source MySQL port< 
    >source user< >source pass< >replica MySQL host< 
    >replica MySQL port< >replica user< >replica pass< 
    All 8 arguments must be passed. Use BLANK for NULL passwords\n" unless @ARGV == 8;

    $m_host  =  $ARGV[0];
    $m_port  =  $ARGV[1];
    $m_user  =  $ARGV[2];
    $m_pass  =  $ARGV[3];
    $s_host  =  $ARGV[4];
    $s_port  =  $ARGV[5];
    $s_user  =  $ARGV[6];
    $s_pass  =  $ARGV[7];

    if ($m_pass eq "BLANK") { $m_pass = '';}
    if ($s_pass eq "BLANK") { $s_pass = '';}
}
```

### Make connections to both databases ###

```perl
sub ConnectToDatabases
{
    ### Connect to both source and replica cluster databases
    ### Connect to source
    $dbhM  =  DBI->connect("dbi:mysql:database=mysql;host=$m_host;port=$m_port",
        "$m_user", "$m_pass")
        or die "Can't connect to source cluster MySQL process!
        Error: $DBI::errstr\n";

    ### Connect to replica
    $dbhS  =  DBI->connect("dbi:mysql:database=mysql;host=$s_host",
        "$s_user", "$s_pass")
        or die "Can't connect to replica cluster MySQL process!
        Error: $DBI::errstr\n";
}
```
### Disconnect from both databases #######

```perl
sub DisconnectFromDatabases
{
    ### Disconnect from source
    $dbhM->disconnect
    or warn " Disconnection failed: $DBI::errstr\n";

    ### Disconnect from replica
    $dbhS->disconnect
    or warn " Disconnection failed: $DBI::errstr\n";
}
```

### Find the last good GCI #######

```perl
sub GetReplicaEpoch
{
    $sth = $dbhS->prepare("SELECT MAX(epoch)
        FROM mysql.ndb_apply_status;")
        or die "Error while preparing to select epoch from replica: ",
        $dbhS->errstr;

    $sth->execute
        or die "Selecting epoch from replica error: ", $sth->errstr;

    $sth->bind_col (1, \$epoch);
    $sth->fetch;
    print "\tReplica epoch =  $epoch\n";
    $sth->finish;
}
```

#### Find the position of the last GCI in the binary log #######

```perl
sub GetSourceInfo
{
    $sth = $dbhM->prepare("SELECT
        SUBSTRING_INDEX(File, '/', -1), Position
        FROM mysql.ndb_binlog_index
        WHERE epoch > $epoch
        ORDER BY epoch ASC LIMIT 1;")
        or die "Prepare to select from source error: ", $dbhM->errstr;

    $sth->execute
        or die "Selecting from source error: ", $sth->errstr;

    $sth->bind_col (1, \$binlog);
    $sth->bind_col (2, \$binpos);
    $sth->fetch;
    print "\tSource binary log file =  $binlog\n";
    print "\tSource binary log position =  $binpos\n";
    $sth->finish;
}
```

##### Set the replica to process from that location #######

```perl
sub UpdateReplica
{
    $sth = $dbhS->prepare("CHANGE MASTER TO
        MASTER_LOG_FILE='$binlog',
        MASTER_LOG_POS=$binpos;")
        or die "Prepare to CHANGE MASTER error: ", $dbhS->errstr;

    $sth->execute
        or die "CHANGE MASTER on replica error: ", $sth->errstr;
    $sth->finish;
}
```
22.6.9.2 Point-In-Time Recovery Using NDB Cluster Replication

Point-in-time recovery—that is, recovery of data changes made since a given point in time—is performed after restoring a full backup that returns the server to its state when the backup was made. Performing point-in-time recovery of NDB Cluster tables with NDB Cluster and NDB Cluster Replication can be accomplished using a native NDB data backup (taken by issuing CREATE_BACKUP in the ndb_mgm client) and restoring the ndb_binlog_index table (from a dump made using mysqldump).

To perform point-in-time recovery of NDB Cluster, it is necessary to follow the steps shown here:

1. Back up all NDB databases in the cluster, using the START_BACKUP command in the ndb_mgm client (see Section 22.5.8, “Online Backup of NDB Cluster”).

2. At some later point, prior to restoring the cluster, make a backup of the mysql.ndb_binlog_index table. It is probably simplest to use mysqldump for this task. Also back up the binary log files at this time.

   This backup should be updated regularly—perhaps even hourly—depending on your needs.

3. (Catastrophic failure or error occurs.)

4. Locate the last known good backup.

5. Clear the data node file systems (using ndbd --initial or ndbmtd --initial).

   Note

   Beginning with NDB 8.0.21, Disk Data tablespace and log files are removed by --initial. Previously, it was necessary to delete these manually.

6. Use DROP TABLE or TRUNCATE TABLE with the mysql.ndb_binlog_index table.

7. Execute ndb_restore, restoring all data. You must include the --restore-epoch option when you run ndb_restore, so that the ndb_apply_status table is populated correctly. (See Section 22.4.23, “ndb_restore — Restore an NDB Cluster Backup”, for more information.)

8. Restore the ndb_binlog_index table from the output of mysqldump and restore the binary log files from backup, if necessary.

9. Find the epoch applied most recently—that is, the maximum epoch column value in the ndb_apply_status table—as the user variable @LATEST_EPOCH (emphasized):

   ```
   SELECT @LATEST_EPOCH:=MAX(epoch)
   FROM mysql.ndb_apply_status;
   ```

10. Find the latest binary log file (@FIRST_FILE) and position (Position column value) within this file that correspond to @LATEST_EPOCH in the ndb_binlog_index table:

    ```
    SELECT Position, @FIRST_FILE:=File
    FROM mysql.ndb_binlog_index
    WHERE epoch > @LATEST_EPOCH ORDER BY epoch ASC LIMIT 1;
    ```

11. Using mysqlbinlog, replay the binary log events from the given file and position up to the point of the failure. (See Section 4.6.8, “mysqlbinlog — Utility for Processing Binary Log Files”.)
See also Section 7.5, “Point-in-Time (Incremental) Recovery”, for more information about the binary log, replication, and incremental recovery.

22.6.10 NDB Cluster Replication: Bidirectional and Circular Replication

It is possible to use NDB Cluster for bidirectional replication between two clusters, as well as for circular replication between any number of clusters.

Circular replication example. In the next few paragraphs we consider the example of a replication setup involving three NDB Clusters numbered 1, 2, and 3, in which Cluster 1 acts as the replication source for Cluster 2, Cluster 2 acts as the source for Cluster 3, and Cluster 3 acts as the source for Cluster 1. Each cluster has two SQL nodes, with SQL nodes A and B belonging to Cluster 1, SQL nodes C and D belonging to Cluster 2, and SQL nodes E and F belonging to Cluster 3.

Circular replication using these clusters is supported as long as the following conditions are met:

• The SQL nodes on all sources and replicas are the same.

• All SQL nodes acting as sources and replicas are started with the log_slave_updates system variable enabled.

This type of circular replication setup is shown in the following diagram:
In this scenario, SQL node A in Cluster 1 replicates to SQL node C in Cluster 2; SQL node C replicates to SQL node E in Cluster 3; SQL node E replicates to SQL node A. In other words, the replication line (indicated by the curved arrows in the diagram) directly connects all SQL nodes used as replication sources and replicas.

It is also possible to set up circular replication in such a way that not all source SQL nodes are also replicas, as shown here:
In this case, different SQL nodes in each cluster are used as replication sources and replicas. You must not start any of the SQL nodes with the `log_slave_updates` system variable enabled. This type of circular replication scheme for NDB Cluster, in which the line of replication (again indicated by the curved arrows in the diagram) is discontinuous, should be possible, but it should be noted that it has not yet been thoroughly tested and must therefore still be considered experimental.

**Using NDB-native backup and restore to initialize a replica cluster.** When setting up circular replication, it is possible to initialize the replica cluster by using the management client `BACKUP` command on one NDB Cluster to create a backup and then applying this backup on another NDB Cluster using `ndb_restore`. This does not automatically create binary logs on the second NDB Cluster’s SQL node acting as the replica; in order to cause the binary logs to be created, you must issue a `SHOW TABLES` statement on that SQL node; this should be done prior to running `START REPLICA | SLAVE`. This is a known issue.

**Multi-source failover example.** In this section, we discuss failover in a multi-source NDB Cluster replication setup with three NDB Clusters having server IDs 1, 2, and 3. In this scenario, Cluster 1 replicates to Clusters 2 and 3; Cluster 2 also replicates to Cluster 3. This relationship is shown here:
In other words, data replicates from Cluster 1 to Cluster 3 through 2 different routes: directly, and by way of Cluster 2.

Not all MySQL servers taking part in multi-source replication must act as both source and replica, and a given NDB Cluster might use different SQL nodes for different replication channels. Such a case is shown here:

MySQL servers acting as replicas must be run with the `log_slave_updates` system variable enabled. Which `mysqld` processes require this option is also shown in the preceding diagram.

**Note**

Using the `log_slave_updates` system variable has no effect on servers not being run as replicas.

The need for failover arises when one of the replicating clusters goes down. In this example, we consider the case where Cluster 1 is lost to service, and so Cluster 3 loses 2 sources of updates from Cluster 1.
Because replication between NDB Clusters is asynchronous, there is no guarantee that Cluster 3’s updates originating directly from Cluster 1 are more recent than those received through Cluster 2. You can handle this by ensuring that Cluster 3 catches up to Cluster 2 with regard to updates from Cluster 1. In terms of MySQL servers, this means that you need to replicate any outstanding updates from MySQL server C to server F.

On server C, perform the following queries:

```sql
mysqlC> SELECT @latest:=MAX(epoch)
         ->     FROM mysql.ndb_apply_status
         ->     WHERE server_id=1;

mysqlC> SELECT
         ->     @file:=SUBSTRING_INDEX(File, '/', -1),
         ->     @pos:=Position
         ->     FROM mysql.ndb_binlog_index
         ->     WHERE orig_epoch >= @latest
         ->     AND orig_server_id = 1
         ->     ORDER BY epoch ASC LIMIT 1;
```

Note
You can improve the performance of this query, and thus likely speed up failover times significantly, by adding the appropriate index to the `ndb_binlog_index` table. See Section 22.6.4, “NDB Cluster Replication Schema and Tables”, for more information.

Copy over the values for `@file` and `@pos` manually from server C to server F (or have your application perform the equivalent). Then, on server F, execute the following `CHANGE MASTER TO` statement:

```sql
mysqlF> CHANGE MASTER TO
         ->     MASTER_HOST = 'serverC'
         ->     MASTER_LOG_FILE='@file',
         ->     MASTER_LOG_POS=@pos;
```

Once this has been done, you can issue a `START REPLICA | SLAVE` statement on MySQL server F; this causes any missing updates originating from server B to be replicated to server F.

The `CHANGE MASTER TO` statement also supports an `IGNORE_SERVER_IDS` option which takes a comma-separated list of server IDs and causes events originating from the corresponding servers to be ignored. For more information, see Section 13.4.2.1, “CHANGE MASTER TO Statement”, and Section 13.7.7.36, “SHOW SLAVE | REPLICA STATUS Statement”. For information about how this option interacts with the `ndb_log_apply_status` variable, see Section 22.6.8, “Implementing Failover with NDB Cluster Replication”.

## 22.6.11 NDB Cluster Replication Conflict Resolution

When using a replication setup involving multiple sources (including circular replication), it is possible that different sources may try to update the same row on the replica with different data. Conflict resolution in NDB Cluster Replication provides a means of resolving such conflicts by permitting a user-defined resolution column to be used to determine whether or not an update on a given source should be applied on the replica.

Some types of conflict resolution supported by NDB Cluster (NDB$OLD(), NDB$MAX(), NDB$MAX_DELETE_WIN()) implement this user-defined column as a “timestamp” column (although its type cannot be `TIMESTAMP`, as explained later in this section). These types of conflict resolution are always applied a row-by-row basis rather than a transactional basis. The epoch-based conflict resolution functions NDB$EPOCH() and NDB$EPOCH_TRANS() compare the order in which epochs are replicated (and thus these functions are transactional). Different methods can be used to compare resolution column values on
the replica when conflicts occur, as explained later in this section; the method used can be set on a per-table basis.

You should also keep in mind that it is the application's responsibility to ensure that the resolution column is correctly populated with relevant values, so that the resolution function can make the appropriate choice when determining whether to apply an update.

**Requirements.** Preparations for conflict resolution must be made on both the source and the replica. These tasks are described in the following list:

- On the source writing the binary logs, you must determine which columns are sent (all columns or only those that have been updated). This is done for the MySQL Server as a whole by applying the `mysqld` startup option `--ndb-log-updated-only` (described later in this section) or on a per-table basis by entries in the `mysql.ndb_replication` table (see The ndb_replication system table).

  ![Note](image)

  If you are replicating tables with very large columns (such as TEXT or BLOB columns), `--ndb-log-updated-only` can also be useful for reducing the size of the binary logs and avoiding possible replication failures due to exceeding `max_allowed_packet`. See Section 17.5.1.20, “Replication and max_allowed_packet”, for more information about this issue.

- On the replica, you must determine which type of conflict resolution to apply (“latest timestamp wins”, “same timestamp wins”, “primary wins”, “primary wins, complete transaction”, or none). This is done using the `mysql.ndb_replication` system table, on a per-table basis (see The ndb_replication system table).

- NDB Cluster also supports read conflict detection, that is, detecting conflicts between reads of a given row in one cluster and updates or deletes of the same row in another cluster. This requires exclusive read locks obtained by setting `ndb_log_exclusive_reads` equal to 1 on the replica. All rows read by a conflicting read are logged in the exceptions table. For more information, see Read conflict detection and resolution.

When using the functions `NDB$OLD()`, `NDB$MAX()`, and `NDB$MAX_DELETE_WIN()` for timestamp-based conflict resolution, we often refer to the column used for determining updates as a “timestamp” column. However, the data type of this column is never `TIMESTAMP`; instead, its data type should be `INT` (INTEGER) or `BIGINT`. The “timestamp” column should also be `UNSIGNED` and `NOT NULL`.

The `NDB$EPOCH()` and `NDB$EPOCH_TRANS()` functions discussed later in this section work by comparing the relative order of replication epochs applied on a primary and secondary NDB Cluster, and do not make use of timestamps.

**Source column control.** We can see update operations in terms of “before” and “after” images—that is, the states of the table before and after the update is applied. Normally, when updating a table with a primary key, the “before” image is not of great interest; however, when we need to determine on a per-update basis whether or not to use the updated values on a replica, we need to make sure that both images are written to the source's binary log. This is done with the `--ndb-log-update-as-write` option for `mysqld`, as described later in this section.

**Important**

Whether logging of complete rows or of updated columns only is done is decided when the MySQL server is started, and cannot be changed online; you must either restart `mysqld`, or start a new `mysqld` instance with different logging options.
Logging Full or Partial Rows (\texttt{--ndb-log-updated-only} Option)

| Command-Line Format          | \texttt{--ndb-log-updated-only[={OFF|ON}]} |
|------------------------------|-------------------------------------------|
| System Variable              | \texttt{ndb_log_updated_only}             |
| Scope                        | Global                                    |
| Dynamic                      | Yes                                       |
| \texttt{SET_VAR} Hint Applies| No                                        |
| Type                         | Boolean                                   |
| Default Value                | \texttt{ON}                               |

For purposes of conflict resolution, there are two basic methods of logging rows, as determined by the setting of the \texttt{--ndb-log-updated-only} option for \texttt{mysqld}:

- Log complete rows
- Log only column data that has been updated—that is, column data whose value has been set, regardless of whether or not this value was actually changed. This is the default behavior.

It is usually sufficient—and more efficient—to log updated columns only; however, if you need to log full rows, you can do so by setting \texttt{--ndb-log-updated-only} to 0 or \texttt{OFF}.

\texttt{--ndb-log-update-as-write} Option: Logging Changed Data as Updates

| Command-Line Format          | \texttt{--ndb-log-update-as-write[={OFF|ON}]} |
|------------------------------|-------------------------------------------|
| System Variable              | \texttt{ndb_log_update_as_write}           |
| Scope                        | Global                                    |
| Dynamic                      | Yes                                       |
| \texttt{SET_VAR} Hint Applies| No                                        |
| Type                         | Boolean                                   |
| Default Value                | \texttt{ON}                               |

The setting of the MySQL Server's \texttt{--ndb-log-update-as-write} option determines whether logging is performed with or without the “before” image. Because conflict resolution is done in the MySQL Server's update handler, it is necessary to control logging performed by the replication source such that updates are updates and not writes; that is, such that updates are treated as changes in existing rows rather than the writing of new rows, even though these replace existing rows. This option is turned on by default; in other words, updates are treated as writes. That is, updates are by default written as \texttt{write_row} events in the binary log, rather than as \texttt{update_row} events.

To disable the option, start the source \texttt{mysqld} with \texttt{--ndb-log-update-as-write=0} or \texttt{--ndb-log-update-as-write=OFF}. You must do this when replicating from NDB tables to tables using a different storage engine; see Replication from NDB to other storage engines, and Replication from NDB to a nontransactional storage engine, for more information.

Conflict resolution control. Conflict resolution is usually enabled on the server where conflicts can occur. Like logging method selection, it is enabled by entries in the \texttt{mysql.ndb_replication} table.

The \texttt{ndb_replication} system table. To enable conflict resolution, it is necessary to create an \texttt{ndb_replication} table in the \texttt{mysql} system database on the source, the replica, or both, depending on the conflict resolution type and method to be employed. This table is used to control logging and conflict resolution functions on a per-table basis, and has one row per table involved in replication.
**ndb_replication** is created and filled with control information on the server where the conflict is to be resolved. In a simple source-replica setup where data can also be changed locally on the replica this is typically the replica. In a more complex replication scheme, such as bidirectional replication, this is usually all of the sources involved. Each row in **mysql.ndb_replication** corresponds to a table being replicated, and specifies how to log and resolve conflicts (that is, which conflict resolution function, if any, to use) for that table. The definition of the **mysql.ndb_replication** table is shown here:

```sql
CREATE TABLE mysql.ndb_replication  (
  db VARBINARY(63),
  table_name VARBINARY(63),
  server_id INT UNSIGNED,
  binlog_type INT UNSIGNED,
  conflict_fn VARBINARY(128),
) PRIMARY KEY USING HASH (db, table_name, server_id)
ENGINE=NDB
PARTITION BY KEY(db,table_name);
```

The columns in this table are described in the next few paragraphs.

**db.** The name of the database containing the table to be replicated. You may employ either or both of the wildcards _ and % as part of the database name. Matching is similar to what is implemented for the **LIKE** operator.

**table_name.** The name of the table to be replicated. The table name may include either or both of the wildcards _ and %. Matching is similar to what is implemented for the **LIKE** operator.

**server_id.** The unique server ID of the MySQL instance (SQL node) where the table resides.

**binlog_type.** The type of binary logging to be employed. This is determined as shown in the following table:

<table>
<thead>
<tr>
<th>Value</th>
<th>Internal Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>NBT_DEFAULT</td>
<td>Use server default</td>
</tr>
<tr>
<td>1</td>
<td>NBT_NO_LOGGING</td>
<td>Do not log this table in the binary log</td>
</tr>
<tr>
<td>2</td>
<td>NBT_UPDATED_ONLY</td>
<td>Only updated attributes are logged</td>
</tr>
<tr>
<td>3</td>
<td>NBT_FULL</td>
<td>Log full row, even if not updated (MySQL server default behavior)</td>
</tr>
<tr>
<td>4</td>
<td>NBT_USE_UPDATE</td>
<td>(For generating NBT_UPDATED_ONLY_USE_UPDATE and NBT_FULL_USE_UPDATE values only—not intended for separate use)</td>
</tr>
<tr>
<td>5</td>
<td>[Not used]</td>
<td>---</td>
</tr>
<tr>
<td>6</td>
<td>NBT_UPDATED_ONLY (equal to NBT_UPDATED_ONLY</td>
<td>Use updated attributes, even if values are unchanged</td>
</tr>
<tr>
<td></td>
<td></td>
<td>NBT_USE_UPDATE)</td>
</tr>
<tr>
<td>7</td>
<td>NBT_FULL_USE_UPDATE (equal to NBT_FULL</td>
<td>Use full row, even if values are unchanged</td>
</tr>
<tr>
<td></td>
<td></td>
<td>NBT_USE_UPDATE)</td>
</tr>
</tbody>
</table>

**conflict_fn.** The conflict resolution function to be applied. This function must be specified as one of those shown in the following list:
NDB Cluster Replication Conflict Resolution

- **NDB$OLD(column_name)**
- **NDB$MAX(column_name)**
- **NDB$MAX_DELETE_WIN()**
- **NDB$EPOCH() and NDB$EPOCH_TRANS()**
- **NDB$EPOCH_TRANS()**
- **NDB$EPOCH2()**
- **NDB$EPOCH2_TRANS()**
- **NULL:** Indicates that conflict resolution is not to be used for the corresponding table.

These functions are described in the next few paragraphs.

**NDB$OLD(column_name).** If the value of `column_name` is the same on both the source and the replica, then the update is applied; otherwise, the update is not applied on the replica and an exception is written to the log. This is illustrated by the following pseudocode:

```plaintext
if (source_old_column_value == replica_current_column_value)
    apply_update();
else
    log_exception();
```

This function can be used for “same value wins” conflict resolution. This type of conflict resolution ensures that updates are not applied on the replica from the wrong source.

**Important**
The column value from the source's “before” image is used by this function.

**NDB$MAX(column_name).** If the “timestamp” column value for a given row coming from the source is higher than that on the replica, it is applied; otherwise it is not applied on the replica. This is illustrated by the following pseudocode:

```plaintext
if (source_new_column_value > replica_current_column_value)
    apply_update();
```

This function can be used for “greatest timestamp wins” conflict resolution. This type of conflict resolution ensures that, in the event of a conflict, the version of the row that was most recently updated is the version that persists.

**Important**
The column value from the source's “after” image is used by this function.

**NDB$MAX_DELETE_WIN().** This is a variation on **NDB$MAX()**. Due to the fact that no timestamp is available for a delete operation, a delete using **NDB$MAX()** is in fact processed as **NDB$OLD**, but for some use cases, this is not optimal. For **NDB$MAX_DELETE_WIN()**, if the “timestamp” column value for a given row adding or updating an existing row coming from the source is higher than that on the replica, it is applied. However, delete operations are treated as always having the higher value. This is illustrated by the following pseudocode:

```plaintext
if (source_new_column_value > replica_current_column_value)
    apply_update();
```

---

4442
This function can be used for “greatest timestamp, delete wins” conflict resolution. This type of conflict resolution ensures that, in the event of a conflict, the version of the row that was deleted or (otherwise) most recently updated is the version that persists.

Note

As with \texttt{NDB$MAX()}, the column value from the source’s “after” image is the value used by this function.

\texttt{NDB$EPOCH()} and \texttt{NDB$EPOCH\_TRANS()}. \texttt{NDB$EPOCH()} function tracks the order in which replicated epochs are applied on a replica cluster relative to changes originating on the replica. This relative ordering is used to determine whether changes originating on the replica are concurrent with any changes that originate locally, and are therefore potentially in conflict.

Most of what follows in the description of \texttt{NDB$EPOCH()} also applies to \texttt{NDB$EPOCH\_TRANS()}. Any exceptions are noted in the text.

\texttt{NDB$EPOCH()} is asymmetric, operating on one NDB Cluster in a bidirectional replication configuration (sometimes referred to as “active-active” replication). We refer here to cluster on which it operates as the primary, and the other as the secondary. The replica on the primary is responsible for detecting and handling conflicts, while the replica on the secondary is not involved in any conflict detection or handling.

When the replica on the primary detects conflicts, it injects events into its own binary log to compensate for these; this ensures that the secondary NDB Cluster eventually realigns itself with the primary and so keeps the primary and secondary from diverging. This compensation and realignment mechanism requires that the primary NDB Cluster always wins any conflicts with the secondary—that is, that the primary’s changes are always used rather than those from the secondary in event of a conflict. This “primary always wins” rule has the following implications:

\begin{itemize}
  \item Operations that change data, once committed on the primary, are fully persistent and are not undone or rolled back by conflict detection and resolution.
  \item Data read from the primary is fully consistent. Any changes committed on the Primary (locally or from the replica) are not reverted later.
  \item Operations that change data on the secondary may later be reverted if the primary determines that they are in conflict.
  \item Individual rows read on the secondary are self-consistent at all times, each row always reflecting either a state committed by the secondary, or one committed by the primary.
  \item Sets of rows read on the secondary may not necessarily be consistent at a given single point in time. For \texttt{NDB$EPOCH\_TRANS()}, this is a transient state; for \texttt{NDB$EPOCH()}, it can be a persistent state.
  \item Assuming a period of sufficient length without any conflicts, all data on the secondary NDB Cluster (eventually) becomes consistent with the primary’s data.
\end{itemize}

\texttt{NDB$EPOCH()} and \texttt{NDB$EPOCH\_TRANS()} do not require any user schema modifications, or application changes to provide conflict detection. However, careful thought must be given to the schema used, and the access patterns used, to verify that the complete system behaves within specified limits.

Each of the \texttt{NDB$EPOCH()} and \texttt{NDB$EPOCH\_TRANS()} functions can take an optional parameter; this is the number of bits to use to represent the lower 32 bits of the epoch, and should be set to no less than the value calculated as shown here:
CEIL( LOG2( TimeBetweenGlobalCheckpoints / TimeBetweenEpochs ), 1)

For the default values of these configuration parameters (2000 and 100 milliseconds, respectively), this gives a value of 5 bits, so the default value (6) should be sufficient, unless other values are used for TimeBetweenGlobalCheckpoints, TimeBetweenEpochs, or both. A value that is too small can result in false positives, while one that is too large could lead to excessive wasted space in the database.

Both NDB$EPOCH() and NDB$EPOCH_TRANS() insert entries for conflicting rows into the relevant exceptions tables, provided that these tables have been defined according to the same exceptions table schema rules as described elsewhere in this section (see NDB$OLD(column_name)). You must create any exceptions table before creating the data table with which it is to be used.

As with the other conflict detection functions discussed in this section, NDB$EPOCH() and NDB$EPOCH_TRANS() are activated by including relevant entries in the mysql.ndb_replication table (see The ndb_replication system table). The roles of the primary and secondary NDB Clusters in this scenario are fully determined by mysql.ndb_replication table entries.

Because the conflict detection algorithms employed by NDB$EPOCH() and NDB$EPOCH_TRANS() are asymmetric, you must use different values for the server_id entries of the primary and secondary replicas.

A conflict between DELETE operations alone is not sufficient to trigger a conflict using NDB$EPOCH() or NDB$EPOCH_TRANS(), and the relative placement within epochs does not matter. (Bug #18459944)

**Conflict detection status variables.** Several status variables can be used to monitor conflict detection. You can see how many rows have been found in conflict by NDB$EPOCH() since this replica was last restarted from the current value of the Ndb_conflict_fn_epoch system status variable.

Ndb_conflict_fn_epoch_trans provides the number of rows that have been found directly in conflict by NDB$EPOCH_TRANS(). Ndb_conflict_fn_epoch2 and Ndb_conflict_fn_epoch2_trans show the number of rows found in conflict by NDB$EPOCH2() and NDB$EPOCH2_TRANS(), respectively. The number of rows actually realigned, including those affected due to their membership in or dependency on the same transactions as other conflicting rows, is given by Ndb_conflict_trans_row_reject_count.

For more information, see NDB Cluster Status Variables.

**Limitations on NDB$EPOCH().** The following limitations currently apply when using NDB$EPOCH() to perform conflict detection:

- Conflicts are detected using NDB Cluster epoch boundaries, with granularity proportional to TimeBetweenEpochs (default: 100 milliseconds). The minimum conflict window is the minimum time during which concurrent updates to the same data on both clusters always report a conflict. This is always a nonzero length of time, and is roughly proportional to $2 \times (\text{latency} + \text{queueing} + \text{TimeBetweenEpochs})$. This implies that—assuming the default for TimeBetweenEpochs and ignoring any latency between clusters (as well as any queuing delays)—the minimum conflict window size is approximately 200 milliseconds. This minimum window should be considered when looking at expected application “race” patterns.

- Additional storage is required for tables using the NDB$EPOCH() and NDB$EPOCH_TRANS() functions; from 1 to 32 bits extra space per row is required, depending on the value passed to the function.

- Conflicts between delete operations may result in divergence between the primary and secondary. When a row is deleted on both clusters concurrently, the conflict can be detected, but is not recorded, since the row is deleted. This means that further conflicts during the propagation of any subsequent realignment operations are not detected, which can lead to divergence.
Deletes should be externally serialized, or routed to one cluster only. Alternatively, a separate row should be updated transactionally with such deletes and any inserts that follow them, so that conflicts can be tracked across row deletes. This may require changes in applications.

- Only two NDB Clusters in a bidirectional “active-active” configuration are currently supported when using `NDB$EPOCH()` or `NDB$EPOCH_TRANS()` for conflict detection.

- Tables having `BLOB` or `TEXT` columns are not currently supported with `NDB$EPOCH()` or `NDB$EPOCH_TRANS()`.

**NDB$EPOCH_TRANS()**. `NDB$EPOCH_TRANS()` extends the `NDB$EPOCH()` function. Conflicts are detected and handled in the same way using the “primary wins all” rule (see `NDB$EPOCH()` and `NDB$EPOCH_TRANS()`), but with the extra condition that any other rows updated in the same transaction in which the conflict occurred are also regarded as being in conflict. In other words, where `NDB$EPOCH()` realigns individual conflicting rows on the secondary, `NDB$EPOCH_TRANS()` realigns conflicting transactions.

In addition, any transactions which are detectably dependent on a conflicting transaction are also regarded as being in conflict, these dependencies being determined by the contents of the secondary cluster's binary log. Since the binary log contains only data modification operations (inserts, updates, and deletes), only overlapping data modifications are used to determine dependencies between transactions.

`NDB$EPOCH_TRANS()` is subject to the same conditions and limitations as `NDB$EPOCH()`, and in addition requires that all transaction IDs are recorded in the secondary's binary log (the `--ndb-log-transaction-id` option), which adds a variable overhead (up to 13 bytes per row). The deprecated `log_bin_use_v1_row_events` system variable, which defaults to `OFF`, must not be set to `ON` with `NDB$EPOCH_TRANS()`.

See `NDB$EPOCH()` and `NDB$EPOCH_TRANS()`.

**Status information.** A server status variable `Ndb_conflict_fn_max` provides a count of the number of times that a row was not applied on the current SQL node due to “greatest timestamp wins” conflict resolution since the last time that `mysqld` was started.

The number of times that a row was not applied as the result of “same timestamp wins” conflict resolution on a given `mysqld` since the last time it was restarted is given by the global status variable `Ndb_conflict_fn_old`. In addition to incrementing `Ndb_conflict_fn_old`, the primary key of the row that was not used is inserted into an exceptions table, as explained later in this section.

**NDB$EPOCH2().** The `NDB$EPOCH2()` function is similar to `NDB$EPOCH()`, except that `NDB$EPOCH2()` provides for delete-delete handling with a bidirectional replication topology. In this scenario, primary and secondary roles are assigned to the two sources by setting the `ndb_slave_conflict_role` system variable to the appropriate value on each source (usually one each of `PRIMARY`, `SECONDARY`). When this is done, modifications made by the secondary are reflected by the primary back to the secondary which then conditionally applies them.

**NDB$EPOCH2_TRANS().** `NDB$EPOCH2_TRANS()` extends the `NDB$EPOCH2()` function. Conflicts are detected and handled in the same way, and assigning primary and secondary roles to the replicating clusters, but with the extra condition that any other rows updated in the same transaction in which the conflict occurred are also regarded as being in conflict. That is, `NDB$EPOCH2()` realigns individual conflicting rows on the secondary, while `NDB$EPOCH_TRANS()` realigns conflicting transactions.

Where `NDB$EPOCH()` and `NDB$EPOCH_TRANS()` use metadata that is specified per row, per last modified epoch, to determine on the primary whether an incoming replicated row change from the secondary is concurrent with a locally committed change; concurrent changes are regarded as conflicting, with
NDB Cluster Replication Conflict Resolution

Subsequent exceptions table updates and realignment of the secondary. A problem arises when a row is deleted on the primary so there is no longer any last-modified epoch available to determine whether any replicated operations conflict, which means that conflicting delete operations are not detected. This can result in divergence, an example being a delete on one cluster which is concurrent with a delete and insert on the other; this why delete operations can be routed to only one cluster when using `NDB$EPOCH()` and `NDB$EPOCH_TRANS()`.

`NDB$EPOCH2()` bypasses the issue just described—storing information about deleted rows on the PRIMARY—by ignoring any delete-delete conflict, and by avoiding any potential resultant divergence as well. This is accomplished by reflecting any operation successfully applied on and replicated from the secondary back to the secondary. On its return to the secondary, it can be used to reapply an operation on the secondary which was deleted by an operation originating from the primary.

When using `NDB$EPOCH2()`, you should keep in mind that the secondary applies the delete from the primary, removing the new row until it is restored by a reflected operation. In theory, the subsequent insert or update on the secondary conflicts with the delete from the primary, but in this case, we choose to ignore this and allow the secondary to “win”, in the interest of preventing divergence between the clusters. In other words, after a delete, the primary does not detect conflicts, and instead adopts the secondary’s following changes immediately. Because of this, the secondary’s state can revisit multiple previous committed states as it progresses to a final (stable) state, and some of these may be visible.

You should also be aware that reflecting all operations from the secondary back to the primary increases the size of the primary’s logbinary log, as well as demands on bandwidth, CPU usage, and disk I/O.

Application of reflected operations on the secondary depends on the state of the target row on the secondary. Whether or not reflected changes are applied on the secondary can be tracked by checking the `Ndb_conflict_reflected_op_prepare_count` and `Ndb_conflict_reflected_op_discard_count` status variables. The number of changes applied is simply the difference between these two values (note that `Ndb_conflict_reflected_op_prepare_count` is always greater than or equal to `Ndb_conflict_reflected_op_discard_count`).

Events are applied if and only if both of the following conditions are true:

- The existence of the row—that is, whether or not it exists—is in accordance with the type of event. For delete and update operations, the row must already exist. For insert operations, the row must not exist.
- The row was last modified by the primary. It is possible that the modification was accomplished through the execution of a reflected operation.

If both of the conditions are not met, the reflected operation is discarded by the secondary.

**Conflict resolution exceptions table.** To use the `NDB$OLD()` conflict resolution function, it is also necessary to create an exceptions table corresponding to each `NDB` table for which this type of conflict resolution is to be employed. This is also true when using `NDB$EPOCH()` or `NDB$EPOCH_TRANS()`. The name of this table is that of the table for which conflict resolution is to be applied, with the string $EX appended. (For example, if the name of the original table is `mytable`, the name of the corresponding exceptions table name should be `mytable$EX`.) The syntax for creating the exceptions table is as shown here:

```
CREATE TABLE original_table$EX  
  ([NDB$]server_id INT UNSIGNED, 
   [NDB$]source_server_id INT UNSIGNED, 
   [NDB$]source_epoch BIGINT UNSIGNED, 
   [NDB$]count INT UNSIGNED, 
   [NDB$OP_TYPE ENUM('WRITE_ROW','UPDATE_ROW', 'DELETE_ROW')
```
The first four columns are required. The names of the first four columns and the columns matching the original table's primary key columns are not critical; however, we suggest for reasons of clarity and consistency, that you use the names shown here for the server_id, source_server_id, source_epoch, and count columns, and that you use the same names as in the original table for the columns matching those in the original table's primary key.

If the exceptions table uses one or more of the optional columns NDB$OP_TYPE, NDB$CFT_CAUSE, or NDB$ORIG_TRANSID discussed later in this section, then each of the required columns must also be named using the prefix NDB$. If desired, you can use the NDB$ prefix to name the required columns even if you do not define any optional columns, but in this case, all four of the required columns must be named using the prefix.

Following these columns, the columns making up the original table's primary key should be copied in the order in which they are used to define the primary key of the original table. The data types for the columns duplicating the primary key columns of the original table should be the same as (or larger than) those of the original columns. A subset of the primary key columns may be used.

The exceptions table must use the NDB storage engine. (An example that uses NDB$OLD() with an exceptions table is shown later in this section.)

Additional columns may optionally be defined following the copied primary key columns, but not before any of them; any such extra columns cannot be NOT NULL. NDB Cluster supports three additional, predefined optional columns NDB$OP_TYPE, NDB$CFT_CAUSE, and NDB$ORIG_TRANSID, which are described in the next few paragraphs.

**NDB$OP_TYPE**: This column can be used to obtain the type of operation causing the conflict. If you use this column, define it as shown here:

```
NDB$OP_TYPE ENUM('WRITE_ROW', 'UPDATE_ROW', 'DELETE_ROW', 'REFRESH_ROW', 'READ_ROW') NOT NULL
```

The WRITE_ROW, UPDATE_ROW, and DELETE_ROW operation types represent user-initiated operations. REFRESH_ROW operations are operations generated by conflict resolution in compensating transactions sent back to the originating cluster from the cluster that detected the conflict. READ_ROW operations are user-initiated read tracking operations defined with exclusive row locks.

**NDB$CFT_CAUSE**: You can define an optional column NDB$CFT_CAUSE which provides the cause of the registered conflict. This column, if used, is defined as shown here:

```
NDB$CFT_CAUSE ENUM('ROW_DOES_NOT_EXIST', 'ROW_ALREADY_EXISTS', 'DATA_IN_CONFLICT', 'TRANS_IN_CONFLICT') NOT NULL
```

ROW_DOES_NOT_EXIST can be reported as the cause for UPDATE_ROW and WRITE_ROW operations; ROW_ALREADY_EXISTS can be reported for WRITE_ROW events. DATA_IN_CONFLICT is reported when...
NDB Cluster Replication Conflict Resolution

A row-based conflict function detects a conflict; `TRANS_IN_CONFLICT` is reported when a transactional conflict function rejects all of the operations belonging to a complete transaction.

**NDB$ORIG_TRANSID:** The `NDB$ORIG_TRANSID` column, if used, contains the ID of the originating transaction. This column should be defined as follows:

```
NDB$ORIG_TRANSID BIGINT UNSIGNED NOT NULL
```

`NDB$ORIG_TRANSID` is a 64-bit value generated by NDB. This value can be used to correlate multiple exceptions table entries belonging to the same conflicting transaction from the same or different exceptions tables.

Additional reference columns which are not part of the original table's primary key can be named `colname$OLD` or `colname$NEW`. `colname$OLD` references old values in update and delete operations—that is, operations containing `DELETE_ROW` events. `colname$NEW` can be used to reference new values in insert and update operations—in other words, operations using `WRITE_ROW` events, `UPDATE_ROW` events, or both types of events. Where a conflicting operation does not supply a value for a given reference column that is not a primary key, the exceptions table row contains either `NULL`, or a defined default value for that column.

**Important**
The `mysql.ndb_replication` table is read when a data table is set up for replication, so the row corresponding to a table to be replicated must be inserted into `mysql.ndb_replication` before the table to be replicated is created.

**Examples**

The following examples assume that you have already a working NDB Cluster replication setup, as described in Section 22.6.5, “Preparing the NDB Cluster for Replication”, and Section 22.6.6, “Starting NDB Cluster Replication (Single Replication Channel)”.

**NDB$MAX() example.** Suppose you wish to enable “greatest timestamp wins” conflict resolution on table `test.t1`, using column `mycol` as the “timestamp”. This can be done using the following steps:

1. Make sure that you have started the source `mysqld` with `--ndb-log-update-as-write=OFF`.
2. On the source, perform this `INSERT` statement:
   ```sql
   INSERT INTO mysql.ndb_replication
   VALUES ('test', 't1', 0, NULL, 'NDB$MAX(mycol)');
   ```

   Inserting a 0 into the `server_id` indicates that all SQL nodes accessing this table should use conflict resolution. If you want to use conflict resolution on a specific `mysqld` only, use the actual server ID.

   Inserting `NULL` into the `binlog_type` column has the same effect as inserting 0 (`NBT_DEFAULT`); the server default is used.

3. Create the `test.t1` table:
   ```sql
   CREATE TABLE test.t1 {
   mycol INT UNSIGNED,
   ) ENGINE=NDB;
   ```

   Now, when updates are performed on this table, conflict resolution is applied, and the version of the row having the greatest value for `mycol` is written to the replica.
Note

Other `binlog_type` options—such as `NBT_UPDATED_ONLY_USE_UPDATE` should be used to control logging on the source using the `ndb_replication` table rather than by using command-line options.

**NDB$OLD() example.** Suppose an NDB table such as the one defined here is being replicated, and you wish to enable “same timestamp wins” conflict resolution for updates to this table:

```sql
CREATE TABLE test.t2  (
  a INT UNSIGNED NOT NULL,
  b CHAR(25) NOT NULL,
  mycol INT UNSIGNED NOT NULL,
  PRIMARY KEY(pk (a, b))
) ENGINE=NDB;
```

The following steps are required, in the order shown:

1. First—and prior to creating `test.t2`—you must insert a row into the `mysql.ndb_replication` table, as shown here:

   ```sql
   INSERT INTO mysql.ndb_replication
   VALUES ('test', 't2', 0, NULL, 'NDB$OLD(mycol)');
   ```

   Possible values for the `binlog_type` column are shown earlier in this section. The value `''NDB$OLD(mycol)''` should be inserted into the `conflict_fn` column.

2. Create an appropriate exceptions table for `test.t2`. The table creation statement shown here includes all required columns; any additional columns must be declared following these columns, and before the definition of the table’s primary key.

   ```sql
   CREATE TABLE test.t2$EX  (
    server_id INT UNSIGNED,
    source_server_id INT UNSIGNED,
    source_epoch BIGINT UNSIGNED,
    count INT UNSIGNED,
    a INT UNSIGNED NOT NULL,
    b CHAR(25) NOT NULL,
    [additional_columns],
    PRIMARY KEY(server_id, source_server_id, source_epoch, count)
  ) ENGINE=NDB;
   ```

   We can include additional columns for information about the type, cause, and originating transaction ID for a given conflict. We are also not required to supply matching columns for all primary key columns in the original table. This means you can create the exceptions table like this:

   ```sql
   CREATE TABLE test.t2$EX  (
    NDB$server_id INT UNSIGNED,
    NDB$source_server_id INT UNSIGNED,
    NDB$source_epoch BIGINT UNSIGNED,
    NDB$count INT UNSIGNED,
    a INT UNSIGNED NOT NULL,
    NDB$OP_TYPE ENUM('WRITE_ROW','UPDATE_ROW', 'DELETE_ROW',
    'REFRESH_ROW', 'READ_ROW') NOT NULL,
    NDB$CFT_CAUSE ENUM('ROW_DOES_NOT_EXIST', 'ROW_ALREADY_EXISTS',
    'DATA_IN_CONFLICT', 'TRANS_IN_CONFLICT') NOT NULL,
    NDB$ORIG_TRANSID BIGINT UNSIGNED NOT NULL,
  ) ENGINE=NDB;
   ```
NDB Cluster Replication Conflict Resolution

```
[additional_columns,]

  PRIMARY KEY(NDB$server_id, NDB$source_server_id, NDB$source_epoch, NDB$count)
)
ENGINE=NDB;
```

**Note**

The `NDB$` prefix is required for the four required columns since we included at least one of the columns `NDB$OP_TYPE`, `NDB$CFT_CAUSE`, or `NDB$ORIG_TRANSID` in the table definition.

3. Create the table `test.t2` as shown previously.

These steps must be followed for every table for which you wish to perform conflict resolution using `NDB$OLD()`. For each such table, there must be a corresponding row in `mysql.ndb_replication`, and there must be an exceptions table in the same database as the table being replicated.

**Read conflict detection and resolution.** NDB Cluster also supports tracking of read operations, which makes it possible in circular replication setups to manage conflicts between reads of a given row in one cluster and updates or deletes of the same row in another. This example uses `employee` and `department` tables to model a scenario in which an employee is moved from one department to another on the source cluster (which we refer to hereafter as cluster `A`) while the replica cluster (hereafter `B`) updates the employee count of the employee’s former department in an interleaved transaction.

The data tables have been created using the following SQL statements:

```
# Employee table
CREATE TABLE employee (  
id INT PRIMARY KEY,  
  name VARCHAR(2000),  
  dept INT NOT NULL  
) ENGINE=NDB;

# Department table
CREATE TABLE department (  
id INT PRIMARY KEY,  
  name VARCHAR(2000),  
  members INT  
) ENGINE=NDB;
```

The contents of the two tables include the rows shown in the (partial) output of the following `SELECT` statements:

```
mysql> SELECT id, name, dept FROM employee;
+---------------+------+
| id   | name   | dept |
+------+--------+------+
| 998  | Mike   | 3    |
| 999  | Joe    | 3    |
| 1000 | Mary   | 3    |
+------+--------+------+

mysql> SELECT id, name, members FROM department;
+-----+-------------+---------+
| id  | name        | members |
+-----+-------------+---------+
| 3   | Old project | 24      |
+-----+-------------+---------+
```
NDB Cluster Replication Conflict Resolution

We assume that we are already using an exceptions table that includes the four required columns (and these are used for this table’s primary key), the optional columns for operation type and cause, and the original table’s primary key column, created using the SQL statement shown here:

```sql
CREATE TABLE employee$EX  (
  NDB$server_id INT UNSIGNED,
  NDB$source_server_id INT UNSIGNED,
  NDB$source_epoch BIGINT UNSIGNED,
  NDB$count INT UNSIGNED,
  NDB$OP_TYPE ENUM( 'WRITE_ROW','UPDATE_ROW', 'DELETE_ROW',
           'REFRESH_ROW','READ_ROW') NOT NULL,
  NDB$CFT_CAUSE ENUM( 'ROW_DOES_NOT_EXIST',
           'ROW_ALREADY_EXISTS',
           'DATA_IN_CONFLICT',
           'TRANS_IN_CONFLICT') NOT NULL,
  id INT NOT NULL,
  PRIMARY KEY(NDB$server_id, NDB$source_server_id, NDB$source_epoch, NDB$count)
) ENGINE=NDB;
```

Suppose there occur the two simultaneous transactions on the two clusters. On cluster A, we create a new department, then move employee number 999 into that department, using the following SQL statements:

```sql
BEGIN ;
  INSERT  INTO department VALUES (4, "New project", 1);
  UPDATE  employee SET dept = 4 WHERE id = 999;
COMMIT;
```

At the same time, on cluster B, another transaction reads from `employee`, as shown here:

```sql
BEGIN;
  SELECT name FROM employee WHERE id = 999;
  UPDATE department SET members = members - 1  WHERE id = 3;
COMMIT;
```

The conflicting transactions are not normally detected by the conflict resolution mechanism, since the conflict is between a read (`SELECT`) and an update operation. You can circumvent this issue by executing `SET ndb_log_exclusive_reads = 1` on the replica cluster. Acquiring exclusive read locks in this way causes any rows read on the source to be flagged as needing conflict resolution on the replica cluster. If we enable exclusive reads in this way prior to the logging of these transactions, the read on cluster B is tracked and sent to cluster A for resolution; the conflict on the employee row is subsequently detected and the transaction on cluster B is aborted.

The conflict is registered in the exceptions table (on cluster A) as a `READ_ROW` operation (see Conflict resolution exceptions table, for a description of operation types), as shown here:

```sql
mysql> SELECT id, NDB$OP_TYPE, NDB$CFT_CAUSE FROM employee$EX;
```

<table>
<thead>
<tr>
<th>id</th>
<th>NDB$OP_TYPE</th>
<th>NDB$CFT_CAUSE</th>
</tr>
</thead>
<tbody>
<tr>
<td>999</td>
<td>READ_ROW</td>
<td>TRANS_IN_CONFLICT</td>
</tr>
</tbody>
</table>

Any existing rows found in the read operation are flagged. This means that multiple rows resulting from the same conflict may be logged in the exception table, as shown by examining the effects a conflict between an update on cluster A and a read of multiple rows on cluster B from the same table in simultaneous transactions. The transaction executed on cluster A is shown here:
Concurrently a transaction containing the statements shown here runs on cluster B:

```sql
SET ndb_log_exclusive_reads = 1;  # Must be set if not already enabled
...
BEGIN;
    SELECT COUNT(*) INTO @count FROM employee WHERE dept = 3 FOR UPDATE;
    UPDATE department SET members = @count WHERE id = 3;
COMMIT;
```

In this case, all three rows matching the WHERE condition in the second transaction's SELECT are read, and are thus flagged in the exceptions table, as shown here:

```
mysql> SELECT id, NDB$OP_TYPE, NDB$CFT_CAUSE FROM employee$EX;
+-------+-------------+-------------------+
<table>
<thead>
<tr>
<th>id</th>
<th>NDB$OP_TYPE</th>
<th>NDB$CFT_CAUSE</th>
</tr>
</thead>
<tbody>
<tr>
<td>998</td>
<td>READ_ROW</td>
<td>TRANS_IN_CONFLICT</td>
</tr>
<tr>
<td>999</td>
<td>READ_ROW</td>
<td>TRANS_IN_CONFLICT</td>
</tr>
<tr>
<td>1000</td>
<td>READ_ROW</td>
<td>TRANS_IN_CONFLICT</td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

Read tracking is performed on the basis of existing rows only. A read based on a given condition track conflicts only of any rows that are found and not of any rows that are inserted in an interleaved transaction. This is similar to how exclusive row locking is performed in a single instance of NDB Cluster.

## 22.7 NDB Cluster Release Notes

Changes in NDB Cluster releases are documented separately from this reference manual; you can find release notes for the changes in each NDB Cluster 8.0 release at [NDB 8.0 Release Notes](#).

You can obtain release notes for older versions of NDB Cluster from [NDB Cluster Release Notes](#).

This chapter discusses user-defined partitioning.

Note
Table partitioning differs from partitioning as used by window functions. For information about window functions, see Section 12.21, "Window Functions".

In MySQL 8.0, partitioning support is provided by the InnoDB and NDB storage engines.

MySQL 8.0 does not currently support partitioning of tables using any storage engine other than InnoDB or NDB, such as MyISAM. An attempt to create a partitioned tables using a storage engine that does not supply native partitioning support fails with ER_CHECK_NOT_IMPLEMENTED.

MySQL 8.0 Community binaries provided by Oracle include partitioning support provided by the InnoDB and NDB storage engines. For information about partitioning support offered in MySQL Enterprise Edition binaries, see Chapter 29, MySQL Enterprise Edition.

If you are compiling MySQL 8.0 from source, configuring the build with InnoDB support is sufficient to produce binaries with partition support for InnoDB tables. For more information, see Section 2.9, "Installing MySQL from Source".

Nothing further needs to be done to enable partitioning support by InnoDB (for example, no special entries are required in the my.cnf file).

It is not possible to disable partitioning support by the InnoDB storage engine.

See Section 23.1, "Overview of Partitioning in MySQL", for an introduction to partitioning and partitioning concepts.
Overview of Partitioning in MySQL

Several types of partitioning are supported, as well as subpartitioning; see Section 23.2, “Partitioning Types”, and Section 23.2.6, “Subpartitioning”.

Section 23.3, “Partition Management”, covers methods of adding, removing, and altering partitions in existing partitioned tables.

Section 23.3.4, “Maintenance of Partitions”, discusses table maintenance commands for use with partitioned tables.

The PARTITIONS table in the INFORMATION_SCHEMA database provides information about partitions and partitioned tables. See Section 25.21, “The INFORMATION_SCHEMA PARTITIONS Table”, for more information; for some examples of queries against this table, see Section 23.2.7, “How MySQL Partitioning Handles NULL”.

For known issues with partitioning in MySQL 8.0, see Section 23.6, “Restrictions and Limitations on Partitioning”.

You may also find the following resources to be useful when working with partitioned tables.

**Additional Resources.** Other sources of information about user-defined partitioning in MySQL include the following:

- **MySQL Partitioning Forum**
  
  This is the official discussion forum for those interested in or experimenting with MySQL Partitioning technology. It features announcements and updates from MySQL developers and others. It is monitored by members of the Partitioning Development and Documentation Teams.

- **Mikael Ronström’s Blog**
  
  MySQL Partitioning Architect and Lead Developer Mikael Ronström frequently posts articles here concerning his work with MySQL Partitioning and NDB Cluster.

- **PlanetMySQL**
  
  A MySQL news site featuring MySQL-related blogs, which should be of interest to anyone using my MySQL. We encourage you to check here for links to blogs kept by those working with MySQL Partitioning, or to have your own blog added to those covered.

## 23.1 Overview of Partitioning in MySQL

This section provides a conceptual overview of partitioning in MySQL 8.0.

For information on partitioning restrictions and feature limitations, see Section 23.6, “Restrictions and Limitations on Partitioning”.

The SQL standard does not provide much in the way of guidance regarding the physical aspects of data storage. The SQL language itself is intended to work independently of any data structures or media underlying the schemas, tables, rows, or columns with which it works. Nonetheless, most advanced database management systems have evolved some means of determining the physical location to be used for storing specific pieces of data in terms of the file system, hardware or even both. In MySQL, the InnoDB storage engine has long supported the notion of a tablespace (see Section 15.6.3, “Tablespaces”), and the MySQL Server, even prior to the introduction of partitioning, could be configured to employ different physical directories for storing different databases (see Section 8.12.2, “Using Symbolic Links”, for an explanation of how this is done).

Partitioning takes this notion a step further, by enabling you to distribute portions of individual tables across a file system according to rules which you can set largely as needed. In effect, different portions of a table
are stored as separate tables in different locations. The user-selected rule by which the division of data is accomplished is known as a partitioning function, which in MySQL can be the modulus, simple matching against a set of ranges or value lists, an internal hashing function, or a linear hashing function. The function is selected according to the partitioning type specified by the user, and takes as its parameter the value of a user-supplied expression. This expression can be a column value, a function acting on one or more column values, or a set of one or more column values, depending on the type of partitioning that is used.

In the case of R**ANGE**, L**IST**, and [L**INEAR**] H**ASH** partitioning, the value of the partitioning column is passed to the partitioning function, which returns an integer value representing the number of the partition in which that particular record should be stored. This function must be nonconstant and nonrandom. It may not contain any queries, but may use an SQL expression that is valid in MySQL, as long as that expression returns either NULL or an integer intval such that

\[
-MAXVALUE <= intval <= MAXVALUE
\]

(MAXVALUE is used to represent the least upper bound for the type of integer in question. –MAXVALUE represents the greatest lower bound.)

For [L**INEAR**] K**EY**, R**ANGE COLUMNS**, and L**IST COLUMNS** partitioning, the partitioning expression consists of a list of one or more columns.

For [L**INEAR**] K**EY** partitioning, the partitioning function is supplied by MySQL.
