When \texttt{PRIVILEGE_CHECKS_USER} is set, setting \texttt{REQUIRE_TABLE_PRIMARY_KEY_CHECK} to \texttt{ON} or \texttt{OFF} means that the user account does not need session administration level privileges to set restricted session variables, which are required to change the value of \texttt{sql_require_primary_key} to match the source's setting for each transaction. For more information, see Section 17.3.3, “Replication Privilege Checks”.

\texttt{SOURCE_CONNECTION_AUTO_FAILOVER} = \{0|1\}

Activates the asynchronous connection failover mechanism for a replication channel if one or more alternative replication source servers are available (so when there are multiple MySQL servers or groups of servers that share the replicated data). \texttt{SOURCE_CONNECTION_AUTO_FAILOVER} is available as of MySQL 8.0.22. The default is 0, meaning that the mechanism is not activated. For full information and instructions to set up this feature, see Section 17.4.9.2, “Asynchronous Connection Failover for Replicas”.

The asynchronous connection failover mechanism takes over after the reconnection attempts controlled by \texttt{MASTER_CONNECT_RETRY} and \texttt{MASTER_RETRY_COUNT} are exhausted. It reconnects the replica to an alternative source chosen from a specified source list, which you manage using the \texttt{asynchronous_connection_failover_add_source} and \texttt{asynchronous_connection_failover_delete_source} functions. To add and remove managed groups of servers, use the \texttt{asynchronous_connection_failover_add_managed} and \texttt{asynchronous_connection_failover_delete_managed} functions instead. For more information, see Section 17.4.9, “Switching Sources and Replicas with Asynchronous Connection Failover”.

\textbf{Important}

1. You can only set \texttt{SOURCE_CONNECTION_AUTO_FAILOVER} = 1 when GTID auto-positioning is in use (\texttt{MASTER_AUTO_POSITION = 1}).

2. When you set \texttt{SOURCE_CONNECTION_AUTO_FAILOVER} = 1, set \texttt{MASTER_RETRY_COUNT} and \texttt{MASTER_CONNECT_RETRY} to minimal numbers that just allow a few retry attempts with the same source in a short time, in case the connection failure is caused by a transient network outage. Otherwise the asynchronous connection failover mechanism cannot be activated promptly. Suitable values are \texttt{MASTER_RETRY_COUNT=3} and \texttt{MASTER_CONNECT_RETRY=10}, which make
the replica retry the connection 3 times with 10-second intervals between.

3. When you set `SOURCE_CONNECTION_AUTO_FAILOVER = 1`, the replication metadata repositories must contain the credentials for a replication user account that can be used to connect to all the servers on the source list for the replication channel. These credentials can be set using the `CHANGE_REPLICATION_SOURCE_TO` statement with the `MASTER_USER` and `MASTER_PASSWORD` options. For more information, see Section 17.4.9, “Switching Sources and Replicas with Asynchronous Connection Failover”.

4. From MySQL 8.0.27, when you set `SOURCE_CONNECTION_AUTO_FAILOVER = 1`, asynchronous connection failover for replicas is automatically activated if this replication channel is on a Group Replication primary in a group in single-primary mode. With this function active, if the primary that is replicating goes offline or into an error state, the new primary starts replication on the same channel when it is elected. If you want to use the function, this replication channel must also be set up on all the secondary servers in the replication group, and on any new joining members. (If the servers are provisioned using MySQL’s clone functionality, this all happens automatically.) If you do not want to use the function, disable it by using the `group_replication_disable_member_action` function to disable the Group Replication member action `mysql_start_failover_channels_if_primary`, which is enabled by default. For more information, see Section 17.4.9.2, “Asynchronous Connection Failover for Replicas”.

Examples

`CHANGE MASTER TO` is useful for setting up a replica when you have the snapshot of the source and have recorded the source's binary log coordinates corresponding to the time of the snapshot. After loading the snapshot into the replica to synchronize it with the source, you can run `CHANGE MASTER TO MASTER_LOG_FILE='log_name', MASTER_LOG_POS=log_pos` on the replica to specify the coordinates at which the replica should begin reading the source's binary log. The following example changes the source server the replica uses and establishes the source's binary log coordinates from which the replica begins reading:

```
CHANGE MASTER TO
```
SQL Statements for Controlling Replica Servers

MASTER_HOST='source2.example.com',
MASTER_USER='replication',
MASTER_PASSWORD='password',
MASTER_PORT=3306,
MASTER_LOG_FILE='source2-bin.001',
MASTER_LOG_POS=4,
MASTER_CONNECT_RETRY=10;

For the procedure to switch an existing replica to a new source during failover, see Section 17.4.8, “Switching Sources During Failover”.

When GTIDs are in use on the source and the replica, specify GTID auto-positioning instead of giving the binary log file position, as in the following example. For full instructions to configure and start GTID-based replication on new or stopped servers, online servers, or additional replicas, see Section 17.1.3, “Replication with Global Transaction Identifiers”.

CHANGE MASTER TO
MASTER_HOST='source3.example.com',
MASTER_USER='replication',
MASTER_PASSWORD='password',
MASTER_PORT=3306,
MASTER_AUTO_POSITION = 1,
FOR CHANNEL "source_3";

In this example, multi-source replication is in use, and the CHANGE MASTER TO statement is applied to the replication channel "source_3" that connects the replica to the specified host. For guidance on setting up multi-source replication, see Section 17.1.5, “MySQL Multi-Source Replication”.

The next example shows how to make the replica apply transactions from relay log files that you want to repeat. To do this, the source need not be reachable. You can use CHANGE MASTER TO to locate the relay log position where you want the replica to start reapplying transactions, and then start the SQL thread:

CHANGE MASTER TO
RELAY_LOG_FILE='replica-relay-bin.006',
RELAY_LOG_POS=4025;
START SLAVE SQL_THREAD;

CHANGE MASTER TO can also be used to skip over transactions in the binary log that are causing replication to stop. The appropriate method to do this depends on whether GTIDs are in use or not. For instructions to skip transactions using CHANGE MASTER TO or another method, see Section 17.1.7.3, “Skipping Transactions”.

13.4.2.2 CHANGE REPLICATION FILTER Statement

CHANGE REPLICATION FILTER filter[, filter]
[,...] [FOR CHANNEL channel]

filter:
{
  REPPLICATE_DO_DB = (db_list)
  | REPPLICATE_IGNORE_DB = (db_list)
  | REPPLICATE_DO_TABLE = (tbl_list)
  | REPPLICATE_IGNORE_TABLE = (tbl_list)
  | REPPLICATE_WILD_DO_TABLE = (wild_tbl_list)
  | REPPLICATE_WILD_IGNORE_TABLE = (wild_tbl_list)
  | REPPLICATE_REWRITE_DB = (db_pair_list)
}

db_list:
  db_name[, db_name][, ...]

tbl_list:
  db_name.table_name[, db_name.table_name][, ...]

wild_tbl_list:
SQL Statements for Controlling Replica Servers

CHANGE REPLICATION FILTER sets one or more replication filtering rules on the replica in the same way as starting the replica `mysqld` with replication filtering options such as `--replicate-do-db` or `--replicate-wild-ignore-table`. Filters set using this statement differ from those set using the server options in two key respects:

1. The statement does not require restarting the server to take effect, only that the replication SQL thread be stopped using `STOP REPLICA SQL_THREAD` first (and restarted with `START REPLICA SQL_THREAD` afterwards).

2. The effects of the statement are not persistent; any filters set using `CHANGE REPLICATION FILTER` are lost following a restart of the replica `mysqld`.

`CHANGE REPLICATION FILTER` requires the `REPLICATION_SLAVE_ADMIN` privilege (or the deprecated `SUPER` privilege).

Use the `FOR CHANNEL channel` clause to make a replication filter specific to a replication channel, for example on a multi-source replica. Filters applied without a specific `FOR CHANNEL` clause are considered global filters, meaning that they are applied to all replication channels.

**Note**

Global replication filters cannot be set on a MySQL server instance that is configured for Group Replication, because filtering transactions on some servers would make the group unable to reach agreement on a consistent state. Channel specific replication filters can be set on replication channels that are not directly involved with Group Replication, such as where a group member also acts as a replica to a source that is outside the group. They cannot be set on the `group_replication_applier` or `group_replication_recovery` channels.

The following list shows the `CHANGE REPLICATION FILTER` options and how they relate to `--replicate-*` server options:

- **REPLICATE_DO_DB**: Include updates based on database name. Equivalent to `--replicate-do-db`.

- **REPLICATE_IGNORE_DB**: Exclude updates based on database name. Equivalent to `--replicate-ignore-db`.

- **REPLICATE_DO_TABLE**: Include updates based on table name. Equivalent to `--replicate-do-table`.

- **REPLICATE_IGNORE_TABLE**: Exclude updates based on table name. Equivalent to `--replicate-ignore-table`.

- **REPLICATE_WILD_DO_TABLE**: Include updates based on wildcard pattern matching table name. Equivalent to `--replicate-wild-do-table`.

- **REPLICATE_WILD_IGNORE_TABLE**: Exclude updates based on wildcard pattern matching table name. Equivalent to `--replicate-wild-ignore-table`.

- **REPLICATE_REWRITE_DB**: Perform updates on replica after substituting new name on replica for specified database on source. Equivalent to `--replicate-rewrite-db`. 

The precise effects of \texttt{REPLICATE\_DO\_DB} and \texttt{REPLICATE\_IGNORE\_DB} filters are dependent on whether statement-based or row-based replication is in effect. See Section 17.2.5, “How Servers Evaluate Replication Filtering Rules”, for more information.

Multiple replication filtering rules can be created in a single \texttt{CHANGE REPLICATION FILTER} statement by separating the rules with commas, as shown here:

\begin{verbatim}
CHANGE REPLICATION FILTER
  REPLICATE\_DO\_DB = (d1), REPLICATE\_IGNORE\_DB = (d2);
\end{verbatim}

Issuing the statement just shown is equivalent to starting the replica \texttt{mysqld} with the options \texttt{--replicate\_do\_db=d1 --replicate\_ignore\_db=d2}.

On a multi-source replica, which uses multiple replication channels to process transaction from different sources, use the \texttt{FOR CHANNEL} clause to set a replication filter on a replication channel:

\begin{verbatim}
CHANGE REPLICATION FILTER REPLICATE\_DO\_DB = (d1) FOR CHANNEL channel_1;
\end{verbatim}

This enables you to create a channel specific replication filter to filter out selected data from a source. When a \texttt{FOR CHANNEL} clause is provided, the replication filter statement acts on that replication channel, removing any existing replication filter which has the same filter type as the specified replication filters, and replacing them with the specified filter. Filter types not explicitly listed in the statement are not modified. If issued against a replication channel which is not configured, the statement fails with an \texttt{ER\_SLAVE\_CONFIGURATION} error. If issued against Group Replication channels, the statement fails with an \texttt{ER\_SLAVE\_CHANNEL\_OPERATION\_NOT\_ALLOWED} error.

On a replica with multiple replication channels configured, issuing \texttt{CHANGE REPLICATION FILTER} with no \texttt{FOR CHANNEL} clause configures the replication filter for every configured replication channel, and for the global replication filters. For every filter type, if the filter type is listed in the statement, then any existing filter rules of that type are replaced by the filter rules specified in the most recently issued statement, otherwise the old value of the filter type is retained. For more information see Section 17.2.5.4, “Replication Channel Based Filters”.

If the same filtering rule is specified multiple times, only the \texttt{last} such rule is actually used. For example, the two statements shown here have exactly the same effect, because the first \texttt{REPLICATE\_DO\_DB} rule in the first statement is ignored:

\begin{verbatim}
CHANGE REPLICATION FILTER
  REPLICATE\_DO\_DB = (db1, db2), REPLICATE\_DO\_DB = (db3, db4);

CHANGE REPLICATION FILTER
  REPLICATE\_DO\_DB = (db3, db4);
\end{verbatim}

\textbf{Caution}
\begin{quote}
This behavior differs from that of the \texttt{--replicate\_*} filter options where specifying the same option multiple times causes the creation of multiple filter rules.
\end{quote}

Names of tables and database not containing any special characters need not be quoted. Values used with \texttt{REPLICATION\_WILD\_TABLE} and \texttt{REPLICATION\_WILD\_IGNORE\_TABLE} are string expressions, possibly containing (special) wildcard characters, and so must be quoted. This is shown in the following example statements:

\begin{verbatim}
CHANGE REPLICATION FILTER
  REP\_WILD\_DO\_TABLE = ('db1.\_old\%',

CHANGE REPLICATION FILTER
  REP\_WILD\_IGNORE\_TABLE = ('db1.\_new\%', 'db2.\_new\%');
\end{verbatim}
Values used with `REPLICATE_REWRITE_DB` represent pairs of database names; each such value must be enclosed in parentheses. The following statement rewrites statements occurring on database `db1` on the source to database `db2` on the replica:

```
CHANGE REPLICATION FILTER REPLICATE_REWRITE_DB = ((db1, db2));
```

The statement just shown contains two sets of parentheses, one enclosing the pair of database names, and the other enclosing the entire list. This is perhaps more easily seen in the following example, which creates two `rewrite-db` rules, one rewriting database `dbA` to `dbB`, and one rewriting database `dbC` to `dbD`:

```
CHANGE REPLICATION FILTER
  REPLICATE_REWRITE_DB = ((dbA, dbB), (dbC, dbD));
```

The `CHANGE REPLICATION FILTER` statement replaces replication filtering rules only for the filter types and replication channels affected by the statement, and leaves other rules and channels unchanged. If you want to unset all filters of a given type, set the filter’s value to an explicitly empty list, as shown in this example, which removes all existing `REPLICATE_DO_DB` and `REPLICATE_IGNORE_DB` rules:

```
CHANGE REPLICATION FILTER
  REPLICATE_DO_DB = (), REPLICATE_IGNORE_DB = ();
```

Setting a filter to empty in this way removes all existing rules, does not create any new ones, and does not restore any rules set at `mysqld` startup using `--replicate-*` options on the command line or in the configuration file.

The `RESET REPLICA ALL` statement removes channel specific replication filters that were set on channels deleted by the statement. When the deleted channel or channels are recreated, any global replication filters specified for the replica are copied to them, and no channel specific replication filters are applied.

For more information, see Section 17.2.5, “How Servers Evaluate Replication Filtering Rules”.

### 13.4.2.3 CHANGE REPLICATION SOURCE TO Statement

```
CHANGE REPLICATION SOURCE TO option [, option] ... [ channel_option ]

option: {
  SOURCE_BIND = 'interface_name'
  | SOURCE_HOST = 'host_name'
  | SOURCE_USER = 'user_name'
  | SOURCE_PASSWORD = 'password'
  | SOURCE_PORT = port_num
  | PRIVILEGE_CHECKS_USER = {NULL | 'account'}
  | REQUIRE_ROW_FORMAT = {0|1}
  | REQUIRE_TABLE_PRIMARY_KEY_CHECK = {STREAM | ON | OFF | GENERATE}
  | ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS = {OFF | LOCAL | uuid}
  | SOURCE_LOG_FILE = 'source_log_name'
  | SOURCE_LOG_POS = source_log_pos
  | SOURCE_AUTO_POSITION = {0|1}
  | RELAY_LOG_FILE = 'relay_log_name'
  | RELAY_LOG_POS = relay_log_pos
  | SOURCE_HEARTBEAT_PERIOD = interval
  | SOURCE_CONNECT_RETRY = interval
  | SOURCE_RETRY_COUNT = count
  | SOURCE_CONNECTION_AUTO_FAILOVER = {0|1}
  | SOURCE_DELAY = interval
  | SOURCE_COMPRESSION_ALGORITHMS = 'algorithm[,algorithm][,algorithm]'`
```

CHANGE REPLICA TO changes the parameters that the replica server uses for connecting to the source and reading data from the source. It also updates the contents of the replication metadata repositories (see Section 17.2.4, “Relay Log and Replication Metadata Repositories”). In MySQL 8.0.23 and later, use CHANGE REPLICA TO in place of the deprecated CHANGE MASTER TO statement.

CHANGE REPLICA TO requires the REPLICATION_SLAVE_ADMIN privilege (or the deprecated SUPER privilege).

Options that you do not specify on a CHANGE REPLICA TO statement retain their value, except as indicated in the following discussion. In most cases, there is therefore no need to specify options that do not change.

Values used for SOURCE_HOST and other CHANGE REPLICA TO options are checked for linefeed (\n or 0x0A) characters. The presence of such characters in these values causes the statement to fail with an error.

The optional FOR CHANNEL channel clause lets you name which replication channel the statement applies to. Providing a FOR CHANNEL channel clause applies the CHANGE REPLICA TO statement to a specific replication channel, and is used to add a new channel or modify an existing channel. For example, to add a new channel called channel2:

```
CHANGE REPLICA TO SOURCE_HOST=host1, SOURCE_PORT=3002 FOR CHANNEL 'channel2';
```

If no clause is named and no extra channels exist, a CHANGE REPLICA TO statement applies to the default channel, whose name is the empty string (""). When you have set up multiple replication channels, every CHANGE REPLICA TO statement must name a channel using the FOR CHANNEL channel clause. See Section 17.2.2, “Replication Channels” for more information.

For some of the options of the CHANGE REPLICA TO statement, you must issue a STOP REPLICA statement prior to issuing a CHANGE REPLICA TO statement (and a START REPLICA statement afterwards). Sometimes, you only need to stop the replication SQL (applier) thread or the replication I/O (receiver) thread, not both:

- When the applier thread is stopped, you can execute CHANGE REPLICA TO using any combination that is otherwise allowed of RELAY_LOG_FILE, RELAY_LOG_POS, and SOURCE_DELAY options, even if the replication receiver thread is running. No other options may be used with this statement when the receiver thread is running.

- When the receiver thread is stopped, you can execute CHANGE REPLICA TO using any of the options for this statement (in any allowed combination) except RELAY_LOG_FILE,
RELAY_LOG_POS, SOURCE_DELAY, or SOURCE_AUTO_POSITION = 1 even when the applier thread is running.

- Both the receiver thread and the applier thread must be stopped before issuing a CHANGE REPLICATION SOURCE TO statement that employs SOURCE_AUTO_POSITION = 1, GTID_ONLY = 1, or ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS.

You can check the current state of the replication applier thread and replication receiver thread using SHOW REPLICA STATUS. Note that the Group Replication applier channel (group_replication_applier) has no receiver thread, only an applier thread.

CHANGE REPLICATION SOURCE TO statements have a number of side-effects and interactions that you should be aware of beforehand:

- CHANGE REPLICATION SOURCE TO causes an implicit commit of an ongoing transaction. See Section 13.3.3, “Statements That Cause an Implicit Commit”.

- CHANGE REPLICATION SOURCE TO causes the previous values for SOURCE_HOST, SOURCE_PORT, SOURCE_LOG_FILE, and SOURCE_LOG_POS to be written to the error log, along with other information about the replica's state prior to execution.

- If you are using statement-based replication and temporary tables, it is possible for a CHANGE REPLICATION SOURCE TO statement following a STOP REPLICA statement to leave behind temporary tables on the replica. A warning (ER_WARN_OPEN_TEMP_TABLES_MUST_BE_ZERO) is issued whenever this occurs. You can avoid this in such cases by making sure that the value of the Replica_open_temp_tables or Slave_open_temp_tables system status variable is equal to 0 prior to executing such a CHANGE REPLICATION SOURCE TO statement.

- When using a multithreaded replica (replica_parallel_workers > 0), stopping the replica can cause gaps in the sequence of transactions that have been executed from the relay log, regardless of whether the replica was stopped intentionally or otherwise. When such gaps exist, issuing CHANGE REPLICATION SOURCE TO fails. The solution in this situation is to issue START REPLICA UNTIL SQL_AFTER_MTS_GAPS which ensures that the gaps are closed. From MySQL 8.0.26, the process of checking for gaps in the sequence of transactions is skipped entirely when GTID-based replication and GTID auto-positioning are in use, because gaps in transactions can be resolved using GTID auto-positioning. In that situation, CHANGE REPLICATION SOURCE TO can still be used.

The following options are available for CHANGE REPLICATION SOURCE TO statements:

ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS = {OFF | LOCAL | uuid}

Makes the replication channel assign a GTID to replicated transactions that do not have one, enabling replication from a source that does not use GTID-based replication, to a replica that does. For a multi-source replica, you can have a mix of channels that use ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS, and channels that do not. The default is OFF, meaning that the feature is not used.

LOCAL assigns a GTID including the replica's own UUID (the server_uuid setting). uuid assigns a GTID including the specified UUID, such as the server_uuid setting for the replication source server. Using a nonlocal UUID lets you differentiate between transactions that originated on the replica and transactions that originated on the source, and for a multi-source replica, between transactions that originated on different sources. The UUID you choose only has significance for the replica's own use. If any of the transactions sent by the source do have a GTID already, that GTID is retained.
Channels specific to Group Replication cannot use `ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS`, but an asynchronous replication channel for another source on a server instance that is a Group Replication group member can do so. In that case, do not specify the Group Replication group name as the UUID for creating the GTIDs.

To set `ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS` to `LOCAL` or `uuid`, the replica must have `gtid_mode=ON` set, and this cannot be changed afterwards. This option is for use with a source that has binary log file position based replication, so `SOURCE_AUTO_POSITION=1` cannot be set for the channel. Both the replication SQL thread and the replication I/O (receiver) thread must be stopped before setting this option.

**Important**

A replica set up with `ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS` on any channel cannot be promoted to replace the replication source server in the event that a failover is required, and a backup taken from the replica cannot be used to restore the replication source server. The same restriction applies to replacing or restoring other replicas that use `ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS` on any channel.

For further restrictions and information, see Section 17.1.3.6, “Replication From a Source Without GTIDs to a Replica With GTIDs”.

**GET_SOURCE_PUBLIC_KEY = {0|1}**  
Enables RSA key pair-based password exchange by requesting the public key from the source. The option is disabled by default.

This option applies to replicas that authenticate with the `caching_sha2_password` authentication plugin. For connections by accounts that authenticate using this plugin, the source does not send the public key unless requested, so it must be requested or specified in the client. If `SOURCE_PUBLIC_KEY_PATH` is given and specifies a valid public key file, it takes precedence over `GET_SOURCE_PUBLIC_KEY`. If you are using a replication user account that authenticates with the `caching_sha2_password` plugin (which is the default from MySQL 8.0), and you are not using a secure connection, you must specify either this option or the `SOURCE_PUBLIC_KEY_PATH` option to provide the RSA public key to the replica.

**GTID_ONLY = {0|1}**  
Stops the replication channel persisting file names and file positions in the replication metadata repositories. `GTID_ONLY` is available as of MySQL 8.0.27. The `GTID_ONLY` option is disabled by default for asynchronous replication channels, but it is enabled by default for Group Replication channels, and it cannot be disabled for them.

For replication channels with this setting, in-memory file positions are still tracked, and file positions can still be observed for debugging.
purposes in error messages and through interfaces such as `SHOW REPLICA STATUS` statements (where they are shown as being invalid if they are out of date). However, the writes and reads required to persist and check the file positions are avoided in situations where GTID-based replication does not actually require them, including the transaction queuing and application process.

This option can be used only if both the replication SQL (applier) thread and replication I/O (receiver) thread are stopped. To set `GTID_ONLY = 1` for a replication channel, GTIDs must be in use on the server (`gtid_mode = ON`), and row-based binary logging must be in use on the source (statement-based replication is not supported). The options `REQUIRE_ROW_FORMAT = 1` and `SOURCE_AUTO_POSITION = 1` must be set for the replication channel.

When `GTID_ONLY = 1` is set, the replica uses `replica_parallel_workers=1` if that system variable is set to zero for the server, so it is always technically a multi-threaded applier. This is because a multi-threaded applier uses saved positions rather than the replication metadata repositories to locate the start of a transaction that it needs to reapply.

If you disable `GTID_ONLY` after setting it, the existing relay logs are deleted and the existing known binary log file positions are persisted, even if they are stale. The file positions for the binary log and relay log in the replication metadata repositories might be invalid, and a warning is returned if this is the case. Provided that `SOURCE_AUTO_POSITION` is still enabled, GTID auto-positioning is used to provide the correct positioning.

If you also disable `SOURCE_AUTO_POSITION`, the file positions for the binary log and relay log in the replication metadata repositories are used for positioning if they are valid. If they are marked as invalid, you must provide a valid binary log file name and position (`SOURCE_LOG_FILE` and `SOURCE_LOG_POS`). If you also provide a relay log file name and position (`RELAY_LOG_FILE` and `RELAY_LOG_POS`), the relay logs are preserved and the applier position is set to the stated position. GTID auto-skip ensures that any transactions already applied are skipped even if the eventual applier position is not correct.

Makes the replica ignore events originating from the specified servers. The option takes a comma-separated list of 0 or more server IDs. Log rotation and deletion events from the servers are not ignored, and are recorded in the relay log.

In circular replication, the originating server normally acts as the terminator of its own events, so that they are not applied more than once. Thus, this option is useful in circular replication when one of the servers in the circle is removed. Suppose that you have a circular replication setup with 4 servers, having server IDs 1, 2, 3, and 4, and server 3 fails. When bridging the gap by starting replication from server 2 to server 4, you can include `IGNORE_SERVER_IDS = (3)` in the `CHANGE REPLICATION SOURCE TO` statement that you issue on server 4 to tell it to use server 2 as its source instead of server 3.
SQL Statements for Controlling Replica Servers

Doing so causes it to ignore and not to propagate any statements that originated with the server that is no longer in use.

If `IGNORE_SERVER_IDS` contains the server's own ID and the server was started with the `--replicate-same-server-id` option enabled, an error results.

**Note**
When global transaction identifiers (GTIDs) are used for replication, transactions that have already been applied are automatically ignored, so the `IGNORE_SERVER_IDS` function is not required and is deprecated. If `gtid_mode=ON` is set for the server, a deprecation warning is issued if you include the `IGNORE_SERVER_IDS` option in a `CHANGE REPLICATION SOURCE TO` statement.

The source metadata repository and the output of `SHOW REPLICA STATUS` provide the list of servers that are currently ignored. For more information, see Section 17.2.4.2, "Replication Metadata Repositories", and Section 13.7.7.35, "SHOW REPLICA STATUS Statement".

If a `CHANGE REPLICATION SOURCE TO` statement is issued without any `IGNORE_SERVER_IDS` option, any existing list is preserved. To clear the list of ignored servers, it is necessary to use the option with an empty list:

```
CHANGE REPLICATION SOURCE TO IGNORE_SERVER_IDS = ();
```

`RESET REPLICA ALL` clears `IGNORE_SERVER_IDS`.

**Note**
A deprecation warning is issued if `SET GTID_MODE=ON` is issued when any channel has existing server IDs set with `IGNORE_SERVER_IDS`. Before starting GTID-based replication, check for and clear all ignored server ID lists on the servers involved. The `SHOW REPLICA STATUS` statement displays the list of ignored IDs, if there is one. If you do receive the deprecation warning, you can still clear a list after `gtid_mode=ON` is set by issuing a `CHANGE REPLICATION SOURCE TO` statement containing the `IGNORE_SERVER_IDS` option with an empty list.

```
NETWORK_NAMESPACE = 'namespace'
```

The network namespace to use for TCP/IP connections to the replication source server or, if the MySQL communication stack is in use, for Group Replication’s group communication connections. The maximum length of the string value is 64 characters. If this option is omitted, connections from the replica use the default (global) namespace. On platforms that do not implement network namespace support, failure occurs when the replica attempts to connect to the
**PRIVILEGE_CHECKS_USER = {NULL | 'account'}**

Names a user account that supplies a security context for the specified channel. **NULL**, which is the default, means no security context is used. **PRIVILEGE_CHECKS_USER** is available as of MySQL 8.0.18.

The user name and host name for the user account must follow the syntax described in Section 6.2.4, “Specifying Account Names”, and the user must not be an anonymous user (with a blank user name) or the **CURRENT_USER**. The account must have the **REPLICATION_APPLIER** privilege, plus the required privileges to execute the transactions replicated on the channel. For details of the privileges required by the account, see Section 17.3.3, “Replication Privilege Checks”. When you restart the replication channel, the privilege checks are applied from that point on. If you do not specify a channel and no other channels exist, the statement is applied to the default channel.

The use of row-based binary logging is strongly recommended when **PRIVILEGE_CHECKS_USER** is set, and you can set **REQUIRE_ROW_FORMAT** to enforce this. For example, to start privilege checks on the channel **channel_1** on a running replica, issue the following statements:

```
STOP REPLICA FOR CHANNEL 'channel_1';

CHANGE REPLICATION SOURCE TO
    PRIVILEGE_CHECKS_USER = 'user'@'host',
    REQUIRE_ROW_FORMAT = 1,
    FOR CHANNEL 'channel_1';

START REPLICA FOR CHANNEL 'channel_1';
```

**RELAY_LOG_FILE = 'relay_log_file', RELAY_LOG_POS = 'relay_log_pos'**

The relay log file name, and the location in that file, at which the replication SQL thread begins reading from the replica’s relay log the next time the thread starts. **RELAY_LOG_FILE** can use either an absolute or relative path, and uses the same base name as **SOURCE_LOG_FILE**. The maximum length of the string value is 511 characters.

A **CHANGE REPLICATION SOURCE TO** statement using **RELAY_LOG_FILE**, **RELAY_LOG_POS**, or both options can be executed on a running replica when the replication SQL (applier) thread is stopped. Relay logs are preserved if at least one of the replication applier thread and the replication I/O (receiver) thread is running. If both threads are stopped, all relay log files are deleted unless at least one of **RELAY_LOG_FILE** or **RELAY_LOG_POS** is specified. For the Group Replication applier channel (**group_replication_applier**), which only has an applier thread and no receiver thread, this is the case if the applier thread is stopped, but with that channel you cannot use the **RELAY_LOG_FILE** and **RELAY_LOG_POS** options.

**REQUIRE_ROW_FORMAT = {0 | 1}**

Permits only row-based replication events to be processed by the replication channel. This option prevents the replication applier from taking actions such as creating temporary tables and executing **LOAD DATA INFILE** requests, which increases the security of the...
channel. The `REQUIRE_ROW_FORMAT` option is disabled by default for asynchronous replication channels, but it is enabled by default for Group Replication channels, and it cannot be disabled for them. For more information, see Section 17.3.3, “Replication Privilege Checks”. `REQUIRE_ROW_FORMAT` is available as of MySQL 8.0.19.

`REQUIRE_TABLE_PRIMARY_KEY_CHECK = {STREAM | ON | OFF | GENERATE}`

As of MySQL 8.0.20, this option lets a replica set its own policy for primary key checks, as follows:

- **ON**: The replica sets `sql_require_primary_key = ON`; any replicated `CREATE TABLE` or `ALTER TABLE` statement must result in a table that contains a primary key.

- **OFF**: The replica sets `sql_require_primary_key = OFF`; no replicated `CREATE TABLE` or `ALTER TABLE` statement is checked for the presence of a primary key.

- **STREAM**: The replica uses whatever value of `sql_require_primary_key` is replicated from the source for each transaction. This is the default value, and the default behavior.

- **GENERATE**: Added in MySQL 8.0.32, this causes the replica to generate an invisible primary key for any InnoDB table that, as replicated, lacks a primary key. See Section 13.1.20.11, “Generated Invisible Primary Keys”, for more information.

`GENERATE` is not compatible with Group Replication; you can use **ON**, **OFF**, or **STREAM**.

A divergence based on the presence of a generated invisible primary key solely on a source or replica table is supported by MySQL Replication as long as the source supports GIPKs (MySQL 8.0.30 and later) and the replica uses MySQL version 8.0.32 or later. If you use GIPKs on a replica and replicate from a source using MySQL 8.0.29 or earlier, you should be aware that in this case such divergences in schema, other than the extra GIPK on the replica, are not supported and may result in replication errors.

For multisource replication, setting `REQUIRE_TABLE_PRIMARY_KEY_CHECK` to **ON** or **OFF** lets the replica normalize behavior across replication channels for different sources, and to keep a consistent setting for `sql_require_primary_key`. Using **ON** safeguards against the accidental loss of primary keys when multiple sources update the same set of tables. Using **OFF** lets sources that can manipulate primary keys to work alongside sources that cannot.

In the case of multiple replicas, when `REQUIRE_TABLE_PRIMARY_KEY_CHECK` is set to **GENERATE**, the generated invisible primary key added by a given replica is independent of any such key added on any other replica. This means that, if generated invisible primary keys are in use, the values in the generated
primary key columns on different replicas are not guaranteed to be the same. This may be an issue when failing over to such a replica.

When `PRIVILEGE_CHECKS_USER` is `NULL` (the default), the user account does not need administration level privileges to set restricted session variables. Setting this option to a value other than `NULL` means that, when `REQUIRE_TABLE_PRIMARY_KEY_CHECK` is `ON` or `OFF`, the user account does not require session administration level privileges to set restricted session variables such as `sql_require_primary_key`, avoiding the need to grant the account such privileges. (Such privileges are required when `PRIVILEGE_CHECKS_USER` is `STREAM` or `GENERATE`.) For more information, see Section 17.3.3, “Replication Privilege Checks”.

`SOURCE_AUTO_POSITION = {0|1}`

Makes the replica attempt to connect to the source using the auto-positioning feature of GTID-based replication, rather than a binary log file based position. This option is used to start a replica using GTID-based replication. The default is 0, meaning that GTID auto-positioning and GTID-based replication are not used. This option can be used with `CHANGE_REPLICATION_SOURCE_TO` only if both the replication SQL (applier) thread and replication I/O (receiver) thread are stopped.

Both the replica and the source must have GTIDs enabled (`GTID_MODE=ON`, `ON_PERMISSIVE`, or `OFF_PERMISSIVE` on the replica, and `GTID_MODE=ON` on the source). `SOURCE_LOG_FILE`, `SOURCE_LOG_POS`, `RELAY_LOG_FILE`, and `RELAY_LOG_POS` cannot be specified together with `SOURCE_AUTO_POSITION = 1`. If multi-source replication is enabled on the replica, you need to set the `SOURCE_AUTO_POSITION = 1` option for each applicable replication channel.

With `SOURCE_AUTO_POSITION = 1` set, in the initial connection handshake, the replica sends a GTID set containing the transactions that it has already received, committed, or both. The source responds by sending all transactions recorded in its binary log whose GTID is not included in the GTID set sent by the replica. This exchange ensures that the source only sends the transactions with a GTID that the replica has not already recorded or committed. If the replica receives transactions from more than one source, as in the case of a diamond topology, the auto-skip function ensures that the transactions are not applied twice. For details of how the GTID set sent by the replica is computed, see Section 17.1.3.3, “GTID Auto-Positioning”.

If any of the transactions that should be sent by the source have been purged from the source’s binary log, or added to the set of GTIDs in the `gtid_purged` system variable by another method, the source sends the error `ER_MASTER_HAS_PURGED_REQUIRED_GTIDS` to the replica, and replication does not start. The GTIDs of the missing purged transactions are identified and listed in the source’s error log in the warning message `ER_FOUND_MISSING_GTIDS`. Also, if during the exchange of transactions it is found that the replica has recorded or committed transactions with the source’s UUID in the GTID, but the source itself has not committed them, the source sends the error `ER_SLAVE_HAS_MORE_GTIDS_THAN_MASTER` to the replica and
replication does not start. For information on how to handle these situations, see Section 17.1.3.3, “GTID Auto-Positioning”.

You can see whether replication is running with GTID auto-positioning enabled by checking the Performance Schema replication_connection_status table or the output of SHOW REPLICA STATUS. Disabling the SOURCE_AUTO_POSITION option again makes the replica revert to file-based replication.

Determines which of the replica's network interfaces is chosen for connecting to the source, for use on replicas that have multiple network interfaces. Specify the IP address of the network interface. The maximum length of the string value is 255 characters.

The IP address configured with this option, if any, can be seen in the Source_Bind column of the output from SHOW REPLICA STATUS. In the source metadata repository table mysql.slave_master_info, the value can be seen as the Source_bind column. The ability to bind a replica to a specific network interface is also supported by NDB Cluster.

Specifies one, two, or three of the permitted compression algorithms for connections to the replication source server, separated by commas. The maximum length of the string value is 99 characters. The default value is uncompressed.

The available algorithms are zlib, zstd, and uncompressed, the same as for the protocol_compression_algorithms system variable. The algorithms can be specified in any order, but it is not an order of preference - the algorithm negotiation process attempts to use zlib, then zstd, then uncompressed, if they are specified. SOURCE_COMPRESSION_ALGORITHMS is available as of MySQL 8.0.18.

The value of SOURCE_COMPRESSION_ALGORITHMS applies only if the replica_compressed_protocol or slave_compressed_protocol system variable is disabled. If replica_compressed_protocol or slave_compressed_protocol is enabled, it takes precedence over SOURCE_COMPRESSION_ALGORITHMS and connections to the source use zlib compression if both source and replica support that algorithm. For more information, see Section 4.2.8, “Connection Compression Control”.

Binary log transaction compression (available as of MySQL 8.0.20), which is activated by the binlog_transaction_compression system variable, can also be used to save bandwidth. If you do this in combination with connection compression, connection compression has less opportunity to act on the data, but can still compress headers and those events and transaction payloads that are uncompressed. For more information on binary log transaction compression, see Section 5.4.4.5, “Binary Log Transaction Compression”.

SOURCE_BIND = 'interface_name'

SOURCE_COMPRESSION_ALGORITHMS = 'algorithm[,algorithm][,algorithm]'
SOURCE_CONNECT_RETRY = interval

Specifies the interval in seconds between the reconnection attempts that the replica makes after the connection to the source times out. The default interval is 60.

The number of attempts is limited by the SOURCE_RETRY_COUNT option. If both the default settings are used, the replica waits 60 seconds between reconnection attempts (SOURCE_CONNECT_RETRY=60), and keeps attempting to reconnect at this rate for 60 days (SOURCE_RETRY_COUNT=86400). These values are recorded in the source metadata repository and shown in the replication_connection_configuration Performance Schema table.

SOURCE_CONNECTION_AUTO_FAILOVER = {0|1}

Activates the asynchronous connection failover mechanism for a replication channel if one or more alternative replication source servers are available (so when there are multiple MySQL servers or groups of servers that share the replicated data). SOURCE_CONNECTION_AUTO_FAILOVER is available as of MySQL 8.0.22. The default is 0, meaning that the mechanism is not activated. For full information and instructions to set up this feature, see Section 17.4.9.2, “Asynchronous Connection Failover for Replicas”.

The asynchronous connection failover mechanism takes over after the reconnection attempts controlled by SOURCE_CONNECT_RETRY and SOURCE_RETRY_COUNT are exhausted. It reconnects the replica to an alternative source chosen from a specified source list, which you manage using the asynchronous_connection_failover_add_source and asynchronous_connection_failover_delete_source functions. To add and remove managed groups of servers, use the asynchronous_connection_failover_add_managed and asynchronous_connection_failover_delete_managed functions instead. For more information, see Section 17.4.9, “Switching Sources and Replicas with Asynchronous Connection Failover”.

Important

1. You can only set
   SOURCE_CONNECTION_AUTO_FAILOVER = 1 when GTID auto-positioning is in use (SOURCE_AUTO_POSITION = 1).

2. When you set
   SOURCE_CONNECTION_AUTO_FAILOVER = 1, set SOURCE_RETRY_COUNT and SOURCE_CONNECT_RETRY to minimal numbers that just allow a few retry attempts with the same source, in case the connection failure is caused by a transient network outage. Otherwise the asynchronous connection failover mechanism cannot be activated promptly. Suitable values are SOURCE_RETRY_COUNT=3 and SOURCE_CONNECT_RETRY=10, which make
the replica retry the connection 3 times with 10-second intervals between.

3. When you set
SOURCE_CONNECTION_AUTO_FAILOVER = 1, the replication metadata repositories must contain the credentials for a replication user account that can be used to connect to all the servers on the source list for the replication channel. The account must also have SELECT permissions on the Performance Schema tables. These credentials can be set using the CHANGE REPLICATION SOURCE TO statement with the SOURCE_USER and SOURCE_PASSWORD options. For more information, see Section 17.4.9, “Switching Sources and Replicas with Asynchronous Connection Failover”.

4. From MySQL 8.0.27, when you set
SOURCE_CONNECTION_AUTO_FAILOVER = 1, asynchronous connection failover for replicas is automatically activated if this replication channel is on a Group Replication primary in a group in single-primary mode. With this function active, if the primary that is replicating goes offline or into an error state, the new primary starts replication on the same channel when it is elected. If you want to use the function, this replication channel must also be set up on all the secondary servers in the replication group, and on any new joining members. (If the servers are provisioned using MySQL’s clone functionality, this all happens automatically.) If you do not want to use the function, disable it by using the group_replication_disable_member_action function to disable the Group Replication member action mysql_start_failover_channels_if_primary, which is enabled by default. For more information, see Section 17.4.9.2, “Asynchronous Connection Failover for Replicas”.

SOURCE_DELAY = interval Specifies how many seconds behind the source the replica must lag. An event received from the source is not executed until at least interval seconds later than its execution on the source. interval must be a
nonnegative integer in the range from 0 to \(2^{31} - 1\). The default is 0. For more information, see Section 17.4.11, “Delayed Replication”.

A `CHANGE REPLICATION SOURCE TO` statement using the `SOURCE_DELAY` option can be executed on a running replica when the replication SQL thread is stopped.

`SOURCE_HEARTBEAT_PERIOD = interval`

Controls the heartbeat interval, which stops the connection timeout occurring in the absence of data if the connection is still good. A heartbeat signal is sent to the replica after that number of seconds, and the waiting period is reset whenever the source's binary log is updated with an event. Heartbeats are therefore sent by the source only if there are no unsent events in the binary log file for a period longer than this.

The heartbeat interval `interval` is a decimal value having the range 0 to 4294967 seconds and a resolution in milliseconds; the smallest nonzero value is 0.001. Setting `interval` to 0 disables heartbeats altogether. The heartbeat interval defaults to half the value of the `replica_net_timeout` or `slave_net_timeout` system variable. It is recorded in the source metadata repository and shown in the `replication_connection_configuration` Performance Schema table.

The system variable `replica_net_timeout` (from MySQL 8.0.26) or `slave_net_timeout` (before MySQL 8.0.26) specifies the number of seconds that the replica waits for either more data or a heartbeat signal from the source, before the replica considers the connection broken, aborts the read, and tries to reconnect. The default value is 60 seconds (one minute). Note that a change to the value or default setting of `replica_net_timeout` or `slave_net_timeout` does not automatically change the heartbeat interval, whether that has been set explicitly or is using a previously calculated default. A warning is issued if you set the global value of `replica_net_timeout` or `slave_net_timeout` to a value less than that of the current heartbeat interval. If `replica_net_timeout` or `slave_net_timeout` is changed, you must also issue `CHANGE REPLICATION SOURCE TO` to adjust the heartbeat interval to an appropriate value so that the heartbeat signal occurs before the connection timeout. If you do not do this, the heartbeat signal has no effect, and if no data is received from the source, the replica can make repeated reconnection attempts, creating zombie dump threads.

`SOURCE_HOST = 'host_name'`

The host name or IP address of the replication source server. The replica uses this to connect to the source. The maximum length of the string value is 255 characters.

If you specify `SOURCE_HOST` or `SOURCE_PORT`, the replica assumes that the source server is different from before (even if the option value is the same as its current value.) In this case, the old values for the source's binary log file name and position are considered no longer applicable, so if you do not specify `SOURCE_LOG_FILE` and
SOURCE_LOG_FILE = 'source_log_name',
SOURCE_LOG_POS = source_log_pos

SOURCE_LOG_FILE in the statement, SOURCE_LOG_FILE='' and SOURCE_LOG_POS=4 are silently appended to it.

Setting SOURCE_HOST='' (that is, setting its value explicitly to an empty string) is not the same as not setting SOURCE_HOST at all. Trying to set SOURCE_HOST to an empty string fails with an error.

The binary log file name, and the location in that file, at which the replication I/O (receiver) thread begins reading from the source's binary log the next time the thread starts. Specify these options if you are using binary log file position based replication.

SOURCE_LOG_FILE must include the numeric suffix of a specific binary log file that is available on the source server, for example, SOURCE_LOG_FILE='binlog.000145'. The maximum length of the string value is 511 characters.

SOURCE_LOG_POS is the numeric position for the replica to start reading in that file. SOURCE_LOG_POS=4 represents the start of the events in a binary log file.

If you specify either of SOURCE_LOG_FILE or SOURCE_LOG_POS, you cannot specify SOURCE_AUTO_POSITION = 1, which is for GTID-based replication.

If neither of SOURCE_LOG_FILE or SOURCE_LOG_POS is specified, the replica uses the last coordinates of the replication SQL thread before CHANGE_REPLICATION SOURCE TO was issued. This ensures that there is no discontinuity in replication, even if the replication SQL (applier) thread was late compared to the replication I/O (receiver) thread.

SOURCE_PASSWORD = 'password'

The password for the replication user account to use for connecting to the replication source server. The maximum length of the string value is 32 characters. If you specify SOURCE_PASSWORD, SOURCE_USER is also required.

The password used for a replication user account in a CHANGE_REPLICATION SOURCE TO statement is limited to 32 characters in length. Trying to use a password of more than 32 characters causes CHANGE_REPLICATION SOURCE TO to fail.

The password is masked in MySQL Server's logs, Performance Schema tables, and SHOW_PROCESSLIST statements.

SOURCE_PORT = port_num

The TCP/IP port number that the replica uses to connect to the replication source server.

Note

Replication cannot use Unix socket files. You must be able to connect to the replication source server using TCP/IP.

If you specify SOURCE_HOST or SOURCE_PORT, the replica assumes that the source server is different from before (even if the option
value is the same as its current value.) In this case, the old values for the source's binary log file name and position are considered no longer applicable, so if you do not specify `SOURCE_LOG_FILE` and `SOURCE_LOG_POS` in the statement, `SOURCE_LOG_FILE=''` and `SOURCE_LOG_POS=4` are silently appended to it.

`SOURCE_PUBLIC_KEY_PATH = 'key_file_name'` Enables RSA key pair-based password exchange by providing the path name to a file containing a replica-side copy of the public key required by the source. The file must be in PEM format. The maximum length of the string value is 511 characters.

This option applies to replicas that authenticate with the `sha256_password` or `caching_sha2_password` authentication plugin. (For `sha256_password`, `SOURCE_PUBLIC_KEY_PATH` can be used only if MySQL was built using OpenSSL.) If you are using a replication user account that authenticates with the `caching_sha2_password` plugin (which is the default from MySQL 8.0), and you are not using a secure connection, you must specify either this option or the `GET_SOURCE_PUBLIC_KEY=1` option to provide the RSA public key to the replica.

`SOURCE_RETRY_COUNT = count` Sets the maximum number of reconnection attempts that the replica makes after the connection to the source times out, as determined by the `replica_net_timeout` or `slave_net_timeout` system variable. If the replica does need to reconnect, the first retry occurs immediately after the timeout. The default is 86400 attempts.

The interval between the attempts is specified by the `SOURCE_CONNECT_RETRY` option. If both the default settings are used, the replica waits 60 seconds between reconnection attempts (`SOURCE_CONNECT_RETRY=60`), and keeps attempting to reconnect at this rate for 60 days (`SOURCE_RETRY_COUNT=86400`). A setting of 0 for `SOURCE_RETRY_COUNT` means that there is no limit on the number of reconnection attempts, so the replica keeps trying to reconnect indefinitely.

The values for `SOURCE_CONNECT_RETRY` and `SOURCE_RETRY_COUNT` are recorded in the source metadata repository and shown in the `replication_connection_configuration` Performance Schema table. `SOURCE_RETRY_COUNT` supersedes the `--master-retry-count` server startup option.

`SOURCE_SSL = {0|1}` Specify whether the replica encrypts the replication connection. The default is 0, meaning that the replica does not encrypt the replication connection. If you set `SOURCE_SSL=1`, you can configure the encryption using the `SOURCE_SSL_`xxx` and `SOURCE_TLS_`xxx` options.

Setting `SOURCE_SSL=1` for a replication connection and then setting no further `SOURCE_SSL_`xxx` options corresponds to setting `--ssl-mode=REQUIRED` for the client, as described in Command Options for Encrypted Connections. With `SOURCE_SSL=1`, the connection attempt only succeeds if an encrypted connection can be established. A replication connection does not fall back to an unencrypted connection, so there is no setting corresponding to the `--ssl-mode=PREFERRED` option.
setting for replication. If `SOURCE_SSL=0` is set, this corresponds to `--ssl-mode=DISABLED`.

**Important**

To help prevent sophisticated man-in-the-middle attacks, it is important for the replica to verify the server’s identity. You can specify additional `SOURCE_SSL_` options to correspond to the settings `--ssl-mode=VERIFY_CA` and `--ssl-mode=VERIFY_IDENTITY`, which are a better choice than the default setting to help prevent this type of attack. With these settings, the replica checks that the server’s certificate is valid, and checks that the host name the replica is using matches the identity in the server’s certificate. To implement one of these levels of verification, you must first ensure that the CA certificate for the server is reliably available to the replica, otherwise availability issues will result. For this reason, they are not the default setting.

**SOURCE_SSL_**, **SOURCE_TLS_**

Specify how the replica uses encryption and ciphers to secure the replication connection. These options can be changed even on replicas that are compiled without SSL support. They are saved to the source metadata repository, but are ignored if the replica does not have SSL support enabled. The maximum length of the value for the string-valued `SOURCE_SSL_` and `SOURCE_TLS_` options is 511 characters, with the exception of `SOURCE_TLS_CIPHERSUITES`, for which it is 4000 characters.

The `SOURCE_SSL_` and `SOURCE_TLS_` options perform the same functions as the `--ssl-` and `--tls-` client options described in Command Options for Encrypted Connections. The correspondence between the two sets of options, and the use of the `SOURCE_SSL_` and `SOURCE_TLS_` options to set up a secure connection, is explained in Section 17.3.1, “Setting Up Replication to Use Encrypted Connections”.

**SOURCE_USER = 'user_name'**

The user name for the replication user account to use for connecting to the replication source server. The maximum length of the string value is 96 characters.

For Group Replication, this account must exist on every member of the replication group. It is used for distributed recovery if the XCom communication stack is in use for the group, and also used for group communication connections if the MySQL communication stack is in use for the group. With the MySQL communication stack, the account must have the `GROUP_REPLICATION_STREAM` permission.

It is possible to set an empty user name by specifying `SOURCE_USER=''`, but the replication channel cannot be started with an empty user name. In releases before MySQL 8.0.21, only set an empty `SOURCE_USER` user name if you need to clear previously used...
credentials from the replication metadata repositories for security purposes. Do not use the channel afterwards, due to a bug in these releases that can substitute a default user name if an empty user name is read from the repositories (for example, during an automatic restart of a Group Replication channel). From MySQL 8.0.21, it is valid to set an empty SOURCE_USER user name and use the channel afterwards if you always provide user credentials using the START REPLICA statement or START GROUP_REPLICATION statement that starts the replication channel. This approach means that the replication channel always needs operator intervention to restart, but the user credentials are not recorded in the replication metadata repositories.

**Important**

To connect to the source using a replication user account that authenticates with the caching_sha2_password plugin, you must either set up a secure connection as described in Section 17.3.1, "Setting Up Replication to Use Encrypted Connections", or enable the unencrypted connection to support password exchange using an RSA key pair. The caching_sha2_password authentication plugin is the default for new users created from MySQL 8.0 (for details, see Section 6.4.1.2, "Caching SHA-2 Pluggable Authentication"). If the user account that you create or use for replication uses this authentication plugin, and you are not using a secure connection, you must enable RSA key pair-based password exchange for a successful connection. You can do this using either the SOURCE_PUBLIC_KEY_PATH option or the GET_SOURCE_PUBLIC_KEY=1 option for this statement.

**SOURCE_ZSTD_COMPRESSION_LEVEL** = *level*

The compression level to use for connections to the replication source server that use the zstd compression algorithm. SOURCE_ZSTD_COMPRESSION_LEVEL is available as of MySQL 8.0.18. The permitted levels are from 1 to 22, with larger values indicating increasing levels of compression. The default level is 3.

The compression level setting has no effect on connections that do not use zstd compression. For more information, see Section 4.2.8, "Connection Compression Control".

**Examples**

**CHANGE REPLICA SOURCE TO** is useful for setting up a replica when you have the snapshot of the source and have recorded the source's binary log coordinates corresponding to the time of the snapshot. After loading the snapshot into the replica to synchronize it with the source, you can run **CHANGE REPLICA SOURCE TO SOURCE_LOG_FILE='log_name', SOURCE_LOG_POS=log_pos** on the replica to specify the coordinates at which the replica should begin reading the source's binary log. The following example changes the source server the replica uses and establishes the source's binary log coordinates from which the replica begins reading: 

```sql
CHANGE REPLICA SOURCE TO
```
CHANGE REPLICA SOURCE TO
  SOURCE_HOST='source2.example.com',
  SOURCE_USER='replication',
  SOURCE_PASSWORD='password',
  SOURCE_PORT=3306,
  SOURCE_LOG_FILE='source2-bin.001',
  SOURCE_LOG_POS=4,
  SOURCE_CONNECT_RETRY=10;

For the procedure to switch an existing replica to a new source during failover, see Section 17.4.8, “Switching Sources During Failover”.

When GTIDs are in use on the source and the replica, specify GTID auto-positioning instead of giving the binary log file position, as in the following example. For full instructions to configure and start GTID-based replication on new or stopped servers, online servers, or additional replicas, see Section 17.1.3, “Replication with Global Transaction Identifiers”.

CHANGE REPLICA SOURCE TO
  SOURCE_HOST='source3.example.com',
  SOURCE_USER='replication',
  SOURCE_PASSWORD='password',
  SOURCE_PORT=3306,
  SOURCE_AUTO_POSITION = 1,
  FOR CHANNEL "source_3";

In this example, multi-source replication is in use, and the CHANGE REPLICA SOURCE TO statement is applied to the replication channel "source_3" that connects the replica to the specified host. For guidance on setting up multi-source replication, see Section 17.1.5, “MySQL Multi-Source Replication”.

The next example shows how to make the replica apply transactions from relay log files that you want to repeat. To do this, the source need not be reachable. You can use CHANGE REPLICA SOURCE TO to locate the relay log position where you want the replica to start reapplying transactions, and then start the SQL thread:

CHANGE REPLICA SOURCE TO
  RELAY_LOG_FILE='replica-relay-bin.006',
  RELAY_LOG_POS=4025;
  START REPLICA SQL_THREAD;

CHANGE REPLICA SOURCE TO can also be used to skip over transactions in the binary log that are causing replication to stop. The appropriate method to do this depends on whether GTIDs are in use or not. For instructions to skip transactions using CHANGE REPLICA SOURCE TO or another method, see Section 17.1.7.3, “Skipping Transactions”.

13.4.2.4 RESET REPLICA Statement

RESET REPLICA [ALL] [channel_option]

channel_option:
  FOR CHANNEL channel

RESET REPLICA makes the replica forget its position in the source’s binary log. From MySQL 8.0.22, use RESET REPLICA in place of RESET SLAVE, which is deprecated from that release. In releases before MySQL 8.0.22, use RESET SLAVE.

This statement is meant to be used for a clean start; it clears the replication metadata repositories, deletes all the relay log files, and starts a new relay log file. It also resets to 0 the replication delay specified with the SOURCE_DELAY | MASTER_DELAY option of the CHANGE REPLICA SOURCE TO statement (from MySQL 8.0.23) or CHANGE MASTER TO statement (before MySQL 8.0.23).
SQL Statements for Controlling Replica Servers

Note
All relay log files are deleted, even if they have not been completely executed by the replication SQL thread. (This is a condition likely to exist on a replica if you have issued a `STOP REPLICA` statement or if the replica is highly loaded.)

For a server where GTIDs are in use (`gtid_mode` is `ON`), issuing `RESET REPLICA` has no effect on the GTID execution history. The statement does not change the values of `gtid_executed` or `gtid_purged`, or the `mysql.gtid_executed` table. If you need to reset the GTID execution history, use `RESET MASTER`, even if the GTID-enabled server is a replica where binary logging is disabled.

`RESET REPLICA` requires the `RELOAD` privilege.

To use `RESET REPLICA`, the replication SQL thread and replication I/O (receiver) thread must be stopped, so on a running replica use `STOP REPLICA` before issuing `RESET REPLICA`. To use `RESET REPLICA` on a Group Replication group member, the member status must be `OFFLINE`, meaning that the plugin is loaded but the member does not currently belong to any group. A group member can be taken offline by using a `STOP GROUP REPLICATION` statement.

The optional `FOR CHANNEL channel` clause enables you to name which replication channel the statement applies to. Providing a `FOR CHANNEL channel` clause applies the `RESET REPLICA` statement to a specific replication channel. Combining a `FOR CHANNEL channel` clause with the `ALL` option deletes the specified channel. If no channel is named and no extra channels exist, the statement applies to the default channel. Issuing a `RESET REPLICA ALL` statement without a `FOR CHANNEL channel` clause when multiple replication channels exist deletes all replication channels and recreates only the default channel. See Section 17.2.2, “Replication Channels” for more information.

`RESET REPLICA` does not change any replication connection parameters, which include the source's host name and port, the replication user account and its password, the `PRIVILEGE_CHECKS_USER` account, the `REQUIRE_ROW_FORMAT` option, the `REQUIRE_TABLE_PRIMARY_KEY_CHECK` option, and the `ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS` option. If you want to change any of the replication connection parameters, you can do this using a `CHANGE REPLICATION SOURCE TO` statement (from MySQL 8.0.23) or `CHANGE MASTER TO` statement (before MySQL 8.0.23) after the server start. If you want to remove all of the replication connection parameters, use `RESET REPLICA ALL`. `RESET REPLICA ALL` also clears the `IGNORE_SERVER_IDS` list set by `CHANGE REPLICATION SOURCE TO` or `CHANGE MASTER TO`. When you have used `RESET REPLICA ALL`, if you want to use the instance as a replica again, you need to issue a `CHANGE REPLICATION SOURCE TO` or `CHANGE MASTER TO` statement after the server start to specify new connection parameters.

From MySQL 8.0.27, you can set the `GTID_ONLY` option on the `CHANGE REPLICATION SOURCE TO` statement to stop a replication channel from persisting file names and file positions in the replication metadata repositories. When you issue a `RESET REPLICA` statement, the replication metadata repositories are synchronized. `RESET REPLICA ALL` deletes rather than updates the repositories, so they are synchronized implicitly.

In the event of an unexpected server exit or deliberate restart after issuing `RESET REPLICA` but before issuing `START REPLICA`, retention of the replication connection parameters depends on the repository used for the replication metadata:

- When `master_info_repository=TABLE` and `relay_log_info_repository=TABLE` are set on the server (which are the default settings from MySQL 8.0), replication connection parameters are preserved in the crash-safe InnoDB tables `mysql.slave_master_info` and `mysql.slave_relay_log_info` as part of the `RESET REPLICA` operation. They are also retained in memory. In the event of an unexpected server exit or deliberate restart after issuing `RESET REPLICA` but before issuing `START REPLICA`, the replication connection parameters are retrieved from the tables.
and reapplied to the channel. This situation applies from MySQL 8.0.13 for the connection metadata repository, and from MySQL 8.0.19 for the applier metadata repository.

- If `master_info_repository=FILE` and `relay_log_info_repository=FILE` are set on the server, which is deprecated from MySQL 8.0, or the MySQL Server release is earlier than those specified above, replication connection parameters are only retained in memory. If the replica `mysqld` is restarted immediately after issuing `RESET REPLICA` due to an unexpected server exit or deliberate restart, the connection parameters are lost. In that case, you must issue a `CHANGE REPLICA SOURCE TO` statement (from MySQL 8.0.23) or `CHANGE MASTER TO` statement (before MySQL 8.0.23) after the server start to respecify the connection parameters before issuing `START REPLICA`.

`RESET REPLICA` does not change any replication filter settings (such as `--replicate-ignore-table`) for channels affected by the statement. However, `RESET REPLICA ALL` removes the replication filters that were set on the channels deleted by the statement. When the deleted channel or channels are recreated, any global replication filters specified for the replica are copied to them, and no channel specific replication filters are applied. For more information see Section 17.2.5.4, “Replication Channel Based Filters”.

`RESET REPLICA` causes an implicit commit of an ongoing transaction. See Section 13.3.3, “Statements That Cause an Implicit Commit”.

If the replication SQL thread was in the middle of replicating temporary tables when it was stopped, and `RESET REPLICA` is issued, these replicated temporary tables are deleted on the replica.

```
Note
When used on an NDB Cluster replica SQL node, `RESET REPLICA` clears the mysql.ndb_apply_status table. You should keep in mind when using this statement that ndb_apply_status uses the NDB storage engine and so is shared by all SQL nodes attached to the cluster.

You can override this behavior by issuing `SET GLOBAL @ndb_clear_apply_status=OFF` prior to executing `RESET REPLICA`, which keeps the replica from purging the ndb_apply_status table in such cases.
```

### 13.4.2.5 RESET SLAVE Statement

```
RESET (SLAVE | REPLICA) [ALL] [channel_option]
```

**channel_option:**

- FOR CHANNEL channel

Makes the replica forget its position in the source’s binary log. From MySQL 8.0.22, `RESET SLAVE` is deprecated and the alias `RESET REPLICA` should be used instead. In releases before MySQL 8.0.22, use `RESET SLAVE`. The statement works in the same way as before, only the terminology used for the statement and its output has changed. Both versions of the statement update the same status variables when used. Please see the documentation for `RESET REPLICA` for a description of the statement.

### 13.4.2.6 START REPLICA Statement

```
START REPLICA [thread_types] [until_option] [connection_options] [channel_option]
```

**thread_types:**

- [thread_type [, thread_type] ... ]

**thread_type:**

- IO_THREAD | SQL_THREAD

**until_option:**

- UNTIL { SQL_BEFORE_GTIDS | SQL_AFTER_GTIDS } = gtid_set
SQL Statements for Controlling Replica Servers

```
MASTER_LOG_FILE = 'log_name', MASTER_LOG_POS = log_pos
SOURCE_LOG_FILE = 'log_name', SOURCE_LOG_POS = log_pos
RELAY_LOG_FILE = 'log_name', RELAY_LOG_POS = log_pos
SQL_AFTER_MTS_GAPS }
```

c `connection_options`:

```
connection_options:
    [USER='user_name'] [PASSWORD='user_pass'] [DEFAULT_AUTH='plugin_name'] [PLUGIN_DIR='plugin_dir']
```

```
channel_option:
    FOR CHANNEL channel
```

gtid_set:

```
gtid_set: 
    [, uuid_set] ... 
| ''
gtid_set: 
    uuid:interval[:interval]...

uuid:
    hhhhhhh-hhhhh-hhhhh-hhhhhhhhhhhhhhh

h:
    [0-9,A-F]

interval:
    n[-n]
```

```
START REPLICA starts the replication threads, either together or separately. From MySQL 8.0.22, use
START REPLICA in place of START SLAVE, which is deprecated from that release. In releases before
MySQL 8.0.22, use START SLAVE.

START REPLICA requires the REPLICATION_SLAVE_ADMIN privilege (or the deprecated SUPER
privilege). START REPLICA causes an implicit commit of an ongoing transaction. See Section 13.3.3,
“Statements That Cause an Implicit Commit”.

For the thread type options, you can specify IO_THREAD, SQL_THREAD, both of these, or neither of them.
Only the threads that are started are affected by the statement.

- START REPLICA with no thread type options starts all of the replication threads, and so does START
  REPLICA with both of the thread type options.

- IO_THREAD starts the replication receiver thread, which reads events from the source server and stores
  them in the relay log.

- SQL_THREAD starts the replication applier thread, which reads events from the relay log and executes
  them. A multithreaded replica (with replica_parallel_workers or slave_parallel_workers >
  0) applies transactions using a coordinator thread and multiple applier threads, and SQL_THREAD starts
  all of these.

```
Important
```

START REPLICA sends an acknowledgment to the user after all the replication
threads have started. However, the replication receiver thread might not yet have
connected to the source successfully, or an applier thread might stop when applying
an event right after starting. START REPLICA does not continue to monitor the
threads after they are started, so it does not warn you if they subsequently stop
or cannot connect. You must check the replica’s error log for error messages
generated by the replication threads, or check that they are running satisfactorily
with SHOW REPLICA STATUS. A successful START REPLICA statement
causes `SHOW REPLICA STATUS` to show `Replica_SQL_Running=True`, but it might or might not show `Replica_IO_Running=True`, because `Replica_IO_Running=True` is only shown if the receiver thread is both running and connected. For more information, see Section 17.1.7.1, “Checking Replication Status”.

The optional `FOR CHANNEL channel` clause enables you to name which replication channel the statement applies to. Providing a `FOR CHANNEL channel` clause applies the `START REPLICA` statement to a specific replication channel. If no clause is named and no extra channels exist, the statement applies to the default channel. If a `START REPLICA` statement does not have a channel defined when using multiple channels, this statement starts the specified threads for all channels. See Section 17.2.2, “Replication Channels” for more information.

The replication channels for Group Replication (`group_replication_applier` and `group_replication_recovery`) are managed automatically by the server instance. `START REPLICA` cannot be used at all with the `group_replication_recovery` channel, and should only be used with the `group_replication_applier` channel when Group Replication is not running. The `group_replication_applier` channel only has an applier thread and has no receiver thread, so it can be started if required by using the `SQL_THREAD` option without the `IO_THREAD` option.

`START REPLICA` supports pluggable user-password authentication (see Section 6.2.17, “Pluggable Authentication”) with the `USER`, `PASSWORD`, `DEFAULT_AUTH` and `PLUGIN_DIR` options, as described in the following list. When you use these options, you must start the receiver thread (`IO_THREAD` option) or all the replication threads; you cannot start the replication applier thread (`SQL_THREAD` option) alone.

- **USER**: The user name for the account. You must set this if `PASSWORD` is used. The option cannot be set to an empty or null string.
- **PASSWORD**: The password for the named user account.
- **DEFAULT_AUTH**: The name of the authentication plugin. The default is MySQL native authentication.
- **PLUGIN_DIR**: The location of the authentication plugin.

**Important**

The password that you set using `START REPLICA` is masked when it is written to MySQL Server’s logs, Performance Schema tables, and `SHOW PROCESSLIST` statements. However, it is sent in plain text over the connection to the replica server instance. To protect the password in transit, use SSL/TLS encryption, an SSH tunnel, or another method of protecting the connection from unauthorized viewing, for the connection between the replica server instance and the client that you use to issue `START REPLICA`.

The `UNTIL` clause makes the replica start replication, then process transactions up to the point that you specify in the `UNTIL` clause, then stop again. The `UNTIL` clause can be used to make a replica proceed until just before the point where you want to skip a transaction that is unwanted, and then skip the transaction as described in Section 17.1.7.3, “Skipping Transactions”. To identify a transaction, you can use `mysqlbinlog` with the source’s binary log or the replica’s relay log, or use a `SHOW BINLOG EVENTS` statement.

You can also use the `UNTIL` clause for debugging replication by processing transactions one at a time or in sections. If you are using the `UNTIL` clause to do this, start the replica with the `--skip-slave-start` option, or from MySQL 8.0.24, the `skip_slave_start` system variable, to prevent the SQL thread from running when the replica server starts. Remove the option or system variable setting after the procedure is complete, so that it is not forgotten in the event of an unexpected server restart.
The `SHOW REPLICA STATUS` statement includes output fields that display the current values of the `UNTIL` condition. The `UNTIL` condition lasts for as long as the affected threads are still running, and is removed when they stop.

The `UNTIL` clause operates on the replication applier thread (`SQL_THREAD` option). You can use the `SQL_THREAD` option or let the replica default to starting both threads. If you use the `IO_THREAD` option alone, the `UNTIL` clause is ignored because the applier thread is not started.

The point that you specify in the `UNTIL` clause can be any one (and only one) of the following options:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>SOURCE_LOG_FILE</code> and <code>SOURCE_LOG_POS</code> (from MySQL 8.0.23), or <code>MASTER_LOG_FILE</code> and <code>MASTER_LOG_POS</code> (to MySQL 8.0.22)</td>
<td>These options make the replication applier process transactions up to a position in its relay log, identified by the file name and file position of the corresponding point in the binary log on the source server. The applier thread finds the nearest transaction boundary at or after the specified position, finishes applying the transaction, and stops there. For compressed transaction payloads, specify the end position of the compressed <code>Transaction_payload_event</code>. These options can still be used when the <code>GTID_ONLY</code> option was set on the <code>CHANGE REPLICATION SOURCE TO</code> statement to stop the replication channel from persisting file names and file positions in the replication metadata repositories. The file names and file positions are tracked in memory.</td>
</tr>
<tr>
<td><code>RELAY_LOG_FILE</code> and <code>RELAY_LOG_POS</code></td>
<td>These options make the replication applier process transactions up to a position in the replica’s relay log, identified by the relay log file name and a position in that file. The applier thread finds the nearest transaction boundary at or after the specified position, finishes applying the transaction, and stops there. For compressed transaction payloads, specify the end position of the compressed <code>Transaction_payload_event</code>. These options can still be used when the <code>GTID_ONLY</code> option was set on the <code>CHANGE REPLICATION SOURCE TO</code> statement to stop the replication channel from persisting file names and file positions in the replication metadata repositories. The file names and file positions are tracked in memory.</td>
</tr>
<tr>
<td><code>SQL_BEFORE_GTIDS</code></td>
<td>This option makes the replication applier start processing transactions and stop when it encounters any transaction that is in the specified GTID set. The encountered transaction from the GTID set is not applied, and nor are any of the other transactions in the GTID set. The option takes a GTID set containing one or more global transaction identifiers as an argument (see GTID Sets). Transactions in a GTID set do not necessarily appear in the replication stream in the order of their GTIDs, so the transaction before which the applier stops is not necessarily the earliest.</td>
</tr>
</tbody>
</table>
| `SQL_AFTER_GTIDS`             | This option makes the replication applier start processing transactions and stop when it has processed all of the transactions in a specified GTID set. The option takes a GTID set containing one or more global transaction identifiers as an argument (see GTID Sets). With `SQL_AFTER_GTIDS`, the replication threads stop after they have processed all transactions in the GTID set. Transactions are processed in the order received, so it is possible that these include
transactions which are not part of the GTID set, but which are received (and processed) before all transactions in the set have been committed. For example, executing `START REPLICA UNTIL SQL_AFTER_GTIDS = 3E11FA47-71CA-11E1-9E33-C80AA9429562:11-56` causes the replica to obtain (and process) all transactions from the source until all of the transactions having the sequence numbers 11 through 56 have been processed, and then to stop without processing any additional transactions after that point has been reached.

For a multithreaded replica only (with `replica_parallel_workers` or `slave_parallel_workers` > 0), this option makes the replica process transactions up to the point where there are no more gaps in the sequence of transactions executed from the relay log. When using a multithreaded replica, there is a chance of gaps occurring in the following situations:

- The coordinator thread is stopped.
- An error occurs in the applier threads.
- `mysqld` shuts down unexpectedly.

When a replication channel has gaps, the replica's database is in a state that might never have existed on the source. The replica tracks the gaps internally and disallows `CHANGE REPLICATION SOURCE TO` statements that would remove the gap information if they executed.

Before MySQL 8.0.26, issuing `START REPLICA` on a multithreaded replica with gaps in the sequence of transactions executed from the relay log generates a warning. To correct this situation, the solution is to use `START REPLICA UNTIL SQL_AFTER_MTS_GAPS`. See Section 17.5.1.34, “Replication and Transaction Inconsistencies” for more information.

From MySQL 8.0.26, the process of checking for gaps in the sequence of transactions is skipped entirely when GTID-based replication and GTID auto-positioning (`SOURCE_AUTO_POSITION=1`) are in use for the channel, because gaps in transactions can be resolved using GTID auto-positioning. In that situation, `START REPLICA UNTIL SQL_AFTER_MTS_GAPS` just stops the applier thread when it finds the first transaction to execute, and does not attempt to check for gaps in the sequence of transactions. You can also continue to use `CHANGE REPLICATION SOURCE TO` statements as normal, and relay log recovery is possible for the channel.

From MySQL 8.0.27, all replicas are multithreaded by default. When `replica_preserve_commit_order=ON` or `slave_preserve_commit_order=ON` is set for the replica, which is also the default setting from MySQL 8.0.27, gaps should not occur except in the specific situations listed in the description for `replica_preserve_commit_order` and `slave_preserve_commit_order`. If `replica_preserve_commit_order=OFF` or `slave_preserve_commit_order=OFF` is set for the replica, which is
the default before MySQL 8.0.27, the commit order of transactions is not preserved, so the chance of gaps occurring is much larger.

If GTIDs are not in use and you need to change a failed multithreaded replica to single-threaded mode, you can issue the following series of statements, in the order shown:

```
START SLAVE UNTIL SQL_AFTER_MTS_GAPS;
SET @@GLOBAL.slave_parallel_workers = 0;
START SLAVE SQL_THREAD;
```

Or from MySQL 8.0.26:

```
START REPLICA UNTIL SQL_AFTER_MTS_GAPS;
SET @@GLOBAL.replica_parallel_workers = 0;
START REPLICA SQL_THREAD;
```

### 13.4.2.7 START SLAVE Statement

Starts the replication threads. From MySQL 8.0.22, **START SLAVE** is deprecated and the alias **START REPLICA** should be used instead. The statement works in the same way as before, only the terminology used for the statement and its output has changed. Both versions of the statement update the same status variables when used. Please see the documentation for **START REPLICA** for a description of the statement.
### 13.4.2.8 STOP REPLICA Statement

```sql
STOP REPLICA [thread_types] [channel_option]

thread_types: [thread_type [, thread_type] ... ]

channel_option: FOR CHANNEL channel
```

Stops the replication threads. From MySQL 8.0.22, use `STOP REPLICA` in place of `STOP SLAVE`, which is now deprecated. In releases before MySQL 8.0.22, use `STOP SLAVE`.

`STOP REPLICA` requires the `REPLICATION_SLAVE_ADMIN` privilege (or the deprecated `SUPER` privilege). Recommended best practice is to execute `STOP REPLICA` on the replica before stopping the replica server (see Section 5.1.19, “The Server Shutdown Process”, for more information).

Like `START REPLICA`, this statement may be used with the `IO_THREAD` and `SQL_THREAD` options to name the replication thread or threads to be stopped. Note that the Group Replication applier channel (`group_replication_applier`) has no replication I/O (receiver) thread, only a replication SQL (applier) thread. Using the `SQL_THREAD` option therefore stops this channel completely.

`STOP REPLICA` causes an implicit commit of an ongoing transaction. See Section 13.3.3, “Statements That Cause an Implicit Commit”.

gtid_next must be set to `AUTOMATIC` before issuing this statement.

You can control how long `STOP REPLICA` waits before timing out by setting the system variable `rpl_stop_replica_timeout` (from MySQL 8.0.26) or `rpl_stop_slave_timeout` (before MySQL 8.0.26). This can be used to avoid deadlocks between `STOP REPLICA` and other SQL statements using different client connections to the replica. When the timeout value is reached, the issuing client returns an error message and stops waiting, but the `STOP REPLICA` instruction remains in effect. Once the replication threads are no longer busy, the `STOP REPLICA` statement is executed and the replica stops.

Some `CHANGE REPLICATION SOURCE TO` | `CHANGE MASTER TO` statements are allowed while the replica is running, depending on the states of the replication threads. However, using `STOP REPLICA` prior to executing a `CHANGE REPLICATION SOURCE TO` | `CHANGE MASTER TO` statement in such cases is still supported. See Section 13.4.2.3, “CHANGE REPLICATION SOURCE TO Statement”, Section 13.4.2.1, “CHANGE MASTER TO Statement”, and Section 17.4.8, “Switching Sources During Failover”, for more information.

The optional `FOR CHANNEL channel` clause enables you to name which replication channel the statement applies to. Providing a `FOR CHANNEL channel` clause applies the `STOP REPLICA` statement to a specific replication channel. If no channel is named and no extra channels exist, the statement applies to the default channel. If a `STOP REPLICA` statement does not name a channel when using multiple channels, this statement stops the specified threads for all channels. See Section 17.2.2, “Replication Channels” for more information.

The replication channels for Group Replication (`group_replication_applier` and `group_replication_recovery`) are managed automatically by the server instance. `STOP REPLICA` cannot be used at all with the `group_replication_recovery` channel, and should only be used with the `group_replication_applier` channel when Group Replication is not running. The `group_replication_applier` channel only has an applier thread and has no receiver thread, so it can be stopped if required by using the `SQL_THREAD` option without the `IO_THREAD` option.
When the replica is multithreaded (replica_parallel_workers or slave_parallel_workers is a nonzero value), any gaps in the sequence of transactions executed from the relay log are closed as part of stopping the worker threads. If the replica is stopped unexpectedly (for example due to an error in a worker thread, or another thread issuing KILL) while a STOP REPLICA statement is executing, the sequence of executed transactions from the relay log may become inconsistent. See Section 17.5.1.34, “Replication and Transaction Inconsistencies”, for more information.

When the source is using the row-based binary logging format, you should execute STOP REPLICA or STOP REPLICA SQL_THREAD on the replica prior to shutting down the replica server if you are replicating any tables that use a nontransactional storage engine. If the current replication event group has modified one or more nontransactional tables, STOP REPLICA waits for up to 60 seconds for the event group to complete, unless you issue a KILL QUERY or KILL CONNECTION statement for the replication SQL thread. If the event group remains incomplete after the timeout, an error message is logged.

When the source is using the statement-based binary logging format, changing the source while it has open temporary tables is potentially unsafe. This is one of the reasons why statement-based replication of temporary tables is not recommended. You can find out whether there are any temporary tables on the replica by checking the value of Replica_open_temp_tables or Slave_open_temp_tables. When using statement-based replication, this value should be 0 before executing CHANGE REPLICATION SOURCE TO | CHANGE MASTER TO. If there are any temporary tables open on the replica, issuing a CHANGE REPLICATION SOURCE TO | CHANGE MASTER TO statement after issuing a STOP REPLICA causes an ER_WARN_OPEN_TEMP_TABLES_MUST_BE_ZERO warning.

### 13.4.2.9 STOP SLAVE Statement

```
STOP {SLAVE | REPLICA} [thread_types] [channel_option]
```

**thread_types:**

```
  [thread_type [, thread_type] ... ]
```

**thread_type:** IO_THREAD | SQL_THREAD

**channel_option:**

```
  FOR CHANNEL channel
```

Stops the replication threads. From MySQL 8.0.22, STOP SLAVE is deprecated and the alias STOP REPLICA should be used instead. The statement works in the same way as before, only the terminology used for the statement and its output has changed. Both versions of the statement update the same status variables when used. Please see the documentation for STOP REPLICA for a description of the statement.

### 13.4.3 SQL Statements for Controlling Group Replication

This section provides information about the statements used for controlling group replication.

#### 13.4.3.1 START GROUP_REPLICATION Statement

```
START GROUP_REPLICATION
  [USER='user_name']
  [, PASSWORD='user_pass']
  [, DEFAULT_AUTH='plugin_name']
```

Starts group replication. This statement requires the GROUP_REPLICATION_ADMIN privilege (or the deprecated SUPER privilege). If super_read_only=ON is set and the member should join as a primary, super_read_only is set to OFF once Group Replication successfully starts.

From MySQL 8.0.21, you can specify user credentials for distributed recovery on the START GROUP_REPLICATION statement using the USER, PASSWORD, and DEFAULT_AUTH options, as follows:
SQL Statements for Controlling Group Replication

- **USER**: The replication user for distributed recovery. For instructions to set up this account, see Section 18.2.1.3, “User Credentials For Distributed Recovery”. You cannot specify an empty or null string, or omit the **USER** option if **PASSWORD** is specified.

- **PASSWORD**: The password for the replication user account. The password cannot be encrypted, but it is masked in the query log.

- **DEFAULT_AUTH**: The name of the authentication plugin used for the replication user account. If you do not specify this option, MySQL native authentication (the **mysql_native_password** plugin) is assumed. This option acts as a hint to the server, and the donor for distributed recovery overrides it if a different plugin is associated with the user account on that server. The authentication plugin used by default when you create user accounts in MySQL 8 is the caching SHA-2 authentication plugin (**caching_sha2_password**). See Section 6.2.17, “Pluggable Authentication” for more information on authentication plugins.

These credentials are used for distributed recovery on the **group_replication_recovery** channel. When you specify user credentials on **START GROUP_REPLICATION**, the credentials are saved in memory only, and are removed by a **STOP GROUP_REPLICATION** statement or server shutdown. You must issue a **START GROUP_REPLICATION** statement to provide the credentials again. This method is therefore not compatible with starting Group Replication automatically on server start, as specified by the **group_replication_start_on_boot** system variable.

User credentials specified on **START GROUP_REPLICATION** take precedence over any user credentials set for the **group_replication_recovery** channel using a **CHANGE REPLICATION SOURCE TO** statement (from MySQL 8.0.23) or **CHANGE MASTER TO** statement (before MySQL 8.0.23). Note that user credentials set using these statements are stored in the replication metadata repositories, and are used when **START GROUP_REPLICATION** is specified without user credentials, including automatic starts if the **group_replication_start_on_boot** system variable is set to **ON**. To gain the security benefits of specifying user credentials on **START GROUP_REPLICATION**, ensure that **group_replication_start_on_boot** is set to **OFF** (the default is **ON**), and clear any user credentials previously set for the **group_replication_recovery** channel, following the instructions in Section 18.6.3, “Securing Distributed Recovery Connections”.

While a member is rejoining a replication group, its status can be displayed as **OFFLINE** or **ERROR** before the group completes the compatibility checks and accepts it as a member. When the member is catching up with the group's transactions, its status is **RECOVERING**.

### 13.4.3.2 STOP GROUP_REPLICATION Statement

**STOP GROUP_REPLICATION**

Stops Group Replication. This statement requires the **GROUP_REPLICATION_ADMIN** privilege (or the deprecated **SUPER** privilege). As soon as you issue **STOP GROUP_REPLICATION** the member is set to **super_read_only=ON**, which ensures that no writes can be made to the member while Group Replication stops. Any other asynchronous replication channels running on the member are also stopped. Any user credentials that you specified in the **START GROUP_REPLICATION** statement when starting Group Replication on this member are removed from memory, and must be supplied when you start Group Replication again.

**Warning**

Use this statement with extreme caution because it removes the server instance from the group, meaning it is no longer protected by Group Replication's consistency guarantee mechanisms. To be completely safe, ensure that your applications can no longer connect to the instance before issuing this statement to avoid any chance of stale reads.
The `STOP GROUP_REPLICATION` statement stops asynchronous replication channels on the group member, but it does not implicitly commit transactions that are in progress on them like `STOP REPLICA` does. This is because on a Group Replication group member, an additional transaction committed during the shutdown operation would leave the member inconsistent with the group and cause an issue with rejoining. To avoid failed commits for transactions that are in progress while stopping Group Replication, from MySQL 8.0.28, the `STOP GROUP_REPLICATION` statement cannot be issued while a GTID is assigned as the value of the `gtid_next` system variable.

The `group_replication_components_stop_timeout` system variable specifies the time for which Group Replication waits for each of its modules to complete ongoing processes after this statement is issued. The timeout is used to resolve situations in which Group Replication components cannot be stopped normally, which can happen if the member is expelled from the group while it is in an error state, or while a process such as MySQL Enterprise Backup is holding a global lock on tables on the member. In such situations, the member cannot stop the applier thread or complete the distributed recovery process to rejoin. `STOP GROUP_REPLICATION` does not complete until either the situation is resolved (for example, by the lock being released), or the component timeout expires and the modules are shut down regardless of their status. Prior to MySQL 8.0.27, the default component timeout is 31536000 seconds, or 365 days. With this setting, the component timeout does not help in situations such as those just described, so a lower setting is recommended in those versions of MySQL 8.0. Beginning with MySQL 8.0.27, the default value is 300 seconds; this means that Group Replication components are stopped after 5 minutes if the situation is not resolved before that time, allowing the member to be restarted and rejoin.

13.5 Prepared Statements

MySQL 8.0 provides support for server-side prepared statements. This support takes advantage of the efficient client/server binary protocol. Using prepared statements with placeholders for parameter values has the following benefits:

- Less overhead for parsing the statement each time it is executed. Typically, database applications process large volumes of almost-identical statements, with only changes to literal or variable values in clauses such as `WHERE` for queries and deletes, `SET` for updates, and `VALUES` for inserts.

- Protection against SQL injection attacks. The parameter values can contain unescaped SQL quote and delimiter characters.

The following sections provide an overview of the characteristics of prepared statements:

- Prepared Statements in Application Programs
- Prepared Statements in SQL Scripts
- PREPARE, EXECUTE, and DEALLOCATE PREPARE Statements
- SQL Syntax Permitted in Prepared Statements

Prepared Statements in Application Programs

You can use server-side prepared statements through client programming interfaces, including the MySQL C API client library for C programs, MySQL Connector/J for Java programs, and MySQL Connector/NET for programs using .NET technologies. For example, the C API provides a set of function calls that make up its prepared statement API. See C API Prepared Statement Interface. Other language interfaces can provide support for prepared statements that use the binary protocol by linking in the C client library, one example being the `mysqli` extension, available in PHP 5.0 and higher.
Prepared Statements in SQL Scripts

An alternative SQL interface to prepared statements is available. This interface is not as efficient as using the binary protocol through a prepared statement API, but requires no programming because it is available directly at the SQL level:

- You can use it when no programming interface is available to you.
- You can use it from any program that can send SQL statements to the server to be executed, such as the mysql client program.
- You can use it even if the client is using an old version of the client library.

SQL syntax for prepared statements is intended to be used for situations such as these:

- To test how prepared statements work in your application before coding it.
- To use prepared statements when you do not have access to a programming API that supports them.
- To interactively troubleshoot application issues with prepared statements.
- To create a test case that reproduces a problem with prepared statements, so that you can file a bug report.

**PREPARE, EXECUTE, and DEALLOCATE PREPARE Statements**

SQL syntax for prepared statements is based on three SQL statements:

- `PREPARE` prepares a statement for execution (see Section 13.5.1, “PREPARE Statement”).
- `EXECUTE` executes a prepared statement (see Section 13.5.2, “EXECUTE Statement”).
- `DEALLOCATE PREPARE` releases a prepared statement (see Section 13.5.3, “DEALLOCATE PREPARE Statement”).

The following examples show two equivalent ways of preparing a statement that computes the hypotenuse of a triangle given the lengths of the two sides.

The first example shows how to create a prepared statement by using a string literal to supply the text of the statement:

```sql
mysql> PREPARE stmt1 FROM 'SELECT SQRT(POW(?,2) + POW(?,2)) AS hypotenuse';
mysql> SET @a = 3;
mysql> SET @b = 4;
mysql> EXECUTE stmt1 USING @a, @b;
+------------+
| hypotenuse |
| 5          |
mysql> DEALLOCATE PREPARE stmt1;
```

The second example is similar, but supplies the text of the statement as a user variable:

```sql
mysql> SET @s = 'SELECT SQRT(POW(?,2) + POW(?,2)) AS hypotenuse';
mysql> PREPARE stmt2 FROM @s;
mysql> SET @a = 6;
mysql> SET @b = 8;
mysql> EXECUTE stmt2 USING @a, @b;
+------------+
| hypotenuse |
| 10          |
```
Here is an additional example that demonstrates how to choose the table on which to perform a query at runtime, by storing the name of the table as a user variable:

```sql
mysql> USE test;
mysql> CREATE TABLE t1 (a INT NOT NULL);
mysql> INSERT INTO t1 VALUES (4), (8), (11), (32), (80);
mysql> SET @table = 't1';
mysql> SET @s = CONCAT('SELECT * FROM ', @table);
mysql> PREPARE stmt3 FROM @s;
mysql> EXECUTE stmt3;
+----+
<table>
<thead>
<tr>
<th>a</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
</tr>
<tr>
<td>8</td>
</tr>
<tr>
<td>11</td>
</tr>
<tr>
<td>32</td>
</tr>
<tr>
<td>80</td>
</tr>
</tbody>
</table>
mysql> DEALLOCATE PREPARE stmt3;
```

A prepared statement is specific to the session in which it was created. If you terminate a session without deallocating a previously prepared statement, the server deallocates it automatically.

A prepared statement is also global to the session. If you create a prepared statement within a stored routine, it is not deallocated when the stored routine ends.

To guard against too many prepared statements being created simultaneously, set the `max_prepared_stmt_count` system variable. To prevent the use of prepared statements, set the value to 0.

### SQL Syntax Permitted in Prepared Statements

The following SQL statements can be used as prepared statements:

- `ALTER TABLE`
- `ALTER USER`
- `ANALYZE TABLE`
- `CACHE INDEX`
- `CALL`
- `CHANGE MASTER`
- `CHECKSUM {TABLE | TABLES}`
- `COMMITS {CREATE | DROP | INDEX}
- `CHECKSUM {TABLE | TABLES}`
- `COMMIT`
- `CREATE | RENAME | DROP | DATABASE`
- `CREATE | DROP | TABLE`
- `CREATE | RENAME | DROP | USER`
- `CREATE | DROP | VIEW`
- `DELETE`
- `DO`
- `FLUSH {TABLE | TABLES | TABLES WITH READ LOCK | HOSTS | PRIVILEGES | LOGS | STATUS | MASTER | SLAVE | USER_RESOURCES}`
- `GRANT`
- `INSERT`
- `INSTALL PLUGIN`
- `KILL`
SQL Syntax Permitted in Prepared Statements

- LOAD INDEX INTO CACHE
- OPTIMIZE TABLE
- RENAME TABLE
- REPAIR TABLE
- REPLACE
- RESET {MASTER | SLAVE}
- REVOKE
- SELECT
- SET
- SHOW BINLOG EVENTS
- SHOW CREATE {PROCEDURE | FUNCTION | EVENT | TABLE | VIEW}
- SHOW {MASTER | BINARY} LOGS
- SHOW {MASTER | SLAVE} STATUS
- SLAVE {START | STOP}
- TRUNCATE TABLE
- UNINSTALL PLUGIN
- UPDATE

Other statements are not supported.

For compliance with the SQL standard, which states that diagnostics statements are not preparable, MySQL does not support the following as prepared statements:

- SHOW WARNINGS, SHOW COUNT(*) WARNINGS
- SHOW ERRORS, SHOW COUNT(*) ERRORS
- Statements containing any reference to the `warning_count` or `error_count` system variable.

Generally, statements not permitted in SQL prepared statements are also not permitted in stored programs. Exceptions are noted in Section 25.8, “Restrictions on Stored Programs”.

Metadata changes to tables or views referred to by prepared statements are detected and cause automatic repreparation of the statement when it is next executed. For more information, see Section 8.10.3, “Caching of Prepared Statements and Stored Programs”.

Placeholders can be used for the arguments of the `LIMIT` clause when using prepared statements. See Section 13.2.13, “SELECT Statement”.

In prepared `CALL` statements used with `PREPARE` and `EXECUTE`, placeholder support for `OUT` and `INOUT` parameters is available beginning with MySQL 8.0. See Section 13.2.1, “CALL Statement”, for an example and a workaround for earlier versions. Placeholders can be used for `IN` parameters regardless of version.

SQL syntax for prepared statements cannot be used in nested fashion. That is, a statement passed to `PREPARE` cannot itself be a `PREPARE`, `EXECUTE`, or `DEALLOCATE PREPARE` statement.

SQL syntax for prepared statements is distinct from using prepared statement API calls. For example, you cannot use the `mysql_stmt_prepare()` C API function to prepare a `PREPARE`, `EXECUTE`, or `DEALLOCATE PREPARE` statement.

SQL syntax for prepared statements can be used within stored procedures, but not in stored functions or triggers. However, a cursor cannot be used for a dynamic statement that is prepared and executed with `PREPARE` and `EXECUTE`. The statement for a cursor is checked at cursor creation time, so the statement cannot be dynamic.

SQL syntax for prepared statements does not support multi-statements (that is, multiple statements within a single string separated by `;` characters).

To write C programs that use the `CALL` SQL statement to execute stored procedures that contain prepared statements, the `CLIENT_MULTI_RESULTS` flag must be enabled. This is because each `CALL` returns

3048
a result to indicate the call status, in addition to any result sets that might be returned by statements executed within the procedure.

CLIENT_MULTI_RESULTS can be enabled when you call mysql_real_connect(), either explicitly by passing the CLIENT_MULTI_RESULTS flag itself, or implicitly by passing CLIENT_MULTI_STATEMENTS (which also enables CLIENT_MULTI_RESULTS). For additional information, see Section 13.2.1, “CALL Statement”.

13.5.1 PREPARE Statement

The PREPARE statement prepares a SQL statement and assigns it a name, \texttt{stmt\_name}, by which to refer to the statement later. The prepared statement is executed with EXECUTE and released with DEALLOCATE PREPARE. For examples, see Section 13.5, “Prepared Statements”.

Statement names are not case-sensitive. \texttt{preparable\_stmt} is either a string literal or a user variable that contains the text of the SQL statement. The text must represent a single statement, not multiple statements. Within the statement, \texttt{?} characters can be used as parameter markers to indicate where data values are to be bound to the query later when you execute it. The \texttt{?} characters should not be enclosed within quotation marks, even if you intend to bind them to string values. Parameter markers can be used only where data values should appear, not for SQL keywords, identifiers, and so forth.

If a prepared statement with the given name already exists, it is deallocated implicitly before the new statement is prepared. This means that if the new statement contains an error and cannot be prepared, an error is returned and no statement with the given name exists.

The scope of a prepared statement is the session within which it is created, which as several implications:

- A prepared statement created in one session is not available to other sessions.
- When a session ends, whether normally or abnormally, its prepared statements no longer exist. If auto-reconnect is enabled, the client is not notified that the connection was lost. For this reason, clients may wish to disable auto-reconnect. See Automatic Reconnection Control.
- A prepared statement created within a stored program continues to exist after the program finishes executing and can be executed outside the program later.
- A statement prepared in stored program context cannot refer to stored procedure or function parameters or local variables because they go out of scope when the program ends and would be unavailable were the statement to be executed later outside the program. As a workaround, refer instead to user-defined variables, which also have session scope; see Section 9.4, “User-Defined Variables”.

Beginning with MySQL 8.0.22, a parameter used in a prepared statement has its type determined when the statement is first prepared, and retains this type whenever EXECUTE is invoked for this prepared statement (unless the statement is reprepared, as explained later in this section). Rules for determining a parameter’s type are listed here:

- A parameter which is an operand of a binary arithmetic operator has the same data type as the other operand.
- If both operands of a binary arithmetic operator are parameters, the type of the parameters is decided by the context of the operator.
- If a parameter is the operand of a unary arithmetic operator, the parameter’s type is decided by the context of the operator.
PREPARE Statement

• If an arithmetic operator has no type-determining context, the derived type for any parameters involved is DOUBLE PRECISION. This can happen, for example, when the parameter is a top-level node in a SELECT list, or when it is part of a comparison operator.

• A parameter which is an operand of a character string operator has the same derived type as the aggregated type of the other operands. If all operands of the operator are parameters, the derived type is VARCHAR; its collation is determined by the value of collation_connection.

• A parameter which is an operand of a temporal operator has type DATETIME if the operator returns a DATETIME, TIME if the operator returns a TIME, and DATE if the operator returns a DATE.

• A parameter which is an operand of a binary comparison operator has the same derived type as the other operand of the comparison.

• A parameter that is an operand of a ternary comparison operator such as BETWEEN has the same derived type as the aggregated type of the other operands.

• A parameter that is an output operand of any of CASE, COALESCE, IF, IFNULL, or NULLIF has the same derived type as the aggregated type of the operator’s other output operands.

• If all output operands of any of CASE, COALESCE, IF, IFNULL, or NULLIF are parameters, or they are all NULL, the type of the parameter is decided by the context of the operator.

• If the parameter is an operand of any of CASE, COALESCE, IF, or IFNULL, and has no type-determining context, the derived type for each of the parameters involved is VARCHAR, and its collation is determined by the value of collation_connection.

• A parameter which is the operand of a CAST() has the same type as specified by the CAST().

• If a parameter is an immediate member of a SELECT list that is not part of an INSERT statement, the derived type of the parameter is VARCHAR, and its collation is determined by the value of collation_connection.

• If a parameter is an immediate member of a SELECT list that is part of an INSERT statement, the derived type of the parameter is the type of the corresponding column into which the parameter is inserted.

• If a parameter is used as source for an assignment in a SET clause of an UPDATE statement or in the ON DUPLICATE KEY UPDATE clause of an INSERT statement, the derived type of the parameter is the type of the corresponding column which is updated by the SET or ON DUPLICATE KEY UPDATE clause.

• If a parameter is an argument of a function, the derived type depends on the function’s return type.

For some combinations of actual type and derived type, an automatic repreparation of the statement is triggered, to ensure closer compatibility with previous versions of MySQL. Repreparation does not occur if any of the following conditions are true:

• NULL is used as the actual parameter value.

• A parameter is an operand of a CAST(). (Instead, a cast to the derived type is attempted, and an exception raised if the cast fails.)

• A parameter is a string. (In this case, an implicit CAST(? AS derived_type) is performed.)

• The derived type and actual type of the parameter are both INTEGER and have the same sign.

• The parameter's derived type is DECIMAL and its actual type is either DECIMAL or INTEGER.
EXECUTE Statement

- The derived type is **DOUBLE** and the actual type is any numeric type.
- Both the derived type and the actual type are string types.
- If the derived type is temporal and the actual type is temporal. **Exceptions:** The derived type is **TIME** and the actual type is not **TIME**; the derived type is **DATE** and the actual type is not **DATE**.
- The derived type is temporal and the actual type is numeric.

For cases other than those just listed, the statement is reprepared and the actual parameter types are used instead of the derived parameter types.

These rules also apply to a user variable referenced in a prepared statement.

Using a different data type for a given parameter or user variable within a prepared statement for executions of the statement subsequent to the first execution causes the statement to be reprepared. This is less efficient; it may also lead to the parameter's (or variable's) actual type to vary, and thus for results to be inconsistent, with subsequent executions of the prepared statement. For these reasons, it is advisable to use the same data type for a given parameter when re-executing a prepared statement.

### 13.5.2 EXECUTE Statement

```
EXECUTE stmt_name
   [USING @var_name [, @var_name] ...]
```

After preparing a statement with **PREPARE**, you execute it with an **EXECUTE** statement that refers to the prepared statement name. If the prepared statement contains any parameter markers, you must supply a **USING** clause that lists user variables containing the values to be bound to the parameters. Parameter values can be supplied only by user variables, and the **USING** clause must name exactly as many variables as the number of parameter markers in the statement.

You can execute a given prepared statement multiple times, passing different variables to it or setting the variables to different values before each execution.

For examples, see Section 13.5, “Prepared Statements”.

### 13.5.3 DEALLOCATE PREPARE Statement

```
{DEALLOCATE | DROP} PREPARE stmt_name
```

To deallocate a prepared statement produced with **PREPARE**, use a **DEALLOCATE PREPARE** statement that refers to the prepared statement name. Attempting to execute a prepared statement after deallocating it results in an error. If too many prepared statements are created and not deallocated by either the **DEALLOCATE PREPARE** statement or the end of the session, you might encounter the upper limit enforced by the **max_prepared_stmt_count** system variable.

For examples, see Section 13.5, “Prepared Statements”.

### 13.6 Compound Statement Syntax

This section describes the syntax for the **BEGIN . . . END** compound statement and other statements that can be used in the body of stored programs: Stored procedures and functions, triggers, and events. These objects are defined in terms of SQL code that is stored on the server for later invocation (see Chapter 25, **Stored Objects**).

A compound statement is a block that can contain other blocks; declarations for variables, condition handlers, and cursors; and flow control constructs such as loops and conditional tests.
BEGIN ... END Compound Statement

13.6.1 BEGIN ... END Compound Statement

BEGIN ... END syntax is used for writing compound statements, which can appear within stored programs (stored procedures and functions, triggers, and events). A compound statement can contain multiple statements, enclosed by the BEGIN and END keywords. statement_list represents a list of one or more statements, each terminated by a semicolon (;) statement delimiter. The statement_list itself is optional, so the empty compound statement (BEGIN END) is legal.

BEGIN ... END blocks can be nested.

Use of multiple statements requires that a client is able to send statement strings containing the ; statement delimiter. In the mysql command-line client, this is handled with the delimiter command. Changing the ; end-of-statement delimiter (for example, to //) permit ; to be used in a program body. For an example, see Section 25.1, “Defining Stored Programs”.

A BEGIN ... END block can be labeled. See Section 13.6.2, “Statement Labels”.

The optional [NOT] ATOMIC clause is not supported. This means that no transactional savepoint is set at the start of the instruction block and the BEGIN clause used in this context has no effect on the current transaction.

Note

Within all stored programs, the parser treats BEGIN [WORK] as the beginning of a BEGIN ... END block. To begin a transaction in this context, use START TRANSACTION instead.

13.6.2 Statement Labels

Labels are permitted for BEGIN ... END blocks and for the LOOP, REPEAT, and WHILE statements. Label use for those statements follows these rules:

• begin_label must be followed by a colon.

• begin_label can be given without end_label. If end_label is present, it must be the same as begin_label.

• end_label cannot be given without begin_label.
• Labels at the same nesting level must be distinct.

• Labels can be up to 16 characters long.

To refer to a label within the labeled construct, use an **ITERATE** or **LEAVE** statement. The following example uses those statements to continue iterating or terminate the loop:

```sql
CREATE PROCEDURE doiterate(p1 INT)
BEGIN
    label1: LOOP
        SET p1 = p1 + 1;
        IF p1 < 10 THEN ITERATE label1; END IF;
        LEAVE label1;
    END LOOP label1;
END;
```

The scope of a block label does not include the code for handlers declared within the block. For details, see Section 13.6.7.2, “DECLARE ... HANDLER Statement”.

### 13.6.3 DECLARE Statement

The **DECLARE** statement is used to define various items local to a program:

• Local variables. See Section 13.6.4, “Variables in Stored Programs”.

• Conditions and handlers. See Section 13.6.7, “Condition Handling”.

• Cursors. See Section 13.6.6, “Cursors”.

**DECLARE** is permitted only inside a **BEGIN ... END** compound statement and must be at its start, before any other statements.

Declarations must follow a certain order. Cursor declarations must appear before handler declarations. Variable and condition declarations must appear before cursor or handler declarations.

### 13.6.4 Variables in Stored Programs

System variables and user-defined variables can be used in stored programs, just as they can be used outside stored-program context. In addition, stored programs can use **DECLARE** to define local variables, and stored routines (procedures and functions) can be declared to take parameters that communicate values between the routine and its caller.

• To declare local variables, use the **DECLARE** statement, as described in Section 13.6.4.1, “Local Variable DECLARE Statement”.

• Variables can be set directly with the **SET** statement. See Section 13.7.6.1, “SET Syntax for Variable Assignment”.

• Results from queries can be retrieved into local variables using **SELECT ... INTO var_list** or by opening a cursor and using **FETCH ... INTO var_list**. See Section 13.2.13.1, “SELECT ... INTO Statement”, and Section 13.6.6, “Cursors”.

For information about the scope of local variables and how MySQL resolves ambiguous names, see Section 13.6.4.2, “Local Variable Scope and Resolution”.

It is not permitted to assign the value **DEFAULT** to stored procedure or function parameters or stored program local variables (for example with a **SET var_name = DEFAULT** statement). In MySQL 8.0, this results in a syntax error.
13.6.4.1 Local Variable DECLARE Statement

```sql
DECLARE var_name [, var_name] ... type [DEFAULT value]
```

This statement declares local variables within stored programs. To provide a default value for a variable, include a `DEFAULT` clause. The value can be specified as an expression; it need not be a constant. If the `DEFAULT` clause is missing, the initial value is `NULL`.

Local variables are treated like stored routine parameters with respect to data type and overflow checking. See Section 13.1.17, “CREATE PROCEDURE and CREATE FUNCTION Statements”.

Variable declarations must appear before cursor or handler declarations.

Local variable names are not case-sensitive. Permissible characters and quoting rules are the same as for other identifiers, as described in Section 9.2, “Schema Object Names”.

The scope of a local variable is the `BEGIN ... END` block within which it is declared. The variable can be referred to in blocks nested within the declaring block, except those blocks that declare a variable with the same name.

For examples of variable declarations, see Section 13.6.4.2, "Local Variable Scope and Resolution".

13.6.4.2 Local Variable Scope and Resolution

The scope of a local variable is the `BEGIN ... END` block within which it is declared. The variable can be referred to in blocks nested within the declaring block, except those blocks that declare a variable with the same name.

Because local variables are in scope only during stored program execution, references to them are not permitted in prepared statements created within a stored program. Prepared statement scope is the current session, not the stored program, so the statement could be executed after the program ends, at which point the variables would no longer be in scope. For example, `SELECT ... INTO local_var` cannot be used as a prepared statement. This restriction also applies to stored procedure and function parameters. See Section 13.5.1, “PREPARE Statement”.

A local variable should not have the same name as a table column. If an SQL statement, such as a `SELECT ... INTO` statement, contains a reference to a column and a declared local variable with the same name, MySQL currently interprets the reference as the name of a variable. Consider the following procedure definition:

```sql
CREATE PROCEDURE sp1 (x VARCHAR(5))
BEGIN
  DECLARE xname VARCHAR(5) DEFAULT 'bob';
  DECLARE newname VARCHAR(5);
  DECLARE xid INT;
  
  SELECT xname, id INTO newname, xid
  FROM table1 WHERE xname = xname;
  SELECT newname;
END;
```

MySQL interprets `xname` in the `SELECT` statement as a reference to the `xname` variable rather than the `xname` column. Consequently, when the procedure `sp1()` is called, the `newname` variable returns the value 'bob' regardless of the value of the `table1.xname` column.

Similarly, the cursor definition in the following procedure contains a `SELECT` statement that refers to `xname`. MySQL interprets this as a reference to the variable of that name rather than a column reference.

```sql
CREATE PROCEDURE sp2 (x VARCHAR(5))
```
BEGIN
    DECLARE xname VARCHAR(5) DEFAULT 'bob';
    DECLARE newname VARCHAR(5);
    DECLARE xid INT;
    DECLARE done TINYINT DEFAULT 0;
    DECLARE cur1 CURSOR FOR SELECT xname, id FROM table1;
    DECLARE CONTINUE HANDLER FOR NOT FOUND SET done = 1;
    OPEN cur1;
    read_loop: LOOP
        FETCH FROM cur1 INTO newname, xid;
        IF done THEN LEAVE read_loop; END IF;
        SELECT newname;
    END LOOP;
    CLOSE cur1;
END;

See also Section 25.8, “Restrictions on Stored Programs”.

13.6.5 Flow Control Statements

MySQL supports the IF, CASE, ITERATE, LEAVE LOOP, WHILE, and REPEAT constructs for flow control within stored programs. It also supports RETURN within stored functions.

Many of these constructs contain other statements, as indicated by the grammar specifications in the following sections. Such constructs may be nested. For example, an IF statement might contain a WHILE loop, which itself contains a CASE statement.

MySQL does not support FOR loops.

13.6.5.1 CASE Statement

```sql
CASE case_value
    WHEN when_value THEN statement_list
    [WHEN when_value THEN statement_list] ...
    [ELSE statement_list]
END CASE
```

Or:

```sql
CASE
    WHEN search_condition THEN statement_list
    [WHEN search_condition THEN statement_list] ...
    [ELSE statement_list]
END CASE
```

The CASE statement for stored programs implements a complex conditional construct.

**Note**

There is also a CASE operator, which differs from the CASE statement described here. See Section 12.5, “Flow Control Functions”. The CASE statement cannot have an ELSE NULL clause, and it is terminated with END CASE instead of END.

For the first syntax, case_value is an expression. This value is compared to the when_value expression in each WHEN clause until one of them is equal. When an equal when_value is found, the corresponding THEN clause statement_list executes. If no when_value is equal, the ELSE clause statement_list executes, if there is one.

This syntax cannot be used to test for equality with NULL because NULL = NULL is false. See Section 3.3.4.6, “Working with NULL Values”.
Flow Control Statements

For the second syntax, each `WHEN` clause `search_condition` expression is evaluated until one is true, at which point its corresponding `THEN` clause `statement_list` executes. If no `search_condition` is equal, the `ELSE` clause `statement_list` executes, if there is one.

If no `when_value` or `search_condition` matches the value tested and the `CASE` statement contains no `ELSE` clause, a `Case not found for CASE statement` error results.

Each `statement_list` consists of one or more SQL statements; an empty `statement_list` is not permitted.

To handle situations where no value is matched by any `WHEN` clause, use an `ELSE` containing an empty `BEGIN ... END` block, as shown in this example. (The indentation used here in the `ELSE` clause is for purposes of clarity only, and is not otherwise significant.)

```sql
DELIMITER |
CREATE PROCEDURE p()
BEGIN
  DECLARE v INT DEFAULT 1;
  CASE v
    WHEN 2 THEN SELECT v;
    WHEN 3 THEN SELECT 0;
    ELSE
      BEGIN
      END;
  END CASE;
END;
|
```

13.6.5.2 IF Statement

```sql
IF search_condition THEN statement_list
  [ELSEIF search_condition THEN statement_list] ...
  [ELSE statement_list]
END IF
```

The `IF` statement for stored programs implements a basic conditional construct.

**Note**

There is also an `IF()` function, which differs from the `IF statement` described here. See Section 12.5, “Flow Control Functions”. The `IF` statement can have `THEN`, `ELSE`, and `ELSEIF` clauses, and it is terminated with `END IF`.

If a given `search_condition` evaluates to true, the corresponding `THEN` or `ELSEIF` clause `statement_list` executes. If no `search_condition` matches, the `ELSE` clause `statement_list` executes.

Each `statement_list` consists of one or more SQL statements; an empty `statement_list` is not permitted.

An `IF ... END IF` block, like all other flow-control blocks used within stored programs, must be terminated with a semicolon, as shown in this example:

```sql
DELIMITER //
CREATE FUNCTION SimpleCompare(n INT, m INT)
  RETURNS VARCHAR(20)
BEGIN
  DECLARE s VARCHAR(20);
```
IF n > m THEN SET s = '>'; 
ELSEIF n = m THEN SET s = '='; 
ELSE SET s = '<'; 
END IF; 

SET s = CONCAT(n, ' ', s, ' ', m); 

RETURN s; 
END //
DELIMITER ;

As with other flow-control constructs, IF ... END IF blocks may be nested within other flow-control constructs, including other IF statements. Each IF must be terminated by its own END IF followed by a semicolon. You can use indentation to make nested flow-control blocks more easily readable by humans (although this is not required by MySQL), as shown here:

DELIMITER //

CREATE FUNCTION VerboseCompare (n INT, m INT)
RETURNS VARCHAR(50)
BEGIN
DECLARE s VARCHAR(50);

IF n = m THEN SET s = 'equals'; 
ELSE 
  IF n > m THEN SET s = 'greater'; 
  ELSE SET s = 'less'; 
  END IF;
  SET s = CONCAT('is ', s, ' than');
END IF;

SET s = CONCAT(n, ' ', s, ' ', m, '.');

RETURN s;
END //
DELIMITER ;

In this example, the inner IF is evaluated only if n is not equal to m.

13.6.5.3 ITERATE Statement

ITERATE label

ITERATE can appear only within LOOP, REPEAT, and WHILE statements. ITERATE means "start the loop again."

For an example, see Section 13.6.5.5, "LOOP Statement".

13.6.5.4 LEAVE Statement

LEAVE label

This statement is used to exit the flow control construct that has the given label. If the label is for the outermost stored program block, LEAVE exits the program.

LEAVE can be used within BEGIN ... END or loop constructs (LOOP, REPEAT, WHILE).

For an example, see Section 13.6.5.5, "LOOP Statement".
13.6.5.5 LOOP Statement

```
[begin_label:] LOOP
  statement_list
END LOOP [end_label]
```

LOOP implements a simple loop construct, enabling repeated execution of the statement list, which consists of one or more statements, each terminated by a semicolon (;) statement delimiter. The statements within the loop are repeated until the loop is terminated. Usually, this is accomplished with a LEAVE statement. Within a stored function, RETURN can also be used, which exits the function entirely.

Neglecting to include a loop-termination statement results in an infinite loop.

A LOOP statement can be labeled. For the rules regarding label use, see Section 13.6.2, “Statement Labels”.

Example:

```
CREATE PROCEDURE doiterate(p1 INT)
BEGIN
  label1: LOOP
    SET p1 = p1 + 1;
    IF p1 < 10 THEN
      ITERATE label1;
    END IF;
    LEAVE label1;
  END LOOP label1;
  SET @x = p1;
END;
```

13.6.5.6 REPEAT Statement

```
[begin_label:] REPEAT
  statement_list
UNTIL search_condition
END REPEAT [end_label]
```

The statement list within a REPEAT statement is repeated until the search_condition expression is true. Thus, a REPEAT always enters the loop at least once. statement_list consists of one or more statements, each terminated by a semicolon (;) statement delimiter.

A REPEAT statement can be labeled. For the rules regarding label use, see Section 13.6.2, “Statement Labels”.

Example:

```
mysql> delimiter //
mymysql> CREATE PROCEDURE dorepeat(p1 INT)
  BEGIN
    SET @x = 0;
    REPEAT
      SET @x = @x + 1;
      UNTIL @x > p1 END REPEAT;
  END
//
Query OK, 0 rows affected (0.00 sec)
mymysql> CALL dorepeat(1000)//
Query OK, 0 rows affected (0.00 sec)
mymysql> SELECT @x//
+------+
|   3058 |
+------+
```
13.6.5.7 RETURN Statement

```
RETURN expr
```

The `RETURN` statement terminates execution of a stored function and returns the value `expr` to the function caller. There must be at least one `RETURN` statement in a stored function. There may be more than one if the function has multiple exit points.

This statement is not used in stored procedures, triggers, or events. The `LEAVE` statement can be used to exit a stored program of those types.

13.6.5.8 WHILE Statement

```
[begin_label:] WHILE search_condition DO
  statement_list
END WHILE [end_label]
```

The statement list within a `WHILE` statement is repeated as long as the `search_condition` expression is true. `statement_list` consists of one or more SQL statements, each terminated by a semicolon (`;`) statement delimiter.

A `WHILE` statement can be labeled. For the rules regarding label use, see Section 13.6.2, "Statement Labels".

Example:

```
CREATE PROCEDURE dowhile()
BEGIN
  DECLARE v1 INT DEFAULT 5;
  WHILE v1 > 0 DO
    ...
    SET v1 = v1 - 1;
  END WHILE;
END;
```

13.6.6 Cursors

MySQL supports cursors inside stored programs. The syntax is as in embedded SQL. Cursors have these properties:

- Asensitive: The server may or may not make a copy of its result table
- Read only: Not updatable
- Nonscrollable: Can be traversed only in one direction and cannot skip rows

Cursor declarations must appear before handler declarations and after variable and condition declarations.

Example:

```
CREATE PROCEDURE curdemo()
BEGIN
  DECLARE done INT DEFAULT FALSE;
  DECLARE a CHAR(16);
```
DECLARE b, c INT;
DECLARE cur1 CURSOR FOR SELECT id, data FROM test.t1;
DECLARE cur2 CURSOR FOR SELECT i FROM test.t2;
DECLARE CONTINUE HANDLER FOR NOT FOUND SET done = TRUE;

OPEN cur1;
OPEN cur2;

read_loop: LOOP
  FETCH cur1 INTO a, b;
  FETCH cur2 INTO c;
  IF done THEN
    LEAVE read_loop;
  END IF;
  IF b < c THEN
    INSERT INTO test.t3 VALUES (a, b);
  ELSE
    INSERT INTO test.t3 VALUES (a, c);
  END IF;
END LOOP;

CLOSE cur1;
CLOSE cur2;
END;

13.6.6.1 Cursor CLOSE Statement

CLOSE cursor_name

This statement closes a previously opened cursor. For an example, see Section 13.6.6, “Cursors”.

An error occurs if the cursor is not open.

If not closed explicitly, a cursor is closed at the end of the BEGIN ... END block in which it was declared.

13.6.6.2 Cursor DECLARE Statement

DECLARE cursor_name CURSOR FOR select_statement

This statement declares a cursor and associates it with a SELECT statement that retrieves the rows to be traversed by the cursor. To fetch the rows later, use a FETCH statement. The number of columns retrieved by the SELECT statement must match the number of output variables specified in the FETCH statement.

The SELECT statement cannot have an INTO clause.

Cursor declarations must appear before handler declarations and after variable and condition declarations.

A stored program may contain multiple cursor declarations, but each cursor declared in a given block must have a unique name. For an example, see Section 13.6.6, “Cursors”.

For information available through SHOW statements, it is possible in many cases to obtain equivalent information by using a cursor with an INFORMATION_SCHEMA table.

13.6.6.3 Cursor FETCH Statement

FETCH [[NEXT] FROM] cursor_name INTO var_name [, var_name] ...

This statement fetches the next row for the SELECT statement associated with the specified cursor (which must be open), and advances the cursor pointer. If a row exists, the fetched columns are stored in the named variables. The number of columns retrieved by the SELECT statement must match the number of output variables specified in the FETCH statement.
If no more rows are available, a No Data condition occurs with SQLSTATE value '02000'. To detect this condition, you can set up a handler for it (or for a NOT FOUND condition). For an example, see Section 13.6.6, “Cursors”.

Be aware that another operation, such as a SELECT or another FETCH, may also cause the handler to execute by raising the same condition. If it is necessary to distinguish which operation raised the condition, place the operation within its own BEGIN ... END block so that it can be associated with its own handler.

**13.6.6.4 Cursor OPEN Statement**

```sql
OPEN cursor_name
```

This statement opens a previously declared cursor. For an example, see Section 13.6.6, “Cursors”.

**13.6.6.5 Restrictions on Server-Side Cursors**

Server-side cursors are implemented in the C API using the `mysql_stmt_attr_set()` function. The same implementation is used for cursors in stored routines. A server-side cursor enables a result set to be generated on the server side, but not transferred to the client except for those rows that the client requests. For example, if a client executes a query but is only interested in the first row, the remaining rows are not transferred.

In MySQL, a server-side cursor is materialized into an internal temporary table. Initially, this is a MEMORY table, but is converted to a MyISAM table when its size exceeds the minimum value of the `max_heap_table_size` and `tmp_table_size` system variables. The same restrictions apply to internal temporary tables created to hold the result set for a cursor as for other uses of internal temporary tables. See Section 8.4.4, “Internal Temporary Table Use in MySQL”. One limitation of the implementation is that for a large result set, retrieving its rows through a cursor might be slow.

Cursors are read only; you cannot use a cursor to update rows.

`UPDATE WHERE CURRENT OF` and `DELETE WHERE CURRENT OF` are not implemented, because updatable cursors are not supported.

Cursors are nonholdable (not held open after a commit).

Cursors are asensitive.

Cursors are nonscrollable.

Cursors are not named. The statement handler acts as the cursor ID.

You can have open only a single cursor per prepared statement. If you need several cursors, you must prepare several statements.

You cannot use a cursor for a statement that generates a result set if the statement is not supported in prepared mode. This includes statements such as `CHECK TABLE`, `HANDLER READ`, and `SHOW BINLOG EVENTS`.

**13.6.7 Condition Handling**

Conditions may arise during stored program execution that require special handling, such as exiting the current program block or continuing execution. Handlers can be defined for general conditions such as warnings or exceptions, or for specific conditions such as a particular error code. Specific conditions can be assigned names and referred to that way in handlers.
**Condition Handling**

To name a condition, use the `DECLARE ... CONDITION` statement. To declare a handler, use the `DECLARE ... HANDLER` statement. See Section 13.6.7.1, “DECLARE ... CONDITION Statement”, and Section 13.6.7.2, “DECLARE ... HANDLER Statement”. For information about how the server chooses handlers when a condition occurs, see Section 13.6.7.6, “Scope Rules for Handlers”.

To raise a condition, use the `SIGNAL` statement. To modify condition information within a condition handler, use `RESIGNAL`. See Section 13.6.7.1, “DECLARE ... CONDITION Statement”, and Section 13.6.7.2, “DECLARE ... HANDLER Statement”.

To retrieve information from the diagnostics area, use the `GET DIAGNOSTICS` statement (see Section 13.6.7.3, “GET DIAGNOSTICS Statement”). For information about the diagnostics area, see Section 13.6.7.7, “The MySQL Diagnostics Area”.

### 13.6.7.1 DECLARE ... CONDITION Statement

```sql
DECLARE condition_name CONDITION FOR condition_value

condition_value: { mysql_error_code | SQLSTATE [VALUE] sqlstate_value }
```

The `DECLARE ... CONDITION` statement declares a named error condition, associating a name with a condition that needs specific handling. The name can be referred to in a subsequent `DECLARE ... HANDLER` statement (see Section 13.6.7.2, “DECLARE ... HANDLER Statement”).

Condition declarations must appear before cursor or handler declarations.

The `condition_value` for `DECLARE ... CONDITION` indicates the specific condition or class of conditions to associate with the condition name. It can take the following forms:

- `mysql_error_code`: An integer literal indicating a MySQL error code.
  
  Do not use MySQL error code 0 because that indicates success rather than an error condition. For a list of MySQL error codes, see Server Error Message Reference.

- `SQLSTATE [VALUE] sqlstate_value`: A 5-character string literal indicating an SQLSTATE value.
  
  Do not use SQLSTATE values that begin with '00' because those indicate success rather than an error condition. For a list of SQLSTATE values, see Server Error Message Reference.

Condition names referred to in `SIGNAL` or use `RESIGNAL` statements must be associated with SQLSTATE values, not MySQL error codes.

Using names for conditions can help make stored program code clearer. For example, this handler applies to attempts to drop a nonexistent table, but that is apparent only if you know that 1051 is the MySQL error code for “unknown table”:

```sql
DECLARE CONTINUE HANDLER FOR 1051
BEGIN
  -- body of handler
END;
```

By declaring a name for the condition, the purpose of the handler is more readily seen:

```sql
DECLARE no_such_table CONDITION FOR 1051;
DECLARE CONTINUE HANDLER FOR no_such_table
BEGIN
  -- body of handler
```
Here is a named condition for the same condition, but based on the corresponding SQLSTATE value rather than the MySQL error code:

```sql
DECLARE no_such_table CONDITION FOR SQLSTATE '42S02';
DECLARE CONTINUE HANDLER FOR no_such_table
BEGIN
    -- body of handler
END;
```

### 13.6.7.2 DECLARE ... HANDLER Statement

```sql
DECLARE handler_action HANDLER
    FOR condition_value [, condition_value] ...
    statement

handler_action: {
    CONTINUE
    | EXIT
    | UNDO
}

condition_value: {
    mysql_error_code
    | SQLSTATE [VALUE] sqlstate_value
    | condition_name
    | SQLWARNING
    | NOT FOUND
    | SQLEXCEPTION
}
```

The `DECLARE ... HANDLER` statement specifies a handler that deals with one or more conditions. If one of these conditions occurs, the specified `statement` executes. `statement` can be a simple statement such as `SET var_name = value`, or a compound statement written using `BEGIN` and `END` (see Section 13.6.1, "BEGIN ... END Compound Statement").

Handler declarations must appear after variable or condition declarations.

The `handler_action` value indicates what action the handler takes after execution of the handler statement:

- **CONTINUE**: Execution of the current program continues.
- **EXIT**: Execution terminates for the `BEGIN ... END` compound statement in which the handler is declared. This is true even if the condition occurs in an inner block.
- **UNDO**: Not supported.

The `condition_value` for `DECLARE ... HANDLER` indicates the specific condition or class of conditions that activates the handler. It can take the following forms:

- **mysql_error_code**: An integer literal indicating a MySQL error code, such as 1051 to specify "unknown table":

```sql
DECLARE CONTINUE HANDLER FOR 1051
BEGIN
    -- body of handler
END;
```

Do not use MySQL error code 0 because that indicates success rather than an error condition. For a list of MySQL error codes, see Server Error Message Reference.
Condition Handling

- **SQLSTATE [VALUE]** `sqlstate_value`: A 5-character string literal indicating an SQLSTATE value, such as `42S01` to specify “unknown table”:

```
DECLARE CONTINUE HANDLER FOR SQLSTATE '42S02'
  BEGIN
  -- body of handler
  END;
```

Do not use SQLSTATE values that begin with `00` because those indicate success rather than an error condition. For a list of SQLSTATE values, see Server Error Message Reference.

- **condition_name**: A condition name previously specified with DECLARE ... CONDITION. A condition name can be associated with a MySQL error code or SQLSTATE value. See Section 13.6.7.1, “DECLARE ... CONDITION Statement”.

- **SQLWARNING**: Shorthand for the class of SQLSTATE values that begin with `01`.

```
DECLARE CONTINUE HANDLER FOR SQLWARNING
  BEGIN
  -- body of handler
  END;
```

- **NOT FOUND**: Shorthand for the class of SQLSTATE values that begin with `02`. This is relevant within the context of cursors and is used to control what happens when a cursor reaches the end of a data set. If no more rows are available, a No Data condition occurs with SQLSTATE value `02000`. To detect this condition, you can set up a handler for it or for a NOT FOUND condition.

```
DECLARE CONTINUE HANDLER FOR NOT FOUND
  BEGIN
  -- body of handler
  END;
```

For another example, see Section 13.6.6, “Cursors”. The NOT FOUND condition also occurs for SELECT ... INTO var_list statements that retrieve no rows.

- **SQLEXCEPTION**: Shorthand for the class of SQLSTATE values that do not begin with `00`, `01`, or `02`.

```
DECLARE CONTINUE HANDLER FOR SQLEXCEPTION
  BEGIN
  -- body of handler
  END;
```

For information about how the server chooses handlers when a condition occurs, see Section 13.6.7.6, “Scope Rules for Handlers”.

If a condition occurs for which no handler has been declared, the action taken depends on the condition class:

- For SQLEXCEPTION conditions, the stored program terminates at the statement that raised the condition, as if there were an EXIT handler. If the program was called by another stored program, the calling program handles the condition using the handler selection rules applied to its own handlers.

- For SQLWARNING conditions, the program continues executing, as if there were a CONTINUE handler.

- For NOT FOUND conditions, if the condition was raised normally, the action is CONTINUE. If it was raised by SIGNAL or RESIGNAL, the action is EXIT.

The following example uses a handler for SQLSTATE `23000`, which occurs for a duplicate-key error:

```
mysql> CREATE TABLE test.t (s1 INT, PRIMARY KEY (s1));
```
Condition Handling

Query OK, 0 rows affected (0.00 sec)

mysql> delimiter //</mysql>

mysql> CREATE PROCEDURE handlerdemo ()
BEGIN
    DECLARE CONTINUE HANDLER FOR SQLSTATE '23000' SET @x2 = 1;
    SET @x = 1;
    INSERT INTO test.t VALUES (1);
    SET @x = 2;
    INSERT INTO test.t VALUES (1);
    SET @x = 3;
END;
//
Query OK, 0 rows affected (0.00 sec)

mysql> CALL handlerdemo()//
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @x//
+-----+
| @x   |
+-----+
| 3    |
+-----+
1 row in set (0.00 sec)

Notice that \@x is 3 after the procedure executes, which shows that execution continued to the end of the procedure after the error occurred. If the DECLARE ... HANDLER statement had not been present, MySQL would have taken the default action (EXIT) after the second INSERT failed due to the PRIMARY KEY constraint, and SELECT @x would have returned 2.

To ignore a condition, declare a CONTINUE handler for it and associate it with an empty block. For example:

DECLARE CONTINUE HANDLER FOR SQLWARNING BEGIN END;

The scope of a block label does not include the code for handlers declared within the block. Therefore, the statement associated with a handler cannot use ITERATE or LEAVE to refer to labels for blocks that enclose the handler declaration. Consider the following example, where the REPEAT block has a label of retry:

CREATE PROCEDURE p ()
BEGIN
    DECLARE i INT DEFAULT 3;
    retry:
    REPEAT
        BEGIN
            DECLARE CONTINUE HANDLER FOR SQLWARNING
            BEGIN
                ITERATE retry; # illegal
            END;
            IF i < 0 THEN
                LEAVE retry; # legal
            END IF;
            SET i = i - 1;
        END;
        UNTIL FALSE END REPEAT;
    END;

The retry label is in scope for the IF statement within the block. It is not in scope for the CONTINUE handler, so the reference there is invalid and results in an error:

ERROR 1308 (42000): LEAVE with no matching label: retry
To avoid references to outer labels in handlers, use one of these strategies:

- To leave the block, use an **EXIT** handler. If no block cleanup is required, the **BEGIN ... END** handler body can be empty:

```sql
DECLARE EXIT HANDLER FOR SQLWARNING BEGIN END;
```

Otherwise, put the cleanup statements in the handler body:

```sql
DECLARE EXIT HANDLER FOR SQLWARNING
BEGIN
    block cleanup statements
END;
```

- To continue execution, set a status variable in a **CONTINUE** handler that can be checked in the enclosing block to determine whether the handler was invoked. The following example uses the variable `done` for this purpose:

```sql
CREATE PROCEDURE p ()
BEGIN
    DECLARE i INT DEFAULT 3;
    DECLARE done INT DEFAULT FALSE;
    retry:
    REPEAT
        DECLARE CONTINUE HANDLER FOR SQLWARNING
        BEGIN
            SET done = TRUE;
        END;
        IF done OR i < 0 THEN
            LEAVE retry;
        END IF;
        SET i = i - 1;
    END;
    UNTIL FALSE END REPEAT;
END;
```

### 13.6.7.3 GET DIAGNOSTICS Statement

GET [CURRENT | STACKED] DIAGNOSTICS {
    statement_information_item
        [, statement_information_item] ... |
    | CONDITION condition_number
        condition_information_item
        [, condition_information_item] ... |
}

**statement_information_item**:

```
target = statement_information_item_name
```

**condition_information_item**:

```
target = condition_information_item_name
```

**statement_information_item_name**:

```
{ NUMBER |
    | ROW_COUNT
}
```

**condition_information_item_name**:

```
{ CLASS_ORIGIN |
    | SUBCLASS_ORIGIN |
    | RETURNED_SQLSTATE |
    | MESSAGE_TEXT |
    | MYSQL_ERRNO |
    | CONSTRAINT_CATALOG
```
SQL statements produce diagnostic information that populates the diagnostics area. The `GET DIAGNOSTICS` statement enables applications to inspect this information. (You can also use `SHOW WARNINGS` or `SHOW ERRORS` to see conditions or errors.)

No special privileges are required to execute `GET DIAGNOSTICS`.

The keyword `CURRENT` means to retrieve information from the current diagnostics area. The keyword `STACKED` means to retrieve information from the second diagnostics area, which is available only if the current context is a condition handler. If neither keyword is given, the default is to use the current diagnostics area.

The `GET DIAGNOSTICS` statement is typically used in a handler within a stored program. It is a MySQL extension that `GET [CURRENT] DIAGNOSTICS` is permitted outside handler context to check the execution of any SQL statement. For example, if you invoke the `mysql` client program, you can enter these statements at the prompt:

```sql
mysql> DROP TABLE test.no_such_table;
ERROR 1051 (42S02): Unknown table 'test.no_such_table'
mysql> GET DIAGNOSTICS CONDITION 1
    @p1 = RETURNED_SQLSTATE, @p2 = MESSAGE_TEXT;
mysql> SELECT @p1, @p2;
+-------+------------------------------------+
| @p1   | @p2                                |
| 42S02 | Unknown table 'test.no_such_table' |
+-------+------------------------------------+
```

This extension applies only to the current diagnostics area. It does not apply to the second diagnostics area because `GET STACKED DIAGNOSTICS` is permitted only if the current context is a condition handler. If that is not the case, a `GET STACKED DIAGNOSTICS when handler not active` error occurs.

For a description of the diagnostics area, see Section 13.6.7.7, “The MySQL Diagnostics Area”. Briefly, it contains two kinds of information:

- Statement information, such as the number of conditions that occurred or the affected-rows count.
- Condition information, such as the error code and message. If a statement raises multiple conditions, this part of the diagnostics area has a condition area for each one. If a statement raises no conditions, this part of the diagnostics area is empty.

For a statement that produces three conditions, the diagnostics area contains statement and condition information like this:

```sql
Statement information:
    row count
    ... other statement information items ...
Condition area list:
    Condition area 1:
        error code for condition 1
        error message for condition 1
```
GET DIAGNOSTICS can obtain either statement or condition information, but not both in the same statement:

- To obtain statement information, retrieve the desired statement items into target variables. This instance of GET DIAGNOSTICS assigns the number of available conditions and the rows-affected count to the user variables @p1 and @p2:

  ```sql
  GET DIAGNOSTICS @p1 = NUMBER, @p2 = ROW_COUNT;
  ```

- To obtain condition information, specify the condition number and retrieve the desired condition items into target variables. This instance of GET_DIAGNOSTICS assigns the SQLSTATE value and error message to the user variables @p3 and @p4:

  ```sql
  GET DIAGNOSTICS CONDITION 1
  @p3 = RETURNED_SQLSTATE, @p4 = MESSAGE_TEXT;
  ```

The retrieval list specifies one or more target = item_name assignments, separated by commas. Each assignment names a target variable and either a statement_information_item_name or condition_information_item_name designator, depending on whether the statement retrieves statement or condition information.

Valid target designators for storing item information can be stored procedure or function parameters, stored program local variables declared with DECLARE, or user-defined variables.

Valid condition_number designators can be stored procedure or function parameters, stored program local variables declared with DECLARE, user-defined variables, system variables, or literals. A character literal may include a _charset introducer. A warning occurs if the condition number is not in the range from 1 to the number of condition areas that have information. In this case, the warning is added to the diagnostics area without clearing it.

When a condition occurs, MySQL does not populate all condition items recognized by GET_DIAGNOSTICS. For example:

```sql
mysql> GET DIAGNOSTICS CONDITION 1
    > @p5 = SCHEMA_NAME, @p6 = TABLE_NAME;
mysql> SELECT @p5, @p6;
+---------+------+
| @p5    | @p6  |
|        |      |
+---------+------+

In standard SQL, if there are multiple conditions, the first condition relates to the SQLSTATE value returned for the previous SQL statement. In MySQL, this is not guaranteed. To get the main error, you cannot do this:

```sql
GET DIAGNOSTICS CONDITION 1 @errno = MYSQL_ERRNO;
```
For information about permissible statement and condition information items, and which ones are populated when a condition occurs, see Diagnostics Area Information Items.

Here is an example that uses GET DIAGNOSTICS and an exception handler in stored procedure context to assess the outcome of an insert operation. If the insert was successful, the procedure uses GET DIAGNOSTICS to get the rows-affected count. This shows that you can use GET DIAGNOSTICS multiple times to retrieve information about a statement as long as the current diagnostics area has not been cleared.

CREATE PROCEDURE do_insert(value INT)
BEGIN
  -- Declare variables to hold diagnostics area information
  DECLARE code CHAR(5) DEFAULT '00000';
  DECLARE msg TEXT;
  DECLARE nrows INT;
  DECLARE result TEXT;
  -- Declare exception handler for failed insert
  DECLARE CONTINUE HANDLER FOR SQLEXCEPTION
  BEGIN
    GET DIAGNOSTICS CONDITION 1
    code = RETURNED_SQLSTATE, msg = MESSAGE_TEXT;
  END;
  -- Perform the insert
  INSERT INTO t1 (int_col) VALUES(value);
  -- Check whether the insert was successful
  IF code = '00000' THEN
    GET DIAGNOSTICS nrows = ROW_COUNT;
    SET result = CONCAT('insert succeeded, row count = ',nrows);
  ELSE
    SET result = CONCAT('insert failed, error = ',code,', message = ',msg);
  END IF;
  -- Say what happened
  SELECT result;
END;

Suppose that t1.int_col is an integer column that is declared as NOT NULL. The procedure produces these results when invoked to insert non-NULL and NULL values, respectively:

mysql> CALL do_insert(1);
+---------------------------------+
| result                          |
+---------------------------------+
| insert succeeded, row count = 1 |
+---------------------------------+

mysql> CALL do_insert(NULL);
+-------------------------------------------------------------------------+
| result                                                                  |
+-------------------------------------------------------------------------+
| insert failed, error = 23000, message = Column 'int_col' cannot be null |
+-------------------------------------------------------------------------+

When a condition handler activates, a push to the diagnostics area stack occurs:

- The first (current) diagnostics area becomes the second (stacked) diagnostics area and a new current diagnostics area is created as a copy of it.

- GET [CURRENT] DIAGNOSTICS and GET STACKED DIAGNOSTICS can be used within the handler to access the contents of the current and stacked diagnostics areas.

- Initially, both diagnostics areas return the same result, so it is possible to get information from the current diagnostics area about the condition that activated the handler, as long as you execute no statements within the handler that change its current diagnostics area.
• However, statements executing within the handler can modify the current diagnostics area, clearing and setting its contents according to the normal rules (see How the Diagnostics Area is Cleared and Populated).

A more reliable way to obtain information about the handler-activating condition is to use the stacked diagnostics area, which cannot be modified by statements executing within the handler except RESIGNAL. For information about when the current diagnostics area is set and cleared, see Section 13.6.7.7, “The MySQL Diagnostics Area”.

The next example shows how GET STACKED DIAGNOSTICS can be used within a handler to obtain information about the handled exception, even after the current diagnostics area has been modified by handler statements.

Within a stored procedure `p()`, we attempt to insert two values into a table that contains a TEXT NOT NULL column. The first value is a non-NULL string and the second is NULL. The column prohibits NULL values, so the first insert succeeds but the second causes an exception. The procedure includes an exception handler that maps attempts to insert NULL into inserts of the empty string:

```sql
DROP TABLE IF EXISTS t1;
CREATE TABLE t1 (c1 TEXT NOT NULL);
DROP PROCEDURE IF EXISTS p;
delimiter //
CREATE PROCEDURE p ()
BEGIN
  -- Declare variables to hold diagnostics area information
  DECLARE errcount INT;
  DECLARE errno INT;
  DECLARE msg TEXT;
  DECLARE EXIT HANDLER FOR SQLEXCEPTION
  BEGIN
    -- Here the current DA is nonempty because no prior statements
    -- executing within the handler have cleared it
    GET CURRENT DIAGNOSTICS CONDITION 1
      errno = MYSQL_ERRNO, msg = MESSAGE_TEXT;
    SELECT 'current DA before mapped insert' AS op, errno, msg;
    GET STACKED DIAGNOSTICS CONDITION 1
      errno = MYSQL_ERRNO, msg = MESSAGE_TEXT;
    SELECT 'stacked DA before mapped insert' AS op, errno, msg;
    -- Map attempted NULL insert to empty string insert
    INSERT INTO t1 (c1) VALUES('');
    -- Here the current DA should be empty (if the INSERT succeeded),
    -- so check whether there are conditions before attempting to
    -- obtain condition information
    GET CURRENT DIAGNOSTICS errcount = NUMBER;
    IF errcount = 0
      THEN
        SELECT 'mapped insert succeeded, current DA is empty' AS op;
      ELSE
        GET CURRENT DIAGNOSTICS CONDITION 1
          errno = MYSQL_ERRNO, msg = MESSAGE_TEXT;
        SELECT 'current DA after mapped insert' AS op, errno, msg;
      END IF;
    GET STACKED DIAGNOSTICS CONDITION 1
      errno = MYSQL_ERRNO, msg = MESSAGE_TEXT;
    SELECT 'stacked DA after mapped insert' AS op, errno, msg;
    END;
    INSERT INTO t1 (c1) VALUES('string 1');
    INSERT INTO t1 (c1) VALUES(NULL);
  END;
  //
delimiter ;
CALL p();
```
SELECT * FROM t1;

When the handler activates, a copy of the current diagnostics area is pushed to the diagnostics area stack. The handler first displays the contents of the current and stacked diagnostics areas, which are both the same initially:

| op                              | errno | msg                        |
|---------------------------------+-------+----------------------------|
| current DA before mapped insert | 1048  | Column 'c1' cannot be null |
| stacked DA before mapped insert | 1048  | Column 'c1' cannot be null |

Statements executing after the `GET DIAGNOSTICS` statements may reset the current diagnostics area. For example, the handler maps the `NULL` insert to an empty-string insert and displays the result. The new insert succeeds and clears the current diagnostics area, but the stacked diagnostics area remains unchanged and still contains information about the condition that activated the handler:

<table>
<thead>
<tr>
<th>op</th>
</tr>
</thead>
<tbody>
<tr>
<td>mapped insert succeeded, current DA is empty</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>op</th>
<th>errno</th>
<th>msg</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>1048</td>
<td>Column 'c1' cannot be null</td>
</tr>
</tbody>
</table>

When the condition handler ends, its current diagnostics area is popped from the stack and the stacked diagnostics area becomes the current diagnostics area in the stored procedure.

After the procedure returns, the table contains two rows. The empty row results from the attempt to insert `NULL` that was mapped to an empty-string insert:

<table>
<thead>
<tr>
<th>c1</th>
</tr>
</thead>
<tbody>
<tr>
<td>string 1</td>
</tr>
</tbody>
</table>

In the preceding example, the first two `GET DIAGNOSTICS` statements within the condition handler that retrieve information from the current and stacked diagnostics areas return the same values. This is not the case if statements that reset the current diagnostics area execute earlier within the handler. Suppose that `p()` is rewritten to place the `DECLARE` statements within the handler definition rather than preceding it:

```
CREATE PROCEDURE p ()
BEGIN
    DECLARE EXIT HANDLER FOR SQLEXCEPTION
    BEGIN
        -- Declare variables to hold diagnostics area information
        DECLARE errcount INT;
        DECLARE errno INT;
        DECLARE msg TEXT;
```
GET CURRENT DIAGNOSTICS CONDITION 1
  errno = MYSQL_ERRNO, msg = MESSAGE_TEXT;
SELECT 'current DA before mapped insert' AS op, errno, msg;
GET STACKED DIAGNOSTICS CONDITION 1
  errno = MYSQL_ERRNO, msg = MESSAGE_TEXT;
SELECT 'stacked DA before mapped insert' AS op, errno, msg;
...

In this case, the result is version dependent:

- Before MySQL 5.7.2, DECLARE does not change the current diagnostics area, so the first two GET DIAGNOSTICS statements return the same result, just as in the original version of p().

In MySQL 5.7.2, work was done to ensure that all nondiagnostic statements populate the diagnostics area, per the SQL standard. DECLARE is one of them, so in 5.7.2 and higher, DECLARE statements executing at the beginning of the handler clear the current diagnostics area and the GET DIAGNOSTICS statements produce different results:

```
| op                              | errno | msg                      |
|---------------------------------+-------+--------------------------|
| current DA before mapped insert | NULL  | NULL                     |
+---------------------------------+-------+--------------------------+
| op                              | errno | msg                      |
| stacked DA before mapped insert | 1048  | Column 'c1' cannot be null|
+---------------------------------+-------+--------------------------+
```

To avoid this issue within a condition handler when seeking to obtain information about the condition that activated the handler, be sure to access the stacked diagnostics area, not the current diagnostics area.

### 13.6.7.4 RESIGNAL Statement

RESIGNAL [condition_value]
  [SET signal_information_item
   [, signal_information_item] ...]

condition_value: 
  { SQLSTATE [VALUE] sqlstate_value
    | condition_name
  }

signal_information_item:
  condition_information_item_name = simple_value_specification

condition_information_item_name: 
  { CLASS_ORIGIN
    | SUBCLASS_ORIGIN
    | MESSAGE_TEXT
    | MYSQL_ERRNO
    | CONSTRAINT_CATALOG
    | CONSTRAINT_SCHEMA
    | CONSTRAINT_NAME
    | CATALOG_NAME
    | SCHEMA_NAME
    | TABLE_NAME
    | COLUMN_NAME
    | CURSOR_NAME
  }

condition_name, simple_value_specification:
  (see following discussion)
**RESIGNAL** passes on the error condition information that is available during execution of a condition handler within a compound statement inside a stored procedure or function, trigger, or event. **RESIGNAL** may change some or all information before passing it on. **RESIGNAL** is related to **SIGNAL**, but instead of originating a condition as **SIGNAL** does, **RESIGNAL** relays existing condition information, possibly after modifying it.

**RESIGNAL** makes it possible to both handle an error and return the error information. Otherwise, by executing an SQL statement within the handler, information that caused the handler's activation is destroyed. **RESIGNAL** also can make some procedures shorter if a given handler can handle part of a situation, then pass the condition “up the line” to another handler.

No privileges are required to execute the **RESIGNAL** statement.

All forms of **RESIGNAL** require that the current context be a condition handler. Otherwise, **RESIGNAL** is illegal and a **RESIGNAL when handler not active** error occurs.

To retrieve information from the diagnostics area, use the **GET DIAGNOSTICS** statement (see Section 13.6.7.3, “GET DIAGNOSTICS Statement”). For information about the diagnostics area, see Section 13.6.7.7, “The MySQL Diagnostics Area”.

- **RESIGNAL Overview**
- **RESIGNAL Alone**
- **RESIGNAL with New Signal Information**
- **RESIGNAL with a Condition Value and Optional New Signal Information**
- **RESIGNAL Requires Condition Handler Context**

**RESIGNAL Overview**

For `condition_value` and `signal_information_item`, the definitions and rules are the same for **RESIGNAL** as for **SIGNAL**. For example, the `condition_value` can be an **SQLSTATE** value, and the value can indicate errors, warnings, or “not found.” For additional information, see Section 13.6.7.5, “**SIGNAL** Statement”.

The **RESIGNAL** statement takes `condition_value` and **SET** clauses, both of which are optional. This leads to several possible uses:

- **RESIGNAL** alone:
  ```sql
  RESIGNAL;
  ```

- **RESIGNAL** with new signal information:
  ```sql
  RESIGNAL SET `signal_information_item` [, `signal_information_item`] ...;
  ```

- **RESIGNAL** with a condition value and possibly new signal information:
  ```sql
  RESIGNAL `condition_value`
  [SET `signal_information_item` [, `signal_information_item`] ...];
  ```

These use cases all cause changes to the diagnostics and condition areas:

- A diagnostics area contains one or more condition areas.

- A condition area contains condition information items, such as the **SQLSTATE** value, **MYSQL_ERRNO**, or **MESSAGE_TEXT**.

---

3073
There is a stack of diagnostics areas. When a handler takes control, it pushes a diagnostics area to the top of the stack, so there are two diagnostics areas during handler execution:

- The first (current) diagnostics area, which starts as a copy of the last diagnostics area, but is overwritten by the first statement in the handler that changes the current diagnostics area.
- The last (stacked) diagnostics area, which has the condition areas that were set up before the handler took control.

The maximum number of condition areas in a diagnostics area is determined by the value of the `max_error_count` system variable. See Diagnostics Area-Related System Variables.

### RESIGNAL Alone

A simple `RESIGNAL` alone means “pass on the error with no change.” It restores the last diagnostics area and makes it the current diagnostics area. That is, it “pops” the diagnostics area stack.

Within a condition handler that catches a condition, one use for `RESIGNAL` alone is to perform some other actions, and then pass on without change the original condition information (the information that existed before entry into the handler).

**Example:**

```sql
DROP TABLE IF EXISTS xx;
delimiter //
CREATE PROCEDURE p ()
BEGIN
    DECLARE EXIT HANDLER FOR SQLEXCEPTION
    BEGIN
        SET @error_count = @error_count + 1;
        IF @a = 0 THEN RESIGNAL; END IF;
    END;
    DROP TABLE xx;
END//
delimiter;
SET @error_count = 0;
SET @a = 0;
CALL p();
```

Suppose that the `DROP TABLE xx` statement fails. The diagnostics area stack looks like this:

```
DA 1. ERROR 1051 (42S02): Unknown table 'xx'
```

Then execution enters the `EXIT` handler. It starts by pushing a diagnostics area to the top of the stack, which now looks like this:

```
DA 1. ERROR 1051 (42S02): Unknown table 'xx'
DA 2. ERROR 1051 (42S02): Unknown table 'xx'
```

At this point, the contents of the first (current) and second (stacked) diagnostics areas are the same. The first diagnostics area may be modified by statements executing subsequently within the handler.

Usually a procedure statement clears the first diagnostics area. `BEGIN` is an exception, it does not clear, it does nothing. `SET` is not an exception, it clears, performs the operation, and produces a result of “success.” The diagnostics area stack now looks like this:

```
DA 1. ERROR 0000 (00000): Successful operation
DA 2. ERROR 1051 (42S02): Unknown table 'xx'
```

At this point, if `@a = 0`, `RESIGNAL` pops the diagnostics area stack, which now looks like this:

```
DA 1. ERROR 1051 (42S02): Unknown table 'xx'
```
And that is what the caller sees.

If \( @a \) is not 0, the handler simply ends, which means that there is no more use for the current diagnostics area (it has been “handled”), so it can be thrown away, causing the stacked diagnostics area to become the current diagnostics area again. The diagnostics area stack looks like this:

```
DA 1. ERROR 0000 (00000): Successful operation
```

The details make it look complex, but the end result is quite useful: Handlers can execute without destroying information about the condition that caused activation of the handler.

**RESIGNAL with New Signal Information**

**RESIGNAL** with a **SET** clause provides new signal information, so the statement means “pass on the error with changes”:

```
RESIGNAL SET signal_information_item [, signal_information_item] ...;
```

As with **RESIGNAL** alone, the idea is to pop the diagnostics area stack so that the original information goes out. Unlike **RESIGNAL** alone, anything specified in the **SET** clause changes.

Example:

```sql
DROP TABLE IF EXISTS xx;
delimiter //
CREATE PROCEDURE p ()
BEGIN
    DECLARE EXIT HANDLER FOR SQLEXCEPTION
    BEGIN
        SET @error_count = @error_count + 1;
        IF @a = 0 THEN RESIGNAL SET MYSQL_ERRNO = 5; END IF;
    END;
    DROP TABLE xx;
END//
delimiter ;
SET @error_count = 0;
SET @a = 0;
CALL p();
```

Remember from the previous discussion that **RESIGNAL** alone results in a diagnostics area stack like this:

```
DA 1. ERROR 1051 (42S02): Unknown table 'xx'
```

The **RESIGNAL SET MYSQL_ERRNO = 5** statement results in this stack instead, which is what the caller sees:

```
DA 1. ERROR 5 (42S02): Unknown table 'xx'
```

In other words, it changes the error number, and nothing else.

The **RESIGNAL** statement can change any or all of the signal information items, making the first condition area of the diagnostics area look quite different.

**RESIGNAL with a Condition Value and Optional New Signal Information**

**RESIGNAL** with a condition value means “push a condition into the current diagnostics area.” If the **SET** clause is present, it also changes the error information.

```
RESIGNAL condition_value
    [SET signal_information_item [, signal_information_item] ...];
```

This form of **RESIGNAL** restores the last diagnostics area and makes it the current diagnostics area. That is, it “pops” the diagnostics area stack, which is the same as what a simple **RESIGNAL** alone would do. However, it also changes the diagnostics area depending on the condition value or signal information.
Example:

```sql
DROP TABLE IF EXISTS xx;
delimiter //
CREATE PROCEDURE p ()
BEGIN
DECLARE EXIT HANDLER FOR SQLSTATE '45000' SET MYSQL_ERRNO=5; END IF;
END;
DROP TABLE xx;
END;//
set @error_count = 0;
set @a = 0;
set @@max_error_count = 2;
call p();
SHOW ERRORS;
```

This is similar to the previous example, and the effects are the same, except that if `RESIGNAL` happens, the current condition area looks different at the end. (The reason the condition adds to rather than replaces the existing condition is the use of a condition value.)

The `RESIGNAL` statement includes a condition value (`SQLSTATE '45000'`), so it adds a new condition area, resulting in a diagnostics area stack that looks like this:

```
DA 1. (condition 2) ERROR 1051 (42S02): Unknown table 'xx'
   (condition 1) ERROR 5 (45000) Unknown table 'xx'
```

The result of `CALL p()` and `SHOW ERRORS` for this example is:

```
mysql> CALL p();
ERROR 5 (45000): Unknown table 'xx'
mysql> SHOW ERRORS;
+-------+------+----------------------------------+
| Level | Code | Message                          |
|-------+------+----------------------------------|
| Error | 1051 | Unknown table 'xx'               |
| Error |    5 | Unknown table 'xx'               |
+-------+------+----------------------------------+
```

**RESIGNAL Requires Condition Handler Context**

All forms of `RESIGNAL` require that the current context be a condition handler. Otherwise, `RESIGNAL` is illegal and a `RESIGNAL when handler not active` error occurs. For example:

```
mysql> CREATE PROCEDURE p () RESIGNAL;
Query OK, 0 rows affected (0.00 sec)
mysql> CALL p();
ERROR 1645 (0K000): RESIGNAL when handler not active
```

Here is a more difficult example:

```sql
delimiter //
CREATE FUNCTION f () RETURNS INT
BEGIN
    RESIGNAL;
    RETURN 5;
END;//
CREATE PROCEDURE p ()
BEGIN
    DECLARE EXIT HANDLER FOR SQLSTATE '45000' SET @a=f();
    SIGNAL SQLSTATE '55555';
END;//
```
Condition Handling

RESIGNAL occurs within the stored function `f()`. Although `f()` itself is invoked within the context of the EXIT handler, execution within `f()` has its own context, which is not handler context. Thus, RESIGNAL within `f()` results in a “handler not active” error.

13.6.7.5 SIGNAL Statement

```
SIGNAL condition_value
  [SET signal_information_item
   [, signal_information_item] ...]

condition_value: {
  SQLSTATE [VALUE] sqlstate_value
  | condition_name
}

signal_information_item:
  condition_information_item_name = simple_valueSpecification

condition_information_item_name: {
  CLASS_ORIGIN
  | SUBCLASS_ORIGIN
  | MESSAGE_TEXT
  | MYSQL_ERRNO
  | CONSTRAINT_CATALOG
  | CONSTRAINT_SCHEMA
  | CONSTRAINT_NAME
  | CATALOG_NAME
  | SCHEMA_NAME
  | TABLE_NAME
  | COLUMN_NAME
  | CURSOR_NAME
}

condition_name, simple_valueSpecification:
  (see following discussion)
```

**SIGNAL Overview**

The `condition_value` in a SIGNAL statement indicates the error value to be returned. It can be an SQLSTATE value (a 5-character string literal) or a `condition_name` that refers to a named condition previously defined with DECLARE ... CONDITION (see Section 13.6.7.1, “DECLARE ... CONDITION Statement”).
An SQLSTATE value can indicate errors, warnings, or “not found.” The first two characters of the value indicate its error class, as discussed in Signal Condition Information Items. Some signal values cause statement termination; see Effect of Signals on Handlers, Cursors, and Statements.

The SQLSTATE value for a SIGNAL statement should not start with '00' because such values indicate success and are not valid for signaling an error. This is true whether the SQLSTATE value is specified directly in the SIGNAL statement or in a named condition referred to in the statement. If the value is invalid, a Bad SQLSTATE error occurs.

To signal a generic SQLSTATE value, use '45000', which means “unhandled user-defined exception.”

The SIGNAL statement optionally includes a SET clause that contains multiple signal items, in a list of condition_information_item_name = simple_value_specification assignments, separated by commas.

Each condition_information_item_name may be specified only once in the SET clause. Otherwise, a Duplicate condition information item error occurs.

Valid simple_value_specification designators can be specified using stored procedure or function parameters, stored program local variables declared with DECLARE, user-defined variables, system variables, or literals. A character literal may include a _charset introducer.

For information about permissible condition_information_item_name values, see Signal Condition Information Items.

The following procedure signals an error or warning depending on the value of pval, its input parameter:

```
CREATE PROCEDURE p (pval INT)
BEGIN
  DECLARE specialty CONDITION FOR SQLSTATE '45000';
  IF pval = 0 THEN
    SIGNAL SQLSTATE '01000';
  ELSEIF pval = 1 THEN
    SIGNAL SQLSTATE '45000'
    SET MESSAGE_TEXT = 'An error occurred';
  ELSEIF pval = 2 THEN
    SIGNAL specialty
    SET MESSAGE_TEXT = 'An error occurred';
  ELSE
    SIGNAL SQLSTATE '01000'
    SET MESSAGE_TEXT = 'An error occurred', MYSQL_ERRNO = 1000;
    SIGNAL SQLSTATE '45000'
    SET MESSAGE_TEXT = 'An error occurred', MYSQL_ERRNO = 1001;
  END IF;
END;
```

If pval is 0, p() signals a warning because SQLSTATE values that begin with '01' are signals in the warning class. The warning does not terminate the procedure, and can be seen with SHOW WARNINGS after the procedure returns.

If pval is 1, p() signals an error and sets the MESSAGE_TEXT condition information item. The error terminates the procedure, and the text is returned with the error information.

If pval is 2, the same error is signaled, although the SQLSTATE value is specified using a named condition in this case.

If pval is anything else, p() first signals a warning and sets the message text and error number condition information items. This warning does not terminate the procedure, so execution continues and p() then signals an error. The error does terminate the procedure. The message text and error number set by the warning are replaced by the values set by the error, which are returned with the error information.
**SIGNAL** is typically used within stored programs, but it is a MySQL extension that it is permitted outside handler context. For example, if you invoke the `mysql` client program, you can enter any of these statements at the prompt:

```sql
SIGNAL SQLSTATE '77777';
CREATE TRIGGER t_bi BEFORE INSERT ON t
    FOR EACH ROW SIGNAL SQLSTATE '77777';
CREATE EVENT e ON SCHEDULE EVERY 1 SECOND
    DO SIGNAL SQLSTATE '77777';
```

**SIGNAL** executes according to the following rules:

If the **SIGNAL** statement indicates a particular **SQLSTATE** value, that value is used to signal the condition specified. Example:

```sql
CREATE PROCEDURE p (divisor INT)
BEGIN
    IF divisor = 0 THEN
        SIGNAL SQLSTATE '22012';
    END IF;
END;
```

If the **SIGNAL** statement uses a named condition, the condition must be declared in some scope that applies to the **SIGNAL** statement, and must be defined using an **SQLSTATE** value, not a MySQL error number. Example:

```sql
CREATE PROCEDURE p (divisor INT)
BEGIN
    DECLARE divide_by_zero CONDITION FOR SQLSTATE '22012';
    IF divisor = 0 THEN
        SIGNAL divide_by_zero;
    END IF;
END;
```

If the named condition does not exist in the scope of the **SIGNAL** statement, an **Undefined CONDITION** error occurs.

If **SIGNAL** refers to a named condition that is defined with a MySQL error number rather than an **SQLSTATE** value, a **SIGNAL/RESIGNAL** can only use a **CONDITION** defined with **SQLSTATE** error occurs. The following statements cause that error because the named condition is associated with a MySQL error number:

```sql
DECLARE no_such_table CONDITION FOR 1051;
SIGNAL no_such_table;
```

If a condition with a given name is declared multiple times in different scopes, the declaration with the most local scope applies. Consider the following procedure:

```sql
CREATE PROCEDURE p (divisor INT)
BEGIN
    DECLARE my_error CONDITION FOR SQLSTATE '45000';
    IF divisor = 0 THEN
        BEGIN
            DECLARE my_error CONDITION FOR SQLSTATE '22012';
            SIGNAL my_error;
        END;
        SIGNAL my_error;
    END;

    IF divisor is 0, the first **SIGNAL** statement executes. The innermost **my_error** condition declaration applies, raising **SQLSTATE '22012'**.
If `divisor` is not 0, the second `SIGNAL` statement executes. The outermost `my_error` condition declaration applies, raising SQLSTATE '45000'.

For information about how the server chooses handlers when a condition occurs, see Section 13.6.7.6, “Scope Rules for Handlers”.

Signals can be raised within exception handlers:

```
CREATE PROCEDURE p ()
BEGIN
  DECLARE EXIT HANDLER FOR SQLEXCEPTION
  BEGIN
    SIGNAL SQLSTATE VALUE '99999'
    SET MESSAGE_TEXT = 'An error occurred';
  END;
  DROP TABLE no_such_table;
END;
```

`CALL p()` reaches the `DROP TABLE` statement. There is no table named `no_such_table`, so the error handler is activated. The error handler destroys the original error ("no such table") and makes a new error with SQLSTATE '99999' and message 'An error occurred'.

### Signal Condition Information Items

The following table lists the names of diagnostics area condition information items that can be set in a `SIGNAL` (or `RESIGNAL`) statement. All items are standard SQL except `MYSQL_ERRNO`, which is a MySQL extension. For more information about these items see Section 13.6.7.7, “The MySQL Diagnostics Area”.

<table>
<thead>
<tr>
<th>Item Name</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLASS_ORIGIN</td>
<td>VARCHAR(64)</td>
</tr>
<tr>
<td>SUBCLASS_ORIGIN</td>
<td>VARCHAR(64)</td>
</tr>
<tr>
<td>CONSTRAINT_CATALOG</td>
<td>VARCHAR(64)</td>
</tr>
<tr>
<td>CONSTRAINT_SCHEMA</td>
<td>VARCHAR(64)</td>
</tr>
<tr>
<td>CONSTRAINT_NAME</td>
<td>VARCHAR(64)</td>
</tr>
<tr>
<td>CATALOG_NAME</td>
<td>VARCHAR(64)</td>
</tr>
<tr>
<td>SCHEMA_NAME</td>
<td>VARCHAR(64)</td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td>VARCHAR(64)</td>
</tr>
<tr>
<td>COLUMN_NAME</td>
<td>VARCHAR(64)</td>
</tr>
<tr>
<td>CURSOR_NAME</td>
<td>VARCHAR(64)</td>
</tr>
<tr>
<td>MESSAGE_TEXT</td>
<td>VARCHAR(128)</td>
</tr>
<tr>
<td>MYSQL_ERRNO</td>
<td>SMALLINT UNSIGNED</td>
</tr>
</tbody>
</table>

The character set for character items is UTF-8.

It is illegal to assign NULL to a condition information item in a `SIGNAL` statement.

A `SIGNAL` statement always specifies an SQLSTATE value, either directly, or indirectly by referring to a named condition defined with an SQLSTATE value. The first two characters of an SQLSTATE value are its class, and the class determines the default value for the condition information items:

- **Class = '00'** (success)
  
  Illegal. SQLSTATE values that begin with '00' indicate success and are not valid for SIGNAL.

- **Class = '01'** (warning)
  
  `MESSAGE_TEXT = 'Unhandled user-defined warning condition';
  MYSQL_ERRNO = ER_SIGNAL_WARN`

- **Class = '02'** (not found)
  
  `MESSAGE_TEXT = 'Unhandled user-defined not found condition';`
Condition Handling

MySQL_errno = ER_SIGNAL_NOT_FOUND

• Class = '02' (exception)

MESSAGE_TEXT = 'Unhandled user-defined exception condition';
MySQL_errno = ER_SIGNAL_EXCEPTION

For legal classes, the other condition information items are set as follows:

CLASS_ORIGIN = SUBCLASS_ORIGIN = '';
CONSTRAINT_CATALOG = CONSTRAINT_SCHEMA = CONSTRAINT_NAME = '';
CATALOG_NAME = SCHEMA_NAME = TABLE_NAME = COLUMN_NAME = '';
CURSOR_NAME = '';

The error values that are accessible after SIGNAL executes are the SQLSTATE value raised by the SIGNAL statement and the MESSAGE_TEXT and MySQL_errno items. These values are available from the C API:

• mysql_sqlstate() returns the SQLSTATE value.
• mysql_errno() returns the MySQL_errno value.
• mysql_error() returns the MESSAGE_TEXT value.

At the SQL level, the output from SHOW WARNINGS and SHOW ERRORS indicates the MySQL_errno and MESSAGE_TEXT values in the Code and Message columns.

To retrieve information from the diagnostics area, use the GET DIAGNOSTICS statement (see Section 13.6.7.3, “GET DIAGNOSTICS Statement”). For information about the diagnostics area, see Section 13.6.7.7, “The MySQL Diagnostics Area”.

Effect of Signals on Handlers, Cursors, and Statements

Signals have different effects on statement execution depending on the signal class. The class determines how severe an error is. MySQL ignores the value of the sql_mode system variable; in particular, strict SQL mode does not matter. MySQL also ignores IGNORE: The intent of SIGNAL is to raise a user-generated error explicitly, so a signal is never ignored.

In the following descriptions, “unhandled” means that no handler for the signaled SQLSTATE value has been defined with DECLARE ... HANDLER.

• Class = '00' (success)

Illegal. SQLSTATE values that begin with '00' indicate success and are not valid for SIGNAL.

• Class = '01' (warning)

The value of the warning_count system variable goes up. SHOW WARNINGS shows the signal. SQLWARNING handlers catch the signal.

Warnings cannot be returned from stored functions because the RETURN statement that causes the function to return clears the diagnostic area. The statement thus clears any warnings that may have been present there (and resets warning_count to 0).

• Class = '02' (not found)

NOT FOUND handlers catch the signal. There is no effect on cursors. If the signal is unhandled in a stored function, statements end.

• Class > '02' (exception)
SQLEXCEPTION handlers catch the signal. If the signal is unhandled in a stored function, statements end.

- Class = '40'

Treated as an ordinary exception.

13.6.7.6 Scope Rules for Handlers

A stored program may include handlers to be invoked when certain conditions occur within the program. The applicability of each handler depends on its location within the program definition and on the condition or conditions that it handles:

- A handler declared in a BEGIN ... END block is in scope only for the SQL statements following the handler declarations in the block. If the handler itself raises a condition, it cannot handle that condition, nor can any other handlers declared in the block. In the following example, handlers $H1$ and $H2$ are in scope for conditions raised by statements $stmt1$ and $stmt2$. But neither $H1$ nor $H2$ are in scope for conditions raised in the body of $H1$ or $H2$.

  ```sql
  BEGIN -- outer block
    DECLARE EXIT HANDLER FOR ...;  -- handler H1
    DECLARE EXIT HANDLER FOR ...;  -- handler H2
    stmt1;
    stmt2;
  END;

  BEGIN -- inner block
    DECLARE EXIT HANDLER FOR ...;  -- handler H1
    stmt1;
    stmt2;
  END;
  ```

- A handler is in scope only for the block in which it is declared, and cannot be activated for conditions occurring outside that block. In the following example, handler $H1$ is in scope for $stmt1$ in the inner block, but not for $stmt2$ in the outer block:

  ```sql
  BEGIN -- outer block
    BEGIN -- inner block
      DECLARE EXIT HANDLER FOR ...;  -- handler H1
      stmt1;
      stmt2;
    END;
  END;
  ```

- A handler can be specific or general. A specific handler is for a MySQL error code, SQLSTATE value, or condition name. A general handler is for a condition in the SQLWARNING, SQLEXCEPTION, or NOT FOUND class. Condition specificity is related to condition precedence, as described later.

Multiple handlers can be declared in different scopes and with different specificities. For example, there might be a specific MySQL error code handler in an outer block, and a general SQLWARNING handler in an inner block. Or there might be handlers for a specific MySQL error code and the general SQLWARNING class in the same block.

Whether a handler is activated depends not only on its own scope and condition value, but on what other handlers are present. When a condition occurs in a stored program, the server searches for applicable handlers in the current scope (current BEGIN ... END block). If there are no applicable handlers, the search continues outward with the handlers in each successive containing scope (block). When the server finds one or more applicable handlers at a given scope, it chooses among them based on condition precedence:

- A MySQL error code handler takes precedence over an SQLSTATE value handler.
- An SQLSTATE value handler takes precedence over general SQLWARNING, SQLEXCEPTION, or NOT FOUND handlers.
• An **SQLEXCEPTION** handler takes precedence over an **SQLWARNING** handler.

• It is possible to have several applicable handlers with the same precedence. For example, a statement could generate multiple warnings with different error codes, for each of which an error-specific handler exists. In this case, the choice of which handler the server activates is nondeterministic, and may change depending on the circumstances under which the condition occurs.

One implication of the handler selection rules is that if multiple applicable handlers occur in different scopes, handlers with the most local scope take precedence over handlers in outer scopes, even over those for more specific conditions.

If there is no appropriate handler when a condition occurs, the action taken depends on the class of the condition:

• For **SQLEXCEPTION** conditions, the stored program terminates at the statement that raised the condition, as if there were an **EXIT** handler. If the program was called by another stored program, the calling program handles the condition using the handler selection rules applied to its own handlers.

• For **SQLWARNING** conditions, the program continues executing, as if there were a **CONTINUE** handler.

• For **NOT FOUND** conditions, if the condition was raised normally, the action is **CONTINUE**. If it was raised by **SIGNAL** or **RESIGNAL**, the action is **EXIT**.

The following examples demonstrate how MySQL applies the handler selection rules.

This procedure contains two handlers, one for the specific **SQLSTATE** value (‘42S02’) that occurs for attempts to drop a nonexistent table, and one for the general **SQLEXCEPTION** class:

```
CREATE PROCEDURE p1()
BEGIN
  DECLARE CONTINUE HANDLER FOR SQLSTATE '42S02'
  SELECT 'SQLSTATE handler was activated' AS msg;
  DECLARE CONTINUE HANDLER FOR SQLEXCEPTION
  SELECT 'SQLEXCEPTION handler was activated' AS msg;
  DROP TABLE test.t;
END;
```

Both handlers are declared in the same block and have the same scope. However, **SQLSTATE** handlers take precedence over **SQLEXCEPTION** handlers, so if the table `t` is nonexistent, the **DROP TABLE** statement raises a condition that activates the **SQLSTATE** handler:

```
mysql> CALL p1();
+----------------------------------+
| msg                             |
| SQLSTATE handler was activated |
+----------------------------------+
```

This procedure contains the same two handlers. But this time, the **DROP TABLE** statement and **SQLEXCEPTION** handler are in an inner block relative to the **SQLSTATE** handler:

```
CREATE PROCEDURE p2()
BEGIN -- outer block
  DECLARE CONTINUE HANDLER FOR SQLSTATE '42S02'
  SELECT 'SQLSTATE handler was activated' AS msg;
END
BEGIN -- inner block
  DECLARE CONTINUE HANDLER FOR SQLEXCEPTION
  SELECT 'SQLEXCEPTION handler was activated' AS msg;
```

Both handlers are declared in the same block and have the same scope. However, **SQLSTATE** handlers take precedence over **SQLEXCEPTION** handlers, so if the table `t` is nonexistent, the **DROP TABLE** statement raises a condition that activates the **SQLSTATE** handler:

```
mysql> CALL p2();
+----------------------------------+
| msg                             |
| SQLSTATE handler was activated |
+----------------------------------+
```

This procedure contains the same two handlers. But this time, the **DROP TABLE** statement and **SQLEXCEPTION** handler are in an inner block relative to the **SQLSTATE** handler:
In this case, the handler that is more local to where the condition occurs takes precedence. The `SQLSTATE` handler activates, even though it is more general than the `SQLSTATE` handler:

```sql
mysql> CALL p2();
+------------------------------------+
| msg                                |
+------------------------------------+
| SQLEXCEPTION handler was activated |
+------------------------------------+
```

In this procedure, one of the handlers is declared in a block inner to the scope of the `DROP TABLE` statement:

```sql
CREATE PROCEDURE p3()
BEGIN -- outer block
  DECLARE CONTINUE HANDLER FOR SQLEXCEPTION
    SELECT 'SQLEXCEPTION handler was activated' AS msg;
BEGIN -- inner block
  DECLARE CONTINUE HANDLER FOR SQLSTATE '42S02'
    SELECT 'SQLSTATE handler was activated' AS msg;
END;
DROP TABLE test.t; -- occurs within outer block
END;
```

Only the `SQLEXCEPTION` handler applies because the other one is not in scope for the condition raised by the `DROP TABLE`:

```sql
mysql> CALL p3();
+------------------------------------+
| msg                                |
+------------------------------------+
| SQLEXCEPTION handler was activated |
+------------------------------------+
```

In this procedure, both handlers are declared in a block inner to the scope of the `DROP TABLE` statement:

```sql
CREATE PROCEDURE p4()
BEGIN -- outer block
  BEGIN -- inner block
    DECLARE CONTINUE HANDLER FOR SQLEXCEPTION
      SELECT 'SQLEXCEPTION handler was activated' AS msg;
    BEGIN -- inner block
      DECLARE CONTINUE HANDLER FOR SQLSTATE '42S02'
        SELECT 'SQLSTATE handler was activated' AS msg;
    END;
  END;
DROP TABLE test.t; -- occurs within outer block
END;
```

Neither handler applies because they are not in scope for the `DROP TABLE`. The condition raised by the statement goes unhandled and terminates the procedure with an error:

```sql
mysql> CALL p4();
ERROR 1051 (42S02): Unknown table 'test.t'
```

### 13.6.7.7 The MySQL Diagnostics Area

SQL statements produce diagnostic information that populates the diagnostics area. Standard SQL has a diagnostics area stack, containing a diagnostics area for each nested execution context. Standard SQL
also supports `GET STACKED DIAGNOSTICS` syntax for referring to the second diagnostics area during condition handler execution.

The following discussion describes the structure of the diagnostics area in MySQL, the information items recognized by MySQL, how statements clear and set the diagnostics area, and how diagnostics areas are pushed to and popped from the stack.

- **Diagnostics Area Structure**
- **Diagnostics Area Information Items**
- **How the Diagnostics Area is Cleared and Populated**
- **How the Diagnostics Area Stack Works**
- **Diagnostics Area-Related System Variables**

### Diagnostics Area Structure

The diagnostics area contains two kinds of information:

- **Statement information**, such as the number of conditions that occurred or the affected-rows count.

- **Condition information**, such as the error code and message. If a statement raises multiple conditions, this part of the diagnostics area has a condition area for each one. If a statement raises no conditions, this part of the diagnostics area is empty.

For a statement that produces three conditions, the diagnostics area contains statement and condition information like this:

```
Statement information:
  row count
  ... other statement information items ...
Condition area list:
  Condition area 1:
    error code for condition 1
    error message for condition 1
    ... other condition information items ...
  Condition area 2:
    error code for condition 2:
    error message for condition 2
    ... other condition information items ...
  Condition area 3:
    error code for condition 3
    error message for condition 3
    ... other condition information items ...
```

### Diagnostics Area Information Items

The diagnostics area contains statement and condition information items. Numeric items are integers. The character set for character items is UTF-8. No item can be `NULL`. If a statement or condition item is not set by a statement that populates the diagnostics area, its value is 0 or the empty string, depending on the item data type.

The statement information part of the diagnostics area contains these items:

- **NUMBER**: An integer indicating the number of condition areas that have information.

- **ROW_COUNT**: An integer indicating the number of rows affected by the statement. `ROW_COUNT` has the same value as the `ROW_COUNT()` function (see Section 12.15, “Information Functions”).
The condition information part of the diagnostics area contains a condition area for each condition. Condition areas are numbered from 1 to the value of the `NUMBER` statement condition item. If `NUMBER` is 0, there are no condition areas.

Each condition area contains the items in the following list. All items are standard SQL except `MYSQL_ERRNO`, which is a MySQL extension. The definitions apply for conditions generated other than by a signal (that is, by a `SIGNAL` or `RESIGNAL` statement). For nonsignal conditions, MySQL populates only those condition items not described as always empty. The effects of signals on the condition area are described later.

- **CLASS_ORIGIN**: A string containing the class of the `RETURNED_SQLSTATE` value. If the `RETURNED_SQLSTATE` value begins with a class value defined in SQL standards document ISO 9075-2 (section 24.1, SQLSTATE), `CLASS_ORIGIN` is 'ISO 9075'. Otherwise, `CLASS_ORIGIN` is 'MySQL'.

- **SUBCLASS_ORIGIN**: A string containing the subclass of the `RETURNED_SQLSTATE` value. If `CLASS_ORIGIN` is 'ISO 9075' or `RETURNED_SQLSTATE` ends with '000', `SUBCLASS_ORIGIN` is 'ISO 9075'. Otherwise, `SUBCLASS_ORIGIN` is 'MySQL'.

- **RETURNED_SQLSTATE**: A string that indicates the `SQLSTATE` value for the condition.

- **MESSAGE_TEXT**: A string that indicates the error message for the condition.

- **MYSQL_ERRNO**: An integer that indicates the MySQL error code for the condition.

- **CONSTRAINT_CATALOG, CONSTRAINT_SCHEMA, CONSTRAINT_NAME**: Strings that indicate the catalog, schema, and name for a violated constraint. They are always empty.

- **CATALOG_NAME, SCHEMA_NAME, TABLE_NAME, COLUMN_NAME**: Strings that indicate the catalog, schema, table, and column related to the condition. They are always empty.

- **CURSOR_NAME**: A string that indicates the cursor name. This is always empty.

For the `RETURNED_SQLSTATE`, `MESSAGE_TEXT`, and `MYSQL_ERRNO` values for particular errors, see Server Error Message Reference.

If a `SIGNAL` (or `RESIGNAL`) statement populates the diagnostics area, its `SET` clause can assign to any condition information item except `RETURNED_SQLSTATE` any value that is legal for the item data type. `SIGNAL` also sets the `RETURNED_SQLSTATE` value, but not directly in its `SET` clause. That value comes from the `SIGNAL` statement `SQLSTATE` argument.

`SIGNAL` also sets statement information items. It sets `NUMBER` to 1. It sets `ROW_COUNT` to −1 for errors and 0 otherwise.

### How the Diagnostics Area is Cleared and Populated

Nondiagnostic SQL statements populate the diagnostics area automatically, and its contents can be set explicitly with the `SIGNAL` and `RESIGNAL` statements. The diagnostics area can be examined with `GET DIAGNOSTICS` to extract specific items, or with `SHOW WARNINGS` or `SHOW ERRORS` to see conditions or errors.

SQL statements clear and set the diagnostics area as follows:

- When the server starts executing a statement after parsing it, it clears the diagnostics area for nondiagnostic statements. Diagnostic statements do not clear the diagnostics area. These statements are diagnostic:
  - `GET DIAGNOSTICS`
• **SHOW ERRORS**

• **SHOW WARNINGS**

• If a statement raises a condition, the diagnostics area is cleared of conditions that belong to earlier statements. The exception is that conditions raised by `GET DIAGNOSTICS` and `RESIGNAL` are added to the diagnostics area without clearing it.

Thus, even a statement that does not normally clear the diagnostics area when it begins executing clears it if the statement raises a condition.

The following example shows the effect of various statements on the diagnostics area, using `SHOW WARNINGS` to display information about conditions stored there.

**This `DROP TABLE` statement clears the diagnostics area and populates it when the condition occurs:**

```sql
mysql> DROP TABLE IF EXISTS test.no_such_table;
Query OK, 0 rows affected, 1 warning (0.01 sec)
```

```sql
mysql> SHOW WARNINGS;
+-------+------+------------------------------------+
| Level | Code | Message                            |
+-------+------+------------------------------------+
| Note  | 1051 | Unknown table 'test.no_such_table' |
+-------+------+------------------------------------+
1 row in set (0.00 sec)
```

**This `SET` statement generates an error, so it clears and populates the diagnostics area:**

```sql
mysql> SET @x = @@x;
ERROR 1193 (HY000): Unknown system variable 'x'
```

```sql
mysql> SHOW WARNINGS;
+-------+------+-----------------------------+
| Level | Code | Message                     |
+-------+------+-----------------------------+
| Error | 1193 | Unknown system variable 'x' |
+-------+------+-----------------------------+
1 row in set (0.00 sec)
```

The previous `SET` statement produced a single condition, so 1 is the only valid condition number for `GET DIAGNOSTICS` at this point. The following statement uses a condition number of 2, which produces a warning that is added to the diagnostics area without clearing it:

```sql
mysql> GET DIAGNOSTICS CONDITION 2 @p = MESSAGE_TEXT;
Query OK, 0 rows affected, 1 warning (0.00 sec)
```

```sql
mysql> SHOW WARNINGS;
+-------+------+-----------------------------+
| Level | Code | Message                     |
+-------+------+-----------------------------+
| Error | 1193 | Unknown system variable 'xx' |
| Error | 1753 | Invalid condition number    |
+-------+------+-----------------------------+
2 rows in set (0.00 sec)
```

Now there are two conditions in the diagnostics area, so the same `GET DIAGNOSTICS` statement succeeds:

```sql
mysql> GET DIAGNOSTICS CONDITION 2 @p = MESSAGE_TEXT;
Query OK, 0 rows affected (0.00 sec)
```

```sql
mysql> SELECT @p;
```
How the Diagnostics Area Stack Works

When a push to the diagnostics area stack occurs, the first (current) diagnostics area becomes the second (stacked) diagnostics area and a new current diagnostics area is created as a copy of it. Diagnostics areas are pushed to and popped from the stack under the following circumstances:

- **Execution of a stored program**
  
  A push occurs before the program executes and a pop occurs afterward. If the stored program ends while handlers are executing, there can be more than one diagnostics area to pop; this occurs due to an exception for which there are no appropriate handlers or due to `RETURN` in the handler.
  
  Any warning or error conditions in the popped diagnostics areas then are added to the current diagnostics area, except that, for triggers, only errors are added. When the stored program ends, the caller sees these conditions in its current diagnostics area.

- **Execution of a condition handler within a stored program**
  
  When a push occurs as a result of condition handler activation, the stacked diagnostics area is the area that was current within the stored program prior to the push. The new now-current diagnostics area is the handler's current diagnostics area. `GET [CURRENT] DIAGNOSTICS` and `GET STACKED DIAGNOSTICS` can be used within the handler to access the contents of the current (handler) and stacked (stored program) diagnostics areas. Initially, they return the same result, but statements executing within the handler modify the current diagnostics area, clearing and setting its contents according to the normal rules (see How the Diagnostics Area is Cleared and Populated). The stacked diagnostics area cannot be modified by statements executing within the handler except `RESIGNAL`.
  
  If the handler executes successfully, the current (handler) diagnostics area is popped and the stacked (stored program) diagnostics area again becomes the current diagnostics area. Conditions added to the handler diagnostics area during handler execution are added to the current diagnostics area.

- **Execution of `RESIGNAL`**
  
  The `RESIGNAL` statement passes on the error condition information that is available during execution of a condition handler within a compound statement inside a stored program. `RESIGNAL` may change some or all information before passing it on, modifying the diagnostics stack as described in Section 13.6.7.4, “RESIGNAL Statement”.

Diagnostics Area-Related System Variables

Certain system variables control or are related to some aspects of the diagnostics area:

- **`max_error_count`** controls the number of condition areas in the diagnostics area. If more conditions than this occur, MySQL silently discards information for the excess conditions. (Conditions added by `RESIGNAL` are always added, with older conditions being discarded as necessary to make room.)

- **`warning_count`** indicates the number of conditions that occurred. This includes errors, warnings, and notes. Normally, `NUMBER` and `warning_count` are the same. However, as the number of conditions generated exceeds `max_error_count`, the value of `warning_count` continues to rise whereas `NUMBER` remains capped at `max_error_count` because no additional conditions are stored in the diagnostics area.
Restrictions on Condition Handling

- error_count indicates the number of errors that occurred. This value includes “not found” and exception conditions, but excludes warnings and notes. Like warning_count, its value can exceed max_error_count.

- If the sql_notes system variable is set to 0, notes are not stored and do not increment warning_count.

Example: If max_error_count is 10, the diagnostics area can contain a maximum of 10 condition areas. Suppose that a statement raises 20 conditions, 12 of which are errors. In that case, the diagnostics area contains the first 10 conditions, NUMBER is 10, warning_count is 20, and error_count is 12.

Changes to the value of max_error_count have no effect until the next attempt to modify the diagnostics area. If the diagnostics area contains 10 condition areas and max_error_count is set to 5, that has no immediate effect on the size or content of the diagnostics area.

13.6.7.8 Condition Handling and OUT or INOUT Parameters

If a stored procedure exits with an unhandled exception, modified values of OUT and INOUT parameters are not propagated back to the caller.

If an exception is handled by a CONTINUE or EXIT handler that contains a RESIGNAL statement, execution of RESIGNAL pops the Diagnostics Area stack, thus signalling the exception (that is, the information that existed before entry into the handler). If the exception is an error, the values of OUT and INOUT parameters are not propagated back to the caller.

13.6.8 Restrictions on Condition Handling

SIGNAL, RESIGNAL, and GET DIAGNOSTICS are not permissible as prepared statements. For example, this statement is invalid:

```
PREPARE stmt1 FROM 'SIGNAL SQLSTATE "02000"';
```

SQLSTATE values in class '04' are not treated specially. They are handled the same as other exceptions.

In standard SQL, the first condition relates to the SQLSTATE value returned for the previous SQL statement. In MySQL, this is not guaranteed, so to get the main error, you cannot do this:

```
GET DIAGNOSTICS CONDITION 1 @errno = MYSQL_ERRNO;
```

Instead, do this:

```
GET DIAGNOSTICS @cno = NUMBER;
GET DIAGNOSTICS CONDITION @cno @errno = MYSQL_ERRNO;
```

13.7 Database Administration Statements

13.7.1 Account Management Statements

MySQL account information is stored in the tables of the mysql system schema. This database and the access control system are discussed extensively in Chapter 5, MySQL Server Administration, which you should consult for additional details.

**Important**

Some MySQL releases introduce changes to the grant tables to add new privileges or features. To make sure that you can take advantage of any new capabilities, update your grant tables to the current structure whenever you upgrade MySQL.

See Section 2.10, “Upgrading MySQL”.
When the `read_only` system variable is enabled, account-management statements require the `CONNECTION_ADMIN` privilege (or the deprecated `SUPER` privilege), in addition to any other required privileges. This is because they modify tables in the `mysql` system schema.

Account management statements are atomic and crash safe. For more information, see Section 13.1.1, “Atomic Data Definition Statement Support”.

### 13.7.1.1 ALTER USER Statement

```sql
ALTER USER [IF EXISTS] 
  user [auth_option] [, user [auth_option]] ...
  [REQUIRE {NONE | tls_option [[AND] tls_option] ...}] 
  [WITH resource_option [resource_option] ...] 
  [password_option | lock_option] ... 
  [COMMENT 'comment_string' | ATTRIBUTE 'json_object']
```

The **ALTER USER** statement modifies MySQL accounts. It enables authentication, role, SSL/TLS, resource-limit, password-management, comment, and attribute properties to be modified for existing accounts. It can also be used to lock and unlock accounts.

In most cases, **ALTER USER** requires the global **CREATE USER** privilege, or the **UPDATE** privilege for the **mysql** system schema. The exceptions are:

- Any client who connects to the server using a nonanonymous account can change the password for that account. (In particular, you can change your own password.) To see which account the server authenticated you as, invoke the **CURRENT_USER()** function:

  ```sql
  SELECT CURRENT_USER();
  ```

- For **DEFAULT ROLE** syntax, **ALTER USER** requires these privileges:

  - Setting the default roles for another user requires the global **CREATE USER** privilege, or the **UPDATE** privilege for the **mysql.default_roles** system table.
  
  - Setting the default roles for yourself requires no special privileges, as long as the roles you want as the default have been granted to you.

- Statements that modify secondary passwords require these privileges:

  - The **APPLICATION_PASSWORD_ADMIN** privilege is required to use the **RETAIN CURRENT PASSWORD** or **DISCARD OLD PASSWORD** clause for **ALTER USER** statements that apply to your own account. The
privilege is required to manipulate your own secondary password because most users require only one password.

• If an account is to be permitted to manipulate secondary passwords for all accounts, it requires the CREATE_USER privilege rather than APPLICATION_PASSWORD_ADMIN.

When the read_only system variable is enabled, ALTER_USER additionally requires the CONNECTION_ADMIN privilege (or the deprecated SUPER privilege).

As of MySQL 8.0.27, these additional privilege considerations apply:

• The authentication_policy system variable places certain constraints on how the authentication-related clauses of ALTER_USER statements may be used; for details, see the description of that variable. These constraints do not apply if you have the AUTHENTICATION_POLICY_ADMIN privilege.

• To modify an account that uses passwordless authentication, you must have the PASSWORDLESS_USER_ADMIN privilege.

By default, an error occurs if you try to modify a user that does not exist. If the IF_EXISTS clause is given, the statement produces a warning for each named user that does not exist, rather than an error.

Important

Under some circumstances, ALTER_USER may be recorded in server logs or on the client side in a history file such as ~/.mysql_history, which means that cleartext passwords may be read by anyone having read access to that information. For information about the conditions under which this occurs for the server logs and how to control it, see Section 6.1.2.3, “Passwords and Logging”. For similar information about client-side logging, see Section 4.5.1.3, “mysql Client Logging”.

There are several aspects to the ALTER_USER statement, described under the following topics:

• ALTER_USER Overview
• ALTER_USER Authentication Options
• ALTER_USER Multifactor Authentication Options
• ALTER_USER Registration Options
• ALTER_USER Role Options
• ALTER_USER SSL/TLS Options
• ALTER_USER Resource-Limit Options
• ALTER_USER Password-Management Options
• ALTER_USER Comment and Attribute Options
• ALTER_USER Account-Locking Options
• ALTER_USER Binary Logging

ALTER_USER Overview

For each affected account, ALTER_USER modifies the corresponding row in the mysql.user system table to reflect the properties specified in the statement. Unspecified properties retain their current values.
Each account name uses the format described in Section 6.2.4, “Specifying Account Names”. The host name part of the account name, if omitted, defaults to '%'. It is also possible to specify CURRENT_USER or CURRENT_USER() to refer to the account associated with the current session.

For one syntax only, the account may be specified with the USER() function:

```
ALTER USER USER() IDENTIFIED BY 'auth_string';
```

This syntax enables changing your own password without naming your account literally. (The syntax also supports the REPLACE, RETAIN CURRENT PASSWORD, and DISCARD OLD PASSWORD clauses described at ALTER USER Authentication Options.)

For ALTER USER syntax that permits an auth_option value to follow a user value, auth_option indicates how the account authenticates by specifying an account authentication plugin, credentials (for example, a password), or both. Each auth_option value applies only to the account named immediately preceding it.

Following the user specifications, the statement may include options for SSL/TLS, resource-limit, password-management, and locking properties. All such options are global to the statement and apply to all accounts named in the statement.

Example: Change an account's password and expire it. As a result, the user must connect with the named password and choose a new one at the next connection:

```
ALTER USER 'jeffrey'@'localhost' IDENTIFIED BY 'new_password' PASSWORD EXPIRE;
```

Example: Modify an account to use the caching_sha2_password authentication plugin and the given password. Require that a new password be chosen every 180 days, and enable failed-login tracking, such that three consecutive incorrect passwords cause temporary account locking for two days:

```
ALTER USER 'jeffrey'@'localhost' IDENTIFIED WITH caching_sha2_password BY 'new_password'
PASSWORD EXPIRE INTERVAL 180 DAY FAILED_LOGIN_ATTEMPTS 3 PASSWORD_LOCK_TIME 2;
```

Example: Lock or unlock an account:

```
ALTER USER 'jeffrey'@'localhost' ACCOUNT LOCK;
ALTER USER 'jeffrey'@'localhost' ACCOUNT UNLOCK;
```

Example: Require an account to connect using SSL and establish a limit of 20 connections per hour:

```
ALTER USER 'jeffrey'@'localhost' REQUIRE SSL WITH MAX_CONNECTIONS_PER_HOUR 20;
```

Example: Alter multiple accounts, specifying some per-account properties and some global properties:

```
ALTER USER
  'jeffrey'@'localhost'
  IDENTIFIED BY 'jeffrey_new_password',
  'jeanne'@'localhost',
  'josh'@'localhost'
  IDENTIFIED BY 'josh_new_password'
  REPLACE 'josh_current_password'
  RETAIN CURRENT PASSWORD
  REQUIRE SSL WITH MAX_USER_CONNECTIONS 2
  PASSWORD HISTORY 5;
```

The IDENTIFIED BY value following jeffrey applies only to its immediately preceding account, so it changes the password to 'jeffrey_new_password' only for jeffrey. For jeanne, there is no per-account value (thus leaving the password unchanged). For josh, IDENTIFIED BY establishes a new password ('josh_new_password'), REPLACE is specified to verify that the user issuing the ALTER
The USER statement knows the current password ("josh_current_password"), and that current password is also retained as the account secondary password. (As a result, josh can connect with either the primary or secondary password.)

The remaining properties apply globally to all accounts named in the statement, so for both accounts:

- Connections are required to use SSL.
- The account can be used for a maximum of two simultaneous connections.
- Password changes cannot reuse any of the five most recent passwords.

Example: Discard the secondary password for josh, leaving the account with only its primary password:

```
ALTER USER 'josh'@'localhost' DISCARD OLD PASSWORD;
```

In the absence of a particular type of option, the account remains unchanged in that respect. For example, with no locking option, the locking state of the account is not changed.

**ALTER USER Authentication Options**

An account name may be followed by an `auth_option` authentication option that specifies the account authentication plugin, credentials, or both. It may also include a password-verification clause that specifies the account current password to be replaced, and clauses that manage whether an account has a secondary password.

### Note

Clauses for random password generation, password verification, and secondary passwords apply only to accounts that use an authentication plugin that stores credentials internally to MySQL. For accounts that use a plugin that performs authentication against a credentials system that is external to MySQL, password management must be handled externally against that system as well. For more information about internal credentials storage, see Section 6.2.15, “Password Management”.

- `auth_plugin` names an authentication plugin. The plugin name can be a quoted string literal or an unquoted name. Plugin names are stored in the `plugin` column of the `mysql.user` system table.

  For `auth_option` syntax that does not specify an authentication plugin, the server assigns the default plugin, determined as described in The Default Authentication Plugin. For descriptions of each plugin, see Section 6.4.1, “Authentication Plugins”.

- Credentials that are stored internally are stored in the `mysql.user` system table. An `auth_string` value or `RANDOM PASSWORD` specifies account credentials, either as a cleartext (unencrypted) string or hashed in the format expected by the authentication plugin associated with the account, respectively:

  - For syntax that uses `BY 'auth_string'`, the string is cleartext and is passed to the authentication plugin for possible hashing. The result returned by the plugin is stored in the `mysql.user` table. A plugin may use the value as specified, in which case no hashing occurs.

  - For syntax that uses `BY RANDOM PASSWORD`, MySQL generates a random password and as cleartext and passes it to the authentication plugin for possible hashing. The result returned by the plugin is stored in the `mysql.user` table. A plugin may use the value as specified, in which case no hashing occurs.

Randomly generated passwords are available as of MySQL 8.0.18 and have the characteristics described in Random Password Generation.
• For syntax that uses AS 'auth_string', the string is assumed to be already in the format the authentication plugin requires, and is stored as is in the mysql.user table. If a plugin requires a hashed value, the value must be already hashed in a format appropriate for the plugin; otherwise, the value cannot be used by the plugin and correct authentication of client connections does not occur.

As of MySQL 8.0.17, a hashed string can be either a string literal or a hexadecimal value. The latter corresponds to the type of value displayed by SHOW CREATE USER for password hashes containing unprintable characters when the print_identified_with_as_hex system variable is enabled.

• If an authentication plugin performs no hashing of the authentication string, the BY 'auth_string' and AS 'auth_string' clauses have the same effect: The authentication string is stored as is in the mysql.user system table.

• The REPLACE 'current_auth_string' clause performs password verification and is available as of MySQL 8.0.13. If given:

  a. REPLACE specifies the account current password to be replaced, as a cleartext (unencrypted) string.

  b. The clause must be given if password changes for the account are required to specify the current password, as verification that the user attempting to make the change actually knows the current password.

  c. The clause is optional if password changes for the account may but need not specify the current password.

  d. The statement fails if the clause is given but does not match the current password, even if the clause is optional.

  e. REPLACE can be specified only when changing the account password for the current user.

For more information about password verification by specifying the current password, see Section 6.2.15, “Password Management”.

• The RETAIN CURRENT PASSWORD and DISCARD OLD PASSWORD clauses implement dual-password capability and are available as of MySQL 8.0.14. Both are optional, but if given, have the following effects:

  a. RETAIN CURRENT PASSWORD retains an account current password as its secondary password, replacing any existing secondary password. The new password becomes the primary password, but clients can use the account to connect to the server using either the primary or secondary password. (Exception: If the new password specified by the ALTER USER statement is empty, the secondary password becomes empty as well, even if RETAIN CURRENT PASSWORD is given.)

  b. If you specify RETAIN CURRENT PASSWORD for an account that has an empty primary password, the statement fails.

  c. If an account has a secondary password and you change its primary password without specifying RETAIN CURRENT PASSWORD, the secondary password remains unchanged.

  d. If you change the authentication plugin assigned to the account, the secondary password is discarded. If you change the authentication plugin and also specify RETAIN CURRENT PASSWORD, the statement fails.

  e. DISCARD OLD PASSWORD discards the secondary password, if one exists. The account retains only its primary password, and clients can use the account to connect to the server only with the primary password.
ALTER USER permits these auth_option syntaxes:

• IDENTIFIED BY 'auth_string' [REPLACE 'current_auth_string'] [RETAIN CURRENT PASSWORD]

Sets the account authentication plugin to the default plugin, passes the cleartext 'auth_string' value to the plugin for possible hashing, and stores the result in the account row in the mysql.user system table.

The REPLACE clause, if given, specifies the account current password, as described previously in this section.

The RETAIN CURRENT PASSWORD clause, if given, causes the account current password to be retained as its secondary password, as described previously in this section.

• IDENTIFIED BY RANDOM PASSWORD [REPLACE 'current_auth_string'] [RETAIN CURRENT PASSWORD]

Sets the account authentication plugin to the default plugin, generates a random password, passes the cleartext password value to the plugin for possible hashing, and stores the result in the account row in the mysql.user system table. The statement also returns the cleartext password in a result set to make it available to the user or application executing the statement. For details about the result set and characteristics of randomly generated passwords, see Random Password Generation.

The REPLACE clause, if given, specifies the account current password, as described previously in this section.

The RETAIN CURRENT PASSWORD clause, if given, causes the account current password to be retained as its secondary password, as described previously in this section.

• IDENTIFIED WITH auth_plugin

Sets the account authentication plugin to auth_plugin, clears the credentials to the empty string (the credentials are associated with the old authentication plugin, not the new one), and stores the result in the account row in the mysql.user system table.

In addition, the password is marked expired. The user must choose a new one when next connecting.

• IDENTIFIED WITH auth_plugin BY 'auth_string' [REPLACE 'current_auth_string'] [RETAIN CURRENT PASSWORD]

Sets the account authentication plugin to auth_plugin, passes the cleartext 'auth_string' value to the plugin for possible hashing, and stores the result in the account row in the mysql.user system table.

The REPLACE clause, if given, specifies the account current password, as described previously in this section.

The RETAIN CURRENT PASSWORD clause, if given, causes the account current password to be retained as its secondary password, as described previously in this section.

• IDENTIFIED WITH auth_plugin BY RANDOM PASSWORD [REPLACE 'current_auth_string'] [RETAIN CURRENT PASSWORD]
Account Management Statements

Sets the account authentication plugin to `auth_plugin`, generates a random password, passes the cleartext password value to the plugin for possible hashing, and stores the result in the account row in the `mysql.user` system table. The statement also returns the cleartext password in a result set to make it available to the user or application executing the statement. For details about the result set and characteristics of randomly generated passwords, see Random Password Generation.

The `REPLACE` clause, if given, specifies the account current password, as described previously in this section.

The `RETAIN CURRENT PASSWORD` clause, if given, causes the account current password to be retained as its secondary password, as described previously in this section.

- **IDENTIFIED WITH `auth_plugin` AS 'auth_string'**

  Sets the account authentication plugin to `auth_plugin` and stores the `auth_string` value as is in the `mysql.user` account row. If the plugin requires a hashed string, the string is assumed to be already hashed in the format the plugin requires.

- **DISCARD OLD PASSWORD**

  Discards the account secondary password, if there is one, as described previously in this section.

Example: Specify the password as cleartext; the default plugin is used:

```sql
ALTER USER 'jeffrey'@'localhost'
  IDENTIFIED BY 'password';
```

Example: Specify the authentication plugin, along with a cleartext password value:

```sql
ALTER USER 'jeffrey'@'localhost'
  IDENTIFIED WITH mysql_native_password
  BY 'password';
```

Example: Like the preceding example, but in addition, specify the current password as a cleartext value to satisfy any account requirement that the user making the change knows that password:

```sql
ALTER USER 'jeffrey'@'localhost'
  IDENTIFIED WITH mysql_native_password
  BY 'password'
  REPLACE 'current_password';
```

The preceding statement fails unless the current user is `jeffrey` because `REPLACE` is permitted only for changes to the current user's password.

Example: Establish a new primary password and retain the existing password as the secondary password:

```sql
ALTER USER 'jeffrey'@'localhost'
  IDENTIFIED BY 'new_password'
  RETAIN CURRENT PASSWORD;
```

Example: Discard the secondary password, leaving the account with only its primary password:

```sql
ALTER USER 'jeffery'@'localhost' DISCARD OLD PASSWORD;
```

Example: Specify the authentication plugin, along with a hashed password value:

```sql
ALTER USER 'jeffrey'@'localhost'
  IDENTIFIED WITH mysql_native_password
  AS '6C8989366EAF75BB670AD8EA7A7FC1176A95CEF4';
```

For additional information about setting passwords and authentication plugins, see Section 6.2.14, "Assigning Account Passwords", and Section 6.2.17, "Pluggable Authentication".
ALTER USER Multifactor Authentication Options

As of MySQL 8.0.27, `ALTER USER` has `ADD`, `MODIFY`, and `DROP` clauses that enable authentication factors to be added, modified, or dropped. In each case, the clause specifies an operation to perform on one authentication factor, and optionally an operation on another authentication factor. For each operation, the `factor` item specifies the `FACTOR` keyword preceded by the number 2 or 3 to indicate whether the operation applies to the second or third authentication factor. (1 is not permitted in this context. To act on the first authentication factor, use the syntax described in `ALTER USER Authentication Options`.)

`ALTER USER` multifactor authentication clause constraints are defined by the `authentication_policy` system variable. For example, the `authentication_policy` setting controls the number of authentication factors that accounts may have, and for each factor, which authentication methods are permitted. See Configuring the Multifactor Authentication Policy.

When `ALTER USER` adds, modifies, or drops second and third factors in a single statement, operations are executed sequentially, but if any operation in the sequence fails the entire `ALTER USER` statement fails.

For `ADD`, each named factor must not already exist or it cannot be added. For `MODIFY` and `DROP`, each named factor must exist to be modified or dropped. If a second and third factor are defined, dropping the second factor causes the third factor to take its place as the second factor.

This statement drops authentication factors 2 and 3, which has the effect of converting the account from 3FA to 1FA:

```
ALTER USER 'user' DROP 2 FACTOR 3 FACTOR;
```

For additional `ADD`, `MODIFY`, and `DROP` examples, see Getting Started with Multifactor Authentication.

For information about factor-specific rules that determine the default authentication plugin for authentication clauses that do not name a plugin, see The Default Authentication Plugin.

ALTER USER Registration Options

As of MySQL 8.0.27, `ALTER USER` has clauses that enable FIDO devices to be registered and unregistered. For more information, see Using FIDO Authentication, FIDO Device Unregistration, and the `mysql` client `--fido-register-factor` option description.

The `mysql` client `--fido-register-factor` option, used for FIDO device registration, causes the `mysql` client to generate and execute `INITIATE REGISTRATION` and `FINISH REGISTRATION` statements. These statements are not intended for manual execution.

ALTER USER Role Options

`ALTER USER ... DEFAULT ROLE` defines which roles become active when the user connects to the server and authenticates, or when the user executes the `SET ROLE DEFAULT` statement during a session.

`ALTER USER ... DEFAULT ROLE` is alternative syntax for `SET DEFAULT ROLE` (see Section 13.7.1.9, “SET DEFAULT ROLE Statement”). However, `ALTER USER` can set the default for only a single user, whereas `SET DEFAULT ROLE` can set the default for multiple users. On the other hand, you can specify `CURRENT_USER` as the user name for the `ALTER USER` statement, whereas you cannot for `SET DEFAULT ROLE`.

Each user account name uses the format described previously.

Each role name uses the format described in Section 6.2.5, “Specifying Role Names”. For example:

```
ALTER USER 'joe'@'10.0.0.1' DEFAULT ROLE administrator, developer;
```

The host name part of the role name, if omitted, defaults to '%'.

3098
The clause following the `DEFAULT ROLE` keywords permits these values:

- **NONE**: Set the default to `NONE` (no roles).
- **ALL**: Set the default to all roles granted to the account.
- **role [, role ] ...**: Set the default to the named roles, which must exist and be granted to the account at the time `ALTER USER ... DEFAULT ROLE` is executed.

**ALTER USER SSL/TLS Options**

MySQL can check X.509 certificate attributes in addition to the usual authentication that is based on the user name and credentials. For background information on the use of SSL/TLS with MySQL, see Section 6.3, “Using Encrypted Connections”.

To specify SSL/TLS-related options for a MySQL account, use a `REQUIRE` clause that specifies one or more `tls_option` values.

Order of `REQUIRE` options does not matter, but no option can be specified twice. The `AND` keyword is optional between `REQUIRE` options.

**ALTER USER** permits these `tls_option` values:

- **NONE**
  
  Indicates that all accounts named by the statement have no SSL or X.509 requirements. Unencrypted connections are permitted if the user name and password are valid. Encrypted connections can be used, at the client's option, if the client has the proper certificate and key files.

  ```sql
  ALTER USER 'jeffrey'@'localhost' REQUIRE NONE;
  ```

  Clients attempt to establish a secure connection by default. For clients that have `REQUIRE NONE`, the connection attempt falls back to an unencrypted connection if a secure connection cannot be established. To require an encrypted connection, a client need specify only the `--ssl-mode=REQUIRED` option; the connection attempt fails if a secure connection cannot be established.

- **SSL**

  Tells the server to permit only encrypted connections for all accounts named by the statement.

  ```sql
  ALTER USER 'jeffrey'@'localhost' REQUIRE SSL;
  ```

  Clients attempt to establish a secure connection by default. For accounts that have `REQUIRE SSL`, the connection attempt fails if a secure connection cannot be established.

- **X509**

  For all accounts named by the statement, requires that clients present a valid certificate, but the exact certificate, issuer, and subject do not matter. The only requirement is that it should be possible to verify its signature with one of the CA certificates. Use of X.509 certificates always implies encryption, so the `SSL` option is unnecessary in this case.

  ```sql
  ALTER USER 'jeffrey'@'localhost' REQUIRE X509;
  ```

  For accounts with `REQUIRE X509`, clients must specify the `--ssl-key` and `--ssl-cert` options to connect. (It is recommended but not required that `--ssl-ca` also be specified so that the public certificate provided by the server can be verified.) This is true for `ISSUER` and `SUBJECT` as well because those `REQUIRE` options imply the requirements of `X509`.

- **ISSUER 'issuer'**
For all accounts named by the statement, requires that clients present a valid X.509 certificate issued by CA 'issuer'. If a client presents a certificate that is valid but has a different issuer, the server rejects the connection. Use of X.509 certificates always implies encryption, so the SSL option is unnecessary in this case.

```sql
ALTER USER 'jeffrey'@'localhost'
    REQUIRE ISSUER '/C=SE/ST=Stockholm/L=Stockholm/
    O=MySQL/CN=CA/emailAddress=ca@example.com';
```

Because ISSUER implies the requirements of X509, clients must specify the --ssl-key and --ssl-cert options to connect. (It is recommended but not required that --ssl-ca also be specified so that the public certificate provided by the server can be verified.)

- **SUBJECT 'subject'**

For all accounts named by the statement, requires that clients present a valid X.509 certificate containing the subject subject. If a client presents a certificate that is valid but has a different subject, the server rejects the connection. Use of X.509 certificates always implies encryption, so the SSL option is unnecessary in this case.

```sql
ALTER USER 'jeffrey'@'localhost'
    REQUIRE SUBJECT '/C=SE/ST=Stockholm/L=Stockholm/
    O=MySQL demo client certificate/
    CN=client/emailAddress=client@example.com';
```

MySQL does a simple string comparison of the 'subject' value to the value in the certificate, so lettercase and component ordering must be given exactly as present in the certificate.

Because SUBJECT implies the requirements of X509, clients must specify the --ssl-key and --ssl-cert options to connect. (It is recommended but not required that --ssl-ca also be specified so that the public certificate provided by the server can be verified.)

- **CIPHER 'cipher'**

For all accounts named by the statement, requires a specific cipher method for encrypting connections. This option is needed to ensure that ciphers and key lengths of sufficient strength are used. Encryption can be weak if old algorithms using short encryption keys are used.

```sql
ALTER USER 'jeffrey'@'localhost'
    REQUIRE CIPHER 'EDH-RSA-DES-CBC3-SHA';
```

The SUBJECT, ISSUER, and CIPHER options can be combined in the REQUIRE clause:

```sql
ALTER USER 'jeffrey'@'localhost'
    REQUIRE SUBJECT '/C=SE/ST=Stockholm/L=Stockholm/
    O=MySQL demo client certificate/
    CN=client/emailAddress=client@example.com'
    AND ISSUER '/C=SE/ST=Stockholm/L=Stockholm/
    O=MySQL/CN=CA/emailAddress=ca@example.com'
    AND CIPHER 'EDH-RSA-DES-CBC3-SHA';
```

**ALTER USER Resource-Limit Options**

It is possible to place limits on use of server resources by an account, as discussed in Section 6.2.21, “Setting Account Resource Limits”. To do so, use a WITH clause that specifies one or more resource_option values.

Order of WITH options does not matter, except that if a given resource limit is specified multiple times, the last instance takes precedence.
ALTER USER permits these resource_option values:

- **MAX_QUERIES_PER_HOUR** count,
  **MAX_UPDATES_PER_HOUR** count,
  **MAX_CONNECTIONS_PER_HOUR** count

For all accounts named by the statement, these options restrict how many queries, updates, and connections to the server are permitted to each account during any given one-hour period. If count is 0 (the default), this means that there is no limitation for the account.

- **MAX_USER_CONNECTIONS** count

For all accounts named by the statement, restricts the maximum number of simultaneous connections to the server by each account. A nonzero count specifies the limit for the account explicitly. If count is 0 (the default), the server determines the number of simultaneous connections for the account from the global value of the max_user_connections system variable. If max_user_connections is also zero, there is no limit for the account.

Example:

```
ALTER USER 'jeffrey'@'localhost'
  WITH MAX_QUERIES_PER_HOUR 500 MAX_UPDATES_PER_HOUR 100;
```

### ALTER USER Password-Management Options

ALTER USER supports several password_option values for password management:

- **Password expiration options:** You can expire an account password manually and establish its password expiration policy. Policy options do not expire the password. Instead, they determine how the server applies automatic expiration to the account based on password age, which is assessed from the date and time of the most recent account password change.

- **Password reuse options:** You can restrict password reuse based on number of password changes, time elapsed, or both.

- **Password verification-required options:** You can indicate whether attempts to change an account password must specify the current password, as verification that the user attempting to make the change actually knows the current password.

- **Incorrect-password failed-login tracking options:** You can cause the server to track failed login attempts and temporarily lock accounts for which too many consecutive incorrect passwords are given. The required number of failures and the lock time are configurable.

This section describes the syntax for password-management options. For information about establishing policy for password management, see Section 6.2.15, “Password Management”.

If multiple password-management options of a given type are specified, the last one takes precedence. For example, **PASSWORD EXPIRE DEFAULT PASSWORD EXPIRE NEVER** is the same as **PASSWORD EXPIRE NEVER**.

**Note**

Except for the options that pertain to failed-login tracking, password-management options apply only to accounts that use an authentication plugin that stores credentials internally to MySQL. For accounts that use a plugin that performs authentication against a credentials system that is external to MySQL, password management must be handled externally against that system as well. For more
A client has an expired password if the account password was expired manually or the password age is considered greater than its permitted lifetime per the automatic expiration policy. In this case, the server either disconnects the client or restricts the operations permitted to it (see Section 6.2.16, “Server Handling of Expired Passwords”). Operations performed by a restricted client result in an error until the user establishes a new account password.

**Note**

Although it is possible to “reset” an expired password by setting it to its current value, it is preferable, as a matter of good policy, to choose a different password. DBAs can enforce non-reuse by establishing an appropriate password-reuse policy. See Password Reuse Policy.

**ALTER USER** permits these **password_option** values for controlling password expiration:

- **PASSWORD EXPIRE**
  
  Immediately marks the password expired for all accounts named by the statement.
  
  ```sql
  ALTER USER 'jeffrey'@'localhost' PASSWORD EXPIRE;
  ```

- **PASSWORD EXPIRE DEFAULT**
  
  Sets all accounts named by the statement so that the global expiration policy applies, as specified by the `default_password_lifetime` system variable.
  
  ```sql
  ALTER USER 'jeffrey'@'localhost' PASSWORD EXPIRE DEFAULT;
  ```

- **PASSWORD EXPIRE NEVER**
  
  This expiration option overrides the global policy for all accounts named by the statement. For each, it disables password expiration so that the password never expires.
  
  ```sql
  ALTER USER 'jeffrey'@'localhost' PASSWORD EXPIRE NEVER;
  ```

- **PASSWORD EXPIRE INTERVAL N DAY**
  
  This expiration option overrides the global policy for all accounts named by the statement. For each, it sets the password lifetime to `N` days. The following statement requires the password to be changed every 180 days:
  
  ```sql
  ALTER USER 'jeffrey'@'localhost' PASSWORD EXPIRE INTERVAL 180 DAY;
  ```

**ALTER USER** permits these **password_option** values for controlling reuse of previous passwords based on required minimum number of password changes:

- **PASSWORD HISTORY DEFAULT**
  
  Sets all accounts named by the statement so that the global policy about password history length applies, to prohibit reuse of passwords before the number of changes specified by the `password_history` system variable.
  
  ```sql
  ALTER USER 'jeffrey'@'localhost' PASSWORD HISTORY DEFAULT;
  ```

- **PASSWORD HISTORY N**
This history-length option overrides the global policy for all accounts named by the statement. For each, it sets the password history length to $N$ passwords, to prohibit reusing any of the $N$ most recently chosen passwords. The following statement prohibits reuse of any of the previous 6 passwords:

```
ALTER USER 'jeffrey'@'localhost' PASSWORD HISTORY 6;
```

**ALTER USER** permits these `password_option` values for controlling reuse of previous passwords based on time elapsed:

- **PASSWORD REUSE INTERVAL DEFAULT**

  Sets all statements named by the account so that the global policy about time elapsed applies, to prohibit reuse of passwords newer than the number of days specified by the `password_reuse_interval` system variable.

  ```
  ALTER USER 'jeffrey'@'localhost' PASSWORD REUSE INTERVAL DEFAULT;
  ```

- **PASSWORD REUSE INTERVAL $N$ DAY**

  This time-elapsed option overrides the global policy for all accounts named by the statement. For each, it sets the password reuse interval to $N$ days, to prohibit reuse of passwords newer than that many days. The following statement prohibits password reuse for 360 days:

  ```
  ALTER USER 'jeffrey'@'localhost' PASSWORD REUSE INTERVAL 360 DAY;
  ```

**ALTER USER** permits these `password_option` values for controlling whether attempts to change an account password must specify the current password, as verification that the user attempting to make the change actually knows the current password:

- **PASSWORD REQUIRE CURRENT**

  This verification option overrides the global policy for all accounts named by the statement. For each, it requires that password changes specify the current password.

  ```
  ALTER USER 'jeffrey'@'localhost' PASSWORD REQUIRE CURRENT;
  ```

- **PASSWORD REQUIRE CURRENT OPTIONAL**

  This verification option overrides the global policy for all accounts named by the statement. For each, it does not require that password changes specify the current password. (The current password may but need not be given.)

  ```
  ALTER USER 'jeffrey'@'localhost' PASSWORD REQUIRE CURRENT OPTIONAL;
  ```

- **PASSWORD REQUIRE CURRENT DEFAULT**

  Sets all statements named by the account so that the global policy about password verification applies, as specified by the `password_require_current` system variable.

  ```
  ALTER USER 'jeffrey'@'localhost' PASSWORD REQUIRE CURRENT DEFAULT;
  ```

As of MySQL 8.0.19, **ALTER USER** permits these `password_option` values for controlling failed-login tracking:

- **FAILED_LOGIN_ATTEMPTS $N$**

  Whether to track account login attempts that specify an incorrect password. $N$ must be a number from 0 to 32767. A value of 0 disables failed-login tracking. Values greater than 0 indicate how many
Account Management Statements

consecutive password failures cause temporary account locking (if PASSWORD_LOCK_TIME is also
nonzero).
• PASSWORD_LOCK_TIME {N | UNBOUNDED}
How long to lock the account after too many consecutive login attempts provide an incorrect password.
N must be a number from 0 to 32767, or UNBOUNDED. A value of 0 disables temporary account locking.
Values greater than 0 indicate how long to lock the account in days. A value of UNBOUNDED causes
the account locking duration to be unbounded; once locked, the account remains in a locked state until
unlocked. For information about the conditions under which unlocking occurs, see Failed-Login Tracking
and Temporary Account Locking.
For failed-login tracking and temporary locking to occur, an account's FAILED_LOGIN_ATTEMPTS and
PASSWORD_LOCK_TIME options both must be nonzero. The following statement modifies an account such
that it remains locked for two days after four consecutive password failures:
ALTER USER 'jeffrey'@'localhost'
FAILED_LOGIN_ATTEMPTS 4 PASSWORD_LOCK_TIME 2;

ALTER USER Comment and Attribute Options
MySQL 8.0.21 and higher supports user comments and user attributes, as described in Section 13.7.1.3,
“CREATE USER Statement”. These can be modified employing ALTER USER by means of the COMMENT
and ATTRIBUTE options, respectively. You cannot specify both options in the same ALTER USER
statement; attempting to do so results in a syntax error.
The user comment and user attribute are stored in the Information Schema USER_ATTRIBUTES table as
a JSON object; the user comment is stored as the value for a comment key in the ATTRIBUTE column
of this table, as shown later in this discussion. The COMMENT text can be any arbitrary quoted text, and
replaces any existing user comment. The ATTRIBUTE value must be the valid string representation of a
JSON object. This is merged with any existing user attribute as if the JSON_MERGE_PATCH() function had
been used on the existing user attribute and the new one; for any keys that are re-used, the new value
overwrites the old one, as shown here:
mysql> SELECT * FROM INFORMATION_SCHEMA.USER_ATTRIBUTES
->
WHERE USER='bill' AND HOST='localhost';
+------+-----------+----------------+
| USER | HOST
| ATTRIBUTE
|
+------+-----------+----------------+
| bill | localhost | {"foo": "bar"} |
+------+-----------+----------------+
1 row in set (0.11 sec)
mysql> ALTER USER 'bill'@'localhost' ATTRIBUTE '{"baz": "faz", "foo": "moo"}';
Query OK, 0 rows affected (0.22 sec)
mysql> SELECT * FROM INFORMATION_SCHEMA.USER_ATTRIBUTES
->
WHERE USER='bill' AND HOST='localhost';
+------+-----------+------------------------------+
| USER | HOST
| ATTRIBUTE
|
+------+-----------+------------------------------+
| bill | localhost | {"baz": "faz", "foo": "moo"} |
+------+-----------+------------------------------+
1 row in set (0.00 sec)

To remove a key and its value from the user attribute, set the key to JSON null (must be lowercase and
unquoted), like this:
mysql> ALTER USER 'bill'@'localhost' ATTRIBUTE '{"foo": null}';
Query OK, 0 rows affected (0.08 sec)

3104


### ALTER USER Account-Locking Options

MySQL supports account locking and unlocking using the `ACCOUNT LOCK` and `ACCOUNT UNLOCK` options, which specify the locking state for an account. For additional discussion, see Section 6.2.20, “Account Locking”.

If multiple account-locking options are specified, the last one takes precedence.

**ALTER USER ... ACCOUNT UNLOCK** unlocks any account named by the statement that is temporarily locked due to too many failed logins. See Section 6.2.15, “Password Management”.

### ALTER USER Binary Logging
ALTER USER is written to the binary log if it succeeds, but not if it fails; in that case, rollback occurs and no changes are made. A statement written to the binary log includes all named users. If the IF EXISTS clause is given, this includes even users that do not exist and were not altered.

If the original statement changes the credentials for a user, the statement written to the binary log specifies the applicable authentication plugin for that user, determined as follows:

- The plugin named in the original statement, if one was specified.
- Otherwise, the plugin associated with the user account if the user exists, or the default authentication plugin if the user does not exist. (If the statement written to the binary log must specify a particular authentication plugin for a user, include it in the original statement.)

If the server adds the default authentication plugin for any users in the statement written to the binary log, it writes a warning to the error log naming those users.

If the original statement specifies the FAILED_LOGIN_ATTEMPTS or PASSWORD_LOCK_TIME option, the statement written to the binary log includes the option.

ALTER USER statements with clauses that support multifactor authentication (MFA) are written to the binary log with the exception of ALTER USER user factor INITIATE REGISTRATION statements.

- ALTER USER user factor FINISH REGISTRATION SET CHALLENGE_RESPONSE AS 'auth_string' statements are written to the binary log as ALTER USER user MODIFY factor IDENTIFIED WITH authentication_fido AS fido_hash_string;
- In a replication context, the replication user requires PASSWORDLESS_USER_ADMIN privilege to execute ALTER USER ... MODIFY operations on accounts configured for passwordless authentication using the authentication_fido plugin.

### 13.7.1.2 CREATE ROLE Statement

CREATE ROLE [IF NOT EXISTS] role [, role ] ...

CREATE ROLE creates one or more roles, which are named collections of privileges. To use this statement, you must have the global CREATE ROLE or CREATE USER privilege. When the read_only system variable is enabled, CREATE ROLE additionally requires the CONNECTION_ADMIN privilege (or the deprecated SUPER privilege).

A role when created is locked, has no password, and is assigned the default authentication plugin. (These role attributes can be changed later with the ALTER USER statement, by users who have the global CREATE USER privilege.)

CREATE ROLE either succeeds for all named roles or rolls back and has no effect if any error occurs. By default, an error occurs if you try to create a role that already exists. If the IF NOT EXISTS clause is given, the statement produces a warning for each named role that already exists, rather than an error.

The statement is written to the binary log if it succeeds, but not if it fails; in that case, rollback occurs and no changes are made. A statement written to the binary log includes all named roles. If the IF NOT EXISTS clause is given, this includes even roles that already exist and were not created.

Each role name uses the format described in Section 6.2.5, “Specifying Role Names”. For example:

```
CREATE ROLE 'admin', 'developer';
CREATE ROLE 'webapp'@'localhost';
```

The host name part of the role name, if omitted, defaults to '%'.

For role usage examples, see Section 6.2.10, “Using Roles”.

3106
13.7.1.3 CREATE USER Statement

CREATE USER [IF NOT EXISTS] user [auth_option] [, user [auth_option]] ...
DEFAULT ROLE role [, role ] ...
[REQUIRE {NONE | tls_option [AND] tls_option] ...)]
[WITH resource_option [resource_option] ...]
[password_option | lock_option] ...
[COMMENT 'comment_string' | ATTRIBUTE 'json_object']

user: (see Section 6.2.4, "Specifying Account Names")

auth_option: 
| IDENTIFIED BY 'auth_string' [AND 2fa_auth_option]
| IDENTIFIED BY RANDOM PASSWORD [AND 2fa_auth_option]
| IDENTIFIED WITH auth_plugin BY 'auth_string' [AND 2fa_auth_option]
| IDENTIFIED WITH auth_plugin BY RANDOM PASSWORD [AND 2fa_auth_option]
| IDENTIFIED WITH auth_plugin AS 'auth_string' [AND 2fa_auth_option]
| IDENTIFIED WITH auth_plugin [initial_auth_option]

2fa_auth_option: 
| IDENTIFIED BY 'auth_string' [AND 3fa_auth_option]
| IDENTIFIED BY RANDOM PASSWORD [AND 3fa_auth_option]
| IDENTIFIED WITH auth_plugin [AND 3fa_auth_option]
| IDENTIFIED WITH auth_plugin BY 'auth_string' [AND 3fa_auth_option]
| IDENTIFIED WITH auth_plugin BY RANDOM PASSWORD [AND 3fa_auth_option]
| IDENTIFIED WITH auth_plugin AS 'auth_string' [AND 3fa_auth_option]

3fa_auth_option: 
| IDENTIFIED BY 'auth_string'
| IDENTIFIED BY RANDOM PASSWORD
| IDENTIFIED WITH auth_plugin
| IDENTIFIED WITH auth_plugin BY 'auth_string'
| IDENTIFIED WITH auth_plugin BY RANDOM PASSWORD
| IDENTIFIED WITH auth_plugin AS 'auth_string'

initial_auth_option: 
| INITIAL AUTHENTICATION IDENTIFIED BY {RANDOM PASSWORD | 'auth_string'}
| INITIAL AUTHENTICATION IDENTIFIED WITH auth_plugin AS 'auth_string'

tls_option: 
| SSL
| X509
| CIPHER 'cipher'
| ISSUER 'issuer'
| SUBJECT 'subject'

resource_option: 
| MAX QUERIES PER HOUR count
| MAX UPDATES PER HOUR count
| MAX CONNECTIONS PER HOUR count
| MAX USER CONNECTIONS count

password_option: 
| PASSWORD EXPIRE [DEFAULT | NEVER | INTERVAL N DAY]
| PASSWORD HISTORY [DEFAULT | N]
| PASSWORD REUSE INTERVAL [DEFAULT | N DAY]
| PASSWORD REQUIRE CURRENT [DEFAULT | OPTIONAL]
| FAILED LOGIN_ATTEMPTS N
The CREATE USER statement creates new MySQL accounts. It enables authentication, role, SSL/TLS, resource-limit, password-management, comment, and attribute properties to be established for new accounts. It also controls whether accounts are initially locked or unlocked.

To use CREATE USER, you must have the global CREATE USER privilege, or the INSERT privilege for the mysql system schema. When the read_only system variable is enabled, CREATE USER additionally requires the CONNECTION_ADMIN privilege (or the deprecated SUPER privilege).

As of MySQL 8.0.27, these additional privilege considerations apply:

- The authentication_policy system variable places certain constraints on how the authentication-related clauses of CREATE USER statements may be used; for details, see the description of that variable. These constraints do not apply if you have the AUTHENTICATION_POLICY_ADMIN privilege.
- To create an account that uses passwordless authentication, you must have the PASSWORDLESS_USER_ADMIN privilege.

As of MySQL 8.0.22, CREATE USER fails with an error if any account to be created is named as the DEFINER attribute for any stored object. (That is, the statement fails if creating an account would cause the account to adopt a currently orphaned stored object.) To perform the operation anyway, you must have the SET_USER_ID privilege; in this case, the statement succeeds with a warning rather than failing with an error. Without SET_USER_ID, to perform the user-creation operation, drop the orphan objects, create the account and grant its privileges, and then re-create the dropped objects. For additional information, including how to identify which objects name a given account as the DEFINER attribute, see Orphan Stored Objects.

CREATE USER either succeeds for all named users or rolls back and has no effect if any error occurs. By default, an error occurs if you try to create a user that already exists. If the IF NOT EXISTS clause is given, the statement produces a warning for each named user that already exists, rather than an error.

Important

Under some circumstances, CREATE USER may be recorded in server logs or on the client side in a history file such as ~/.mysql_history, which means that cleartext passwords may be read by anyone having read access to that information. For information about the conditions under which this occurs for the server logs and how to control it, see Section 6.1.2.3, “Passwords and Logging”. For similar information about client-side logging, see Section 4.5.1.3, “mysql Client Logging”.

There are several aspects to the CREATE USER statement, described under the following topics:

- CREATE USER Overview
- CREATE USER Authentication Options
- CREATE USER Multifactor Authentication Options
- CREATE USER Role Options
- CREATE USER SSL/TLS Options
- CREATE USER Resource-Limit Options
CREATE USER Overview

For each account, CREATE USER creates a new row in the mysql.user system table. The account row reflects the properties specified in the statement. Unspecified properties are set to their default values:

- Authentication: The default authentication plugin (determined as described in The Default Authentication Plugin), and empty credentials
- Default role: NONE
- SSL/TLS: NONE
- Resource limits: Unlimited
- Password management: PASSWORD EXPIRE DEFAULT PASSWORD HISTORY DEFAULT PASSWORD REUSE INTERVAL DEFAULT PASSWORD REQUIRE CURRENT DEFAULT; failed-login tracking and temporary account locking are disabled
- Account locking: ACCOUNT UNLOCK

An account when first created has no privileges and a default role of NONE. To assign privileges or roles, use the GRANT statement.

Each account name uses the format described in Section 6.2.4, “Specifying Account Names”. For example:

CREATE USER 'jeffrey'@'localhost' IDENTIFIED BY 'password';

The host name part of the account name, if omitted, defaults to '%'.

Each user value naming an account may be followed by an optional auth_option value that indicates how the account authenticates. These values enable account authentication plugins and credentials (for example, a password) to be specified. Each auth_option value applies only to the account named immediately preceding it.

Following the user specifications, the statement may include options for SSL/TLS, resource-limit, password-management, and locking properties. All such options are global to the statement and apply to all accounts named in the statement.

Example: Create an account that uses the default authentication plugin and the given password. Mark the password expired so that the user must choose a new one at the first connection to the server:

CREATE USER 'jeffrey'@'localhost'
  IDENTIFIED BY 'new_password' PASSWORD EXPIRE;

Example: Create an account that uses the caching_sha2_password authentication plugin and the given password. Require that a new password be chosen every 180 days, and enable failed-login tracking, such that three consecutive incorrect passwords cause temporary account locking for two days:

CREATE USER 'jeffrey'@'localhost'
  IDENTIFIED WITH caching_sha2_password BY 'new_password'
  PASSWORD EXPIRE INTERVAL 180 DAY
  FAILED_LOGIN_ATTEMPTS 3 PASSWORD_LOCK_TIME 2;
Example: Create multiple accounts, specifying some per-account properties and some global properties:

```
CREATE USER 'jeffrey'@'localhost' IDENTIFIED WITH mysql_native_password BY 'new_password1',
       'jeanne'@'localhost' IDENTIFIED WITH caching_sha2_password BY 'new_password2'
REQUIRE X509 WITH MAX QUERIES PER HOUR 60
PASSWORD HISTORY 5
ACCOUNT LOCK;
```

Each `auth_option` value (`IDENTIFIED WITH ... BY` in this case) applies only to the account named immediately preceding it, so each account uses the immediately following authentication plugin and password.

The remaining properties apply globally to all accounts named in the statement, so for both accounts:

- Connections must be made using a valid X.509 certificate.
- Up to 60 queries per hour are permitted.
- Password changes cannot reuse any of the five most recent passwords.
- The account is locked initially, so effectively it is a placeholder and cannot be used until an administrator unlocks it.

**CREATE USER Authentication Options**

An account name may be followed by an `auth_option` authentication option that specifies the account authentication plugin, credentials, or both.

**Note**

Prior to MySQL 8.0.27, `auth_option` defines the sole method by which an account authenticates. That is, all accounts use one-factor/single-factor authentication (1FA/SFA). MySQL 8.0.27 and higher supports multifactor authentication (MFA), such that accounts can have up to three authentication methods. That is, accounts can use two-factor authentication (2FA) or three-factor authentication (3FA). The syntax and semantics of `auth_option` remain unchanged, but `auth_option` may be followed by specifications for additional authentication methods. This section describes `auth_option`. For details about the optional MFA-related following clauses, see CREATE USER Multifactor Authentication Options.

**Note**

Clauses for random password generation apply only to accounts that use an authentication plugin that stores credentials internally to MySQL. For accounts that use a plugin that performs authentication against a credentials system that is external to MySQL, password management must be handled externally against that system as well. For more information about internal credentials storage, see Section 6.2.15, “Password Management”.

- `auth_plugin` names an authentication plugin. The plugin name can be a quoted string literal or an unquoted name. Plugin names are stored in the `plugin` column of the `mysql.user` system table.

For `auth_option` syntax that does not specify an authentication plugin, the server assigns the default plugin, determined as described in The Default Authentication Plugin. For descriptions of each plugin, see Section 6.4.1, “Authentication Plugins”.

3110
Account Management Statements

• Credentials that are stored internally are stored in the **mysql.user** system table. An **'auth_string'** value or **RANDOM PASSWORD** specifies account credentials, either as a cleartext (unencrypted) string or hashed in the format expected by the authentication plugin associated with the account, respectively:

• For syntax that uses **BY 'auth_string'**, the string is cleartext and is passed to the authentication plugin for possible hashing. The result returned by the plugin is stored in the **mysql.user** table. A plugin may use the value as specified, in which case no hashing occurs.

• For syntax that uses **BY RANDOM PASSWORD**, MySQL generates a random password and as cleartext and passes it to the authentication plugin for possible hashing. The result returned by the plugin is stored in the **mysql.user** table. A plugin may use the value as specified, in which case no hashing occurs.

Randomly generated passwords are available as of MySQL 8.0.18 and have the characteristics described in **Random Password Generation**.

• For syntax that uses **AS 'auth_string'**, the string is assumed to be already in the format the authentication plugin requires, and is stored as is in the **mysql.user** table. If a plugin requires a hashed value, the value must be already hashed in a format appropriate for the plugin; otherwise, the value cannot be used by the plugin and correct authentication of client connections does not occur.

As of MySQL 8.0.17, a hashed string can be either a string literal or a hexadecimal value. The latter corresponds to the type of value displayed by **SHOW CREATE USER** for password hashes containing unprintable characters when the **print_identified_with_as_hex** system variable is enabled.

• If an authentication plugin performs no hashing of the authentication string, the **BY 'auth_string'** and **AS 'auth_string'** clauses have the same effect: The authentication string is stored as is in the **mysql.user** system table.

**CREATE USER** permits these **auth_option** syntaxes:

• **IDENTIFIED BY 'auth_string'**

Sets the account authentication plugin to the default plugin, passes the cleartext **'auth_string'** value to the plugin for possible hashing, and stores the result in the account row in the **mysql.user** system table.

• **IDENTIFIED BY RANDOM PASSWORD**

Sets the account authentication plugin to the default plugin, generates a random password, passes the cleartext password value to the plugin for possible hashing, and stores the result in the account row in the **mysql.user** system table. The statement also returns the cleartext password in a result set to make it available to the user or application executing the statement. For details about the result set and characteristics of randomly generated passwords, see **Random Password Generation**.

• **IDENTIFIED WITH auth_plugin**

Sets the account authentication plugin to **auth_plugin**, clears the credentials to the empty string, and stores the result in the account row in the **mysql.user** system table.

• **IDENTIFIED WITH auth_plugin BY 'auth_string'**

Sets the account authentication plugin to **auth_plugin**, passes the cleartext **'auth_string'** value to the plugin for possible hashing, and stores the result in the account row in the **mysql.user** system table.

• **IDENTIFIED WITH auth_plugin BY RANDOM PASSWORD**
Sets the account authentication plugin to `auth_plugin`, generates a random password, passes the cleartext password value to the plugin for possible hashing, and stores the result in the account row in the `mysql.user` system table. The statement also returns the cleartext password in a result set to make it available to the user or application executing the statement. For details about the result set and characteristics of randomly generated passwords, see Random Password Generation.

- **IDENTIFIED WITH `auth_plugin` AS 'auth_string'**

  Sets the account authentication plugin to `auth_plugin` and stores the `auth_string` value as is in the `mysql.user` account row. If the plugin requires a hashed string, the string is assumed to be already hashed in the format the plugin requires.

Example: Specify the password as cleartext; the default plugin is used:

```sql
CREATE USER 'jeffrey'@'localhost'
  IDENTIFIED BY 'password';
```

Example: Specify the authentication plugin, along with a cleartext password value:

```sql
CREATE USER 'jeffrey'@'localhost'
  IDENTIFIED WITH mysql_native_password BY 'password';
```

In each case, the password value stored in the account row is the cleartext value `password` after it has been hashed by the authentication plugin associated with the account.

For additional information about setting passwords and authentication plugins, see Section 6.2.14, "Assigning Account Passwords", and Section 6.2.17, "Pluggable Authentication".

### CREATE USER Multifactor Authentication Options

The `auth_option` part of CREATE USER defines an authentication method for one-factor/single-factor authentication (1FA/SFA). As of MySQL 8.0.27, CREATE USER has clauses that support multifactor authentication (MFA), such that accounts can have up to three authentication methods. That is, accounts can use two-factor authentication (2FA) or three-factor authentication (3FA).

The `authentication_policy` system variable defines constraints for CREATE USER statements with multifactor authentication (MFA) clauses. For example, the `authentication_policy` setting controls the number of authentication factors that accounts may have, and for each factor, which authentication methods are permitted. See Configuring the Multifactor Authentication Policy.

For information about factor-specific rules that determine the default authentication plugin for authentication clauses that name no plugin, see The Default Authentication Plugin.

Following `auth_option`, there may appear different optional MFA clauses:

- **2fa_auth_option**: Specifies a factor 2 authentication method. The following example defines `caching_sha2_password` as the factor 1 authentication method, and `authentication_ldap_sasl` as the factor 2 authentication method.

  ```sql
  CREATE USER 'u1'@'localhost'
    IDENTIFIED WITH caching_sha2_password BY 'sha2_password'
    AND IDENTIFIED WITH authentication_ldap_sasl AS 'uid=u1_ldap,ou=People,dc=example,dc=com';
  ```

- **3fa_auth_option**: Following `2fa_auth_option`, there may appear a `3fa_auth_option` clause to specify a factor 3 authentication method. The following example defines `caching_sha2_password` as the factor 1 authentication method, `authentication_ldap_sasl` as the factor 2 authentication method, and `authentication_fido` as the factor 3 authentication method.
CREATE USER 'u1'@'localhost' IDENTIFIED WITH caching_sha2_password BY 'sha2_password' AND IDENTIFIED WITH authentication_ldap_sasl AS 'uid=u1_ldap,ou=People,dc=example,dc=com' AND IDENTIFIED WITH authentication_fido;

- **initial_auth_option**: Specifies an initial authentication method for configuring FIDO passwordless authentication. As shown in the following, temporary authentication using either a generated random password or a user-specified `auth-string` is required to enable FIDO passwordless authentication.

CREATE USER user IDENTIFIED WITH authentication_fido INITIAL AUTHENTICATION IDENTIFIED BY {RANDOM PASSWORD | 'auth_string'};

For information about configuring passwordless authentication using FIDO pluggable authentication, see [FIDO Passwordless Authentication](#).

**CREATE USER Role Options**

The **DEFAULT ROLE** clause defines which roles become active when the user connects to the server and authenticates, or when the user executes the `SET ROLE DEFAULT` statement during a session.

Each role name uses the format described in Section 6.2.5, “Specifying Role Names”. For example:

CREATE USER 'joe'@'10.0.0.1' DEFAULT ROLE administrator, developer;

The host name part of the role name, if omitted, defaults to '%'.

The **DEFAULT ROLE** clause permits a list of one or more comma-separated role names. These roles must exist at the time `CREATE USER` is executed; otherwise the statement raises an error (ER_USER_DOES_NOT_EXIST), and the user is not created.

**CREATE USER SSL/TLS Options**

MySQL can check X.509 certificate attributes in addition to the usual authentication that is based on the user name and credentials. For background information on the use of SSL/TLS with MySQL, see Section 6.3, “Using Encrypted Connections”.

To specify SSL/TLS-related options for a MySQL account, use a **REQUIRE** clause that specifies one or more `tls_option` values.

Order of **REQUIRE** options does not matter, but no option can be specified twice. The **AND** keyword is optional between **REQUIRE** options.

**CREATE USER** permits these `tls_option` values:

- **NONE**

  Indicates that all accounts named by the statement have no SSL or X.509 requirements. Unencrypted connections are permitted if the user name and password are valid. Encrypted connections can be used, at the client's option, if the client has the proper certificate and key files.

CREATE USER 'jeffrey'@'localhost' REQUIRE NONE;

Clients attempt to establish a secure connection by default. For clients that have **REQUIRE NONE**, the connection attempt falls back to an unencrypted connection if a secure connection cannot be established. To require an encrypted connection, a client need specify only the `--ssl-mode=REQUIRED` option; the connection attempt fails if a secure connection cannot be established.
NONE is the default if no SSL-related REQUIRE options are specified.

- **SSL**

  Tells the server to permit only encrypted connections for all accounts named by the statement.

  ```sql
  CREATE USER 'jeffrey'@'localhost' REQUIRE SSL;
  ```

  Clients attempt to establish a secure connection by default. For accounts that have REQUIRE SSL, the connection attempt fails if a secure connection cannot be established.

- **X509**

  For all accounts named by the statement, requires that clients present a valid certificate, but the exact certificate, issuer, and subject do not matter. The only requirement is that it should be possible to verify its signature with one of the CA certificates. Use of X.509 certificates always implies encryption, so the SSL option is unnecessary in this case.

  ```sql
  CREATE USER 'jeffrey'@'localhost' REQUIRE X509;
  ```

  For accounts with REQUIRE X509, clients must specify the --ssl-key and --ssl-cert options to connect. (It is recommended but not required that --ssl-ca also be specified so that the public certificate provided by the server can be verified.) This is true for ISSUER and SUBJECT as well because those REQUIRE options imply the requirements of X509.

- **ISSUER 'issuer'**

  For all accounts named by the statement, requires that clients present a valid X.509 certificate issued by CA 'issuer'. If a client presents a certificate that is valid but has a different issuer, the server rejects the connection. Use of X.509 certificates always implies encryption, so the SSL option is unnecessary in this case.

  ```sql
  CREATE USER 'jeffrey'@'localhost'
  REQUIRE ISSUER '/C=SE/ST=Stockholm/L=Stockholm/
  O=MySQL/CN=CA/emailAddress=ca@example.com';
  ```

  Because ISSUER implies the requirements of X509, clients must specify the --ssl-key and --ssl-cert options to connect. (It is recommended but not required that --ssl-ca also be specified so that the public certificate provided by the server can be verified.)

- **SUBJECT 'subject'**

  For all accounts named by the statement, requires that clients present a valid X.509 certificate containing the subject subject. If a client presents a certificate that is valid but has a different subject, the server rejects the connection. Use of X.509 certificates always implies encryption, so the SSL option is unnecessary in this case.

  ```sql
  CREATE USER 'jeffrey'@'localhost'
  REQUIRE SUBJECT '/C=SE/ST=Stockholm/L=Stockholm/
  O=MySQL demo client certificate/
  CN=client/emailAddress=client@example.com';
  ```

  MySQL does a simple string comparison of the 'subject' value to the value in the certificate, so lettercase and component ordering must be given exactly as present in the certificate.

  Because SUBJECT implies the requirements of X509, clients must specify the --ssl-key and --ssl-cert options to connect. (It is recommended but not required that --ssl-ca also be specified so that the public certificate provided by the server can be verified.)
Account Management Statements

- **CIPHER 'cipher'

  For all accounts named by the statement, requires a specific cipher method for encrypting connections. This option is needed to ensure that ciphers and key lengths of sufficient strength are used. Encryption can be weak if old algorithms using short encryption keys are used.

  
  CREATE USER 'jeffrey'@'localhost'
  REQUIRE CIPHER 'EDH-RSA-DES-CBC3-SHA';

  The **SUBJECT**, **ISSUER**, and **CIPHER** options can be combined in the **REQUIRE** clause:

  CREATE USER 'jeffrey'@'localhost'
  REQUIRE SUBJECT '/C=SE/ST=Stockholm/L=Stockholm/
  O=MySQL demo client certificate/
  CN=client/emailAddress=client@example.com'
  AND ISSUER '/C=SE/ST=Stockholm/L=Stockholm/
  O=MySQL/CN=CA/emailAddress=ca@example.com'
  AND CIPHER 'EDH-RSA-DES-CBC3-SHA';

**CREATE USER Resource-Limit Options**

It is possible to place limits on use of server resources by an account, as discussed in Section 6.2.21, “Setting Account Resource Limits”. To do so, use a **WITH** clause that specifies one or more **resource_option** values.

Order of **WITH** options does not matter, except that if a given resource limit is specified multiple times, the last instance takes precedence.

**CREATE USER** permits these **resource_option** values:

- **MAX_QUERIES_PER_HOUR** count, **MAX_UPDATES_PER_HOUR** count, **MAX_CONNECTIONS_PER_HOUR** count

  For all accounts named by the statement, these options restrict how many queries, updates, and connections to the server are permitted to each account during any given one-hour period. If count is 0 (the default), this means that there is no limitation for the account.

- **MAX_USER_CONNECTIONS** count

  For all accounts named by the statement, restricts the maximum number of simultaneous connections to the server by each account. A nonzero count specifies the limit for the account explicitly. If count is 0 (the default), the server determines the number of simultaneous connections for the account from the global value of the **max_user_connections** system variable. If **max_user_connections** is also zero, there is no limit for the account.

Example:

CREATE USER 'jeffrey'@'localhost'
WITH MAX_QUERIES_PER_HOUR 500 MAX_UPDATES_PER_HOUR 100;

**CREATE USER Password-Management Options**

**CREATE USER** supports several **password_option** values for password management:

- **Password expiration options**: You can expire an account password manually and establish its password expiration policy. Policy options do not expire the password. Instead, they determine how the server applies automatic expiration to the account based on password age, which is assessed from the date and time of the most recent account password change.

- **Password reuse options**: You can restrict password reuse based on number of password changes, time elapsed, or both.
Account Management Statements

- Password verification-required options: You can indicate whether attempts to change an account password must specify the current password, as verification that the user attempting to make the change actually knows the current password.

- Incorrect-password failed-login tracking options: You can cause the server to track failed login attempts and temporarily lock accounts for which too many consecutive incorrect passwords are given. The required number of failures and the lock time are configurable.

This section describes the syntax for password-management options. For information about establishing policy for password management, see Section 6.2.15, “Password Management”.

If multiple password-management options of a given type are specified, the last one takes precedence. For example, `PASSWORD EXPIRE DEFAULT PASSWORD EXPIRE NEVER` is the same as `PASSWORD EXPIRE NEVER`.

**Note**

Except for the options that pertain to failed-login tracking, password-management options apply only to accounts that use an authentication plugin that stores credentials internally to MySQL. For accounts that use a plugin that performs authentication against a credentials system that is external to MySQL, password management must be handled externally against that system as well. For more information about internal credentials storage, see Section 6.2.15, “Password Management”.

A client has an expired password if the account password was expired manually or the password age is considered greater than its permitted lifetime per the automatic expiration policy. In this case, the server either disconnects the client or restricts the operations permitted to it (see Section 6.2.16, “Server Handling of Expired Passwords”). Operations performed by a restricted client result in an error until the user establishes a new account password.

`CREATE USER` permits these `password_option` values for controlling password expiration:

- **PASSWORD EXPIRE**
  
  Immediately marks the password expired for all accounts named by the statement.

  ```sql
  CREATE USER 'jeffrey'@'localhost' PASSWORD EXPIRE;
  ```

- **PASSWORD EXPIRE DEFAULT**
  
  Sets all accounts named by the statement so that the global expiration policy applies, as specified by the `default_password_lifetime` system variable.

  ```sql
  CREATE USER 'jeffrey'@'localhost' PASSWORD EXPIRE DEFAULT;
  ```

- **PASSWORD EXPIRE NEVER**
  
  This expiration option overrides the global policy for all accounts named by the statement. For each, it disables password expiration so that the password never expires.

  ```sql
  CREATE USER 'jeffrey'@'localhost' PASSWORD EXPIRE NEVER;
  ```

- **PASSWORD EXPIRE INTERVAL N DAY**
  
  This expiration option overrides the global policy for all accounts named by the statement. For each, it sets the password lifetime to \( N \) days. The following statement requires the password to be changed every 180 days:

  ```sql
  CREATE USER 'jeffrey'@'localhost' PASSWORD EXPIRE INTERVAL 180 DAY;
  ```
CREATE USER 'jeffrey'@'localhost' PASSWORD EXPIRE INTERVAL 180 DAY;

CREATE USER permits these password_option values for controlling reuse of previous passwords based on required minimum number of password changes:

• PASSWORD HISTORY DEFAULT

Sets all accounts named by the statement so that the global policy about password history length applies, to prohibit reuse of passwords before the number of changes specified by the password_history system variable.

CREATE USER 'jeffrey'@'localhost' PASSWORD HISTORY DEFAULT;

• PASSWORD HISTORY N

This history-length option overrides the global policy for all accounts named by the statement. For each, it sets the password history length to N passwords, to prohibit reusing any of the N most recently chosen passwords. The following statement prohibits reuse of any of the previous 6 passwords:

CREATE USER 'jeffrey'@'localhost' PASSWORD HISTORY 6;

CREATE USER permits these password_option values for controlling reuse of previous passwords based on time elapsed:

• PASSWORD REUSE INTERVAL DEFAULT

Sets all statements named by the account so that the global policy about time elapsed applies, to prohibit reuse of passwords newer than the number of days specified by the password_reuse_interval system variable.

CREATE USER 'jeffrey'@'localhost' PASSWORD REUSE INTERVAL DEFAULT;

• PASSWORD REUSE INTERVAL N DAY

This time-elapsed option overrides the global policy for all accounts named by the statement. For each, it sets the password reuse interval to N days, to prohibit reuse of passwords newer than that many days. The following statement prohibits password reuse for 360 days:

CREATE USER 'jeffrey'@'localhost' PASSWORD REUSE INTERVAL 360 DAY;

CREATE USER permits these password_option values for controlling whether attempts to change an account password must specify the current password, as verification that the user attempting to make the change actually knows the current password:

• PASSWORD REQUIRE CURRENT

This verification option overrides the global policy for all accounts named by the statement. For each, it requires that password changes specify the current password.

CREATE USER 'jeffrey'@'localhost' PASSWORD REQUIRE CURRENT;

• PASSWORD REQUIRE CURRENT OPTIONAL

This verification option overrides the global policy for all accounts named by the statement. For each, it does not require that password changes specify the current password. (The current password may but need not be given.)

CREATE USER 'jeffrey'@'localhost' PASSWORD REQUIRE CURRENT OPTIONAL;
Account Management Statements

- **PASSWORD REQUIRE CURRENT DEFAULT**

  Sets all statements named by the account so that the global policy about password verification applies, as specified by the `password_require_current` system variable.

  ```sql
  CREATE USER 'jeffrey'@'localhost' PASSWORD REQUIRE CURRENT DEFAULT;
  ```

  As of MySQL 8.0.19, `CREATE USER` permits these `password_option` values for controlling failed-login tracking:

  - **FAILED_LOGIN_ATTEMPTS N**
    
    Whether to track account login attempts that specify an incorrect password. \( N \) must be a number from 0 to 32767. A value of 0 disables failed-login tracking. Values greater than 0 indicate how many consecutive password failures cause temporary account locking (if `PASSWORD_LOCK_TIME` is also nonzero).

  - **PASSWORD_LOCK_TIME \( N \) | UNBOUNDED**
    
    How long to lock the account after too many consecutive login attempts provide an incorrect password. \( N \) must be a number from 0 to 32767, or `UNBOUNDED`. A value of 0 disables temporary account locking. Values greater than 0 indicate how long to lock the account in days. A value of `UNBOUNDED` causes the account locking duration to be unbounded; once locked, the account remains in a locked state until unlocked. For information about the conditions under which unlocking occurs, see Failed-Login Tracking and Temporary Account Locking.

  For failed-login tracking and temporary locking to occur, an account's `FAILED_LOGIN_ATTEMPTS` and `PASSWORD_LOCK_TIME` options both must be nonzero. The following statement creates an account that remains locked for two days after four consecutive password failures:

  ```sql
  CREATE USER 'jeffrey'@'localhost'
  FAILED_LOGIN_ATTEMPTS 4 PASSWORD_LOCK_TIME 2;
  ```

**CREATE USER Comment and Attribute Options**

As of MySQL 8.0.21, you can create an account with an optional comment or attribute, as described here:

- **User comment**

  To set a user comment, add `COMMENT 'user_comment'` to the `CREATE USER` statement, where `user_comment` is the text of the user comment.

  Example (omitting any other options):

  ```sql
  CREATE USER 'jon'@'localhost' COMMENT 'Some information about Jon';
  ```

- **User attribute**

  A user attribute is a JSON object made up of one or more key-value pairs, and is set by including `ATTRIBUTE 'json_object'` as part of `CREATE USER`. `json_object` must be a valid JSON object.

  Example (omitting any other options):

  ```sql
  CREATE USER 'jim'@'localhost'
  ATTRIBUTE '{"fname": "James", "lname": "Scott", "phone": "123-456-7890"}';
  ```

  User comments and user attributes are stored together in the `ATTRIBUTE` column of the Information Schema `USER_ATTRIBUTES` table. This query displays the row in this table inserted by the statement just shown for creating the user `jim@localhost`:

  ```sql
  ```

3118
Account Management Statements

mysql> SELECT * FROM INFORMATION_SCHEMA.USER_ATTRIBUTES
->
WHERE USER = 'jim' AND HOST = 'localhost'\G
*************************** 1. row ***************************
USER: jim
HOST: localhost
ATTRIBUTE: {"fname": "James", "lname": "Scott", "phone": "123-456-7890"}
1 row in set (0.00 sec)

The COMMENT option in actuality provides a shortcut for setting a user attribute whose only element
has comment as its key and whose value is the argument supplied for the option. You can see this by
executing the statement CREATE USER 'jon'@'localhost' COMMENT 'Some information
about Jon', and observing the row which it inserts into the USER_ATTRIBUTES table:
mysql> CREATE USER 'jon'@'localhost' COMMENT 'Some information about Jon';
Query OK, 0 rows affected (0.06 sec)
mysql> SELECT * FROM INFORMATION_SCHEMA.USER_ATTRIBUTES
->
WHERE USER = 'jon' AND HOST = 'localhost';
+------+-----------+-------------------------------------------+
| USER | HOST
| ATTRIBUTE
|
+------+-----------+-------------------------------------------+
| jon | localhost | {"comment": "Some information about Jon"} |
+------+-----------+-------------------------------------------+
1 row in set (0.00 sec)

You cannot use COMMENT and ATTRIBUTE together in the same CREATE USER statement; attempting
to do so causes a syntax error. To set a user comment concurrently with setting a user attribute, use
ATTRIBUTE and include in its argument a value with a comment key, like this:
mysql> CREATE USER 'bill'@'localhost'
->
ATTRIBUTE '{"fname":"William", "lname":"Schmidt",
->
"comment":"Website developer"}';
Query OK, 0 rows affected (0.16 sec)

Since the content of the ATTRIBUTE row is a JSON object, you can employ any appropriate MySQL JSON
functions or operators to manipulate it, as shown here:
mysql> SELECT
->
USER AS User,
->
HOST AS Host,
->
CONCAT(ATTRIBUTE->>"$.fname"," ",ATTRIBUTE->>"$.lname") AS 'Full Name',
->
ATTRIBUTE->>"$.comment" AS Comment
-> FROM INFORMATION_SCHEMA.USER_ATTRIBUTES
-> WHERE USER='bill' AND HOST='localhost';
+------+-----------+-----------------+-------------------+
| User | Host
| Full Name
| Comment
|
+------+-----------+-----------------+-------------------+
| bill | localhost | William Schmidt | Website developer |
+------+-----------+-----------------+-------------------+
1 row in set (0.00 sec)

To set or to make changes in the user comment or user attribute for an existing user, you can use a
COMMENT or ATTRIBUTE option with an ALTER USER statement.
Because the user comment and user attribute are stored together internally in a single JSON column,
this sets an upper limit on their maximum combined size; see JSON Storage Requirements, for more
information.
See also the description of the Information Schema USER_ATTRIBUTES table for more information and
examples.

CREATE USER Account-Locking Options
3119


MySQL supports account locking and unlocking using the `ACCOUNT LOCK` and `ACCOUNT UNLOCK` options, which specify the locking state for an account. For additional discussion, see Section 6.2.20, “Account Locking”.

If multiple account-locking options are specified, the last one takes precedence.

**CREATE USER Binary Logging**

`CREATE USER` is written to the binary log if it succeeds, but not if it fails; in that case, rollback occurs and no changes are made. A statement written to the binary log includes all named users. If the `IF NOT EXISTS` clause is given, this includes even users that already exist and were not created.

The statement written to the binary log specifies an authentication plugin for each user, determined as follows:

- The plugin named in the original statement, if one was specified.
- Otherwise, the default authentication plugin. In particular, if a user `u1` already exists and uses a nondefault authentication plugin, the statement written to the binary log for `CREATE USER IF NOT EXISTS u1` names the default authentication plugin. (If the statement written to the binary log must specify a nondefault authentication plugin for a user, include it in the original statement.)

If the server adds the default authentication plugin for any nonexisting users in the statement written to the binary log, it writes a warning to the error log naming those users.

If the original statement specifies the `FAILED_LOGIN_ATTEMPTS` or `PASSWORD_LOCK_TIME` option, the statement written to the binary log includes the option.

`CREATE USER` statements with clauses that support multifactor authentication (MFA) are written to the binary log.

- `CREATE USER ... IDENTIFIED WITH .. INITIAL AUTHENTICATION IDENTIFIED WITH ..` statements are written to the binary log as `CREATE USER .. IDENTIFIED WITH .. INITIAL AUTHENTICATION IDENTIFIED WITH .. AS 'password-hash'`, where the `password-hash` is the user-specified `auth-string` or the random password generated by server when the `RANDOM PASSWORD` clause is specified.

**13.7.1.4 DROP ROLE Statement**

`DROP ROLE [IF EXISTS] role [, role ]`...

`DROP ROLE` removes one or more roles (named collections of privileges). To use this statement, you must have the global `DROP ROLE` or `CREATE USER` privilege. When the `read_only` system variable is enabled, `DROP ROLE` additionally requires the `CONNECTION_ADMIN` privilege (or the deprecated `SUPER` privilege).

As of MySQL 8.0.16, users who have the `CREATE USER` privilege can use this statement to drop accounts that are locked or unlocked. Users who have the `DROP ROLE` privilege can use this statement only to drop accounts that are locked (unlocked accounts are presumably user accounts used to log in to the server and not just as roles).

Roles named in the `mandatory_roles` system variable value cannot be dropped.

`DROP ROLE` either succeeds for all named roles or rolls back and has no effect if any error occurs. By default, an error occurs if you try to drop a role that does not exist. If the `IF EXISTS` clause is given, the statement produces a warning for each named role that does not exist, rather than an error.
The statement is written to the binary log if it succeeds, but not if it fails; in that case, rollback occurs and no changes are made. A statement written to the binary log includes all named roles. If the `IF EXISTS` clause is given, this includes even roles that do not exist and were not dropped.

Each role name uses the format described in Section 6.2.5, “Specifying Role Names”. For example:

```sql
DROP ROLE 'admin', 'developer';
DROP ROLE 'webapp'@'localhost';
```

The host name part of the role name, if omitted, defaults to `%'.

A dropped role is automatically revoked from any user account (or role) to which the role was granted. Within any current session for such an account, its adjusted privileges apply beginning with the next statement executed.

For role usage examples, see Section 6.2.10, “Using Roles”.

### 13.7.1.5 DROP USER Statement

```sql
DROP USER [IF EXISTS] user [, user] ...
```

The `DROP USER` statement removes one or more MySQL accounts and their privileges. It removes privilege rows for the account from all grant tables.

Roles named in the `mandatory_roles` system variable value cannot be dropped.

To use `DROP USER`, you must have the global `CREATE USER` privilege, or the `DELETE` privilege for the `mysql` system schema. When the `read_only` system variable is enabled, `DROP USER` additionally requires the `CONNECTION_ADMIN` privilege (or the deprecated `SUPER` privilege).

As of MySQL 8.0.22, `DROP USER` fails with an error if any account to be dropped is named as the `DEFINER` attribute for any stored object. (That is, the statement fails if dropping an account would cause a stored object to become orphaned.) To perform the operation anyway, you must have the `SET_USER_ID` privilege; in this case, the statement succeeds with a warning rather than failing with an error. For additional information, including how to identify which objects name a given account as the `DEFINER` attribute, see Orphan Stored Objects.

`DROP USER` either succeeds for all named users or rolls back and has no effect if any error occurs. By default, an error occurs if you try to drop a user that does not exist. If the `IF EXISTS` clause is given, the statement produces a warning for each named user that does not exist, rather than an error.

The statement is written to the binary log if it succeeds, but not if it fails; in that case, rollback occurs and no changes are made. A statement written to the binary log includes all named users. If the `IF EXISTS` clause is given, this includes even users that do not exist and were not dropped.

Each account name uses the format described in Section 6.2.4, “Specifying Account Names”. For example:

```sql
DROP USER 'jeffrey'@'localhost';
```

The host name part of the account name, if omitted, defaults to `%'.
DROP USER does not automatically drop or invalidate databases or objects within them that the old user created. This includes stored programs or views for which the DEFINER attribute names the dropped user. Attempts to access such objects may produce an error if they execute in definer security context. (For information about security context, see Section 25.6, “Stored Object Access Control”.)

13.7.1.6 GRANT Statement

```
GRANT
   priv_type [{column_list}]
   [, priv_type [{column_list}]] ...
ON [object_type] priv_level
TO user_or_role [, user_or_role] ...
[WITH GRANT OPTION]
[AS user]
   [WITH ROLE]
   DEFAULT
   NONE
   ALL
   ALL EXCEPT role [, role ] ...
   role [, role ] ...
]
]

GRANT PROXY ON user_or_role
   TO user_or_role [, user_or_role] ...
   [WITH GRANT OPTION]

GRANT role [, role] ...
   TO user_or_role [, user_or_role] ...
   [WITH ADMIN OPTION]

object_type: {
   | TABLE
   | FUNCTION
   | PROCEDURE
}

priv_level: {
   * |
   | db_name.*
   | db_name.tbl_name
   | tbl_name
   | db_name.routine_name
}

user_or_role: {
   | user (see Section 6.2.4, “Specifying Account Names”)
   | role (see Section 6.2.5, “Specifying Role Names”)
}
```

The GRANT statement assigns privileges and roles to MySQL user accounts and roles. There are several aspects to the GRANT statement, described under the following topics:

- GRANT General Overview
- Object Quoting Guidelines
- Account Names
- Privileges Supported by MySQL
- Global Privileges
The `GRANT` statement enables system administrators to grant privileges and roles, which can be granted to user accounts and roles. These syntax restrictions apply:

- `GRANT` cannot mix granting both privileges and roles in the same statement. A given `GRANT` statement must grant either privileges or roles.
- The `ON` clause distinguishes whether the statement grants privileges or roles:
  - With `ON`, the statement grants privileges.
  - Without `ON`, the statement grants roles.
- It is permitted to assign both privileges and roles to an account, but you must use separate `GRANT` statements, each with syntax appropriate to what is to be granted.

For more information about roles, see Section 6.2.10, “Using Roles”.

To grant a privilege with `GRANT`, you must have the `GRANT OPTION` privilege, and you must have the privileges that you are granting. (Alternatively, if you have the `UPDATE` privilege for the grant tables in the `mysql` system schema, you can grant any account any privilege.) When the `read_only` system variable is enabled, `GRANT` additionally requires the `CONNECTION_ADMIN` privilege (or the deprecated `SUPER` privilege).

`GRANT` either succeeds for all named users and roles or rolls back and has no effect if any error occurs. The statement is written to the binary log only if it succeeds for all named users and roles.

The `REVOKE` statement is related to `GRANT` and enables administrators to remove account privileges. See Section 13.7.1.8, “REVOKE Statement”.

Each account name uses the format described in Section 6.2.4, “Specifying Account Names”. Each role name uses the format described in Section 6.2.5, “Specifying Role Names”. For example:

```
GRANT ALL ON db1.* TO 'jeffrey'@'localhost';
GRANT 'role1', 'role2' TO 'user1'@'localhost', 'user2'@'localhost';
GRANT SELECT ON world.* TO 'role3';
```

The host name part of the account or role name, if omitted, defaults to `'%'`. 
Normally, a database administrator first uses \texttt{CREATE USER} to create an account and define its nonprivilege characteristics such as its password, whether it uses secure connections, and limits on access to server resources, then uses \texttt{GRANT} to define its privileges. \texttt{ALTER USER} may be used to change the nonprivilege characteristics of existing accounts. For example:

\begin{verbatim}
CREATE USER 'jeffrey'@'localhost' IDENTIFIED BY 'password';
GRANT ALL ON db1.* TO 'jeffrey'@'localhost';
GRANT SELECT ON db2.invoice TO 'jeffrey'@'localhost';
ALTER USER 'jeffrey'@'localhost' WITH MAX_QUERIES_PER_HOUR 90;
\end{verbatim}

From the \texttt{mysql} program, \texttt{GRANT} responds with \texttt{Query OK, 0 rows affected} when executed successfully. To determine what privileges result from the operation, use \texttt{SHOW GRANTS}. See Section 13.7.7.21, \enquote{SHOW GRANTS Statement}.

\begin{quote}
\textbf{Important}

Under some circumstances, \texttt{GRANT} may be recorded in server logs or on the client side in a history file such as \texttt{-./mysql_history}, which means that cleartext passwords may be read by anyone having read access to that information. For information about the conditions under which this occurs for the server logs and how to control it, see Section 6.1.2.3, \enquote{Passwords and Logging}. For similar information about client-side logging, see Section 4.5.1.3, \enquote{mysql Client Logging}.
\end{quote}

\texttt{GRANT} supports host names up to 255 characters long (60 characters prior to MySQL 8.0.17). User names can be up to 32 characters. Database, table, column, and routine names can be up to 64 characters.

\begin{quote}
\textbf{Warning}

\textit{Do not attempt to change the permissible length for user names by altering the \texttt{mysql.user} system table. Doing so results in unpredictable behavior which may even make it impossible for users to log in to the MySQL server. Never alter the structure of tables in the \texttt{mysql} system schema in any manner except by means of the procedure described in Section 2.10, \enquote{Upgrading MySQL}}.
\end{quote}

\section*{Object Quoting Guidelines}

Several objects within \texttt{GRANT} statements are subject to quoting, although quoting is optional in many cases: Account, role, database, table, column, and routine names. For example, if a \texttt{user_name} or \texttt{host_name} value in an account name is legal as an unquoted identifier, you need not quote it. However, quotation marks are necessary to specify a \texttt{user_name} string containing special characters (such as \texttt{-}), or a \texttt{host_name} string containing special characters or wildcard characters such as \texttt{%} (for example, \texttt{'test-user'@'%.com'}). Quote the user name and host name separately.

To specify quoted values:

\begin{itemize}
  \item Quote database, table, column, and routine names as identifiers.
  \item Quote user names and host names as identifiers or as strings.
  \item Quote passwords as strings.
\end{itemize}

For string-quoting and identifier-quoting guidelines, see Section 9.1.1, \enquote{String Literals}, and Section 9.2, \enquote{Schema Object Names}.

The \texttt{_} and \texttt{%} wildcards are permitted when specifying database names in \texttt{GRANT} statements that grant privileges at the database level (\texttt{GRANT ... ON db_name.*}). This means, for example, that to use a \texttt{_} character as part of a database name, specify it using the \texttt{\_} escape character as \texttt{\_} in the \texttt{GRANT}
statement, to prevent the user from being able to access additional databases matching the wildcard pattern (for example, `GRANT ... ON `foo_bar`.* TO ...`).

Issuing multiple `GRANT` statements containing wildcards may not have the expected effect on DML statements; when resolving grants involving wildcards, MySQL takes only the first matching grant into consideration. In other words, if a user has two database-level grants using wildcards that match the same database, the grant which was created first is applied. Consider the database `db` and table `t` created using the statements shown here:

```sql
mysql> CREATE DATABASE db;
Query OK, 1 row affected (0.01 sec)

mysql> CREATE TABLE db.t (c INT);
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO db.t VALUES ROW(1);
Query OK, 1 row affected (0.00 sec)
```

Next (assuming that the current account is the MySQL `root` account or another account having the necessary privileges), we create a user `u` then issue two `GRANT` statements containing wildcards, like this:

```sql
mysql> CREATE USER u;
Query OK, 0 rows affected (0.01 sec)

mysql> GRANT SELECT ON `d_`.* TO u;
Query OK, 0 rows affected (0.01 sec)

mysql> GRANT INSERT ON `d%`.* TO u;
Query OK, 0 rows affected (0.00 sec)
```

Bye

If we end the session and then log in again with the `mysql` client, this time as `u`, we see that this account has only the privilege provided by the first matching grant, but not the second:

```
$> mysql -uu -hlocalhost
Welcome to the MySQL monitor. Commands end with ; or \g.
Your MySQL connection id is 10
Server version: 8.0.35-tr Source distribution

Type 'help;' or '\h' for help. Type '\c' to clear the current input statement.

mysql> TABLE db.t;
+---+
| c |
+---+
| 1 |
1 row in set (0.00 sec)

mysql> INSERT INTO db.t VALUES ROW(2);
ERROR 1142 (42000): INSERT command denied to user 'u'@'localhost' for table 't'
```

In privilege assignments, MySQL interprets occurrences of unescaped `_` and `%` SQL wildcard characters in database names as literal characters under these circumstances:
Account Management Statements

- When a database name is not used to grant privileges at the database level, but as a qualifier for granting privileges to some other object such as a table or routine (for example, `GRANT ... ON db_name.tbl_name`).

- Enabling `partial_revokes` causes MySQL to interpret unescaped `_` and `%` wildcard characters in database names as literal characters, just as if they had been escaped as `\_` and `\%`. Because this changes how MySQL interprets privileges, it may be advisable to avoid unescaped wildcard characters in privilege assignments for installations where `partial_revokes` may be enabled. For more information, see Section 6.2.12, “Privilege Restriction Using Partial Revokes”.

Account Names

A `user` value in a `GRANT` statement indicates a MySQL account to which the statement applies. To accommodate granting rights to users from arbitrary hosts, MySQL supports specifying the `user` value in the form `user_name'@'host_name`.

You can specify wildcards in the host name. For example, `user_name'@'%.example.com` applies to `user_name` for any host in the example.com domain, and `user_name'@'198.51.100.%` applies to `user_name` for any host in the 198.51.100 class C subnet.

The simple form `user_name` is a synonym for `user_name'@'%`.

MySQL does not support wildcards in user names. To refer to an anonymous user, specify an account with an empty user name with the `GRANT` statement:

```
GRANT ALL ON test.* TO ''@'localhost' ...;
```

In this case, any user who connects from the local host with the correct password for the anonymous user is permitted access, with the privileges associated with the anonymous-user account.

For additional information about user name and host name values in account names, see Section 6.2.4, “Specifying Account Names”.

Warning

If you permit local anonymous users to connect to the MySQL server, you should also grant privileges to all local users as `user_name'@'localhost`. Otherwise, the anonymous user account for `localhost` in the `mysql.user` system table is used when named users try to log in to the MySQL server from the local machine. For details, see Section 6.2.6, “Access Control, Stage 1: Connection Verification”.

To determine whether this issue applies to you, execute the following query, which lists any anonymous users:

```
SELECT Host, User FROM mysql.user WHERE User='';
```

To avoid the problem just described, delete the local anonymous user account using this statement:

```
DROP USER ''@'localhost';
```

Privileges Supported by MySQL

The following tables summarize the permissible static and dynamic `priv_type` privilege types that can be specified for the `GRANT` and `REVOKE` statements, and the levels at which each privilege can be granted. For additional information about each privilege, see Section 6.2.2, “Privileges Provided by MySQL”. For
information about the differences between static and dynamic privileges, see Static Versus Dynamic Privileges.

Table 13.11 Permissible Static Privileges for GRANT and REVOKE

<table>
<thead>
<tr>
<th>Privilege</th>
<th>Meaning and Grantable Levels</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALL [PRIVILEGES]</td>
<td>Grant all privileges at specified access level except GRANT OPTION and PROXY.</td>
</tr>
<tr>
<td>ALTER</td>
<td>Enable use of ALTER TABLE. Levels: Global, database, table.</td>
</tr>
<tr>
<td>ALTER ROUTINE</td>
<td>Enable stored routines to be altered or dropped. Levels: Global, database, routine.</td>
</tr>
<tr>
<td>CREATE</td>
<td>Enable database and table creation. Levels: Global, database, table.</td>
</tr>
<tr>
<td>CREATE ROLE</td>
<td>Enable role creation. Level: Global.</td>
</tr>
<tr>
<td>CREATE ROUTINE</td>
<td>Enable stored routine creation. Levels: Global, database.</td>
</tr>
<tr>
<td>CREATE TABLESPACE</td>
<td>Enable tablespaces and log file groups to be created, altered, or dropped. Level: Global.</td>
</tr>
<tr>
<td>CREATE TEMPORARY TABLES</td>
<td>Enable use of CREATE TEMPORARY TABLE. Levels: Global, database.</td>
</tr>
<tr>
<td>CREATE USER</td>
<td>Enable use of CREATE USER, DROP USER, RENAME USER, and REVOKE ALL PRIVILEGES. Level: Global.</td>
</tr>
<tr>
<td>CREATE VIEW</td>
<td>Enable views to be created or altered. Levels: Global, database, table.</td>
</tr>
<tr>
<td>DELETE</td>
<td>Enable use of DELETE. Level: Global, database, table.</td>
</tr>
<tr>
<td>DROP</td>
<td>Enable databases, tables, and views to be dropped. Levels: Global, database, table.</td>
</tr>
<tr>
<td>DROP ROLE</td>
<td>Enable roles to be dropped. Level: Global.</td>
</tr>
<tr>
<td>EVENT</td>
<td>Enable use of events for the Event Scheduler. Levels: Global, database.</td>
</tr>
<tr>
<td>EXECUTE</td>
<td>Enable the user to execute stored routines. Levels: Global, database, routine.</td>
</tr>
<tr>
<td>FILE</td>
<td>Enable the user to cause the server to read or write files. Level: Global.</td>
</tr>
<tr>
<td>GRANT OPTION</td>
<td>Enable privileges to be granted to or removed from other accounts. Levels: Global, database, table, routine, proxy.</td>
</tr>
<tr>
<td>INDEX</td>
<td>Enable indexes to be created or dropped. Levels: Global, database, table.</td>
</tr>
<tr>
<td>INSERT</td>
<td>Enable use of INSERT. Levels: Global, database, table, column.</td>
</tr>
<tr>
<td>LOCK TABLES</td>
<td>Enable use of LOCK TABLES on tables for which you have the SELECT privilege. Levels: Global, database.</td>
</tr>
</tbody>
</table>
### Privilege

<table>
<thead>
<tr>
<th>Privilege</th>
<th>Meaning and Grantable Levels</th>
</tr>
</thead>
<tbody>
<tr>
<td>PROCESS</td>
<td>Enable the user to see all processes with <strong>SHOW PROCESSLIST</strong>. Level: Global.</td>

<td>Do not rewrite queries executed by this user. Level: Global.</td>
</tr>
<tr>
<td>SYSTEM_USER</td>
<td>Designate account as system account. Level: Global.</td>
</tr>
</tbody>
</table>
Privilege | Meaning and Grantable Levels
---|---
SYSTEM_VARIABLES_ADMIN | Enable modifying or persisting global system variables. Level: Global.
TABLE_ENCRYPTION_ADMIN | Enable overriding default encryption settings. Level: Global.
TELEMETRY_LOG_ADMIN | Enable telemetry log configuration for MySQL HeatWave on AWS. Level: Global.
TP_CONNECTION_ADMIN | Enable thread pool connection administration. Level: Global.
VERSION_TOKEN_ADMIN | Enable use of Version Tokens functions. Level: Global.
XA_RECOVER_ADMIN | Enable XA RECOVER execution. Level: Global.

A trigger is associated with a table. To create or drop a trigger, you must have the TRIGGER privilege for the table, not the trigger.

In GRANT statements, the ALL [PRIVILEGES] or PROXY privilege must be named by itself and cannot be specified along with other privileges. ALL [PRIVILEGES] stands for all privileges available for the level at which privileges are to be granted except for the GRANT OPTION and PROXY privileges.

MySQL account information is stored in the tables of the mysql system schema. For additional details, consult Section 6.2, “Access Control and Account Management”, which discusses the mysql system schema and the access control system extensively.

If the grant tables hold privilege rows that contain mixed-case database or table names and the lower_case_table_names system variable is set to a nonzero value, REVOKE cannot be used to revoke these privileges. It is necessary in such cases to manipulate the grant tables directly. (GRANT does not create such rows when lower_case_table_names is set, but such rows might have been created prior to setting that variable. The lower_case_table_names setting can only be configured at server startup.)

Privileges can be granted at several levels, depending on the syntax used for the ON clause. For REVOKE, the same ON syntax specifies which privileges to remove.

For the global, database, table, and routine levels, GRANT ALL assigns only the privileges that exist at the level you are granting. For example, GRANT ALL ON db_name.* is a database-level statement, so it does not grant any global-only privileges such as FILE. Granting ALL does not assign the GRANT OPTION or PROXY privilege.

The object_type clause, if present, should be specified as TABLE, FUNCTION, or PROCEDURE when the following object is a table, a stored function, or a stored procedure.

The privileges that a user holds for a database, table, column, or routine are formed additively as the logical OR of the account privileges at each of the privilege levels, including the global level. It is not possible to deny a privilege granted at a higher level by absence of that privilege at a lower level. For example, this statement grants the SELECT and INSERT privileges globally:

```
GRANT SELECT, INSERT ON *.* TO u1;
```

The globally granted privileges apply to all databases, tables, and columns, even though not granted at any of those lower levels.

As of MySQL 8.0.16, it is possible to explicitly deny a privilege granted at the global level by revoking it for particular databases, if the partial_revokes system variable is enabled:
Account Management Statements

GRANT SELECT, INSERT, UPDATE ON *.* TO u1;
REVOKE INSERT, UPDATE ON db1.* FROM u1;

The result of the preceding statements is that SELECT applies globally to all tables, whereas INSERT and UPDATE apply globally except to tables in db1. Account access to db1 is read only.

Details of the privilege-checking procedure are presented in Section 6.2.7, “Access Control, Stage 2: Request Verification”.

If you are using table, column, or routine privileges for even one user, the server examines table, column, and routine privileges for all users and this slows down MySQL a bit. Similarly, if you limit the number of queries, updates, or connections for any users, the server must monitor these values.

MySQL enables you to grant privileges on databases or tables that do not exist. For tables, the privileges to be granted must include the CREATE privilege. This behavior is by design, and is intended to enable the database administrator to prepare user accounts and privileges for databases or tables that are to be created at a later time.

Important
MySQL does not automatically revoke any privileges when you drop a database or table. However, if you drop a routine, any routine-level privileges granted for that routine are revoked.

Global Privileges

Global privileges are administrative or apply to all databases on a given server. To assign global privileges, use ON *.* syntax:

GRANT ALL ON *.* TO 'someuser'@'somehost';
GRANT SELECT, INSERT ON *.* TO 'someuser'@'somehost';

The CREATE TABLESPACE, CREATE USER, FILE, PROCESS, RELOAD, REPLICATION CLIENT, REPLICATION SLAVE, SHOW DATABASES, SHUTDOWN, and SUPER static privileges are administrative and can only be granted globally.

Dynamic privileges are all global and can only be granted globally.

Other privileges can be granted globally or at more specific levels.

The effect of GRANT OPTION granted at the global level differs for static and dynamic privileges:

• GRANT OPTION granted for any static global privilege applies to all static global privileges.
• GRANT OPTION granted for any dynamic privilege applies only to that dynamic privilege.

GRANT ALL at the global level grants all static global privileges and all currently registered dynamic privileges. A dynamic privilege registered subsequent to execution of the GRANT statement is not granted retroactively to any account.

MySQL stores global privileges in the mysql.user system table.

Database Privileges

Database privileges apply to all objects in a given database. To assign database-level privileges, use ON db_name.* syntax:

GRANT ALL ON mydb.* TO 'someuser'@'somehost';
Account Management Statements

GRANT SELECT, INSERT ON mydb.* TO 'someuser'@'somehost';

If you use **ON * syntax** (rather than **ON *.*)), privileges are assigned at the database level for the default database. An error occurs if there is no default database.

The **CREATE, DROP, EVENT, GRANT OPTION, LOCK TABLES, and REFERENCES** privileges can be specified at the database level. Table or routine privileges also can be specified at the database level, in which case they apply to all tables or routines in the database.

MySQL stores database privileges in the *mysql.db* system table.

---

**Table Privileges**

Table privileges apply to all columns in a given table. To assign table-level privileges, use **ON db_name.tbl_name syntax**:

```sql
GRANT ALL ON mydb.mytbl TO 'someuser'@'somehost';
GRANT SELECT, INSERT ON mydb.mytbl TO 'someuser'@'somehost';
```

If you specify **tbl_name** rather than **db_name.tbl_name**, the statement applies to **tbl_name** in the default database. An error occurs if there is no default database.

The permissible **priv_type** values at the table level are **ALTER, CREATE VIEW, CREATE, DELETE, DROP, GRANT OPTION, INDEX, INSERT, REFERENCES, SELECT, SHOW VIEW, TRIGGER, and UPDATE**.

Table-level privileges apply to base tables and views. They do not apply to tables created with **CREATE TEMPORARY TABLE**, even if the table names match. For information about **TEMPORARY** table privileges, see Section 13.1.20.2, “CREATE TEMPORARY TABLE Statement”.

MySQL stores table privileges in the *mysql.tables_priv* system table.

---

**Column Privileges**

Column privileges apply to single columns in a given table. Each privilege to be granted at the column level must be followed by the column or columns, enclosed within parentheses.

```sql
GRANT SELECT (col1), INSERT (col1, col2) ON mydb.mytbl TO 'someuser'@'somehost';
```

The permissible **priv_type** values for a column (that is, when you use a **column_list** clause) are **INSERT, REFERENCES, SELECT, and UPDATE**.

MySQL stores column privileges in the *mysql.columns_priv* system table.

---

**Stored Routine Privileges**

The **ALTER ROUTINE, CREATE ROUTINE, EXECUTE, and GRANT OPTION** privileges apply to stored routines (procedures and functions). They can be granted at the global and database levels. Except for **CREATE ROUTINE**, these privileges can be granted at the routine level for individual routines.

```sql
GRANT CREATE ROUTINE ON mydb.* TO 'someuser'@'somehost';
GRANT EXECUTE ON PROCEDURE mydb.myproc TO 'someuser'@'somehost';
```

The permissible **priv_type** values at the routine level are **ALTER ROUTINE, EXECUTE, and GRANT OPTION. CREATE ROUTINE** is not a routine-level privilege because you must have the privilege at the global or database level to create a routine in the first place.

MySQL stores routine-level privileges in the *mysql.procs_priv* system table.
Account Management Statements

Proxy User Privileges

The PROXY privilege enables one user to be a proxy for another. The proxy user impersonates or takes the identity of the proxied user; that is, it assumes the privileges of the proxied user.

```sql
GRANT PROXY ON 'localuser'@'localhost' TO 'externaluser'@'somehost';
```

When PROXY is granted, it must be the only privilege named in the GRANT statement, and the only permitted WITH option is WITH GRANT OPTION.

Proxying requires that the proxy user authenticate through a plugin that returns the name of the proxied user to the server when the proxy user connects, and that the proxy user have the PROXY privilege for the proxied user. For details and examples, see Section 6.2.19, “Proxy Users”.

MySQL stores proxy privileges in the mysql.proxies_priv system table.

Granting Roles

GRANT syntax without an ON clause grants roles rather than individual privileges. A role is a named collection of privileges; see Section 6.2.10, “Using Roles”. For example:

```sql
GRANT 'role1', 'role2' TO 'user1'@'localhost', 'user2'@'localhost';
```

Each role to be granted must exist, as well as each user account or role to which it is to be granted. As of MySQL 8.0.16, roles cannot be granted to anonymous users.

Granting a role does not automatically cause the role to be active. For information about role activation and inactivation, see Activating Roles.

These privileges are required to grant roles:

- If you have the ROLE_ADMIN privilege (or the deprecated SUPER privilege), you can grant or revoke any role to users or roles.

- If you were granted a role with a GRANT statement that includes the WITH ADMIN OPTION clause, you become able to grant that role to other users or roles, or revoke it from other users or roles, as long as the role is active at such time as you subsequently grant or revoke it. This includes the ability to use WITH ADMIN OPTION itself.

- To grant a role that has the SYSTEM_USER privilege, you must have the SYSTEM_USER privilege.

It is possible to create circular references with GRANT. For example:

```sql
CREATE USER 'u1', 'u2';
CREATE ROLE 'r1', 'r2';
GRANT 'u1' TO 'u1';   -- simple loop: u1 => u1
GRANT 'r1' TO 'r1';   -- simple loop: r1 => r1
GRANT 'r2' TO 'u2';
GRANT 'u2' TO 'r2';   -- mixed user/role loop: u2 => r2 => u2
```

Circular grant references are permitted but add no new privileges or roles to the grantee because a user or role already has its privileges and roles.

The AS Clause and Privilege Restrictions

As of MySQL 8.0.16, GRANT has an AS user [WITH ROLE] clause that specifies additional information about the privilege context to use for statement execution. This syntax is visible at the SQL level, although its primary purpose is to enable uniform replication across all nodes of grantor privilege restrictions.
imposed by partial revokes, by causing those restrictions to appear in the binary log. For information about partial revokes, see Section 6.2.12, “Privilege Restriction Using Partial Revokes”.

When the AS user clause is specified, statement execution takes into account any privilege restrictions associated with the named user, including all roles specified by WITH ROLE, if present. The result is that the privileges actually granted by the statement may be reduced relative to those specified.

These conditions apply to the AS user clause:

- **AS** has an effect only when the named user has privilege restrictions (which implies that the partial_revokes system variable is enabled).
- If WITH ROLE is given, all roles named must be granted to the named user.
- The named user should be a MySQL account specified as 'user_name'@'host_name', CURRENT_USER, or CURRENT_USER(). The current user may be named together with WITH ROLE for the case that the executing user wants GRANT to execute with a set of roles applied that may differ from the roles active within the current session.
- AS cannot be used to gain privileges not possessed by the user who executes the GRANT statement. The executing user must have at least the privileges to be granted, but the AS clause can only restrict the privileges granted, not escalate them. 
- With respect to the privileges to be granted, AS cannot specify a user/role combination that has more privileges (fewer restrictions) than the user who executes the GRANT statement. The AS user/role combination is permitted to have more privileges than the executing user, but only if the statement does not grant those additional privileges.
- **AS** is supported only for granting global privileges (ON *.*).
- **AS** is not supported for PROXY grants.

The following example illustrates the effect of the AS clause. Create a user u1 that has some global privileges, as well as restrictions on those privileges:

```sql
CREATE USER u1;
GRANT SELECT, INSERT, UPDATE, DELETE ON *.* TO u1;
REVOKE INSERT, UPDATE ON schema1.* FROM u1;
REVOKE SELECT ON schema2.* FROM u1;
```

Also create a role r1 that lifts some of the privilege restrictions and grant the role to u1:

```sql
CREATE ROLE r1;
GRANT INSERT ON schema1.* TO r1;
GRANT SELECT ON schema2.* TO r1;
GRANT r1 TO u1;
```

Now, using an account that has no privilege restrictions of its own, grant to multiple users the same set of global privileges, but each with different restrictions imposed by the AS clause, and check which privileges are actually granted.

- The GRANT statement here has no AS clause, so the privileges granted are exactly those specified:

```sql
mysql> CREATE USER u2;
mysql> GRANT SELECT, INSERT, UPDATE ON *.* TO u2;
mysql> SHOW GRANTS FOR u2;
+-----------------------------+
<table>
<thead>
<tr>
<th>Grants for u2@%</th>
</tr>
</thead>
<tbody>
<tr>
<td>GRANT SELECT, INSERT, UPDATE ON <em>.</em> TO <code>u2</code>@<code>%</code></td>
</tr>
<tr>
<td>------------------------------</td>
</tr>
</tbody>
</table>
```
• The `GRANT` statement here has an `AS` clause, so the privileges granted are those specified but with the restrictions from `u1` applied:

```
mysql> CREATE USER u3;
mysql> GRANT SELECT, INSERT, UPDATE ON *.* TO u3 AS u1;
mysql> SHOW GRANTS FOR u3;
```

```
+------------------------------------------+
<table>
<thead>
<tr>
<th>Grants for u3@%</th>
</tr>
</thead>
<tbody>
<tr>
<td>GRANT SELECT, INSERT, UPDATE ON <code>*</code>.* TO <code>u3</code>@<code>%</code></td>
</tr>
<tr>
<td>REVOKE INSERT, UPDATE ON <code>schema1</code>.* FROM <code>u3</code>@<code>%</code></td>
</tr>
<tr>
<td>REVOKE SELECT ON <code>schema2</code>.* FROM <code>u3</code>@<code>%</code></td>
</tr>
</tbody>
</table>
|------------------------------------------+
```

As mentioned previously, the `AS` clause can only add privilege restrictions; it cannot escalate privileges. Thus, although `u1` has the `DELETE` privilege, that is not included in the privileges granted because the statement does not specify granting `DELETE`.

• The `AS` clause for the `GRANT` statement here makes the role `r1` active for `u1`. That role lifts some of the restrictions on `u1`. Consequently, the privileges granted have some restrictions, but not so many as for the previous `GRANT` statement:

```
mysql> CREATE USER u4;
mysql> GRANT SELECT, INSERT, UPDATE ON *.* TO u4 AS u1 WITH ROLE r1;
mysql> SHOW GRANTS FOR u4;
```

```
+---------------------------------+
<table>
<thead>
<tr>
<th>Grants for u4@%</th>
</tr>
</thead>
<tbody>
<tr>
<td>GRANT SELECT, INSERT, UPDATE ON <code>*</code>.* TO <code>u4</code>@<code>%</code></td>
</tr>
<tr>
<td>REVOKE UPDATE ON <code>schema1</code>.* FROM <code>u4</code>@<code>%</code></td>
</tr>
</tbody>
</table>
|---------------------------------+
```

If a `GRANT` statement includes an `AS` user clause, privilege restrictions on the user who executes the statement are ignored (rather than applied as they would be in the absence of an `AS` clause).

### Other Account Characteristics

The optional `WITH` clause is used to enable a user to grant privileges to other users. The `WITH GRANT OPTION` clause gives the user the ability to give to other users any privileges the user has at the specified privilege level.

To grant the `GRANT OPTION` privilege to an account without otherwise changing its privileges, do this:

```
GRANT USAGE ON *.* TO 'someuser'@'somehost' WITH GRANT OPTION;
```

Be careful to whom you give the `GRANT OPTION` privilege because two users with different privileges may be able to combine privileges!

You cannot grant another user a privilege which you yourself do not have; the `GRANT OPTION` privilege enables you to assign only those privileges which you yourself possess.

Be aware that when you grant a user the `GRANT OPTION` privilege at a particular privilege level, any privileges the user possesses (or may be given in the future) at that level can also be granted by that user to other users. Suppose that you grant a user the `INSERT` privilege on a database. If you then grant the `SELECT` privilege on the database and specify `WITH GRANT OPTION`, that user can give to other users not only the `SELECT` privilege, but also `INSERT`. If you then grant the `UPDATE` privilege to the user on the database, the user can grant `INSERT`, `SELECT`, and `UPDATE`.

For a nonadministrative user, you should not grant the `ALTER` privilege globally or for the `mysql` system schema. If you do that, the user can try to subvert the privilege system by renaming tables!
Account Management Statements

For additional information about security risks associated with particular privileges, see Section 6.2.2, “Privileges Provided by MySQL”.

MySQL and Standard SQL Versions of GRANT

The biggest differences between the MySQL and standard SQL versions of GRANT are:

• MySQL associates privileges with the combination of a host name and user name and not with only a user name.

• Standard SQL does not have global or database-level privileges, nor does it support all the privilege types that MySQL supports.

• MySQL does not support the standard SQL UNDER privilege.

• Standard SQL privileges are structured in a hierarchical manner. If you remove a user, all privileges the user has been granted are revoked. This is also true in MySQL if you use DROP USER. See Section 13.7.1.5, “DROP USER Statement”.

• In standard SQL, when you drop a table, all privileges for the table are revoked. In standard SQL, when you revoke a privilege, all privileges that were granted based on that privilege are also revoked. In MySQL, privileges can be dropped with DROP USER or REVOKE statements.

• In MySQL, it is possible to have the INSERT privilege for only some of the columns in a table. In this case, you can still execute INSERT statements on the table, provided that you insert values only for those columns for which you have the INSERT privilege. The omitted columns are set to their implicit default values if strict SQL mode is not enabled. In strict mode, the statement is rejected if any of the omitted columns have no default value. (Standard SQL requires you to have the INSERT privilege on all columns.) For information about strict SQL mode and implicit default values, see Section 5.1.11, “Server SQL Modes”, and Section 11.6, “Data Type Default Values”.

13.7.1.7 RENAME USER Statement

```
RENAME USER old_user TO new_user
[, old_user TO new_user] ...
```

The RENAME USER statement renames existing MySQL accounts. An error occurs for old accounts that do not exist or new accounts that already exist.

To use RENAME USER, you must have the global CREATE USER privilege, or the UPDATE privilege for the mysql system schema. When the read_only system variable is enabled, RENAME USER additionally requires the CONNECTION_ADMIN privilege (or the deprecated SUPER privilege).

As of MySQL 8.0.22, RENAME USER fails with an error if any account to be renamed is named as the DEFINER attribute for any stored object. (That is, the statement fails if renaming an account would cause a stored object to become orphaned.) To perform the operation anyway, you must have the SET_USER_ID privilege; in this case, the statement succeeds with a warning rather than failing with an error. For additional information, including how to identify which objects name a given account as the DEFINER attribute, see Orphan Stored Objects.

Each account name uses the format described in Section 6.2.4, “Specifying Account Names”. For example:

```
RENAME USER 'jeffrey'@'localhost' TO 'jeff'@'127.0.0.1';
```

The host name part of the account name, if omitted, defaults to '%'.

RENAME USER causes the privileges held by the old user to be those held by the new user. However, RENAME USER does not automatically drop or invalidate databases or objects within them that the old
user created. This includes stored programs or views for which the \texttt{DEFINER} attribute names the old user. Attempts to access such objects may produce an error if they execute in definers security context. (For information about security context, see Section 25.6, “Stored Object Access Control”.)

The privilege changes take effect as indicated in Section 6.2.13, “When Privilege Changes Take Effect”.

### 13.7.1.8 REVOKE Statement

The \texttt{REVOKE} statement enables system administrators to revoke privileges and roles, which can be revoked from user accounts and roles.

For details on the levels at which privileges exist, the permissible \texttt{priv_type}, \texttt{priv_level}, and \texttt{object_type} values, and the syntax for specifying users and passwords, see Section 13.7.1.6, “GRANT Statement”.

For information about roles, see Section 6.2.10, “Using Roles”.

The \texttt{read_only} system variable is enabled, \texttt{REVOKE} requires the \texttt{CONNECTION_ADMIN} or privilege (or the deprecated \texttt{SUPER} privilege), in addition to any other required privileges described in the following discussion.

Beginning with MySQL 8.0.30, all the forms shown for \texttt{REVOKE} support an \texttt{IF EXISTS} option as well as an \texttt{IGNORE UNKNOWN USER} option. With neither of these modifications, \texttt{REVOKE} either succeeds for all named users and roles, or rolls back and has no effect if any error occurs; the statement is written to the binary log only if it succeeds for all named users and roles. The precise effects of \texttt{IF EXISTS} and \texttt{IGNORE UNKNOWN USER} are discussed later in this section.

Each account name uses the format described in Section 6.2.4, “Specifying Account Names”. Each role name uses the format described in Section 6.2.5, “Specifying Role Names”. For example:

- \texttt{REVOKE INSERT ON *.* FROM 'jeffrey'@'localhost';}
- \texttt{REVOKE 'role1', 'role2' FROM 'user1'@'localhost', 'user2'@'localhost';}
- \texttt{REVOKE SELECT ON world.* FROM 'role3';}

The host name part of the account or role name, if omitted, defaults to \texttt{'%'}.

To use the first \texttt{REVOKE} syntax, you must have the \texttt{GRANT OPTION} privilege, and you must have the privileges that you are revoking.
Account Management Statements

To revoke all privileges, use the second syntax, which drops all global, database, table, column, and routine privileges for the named users or roles:

```
REVOKE ALL PRIVILEGES, GRANT OPTION
    FROM user_or_role [, user_or_role] ...
```

REVOKE ALL PRIVILEGES, GRANT OPTION does not revoke any roles.

To use this REVOKE syntax, you must have the global CREATE USER privilege, or the UPDATE privilege for the mysql system schema.

The syntax for which the REVOKE keyword is followed by one or more role names takes a FROM clause indicating one or more users or roles from which to revoke the roles.

The IF EXISTS and IGNORE UNKNOWN USER options (MySQL 8.0.30 and later) have the effects listed here:

- IF EXISTS means that, if the target user or role exists but no such privilege or role is found assigned to the target for any reason, a warning is raised, instead of an error; if no privilege or role named by the statement is assigned to the target, the statement has no (other) effect. Otherwise, REVOKE executes normally; if the user does not exist, the statement raises an error.

Example: Given table t1 in database test, we execute the following statements, with the results shown.

```
mysql> CREATE USER jerry@localhost;
Query OK, 0 rows affected (0.01 sec)

mysql> REVOKE SELECT ON test.t1 FROM jerry@localhost;
ERROR 1147 (42000): There is no such grant defined for user 'jerry' on host 'localhost' on table 't1'

mysql> REVOKE IF EXISTS SELECT ON test.t1 FROM jerry@localhost;
Query OK, 0 rows affected, 1 warning (0.00 sec)

mysql> SHOW WARNINGS\G
*************************** 1. row ***************************
  Level: Warning
  Code: 1147
  Message: There is no such grant defined for user 'jerry' on host 'localhost' on table 't1'

1 row in set (0.00 sec)
```

IF EXISTS causes an error to be demoted to a warning even if the privilege or role named does not exist, or the statement attempts to assign it at the wrong level.

- If the REVOKE statement includes IGNORE UNKNOWN USER, the statement raises a warning for any target user or role named in the statement but not found; if no target named by the statement exists, REVOKE succeeds but has no actual effect. Otherwise, the statement executes as usual, and attempting to revoke a privilege not assigned to the target for whatever reason raises an error, as expected.

Example (continuing from the previous example):

```
mysql> DROP USER IF EXISTS jerry@localhost;
Query OK, 0 rows affected (0.01 sec)

mysql> REVOKE SELECT ON test.t1 FROM jerry@localhost;
ERROR 1147 (42000): There is no such grant defined for user 'jerry' on host 'localhost' on table 't1'

mysql> REVOKE SELECT ON test.t1 FROM jerry@localhost IGNORE UNKNOWN USER;
Query OK, 0 rows affected, 1 warning (0.01 sec)

mysql> SHOW WARNINGS\G
*************************** 1. row ***************************
3138
```

3138
Account Management Statements

Level: Warning
Code: 3162
Message: Authorization ID jerry does not exist.
1 row in set (0.00 sec)

- The combination of IF EXISTS and IGNORE UNKNOWN USER means that REVOKE never raises an error for an unknown target user or role or for an unassigned or unavailable privilege, and the statement as whole in such cases succeeds; roles or privileges are removed from existing target users or roles whenever possible, and any revocation which is not possible raises a warning and executes as a NOOP.

Example (again continuing from example in the previous item):

```sql
# No such user, no such role
mysql> DROP ROLE IF EXISTS Bogus;
Query OK, 0 rows affected, 1 warning (0.02 sec)

mysql> SHOW WARNINGS;
+-------+-------+----------------------------------------------+
| Level | Code | Message                                      |
+-------+-------+----------------------------------------------+
| Note  | 3162 | Authorization ID 'Bogus'@'%' does not exist. |
+-------+-------+----------------------------------------------+
1 row in set (0.00 sec)

# This statement attempts to revoke a nonexistent role from a nonexistent user
mysql> REVOKE Bogus ON test FROM jerry@localhost;
ERROR 3619 (HY000): Illegal privilege level specified for test

# The same, with IF EXISTS
mysql> REVOKE IF EXISTS Bogus ON test FROM jerry@localhost;
ERROR 1147 (42000): There is no such grant defined for user 'jerry' on host 'localhost' on table 'test'

# The same, with IGNORE UNKNOWN USER
mysql> REVOKE Bogus ON test FROM jerry@localhost IGNORE UNKNOWN USER;
ERROR 3619 (HY000): Illegal privilege level specified for test

# The same, with both options
mysql> REVOKE IF EXISTS Bogus ON test FROM jerry@localhost IGNORE UNKNOWN USER;
Query OK, 0 rows affected, 2 warnings (0.01 sec)

mysql> SHOW WARNINGS;
+---------+-------+--------------------------------------------+
| Level   | Code | Message                                    |
+---------+-------+--------------------------------------------+
| Warning | 3619 | Illegal privilege level specified for test |
| Warning | 3162 | Authorization ID jerry does not exist.     |
+---------+-------+--------------------------------------------+
2 rows in set (0.00 sec)
```

Roles named in the mandatory_roles system variable value cannot be revoked. When IF EXISTS and IGNORE UNKNOWN USER are used together in a statement that tries to remove a mandatory privilege, the error normally raised by attempting to do this is demoted to a warning; the statement executes successfully, but does not make any changes.

A revoked role immediately affects any user account from which it was revoked, such that within any current session for the account, its privileges are adjusted for the next statement executed.

Revoking a role revokes the role itself, not the privileges that it represents. Suppose that an account is granted a role that includes a given privilege, and is also granted the privilege explicitly or another role that includes the privilege. In this case, the account still possesses that privilege if the first role is revoked. For example, if an account is granted two roles that each include SELECT, the account still can select after either role is revoked.
**Account Management Statements**

REVOKE ALL ON *.* (at the global level) revokes all granted static global privileges and all granted dynamic privileges.

A revoked privilege that is granted but not known to the server is revoked with a warning. This situation can occur for dynamic privileges. For example, a dynamic privilege can be granted while the component that registers it is installed, but if that component is subsequently uninstalled, the privilege becomes unregistered, although accounts that possess the privilege still possess it and it can be revoked from them.

REVOKE removes privileges, but does not remove rows from the mysql.user system table. To remove a user account entirely, use DROP USER. See Section 13.7.1.5, “DROP USER Statement”.

If the grant tables hold privilege rows that contain mixed-case database or table names and the lower_case_table_names system variable is set to a nonzero value, REVOKE cannot be used to revoke these privileges. It is necessary in such cases to manipulate the grant tables directly. (GRANT does not create such rows when lower_case_table_names is set, but such rows might have been created prior to setting the variable. The lower_case_table_names setting can only be configured when initializing the server.)

When successfully executed from the mysql program, REVOKE responds with Query OK, 0 rows affected. To determine what privileges remain after the operation, use SHOW GRANTS. See Section 13.7.7.21, “SHOW GRANTS Statement”.

### 13.7.1.9 SET DEFAULT ROLE Statement

```
SET DEFAULT ROLE {NONE | ALL | role [, role] ...}
TO user [, user] ...
```

For each user named immediately after the TO keyword, this statement defines which roles become active when the user connects to the server and authenticates, or when the user executes the SET ROLE DEFAULT statement during a session.

SET DEFAULT ROLE is alternative syntax for ALTER USER ... DEFAULT ROLE (see Section 13.7.1.1, “ALTER USER Statement”). However, ALTER USER can set the default for only a single user, whereas SET DEFAULT ROLE can set the default for multiple users. On the other hand, you can specify CURRENT_USER as the user name for the ALTER USER statement, whereas you cannot for SET DEFAULT ROLE.

SET DEFAULT ROLE requires these privileges:

- Setting the default roles for another user requires the global CREATE USER privilege, or the UPDATE privilege for the mysql.default_roles system table.

- Setting the default roles for yourself requires no special privileges, as long as the roles you want as the default have been granted to you.

Each role name uses the format described in Section 6.2.5, “Specifying Role Names”. For example:

```
SET DEFAULT ROLE 'admin', 'developer' TO 'joe'@'10.0.0.1';
```

The host name part of the role name, if omitted, defaults to '%'.

The clause following the DEFAULT ROLE keywords permits these values:

- **NONE**: Set the default to NONE (no roles).
- **ALL**: Set the default to all roles granted to the account.
• `role [, role ] . . .`: Set the default to the named roles, which must exist and be granted to the account at the time `SET DEFAULT ROLE` is executed.

**Note**

`SET DEFAULT ROLE` and `SET ROLE DEFAULT` are different statements:

- `SET DEFAULT ROLE` defines which account roles to activate by default within account sessions.
- `SET ROLE DEFAULT` sets the active roles within the current session to the current account default roles.

For role usage examples, see Section 6.2.10, “Using Roles”.

### 13.7.1.10 SET PASSWORD Statement

```sql
SET PASSWORD [FOR `user`] `auth_option`
[REPLACE `current_auth_string`]
[RETAINT CURRENT PASSWORD]
```

auth_option: {
  = `auth_string`
  | TO RANDOM
}

The `SET PASSWORD` statement assigns a password to a MySQL user account. The password may be either explicitly specified in the statement or randomly generated by MySQL. The statement may also include a password-verification clause that specifies the account current password to be replaced, and a clause that manages whether an account has a secondary password. `'auth_string'` and `'current_auth_string'` each represent a cleartext (unencrypted) password.

**Note**

Rather than using `SET PASSWORD` to assign passwords, `ALTER USER` is the preferred statement for account alterations, including assigning passwords. For example:

```sql
ALTER USER `user` IDENTIFIED BY `'auth_string'`;
```

**Note**

Clauses for random password generation, password verification, and secondary passwords apply only to accounts that use an authentication plugin that stores credentials internally to MySQL. For accounts that use a plugin that performs authentication against a credentials system that is external to MySQL, password management must be handled externally against that system as well. For more information about internal credentials storage, see Section 6.2.15, “Password Management”.

The `REPLACE `current_auth_string'` clause performs password verification and is available as of MySQL 8.0.13. If given:

- `REPLACE` specifies the account current password to be replaced, as a cleartext (unencrypted) string.
- The clause must be given if password changes for the account are required to specify the current password, as verification that the user attempting to make the change actually knows the current password.
• The clause is optional if password changes for the account may but need not specify the current password.

• The statement fails if the clause is given but does not match the current password, even if the clause is optional.

• REPLACE can be specified only when changing the account password for the current user.

For more information about password verification by specifying the current password, see Section 6.2.15, “Password Management”.

The RETAIN CURRENT PASSWORD clause implements dual-password capability and is available as of MySQL 8.0.14. If given:

• RETAIN CURRENT PASSWORD retains an account current password as its secondary password, replacing any existing secondary password. The new password becomes the primary password, but clients can use the account to connect to the server using either the primary or secondary password. (Exception: If the new password specified by the SET PASSWORD statement is empty, the secondary password becomes empty as well, even if RETAIN CURRENT PASSWORD is given.)

• If you specify RETAIN CURRENT PASSWORD for an account that has an empty primary password, the statement fails.

• If an account has a secondary password and you change its primary password without specifying RETAIN CURRENT PASSWORD, the secondary password remains unchanged.

For more information about use of dual passwords, see Section 6.2.15, “Password Management”.

SET PASSWORD permits these auth_option syntaxes:

• = 'auth_string'

Assigns the account the given literal password.

• TO RANDOM

Assigns the account a password randomly generated by MySQL. The statement also returns the cleartext password in a result set to make it available to the user or application executing the statement.

For details about the result set and characteristics of randomly generated passwords, see Random Password Generation.

Random password generation is available as of MySQL 8.0.18.

Important

Under some circumstances, SET PASSWORD may be recorded in server logs or on the client side in a history file such as ~/.mysql_history, which means that cleartext passwords may be read by anyone having read access to that information. For information about the conditions under which this occurs for the server logs and how to control it, see Section 6.1.2.3, “Passwords and Logging”. For similar information about client-side logging, see Section 4.5.1.3, “mysql Client Logging”.

SET PASSWORD can be used with or without a FOR clause that explicitly names a user account:

• With a FOR user clause, the statement sets the password for the named account, which must exist:

  SET PASSWORD FOR 'jeffrey'@'localhost' = 'auth_string';
• With no `FOR user` clause, the statement sets the password for the current user:

```
SET PASSWORD = 'auth_string';
```

Any client who connects to the server using a nonanonymous account can change the password for that account. (In particular, you can change your own password.) To see which account the server authenticated you as, invoke the `CURRENT_USER()` function:

```
SELECT CURRENT_USER();
```

If a `FOR user` clause is given, the account name uses the format described in Section 6.2.4, “Specifying Account Names”. For example:

```
SET PASSWORD FOR 'bob'@'%.example.org' = 'auth_string';
```

The host name part of the account name, if omitted, defaults to `%`.

`SET PASSWORD` interprets the string as a cleartext string, passes it to the authentication plugin associated with the account, and stores the result returned by the plugin in the account row in the `mysql.user` system table. (The plugin is given the opportunity to hash the value into the encryption format it expects. The plugin may use the value as specified, in which case no hashing occurs.)

Setting the password for a named account (with a `FOR user` clause) requires the `UPDATE` privilege for the `mysql` system schema. Setting the password for yourself (for a nonanonymous account with no `FOR` clause) requires no special privileges.

Statements that modify secondary passwords require these privileges:

• The `APPLICATION_PASSWORD_ADMIN` privilege is required to use the `RETAIN CURRENT PASSWORD` clause for `SET PASSWORD` statements that apply to your own account. The privilege is required to manipulate your own secondary password because most users require only one password.

• If an account is to be permitted to manipulate secondary passwords for all accounts, it should be granted the `CREATE USER` privilege rather than `APPLICATION_PASSWORD_ADMIN`.

When the `read_only` system variable is enabled, `SET PASSWORD` requires the `CONNECTION_ADMIN` privilege (or the deprecated `SUPER` privilege), in addition to any other required privileges.

For additional information about setting passwords and authentication plugins, see Section 6.2.14, “Assigning Account Passwords”, and Section 6.2.17, “Pluggable Authentication”.

### 13.7.1.11 SET ROLE Statement

```
SET ROLE {
  DEFAULT
  | NONE
  | ALL
  | ALL EXCEPT role [, role ] ...
  | role [, role ] ...
}
```

`SET ROLE` modifies the current user's effective privileges within the current session by specifying which of its granted roles are active. Granted roles include those granted explicitly to the user and those named in the `mandatory_roles` system variable value.

Examples:

```
SET ROLE DEFAULT;
SET ROLE 'role1', 'role2';
SET ROLE ALL;
```
SET ROLE ALL EXCEPT 'role1', 'role2';

Each role name uses the format described in Section 6.2.5, “Specifying Role Names”. The host name part of the role name, if omitted, defaults to '%'.

Privileges that the user has been granted directly (rather than through roles) remain unaffected by changes to the active roles.

The statement permits these role specifiers:

- **DEFAULT**: Activate the account default roles. Default roles are those specified with `SET DEFAULT ROLE`.

  When a user connects to the server and authenticates successfully, the server determines which roles to activate as the default roles. If the `activate_all_roles_on_login` system variable is enabled, the server activates all granted roles. Otherwise, the server executes `SET ROLE DEFAULT` implicitly. The server activates only default roles that can be activated. The server writes warnings to its error log for default roles that cannot be activated, but the client receives no warnings.

  If a user executes `SET ROLE DEFAULT` during a session, an error occurs if any default role cannot be activated (for example, if it does not exist or is not granted to the user). In this case, the current active roles are not changed.

- **NONE**: Set the active roles to NONE (no active roles).

- **ALL**: Activate all roles granted to the account.

- **ALL EXCEPT role [, role ] ...**: Activate all roles granted to the account except those named. The named roles need not exist or be granted to the account.

- **role [, role ] ...**: Activate the named roles, which must be granted to the account.

**Note**

`SET DEFAULT ROLE` and `SET ROLE DEFAULT` are different statements:

- `SET DEFAULT ROLE` defines which account roles to activate by default within account sessions.
- `SET ROLE DEFAULT` sets the active roles within the current session to the current account default roles.

For role usage examples, see Section 6.2.10, “Using Roles”.

### 13.7.2 Resource Group Management Statements

MySQL supports creation and management of resource groups, and permits assigning threads running within the server to particular groups so that threads execute according to the resources available to the group. This section describes the SQL statements available for resource group management. For general discussion of the resource group capability, see Section 5.1.16, “Resource Groups”.

#### 13.7.2.1 ALTER RESOURCE GROUP Statement

**ALTER RESOURCE GROUP**

```
ALTER RESOURCE GROUP  group_name
  [VCPU [-] vcpu_spec [, vcpu_spec] ...]
  [THREAD_PRIORITY [-] N]
  [ENABLE|DISABLE [FORCE]]
```

**vcpu_spec**: `{ N | M - N}`
**ALTER RESOURCE GROUP** is used for resource group management (see Section 5.1.16, “Resource Groups”). This statement alters modifiable attributes of an existing resource group. It requires the **RESOURCE_GROUP_ADMIN** privilege.

*group_name* identifies which resource group to alter. If the group does not exist, an error occurs.

The attributes for CPU affinity, priority, and whether the group is enabled can be modified with **ALTER RESOURCE GROUP**. These attributes are specified the same way as described for **CREATE RESOURCE GROUP** (see Section 13.7.2.2, “CREATE RESOURCE GROUP Statement”). Only the attributes specified are altered. Unspecified attributes retain their current values.

The **FORCE** modifier is used with **DISABLE**. It determines statement behavior if the resource group has any threads assigned to it:

- If **FORCE** is not given, existing threads in the group continue to run until they terminate, but new threads cannot be assigned to the group.
- If **FORCE** is given, existing threads in the group are moved to their respective default group (system threads to **SYS_default**, user threads to **USR_default**).

The name and type attributes are set at group creation time and cannot be modified thereafter with **ALTER RESOURCE GROUP**.

Examples:

- Alter a group CPU affinity:
  ```sql
  ALTER RESOURCE GROUP rg1 VCPU = 0-63;
  ```

- Alter a group thread priority:
  ```sql
  ALTER RESOURCE GROUP rg2 THREAD_PRIORITY = 5;
  ```

- Disable a group, moving any threads assigned to it to the default groups:
  ```sql
  ALTER RESOURCE GROUP rg3 DISABLE FORCE;
  ```

Resource group management is local to the server on which it occurs. **ALTER RESOURCE GROUP** statements are not written to the binary log and are not replicated.

### 13.7.2.2 CREATE RESOURCE GROUP Statement

**CREATE RESOURCE GROUP** is used for resource group management (see Section 5.1.16, “Resource Groups”). This statement creates a new resource group and assigns its initial attribute values. It requires the **RESOURCE_GROUP_ADMIN** privilege.

*group_name* identifies which resource group to create. If the group already exists, an error occurs.

The **TYPE** attribute is required. It should be **SYSTEM** for a system resource group, **USER** for a user resource group. The group type affects permitted **THREAD_PRIORITY** values, as described later.

The **VCPU** attribute indicates the CPU affinity; that is, the set of virtual CPUs the group can use:
Resource Group Management Statements

• If \texttt{VCPU} is not given, the resource group has no CPU affinity and can use all available CPUs.

• If \texttt{VCPU} is given, the attribute value is a list of comma-separated CPU numbers or ranges:
  
  • Each number must be an integer in the range from 0 to the number of CPUs – 1. For example, on a system with 64 CPUs, the number can range from 0 to 63.

  • A range is given in the form \( M - N \), where \( M \) is less than or equal to \( N \) and both numbers are in the CPU range.

  • If a CPU number is an integer outside the permitted range or is not an integer, an error occurs.

Example \texttt{VCPU} specifiers (these are all equivalent):

\begin{verbatim}
VCPU = 0,1,2,3,9,10
VCPU = 0-3,9-10
VCPU = 9,10,0-3
VCPU = 0,10,1,9,3,2
\end{verbatim}

The \texttt{THREAD_PRIORITY} attribute indicates the priority for threads assigned to the group:

• If \texttt{THREAD_PRIORITY} is not given, the default priority is 0.

• If \texttt{THREAD_PRIORITY} is given, the attribute value must be in the range from -20 (highest priority) to 19 (lowest priority). The priority for system resource groups must be in the range from -20 to 0. The priority for user resource groups must be in the range from 0 to 19. Use of different ranges for system and user groups ensures that user threads never have a higher priority than system threads.

\texttt{ENABLE} and \texttt{DISABLE} specify that the resource group is initially enabled or disabled. If neither is specified, the group is enabled by default. A disabled group cannot have threads assigned to it.

Examples:

• Create an enabled user group that has a single CPU and the lowest priority:

\begin{verbatim}
CREATE RESOURCE GROUP rg1
  TYPE = USER
  VCPU = 0
  THREAD_PRIORITY = 19;
\end{verbatim}

• Create a disabled system group that has no CPU affinity (can use all CPUs) and the highest priority:

\begin{verbatim}
CREATE RESOURCE GROUP rg2
  TYPE = SYSTEM
  THREAD_PRIORITY = -20
  DISABLE;
\end{verbatim}

Resource group management is local to the server on which it occurs. \texttt{CREATE RESOURCE GROUP} statements are not written to the binary log and are not replicated.

13.7.2.3 DROP RESOURCE GROUP Statement

\texttt{DROP RESOURCE GROUP group_name [FORCE]}

\texttt{DROP RESOURCE GROUP} is used for resource group management (see Section 5.1.16, “Resource Groups”). This statement drops a resource group. It requires the \texttt{RESOURCE_GROUP_ADMIN} privilege.

\texttt{group_name} identifies which resource group to drop. If the group does not exist, an error occurs.

The \texttt{FORCE} modifier determines statement behavior if the resource group has any threads assigned to it:
Table Maintenance Statements

• If `FORCE` is not given and any threads are assigned to the group, an error occurs.

• If `FORCE` is given, existing threads in the group are moved to their respective default group (system threads to `SYS_default`, user threads to `USR_default`).

Examples:

• Drop a group, failing if the group contains any threads:

  ```sql
  DROP RESOURCE GROUP rg1;
  ```

• Drop a group and move existing threads to the default groups:

  ```sql
  DROP RESOURCE GROUP rg2 FORCE;
  ```

Resource group management is local to the server on which it occurs. `DROP RESOURCE GROUP` statements are not written to the binary log and are not replicated.

13.7.2.4 SET RESOURCE GROUP Statement

```sql
SET RESOURCE GROUP group_name
[FOR thread_id [, thread_id] ...]
```

SET RESOURCE GROUP is used for resource group management (see Section 5.1.16, “Resource Groups”). This statement assigns threads to a resource group. It requires the `RESOURCE_GROUP_ADMIN` or `RESOURCE_GROUP_USER` privilege.

`group_name` identifies which resource group to be assigned. Any `thread_id` values indicate threads to assign to the group. Thread IDs can be determined from the Performance Schema `threads` table. If the resource group or any named thread ID does not exist, an error occurs.

With no `FOR` clause, the statement assigns the current thread for the session to the resource group.

With a `FOR` clause that names thread IDs, the statement assigns those threads to the resource group.

For attempts to assign a system thread to a user resource group or a user thread to a system resource group, a warning occurs.

Examples:

• Assign the current session thread to a group:

  ```sql
  SET RESOURCE GROUP rg1;
  ```

• Assign the named threads to a group:

  ```sql
  SET RESOURCE GROUP rg2 FOR 14, 78, 4;
  ```

Resource group management is local to the server on which it occurs. SET RESOURCE GROUP statements are not written to the binary log and are not replicated.

An alternative to SET RESOURCE GROUP is the RESOURCE_GROUP optimizer hint, which assigns individual statements to a resource group. See Section 8.9.3, “Optimizer Hints”.

13.7.3 Table Maintenance Statements

13.7.3.1 ANALYZE TABLE Statement

```sql
ANALYZE [NO_WRITE_TO_BINLOG | LOCAL]
TABLE tbl_name [, tbl_name] ...```
ANALYZE [NO_WRITE_TO_BINLOG | LOCAL] TABLE tbl_name
    UPDATE HISTOGRAM ON col_name [, col_name] ...
    [WITH N BUCKETS]

ANALYZE [NO_WRITE_TO_BINLOG | LOCAL] TABLE tbl_name
    UPDATE HISTOGRAM ON col_name [USING DATA 'json_data']

ANALYZE [NO_WRITE_TO_BINLOG | LOCAL] TABLE tbl_name
    DROP HISTOGRAM ON col_name [, col_name] ...

ANALYZE TABLE generates table statistics:

• ANALYZE TABLE without either HISTOGRAM clause performs a key distribution analysis and stores
  the distribution for the named table or tables. For MyISAM tables, ANALYZE TABLE for key distribution
  analysis is equivalent to using myisamchk --analyze.

• ANALYZE TABLE with the UPDATE HISTOGRAM clause generates histogram statistics for the named
  table columns and stores them in the data dictionary. Only one table name is permitted for this syntax.
MySQL 8.0.31 and later also supports setting the histogram of a single column to a user-defined JSON
value.

• ANALYZE TABLE with the DROP HISTOGRAM clause removes histogram statistics for the named table
  columns from the data dictionary. Only one table name is permitted for this syntax.

This statement requires SELECT and INSERT privileges for the table.

ANALYZE TABLE works with InnoDB, NDB, and MyISAM tables. It does not work with views.

If the innodb_read_only system variable is enabled, ANALYZE TABLE may fail because it
cannot update statistics tables in the data dictionary, which use InnoDB. For ANALYZE TABLE
operations that update the key distribution, failure may occur even if the operation updates the

table itself (for example, if it is a MyISAM table). To obtain the updated distribution statistics, set
information_schema_stats_expiry=0.

ANALYZE TABLE is supported for partitioned tables, and you can use ALTER TABLE ... ANALYZE
PARTITION to analyze one or more partitions; for more information, see Section 13.1.9, "ALTER TABLE
Statement", and Section 24.3.4, "Maintenance of Partitions".

During the analysis, the table is locked with a read lock for InnoDB and MyISAM.

ANALYZE TABLE removes the table from the table definition cache, which requires a flush lock. If there
are long running statements or transactions still using the table, subsequent statements and transactions
must wait for those operations to finish before the flush lock is released. Because ANALYZE TABLE itself
typically finishes quickly, it may not be apparent that delayed transactions or statements involving the same
table are due to the remaining flush lock.

By default, the server writes ANALYZE TABLE statements to the binary log so that they replicate to
replicas. To suppress logging, specify the optional NO_WRITE_TO_BINLOG keyword or its alias LOCAL.

• ANALYZE TABLE Output

• Key Distribution Analysis

• Histogram Statistics Analysis

• Other Considerations
**ANALYZE TABLE**

**ANALYZE TABLE** returns a result set with the columns shown in the following table.

<table>
<thead>
<tr>
<th>Column</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table</td>
<td>The table name</td>
</tr>
<tr>
<td>Op</td>
<td>analyze or histogram</td>
</tr>
<tr>
<td>Msg_type</td>
<td>status, error, info, note, or warning</td>
</tr>
<tr>
<td>Msg_text</td>
<td>An informational message</td>
</tr>
</tbody>
</table>

**Key Distribution Analysis**

**ANALYZE TABLE** without either **HISTOGRAM** clause performs a key distribution analysis and stores the distribution for the table or tables. Any existing histogram statistics remain unaffected.

If the table has not changed since the last key distribution analysis, the table is not analyzed again.

MySQL uses the stored key distribution to decide the order in which tables should be joined for joins on something other than a constant. In addition, key distributions can be used when deciding which indexes to use for a specific table within a query.

To check the stored key distribution cardinality, use the **SHOW INDEX** statement or the **INFORMATION_SCHEMA STATISTICS** table. See Section 13.7.7.22, “SHOW INDEX Statement”, and Section 26.3.34, “The INFORMATION_SCHEMA STATISTICS Table”.

For **InnoDB** tables, **ANALYZE TABLE** determines index cardinality by performing random dives on each of the index trees and updating index cardinality estimates accordingly. Because these are only estimates, repeated runs of **ANALYZE TABLE** could produce different numbers. This makes **ANALYZE TABLE** fast on **InnoDB** tables but not 100% accurate because it does not take all rows into account.

You can make the statistics collected by **ANALYZE TABLE** more precise and more stable by enabling **innodb_stats_persistent**, as explained in Section 15.8.10.1, “Configuring Persistent Optimizer Statistics Parameters”. When **innodb_stats_persistent** is enabled, it is important to run **ANALYZE TABLE** after major changes to index column data, as statistics are not recalculated periodically (such as after a server restart).

If **innodb_stats_persistent** is enabled, you can change the number of random dives by modifying the **innodb_stats_persistent_sample_pages** system variable. If **innodb_stats_persistent** is disabled, modify **innodb_stats_transient_sample_pages** instead.

For more information about key distribution analysis in **InnoDB**, see Section 15.8.10.1, “Configuring Persistent Optimizer Statistics Parameters”, and Section 15.8.10.3, “Estimating ANALYZE TABLE Complexity for InnoDB Tables”.

MySQL uses index cardinality estimates in join optimization. If a join is not optimized in the right way, try running **ANALYZE TABLE**. In the few cases that **ANALYZE TABLE** does not produce values good enough for your particular tables, you can use **FORCE INDEX** with your queries to force the use of a particular index, or set the **max_seeks_for_key** system variable to ensure that MySQL prefers index lookups over table scans. See Section B.3.5, “Optimizer-Related Issues”.

**Histogram Statistics Analysis**

**ANALYZE TABLE** with the **HISTOGRAM** clause enables management of histogram statistics for table column values. For information about histogram statistics, see Section 8.9.6, “Optimizer Statistics”.
These histogram operations are available:

- **ANALYZE TABLE** with an **UPDATE HISTOGRAM** clause generates histogram statistics for the named table columns and stores them in the data dictionary. Only one table name is permitted for this syntax.

  The optional **WITH N BUCKETS** clauses specifies the number of buckets for the histogram. The value of \( N \) must be an integer in the range from 1 to 1024. If this clause is omitted, the number of buckets is 100.

- **ANALYZE TABLE** with a **DROP HISTOGRAM** clause removes histogram statistics for the named table columns from the data dictionary. Only one table name is permitted for this syntax.

Stored histogram management statements affect only the named columns. Consider these statements:

```
ANALYZE TABLE t UPDATE HISTOGRAM ON c1, c2, c3 WITH 10 BUCKETS;
ANALYZE TABLE t UPDATE HISTOGRAM ON c1, c3 WITH 10 BUCKETS;
ANALYZE TABLE t DROP HISTOGRAM ON c2;
```

The first statement updates the histograms for columns \( c1, c2, \) and \( c3 \), replacing any existing histograms for those columns. The second statement updates the histograms for \( c1 \) and \( c3 \), leaving the \( c2 \) histogram unaffected. The third statement removes the histogram for \( c2 \), leaving those for \( c1 \) and \( c3 \) unaffected.

When sampling user data as part of building a histogram, not all values are read; this may lead to missing some values considered important. In such cases, it might be useful to modify the histogram, or to set your own histogram explicitly based on your own criteria, such as the complete data set. MySQL 8.0.31 adds support for **ANALYZE TABLE tbl_name UPDATE HISTOGRAM ON col_name USING DATA 'json_data'** for updating a column of the histogram table with data supplied in the same JSON format used to display HISTOGRAM column values from the Information Schema COLUMN_STATISTICS table. Only one column can be modified when updating the histogram with JSON data.

We can illustrate the use of **USING DATA** by first generating a histogram on column \( c1 \) of table \( t \), like this:

```
mysql> ANALYZE TABLE t UPDATE HISTOGRAM ON c1;
```

We can see the histogram generated in the **COLUMN_STATISTICS** table:

```
mysql> TABLE information_schema.column_statistics\G
```

Now we drop the histogram, and when we check **COLUMN_STATISTICS**, it is now empty:

```
mysql> ANALYZE TABLE t DROP HISTOGRAM ON c1;
```

```
mysql> TABLE information_schema.column_statistics\G
empty set (0.00 sec)
```
We can restore the dropped histogram by inserting its JSON representation obtained previously from the `HISTOGRAM` column of the `COLUMN_STATISTICS` table, and when we query that table again, we can see that the histogram has been restored to its previous state:

```
mysql> ANALYZE TABLE t UPDATE HISTOGRAM ON c1
-> USING DATA '({"buckets": [[206, 0.0625], [456, 0.125], [608, 0.1875]],
-> "data-type": "int", "null-values": 0.0, "collation-id":
-> "sampling-rate": 1.0, "histogram-type": "singleton",
-> "number-of-buckets-specified": 100});
```

```
+--------+-----------+----------+-----------------------------------------------+
| Table  | Op        | Msg_type | Msg_text                                      |
+--------+-----------+----------+-----------------------------------------------+
| mydb.t | histogram | status   | Histogram statistics created for column 'c1'. |
+--------+-----------+----------+-----------------------------------------------+
```

```
mysql> TABLE information_schema.column_statistics
```

```
*************************** 1. row ***************************
SCHEMA_NAME: mydb
TABLE_NAME: t
COLUMN_NAME: c1
HISTOGRAM: {"buckets": [[206, 0.0625], [456, 0.125], [608, 0.1875]],
"data-type": "int", "null-values": 0.0, "collation-id":
8, "last-updated": "2022-10-11 16:13:14.563319", "sampling-rate": 1.0, "histogram-type":
"singleton", "number-of-buckets-specified": 100}
```

Histogram generation is not supported for encrypted tables (to avoid exposing data in the statistics) or `TEMPORARY` tables.

Histogram generation applies to columns of all data types except geometry types (spatial data) and JSON.

Histograms can be generated for stored and virtual generated columns.

Histograms cannot be generated for columns that are covered by single-column unique indexes.

Histogram management statements attempt to perform as much of the requested operation as possible, and report diagnostic messages for the remainder. For example, if an `UPDATE HISTOGRAM` statement names multiple columns, but some of them do not exist or have an unsupported data type, histograms are generated for the other columns, and messages are produced for the invalid columns.

Histograms are affected by these DDL statements:

- `DROP TABLE` removes histograms for columns in the dropped table.
- `DROP DATABASE` removes histograms for any table in the dropped database because the statement drops all tables in the database.
- `RENAME TABLE` does not remove histograms. Instead, it renames histograms for the renamed table to be associated with the new table name.
- `ALTER TABLE` statements that remove or modify a column remove histograms for that column.
- `ALTER TABLE ... CONVERT TO CHARACTER SET` removes histograms for character columns because they are affected by the change of character set. Histograms for noncharacter columns remain unaffected.

The `histogram_generation_max_mem_size` system variable controls the maximum amount of memory available for histogram generation. The global and session values may be set at runtime.

Changing the global `histogram_generation_max_mem_size` value requires privileges sufficient to set global system variables. Changing the session `histogram_generation_max_mem_size` value requires
Table Maintenance Statements

privileges sufficient to set restricted session system variables. See Section 5.1.9.1, “System Variable Privileges”.

If the estimated amount of data to be read into memory for histogram generation exceeds the limit defined by `histogram_generation_max_mem_size`, MySQL samples the data rather than reading all of it into memory. Sampling is evenly distributed over the entire table. MySQL uses `SYSTEM` sampling, which is a page-level sampling method.

The `sampling_rate` value in the `HISTOGRAM` column of the Information Schema `COLUMN_STATISTICS` table can be queried to determine the fraction of data that was sampled to create the histogram. The `sampling_rate` is a number between 0.0 and 1.0. A value of 1 means that all of the data was read (no sampling).

The following example demonstrates sampling. To ensure that the amount of data exceeds the `histogram_generation_max_mem_size` limit for the purpose of the example, the limit is set to a low value (2000000 bytes) prior to generating histogram statistics for the `birth_date` column of the `employees` table.

```
mysql> SET histogram_generation_max_mem_size = 2000000;
mysql> USE employees;
mysql> ANALYZE TABLE employees UPDATE HISTOGRAM ON birth_date WITH 16 BUCKETS\G
*************************** 1. row ***************************
Table: employees.employees
Op: histogram
Msg_type: status
Msg_text: Histogram statistics created for column 'birth_date'.
mysql> SELECT HISTOGRAM->>'$."sampling-rate"'
FROM INFORMATION_SCHEMA.COLUMN_STATISTICS
WHERE TABLE_NAME = "employees"
AND COLUMN_NAME = "birth_date";
+---------------------------------+
<table>
<thead>
<tr>
<th>HISTOGRAM-&gt;&gt;'$.&quot;sampling-rate&quot;'</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.0491431208869665</td>
</tr>
</tbody>
</table>
+---------------------------------+
```

A `sampling_rate` value of 0.0491431208869665 means that approximately 4.9% of the data from the `birth_date` column was read into memory for generating histogram statistics.

As of MySQL 8.0.19, the `InnoDB` storage engine provides its own sampling implementation for data stored in InnoDB tables. The default sampling implementation used by MySQL when storage engines do not provide their own requires a full table scan, which is costly for large tables. The InnoDB sampling implementation improves sampling performance by avoiding full table scans.

The `sampled_pages_read` and `sampled_pages_skipped` `INNODB_METRICS` counters can be used to monitor sampling of InnoDB data pages. (For general `INNODB_METRICS` counter usage information, see Section 26.4.21, “The INFORMATION_SCHEMA INNODB_METRICS Table”.)

The following example demonstrates sampling counter usage, which requires enabling the counters prior to generating histogram statistics.

```
mysql> SET GLOBAL innodb_monitor_enable = 'sampled%';
mysql> USE employees;
mysql> ANALYZE TABLE employees UPDATE HISTOGRAM ON birth_date WITH 16 BUCKETS\G
*************************** 1. row ***************************
Table: employees.employees
Op: histogram
```

3152
This formula approximates a sampling rate based on the sampling counter data:

\[
\text{sampling rate} = \frac{\text{sampled_page_read}}{\text{sampled_pages_read} + \text{sampled_pages_skipped}}
\]

A sampling rate based on sampling counter data is roughly the same as the `sampling-rate` value in the `HISTOGRAM` column of the Information Schema `COLUMN_STATISTICS` table.

For information about memory allocations performed for histogram generation, monitor the Performance Schema `memory/sql/histograms` instrument. See Section 27.12.20.10, “Memory Summary Tables”.

Other Considerations

`ANALYZE TABLE` clears table statistics from the Information Schema `INNODB_TABLESTATS` table and sets the `STATS_INITIALIZED` column to `Uninitialized`. Statistics are collected again the next time the table is accessed.

13.7.3.2 CHECK TABLE Statement

```
CHECK TABLE tbl_name [, tbl_name] ... [option] ...
```

- `option`: {
  - `FOR UPGRADE`  
  - `QUICK`  
  - `FAST`  
  - `MEDIUM`  
  - `EXTENDED`  
  - `CHANGED`  
}

`CHECK TABLE` checks a table or tables for errors. `CHECK TABLE` can also check views for problems, such as tables that are referenced in the view definition that no longer exist.

To check a table, you must have some privilege for it.

`CHECK TABLE` works for InnoDB, MyISAM, ARCHIVE, and CSV tables.

Before running `CHECK TABLE` on InnoDB tables, see `CHECK TABLE Usage Notes for InnoDB Tables`.

`CHECK TABLE` is supported for partitioned tables, and you can use `ALTER TABLE ... CHECK PARTITION` to check one or more partitions; for more information, see Section 13.1.9, “ALTER TABLE Statement”, and Section 24.3.4, “Maintenance of Partitions”.

`CHECK TABLE` ignores virtual generated columns that are not indexed.

- `CHECK TABLE Output`
- `Checking Version Compatibility`
- `Checking Data Consistency`
Table Maintenance Statements

- CHECK TABLE Usage Notes for InnoDB Tables
- CHECK TABLE Usage Notes for MyISAM Tables

CHECK TABLE Output

CHECK TABLE returns a result set with the columns shown in the following table.

<table>
<thead>
<tr>
<th>Column</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table</td>
<td>The table name</td>
</tr>
<tr>
<td>Op</td>
<td>Always check</td>
</tr>
<tr>
<td>Msg_type</td>
<td>status, error, info, note, or warning</td>
</tr>
<tr>
<td>Msg_text</td>
<td>An informational message</td>
</tr>
</tbody>
</table>

The statement might produce many rows of information for each checked table. The last row has a Msg_type value of status and the Msg_text normally should be OK. Table is already up to date means that the storage engine for the table indicated that there was no need to check the table.

Checking Version Compatibility

The FOR UPGRADE option checks whether the named tables are compatible with the current version of MySQL. With FOR UPGRADE, the server checks each table to determine whether there have been any incompatible changes in any of the table's data types or indexes since the table was created. If not, the check succeeds. Otherwise, if there is a possible incompatibility, the server runs a full check on the table (which might take some time).

Incompatibilities might occur because the storage format for a data type has changed or because its sort order has changed. Our aim is to avoid these changes, but occasionally they are necessary to correct problems that would be worse than an incompatibility between releases.

FOR UPGRADE discovers these incompatibilities:

- The indexing order for end-space in TEXT columns for InnoDB and MyISAM tables changed between MySQL 4.1 and 5.0.
- The storage method of the new DECIMAL data type changed between MySQL 5.0.3 and 5.0.5.
- Changes are sometimes made to character sets or collations that require table indexes to be rebuilt. For details about such changes, see Section 2.10.4, “Changes in MySQL 8.0”. For information about rebuilding tables, see Section 2.10.13, “Rebuilding or Repairing Tables or Indexes”.
- MySQL 8.0 does not support the 2-digit YEAR(2) data type permitted in older versions of MySQL. For tables containing YEAR(2) columns, CHECK TABLE recommends REPAIR TABLE, which converts 2-digit YEAR(2) columns to 4-digit YEAR columns.
- Trigger creation time is maintained.
- A table is reported as needing a rebuild if it contains old temporal columns in pre-5.6.4 format (TIME, DATETIME, and TIMESTAMP columns without support for fractional seconds precision) and the avoid_temporal_upgrade system variable is disabled. This helps the MySQL upgrade procedure detect and upgrade tables containing old temporal columns. If avoid_temporal_upgrade is enabled, FOR UPGRADE ignores the old temporal columns present in the table; consequently, the upgrade procedure does not upgrade them.

To check for tables that contain such temporal columns and need a rebuild, disable avoid_temporal_upgrade before executing CHECK TABLE ... FOR UPGRADE.
• Warnings are issued for tables that use nonnative partitioning because nonnative partitioning is removed in MySQL 8.0. See Chapter 24, Partitioning.

Checking Data Consistency

The following table shows the other check options that can be given. These options are passed to the storage engine, which may use or ignore them.

<table>
<thead>
<tr>
<th>Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>QUICK</td>

</tr>
</tbody>
</table>

You can combine check options, as in the following example that does a quick check on the table to determine whether it was closed properly:

CHECK TABLE test_table FAST QUICK;

Note

If CHECK TABLE finds no problems with a table that is marked as “corrupted” or “not closed properly”, CHECK TABLE may remove the mark.

If a table is corrupted, the problem is most likely in the indexes and not in the data part. All of the preceding check types check the indexes thoroughly and should thus find most errors.

To check a table that you assume is okay, use no check options or the QUICK option. The latter should be used when you are in a hurry and can take the very small risk that QUICK does not find an error in the data file. (In most cases, under normal usage, MySQL should find any error in the data file. If this happens, the table is marked as “corrupted” and cannot be used until it is repaired.)

FAST and CHANGED are mostly intended to be used from a script (for example, to be executed from cron) to check tables periodically. In most cases, FAST is to be preferred over CHANGED. (The only case when it is not preferred is when you suspect that you have found a bug in the MyISAM code.)

EXTENDED is to be used only after you have run a normal check but still get errors from a table when MySQL tries to update a row or find a row by key. This is very unlikely if a normal check has succeeded.

Use of CHECK TABLE ... EXTENDED might influence execution plans generated by the query optimizer.
Table Maintenance Statements

Some problems reported by **CHECK TABLE** cannot be corrected automatically:

- **Found row where the auto_increment column has the value 0.**

  This means that you have a row in the table where the `AUTO_INCREMENT` index column contains the value 0. (It is possible to create a row where the `AUTO_INCREMENT` column is 0 by explicitly setting the column to 0 with an **UPDATE** statement.)

  This is not an error in itself, but could cause trouble if you decide to dump the table and restore it or do an **ALTER TABLE** on the table. In this case, the `AUTO_INCREMENT` column changes value according to the rules of `AUTO_INCREMENT` columns, which could cause problems such as a duplicate-key error.

  To get rid of the warning, execute an **UPDATE** statement to set the column to some value other than 0.

**CHECK TABLE Usage Notes for InnoDB Tables**

The following notes apply to **InnoDB** tables:

- If **CHECK TABLE** encounters a corrupt page, the server exits to prevent error propagation (Bug #10132). If the corruption occurs in a secondary index but table data is readable, running **CHECK TABLE** can still cause a server exit.

- If **CHECK TABLE** encounters a corrupted `DB_TRX_ID` or `DB_ROLL_PTR` field in a clustered index, **CHECK TABLE** can cause **InnoDB** to access an invalid undo log record, resulting in an **MVCC**-related server exit.

- If **CHECK TABLE** encounters errors in **InnoDB** tables or indexes, it reports an error, and usually marks the index and sometimes marks the table as corrupted, preventing further use of the index or table. Such errors include an incorrect number of entries in a secondary index or incorrect links.

- If **CHECK TABLE** finds an incorrect number of entries in a secondary index, it reports an error but does not cause a server exit or prevent access to the file.

- **CHECK TABLE** surveys the index page structure, then surveys each key entry. It does not validate the key pointer to a clustered record or follow the path for **BLOB** pointers.

- When an **InnoDB** table is stored in its own `.ibd` file, the first 3 pages of the `.ibd` file contain header information rather than table or index data. The **CHECK TABLE** statement does not detect inconsistencies that affect only the header data. To verify the entire contents of an **InnoDB** `.ibd` file, use the **innochecksum** command.

- When running **CHECK TABLE** on large **InnoDB** tables, other threads may be blocked during **CHECK TABLE** execution. To avoid timeouts, the semaphore wait threshold (600 seconds) is extended by 2 hours (7200 seconds) for **CHECK TABLE** operations. If **InnoDB** detects semaphore waits of 240 seconds or more, it starts printing **InnoDB** monitor output to the error log. If a lock request extends beyond the semaphore wait threshold, **InnoDB** aborts the process. To avoid the possibility of a semaphore wait timeout entirely, run **CHECK TABLE QUICK** instead of **CHECK TABLE**.

- **CHECK TABLE** functionality for **InnoDB SPATIAL** indexes includes an R-tree validity check and a check to ensure that the R-tree row count matches the clustered index.

- **CHECK TABLE** supports secondary indexes on virtual generated columns, which are supported by **InnoDB**.

- As of **MySQL 8.0.14**, **InnoDB** supports parallel clustered index reads, which can improve **CHECK TABLE** performance. **InnoDB** reads the clustered index twice during a **CHECK TABLE** operation. The second read can be performed in parallel. The **innodb_parallel_read_threads** session variable...
Table Maintenance Statements

must be set to a value greater than 1 for parallel clustered index reads to occur. The default value is 4. The actual number of threads used to perform a parallel clustered index read is determined by the `innodb_parallel_read_threads` setting or the number of index subtrees to scan, whichever is smaller.

CHECK TABLE Usage Notes for MyISAM Tables

The following notes apply to MyISAM tables:

- **CHECK TABLE** updates key statistics for MyISAM tables.

- If **CHECK TABLE** output does not return OK or Table is already up to date, you should normally run a repair of the table. See Section 7.6, “MyISAM Table Maintenance and Crash Recovery”.

- If none of the **CHECK TABLE** options QUICK, MEDIUM, or EXTENDED are specified, the default check type for dynamic-format MyISAM tables is MEDIUM. This has the same result as running `myisamchk --medium-check tbl_name` on the table. The default check type also is MEDIUM for static-format MyISAM tables, unless CHANGED or FAST is specified. In that case, the default is QUICK. The row scan is skipped for CHANGED and FAST because the rows are very seldom corrupted.

13.7.3.3 CHECKSUM TABLE Statement

| CHECKSUM TABLE  tbl_name [, tbl_name] ... [QUICK | EXTENDED] |

**CHECKSUM TABLE** reports a checksum for the contents of a table. You can use this statement to verify that the contents are the same before and after a backup, rollback, or other operation that is intended to put the data back to a known state.

This statement requires the **SELECT** privilege for the table.

This statement is not supported for views. If you run **CHECKSUM TABLE** against a view, the Checksum value is always NULL, and a warning is returned.

For a nonexistent table, **CHECKSUM TABLE** returns NULL and generates a warning.

During the checksum operation, the table is locked with a read lock for InnoDB and MyISAM.

Performance Considerations

By default, the entire table is read row by row and the checksum is calculated. For large tables, this could take a long time, thus you would only perform this operation occasionally. This row-by-row calculation is what you get with the EXTENDED clause, with InnoDB and all other storage engines other than MyISAM, and with MyISAM tables not created with the CHECKSUM=1 clause.

For MyISAM tables created with the CHECKSUM=1 clause, **CHECKSUM TABLE** or **CHECKSUM TABLE** ... QUICK returns the “live” table checksum that can be returned very fast. If the table does not meet all these conditions, the QUICK method returns NULL. The QUICK method is not supported with InnoDB tables. See Section 13.1.20, “CREATE TABLE Statement” for the syntax of the CHECKSUM clause.

The checksum value depends on the table row format. If the row format changes, the checksum also changes. For example, the storage format for temporal types such as TIME, DATETIME, and TIMESTAMP changed in MySQL 5.6 prior to MySQL 5.6.5, so if a 5.5 table is upgraded to MySQL 5.6, the checksum value may change.

Important

If the checksums for two tables are different, then it is almost certain that the tables are different in some way. However, because the hashing function used by...
CHECKSUM TABLE is not guaranteed to be collision-free, there is a slight chance that two tables which are not identical can produce the same checksum.

13.7.3.4 OPTIMIZE TABLE Statement

```sql
OPTIMIZE [NO_WRITE_TO_BINLOG | LOCAL] TABLE tbl_name [, tbl_name] ...
```

OPTIMIZE TABLE reorganizes the physical storage of table data and associated index data, to reduce storage space and improve I/O efficiency when accessing the table. The exact changes made to each table depend on the storage engine used by that table.

Use OPTIMIZE TABLE in these cases, depending on the type of table:

- After doing substantial insert, update, or delete operations on an InnoDB table that has its own .ibd file because it was created with the innodb_file_per_table option enabled. The table and indexes are reorganized, and disk space can be reclaimed for use by the operating system.

- After doing substantial insert, update, or delete operations on columns that are part of a FULLTEXT index in an InnoDB table. Set the configuration option innodb_optimize_fulltext_only=1 first. To keep the index maintenance period to a reasonable time, set the innodb_ft_num_word_optimize option to specify how many words to update in the search index, and run a sequence of OPTIMIZE TABLE statements until the search index is fully updated.

- After deleting a large part of a MyISAM or ARCHIVE table, or making many changes to a MyISAM or ARCHIVE table with variable-length rows (tables that have VARCHAR, VARBINARY, BLOB, or TEXT columns). Deleted rows are maintained in a linked list and subsequent INSERT operations reuse old row positions. You can use OPTIMIZE TABLE to reclaim the unused space and to defragment the data file. After extensive changes to a table, this statement may also improve performance of statements that use the table, sometimes significantly.

This statement requires SELECT and INSERT privileges for the table.

OPTIMIZE TABLE works for InnoDB, MyISAM, and ARCHIVE tables. OPTIMIZE TABLE is also supported for dynamic columns of in-memory NDB tables. It does not work for fixed-width columns of in-memory tables, nor does it work for Disk Data tables. The performance of OPTIMIZE on NDB Cluster tables can be tuned using --ndb-optimization-delay, which controls the length of time to wait between processing batches of rows by OPTIMIZE TABLE. For more information, see Section 23.2.7.11, “Previous NDB Cluster Issues Resolved in NDB Cluster 8.0”.

For NDB Cluster tables, OPTIMIZE TABLE can be interrupted by (for example) killing the SQL thread performing the OPTIMIZE operation.

By default, OPTIMIZE TABLE does not work for tables created using any other storage engine and returns a result indicating this lack of support. You can make OPTIMIZE TABLE work for other storage engines by starting mysqld with the --skip-new option. In this case, OPTIMIZE TABLE is just mapped to ALTER TABLE.

This statement does not work with views.

OPTIMIZE TABLE is supported for partitioned tables. For information about using this statement with partitioned tables and table partitions, see Section 24.3.4, “Maintenance of Partitions”.

By default, the server writes OPTIMIZE TABLE statements to the binary log so that they replicate to replicas. To suppress logging, specify the optional NO_WRITE_TO_BINLOG keyword or its alias LOCAL.

- OPTIMIZE TABLE Output
Table Maintenance Statements

- InnoDB Details
- MyISAM Details
- Other Considerations

**OPTIMIZE TABLE Output**

`OPTIMIZE TABLE` returns a result set with the columns shown in the following table.

<table>
<thead>
<tr>
<th>Column</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table</td>
<td>The table name</td>
</tr>
<tr>
<td>Op</td>
<td>Always optimize</td>
</tr>
<tr>
<td>Msg_type</td>
<td>status, error, info, note, or warning</td>
</tr>
<tr>
<td>Msg_text</td>
<td>An informational message</td>
</tr>
</tbody>
</table>

`OPTIMIZE TABLE` table catches and throws any errors that occur while copying table statistics from the old file to the newly created file. For example, if the user ID of the owner of the `.MYD` or `.MYI` file is different from the user ID of the `mysqld` process, `OPTIMIZE TABLE` generates a "cannot change ownership of the file" error unless `mysqld` is started by the root user.

**InnoDB Details**

For InnoDB tables, `OPTIMIZE TABLE` is mapped to `ALTER TABLE ... FORCE`, which rebuilds the table to update index statistics and free unused space in the clustered index. This is displayed in the output of `OPTIMIZE TABLE` when you run it on an InnoDB table, as shown here:

```
mysql> OPTIMIZE TABLE foo;
+----------+----------+----------+-------------------------------------------------------------------+
| Table    | Op       | Msg_type | Msg_text                                                          |
+----------+----------+----------+-------------------------------------------------------------------+
| test.foo | optimize | status   | OK                                                                |
+----------+----------+----------+-------------------------------------------------------------------+
```

`OPTIMIZE TABLE` uses online DDL for regular and partitioned InnoDB tables, which reduces downtime for concurrent DML operations. The table rebuild triggered by `OPTIMIZE TABLE` is completed in place. An exclusive table lock is only taken briefly during the prepare phase and the commit phase of the operation. During the prepare phase, metadata is updated and an intermediate table is created. During the commit phase, table metadata changes are committed.

`OPTIMIZE TABLE` rebuilds the table using the table copy method under the following conditions:

- When the `old_alter_table` system variable is enabled.
- When the server is started with the `--skip-new` option.

`OPTIMIZE TABLE` using online DDL is not supported for InnoDB tables that contain FULLTEXT indexes. The table copy method is used instead.

InnoDB stores data using a page-allocation method and does not suffer from fragmentation in the same way that legacy storage engines (such as MyISAM) do. When considering whether or not to run optimize, consider the workload of transactions that your server is expected to process:

- Some level of fragmentation is expected. InnoDB only fills pages 93% full, to leave room for updates without having to split pages.
Table Maintenance Statements

- Delete operations might leave gaps that leave pages less filled than desired, which could make it worthwhile to optimize the table.

- Updates to rows usually rewrite the data within the same page, depending on the data type and row format, when sufficient space is available. See Section 15.9.1.5, “How Compression Works for InnoDB Tables” and Section 15.10, “InnoDB Row Formats”.

- High-concurrency workloads might leave gaps in indexes over time, as InnoDB retains multiple versions of the same data due through its MVCC mechanism. See Section 15.3, “InnoDB Multi-Versioning”.

MyISAM Details

For MyISAM tables, OPTIMIZE TABLE works as follows:

1. If the table has deleted or split rows, repair the table.
2. If the index pages are not sorted, sort them.
3. If the table’s statistics are not up to date (and the repair could not be accomplished by sorting the index), update them.

Other Considerations

OPTIMIZE TABLE is performed online for regular and partitioned InnoDB tables. Otherwise, MySQL locks the table during the time OPTIMIZE TABLE is running.

OPTIMIZE TABLE does not sort R-tree indexes, such as spatial indexes on POINT columns. (Bug #23578)

13.7.3.5 REPAIR TABLE Statement

REPAIR [NO_WRITE_TO_BINLOG | LOCAL] TABLE tbl_name [, tbl_name] ... [QUICK] [EXTENDED] [USE_FRM]

REPAIR TABLE repairs a possibly corrupted table, for certain storage engines only.

This statement requires SELECT and INSERT privileges for the table.

Although normally you should never have to run REPAIR TABLE, if disaster strikes, this statement is very likely to get back all your data from a MyISAM table. If your tables become corrupted often, try to find the reason for it, to eliminate the need to use REPAIR TABLE. See Section B.3.3.3, “What to Do If MySQL Keeps Crashing”, and Section 16.2.4, “MyISAM Table Problems”.

REPAIR TABLE checks the table to see whether an upgrade is required. If so, it performs the upgrade, following the same rules as CHECK TABLE ... FOR UPGRADE. See Section 13.7.3.2, “CHECK TABLE Statement”, for more information.

Important

- Make a backup of a table before performing a table repair operation; under some circumstances the operation might cause data loss. Possible causes include but are not limited to file system errors. See Chapter 7, Backup and Recovery.

- If the server exits during a REPAIR TABLE operation, it is essential after restarting it that you immediately execute another REPAIR TABLE statement for the table before performing any other operations on it. In the worst case, you
might have a new clean index file without information about the data file, and then the next operation you perform could overwrite the data file. This is an unlikely but possible scenario that underscores the value of making a backup first.

- In the event that a table on the source becomes corrupted and you run `REPAIR TABLE` on it, any resulting changes to the original table are not propagated to replicas.

- **REPAIR TABLE Storage Engine and Partitioning Support**

- **REPAIR TABLE Options**

- **REPAIR TABLE Output**

- **Table Repair Considerations**

**REPAIR TABLE Storage Engine and Partitioning Support**

`REPAIR TABLE` works for **MyISAM**, **ARCHIVE**, and **CSV** tables. For **MyISAM** tables, it has the same effect as `myisamchk --recover tbl_name` by default. This statement does not work with views.

`REPAIR TABLE` is supported for partitioned tables. However, the **USE_FRM** option cannot be used with this statement on a partitioned table.

You can use `ALTER TABLE ... REPAIR PARTITION` to repair one or more partitions; for more information, see Section 13.1.9, “ALTER TABLE Statement”, and Section 24.3.4, “Maintenance of Partitions”.

**REPAIR TABLE Options**

- **NO_WRITE_TO_BINLOG** or **LOCAL**

  By default, the server writes `REPAIR TABLE` statements to the binary log so that they replicate to replicas. To suppress logging, specify the optional **NO_WRITE_TO_BINLOG** keyword or its alias **LOCAL**.

- **QUICK**

  If you use the **QUICK** option, `REPAIR TABLE` tries to repair only the index file, and not the data file. This type of repair is like that done by `myisamchk --recover --quick`.

- **EXTENDED**

  If you use the **EXTENDED** option, MySQL creates the index row by row instead of creating one index at a time with sorting. This type of repair is like that done by `myisamchk --safe-recover`.

- **USE_FRM**

  The **USE_FRM** option is available for use if the **.MYI** index file is missing or if its header is corrupted. This option tells MySQL not to trust the information in the **.MYI** file header and to re-create it using information from the data dictionary. This kind of repair cannot be done with `myisamchk`.

**Caution**

Use the **USE_FRM** option only if you cannot use regular **REPAIR** modes. Telling the server to ignore the **.MYI** file makes important table metadata stored in the **.MYI** unavailable to the repair process, which can have deleterious consequences:
Table Maintenance Statements

- The current `AUTO_INCREMENT` value is lost.
- The link to deleted records in the table is lost, which means that free space for deleted records remains unoccupied thereafter.
- The `.MYI` header indicates whether the table is compressed. If the server ignores this information, it cannot tell that a table is compressed and repair can cause change or loss of table contents. This means that `USE_FRM` should not be used with compressed tables. That should not be necessary, anyway: Compressed tables are read only, so they should not become corrupt.

If you use `USE_FRM` for a table that was created by a different version of the MySQL server than the one you are currently running, `REPAIR TABLE` does not attempt to repair the table. In this case, the result set returned by `REPAIR TABLE` contains a line with a `Msg_type` value of `error` and a `Msg_text` value of `Failed repairing incompatible .FRM file`.

If `USE_FRM` is used, `REPAIR TABLE` does not check the table to see whether an upgrade is required.

**REPAIR TABLE Output**

`REPAIR TABLE` returns a result set with the columns shown in the following table.

<table>
<thead>
<tr>
<th>Column</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table</td>
<td>The table name</td>
</tr>
<tr>
<td>Op</td>
<td>Always repair</td>
</tr>
<tr>
<td>Msg_type</td>
<td><code>status, error, info, note, or warning</code></td>
</tr>
<tr>
<td>Msg_text</td>
<td>An informational message</td>
</tr>
</tbody>
</table>

The `REPAIR TABLE` statement might produce many rows of information for each repaired table. The last row has a `Msg_type` value of `status` and `Msg_test` normally should be `OK`. For a MyISAM table, if you do not get `OK`, you should try repairing it with `myisamchk --safe-recover`. (`REPAIR TABLE` does not implement all the options of `myisamchk`. With `myisamchk --safe-recover`, you can also use options that `REPAIR TABLE` does not support, such as `--max-record-length`).

`REPAIR TABLE` table catches and throws any errors that occur while copying table statistics from the old corrupted file to the newly created file. For example, if the user ID of the owner of the `.MYD` or `.MYI` file is different from the user ID of the `mysqld` process, `REPAIR TABLE` generates a "cannot change ownership of the file" error unless `mysqld` is started by the `root` user.

**Table Repair Considerations**

`REPAIR TABLE` upgrades a table if it contains old temporal columns in pre-5.6.4 format (`TIME`, `DATETIME`, and `TIMESTAMP` columns without support for fractional seconds precision) and the `avoid_temporal_upgrade` system variable is disabled. If `avoid_temporal_upgrade` is enabled, `REPAIR TABLE` ignores the old temporal columns present in the table and does not upgrade them.

To upgrade tables that contain such temporal columns, disable `avoid_temporal_upgrade` before executing `REPAIR TABLE`.

You may be able to increase `REPAIR TABLE` performance by setting certain system variables. See `Section 8.6.3, "Optimizing REPAIR TABLE Statements"`. 3162
13.7.4 Component, Plugin, and Loadable Function Statements

13.7.4.1 CREATE FUNCTION Statement for Loadable Functions

```
CREATE [AGGREGATE] FUNCTION [IF NOT EXISTS] function_name
    RETURNS {STRING|INTEGER|REAL|DECIMAL}
    SONAME shared_library_name
```

This statement loads the loadable function named `function_name`. (CREATE FUNCTION is also used to created stored functions; see Section 13.1.17, “CREATE PROCEDURE and CREATE FUNCTION Statements”.)

A loadable function is a way to extend MySQL with a new function that works like a native (built-in) MySQL function such as `ABS()` or `CONCAT()`. See Adding a Loadable Function.

`function_name` is the name that should be used in SQL statements to invoke the function. The `RETURNS` clause indicates the type of the function's return value. `DECIMAL` is a legal value after `RETURNS`, but currently `DECIMAL` functions return string values and should be written like `STRING` functions.

`IF NOT EXISTS` prevents an error from occurring if there already exists a loadable function with the same name. It does not prevent an error from occurring if there already exists a built-in function having the same name. `IF NOT EXISTS` is supported for CREATE FUNCTION statements beginning with MySQL 8.0.29. See also Function Name Resolution.

The `AGGREGATE` keyword, if given, signifies that the function is an aggregate (group) function. An aggregate function works exactly like a native MySQL aggregate function such as `SUM()` or `COUNT()`.

`shared_library_name` is the base name of the shared library file containing the code that implements the function. The file must be located in the plugin directory. This directory is given by the value of the `plugin_dir` system variable. For more information, see Section 5.7.1, “Installing and Uninstalling Loadable Functions”.

`CREATE FUNCTION` requires the `INSERT` privilege for the `mysql` system schema because it adds a row to the `mysql.func` system table to register the function.

`CREATE FUNCTION` also adds the function to the Performance Schema `user_defined_functions` table that provides runtime information about installed loadable functions. See Section 27.12.21.10, “The `user_defined_functions` Table”.

**Note**

Like the `mysql.func` system table, the Performance Schema `user_defined_functions` table lists loadable functions installed using `CREATE FUNCTION`. Unlike the `mysql.func` table, the `user_defined_functions` table also lists loadable functions installed automatically by server components or plugins. This difference makes `user_defined_functions` preferable to `mysql.func` for checking which loadable functions are installed.

During the normal startup sequence, the server loads functions registered in the `mysql.func` table. If the server is started with the `--skip-grant-tables` option, functions registered in the table are not loaded and are unavailable.

**Note**

To upgrade the shared library associated with a loadable function, issue a `DROP FUNCTION` statement, upgrade the shared library, and then issue a `CREATE
Component, Plugin, and Loadable Function Statements

13.7.4.2 DROP FUNCTION Statement for Loadable Functions

DROP FUNCTION [IF EXISTS] function_name

This statement drops the loadable function named function_name. (DROP FUNCTION is also used to drop stored functions; see Section 13.1.29, “DROP PROCEDURE and DROP FUNCTION Statements”.)

DROP FUNCTION is the complement of CREATE FUNCTION. It requires the DELETE privilege for the mysql system schema because it removes the row from the mysql.func system table that registers the function.

DROP FUNCTION also removes the function from the Performance Schema user_defined_functions table that provides runtime information about installed loadable functions. See Section 27.12.21.10, “The user_defined_functions Table”.

During the normal startup sequence, the server loads functions registered in the mysql.func table. Because DROP FUNCTION removes the mysql.func row for the dropped function, the server does not load the function during subsequent restarts.

DROP FUNCTION cannot be used to drop a loadable function that is installed automatically by components or plugins rather than by using CREATE FUNCTION. Such a function is also dropped automatically, when the component or plugin that installed it is uninstalled.

Note

To upgrade the shared library associated with a loadable function, issue a DROP FUNCTION statement, upgrade the shared library, and then issue a CREATE FUNCTION statement. If you upgrade the shared library first and then use DROP FUNCTION, the server may unexpectedly shut down.

13.7.4.3 INSTALL COMPONENT Statement

INSTALL COMPONENT component_name [, component_name ...]

[SET variable = expr [, variable = expr] ...]

variable: { {GLOBAL | @@GLOBAL.} [component_prefix.]system_var_name
| {PERSIST | @@PERSIST.} [component_prefix.]system_var_name
}

This statement installs one or more components, which become active immediately. A component provides services that are available to the server and other components; see Section 5.5, “MySQL Components”. INSTALL COMPONENT requires the INSERT privilege for the mysql.component system table because it adds a row to that table to register the component.

Example:

INSTALL COMPONENT 'file://component1', 'file://component2';

A component is named using a URN that begins with file:// and indicates the base name of the library file that implements the component, located in the directory named by the plugin_dir system variable. Component names do not include any platform-dependent file name suffix such as .so or .dll. (These naming details are subject to change because component name interpretation is itself performed by a service and the component infrastructure makes it possible to replace the default service implementation with alternative implementations.)
**Component, Plugin, and Loadable Function Statements**

**INSTALL COMPONENT** (from 8.0.33) permits setting the values of component system variables when you install one or more components. The **SET** clause enables you to specify variable values precisely when they are needed, without the inconvenience or limitations associated with other forms of assignment. Specifically, you can also set component variables with these alternatives:

- At server startup using options on the command line or in an option file, but doing so involves a server restart. The values do not take effect until you install the component. You can specify an invalid variable name for a component on the command line without triggering an error.

- Dynamically while the server is running by means of the **SET** statement, which enables you to modify operation of the server without having to stop and restart it. Setting a read-only variable is not permitted.

The optional **SET** clause applies a value, or values, only to the component specified in the **INSTALL COMPONENT** statement, rather than to all subsequent installations of that component. **SET GLOBAL|PERSIST** works for all types of variables, including read-only variables, without having to restart the server. A component system variable that you set using **INSTALL COMPONENT** takes precedence over any conflicting value coming from the command line or an option file.

Example:

```sql
INSTALL COMPONENT 'file://component1', 'file://component2'
  SET GLOBAL component1.var1 = 12 + 3, PERSIST component2.var2 = 'strings';
```

Omitting **PERSIST** or **GLOBAL** is equivalent to specifying **GLOBAL**.

Specifying **PERSIST** for any variable in **SET** silently executes **SET PERSIST_ONLY** immediately after **INSTALL COMPONENT** loads the components, but before updating the mysql.component table. If **SET PERSIST_ONLY** fails, then the server unloads all of the previously loaded new components without persisting anything to mysql.component.

The **SET** clause accepts only valid variable names of the component being installed and emits an error message for all invalid names. Subqueries, stored functions, and aggregate functions are not permitted as part of the value expression. If you install a single component, it is not necessary to prefix the variable name with the component name.

**Note**

While specifying a variable value using the **SET** clause is similar to that of the command line—it is available immediately at variable registration—there is a distinct difference in how the **SET** clause handles **invalid numerical** values for boolean variables. For example, if you set a boolean variable to **11 (component1.boolvar = 11)**, you see the following behavior:

- **SET** clause yields true
- Command line yields false (11 is neither ON nor 1)

If any error occurs, the statement fails and has no effect. For example, this happens if a component name is erroneous, a named component does not exist or is already installed, or component initialization fails.

A loader service handles component loading, which includes adding installed components to the mysql.component system table that serves as a registry. For subsequent server restarts, any components listed in mysql.component are loaded by the loader service during the startup sequence. This occurs even if the server is started with the **--skip-grant-tables** option.

If a component depends on services not present in the registry and you attempt to install the component without also installing the component or components that provide the services on which it depends, an error occurs:
Component, Plugin, and Loadable Function Statements

ERROR 3527 (HY000): Cannot satisfy dependency for service 'component_a' required by component 'component_b'.

To avoid this problem, either install all components in the same statement, or install the dependent component after installing any components on which it depends.

Note
For keyring components, do not use INSTALL COMPONENT. Instead, configure keyring component loading using a manifest file. See Section 6.4.4.2, “Keyring Component Installation”.

13.7.4.4 INSTALL PLUGIN Statement

INSTALL PLUGIN plugin_name SONAME 'shared_library_name'

This statement installs a server plugin. It requires the INSERT privilege for the mysql.plugin system table because it adds a row to that table to register the plugin.

plugin_name is the name of the plugin as defined in the plugin descriptor structure contained in the library file (see Plugin Data Structures). Plugin names are not case-sensitive. For maximal compatibility, plugin names should be limited to ASCII letters, digits, and underscore because they are used in C source files, shell command lines, M4 and Bourne shell scripts, and SQL environments.

shared_library_name is the name of the shared library that contains the plugin code. The name includes the file name extension (for example, libmyplugin.so, libmyplugin.dll, or libmyplugin.dylib).

The shared library must be located in the plugin directory (the directory named by the plugin_dir system variable). The library must be in the plugin directory itself, not in a subdirectory. By default, plugin_dir is the plugin directory under the directory named by the pkglibdir configuration variable, but it can be changed by setting the value of plugin_dir at server startup. For example, set its value in a my.cnf file:

```
[mysqld]
plugin_dir=/path/to/plugin/directory
```

If the value of plugin_dir is a relative path name, it is taken to be relative to the MySQL base directory (the value of the basedir system variable).

INSTALL PLUGIN loads and initializes the plugin code to make the plugin available for use. A plugin is initialized by executing its initialization function, which handles any setup that the plugin must perform before it can be used. When the server shuts down, it executes the deinitialization function for each plugin that is loaded so that the plugin has a chance to perform any final cleanup.

INSTALL PLUGIN also registers the plugin by adding a line that indicates the plugin name and library file name to the mysql.plugin system table. During the normal startup sequence, the server loads and initializes plugins registered in mysql.plugin. This means that a plugin is installed with INSTALL PLUGIN only once, not every time the server starts. If the server is started with the --skip-grant-tables option, plugins registered in the mysql.plugin table are not loaded and are unavailable.

A plugin library can contain multiple plugins. For each of them to be installed, use a separate INSTALL PLUGIN statement. Each statement names a different plugin, but all of them specify the same library name.

INSTALL PLUGIN causes the server to read option (my.cnf) files just as during server startup. This enables the plugin to pick up any relevant options from those files. It is possible to add plugin options to an option file even before loading a plugin (if the loose prefix is used). It is also possible to uninstall a plugin,
edit my.cnf, and install the plugin again. Restarting the plugin this way enables it to the new option values without a server restart.

For options that control individual plugin loading at server startup, see Section 5.6.1, “Installing and Uninstalling Plugins”. If you need to load plugins for a single server startup when the --skip-grant-tables option is given (which tells the server not to read system tables), use the --plugin-load option. See Section 5.1.7, “Server Command Options”.

To remove a plugin, use the UNINSTALL PLUGIN statement.

For additional information about plugin loading, see Section 5.6.1, “Installing and Uninstalling Plugins”.

To see what plugins are installed, use the SHOW PLUGINS statement or query the INFORMATION_SCHEMA the PLUGINS table.

If you recompile a plugin library and need to reinstall it, you can use either of the following methods:

• Use UNINSTALL PLUGIN to uninstall all plugins in the library, install the new plugin library file in the plugin directory, and then use INSTALL PLUGIN to install all plugins in the library. This procedure has the advantage that it can be used without stopping the server. However, if the plugin library contains many plugins, you must issue many INSTALL PLUGIN and UNINSTALL PLUGIN statements.

• Stop the server, install the new plugin library file in the plugin directory, and restart the server.

13.7.4.5 UNINSTALL COMPONENT Statement

UNINSTALL COMPONENT component_name [, component_name ] ...

This statement deactivates and uninstalls one or more components. A component provides services that are available to the server and other components; see Section 5.5, “MySQL Components”. UNINSTALL COMPONENT is the complement of INSTALL COMPONENT. It requires the DELETE privilege for the mysql.component system table because it removes the row from that table that registers the component.

UNINSTALL COMPONENT does not undo persisted variables, including the variables persisted using INSTALL COMPONENT ... SET PERSIST.

Example:

UNINSTALL COMPONENT 'file://component1', 'file://component2';

For information about component naming, see Section 13.7.4.3, “INSTALL COMPONENT Statement”.

If any error occurs, the statement fails and has no effect. For example, this happens if a component name is erroneous, a named component is not installed, or cannot be uninstalled because other installed components depend on it.

A loader service handles component unloading, which includes removing unloaded components from the mysql.component system table that serves as a registry. As a result, unloaded components are not loaded during the startup sequence for subsequent server restarts.

Note

This statement has no effect for keyring components, which are loaded using a manifest file and cannot be unloaded. See Section 6.4.4.2, “Keyring Component Installation”.

13.7.4.6 UNINSTALL PLUGIN Statement
UNINSTALL PLUGIN plugin_name

This statement removes an installed server plugin. UNINSTALL PLUGIN is the complement of INSTALL PLUGIN. It requires the DELETE privilege for the mysql.plugin system table because it removes the row from that table that registers the plugin.

plugin_name must be the name of some plugin that is listed in the mysql.plugin table. The server executes the plugin's deinitialization function and removes the row for the plugin from the mysql.plugin system table, so that subsequent server restarts do not load and initialize the plugin. UNINSTALL PLUGIN does not remove the plugin's shared library file.

You cannot uninstall a plugin if any table that uses it is open.

Plugin removal has implications for the use of associated tables. For example, if a full-text parser plugin is associated with a FULLTEXT index on the table, uninstalling the plugin makes the table unusable. Any attempt to access the table results in an error. The table cannot even be opened, so you cannot drop an index for which the plugin is used. This means that uninstalling a plugin is something to do with care unless you do not care about the table contents. If you are uninstalling a plugin with no intention of reinstalling it later and you care about the table contents, you should dump the table with mysqldump and remove the WITH PARSER clause from the dumped CREATE TABLE statement so that you can reload the table later. If you do not care about the table, DROP TABLE can be used even if any plugins associated with the table are missing.

For additional information about plugin loading, see Section 5.6.1, “Installing and Uninstalling Plugins”.

13.7.5 CLONE Statement

The CLONE statement is used to clone data locally or from a remote MySQL server instance. To use CLONE syntax, the clone plugin must be installed. See Section 5.6.7, “The Clone Plugin”.

CLONE clone_action syntax clones data from the local MySQL data directory to a directory on the same server or node where the MySQL server instance runs. The 'clone_dir' directory is the full path of the local directory that data is cloned to. An absolute path is required. The specified directory must not exist, but the specified path must be an existent path. The MySQL server requires the necessary write access to create the specified directory. For more information, see Section 5.6.7.2, “Cloning Data Locally”.

CLONE INSTANCE syntax clones data from a remote MySQL server instance (the donor) and transfers it to the MySQL instance where the cloning operation was initiated (the recipient).

- user is the clone user on the donor MySQL server instance.

- host is the hostname address of the donor MySQL server instance. Internet Protocol version 6 (IPv6) address format is not supported. An alias to the IPv6 address can be used instead. An IPv4 address can be used as is.

- port is the port number of the donor MySQL server instance. (The X Protocol port specified by mysqlx_port is not supported. Connecting to the donor MySQL server instance through MySQL Router is also not supported.)
SET Statements

- **IDENTIFIED BY 'password'** specifies the password of the clone user on the donor MySQL server instance.

- **DATA DIRECTORY [=] 'clone_dir'** is an optional clause used to specify a directory on the recipient for the data you are cloning. Use this option if you do not want to remove existing data in the recipient data directory. An absolute path is required, and the directory must not exist. The MySQL server must have the necessary write access to create the directory.

  When the optional `DATA DIRECTORY [=] 'clone_dir'` clause is not used, a cloning operation removes existing data in the recipient data directory, replaces it with the cloned data, and automatically restarts the server afterward.

- **[REQUIRE [NO] SSL]** explicitly specifies whether an encrypted connection is to be used or not when transferring cloned data over the network. An error is returned if the explicit specification cannot be satisfied. If an SSL clause is not specified, clone attempts to establish an encrypted connection by default, falling back to an insecure connection if the secure connection attempt fails. A secure connection is required when cloning encrypted data regardless of whether this clause is specified. For more information, see Configuring an Encrypted Connection for Cloning.

  For additional information about cloning data from a remote MySQL server instance, see **Section 5.6.7.3, “Cloning Remote Data”**.

**13.7.6 SET Statements**

The **SET** statement has several forms. Descriptions for those forms that are not associated with a specific server capability appear in subsections of this section:

- **SET var_name = value** enables you to assign values to variables that affect the operation of the server or clients. See **Section 13.7.6.1, “SET Syntax for Variable Assignment”**.

- **SET CHARACTER SET** and **SET NAMES** assign values to character set and collation variables associated with the current connection to the server. See **Section 13.7.6.2, “SET CHARACTER SET Statement”**, and **Section 13.7.6.3, “SET NAMES Statement”**.

  Descriptions for the other forms appear elsewhere, grouped with other statements related to the capability they help implement:

  - **SET DEFAULT ROLE** and **SET ROLE** set the default role and current role for user accounts. See **Section 13.7.1.9, “SET DEFAULT ROLE Statement”**, and **Section 13.7.1.11, “SET ROLE Statement”**.

  - **SET PASSWORD** assigns account passwords. See **Section 13.7.1.10, “SET PASSWORD Statement”**.

  - **SET RESOURCE GROUP** assigns threads to a resource group. See **Section 13.7.2.4, “SET RESOURCE GROUP Statement”**.

  - **SET TRANSACTION ISOLATION LEVEL** sets the isolation level for transaction processing. See **Section 13.3.7, “SET TRANSACTION Statement”**.

**13.7.6.1 SET Syntax for Variable Assignment**

```
SET variable = expr [, variable = expr] ...

variable: {
    user_var_name
    param_name
    local_var_name
    {GLOBAL | @@GLOBAL.} system_var_name
    {PERSIST | @@PERSIST.} system_var_name
```

3169
**SET Statements**

`SET` syntax for variable assignment enables you to assign values to different types of variables that affect the operation of the server or clients:

- User-defined variables. See Section 9.4, “User-Defined Variables”.

- Stored procedure and function parameters, and stored program local variables. See Section 13.6.4, “Variables in Stored Programs”.

- System variables. See Section 5.1.8, “Server System Variables”. System variables also can be set at server startup, as described in Section 5.1.9, “Using System Variables”.

A `SET` statement that assigns variable values is not written to the binary log, so in replication scenarios it affects only the host on which you execute it. To affect all replication hosts, execute the statement on each host.

The following sections describe `SET` syntax for setting variables. They use the `=` assignment operator, but the `:=` assignment operator is also permitted for this purpose.

- User-Defined Variable Assignment

- Parameter and Local Variable Assignment

- System Variable Assignment

- SET Error Handling

- Multiple Variable Assignment

- System Variable References in Expressions

### User-Defined Variable Assignment

User-defined variables are created locally within a session and exist only within the context of that session; see Section 9.4, “User-Defined Variables”.

A user-defined variable is written as `@var_name` and is assigned an expression value as follows:

```sql
SET @var_name = expr;
```

**Examples:**

```sql
SET @name = 43;
SET @total_tax = (SELECT SUM(tax) FROM taxable_transactions);
```

As demonstrated by those statements, `expr` can range from simple (a literal value) to more complex (the value returned by a scalar subquery).

The Performance Schema `user_variables_by_thread` table contains information about user-defined variables. See Section 27.12.10, “Performance Schema User-Defined Variable Tables”.

### Parameter and Local Variable Assignment

`SET` applies to parameters and local variables in the context of the stored object within which they are defined. The following procedure uses the `increment` procedure parameter and `counter` local variable:

```sql
CREATE PROCEDURE p(increment INT)
```
BEGIN
  DECLARE counter INT DEFAULT 0;
  WHILE counter < 10 DO
    -- ... do work ... 
    SET counter = counter + increment;
  END WHILE;
END;

System Variable Assignment

The MySQL server maintains system variables that configure its operation. A system variable can have a global value that affects server operation as a whole, a session value that affects the current session, or both. Many system variables are dynamic and can be changed at runtime using the SET statement to affect operation of the current server instance. SET can also be used to persist certain system variables to the mysql-auto.cnf file in the data directory, to affect server operation for subsequent startups.

If a SET statement is issued for a sensitive system variable, the query is rewritten to replace the value with "<redacted>" before it is logged to the general log and audit log. This takes place even if secure storage through a keyring component is not available on the server instance.

If you change a session system variable, the value remains in effect within your session until you change the variable to a different value or the session ends. The change has no effect on other sessions.

If you change a global system variable, the value is remembered and used to initialize the session value for new sessions until you change the variable to a different value or the server exits. The change is visible to any client that accesses the global value. However, the change affects the corresponding session value only for clients that connect after the change. The global variable change does not affect the session value for any current client sessions (not even the session within which the global value change occurs).

To make a global system variable setting permanent so that it applies across server restarts, you can persist it to the mysql-auto.cnf file in the data directory. It is also possible to make persistent configuration changes by manually modifying a my.cnf option file, but that is more cumbersome, and an error in a manually entered setting might not be discovered until much later. SET statements that persist system variables are more convenient and avoid the possibility of malformed settings because settings with syntax errors do not succeed and do not change server configuration. For more information about persisting system variables and the mysql-auto.cnf file, see Section 5.1.9.3, “Persisted System Variables”.

Note

Setting or persisting a global system variable value always requires special privileges. Setting a session system variable value normally requires no special privileges and can be done by any user, although there are exceptions. For more information, see Section 5.1.9.1,”System Variable Privileges”.

The following discussion describes the syntax options for setting and persisting system variables:

- To assign a value to a global system variable, precede the variable name by the GLOBAL keyword or the @@GLOBAL. qualifier:

  SET GLOBAL max_connections = 1000;
  SET @@GLOBAL.max_connections = 1000;

- To assign a value to a session system variable, precede the variable name by the SESSION or LOCAL keyword, by the @@SESSION., @@LOCAL., or @@ qualifier, or by no keyword or no modifier at all:

  SET SESSION sql_mode = 'TRADITIONAL';
  SET LOCAL sql_mode = 'TRADITIONAL';
A client can change its own session variables, but not those of any other client.

- To persist a global system variable to the `mysqld-auto.cnf` option file in the data directory, precede the variable name by the `PERSIST` keyword or the `@@PERSIST` qualifier:

  ```sql
  SET PERSIST max_connections = 1000;
  SET @@PERSIST.max_connections = 1000;
  ```

  This `SET` syntax enables you to make configuration changes at runtime that also persist across server restarts. Like `SET GLOBAL`, `SET PERSIST` sets the global variable runtime value, but also writes the variable setting to the `mysqld-auto.cnf` file (replacing any existing variable setting if there is one).

- To persist a global system variable to the `mysqld-auto.cnf` file without setting the global variable runtime value, precede the variable name by the `PERSIST_ONLY` keyword or the `@@PERSIST_ONLY` qualifier:

  ```sql
  SET PERSIST_ONLY back_log = 100;
  SET @@PERSIST_ONLY.back_log = 100;
  ```

  Like `PERSIST`, `PERSIST_ONLY` writes the variable setting to `mysqld-auto.cnf`. However, unlike `PERSIST`, `PERSIST_ONLY` does not modify the global variable runtime value. This makes `PERSIST_ONLY` suitable for configuring read-only system variables that can be set only at server startup.

To set a global system variable value to the compiled-in MySQL default value or a session system variable to the current corresponding global value, set the variable to the value `DEFAULT`. For example, the following two statements are identical in setting the session value of `max_join_size` to the current global value:

```sql
SET @@SESSION.max_join_size = DEFAULT;
SET @@SESSION.max_join_size = @@GLOBAL.max_join_size;
```

Using `SET` to persist a global system variable to a value of `DEFAULT` or to its literal default value assigns the variable its default value and adds a setting for the variable to `mysqld-auto.cnf`. To remove the variable from the file, use `RESET PERSIST`.

Some system variables cannot be persisted or are persist-restricted. See Section 5.1.9.4, “Nonpersistible and Persist-Restricted System Variables”.

A system variable implemented by a plugin can be persisted if the plugin is installed when the `SET` statement is executed. Assignment of the persisted plugin variable takes effect for subsequent server restarts if the plugin is still installed. If the plugin is no longer installed, the plugin variable no longer exists when the server reads the `mysqld-auto.cnf` file. In this case, the server writes a warning to the error log and continues:

```sql
currently unknown variable 'var_name'
was read from the persisted config file
```

To display system variable names and values:

- Use the `SHOW VARIABLES` statement; see Section 13.7.7.41, “SHOW VARIABLES Statement”.

- Several Performance Schema tables provide system variable information. See Section 27.12.14, “Performance Schema System Variable Tables”.

3172
SET Statements

- The Performance Schema `variables_info` table contains information showing when and by which user each system variable was most recently set. See Section 27.12.14.2, “Performance Schema variables_info Table”.

- The Performance Schema `persisted_variables` table provides an SQL interface to the `mysqld-auto.cnf` file, enabling its contents to be inspected at runtime using `SELECT` statements. See Section 27.12.14.1, “Performance Schema persisted_variables Table”.

SET Error Handling

If any variable assignment in a `SET` statement fails, the entire statement fails and no variables are changed, nor is the `mysqld-auto.cnf` file changed.

`SET` produces an error under the circumstances described here. Most of the examples show `SET` statements that use keyword syntax (for example, `GLOBAL` or `SESSION`), but the principles are also true for statements that use the corresponding modifiers (for example, `@@GLOBAL` or `@@SESSION`).

- Use of `SET` (any variant) to set a read-only variable:

  ```
  mysql> SET GLOBAL version = 'abc';
  ERROR 1238 (HY000): Variable 'version' is a read only variable
  ```

- Use of `GLOBAL`, `PERSIST`, or `PERSIST_ONLY` to set a variable that has only a session value:

  ```
  mysql> SET GLOBAL sql_log_bin = ON;
  ERROR 1228 (HY000): Variable 'sql_log_bin' is a SESSION variable and can't be used with SET GLOBAL
  ```

- Use of `SESSION` to set a variable that has only a global value:

  ```
  mysql> SET SESSION max_connections = 1000;
  ERROR 1229 (HY000): Variable 'max_connections' is a GLOBAL variable and should be set with SET GLOBAL
  ```

- Omission of `GLOBAL`, `PERSIST`, or `PERSIST_ONLY` to set a variable that has only a global value:

  ```
  mysql> SET max_connections = 1000;
  ERROR 1229 (HY000): Variable 'max_connections' is a GLOBAL variable and should be set with SET GLOBAL
  ```

- Use of `PERSIST` or `PERSIST_ONLY` to set a variable that cannot be persisted:

  ```
  mysql> SET PERSIST port = 3307;
  ERROR 1238 (HY000): Variable 'port' is a read only variable
  mysql> SET PERSIST_ONLY port = 3307;
  ERROR 1238 (HY000): Variable 'port' is a non persistent read only variable
  ```

- The `@@GLOBAL`, `@@PERSIST`, `@@PERSIST_ONLY`, `@@SESSION`, and `@@` modifiers apply only to system variables. An error occurs for attempts to apply them to user-defined variables, stored procedure or function parameters, or stored program local variables.

- Not all system variables can be set to `DEFAULT`. In such cases, assigning `DEFAULT` results in an error.

- An error occurs for attempts to assign `DEFAULT` to user-defined variables, stored procedure or function parameters, or stored program local variables.

Multiple Variable Assignment

A `SET` statement can contain multiple variable assignments, separated by commas. This statement assigns values to a user-defined variable and a system variable:

```
SET Statements

```sql
SET @x = 1, SESSION sql_mode = '';
```

If you set multiple system variables in a single statement, the most recent `GLOBAL`, `PERSIST`, `PERSIST_ONLY`, or `SESSION` keyword in the statement is used for following assignments that have no keyword specified.

Examples of multiple-variable assignment:

```sql
SET GLOBAL sort_buffer_size = 1000000, SESSION sort_buffer_size = 1000000;
SET @@GLOBAL.sort_buffer_size = 1000000, @@LOCAL.sort_buffer_size = 1000000;
SET GLOBAL max_connections = 1000, sort_buffer_size = 1000000;
```

The `@@GLOBAL`, `@@PERSIST`, `@@PERSIST_ONLY`, `@@SESSION`, and `@@` modifiers apply only to the immediately following system variable, not any remaining system variables. This statement sets the `sort_buffer_size` global value to 50000 and the session value to 1000000:

```sql
SET @@GLOBAL.sort_buffer_size = 50000, sort_buffer_size = 1000000;
```

### System Variable References in Expressions

To refer to the value of a system variable in expressions, use one of the `@@`-modifiers (except `@@PERSIST` and `@@PERSIST_ONLY`, which are not permitted in expressions). For example, you can retrieve system variable values in a `SELECT` statement like this:

```sql
SELECT @@GLOBAL.sql_mode, @@SESSION.sql_mode, @@sql_mode;
```

**Note**

A reference to a system variable in an expression as `@@var_name` (with `@@` rather than `@@GLOBAL` or `@@SESSION`) returns the session value if it exists and the global value otherwise. This differs from `SET @@var_name = expr`, which always refers to the session value.

#### 13.7.6.2 SET CHARACTER SET Statement

```sql
SET {CHARACTER SET | CHARSET}{'charset_name'}
```

This statement maps all strings sent between the server and the current client with the given mapping. `SET CHARACTER SET` sets three session system variables: `character_set_client` and `character_set_results` are set to the given character set, and `character_set_connection` to the value of `character_set_database`. See Section 10.4, “Connection Character Sets and Collations”.

`charset_name` may be quoted or unquoted.

The default character set mapping can be restored by using the value `DEFAULT`. The default depends on the server configuration.

Some character sets cannot be used as the client character set. Attempting to use them with `SET CHARACTER SET` produces an error. See `Impermissible Client Character Sets`.

#### 13.7.6.3 SET NAMES Statement

```sql
SET NAMES {'charset_name'} [COLLATE 'collation_name'] | DEFAULT
```

This statement sets the three session system variables `character_set_client`, `character_set_connection`, and `character_set_results` to the given character set. Setting `character_set_connection` to `charset_name` also sets `collation_connection` to the default collation for `charset_name`. See Section 10.4, “Connection Character Sets and Collations”.
SHOW Statements

The optional `COLLATE` clause may be used to specify a collation explicitly. If given, the collation must one of the permitted collations for `charset_name`.

`charset_name` and `collation_name` may be quoted or unquoted.

The default mapping can be restored by using a value of `DEFAULT`. The default depends on the server configuration.

Some character sets cannot be used as the client character set. Attempting to use them with `SET NAMES` produces an error. See `Impermissible Client Character Sets`.

13.7.7 SHOW Statements

`SHOW` has many forms that provide information about databases, tables, columns, or status information about the server. This section describes those following:

```
SHOW (BINARY | MASTER) LOGS
SHOW BINLOG EVENTS [IN 'log_name'] [FROM pos] [LIMIT [offset,] row_count]
SHOW (CHARACTER SET | CHARSET) [like_or_where]
SHOW COLLATION [like_or_where]
SHOW [FULL] COLUMNS FROM tbl_name [FROM db_name] [like_or_where]
SHOW CREATE DATABASE db_name
SHOW CREATE EVENT event_name
SHOW CREATE FUNCTION func_name
SHOW CREATE PROCEDURE proc_name
SHOW CREATE TABLE tbl_name
SHOW CREATE TRIGGER trigger_name
SHOW CREATE VIEW view_name
SHOW DATABASES [like_or_where]
SHOW ENGINE engine_name (STATUS | MUTEX)
SHOW [STORAGE] ENGINES
SHOW ERRORS [LIMIT [offset,] row_count]
SHOW EVENTS
SHOW FUNCTION CODE func_name
SHOW FUNCTION STATUS [like_or_where]
SHOW GRANTS FOR user
SHOW INDEX FROM tbl_name [FROM db_name]
SHOW MASTER STATUS
SHOW OPEN TABLES [FROM db_name] [like_or_where]
SHOW PLUGINS
SHOW PROCEDURE CODE proc_name
SHOW PROCEDURE STATUS [like_or_where]
SHOW PRIVILEGES
SHOW [FULL] PROCESSLIST
SHOW PROFILE [types] [FOR QUERY n] [OFFSET n] [LIMIT n]
SHOW PROFILES
SHOW RELAYLOG EVENTS [IN 'log_name'] [FROM pos] [LIMIT [offset,] row_count]
SHOW (REPLICA | SLAVE HOSTS)
SHOW (REPLICA | SLAVE) STATUS [FOR CHANNEL channel]
SHOW [GLOBAL | SESSION] STATUS [like_or_where]
SHOW TABLE STATUS [FROM db_name] [like_or_where]
SHOW [FULL] TABLES [FROM db_name] [like_or_where]
SHOW TRIGGERS [FROM db_name] [like_or_where]
SHOW [GLOBAL | SESSION] VARIABLES [like_or_where]
SHOW WARNINGS [LIMIT [offset,] row_count]
```

```
like_or_where: { 
    LIKE 'pattern'
    | WHERE expr
}
```

If the syntax for a given `SHOW` statement includes a `LIKE 'pattern'` part, `pattern` is a string that can contain the SQL `%` and `_` wildcard characters. The pattern is useful for restricting statement output to matching values.
Several `SHOW` statements also accept a `WHERE` clause that provides more flexibility in specifying which rows to display. See Section 26.8, “Extensions to SHOW Statements”.

In `SHOW` statement results, user names and host names are quoted using backticks (`).

Many MySQL APIs (such as PHP) enable you to treat the result returned from a `SHOW` statement as you would a result set from a `SELECT`; see Chapter 29, Connectors and APIs, or your API documentation for more information. In addition, you can work in SQL with results from queries on tables in the `INFORMATION_SCHEMA` database, which you cannot easily do with results from `SHOW` statements. See Chapter 26, `INFORMATION_SCHEMA` Tables.

### 13.7.7.1 SHOW BINARY LOGS Statement

```
SHOW BINARY LOGS
SHOW MASTER LOGS
```

Lists the binary log files on the server. This statement is used as part of the procedure described in Section 13.4.1.1, “PURGE BINARY LOGS Statement”, that shows how to determine which logs can be purged. `SHOW BINARY LOGS` requires the `REPLICATION CLIENT` privilege (or the deprecated `SUPER` privilege).

Encrypted binary log files have a 512-byte file header that stores information required for encryption and decryption of the file. This is included in the file size displayed by `SHOW BINARY LOGS`. The `Encrypted` column shows whether or not the binary log file is encrypted. Binary log encryption is active if `binlog_encryption=ON` is set for the server. Existing binary log files are not encrypted or decrypted if binary log encryption is activated or deactivated while the server is running.

```
mysql> SHOW BINARY LOGS;
+---------------+-----------+-----------+
| Log_name      | File_size | Encrypted |
+---------------+-----------+-----------+
| binlog.000015 |    724935 |       Yes |
| binlog.000016 |    733481 |       Yes |
+---------------+-----------+-----------+
```

`SHOW MASTER LOGS` is equivalent to `SHOW BINARY LOGS`.

### 13.7.7.2 SHOW BINLOG EVENTS Statement

```
SHOW BINLOG EVENTS
[IN 'log_name']
[FROM pos]
[LIMIT [offset,] row_count]
```

Shows the events in the binary log. If you do not specify `log_name`, the first binary log is displayed. `SHOW BINLOG EVENTS` requires the `REPLICATION SLAVE` privilege.

The `LIMIT` clause has the same syntax as for the `SELECT` statement. See Section 13.2.13, “SELECT Statement”.

**Note**

Issuing a `SHOW BINLOG EVENTS` with no `LIMIT` clause could start a very time- and resource-consuming process because the server returns to the client the complete contents of the binary log (which includes all statements executed by the server that modify data). As an alternative to `SHOW BINLOG EVENTS`, use the `mysqlbinlog` utility to save the binary log to a text file for later examination and analysis. See Section 4.6.9, “mysqlbinlog — Utility for Processing Binary Log Files”.

`SHOW BINLOG EVENTS` displays the following fields for each event in the binary log:
SHOW Statements

• **Log_name**
  The name of the file that is being listed.

• **Pos**
  The position at which the event occurs.

• **Event_type**
  An identifier that describes the event type.

• **Server_id**
  The server ID of the server on which the event originated.

• **End_log_pos**
  The position at which the next event begins, which is equal to Pos plus the size of the event.

• **Info**
  More detailed information about the event type. The format of this information depends on the event type.

For compressed transaction payloads, the `Transaction_payload_event` is first printed as a single unit, then it is unpacked and each event inside it is printed.

Some events relating to the setting of user and system variables are not included in the output from `SHOW BINLOG EVENTS`. To get complete coverage of events within a binary log, use `mysqlbinlog`.

`SHOW BINLOG EVENTS` does not work with relay log files. You can use `SHOW RELAYLOG EVENTS` for this purpose.

### 13.7.7.3 SHOW CHARACTER SET Statement

```
SHOW {CHARACTER SET | CHARSET}
[LIKE 'pattern' | WHERE expr]
```

The `SHOW CHARACTER SET` statement shows all available character sets. The `LIKE` clause, if present, indicates which character set names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in Section 26.8, “Extensions to SHOW Statements”. For example:

```
mysql> SHOW CHARACTER SET LIKE 'latin%';
```

<table>
<thead>
<tr>
<th>Charset</th>
<th>Description</th>
<th>Default collation</th>
<th>Maxlen</th>
</tr>
</thead>
<tbody>
<tr>
<td>latin1</td>
<td>cp1252 West European</td>
<td>latin1_swedish_ci</td>
<td>1</td>
</tr>
<tr>
<td>latin2</td>
<td>ISO 8859-2 Central European</td>
<td>latin2_general_ci</td>
<td>1</td>
</tr>
<tr>
<td>latin5</td>
<td>ISO 8859-9 Turkish</td>
<td>latin5_turkish_ci</td>
<td>1</td>
</tr>
<tr>
<td>latin7</td>
<td>ISO 8859-13 Baltic</td>
<td>latin7_general_ci</td>
<td>1</td>
</tr>
</tbody>
</table>

`SHOW CHARACTER SET` output has these columns:

• **Charset**
  The character set name.

• **Description**
SHOW Statements

A description of the character set.

• Default collation

The default collation for the character set.

• Maxlen

The maximum number of bytes required to store one character.

The filename character set is for internal use only; consequently, SHOW CHARACTER SET does not display it.

Character set information is also available from the INFORMATION_SCHEMA CHARACTER_SETS table.

13.7.7.4 SHOW COLLATION Statement

SHOW COLLATION

[LIKE 'pattern' | WHERE expr]

This statement lists collations supported by the server. By default, the output from SHOW COLLATION includes all available collations. The LIKE clause, if present, indicates which collation names to match. The WHERE clause can be given to select rows using more general conditions, as discussed in Section 26.8, "Extensions to SHOW Statements". For example:

mysql> SHOW COLLATION WHERE Charset = 'latin1';

+-------------------+---------+----+---------+----------+---------+
| Collation          | Charset | Id | Default | Compiled | Sortlen |
+-------------------+---------+----+---------+----------+---------+
| latin1_german1_ci | latin1  |  5 |         | Yes      |       1 |
| latin1_swedish_ci | latin1  |  8 | Yes     | Yes      |       1 |
| latin1_danish_ci  | latin1  | 15 |         | Yes      |       1 |
| latin1_german2_ci | latin1  | 31 |         | Yes      |       2 |
| latin1_bin        | latin1  | 47 |         | Yes      |       1 |
| latin1_general_ci | latin1  | 48 |         | Yes      |       1 |
| latin1_general_cs | latin1  | 49 |         | Yes      |       1 |
| latin1_spanish_ci | latin1  | 94 |         | Yes      |       1 |
+-------------------+---------+----+---------+----------+---------+

SHOW COLLATION output has these columns:

• Collation

The collation name.

• Charset

The name of the character set with which the collation is associated.

• Id

The collation ID.

• Default

Whether the collation is the default for its character set.

• Compiled

Whether the character set is compiled into the server.
• **Sortlen**

This is related to the amount of memory required to sort strings expressed in the character set.

To see the default collation for each character set, use the following statement. **Default** is a reserved word, so to use it as an identifier, it must be quoted as such:

```sql
mysql> SHOW COLLATION WHERE `Default` = 'Yes';
```

<table>
<thead>
<tr>
<th>Collation</th>
<th>Charset</th>
<th>Id</th>
<th>Default</th>
<th>Compiled</th>
<th>Sortlen</th>
</tr>
</thead>
<tbody>
<tr>
<td>big5_chinese_ci</td>
<td>big5</td>
<td>1</td>
<td>Yes</td>
<td>Yes</td>
<td>1</td>
</tr>
<tr>
<td>dec8_swedish_ci</td>
<td>dec8</td>
<td>3</td>
<td>Yes</td>
<td>Yes</td>
<td>1</td>
</tr>
<tr>
<td>cp850_general_ci</td>
<td>cp850</td>
<td>4</td>
<td>Yes</td>
<td>Yes</td>
<td>1</td>
</tr>
<tr>
<td>hp8_english_ci</td>
<td>hp8</td>
<td>6</td>
<td>Yes</td>
<td>Yes</td>
<td>1</td>
</tr>
<tr>
<td>koi8r_general_ci</td>
<td>koi8r</td>
<td>7</td>
<td>Yes</td>
<td>Yes</td>
<td>1</td>
</tr>
<tr>
<td>latin1_swedish_ci</td>
<td>latin1</td>
<td>8</td>
<td>Yes</td>
<td>Yes</td>
<td>1</td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Collation information is also available from the **INFORMATION_SCHEMA** COLLATIONS table. See Section 26.3.6, “The INFORMATION_SCHEMA COLLATIONS Table”.

### 13.7.7.5 **SHOW COLUMNS** Statement

**SHOW [EXTENDED] [FULL] [COLUMNS | FIELDS]
FROM | IN
tbl_name
| [FROM | IN] db_name
| [LIKE 'pattern' | WHERE expr]

**SHOW COLUMNS** displays information about the columns in a given table. It also works for views. **SHOW COLUMNS** displays information only for those columns for which you have some privilege.

```sql
mysql> SHOW COLUMNS FROM City;
```

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Null</th>
<th>Key</th>
<th>Default</th>
<th>Extra</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID</td>
<td>int(11)</td>
<td>NO</td>
<td>PRI</td>
<td>NULL</td>
<td>auto_increment</td>
</tr>
<tr>
<td>Name</td>
<td>char(35)</td>
<td>NO</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>CountryCode</td>
<td>char(3)</td>
<td>NO</td>
<td>MUL</td>
<td></td>
<td></td>
</tr>
<tr>
<td>District</td>
<td>char(20)</td>
<td>NO</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Population</td>
<td>int(11)</td>
<td>NO</td>
<td></td>
<td>0</td>
<td></td>
</tr>
</tbody>
</table>

An alternative to **tbl_name** FROM **db_name** syntax is **db_name.tbl_name**. These two statements are equivalent:

```sql
SHOW COLUMNS FROM mytable FROM mydb;
SHOW COLUMNS FROM mydb.mytable;
```

The optional **EXTENDED** keyword causes the output to include information about hidden columns that MySQL uses internally and are not accessible by users.

The optional **FULL** keyword causes the output to include the column collation and comments, as well as the privileges you have for each column.

The **LIKE** clause, if present, indicates which column names to match. The **WHERE** clause can be given to select rows using more general conditions, as discussed in Section 26.8, “Extensions to SHOW Statements”.

The data types may differ from what you expect them to be based on a **CREATE TABLE** statement because MySQL sometimes changes data types when you create or alter a table. The conditions under which this occurs are described in Section 13.1.20.7, “Silent Column Specification Changes”. 

3179
SHOW Statements

SHOW COLUMNS displays the following values for each table column:

• Field
  The name of the column.

• Type
  The column data type.

• Collation
  The collation for nonbinary string columns, or NULL for other columns. This value is displayed only if you use the FULL keyword.

• Null
  The column nullability. The value is YES if NULL values can be stored in the column, NO if not.

• Key
  Whether the column is indexed:
  • If Key is empty, the column either is not indexed or is indexed only as a secondary column in a multiple-column, nonunique index.
  • If Key is PRI, the column is a PRIMARY KEY or is one of the columns in a multiple-column PRIMARY KEY.
  • If Key is UNI, the column is the first column of a UNIQUE index. (A UNIQUE index permits multiple NULL values, but you can tell whether the column permits NULL by checking the Null field.)
  • If Key is MUL, the column is the first column of a nonunique index in which multiple occurrences of a given value are permitted within the column.

If more than one of the Key values applies to a given column of a table, Key displays the one with the highest priority, in the order PRI, UNI, MUL.

A UNIQUE index may be displayed as PRI if it cannot contain NULL values and there is no PRIMARY KEY in the table. A UNIQUE index may display as MUL if several columns form a composite UNIQUE index; although the combination of the columns is unique, each column can still hold multiple occurrences of a given value.

• Default
  The default value for the column. This is NULL if the column has an explicit default of NULL, or if the column definition includes no DEFAULT clause.

• Extra
  Any additional information that is available about a given column. The value is nonempty in these cases:
  • auto_increment for columns that have the AUTO_INCREMENT attribute.
  • on update CURRENT_TIMESTAMP for TIMESTAMP or DATETIME columns that have the ON UPDATE CURRENT_TIMESTAMP attribute.
  • VIRTUAL GENERATED or STORED GENERATED for generated columns.
SHOW Statements

• **DEFAULT_GENERATED** for columns that have an expression default value.

• **Privileges**

  The privileges you have for the column. This value is displayed only if you use the **FULL** keyword.

• **Comment**

  Any comment included in the column definition. This value is displayed only if you use the **FULL** keyword.

Table column information is also available from the **INFORMATION_SCHEMA COLUMNS** table. See Section 26.3.8, “The INFORMATION_SCHEMA COLUMNS Table”. The extended information about hidden columns is available only using **SHOW EXTENDED COLUMNS**; it cannot be obtained from the **COLUMNS** table.

You can list a table's columns with the **mysqlshow db_name tbl_name** command.

The **DESCRIBE** statement provides information similar to **SHOW COLUMNS**. See Section 13.8.1, “DESCRIBE Statement”.

The **SHOW CREATE TABLE**, **SHOW TABLE STATUS**, and **SHOW INDEX** statements also provide information about tables. See Section 13.7.7, “SHOW Statements”.

In MySQL 8.0.30 and later, **SHOW COLUMNS** includes the table's generated invisible primary key, if it has one, by default. You can cause this information to be suppressed in the statement's output by setting `show_gipk_in_create_table_and_information_schema = OFF`. For more information, see Section 13.1.20.11, “Generated Invisible Primary Keys”.

### 13.7.7.6 SHOW CREATE DATABASE Statement

```
SHOW CREATE {DATABASE | SCHEMA} [IF NOT EXISTS] db_name
```

Shows the **CREATE DATABASE** statement that creates the named database. If the **SHOW** statement includes an **IF NOT EXISTS** clause, the output too includes such a clause. **SHOW CREATE SCHEMA** is a synonym for **SHOW CREATE DATABASE**.

```
mysql> SHOW CREATE DATABASE test\G
*************************** 1. row ***************************
  Database: test
  Create Database: CREATE DATABASE `test` /*!40100 DEFAULT CHARACTER SET utf8mb4 COLLATE utf8mb4_0900_ai_ci */ /*!80014 DEFAULT ENCRYPTION='N' */

mysql> SHOW CREATE SCHEMA test\G
*************************** 1. row ***************************
  Database: test
  Create Database: CREATE DATABASE `test` /*!40100 DEFAULT CHARACTER SET utf8mb4 COLLATE utf8mb4_0900_ai_ci */ /*!80014 DEFAULT ENCRYPTION='N' */
```

**SHOW CREATE DATABASE** quotes table and column names according to the value of the **sql_quote_show_create** option. See Section 5.1.8, “Server System Variables”.

### 13.7.7.7 SHOW CREATE EVENT Statement

```
SHOW CREATE EVENT event_name
```

This statement displays the **CREATE EVENT** statement needed to re-create a given event. It requires the **EVENT** privilege for the database from which the event is to be shown. For example (using the same event **e_daily** defined and then altered in Section 13.7.7.18, “SHOW EVENTS Statement”):
SHOW Statements

mysql> SHOW CREATE EVENT myschema.e_daily\G
*************************** 1. row ***************************
   Event: e_daily
      sql_mode: ONLY_FULL_GROUP_BY, STRICT_TRANS_TABLES,
               NO_ZERO_IN_DATE, NO_ZERO_DATE,
               ERROR_FOR_DIVISION_BY_ZERO,
               NO_ENGINE_SUBSTITUTION
     time_zone: SYSTEM
Create Event: CREATE DEFINER=`jon`@`ghidora` EVENT `e_daily`
     ON SCHEDULE EVERY 1 DAY
              STARTS CURRENT_TIMESTAMP + INTERVAL 6 HOUR
          ON COMPLETION NOT PRESERVE
            ENABLE
           COMMENT 'Saves total number of sessions then
                     clears the table each day'
            DO BEGIN
                      INSERT INTO site_activity.totals (time, total)
                       SELECT CURRENT_TIMESTAMP, COUNT(*)
                                FROM site_activity.sessions;
                      DELETE FROM site_activity.sessions;
                   END
character_set_client: utf8mb4
   collation_connection: utf8mb4_0900_ai_ci
Database Collation: utf8mb4_0900_ai_ci

character_set_client is the session value of the character_set_client system variable when
the event was created. collation_connection is the session value of the collation_connection
system variable when the event was created. Database Collation is the collation of the database with
which the event is associated.

The output reflects the current status of the event (ENABLE) rather than the status with which it was
created.

13.7.7.8 SHOW CREATE FUNCTION Statement

SHOW CREATE FUNCTION func_name

This statement is similar to SHOW CREATE PROCEDURE but for stored functions. See Section 13.7.7.9,
"SHOW CREATE PROCEDURE Statement".

13.7.7.9 SHOW CREATE PROCEDURE Statement

SHOW CREATE PROCEDURE proc_name

This statement is a MySQL extension. It returns the exact string that can be used to re-create the named
stored procedure. A similar statement, SHOW CREATE FUNCTION, displays information about stored
functions (see Section 13.7.7.8, "SHOW CREATE FUNCTION Statement").

To use either statement, you must be the user named as the routine DEFINER, have the SHOW_ROUTINE
privilege, have the SELECT privilege at the global level, or have the CREATE_ROUTINE, ALTER_ROUTINE,
or EXECUTE privilege granted at a scope that includes the routine. The value displayed for the Create
Procedure or Create Function field is NULL if you have only CREATE ROUTINE, ALTER ROUTINE, or
EXECUTE.

mysql> SHOW CREATE PROCEDURE test.citycount\G
*************************** 1. row ***************************
 Procedure: citycount
      sql_mode: ONLY_FULL_GROUP_BY, STRICT_TRANS_TABLES,
               NO_ZERO_IN_DATE, NO_ZERO_DATE,
               ERROR_FOR_DIVISION_BY_ZERO,
               NO_ENGINE_SUBSTITUTION
CREATE DEFINER=`me`@`localhost`
PROCEDURE `citycount`(IN country CHAR(3), OUT cities INT)
BEGIN
SELECT COUNT(*) INTO cities FROM world.city
WHERE CountryCode = country;
END

character_set_client: utf8mb4
collation_connection: utf8mb4_0900_ai_ci
Database Collation: utf8mb4_0900_ai_ci

mysql> SHOW CREATE FUNCTION test.hello\G
*************************** 1. row ***************************
Function: hello
sql_mode: ONLY_FULL_GROUP_BY,STRICT_TRANS_TABLES,
NO_ZERO_IN_DATE,NO_ZERO_DATE,
ERROR_FOR_DIVISION_BY_ZERO,
NO_ENGINE_SUBSTITUTION
Create Function: CREATE DEFINER=`me`@`localhost`
FUNCTION `hello`(s CHAR(20))
RETURNS char(50) CHARSET utf8mb4
DETERMINISTIC
RETURN CONCAT('Hello, ',s,'!')
character_set_client: utf8mb4
collation_connection: utf8mb4_0900_ai_ci
Database Collation: utf8mb4_0900_ai_ci

character_set_client is the session value of the character_set_client system variable when
the routine was created. collation_connection is the session value of the collation_connection
system variable when the routine was created. Database Collation is the collation of the database
with which the routine is associated.

13.7.7.10 SHOW CREATE TABLE Statement

SHOW CREATE TABLE tbl_name

Shows the CREATE TABLE statement that creates the named table. To use this statement, you must have
some privilege for the table. This statement also works with views.

mysql> SHOW CREATE TABLE t\G
*************************** 1. row ***************************
Table: t
Create Table: CREATE TABLE `t` (  
`id` int NOT NULL AUTO_INCREMENT,  
`s` char(60) DEFAULT NULL,  
PRIMARY KEY (`id`) ) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_0900_ai_ci

As of MySQL 8.0.16, MySQL implements CHECK constraints and SHOW CREATE TABLE displays them.
All CHECK constraints are displayed as table constraints. That is, a CHECK constraint originally specified as
part of a column definition displays as a separate clause not part of the column definition. Example:

mysql> CREATE TABLE t1 (  
  i1 INT CHECK (i1 <> 0), -- column constraint  
  i2 INT,  
  CHECK (i2 > i1), -- table constraint  
  CHECK (i2 <> 0) NOT ENFORCED -- table constraint, not enforced  
);  

mysql> SHOW CREATE TABLE t1\G
*************************** 1. row ***************************
Table: t1
Create Table: CREATE TABLE `t1` (  
`i1` int DEFAULT NULL,
SHOW CREATE TABLE quotes table and column names according to the value of the `sql_quote_show_create` option. See Section 5.1.8, “Server System Variables”.

When altering the storage engine of a table, table options that are not applicable to the new storage engine are retained in the table definition to enable reverting the table with its previously defined options to the original storage engine, if necessary. For example, when changing the storage engine from InnoDB to MyISAM, options specific to InnoDB, such as ROW_FORMAT=COMPACT, are retained, as shown here:

```sql
mysql> CREATE TABLE t1 (c1 INT PRIMARY KEY) ROW_FORMAT=COMPACT ENGINE=InnoDB;
mysql> ALTER TABLE t1 ENGINE=MyISAM;
mysql> SHOW CREATE TABLE t1\G
```

When creating a table with strict mode disabled, the storage engine’s default row format is used if the specified row format is not supported. The actual row format of the table is reported in the Row_format column in response to SHOW TABLE STATUS. SHOW CREATE TABLE shows the row format that was specified in the CREATE TABLE statement.

In MySQL 8.0.30 and later, SHOW CREATE TABLE includes the definition of the table’s generated invisible primary key, if it has such a key, by default. You can cause this information to be suppressed in the statement's output by setting show_gipk_in_create_table_and_information_schema = OFF. For more information, see Section 13.1.20.11, “Generated Invisible Primary Keys”.

### 13.7.7.11 SHOW CREATE TRIGGER Statement

SHOW CREATE TRIGGER `trigger_name`

This statement shows the CREATE TRIGGER statement that creates the named trigger. This statement requires the TRIGGER privilege for the table associated with the trigger.

```sql
mysql> SHOW CREATE TRIGGER ins_sum\G
```

SHOW CREATE TRIGGER output has these columns:

- **Trigger**: The trigger name.
- **sql_mode**: The SQL mode in effect when the trigger executes.
SHOW Statements

• **SQL Original Statement**: The `CREATE TRIGGER` statement that defines the trigger.

• **character_set_client**: The session value of the `character_set_client` system variable when the trigger was created.

• **collation_connection**: The session value of the `collation_connection` system variable when the trigger was created.

• **Database Collation**: The collation of the database with which the trigger is associated.

• **Created**: The date and time when the trigger was created. This is a `TIMESTAMP(2)` value (with a fractional part in hundredths of seconds) for triggers.

Trigger information is also available from the `INFORMATION_SCHEMA TRIGGERS` table. See Section 26.3.45, “The INFORMATION_SCHEMA TRIGGERS Table”.

### 13.7.7.12 SHOW CREATE USER Statement

#### Synopsis

```
SHOW CREATE USER user
```

#### Description

This statement shows the `CREATE USER` statement that creates the named user. An error occurs if the user does not exist. The statement requires the `SELECT` privilege for the `mysql` system schema, except to see information for the current user. For the current user, the `SELECT` privilege for the `mysql.user` system table is required for display of the password hash in the `IDENTIFIED AS` clause; otherwise, the hash displays as `<secret>`.

To name the account, use the format described in Section 6.2.4, “Specifying Account Names”. The host name part of the account name, if omitted, defaults to `'%'`. It is also possible to specify `CURRENT_USER` or `CURRENT_USER()` to refer to the account associated with the current session.

Password hash values displayed in the `IDENTIFIED WITH` clause of output from `SHOW CREATE USER` may contain unprintable characters that have adverse effects on terminal displays and in other environments. Enabling the `print_identified_with_as_hex` system variable (available as of MySQL 8.0.17) causes `SHOW CREATE USER` to display such hash values as hexadecimal strings rather than as regular string literals. Hash values that do not contain unprintable characters still display as regular string literals, even with this variable enabled.

```
mysql> CREATE USER 'u1'@'localhost' IDENTIFIED BY 'secret';
mysql> SET print_identified_with_as_hex = ON;
mysql> SHOW CREATE USER 'u1'@'localhost'
```

```
*************************** 1. row ***************************
CREATE USER for u1@localhost: CREATE USER `u1`@`localhost`
IDENTIFIED WITH 'caching_sha2_password'
AS 0x244124303035240C7745603626313D613C4C10633E0A104B1E14135A544A7871567245614F4872344643546336546F624F6C7861326932752F45622F4F473273597557627139
REQUIRE NONE PASSWORD EXPIRE DEFAULT ACCOUNT UNLOCK
PASSWORD HISTORY DEFAULT PASSWORD REUSE INTERVAL DEFAULT
PASSWORD REQUIRE CURRENT DEFAULT
```

To display the privileges granted to an account, use the `SHOW GRANTS` statement. See Section 13.7.7.21, “SHOW GRANTS Statement”.

### 13.7.7.13 SHOW CREATE VIEW Statement

#### Synopsis

```
SHOW CREATE VIEW view_name
```

#### Description

This statement shows the `CREATE VIEW` statement that creates the named view.

```
mysql> SHOW CREATE VIEW v
```

3185
SHOW Statements

SHOW Statements

*************************** 1. row ***************************
View: v
Create View: CREATE VIEW `v` AS select 1 AS `a`,2 AS `b`
collation_connection: utf8mb4

character_set_client is the session value of the character_set_client system variable when the view was created. collation_connection is the session value of the collation_connection system variable when the view was created.

Use of SHOW CREATE VIEW requires the SHOW VIEW privilege, and the SELECT privilege for the view in question.

View information is also available from the INFORMATION_SCHEMA VIEWS table. See Section 26.3.48, “The INFORMATION_SCHEMA VIEWS Table”.

MySQL lets you use different sql_mode settings to tell the server the type of SQL syntax to support. For example, you might use the ANSI SQL mode to ensure MySQL correctly interprets the standard SQL concatenation operator, the double bar (||), in your queries. If you then create a view that concatenates items, you might worry that changing the sql_mode setting to a value different from ANSI could cause the view to become invalid. But this is not the case. No matter how you write out a view definition, MySQL always stores it the same way, in a canonical form. Here is an example that shows how the server changes a double bar concatenation operator to a CONCAT() function:

```
mysql> SET sql_mode = 'ANSI';
Query OK, 0 rows affected (0.00 sec)
mysql> CREATE VIEW test.v AS SELECT 'a' || 'b' as col1;
Query OK, 0 rows affected (0.01 sec)
mysql> SHOW CREATE VIEW test.v\G
*************************** 1. row ***************************
View: v
Create View: CREATE VIEW "v" AS select concat('a','b') AS "col1"

mysql> SHOW CREATE VIEW test.v\G
*************************** 1. row ***************************
View: v
Create View: CREATE VIEW "v" AS select concat('a','b') AS "col1"
```

The advantage of storing a view definition in canonical form is that changes made later to the value of sql_mode do not affect the results from the view. However an additional consequence is that comments prior to SELECT are stripped from the definition by the server.

13.7.7.14 SHOW DATABASES Statement

SHOW {DATABASES | SCHEMAS} [LIKE 'pattern' | WHERE expr]

SHOW DATABASES lists the databases on the MySQL server host. SHOW SCHEMAS is a synonym for SHOW DATABASES. The LIKE clause, if present, indicates which database names to match. The WHERE clause can be given to select rows using more general conditions, as discussed in Section 26.8, “Extensions to SHOW Statements”.

You see only those databases for which you have some kind of privilege, unless you have the global SHOW DATABASES privilege. You can also get this list using the mysqlshow command.

If the server was started with the --skip-show-database option, you cannot use this statement at all unless you have the SHOW DATABASES privilege.
SHOW Statements

MySQL implements databases as directories in the data directory, so this statement simply lists directories in that location. However, the output may include names of directories that do not correspond to actual databases.

Database information is also available from the INFORMATION_SCHEMA SCHEMATA table. See Section 26.3.31, "The INFORMATION_SCHEMA SCHEMATA Table".

Caution
Because any static global privilege is considered a privilege for all databases, any static global privilege enables a user to see all database names with SHOW DATABASES or by examining the SCHEMATA table of INFORMATION_SCHEMA, except databases that have been restricted at the database level by partial revokes.

13.7.7.15 SHOW ENGINE Statement

SHOW ENGINE engine_name {STATUS | MUTEX};

SHOW ENGINE displays operational information about a storage engine. It requires the PROCESS privilege. The statement has these variants:

- SHOW ENGINE INNODB STATUS
- SHOW ENGINE INNODB MUTEX
- SHOW ENGINE PERFORMANCE_SCHEMA STATUS

SHOW ENGINE INNODB STATUS displays extensive information from the standard InnoDB Monitor about the state of the InnoDB storage engine. For information about the standard monitor and other InnoDB Monitors that provide information about InnoDB processing, see Section 15.17, “InnoDB Monitors”.

SHOW ENGINE INNODB MUTEX displays InnoDB mutex and rw-lock statistics.

Note
InnoDB mutexes and rwlocks can also be monitored using Performance Schema tables. See Section 15.16.2, “Monitoring InnoDB Mutex Waits Using Performance Schema”.

Mutex statistics collection is configured dynamically using the following options:

- To enable the collection of mutex statistics, run:
  
  SET GLOBAL innodb_monitor_enable='latch';

- To reset mutex statistics, run:
  
  SET GLOBAL innodb_monitor_reset='latch';

- To disable the collection of mutex statistics, run:
  
  SET GLOBAL innodb_monitor_disable='latch';

Collection of mutex statistics for SHOW ENGINE INNODB MUTEX can also be enabled by setting innodb_monitor_enable='all', or disabled by setting innodb_monitor_disable='all'.

SHOW ENGINE INNODB MUTEX output has these columns:

- Type
  
  Always InnoDB.
SHOW Statements

- **Name**
  
  For mutexes, the *Name* field reports only the mutex name. For rw-locks, the *Name* field reports the source file where the rwlock is implemented, and the line number in the file where the rwlock is created. The line number is specific to your version of MySQL.

- **Status**
  
  The mutex status. This field reports the number of spins, waits, and calls. Statistics for low-level operating system mutexes, which are implemented outside of *InnoDB*, are not reported.

  - *spins* indicates the number of spins.
  
  - *waits* indicates the number of mutex waits.
  
  - *calls* indicates how many times the mutex was requested.

  *SHOW ENGINE INNODB_MUTEX* does not list mutexes and rw-locks for each buffer pool block, as the amount of output would be overwhelming on systems with a large buffer pool. *SHOW ENGINE INNODB_MUTEX* does, however, print aggregate *BUF_BLOCK_MUTEX* spin, wait, and call values for buffer pool block mutexes and rw-locks. *SHOW ENGINE INNODB_MUTEX* also does not list any mutexes or rw-locks that have never been waited on (*os_waits=0*). Thus, *SHOW ENGINE INNODB_MUTEX* only displays information about mutexes and rw-locks outside of the buffer pool that have caused at least one OS-level wait.

  Use *SHOW ENGINE PERFORMANCE_SCHEMA STATUS* to inspect the internal operation of the Performance Schema code:

```sql
mysql> SHOW ENGINE PERFORMANCE_SCHEMA STATUS\G
...  
*************************** 3. row ***************************
| Type: performance_schema |
| Name: events_waits_history.size |
| Status: 76 |

*************************** 4. row ***************************
| Type: performance_schema |
| Name: events_waits_history.count |
| Status: 10000 |

*************************** 5. row ***************************
| Type: performance_schema |
| Name: events_waits_history.memory |
| Status: 760000 |

...  
*************************** 57. row ***************************
| Type: performance_schema |
| Name: performance_schema.memory |
| Status: 26459600 |

...  
```

This statement is intended to help the DBA understand the effects that different Performance Schema options have on memory requirements.

*Name* values consist of two parts, which name an internal buffer and a buffer attribute, respectively. Interpret buffer names as follows:

- An internal buffer that is not exposed as a table is named within parentheses. Examples: *(pfs_cond_class).size*, *(pfs_mutex_class).memory*.

- An internal buffer that is exposed as a table in the *performance_schema* database is named after the table, without parentheses. Examples: *events_waits_history.size*, *mutex_instances.count*. 

3188
SHOW Statements

Buffer attributes have these meanings:

- `size` is the size of the internal record used by the implementation, such as the size of a row in a table. `size` values cannot be changed.

- `count` is the number of internal records, such as the number of rows in a table. `count` values can be changed using Performance Schema configuration options.

- For a table, `tbl_name.memory` is the product of `size` and `count`. For the Performance Schema as a whole, `performance_schema.memory` is the sum of all the memory used (the sum of all other `memory` values).

In some cases, there is a direct relationship between a Performance Schema configuration parameter and a `SHOW ENGINE` value. For example, `events_waits_history_long.count` corresponds to `performance_schema_events_waits_history_long_size`. In other cases, the relationship is more complex. For example, `events_waits_history.count` corresponds to `performance_schema_events_waits_history_size` (the number of rows per thread) multiplied by `performance_schema_max_thread_instances` (the number of threads).

**SHOW ENGINE NDB STATUS.** If the server has the NDB storage engine enabled, `SHOW ENGINE NDB STATUS` displays cluster status information such as the number of connected data nodes, the cluster connectstring, and cluster binary log epochs, as well as counts of various Cluster API objects created by the MySQL Server when connected to the cluster. Sample output from this statement is shown here:

```
mysql> SHOW ENGINE NDB STATUS;
+------------+-----------------------+--------------------------------------------------+
| Type       | Name                  | Status                                           |
|------------|-----------------------+--------------------------------------------------|
| ndbcluster | connection            | cluster_node_id=7,                                 |
|            |                       | connected_host=198.51.100.103, connected_port=1186, number_of_data_nodes=4, |
|            |                       | number_of_ready_data_nodes=3, connect_count=0     |
| ndbcluster | NdbTransaction        | created=6, free=0, sizeof=212                     |
| ndbcluster | NdbOperation          | created=8, free=8, sizeof=660                     |
| ndbcluster | NdbIndexScanOperation | created=1, free=1, sizeof=744                     |
| ndbcluster | NdbIndexOperation     | created=0, free=0, sizeof=664                     |
| ndbcluster | NdbRecAttr            | created=1285, free=1285, sizeof=60               |
| ndbcluster | NdbApiSignal          | created=16, free=16, sizeof=136                   |
| ndbcluster | NdbBranch             | created=0, free=0, sizeof=24                      |
| ndbcluster | NdbSubroutine         | created=0, free=0, sizeof=68                      |
| ndbcluster | NdbCall               | created=0, free=0, sizeof=16                      |
| ndbcluster | NdbBlob               | created=1, free=1, sizeof=264                     |
| ndbcluster | NdbReceiver           | created=4, free=0, sizeof=68                      |
| ndbcluster | binlog                | latest_epoch=155467, latest_trans_epoch=148126, |
|            |                       | latest_received_binlog_epoch=0,                   |
|            |                       | latest_handled_binlog_epoch=0,                   |
|            |                       | latest_applied_binlog_epoch=0                    |
+------------+-----------------------+--------------------------------------------------+
```

The `Status` column in each of these rows provides information about the MySQL server’s connection to the cluster and about the cluster binary log’s status, respectively. The `Status` information is in the form of comma-delimited set of name/value pairs.

The `connection` row’s `Status` column contains the name/value pairs described in the following table.

<table>
<thead>
<tr>
<th>Name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>cluster_node_id</td>
<td>The node ID of the MySQL server in the cluster</td>
</tr>
</tbody>
</table>
The **binlog** row’s **Status** column contains information relating to NDB Cluster Replication. The name/value pairs it contains are described in the following table.

<table>
<thead>
<tr>
<th>Name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>latest_epoch</strong></td>
<td>The most recent epoch most recently run on this MySQL server (that is, the sequence number of the most recent transaction run on the server)</td>
</tr>
<tr>
<td><strong>latest_trans_epoch</strong></td>
<td>The most recent epoch processed by the cluster’s data nodes</td>
</tr>
<tr>
<td><strong>latest_received_binlog_epoch</strong></td>
<td>The most recent epoch received by the binary log thread</td>
</tr>
<tr>
<td><strong>latest_handled_binlog_epoch</strong></td>
<td>The most recent epoch processed by the binary log thread (for writing to the binary log)</td>
</tr>
<tr>
<td><strong>latest_applied_binlog_epoch</strong></td>
<td>The most recent epoch actually written to the binary log</td>
</tr>
</tbody>
</table>

See Section 23.7, “NDB Cluster Replication”, for more information.

The remaining rows from the output of **SHOW ENGINE NDB STATUS** which are most likely to prove useful in monitoring the cluster are listed here by **Name**:

- **NdbTransaction**: The number and size of **NdbTransaction** objects that have been created. An **NdbTransaction** is created each time a table schema operation (such as **CREATE TABLE** or **ALTER TABLE**) is performed on an **NDB** table.

- **NdbOperation**: The number and size of **NdbOperation** objects that have been created.

- **NdbIndexScanOperation**: The number and size of **NdbIndexScanOperation** objects that have been created.

- **NdbIndexOperation**: The number and size of **NdbIndexOperation** objects that have been created.

- **NdbRecAttr**: The number and size of **NdbRecAttr** objects that have been created. In general, one of these is created each time a data manipulation statement is performed by an SQL node.

- **NdbBlob**: The number and size of **NdbBlob** objects that have been created. An **NdbBlob** is created for each new operation involving a **BLOB** column in an **NDB** table.
• **NdbReceiver**: The number and size of any NdbReceiver object that have been created. The number in the created column is the same as the number of data nodes in the cluster to which the MySQL server has connected.

**Note**

SHOW ENGINE NDB STATUS returns an empty result if no operations involving NDB tables have been performed during the current session by the MySQL client accessing the SQL node on which this statement is run.

### 13.7.7.16 SHOW ENGINES Statement

**SHOW [STORAGE] ENGINES**

SHOW ENGINES displays status information about the server's storage engines. This is particularly useful for checking whether a storage engine is supported, or to see what the default engine is.

For information about MySQL storage engines, see Chapter 15, *The InnoDB Storage Engine*, and Chapter 16, *Alternative Storage Engines*.

```
mysql> SHOW ENGINES\G
*************************** 1. row ***************************
    Engine: ARCHIVE
      Support: YES
    Comment: Archive storage engine
Transactions: NO
     XA: NO
Savepoints: NO
*************************** 2. row ***************************
    Engine: BLACKHOLE
      Support: YES
    Comment: /dev/null storage engine (anything you write to it disappears)
Transactions: NO
     XA: NO
Savepoints: NO
*************************** 3. row ***************************
    Engine: MRG_MYISAM
      Support: YES
    Comment: Collection of identical MyISAM tables
Transactions: NO
     XA: NO
Savepoints: NO
*************************** 4. row ***************************
    Engine: FEDERATED
      Support: NO
    Comment: Federated MySQL storage engine
Transactions: NULL
     XA: NULL
Savepoints: NULL
*************************** 5. row ***************************
    Engine: MyISAM
      Support: YES
    Comment: MyISAM storage engine
Transactions: NO
     XA: NO
Savepoints: NO
*************************** 6. row ***************************
    Engine: PERFORMANCE_SCHEMA
      Support: YES
    Comment: Performance Schema
Transactions: NO
     XA: NO
Savepoints: NO
*************************** 7. row ***************************
```
The output from `SHOW ENGINES` may vary according to the MySQL version used and other factors.

`SHOW ENGINES` output has these columns:

- **Engine**
  The name of the storage engine.

- **Support**
  The server's level of support for the storage engine, as shown in the following table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>YES</td>
<td>The engine is supported and is active</td>
</tr>
<tr>
<td>DEFAULT</td>
<td>Like YES, plus this is the default engine</td>
</tr>
<tr>
<td>NO</td>
<td>The engine is not supported</td>
</tr>
<tr>
<td>DISABLED</td>
<td>The engine is supported but has been disabled</td>
</tr>
</tbody>
</table>

A value of **NO** means that the server was compiled without support for the engine, so it cannot be enabled at runtime.

A value of **DISABLED** occurs either because the server was started with an option that disables the engine, or because not all options required to enable it were given. In the latter case, the error log should contain a reason indicating why the option is disabled. See Section 5.4.2, “The Error Log”.

You might also see **DISABLED** for a storage engine if the server was compiled to support it, but was started with a `--skip-engine_name` option. For the NDB storage engine, **DISABLED** means the server was compiled with support for NDB Cluster, but was not started with the `--ndbcluster` option.

All MySQL servers support **MyISAM** tables. It is not possible to disable **MyISAM**.

- **Comment**
  A brief description of the storage engine.

- **Transactions**
  Whether the storage engine supports transactions.
SHOW Statements

- **XA**
  Whether the storage engine supports XA transactions.

- **Savepoints**
  Whether the storage engine supports savepoints.

Storage engine information is also available from the INFORMATION_SCHEMA_ENGINES table. See Section 26.3.13, “The INFORMATION_SCHEMA_ENGINES Table”.

### 13.7.7.17 SHOW ERRORS Statement

SHOW ERRORS [LIMIT [offset,] row_count]
SHOW COUNT(*) ERRORS

SHOW ERRORS is a diagnostic statement that is similar to SHOW WARNINGS, except that it displays information only for errors, rather than for errors, warnings, and notes.

The LIMIT clause has the same syntax as for the SELECT statement. See Section 13.2.13, “SELECT Statement”.

The SHOW COUNT(*) ERRORS statement displays the number of errors. You can also retrieve this number from the error_count variable:

SHOW COUNT(*) ERRORS;
SELECT @@error_count;

SHOW ERRORS and error_count apply only to errors, not warnings or notes. In other respects, they are similar to SHOW WARNINGS and warning_count. In particular, SHOW ERRORS cannot display information for more than max_error_count messages, and error_count can exceed the value of max_error_count if the number of errors exceeds max_error_count.

For more information, see Section 13.7.7.42, “SHOW WARNINGS Statement”.

### 13.7.7.18 SHOW EVENTS Statement

SHOW EVENTS
[[FROM | IN] schema_name]
LIKE 'pattern' | WHERE expr

This statement displays information about Event Manager events, which are discussed in Section 25.4, “Using the Event Scheduler”. It requires the EVENT privilege for the database from which the events are to be shown.

In its simplest form, SHOW EVENTS lists all of the events in the current schema:

mysql> SELECT CURRENT_USER(), SCHEMA();
+----------------+----------+
| CURRENT_USER() | SCHEMA() |
|----------------+----------|
| jon@ghidora    | myschema |
+----------------+----------+
1 row in set (0.00 sec)

mysql> SHOW EVENTS\G
*************************** 1. row ***************************
Db: myschema
Name: e_daily
Definer: jon@ghidora
Time zone: SYSTEM
To see events for a specific schema, use the `FROM` clause. For example, to see events for the `test` schema, use the following statement:

```
SHOW EVENTS FROM test;
```

The `LIKE` clause, if present, indicates which event names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in Section 26.8, “Extensions to SHOW Statements”.

`SHOW EVENTS` output has these columns:

- **Db**
  The name of the schema (database) to which the event belongs.

- **Name**
  The name of the event.

- **Definer**
  The account of the user who created the event, in `${user_name}@${host_name}` format.

- **Time zone**
  The event time zone, which is the time zone used for scheduling the event and that is in effect within the event as it executes. The default value is `SYSTEM`.

- **Type**
  The event repetition type, either `ONE TIME` (transient) or `RECURRING` (repeating).

- **Execute At**
  For a one-time event, this is the `DATETIME` value specified in the `AT` clause of the `CREATE EVENT` statement used to create the event, or of the last `ALTER EVENT` statement that modified the event. The value shown in this column reflects the addition or subtraction of any `INTERVAL` value included in the event's `AT` clause. For example, if an event is created using `ON SCHEDULE AT CURRENT_TIMESTAMP + '1:6' DAY_HOUR`, and the event was created at 2018-02-09 14:05:30, the value shown in this column would be `2018-02-10 20:05:30`. If the event's timing is determined by an `EVERY` clause instead of an `AT` clause (that is, if the event is recurring), the value of this column is `NULL`.

- **Interval Value**
  For a recurring event, the number of intervals to wait between event executions. For a transient event, the value of this column is always `NULL`.

- **Interval Field**
The time units used for the interval which a recurring event waits before repeating. For a transient event, the value of this column is always NULL.

- **Starts**

  The start date and time for a recurring event. This is displayed as a DATETIME value, and is NULL if no start date and time are defined for the event. For a transient event, this column is always NULL. For a recurring event whose definition includes a STARTS clause, this column contains the corresponding DATETIME value. As with the Execute At column, this value resolves any expressions used. If there is no STARTS clause affecting the timing of the event, this column is NULL.

- **Ends**

  For a recurring event whose definition includes a ENDS clause, this column contains the corresponding DATETIME value. As with the Execute At column, this value resolves any expressions used. If there is no ENDS clause affecting the timing of the event, this column is NULL.

- **Status**

  The event status. One of ENABLED, DISABLED, or SLAVESIDE_DISABLED. SLAVESIDE_DISABLED indicates that the creation of the event occurred on another MySQL server acting as a replication source and replicated to the current MySQL server which is acting as a replica, but the event is not presently being executed on the replica. For more information, see Section 17.5.1.16, “Replication of Invoked Features”. Information.

- **Originator**

  The server ID of the MySQL server on which the event was created; used in replication. This value may be updated by ALTER EVENT to the server ID of the server on which that statement occurs, if executed on a source server. The default value is 0.

- **character_set_client**

  The session value of the character_set_client system variable when the event was created.

- **collation_connection**

  The session value of the collation_connection system variable when the event was created.

- **Database Collation**

  The collation of the database with which the event is associated.

  For more information about SLAVESIDE_DISABLED and the Originator column, see Section 17.5.1.16, “Replication of Invoked Features”.

  Times displayed by SHOW EVENTS are given in the event time zone, as discussed in Section 25.4.4, “Event Metadata”.

  Event information is also available from the INFORMATION_SCHEMA EVENTS table. See Section 26.3.14, “The INFORMATION_SCHEMA EVENTS Table”.

  The event action statement is not shown in the output of SHOW EVENTS. Use SHOW CREATE EVENT or the INFORMATION_SCHEMA EVENTS table.

**13.7.7.19 SHOW FUNCTION CODE Statement**
SHOW FUNCTION CODE `func_name`

This statement is similar to `SHOW PROCEDURE CODE` but for stored functions. See Section 13.7.7.27, “SHOW PROCEDURE CODE Statement”.

### 13.7.7.20 SHOW FUNCTION STATUS Statement

```sql
SHOW FUNCTION STATUS
    [LIKE 'pattern' | WHERE expr]
```

This statement is similar to `SHOW PROCEDURE STATUS` but for stored functions. See Section 13.7.7.28, “SHOW PROCEDURE STATUS Statement”.

### 13.7.7.21 SHOW GRANTS Statement

```sql
SHOW GRANTS
    [FOR user_or_role
    [USING role [, role] ...]]
```

user_or_role: { user (see Section 6.2.4, “Specifying Account Names”) | role (see Section 6.2.5, “Specifying Role Names”). }

This statement displays the privileges and roles that are assigned to a MySQL user account or role, in the form of `GRANT` statements that must be executed to duplicate the privilege and role assignments.

---

**Note**

To display nonprivilege information for MySQL accounts, use the `SHOW CREATE USER` statement. See Section 13.7.7.12, “SHOW CREATE USER Statement”.

`SHOW GRANTS` requires the `SELECT` privilege for the `mysql` system schema, except to display privileges and roles for the current user.

To name the account or role for `SHOW GRANTS`, use the same format as for the `GRANT` statement (for example, `'jeffrey'@'localhost'`):

```sql
mysql> SHOW GRANTS FOR 'jeffrey'@'localhost';
```

The host part, if omitted, defaults to `'%'`. For additional information about specifying account and role names, see Section 6.2.4, “Specifying Account Names”, and Section 6.2.5, “Specifying Role Names”.

To display the privileges granted to the current user (the account you are using to connect to the server), you can use any of the following statements:

```sql
SHOW GRANTS;
SHOW GRANTS FOR CURRENT_USER;
SHOW GRANTS FOR CURRENT_USER();
```

If `SHOW GRANTS FOR CURRENT_USER` (or any equivalent syntax) is used in definer context, such as within a stored procedure that executes with definer rather than invoker privileges, the grants displayed are those of the definer and not the invoker.
In MySQL 8.0 compared to previous series, `SHOW GRANTS` no longer displays `ALL PRIVILEGES` in its global-privileges output because the meaning of `ALL PRIVILEGES` at the global level varies depending on which dynamic privileges are defined. Instead, `SHOW GRANTS` explicitly lists each granted global privilege:

```sql
mysql> SHOW GRANTS FOR 'root'@'localhost';
+---------------------------------------------------------------------+
| Grants for root@localhost                                           |
| GRANT SELECT, INSERT, UPDATE, DELETE, CREATE, DROP, RELOAD,         |
| SHUTDOWN, PROCESS, FILE, REFERENCES, INDEX, ALTER, SHOW DATABASES, |
| SUPER, CREATE TEMPORARY TABLES, LOCK TABLES, EXECUTE, REPLICATION   |
| SLAVE, REPLICATION CLIENT, CREATE VIEW, CREATE ROUTINE,             |
| ALTER ROUTINE, CREATE USER, EVENT, TRIGGER, CREATE TABLESPACE,      |
| CREATE ROLE, DROP ROLE ON *.* TO `root`@`localhost` WITH GRANT      |
| OPTION                                                              |
| GRANT PROXY ON ''@'' TO `root`@`localhost` WITH GRANT OPTION        |
+---------------------------------------------------------------------+
```

Applications that process `SHOW GRANTS` output should be adjusted accordingly.

At the global level, `GRANT OPTION` applies to all granted static global privileges if granted for any of them, but applies individually to granted dynamic privileges. `SHOW GRANTS` displays global privileges this way:

- One line listing all granted static privileges, if there are any, including `WITH GRANT OPTION` if appropriate.
- One line listing all granted dynamic privileges for which `GRANT OPTION` is granted, if there are any, including `WITH GRANT OPTION`.
- One line listing all granted dynamic privileges for which `GRANT OPTION` is not granted, if there are any, without `WITH GRANT OPTION`.

With the optional `USING` clause, `SHOW GRANTS` enables you to examine the privileges associated with roles for the user. Each role named in the `USING` clause must be granted to the user.

Suppose that user `u1` is assigned roles `r1` and `r2`, as follows:

```sql
CREATE ROLE 'r1', 'r2';
GRANT SELECT ON db1.* TO 'r1';
GRANT INSERT, UPDATE, DELETE ON db1.* TO 'r2';
CREATE USER 'u1'@'localhost' IDENTIFIED BY 'u1pass';
GRANT 'r1', 'r2' TO 'u1'@'localhost';
```

`SHOW GRANTS` without `USING` shows the granted roles:

```sql
mysql> SHOW GRANTS FOR 'u1'@'localhost';
+---------------------------------------------+
| Grants for u1@localhost                     |
| GRANT USAGE ON *.* TO `u1`@`localhost`      |
| GRANT `r1`@`%`,`r2`@`%` TO `u1`@`localhost` |
+---------------------------------------------+
```

Adding a `USING` clause causes the statement to also display the privileges associated with each role named in the clause:

```sql
mysql> SHOW GRANTS FOR 'u1'@'localhost' USING 'r1';
+---------------------------------------------+
| Grants for u1@localhost                     |
| GRANT USAGE ON *.* TO `u1`@`localhost`      |
| GRANT `r1`@`%`,`r2`@`%` TO `u1`@`localhost` |
+---------------------------------------------+
```

3197
SHOW Statements

<table>
<thead>
<tr>
<th>GRANT <code>r1</code>@<code>%</code>,'r2<code>@</code>%<code>TO</code>u1<code>@</code>localhost`</th>
</tr>
</thead>
<tbody>
<tr>
<td>mysql&gt; SHOW GRANTS FOR 'u1'@'localhost' USING 'r2';</td>
</tr>
<tr>
<td>Grants for u1@localhost</td>
</tr>
<tr>
<td>GRANT USAGE ON <code>*</code>.* TO <code>u1</code>@<code>localhost</code></td>
</tr>
<tr>
<td>GRANT INSERT, UPDATE, DELETE ON <code>db1</code>.* TO <code>u1</code>@<code>localhost</code></td>
</tr>
<tr>
<td>GRANT <code>r1</code>@<code>%</code>,'r2<code>@</code>%<code>TO</code>u1<code>@</code>localhost`</td>
</tr>
<tr>
<td>mysql&gt; SHOW GRANTS FOR 'u1'@'localhost' USING 'r1', 'r2';</td>
</tr>
<tr>
<td>Grants for u1@localhost</td>
</tr>
<tr>
<td>GRANT USAGE ON <code>*</code>.* TO <code>u1</code>@<code>localhost</code></td>
</tr>
<tr>
<td>GRANT SELECT, INSERT, UPDATE, DELETE ON <code>db1</code>.* TO <code>u1</code>@<code>localhost</code></td>
</tr>
<tr>
<td>GRANT <code>r1</code>@<code>%</code>,'r2<code>@</code>%<code>TO</code>u1<code>@</code>localhost`</td>
</tr>
</tbody>
</table>

**Note**

A privilege granted to an account is always in effect, but a role is not. The active roles for an account can differ across and within sessions, depending on the value of the `activate_all_roles_on_login` system variable, the account default roles, and whether `SET ROLE` has been executed within a session.

MySQL 8.0.16 and higher supports partial revokes of global privileges, such that a global privilege can be restricted from applying to particular schemas (see Section 6.2.12, "Privilege Restriction Using Partial Revokes"). To indicate which global schema privileges have been revoked for particular schemas, `SHOW GRANTS` output includes `REVOKE` statements:

```
mysql> SET PERSIST partial_revokes = ON;
mysql> CREATE USER u1;
mysql> GRANT SELECT, INSERT, DELETE ON `*`.* TO u1;
mysql> REVOKE SELECT, INSERT ON `mysql`.* FROM u1;
mysql> REVOKE DELETE ON `world`.* FROM u1;
mysql> SHOW GRANTS FOR u1;
```

```
<table>
<thead>
<tr>
<th>Grants for u1@%</th>
</tr>
</thead>
<tbody>
<tr>
<td>GRANT SELECT, INSERT, DELETE ON <code>*</code>.* TO <code>u1</code>@<code>%</code></td>
</tr>
<tr>
<td>REVOKE SELECT, INSERT ON <code>mysql</code>.* FROM <code>u1</code>@<code>%</code></td>
</tr>
<tr>
<td>REVOKE DELETE ON <code>world</code>.* FROM <code>u1</code>@<code>%</code></td>
</tr>
</tbody>
</table>
```

`SHOW GRANTS` does not display privileges that are available to the named account but are granted to a different account. For example, if an anonymous account exists, the named account might be able to use its privileges, but `SHOW GRANTS` does not display them.

`SHOW GRANTS` displays mandatory roles named in the `mandatory_roles` system variable value as follows:

- **SHOW GRANTS** without a `FOR` clause displays privileges for the current user, and includes mandatory roles.
- **SHOW GRANTS FOR user** displays privileges for the named user, and does not include mandatory roles.

This behavior is for the benefit of applications that use the output of `SHOW GRANTS FOR user` to determine which privileges are granted explicitly to the named user. Were that output to include mandatory roles, it would be difficult to distinguish roles granted explicitly to the user from mandatory roles.
For the current user, applications can determine privileges with or without mandatory roles by using `SHOW GRANTS` or `SHOW GRANTS FOR CURRENT_USER`, respectively.

### 13.7.7.22 SHOW INDEX Statement

```
SHOW [EXTENDED] {INDEX | INDEXES | KEYS}
{FROM | IN} tbl_name
{{FROM | IN} db_name}
WHERE expr
```

`SHOW INDEX` returns table index information. The format resembles that of the `SQLStatistics` call in ODBC. This statement requires some privilege for any column in the table.

```
mysql> SHOW INDEX FROM City
*************************** 1. row ***************************
    Table: city
 Non_unique: 0
 Key_name: PRIMARY
 Seq_in_index: 1
 Column_name: ID
  Collation: A
Cardinality: 4188
 Sub_part: NULL
 Packed: NULL
 Null: NULL
 Index_type: BTREE
 Comment:
Index_comment: Visible: YES
Expression: NULL
*************************** 2. row ***************************
    Table: city
 Non_unique: 1
 Key_name: CountryCode
 Seq_in_index: 1
 Column_name: CountryCode
  Collation: A
Cardinality: 232
 Sub_part: NULL
 Packed: NULL
 Null: NULL
 Index_type: BTREE
 Comment:
Index_comment: Visible: YES
Expression: NULL
```

An alternative to `tbl_name FROM db_name` syntax is `db_name.tbl_name`. These two statements are equivalent:

```
SHOW INDEX FROM mytable FROM mydb;
SHOW INDEX FROM mydb.mytable;
```

The optional `EXTENDED` keyword causes the output to include information about hidden indexes that MySQL uses internally and are not accessible by users.

The `WHERE` clause can be given to select rows using more general conditions, as discussed in Section 26.8, “Extensions to SHOW Statements”.

`SHOW INDEX` returns the following fields:

- **Table**
  - The name of the table.
SHOW Statements

- **Non_unique**
  0 if the index cannot contain duplicates, 1 if it can.

- **Key_name**
  The name of the index. If the index is the primary key, the name is always \texttt{PRIMARY}.

- **Seq_in_index**
  The column sequence number in the index, starting with 1.

- **Column_name**
  The column name. See also the description for the \texttt{Expression} column.

- **Collation**
  How the column is sorted in the index. This can have values \texttt{A} (ascending), \texttt{D} (descending), or \texttt{NULL} (not sorted).

- **Cardinality**
  An estimate of the number of unique values in the index. To update this number, run \texttt{ANALYZE TABLE} or (for \texttt{MyISAM} tables) \texttt{myisamchk -a}.

  \texttt{Cardinality} is counted based on statistics stored as integers, so the value is not necessarily exact even for small tables. The higher the cardinality, the greater the chance that MySQL uses the index when doing joins.

- **Sub_part**
  The index prefix. That is, the number of indexed characters if the column is only partly indexed, \texttt{NULL} if the entire column is indexed.

\begin{center}
\textbf{Note}
\end{center}

Prefix \textit{limits} are measured in bytes. However, prefix \textit{lengths} for index specifications in \texttt{CREATE TABLE}, \texttt{ALTER TABLE}, and \texttt{CREATE INDEX} statements are interpreted as number of characters for nonbinary string types \texttt{(CHAR, VARCHAR, TEXT)} and number of bytes for binary string types \texttt{(BINARY, VARBINARY, BLOB)}. Take this into account when specifying a prefix length for a nonbinary string column that uses a multibyte character set.

For additional information about index prefixes, see Section 8.3.5, “Column Indexes”, and Section 13.1.15, “CREATE INDEX Statement”.

- **Packed**
  Indicates how the key is packed. \texttt{NULL} if it is not.

- **Null**
  Contains \texttt{YES} if the column may contain \texttt{NULL} values and \texttt{''} if not.

- **Index_type**
  The index method used \texttt{(BTREE, FULLTEXT, HASH, RTREE)}.
SHOW Statements

• Comment
  Information about the index not described in its own column, such as disabled if the index is disabled.

• Index_comment
  Any comment provided for the index with a COMMENT attribute when the index was created.

• Visible
  Whether the index is visible to the optimizer. See Section 8.3.12, “Invisible Indexes”.

• Expression
  MySQL 8.0.13 and higher supports functional key parts (see Functional Key Parts), which affects both the Column_name and Expression columns:
  • For a nonfunctional key part, Column_name indicates the column indexed by the key part and Expression is NULL.
  • For a functional key part, Column_name column is NULL and Expression indicates the expression for the key part.

Information about table indexes is also available from the INFORMATION_SCHEMA STATISTICS table. See Section 26.3.34, “The INFORMATION_SCHEMA STATISTICS Table”. The extended information about hidden indexes is available only using SHOW EXTENDED INDEX; it cannot be obtained from the STATISTICS table.

You can list a table’s indexes with the mysqlshow -k db_name tbl_name command.

In MySQL 8.0.30 and later, SHOW_INDEX includes the table’s generated invisible key, if it has one, by default. You can cause this information to be suppressed in the statement’s output by setting show_gipk_in_create_table_and_information_schema = OFF. For more information, see Section 13.1.20.11, “Generated Invisible Primary Keys”.

13.7.7.23 SHOW MASTER STATUS Statement

SHOW MASTER STATUS

This statement provides status information about the binary log files of the source server. It requires the REPLICATION CLIENT privilege (or the deprecated SUPER privilege).

Example:

mysql> SHOW MASTER STATUS\G
*************************** 1. row ***************************
  File: source-bin.000002
  Position: 1307
  Binlog_Do_DB: test
  BinlogIgnore_DB: manual, mysql
  Executed_Gtid_Set: 3E11FA47-71CA-11E1-9E33-C80AA9429562:1-5
1 row in set (0.00 sec)

When global transaction IDs are in use, Executed_Gtid_Set shows the set of GTIDs for transactions that have been executed on the source. This is the same as the value for the gtid_executed system variable on this server, as well as the value for Executed_Gtid_Set in the output of SHOW REPLICATION STATUS (or before MySQL 8.0.22, SHOW SLAVE STATUS) on this server.

13.7.7.24 SHOW OPEN TABLES Statement
SHOW OPEN TABLES

```sql
SHOW OPEN TABLES
  [(FROM | IN) db_name]
  [LIKE 'pattern' | WHERE expr]
```

**SHOW OPEN TABLES** lists the non-TEMPORARY tables that are currently open in the table cache. See Section 8.4.3.1, “How MySQL Opens and Closes Tables”. The **FROM** clause, if present, restricts the tables shown to those present in the **db_name** database. The **LIKE** clause, if present, indicates which table names to match. The **WHERE** clause can be given to select rows using more general conditions, as discussed in Section 26.8, “Extensions to SHOW Statements”.

**SHOW OPEN TABLES** output has these columns:

- **Database**
  
  The database containing the table.

- **Table**
  
  The table name.

- **In_use**
  
  The number of table locks or lock requests there are for the table. For example, if one client acquires a lock for a table using `LOCK TABLE t1 WRITE`, **In_use** is 1. If another client issues `LOCK TABLE t1 WRITE` while the table remains locked, the client blocks, waiting for the lock, but the lock request causes **In_use** to be 2. If the count is zero, the table is open but not currently being used. **In_use** is also increased by the `HANDLER ... OPEN` statement and decreased by `HANDLER ... CLOSE`.

- **Name_locked**
  
  Whether the table name is locked. Name locking is used for operations such as dropping or renaming tables.

If you have no privileges for a table, it does not show up in the output from **SHOW OPEN TABLES**.

### 13.7.7.25 SHOW PLUGINS Statement

**SHOW PLUGINS**

**SHOW PLUGINS** displays information about server plugins.

**Example of SHOW PLUGINS output:**

```sql
mysql> SHOW PLUGINS\G
*************************** 1. row ***************************
  Name: binlog
  Status: ACTIVE
  Type: STORAGE ENGINE
  Library: NULL
  License: GPL

*************************** 2. row ***************************
  Name: CSV
  Status: ACTIVE
  Type: STORAGE ENGINE
  Library: NULL
  License: GPL

*************************** 3. row ***************************
  Name: MEMORY
  Status: ACTIVE
```

SHOW PLUGINS output has these columns:

- **Name**
  The name used to refer to the plugin in statements such as `INSTALL PLUGIN` and `UNINSTALL PLUGIN`.

- **Status**
  The plugin status, one of `ACTIVE`, `INACTIVE`, `DISABLED`, `DELETING`, or `DELETED`.

- **Type**
  The type of plugin, such as `STORAGE ENGINE`, `INFORMATION_SCHEMA`, or `AUTHENTICATION`.

- **Library**
  The name of the plugin shared library file. This is the name used to refer to the plugin file in statements such as `INSTALL PLUGIN` and `UNINSTALL PLUGIN`. This file is located in the directory named by the `plugin_dir` system variable. If the library name is `NULL`, the plugin is compiled in and cannot be uninstalled with `UNINSTALL PLUGIN`.

- **License**
  How the plugin is licensed (for example, `GPL`).

  For plugins installed with `INSTALL PLUGIN`, the `Name` and `Library` values are also registered in the `mysql.plugin` system table.

  For information about plugin data structures that form the basis of the information displayed by `SHOW PLUGINS`, see The MySQL Plugin API.

  Plugin information is also available from the `INFORMATION_SCHEMA.PLUGINS` table. See Section 26.3.22, “The INFORMATION_SCHEMA PLUGINS Table”.

### 13.7.7.26 SHOW PRIVILEGES Statement

`SHOW PRIVILEGES` shows the list of system privileges that the MySQL server supports. The privileges displayed include all static privileges, and all currently registered dynamic privileges.

```sql
mysql> SHOW PRIVILEGES\G
*************************** 1. row ***************************
Privilege: Alter
  Context: Tables
  Comment: To alter the table

*************************** 2. row ***************************
Privilege: Alter routine
```
SHOW Statements

Privileges belonging to a specific user are displayed by the `SHOW GRANTS` statement. See Section 13.7.7.21, “SHOW GRANTS Statement”, for more information.

13.7.7.27 SHOW PROCEDURE CODE Statement

SHOW PROCEDURE CODE `proc_name`

This statement is a MySQL extension that is available only for servers that have been built with debugging support. It displays a representation of the internal implementation of the named stored procedure. A similar statement, `SHOW FUNCTION CODE`, displays information about stored functions (see Section 13.7.7.19, “SHOW FUNCTION CODE Statement”).

To use either statement, you must be the user named as the routine DEFINER, have the SHOW_ROUTINE privilege, or have the SELECT privilege at the global level.

If the named routine is available, each statement produces a result set. Each row in the result set corresponds to one “instruction” in the routine. The first column is Pos, which is an ordinal number beginning with 0. The second column is Instruction, which contains an SQL statement (usually changed from the original source), or a directive which has meaning only to the stored-routine handler.

```sql
mysql> DELIMITER //
mysql> CREATE PROCEDURE p1 ()
    -> BEGIN
    -> DECLARE fanta INT DEFAULT 55;
    -> DROP TABLE t2;
    -> LOOP
    -> INSERT INTO t3 VALUES (fanta);
    -> END LOOP;
    -> END;//
Query OK, 0 rows affected (0.01 sec)

mysql> SHOW PROCEDURE CODE p1;//
+-----+----------------------------------------+
| Pos | Instruction                            |
+-----+----------------------------------------+
|   0 | set fanta@0 55                         |
|   1 | stmt 9 "DROP TABLE t2"                 |
|   2 | stmt 5 "INSERT INTO t3 VALUES (fanta)" |
|   3 | jump 2                                 |
+-----+----------------------------------------+
4 rows in set (0.00 sec)

mysql> CREATE FUNCTION test.hello (s CHAR(20))
    -> RETURNS CHAR(50) DETERMINISTIC
    -> RETURN CONCAT('Hello, ',s,'!');
Query OK, 0 rows affected (0.00 sec)
```
SHOW Statements

mysql> SHOW FUNCTION CODE test.hello;
<table>
<thead>
<tr>
<th>Pos</th>
<th>Instruction</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>freturn 254 concat('Hello, ',s@0,'!')</td>
</tr>
</tbody>
</table>
+-----+---------------------------------------+
1 row in set (0.00 sec)

In this example, the nonexecutable BEGIN and END statements have disappeared, and for the DECLARE variable_name statement, only the executable part appears (the part where the default is assigned). For each statement that is taken from source, there is a code word stmt followed by a type (9 means DROP, 5 means INSERT, and so on). The final row contains an instruction jump 2, meaning GOTO instruction #2.

13.7.7.28 SHOW PROCEDURE STATUS Statement

SHOW PROCEDURE STATUS
LIKE 'pattern' | WHERE expr

This statement is a MySQL extension. It returns characteristics of a stored procedure, such as the database, name, type, creator, creation and modification dates, and character set information. A similar statement, SHOW FUNCTION STATUS, displays information about stored functions (see Section 13.7.7.20, “SHOW FUNCTION STATUS Statement”).

To use either statement, you must be the user named as the routine DEFINER, have the SHOW_ROUTINE privilege, have the SELECT privilege at the global level, or have the CREATE_ROUTINE, ALTER_ROUTINE, or EXECUTE privilege granted at a scope that includes the routine.

The LIKE clause, if present, indicates which procedure or function names to match. The WHERE clause can be given to select rows using more general conditions, as discussed in Section 26.8, “Extensions to SHOW Statements”.

mysql> SHOW PROCEDURE STATUS LIKE 'sp1'
*************************** 1. row ***************************
Db: test
Name: sp1
Type: PROCEDURE
Definer: testuser@localhost
Modified: 2018-08-08 13:54:11
Created: 2018-08-08 13:54:11
Security_type: DEFINER
Comment:
collation_connection: utf8mb4_0900_ai_ci
Database Collation: utf8mb4_0900_ai_ci

mysql> SHOW FUNCTION STATUS LIKE 'hello'
*************************** 1. row ***************************
Db: test
Name: hello
Type: FUNCTION
Definer: testuser@localhost
Modified: 2020-03-10 11:10:03
Created: 2020-03-10 11:10:03
Security_type: DEFINER
Comment:
collation_connection: utf8mb4_0900_ai_ci
Database Collation: utf8mb4_0900_ai_ci

character_set_client is the session value of the character_set_client system variable when the routine was created. collation_connection is the session value of the collation_connection system variable.
system variable when the routine was created. Database Collation is the collation of the database
with which the routine is associated.

Stored routine information is also available from the INFORMATION_SCHEMA PARAMETERS and ROUTINES
tables. See Section 26.3.20, “The INFORMATION_SCHEMA PARAMETERS Table”, and Section 26.3.30,
“The INFORMATION_SCHEMA ROUTINES Table”.

13.7.7.29 SHOW PROCESSLIST Statement

SHOW [FULL] PROCESSLIST

The MySQL process list indicates the operations currently being performed by the set of threads executing
within the server. The SHOW PROCESSLIST statement is one source of process information. For a
comparison of this statement with other sources, see Sources of Process Information.

Note
As of MySQL 8.0.22, an alternative implementation for SHOW PROCESSLIST is
available based on the Performance Schema processlist table, which, unlike
the default SHOW PROCESSLIST implementation, does not require a mutex and
has better performance characteristics. For details, see Section 27.12.21.7, “The
processlist Table”.

If you have the PROCESS privilege, you can see all threads, even those belonging to other users. Otherwise
(without the PROCESS privilege), nonanonymous users have access to information about their own threads
but not threads for other users, and anonymous users have no access to thread information.

Without the FULL keyword, SHOW PROCESSLIST displays only the first 100 characters of each statement in the Info field.

The SHOW PROCESSLIST statement is very useful if you get the “too many connections” error message
and want to find out what is going on. MySQL reserves one extra connection to be used by accounts that
have the CONNECTION_ADMIN privilege (or the deprecated SUPER privilege), to ensure that administrators
should always be able to connect and check the system (assuming that you are not giving this privilege to
all your users).

Threads can be killed with the KILL statement. See Section 13.7.8.4, “KILL Statement”.

Example of SHOW PROCESSLIST output:

mysql> SHOW FULL PROCESSLIST\G
*************************** 1. row ***************************
     Id: 1
   User: system user
   Host: 
  Command: Connect
   Time: 1030455
   State: Waiting for source to send event
   Info: NULL

*************************** 2. row ***************************
     Id: 2
   User: system user
   Host: 
  Command: Connect
   Time: 1004
   State: Has read all relay log; waiting for the replica I/O thread to update it
### SHOW Statements

<table>
<thead>
<tr>
<th>Info: NULL</th>
</tr>
</thead>
<tbody>
<tr>
<td>******************* 3. row *******************</td>
</tr>
<tr>
<td>Id: 3112</td>
</tr>
<tr>

</tr>
<tr>
<td>State: Has sent all binlog to replica; waiting for binlog to be updated</td>
</tr>
<tr>
<td>Info: NULL</td>
</tr>
</tbody>
</table>

| ******************* 4. row ******************* |
| Id: 3113     |
| User: replikator |
| Host: iconnect2:45781 |
| db: NULL     |
| Command: Binlog Dump |
| Time: 2086   |
| State: Has sent all binlog to replica; waiting for binlog to be updated |
| Info: NULL  |

| ******************* 5. row ******************* |
| Id: 3123     |
| User: stefan |
| Host: localhost |
| db: apollon  |
| Command: Query |
| Time: 0      |
| State: NULL  |
| Info: SHOW FULL PROCESSLIST |

**SHOW PROCESSLIST** output has these columns:

- **Id**
  
The connection identifier. This is the same value displayed in the `ID` column of the `INFORMATION_SCHEMA.PROCESSLIST` table, displayed in the `PROCESSLIST_ID` column of the Performance Schema `threads` table, and returned by the `CONNECTION_ID()` function within the thread.

- **User**
  
The MySQL user who issued the statement. A value of system user refers to a nonclient thread spawned by the server to handle tasks internally, for example, a delayed-row handler thread or an I/O (receiver) or SQL (applier) thread used on replica hosts. For system user, there is no host specified in the Host column. unauthenticated user refers to a thread that has become associated with a client connection but for which authentication of the client user has not yet occurred. event_scheduler refers to the thread that monitors scheduled events (see Section 25.4, “Using the Event Scheduler”).

**Note**

A User value of system user is distinct from the SYSTEM_USER privilege. The former designates internal threads. The latter distinguishes the system user and regular user account categories (see Section 6.2.11, “Account Categories”).

- **Host**
  
The host name of the client issuing the statement (except for system user, for which there is no host). The host name for TCP/IP connections is reported in `host_name:client_port` format to make it easier to determine which client is doing what.

- **db**
  
The default database for the thread, or NULL if none has been selected.
SHOW Statements

• **Command**

  The type of command the thread is executing on behalf of the client, or *Sleep* if the session is idle. For descriptions of thread commands, see Section 8.14, “Examining Server Thread (Process) Information”. The value of this column corresponds to the `COM_xxx` commands of the client/server protocol and `Com_xxx` status variables. See Section 5.1.10, “Server Status Variables”.

• **Time**

  The time in seconds that the thread has been in its current state. For a replica SQL thread, the value is the number of seconds between the timestamp of the last replicated event and the real time of the replica host. See Section 17.2.3, “Replication Threads”.

• **State**

  An action, event, or state that indicates what the thread is doing. For descriptions of *State* values, see Section 8.14, “Examining Server Thread (Process) Information”.

  Most states correspond to very quick operations. If a thread stays in a given state for many seconds, there might be a problem that needs to be investigated.

• **Info**

  The statement the thread is executing, or *NULL* if it is executing no statement. The statement might be the one sent to the server, or an innermost statement if the statement executes other statements. For example, if a *CALL* statement executes a stored procedure that is executing a *SELECT* statement, the *Info* value shows the *SELECT* statement.

13.7.7.30 SHOW PROFILE Statement

```
SHOW PROFILE [type [, type] ... ]
  [FOR QUERY n]
  [LIMIT row_count [OFFSET offset]]

type: {
  ALL
  | BLOCK IO
  | CONTEXT SWITCHES
  | CPU
  | IPC
  | MEMORY
  | PAGE FAULTS
  | SOURCE
  | SWAPS
}
```

The *SHOW PROFILE* and *SHOW PROFILES* statements display profiling information that indicates resource usage for statements executed during the course of the current session.

**Note**

The *SHOW PROFILE* and *SHOW PROFILES* statements are deprecated; expect them to be removed in a future MySQL release. Use the Performance Schema instead; see Section 27.19.1, “Query Profiling Using Performance Schema”.

To control profiling, use the *profiling* session variable, which has a default value of 0 (*OFF*). Enable profiling by setting *profiling* to 1 or *ON*:

```
mysql> SET profiling = 1;
```
SHOW Statements

SHOW PROFILES displays a list of the most recent statements sent to the server. The size of the list is controlled by the `profiling_history_size` session variable, which has a default value of 15. The maximum value is 100. Setting the value to 0 has the practical effect of disabling profiling.

All statements are profiled except `SHOW PROFILE` and `SHOW PROFILES`, so neither of those statements appears in the profile list. Malformed statements are profiled. For example, `SHOW PROFILING` is an illegal statement, and a syntax error occurs if you try to execute it, but it shows up in the profiling list.

`SHOW PROFILE` displays detailed information about a single statement. Without the `FOR QUERY n` clause, the output pertains to the most recently executed statement. If `FOR QUERY n` is included, `SHOW PROFILE` displays information for statement `n`. The values of `n` correspond to the `Query_ID` values displayed by `SHOW PROFILES`.

The `LIMIT row_count` clause may be given to limit the output to `row_count` rows. If `LIMIT` is given, `OFFSET offset` may be added to begin the output `offset` rows into the full set of rows.

By default, `SHOW PROFILE` displays `Status` and `Duration` columns. The `Status` values are like the `State` values displayed by `SHOW PROCESSLIST`, although there might be some minor differences in interpretation for the two statements for some status values (see Section 8.14, "Examining Server Thread (Process) Information").

Optional `type` values may be specified to display specific additional types of information:

- `ALL` displays all information
- `BLOCK IO` displays counts for block input and output operations
- `CONTEXT SWITCHES` displays counts for voluntary and involuntary context switches
- `CPU` displays user and system CPU usage times
- `IPC` displays counts for messages sent and received
- `MEMORY` is not currently implemented
- `PAGE FAULTS` displays counts for major and minor page faults
- `SOURCE` displays the names of functions from the source code, together with the name and line number of the file in which the function occurs
- `SWAPS` displays swap counts

Profiling is enabled per session. When a session ends, its profiling information is lost.

```sql
mysql> SELECT @@profiling;
+-------------+
| @@profiling |
+-------------+
|           0 |
+-------------+
1 row in set (0.00 sec)

mysql> SET profiling = 1;
Query OK, 0 rows affected (0.00 sec)

mysql> DROP TABLE IF EXISTS t1;
Query OK, 0 rows affected, 1 warning (0.00 sec)

mysql> CREATE TABLE t1 (id INT);
Query OK, 0 rows affected (0.01 sec)

mysql> SHOW PROFILES;
```

<td>0.000003</td>
<td>0.000002</td>
</tr>
</tbody>
</table>

7 rows in set (0.00 sec)

---

**Note**

Profiling is only partially functional on some architectures. For values that depend on the `getrusage()` system call, `NULL` is returned on systems such as Windows that do not support the call. In addition, profiling is per process and not per thread. This means that activity on threads within the server other than your own may affect the timing information that you see.

Profiling information is also available from the `INFORMATION_SCHEMA.PROFILING` table. See [Section 26.3.24, “The INFORMATION_SCHEMA.PROFILING Table”](#). For example, the following queries are equivalent:

```sql
SHOW PROFILE FOR QUERY 2;
SELECT STATE, FORMAT(DURATION, 6) AS DURATION
FROM INFORMATION_SCHEMA.PROFILING
WHERE QUERY_ID = 2 ORDER BY SEQ;
```
13.7.31 SHOW PROFILES Statement

The SHOW PROFILES statement, together with SHOW PROFILE, displays profiling information that indicates resource usage for statements executed during the course of the current session. For more information, see Section 13.7.30, “SHOW PROFILE Statement”.

Note
The SHOW PROFILE and SHOW PROFILES statements are deprecated; expect it to be removed in a future MySQL release. Use the Performance Schema instead; see Section 27.19.1, “Query Profiling Using Performance Schema”.

13.7.32 SHOW RELAYLOG EVENTS Statement

SHOW RELAYLOG EVENTS
[IN 'log_name']
[FROM pos]
[LIMIT [offset,] row_count]
[channel_option]

channel_option:
   FOR CHANNEL channel

Shows the events in the relay log of a replica. If you do not specify 'log_name', the first relay log is displayed. This statement has no effect on the source. SHOW RELAYLOG EVENTS requires the REPLICATION SLAVE privilege.

The LIMIT clause has the same syntax as for the SELECT statement. See Section 13.2.13, “SELECT Statement”.

Note
Issuing a SHOW RELAYLOG EVENTS with no LIMIT clause could start a very time- and resource-consuming process because the server returns to the client the complete contents of the relay log (including all statements modifying data that have been received by the replica).

The optional FOR CHANNEL channel clause enables you to name which replication channel the statement applies to. Providing a FOR CHANNEL channel clause applies the statement to a specific replication channel. If no channel is named and no extra channels exist, the statement applies to the default channel.

When using multiple replication channels, if a SHOW RELAYLOG EVENTS statement does not have a channel defined using a FOR CHANNEL channel clause an error is generated. See Section 17.2.2, “Replication Channels” for more information.

SHOW RELAYLOG EVENTS displays the following fields for each event in the relay log:

- Log_name
  The name of the file that is being listed.

- Pos
  The position at which the event occurs.

- Event_type
SHOW Statements

An identifier that describes the event type.

- **Server_id**
  The server ID of the server on which the event originated.

- **End_log_pos**
  The value of `End_log_pos` for this event in the source's binary log.

- **Info**
  More detailed information about the event type. The format of this information depends on the event type.

For compressed transaction payloads, the `Transaction_payload_event` is first printed as a single unit, then it is unpacked and each event inside it is printed.

Some events relating to the setting of user and system variables are not included in the output from `SHOW RELAYLOG EVENTS`. To get complete coverage of events within a relay log, use `mysqlbinlog`.

### 13.7.7.33 SHOW REPLICAS Statement

```sql
[SHOW REPLICAS]
```

Displays a list of replicas currently registered with the source. From MySQL 8.0.22, use `SHOW REPLICAS` in place of `SHOW SLAVE HOSTS`, which is deprecated from that release. In releases before MySQL 8.0.22, use `SHOW SLAVE HOSTS`. `SHOW REPLICAS` requires the `REPLICATION SLAVE` privilege.

`SHOW REPLICAS` should be executed on a server that acts as a replication source. The statement displays information about servers that are or have been connected as replicas, with each row of the result corresponding to one replica server, as shown here:

```
mysql> SHOW REPLICAS;
+------------+-----------+------+-----------+--------------------------------------+
<table>
<thead>
<tr>
<th>Server_id</th>
<th>Host</th>
<th>Port</th>
<th>Source_id</th>
<th>Replica_UUID</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>iconnect2</td>
<td>3306</td>
<td>3</td>
<td>14cb6624-7f93-11e0-b2c0-c80aa9429562</td>
</tr>
<tr>
<td>21</td>
<td>athena</td>
<td>3306</td>
<td>3</td>
<td>07af4990-f41f-11df-a566-7ac56fda645</td>
</tr>
</tbody>
</table>
+------------+-----------+------+-----------+--------------------------------------+
```

- **Server_id**: The unique server ID of the replica server, as configured in the replica server's option file, or on the command line with `--server-id=value`.

- **Host**: The host name of the replica server, as specified on the replica with the `--report-host` option. This can differ from the machine name as configured in the operating system.

- **User**: The replica server user name, as specified on the replica with the `--report-user` option. Statement output includes this column only if the source server is started with the `--show-replica-auth-info` or `--show-slave-auth-info` option.

- **Password**: The replica server password, as specified on the replica with the `--report-password` option. Statement output includes this column only if the source server is started with the `--show-replica-auth-info` or `--show-slave-auth-info` option.

- **Port**: The port on the source to which the replica server is listening, as specified on the replica with the `--report-port` option.

A zero in this column means that the replica port (`--report-port`) was not set.
SHOW Statements

- **Source_id**: The unique server ID of the source server that the replica server is replicating from. This is the server ID of the server on which `SHOW REPLICAS` is executed, so this same value is listed for each row in the result.

- **Replica_UUID**: The globally unique ID of this replica, as generated on the replica and found in the replica's `auto.cnf` file.

### 13.7.7.34 SHOW SLAVE HOSTS | SHOW REPLICAS Statement

```
{SHOW SLAVE HOSTS | SHOW REPLICAS}
```

Displays a list of replicas currently registered with the source. From MySQL 8.0.22, `SHOW SLAVE HOSTS` is deprecated and the alias `SHOW REPLICAS` should be used instead. The statement works in the same way as before, only the terminology used for the statement and its output has changed. Both versions of the statement update the same status variables when used. Please see the documentation for `SHOW REPLICAS` for a description of the statement.

### 13.7.7.35 SHOW REPLICATION STATUS Statement

```
SHOW {REPLICA | SLAVE} STATUS [FOR CHANNEL channel]
```

This statement provides status information on essential parameters of the replica threads. From MySQL 8.0.22, use `SHOW REPLICA STATUS` in place of `SHOW SLAVE STATUS`, which is deprecated from that release. In releases before MySQL 8.0.22, use `SHOW SLAVE STATUS`. The statement requires the `REPLICATION CLIENT` privilege (or the deprecated `SUPER` privilege).

`SHOW REPLICA STATUS` is nonblocking. When run concurrently with `STOP REPLICA`, `SHOW REPLICA STATUS` returns without waiting for `STOP REPLICA` to finish shutting down the replication SQL (applier) thread or replication I/O (receiver) thread (or both). This permits use in monitoring and other applications where getting an immediate response from `SHOW REPLICA STATUS` is more important than ensuring that it returned the latest data. The SLAVE keyword was replaced with REPLICA in MySQL 8.0.22.

If you issue this statement using the `mysql` client, you can use a `\G` statement terminator rather than a semicolon to obtain a more readable vertical layout:

```
mysql> SHOW REPLICA STATUS\G
*************************** 1. row ***************************
Replica_IO_State: Waiting for source to send event
Source_Recipient: localhost
Source_User: repl
Source_Port: 13000
Connect_Retry: 60
Source_Log_File: source-bin.000002
Read_Source_Log_Pos: 1307
Relay_Log_File: replica-relay-bin.000003
Relay_Log_Pos: 1508
Relay_Source_Log_File: source-bin.000002
Replica_IO_Running: Yes
Replica_SQL_Running: Yes
Replicate_Do_DB: Replicate_Ignore_DB:
Replicate_Do_Table: Replicate_Ignore_Table:
Replicate_Wild_Do_Table: Replicate_Wild_Ignore_Table:
Last_Errno: 0
Last_Error:
Skip_Counter: 0
Send_Source_Log_Pos: 1307
Relay_Log_Space: 1858
Until_Condition: None
```
The Performance Schema provides tables that expose replication information. This is similar to the information available from the `SHOW REPLICA STATUS` statement, but represented in table form. For details, see Section 27.12.11, “Performance Schema Replication Tables”.

From MySQL 8.0.27, you can set the `GTID_ONLY` option on the `CHANGE REPLICATION SOURCE TO` statement to stop a replication channel from persisting file names and file positions in the replication metadata repositories. With this setting, file positions for the source binary log file and the relay log file are tracked in memory. The `SHOW REPLICA STATUS` statement still displays file positions in normal use. However, because the file positions are not being regularly updated in the connection metadata repository and the applier metadata repository except in a few situations, they are likely to be out of date if the server is restarted.

For a replication channel with the `GTID_ONLY` setting after a server start, the read and applied file positions for the source binary log file (`Read_Source_Log_Pos` and `Exec_Source_Log_Pos`) are set to zero, and the file names (`Source_Log_File` and `Relay_Source_Log_File`) are set to `INVALID`. The relay log file name (`Relay_Log_File`) is set according to the `relay_log_recovery` setting, either a new file that was created at server start or the first relay log file present. The file position (`Relay_Log_Pos`) is set to position 4, and GTID auto-skip is used to skip any transactions in the file that were already applied.

When the receiver thread contacts the source and gets valid position information, the read position (`Read_Source_Log_Pos`) and file name (`Source_Log_File`) are updated with the correct data and become valid. When the applier thread applies a transaction from the source, or skips an already executed transaction, the executed position (`Exec_Source_Log_Pos`) and file name (`Relay_Source_Log_File`) are updated with the correct data and become valid. The relay log file position (`Relay_Log_Pos`) is also updated at that time.
SHOW Statements

The following list describes the fields returned by `SHOW REPLICA STATUS`. For additional information about interpreting their meanings, see Section 17.1.7.1, “Checking Replication Status”.

- **Replica_IO_State**
  A copy of the `State` field of the `SHOW PROCESSLIST` output for the replica I/O (receiver) thread. This tells you what the thread is doing: trying to connect to the source, waiting for events from the source, reconnecting to the source, and so on. For a listing of possible states, see Section 8.14.5, “Replication I/O (Receiver) Thread States”.

- **Source_Host**
  The source host that the replica is connected to.

- **Source_User**
  The user name of the account used to connect to the source.

- **Source_Port**
  The port used to connect to the source.

- **Connect_Retry**
  The number of seconds between connect retries (default 60). This can be set with a `CHANGE REPLICA SOURCE TO` statement (from MySQL 8.0.23) or `CHANGE MASTER TO` statement (before MySQL 8.0.23).

- **Source_Log_File**
  The name of the source binary log file from which the I/O (receiver) thread is currently reading. This is set to `INVALID` for a replication channel with the `GTID_ONLY` setting after a server start. It will be updated when the replica contacts the source.

- **Read_Source_Log_Pos**
  The position in the current source binary log file up to which the I/O (receiver) thread has read. This is set to zero for a replication channel with the `GTID_ONLY` setting after a server start. It will be updated when the replica contacts the source.

- **Relay_Log_File**
  The name of the relay log file from which the SQL (applier) thread is currently reading and executing.

- **Relay_Log_Pos**
  The position in the current relay log file up to which the SQL (applier) thread has read and executed.

- **Relay_Source_Log_File**
  The name of the source binary log file containing the most recent event executed by the SQL (applier) thread. This is set to `INVALID` for a replication channel with the `GTID_ONLY` setting after a server start. It will be updated when a transaction is executed or skipped.

- **Replica_IO_Running**
  Whether the replication I/O (receiver) thread is started and has connected successfully to the source. Internally, the state of this thread is represented by one of the following three values:
SHOW Statements

- **MYSQL_REPLICA_NOT_RUN.** The replication I/O (receiver) thread is not running. For this state, `Replica_IO_Running` is **No**.

- **MYSQL_REPLICA_RUN_NOT_CONNECT.** The replication I/O (receiver) thread is running, but is not connected to a replication source. For this state, `Replica_IO_Running` is **Connecting**.

- **MYSQL_REPLICA_RUN_CONNECT.** The replication I/O (receiver) thread is running, and is connected to a replication source. For this state, `Replica_IO_Running` is **Yes**.

- **Replica_SQL_Running**
  Whether the replication SQL (applier) thread is started.

- **Replicate_Do_DB**, **Replicate_Ignore_DB**
  The names of any databases that were specified with the `--replicate-do-db` and `--replicate-ignore-db` options, or the `CHANGE REPLICATION FILTER` statement. If the `FOR CHANNEL` clause was used, the channel specific replication filters are shown. Otherwise, the replication filters for every replication channel are shown.

- **Replicate_Do_Table**, **Replicate_Ignore_Table**, **Replicate_Wild_Do_Table**, **Replicate_Wild_Ignore_Table**
  The names of any tables that were specified with the `--replicate-do-table`, `--replicate-ignore-table`, `--replicate-wild-do-table`, and `--replicate-wild-ignore-table` options, or the `CHANGE REPLICATION FILTER` statement. If the `FOR CHANNEL` clause was used, the channel specific replication filters are shown. Otherwise, the replication filters for every replication channel are shown.

- **Last_Errno**, **Last_Error**
  These columns are aliases for `Last_SQL_Errno` and `Last_SQL_Error`.

  Issuing `RESET MASTER` or `RESET REPLICA` resets the values shown in these columns.

  **Note**
  When the replication SQL thread receives an error, it reports the error first, then stops the SQL thread. This means that there is a small window of time during which `SHOW REPLICA STATUS` shows a nonzero value for `Last_SQL_Errno` even though `Replica_SQL_Running` still displays **Yes**.

- **Skip_Counter**

- **Exec_Source_Log_Pos**
  The position in the current source binary log file to which the replication SQL thread has read and executed, marking the start of the next transaction or event to be processed. This is set to zero for a replication channel with the `GTID_ONLY` setting after a server start. It will be updated when a transaction is executed or skipped.

  You can use this value with the `CHANGE REPLICATION SOURCE TO` statement's `SOURCE_LOG_POS` option (from MySQL 8.0.23) or the `CHANGE MASTER TO` statement's `MASTER_LOG_POS` option (before MySQL 8.0.23) when starting a new replica from an existing replica, so that the new replica reads from
this point. The coordinates given by \((\text{Relay}_\text{Source}_\text{Log}_\text{File},\text{Exec}_\text{Source}_\text{Log}_\text{Pos})\) in the source’s binary log correspond to the coordinates given by \((\text{Relay}_\text{Log}_\text{File},\text{Relay}_\text{Log}_\text{Pos})\) in the relay log.

Inconsistencies in the sequence of transactions from the relay log which have been executed can cause this value to be a “low-water mark”. In other words, transactions appearing before the position are guaranteed to have committed, but transactions after the position may have committed or not. If these gaps need to be corrected, use \texttt{START REPLICA UNTIL SQL AFTER MTS GAPS}. See Section 17.5.1.34, “Replication and Transaction Inconsistencies” for more information.

- **\texttt{Relay}_\text{Log}_\text{Space}**
  
  The total combined size of all existing relay log files.

- **\texttt{Until}_\text{Condition}, \texttt{Until}_\text{Log}_\text{File}, \texttt{Until}_\text{Log}_\text{Pos}**
  
  The values specified in the \texttt{UNTIL} clause of the \texttt{START REPLICA} statement.

  - **Until\texttt{Condition}** has these values:
    - **\texttt{None}** if no \texttt{UNTIL} clause was specified.
    - **\texttt{Source}** if the replica is reading until a given position in the source’s binary log.
    - **\texttt{Relay}** if the replica is reading until a given position in its relay log.
    - **\texttt{SQL BEFORE GTIDS}** if the replication SQL thread is processing transactions until it has reached the first transaction whose GTID is listed in the \texttt{gtid_set}.
    - **\texttt{SQL AFTER GTIDS}** if the replication threads are processing all transactions until the last transaction in the \texttt{gtid_set} has been processed by both threads.
    - **\texttt{SQL AFTER MTS GAPS}** if a multithreaded replica’s SQL threads are running until no more gaps are found in the relay log.

  - **Until\texttt{Log}_\text{File} and Until\texttt{Log}_\text{Pos}** indicate the log file name and position that define the coordinates at which the replication SQL thread stops executing.

  For more information on \texttt{UNTIL} clauses, see Section 13.4.2.7, “START SLAVE Statement”.

- **\texttt{Source}_\text{SSL}_\text{Allowed}, Source\texttt{SSL}_\text{CA}_\text{File}, Source\texttt{SSL}_\text{CA}_\text{Path}, Source\texttt{SSL}_\text{Cert}, Source\texttt{SSL}_\text{Cipher}, Source\texttt{SSL}_\text{CRL}_\text{File}, Source\texttt{SSL}_\text{CRL}_\text{Path}, Source\texttt{SSL}_\text{Key}, Source\texttt{SSL}_\text{Verify}_\text{Server}_\text{Cert}**

  These fields show the SSL parameters used by the replica to connect to the source, if any.

  - **Source\texttt{SSL}_\text{Allowed}** has these values:
    - **\texttt{Yes}** if an SSL connection to the source is permitted.
    - **\texttt{No}** if an SSL connection to the source is not permitted.
    - **\texttt{Ignored}** if an SSL connection is permitted but the replica server does not have SSL support enabled.

  The values of the other SSL-related fields correspond to the values of the \texttt{SOURCE_SSL_*} options of the \texttt{CHANGE REPLICATION SOURCE TO} statement (from MySQL 8.0.23), or the \texttt{MASTER_SSL_*} options of the \texttt{CHANGE MASTER TO} statement (before MySQL 8.0.23). See Section 13.4.2.1, “CHANGE MASTER TO Statement”. 
SHOW Statements

- **Seconds_Behind_Source**

  This field is an indication of how “late” the replica is:

  - When the replica is actively processing updates, this field shows the difference between the current timestamp on the replica and the original timestamp logged on the source for the event currently being processed on the replica.

  - When no event is currently being processed on the replica, this value is 0.

  In essence, this field measures the time difference in seconds between the replication SQL (applier) thread and the replication I/O (receiver) thread. If the network connection between source and replica is fast, the replication receiver thread is very close to the source, so this field is a good approximation of how late the replication applier thread is compared to the source. If the network is slow, this is not a good approximation; the replication applier thread may quite often be caught up with the slow-reading replication receiver thread, so **Seconds_Behind_Source** often shows a value of 0, even if the replication receiver thread is late compared to the source. In other words, this column is useful only for fast networks.

  This time difference computation works even if the source and replica do not have identical clock times, provided that the difference, computed when the replica receiver thread starts, remains constant from then on. Any changes, including NTP updates, can lead to clock skews that can make calculation of **Seconds_Behind_Source** less reliable.

  In MySQL 8.0, this field is **NULL** (undefined or unknown) if the replication applier thread is not running, or if the applier thread has consumed all of the relay log and the replication receiver thread is not running. (In older versions of MySQL, this field was **NULL** if the replication applier thread or the replication receiver thread was not running or was not connected to the source.) If the replication receiver thread is running but the relay log is exhausted, **Seconds_Behind_Source** is set to 0.

  The value of **Seconds_Behind_Source** is based on the timestamps stored in events, which are preserved through replication. This means that if a source M1 is itself a replica of M0, any event from M1’s binary log that originates from M0’s binary log has M0’s timestamp for that event. This enables MySQL to replicate **TIMESTAMP** successfully. However, the problem for **Seconds_Behind_Source** is that if M1 also receives direct updates from clients, the **Seconds_Behind_Source** value randomly fluctuates because sometimes the last event from M1 originates from M0 and sometimes is the result of a direct update on M1.

  When using a multithreaded replica, you should keep in mind that this value is based on **Exec_Source_Log_Pos**, and so may not reflect the position of the most recently committed transaction.

- **Last_IO_Errno, Last_IO_Error**

  The error number and error message of the most recent error that caused the replication I/O (receiver) thread to stop. An error number of 0 and message of the empty string mean “no error.” If the **Last_IO_Error** value is not empty, the error values also appear in the replica’s error log.

  I/O error information includes a timestamp showing when the most recent I/O (receiver) thread error occurred. This timestamp uses the format **YYMMDD hh:mm:ss**, and appears in the **Last_IO_Error_Timestamp** column.

  Issuing **RESET MASTER** or **RESET REPLICA** resets the values shown in these columns.
SHOW Statements

• **Last_SQL_Errno, Last_SQL_Error**

  The error number and error message of the most recent error that caused the replication SQL (applier) thread to stop. An error number of 0 and message of the empty string mean “no error.” If the **Last_SQL_Error** value is not empty, the error values also appear in the replica’s error log.

  If the replica is multithreaded, the replication SQL thread is the coordinator for worker threads. In this case, the **Last_SQL_Error** field shows exactly what the **Last_Error_Message** column in the Performance Schema `replication_applier_status_by_coordinator` table shows. The field value is modified to suggest that there may be more failures in the other worker threads which can be seen in the `replication_applier_status_by_worker` table that shows each worker thread's status. If that table is not available, the replica error log can be used. The log or the `replication_applier_status_by_worker` table should also be used to learn more about the failure shown by **SHOW REPLICA STATUS** or the coordinator table.

  SQL error information includes a timestamp showing when the most recent SQL (applier) thread error occurred. This timestamp uses the format `YYMMDD hh:mm:ss`, and appears in the **Last_SQL_Error_Timestamp** column.

  Issuing **RESET MASTER** or **RESET REPLICA** resets the values shown in these columns.

  In MySQL 8.0, all error codes and messages displayed in the **Last_SQL_Errno** and **Last_SQL_Error** columns correspond to error values listed in **Server Error Message Reference**. This was not always true in previous versions. (Bug #11760365, Bug #52768)

• **Replicate_Ignore_Server_Ids**

  Any server IDs that have been specified using the **IGNORE_SERVER_IDS** option of the **CHANGE REPLICATION SOURCE TO | CHANGE MASTER TO** statement, so that the replica ignores events from these servers. This option is used in a circular or other multi-source replication setup when one of the servers is removed. If any server IDs have been set in this way, a comma-delimited list of one or more numbers is shown. If no server IDs have been set, the field is blank.

  **Note**

  The **Ignored_server_ids** value in the `slave_master_info` table also shows the server IDs to be ignored, but as a space-delimited list, preceded by the total number of server IDs to be ignored. For example, if a **CHANGE REPLICATION SOURCE TO | CHANGE MASTER TO** statement containing the **IGNORE_SERVER_IDS = (2, 6, 9)** option has been issued to tell a replica to ignore sources having the server ID 2, 6, or 9, that information appears as shown here:

  ```
  Replicate_Ignore_Server_Ids: 2, 6, 9
  Ignored_server_ids: 3, 2, 6, 9
  ```

  **Replicate_Ignore_Server_Ids** filtering is performed by the I/O (receiver) thread, rather than by the SQL (applier) thread, which means that events which are filtered out are not written to the relay log. This differs from the filtering actions taken by server options such **--replicate-do-table**, which apply to the applier thread.

  **Note**

  From MySQL 8.0, a deprecation warning is issued if **SET GTID_MODE=ON** is issued when any channel has existing server IDs set with **IGNORE_SERVER_IDS**.
Before starting GTID-based replication, use `SHOW REPLICA STATUS` to check for and clear all ignored server ID lists on the servers involved. You can clear a list by issuing a `CHANGE REPLICATION SOURCE TO` | `CHANGE MASTER TO` statement containing the `IGNORE_SERVER_IDS` option with an empty list.

- **Source_Server_Id**
  The `server_id` value from the source.

- **Source_UUID**
  The `server_uuid` value from the source.

- **Source_Info_File**
  The location of the `master.info` file, the use of which is now deprecated. By default from MySQL 8.0, a table is used instead for the replica's connection metadata repository.

- **SQL_Delay**
  The number of seconds that the replica must lag the source.

- **SQL_Remaining_Delay**
  When `Replica_SQL_Running_State` is `Waiting until MASTER_DELAY seconds after source executed event`, this field contains the number of delay seconds remaining. At other times, this field is `NULL`.

- **Replica_SQL_Running_State**
  The state of the SQL thread (analogous to `Replica_IO_State`). The value is identical to the `State` value of the SQL thread as displayed by `SHOW PROCESSLIST`. Section 8.14.6, “Replication SQL Thread States”, provides a listing of possible states.

- **Source_Retry_Count**
  The number of times the replica can attempt to reconnect to the source in the event of a lost connection. This value can be set using the `SOURCE_RETRY_COUNT` | `MASTER_RETRY_COUNT` option of the `CHANGE REPLICATION SOURCE TO` statement (from MySQL 8.0.23) or `CHANGE MASTER TO` statement (before MySQL 8.0.23), or the older `--master-retry-count` server option (still supported for backward compatibility).

- **Source_Bind**
  The network interface that the replica is bound to, if any. This is set using the `SOURCE_BIND` | `MASTER_BIND` option for the `CHANGE REPLICATION SOURCE TO` statement (from MySQL 8.0.23) or `CHANGE MASTER TO` statement (before MySQL 8.0.23).

- **Last_IO_Error_Timestamp**
  A timestamp in `YYMMDD hh:mm:ss` format that shows when the most recent I/O error took place.

- **Last_SQL_Error_Timestamp**
  A timestamp in `YYMMDD hh:mm:ss` format that shows when the most recent SQL error occurred.
SHOW Statements

• **Retrieved_Gtid_Set**

  The set of global transaction IDs corresponding to all transactions received by this replica. Empty if GTIDs are not in use. See **GTID Sets** for more information.

  This is the set of all GTIDs that exist or have existed in the relay logs. Each GTID is added as soon as the `Gtid_log_event` is received. This can cause partially transmitted transactions to have their GTIDs included in the set.

  When all relay logs are lost due to executing `RESET REPLICA` or `CHANGE REPLICATION SOURCE TO | CHANGE MASTER TO`, or due to the effects of the `--relay-log-recovery` option, the set is cleared. When `relay_log_purge = 1`, the newest relay log is always kept, and the set is not cleared.

• **Executed_Gtid_Set**

  The set of global transaction IDs written in the binary log. This is the same as the value for the global `gtid_executed` system variable on this server, as well as the value for `Executed_Gtid_Set` in the output of `SHOW MASTER STATUS` on this server. Empty if GTIDs are not in use. See **GTID Sets** for more information.

• **Auto_Position**

  1 if GTID auto-positioning is in use for the channel, otherwise 0.

• **Replicate_Rewrite_DB**

  The **Replicate_Rewrite_DB** value displays any replication filtering rules that were specified. For example, if the following replication filter rule was set:

  ```sql
  CHANGE REPLICATION FILTER REPLICATE_REWRITE_DB=((db1,db2), (db3,db4));
  ```

  the **Replicate_Rewrite_DB** value displays:

  ```
  Replicate_Rewrite_DB: (db1,db2),(db3,db4)
  ```

  For more information, see **Section 13.4.2.2, “CHANGE REPLICATION FILTER Statement”**.

• **Channel_name**

  The replication channel which is being displayed. There is always a default replication channel, and more replication channels can be added. See **Section 17.2.2, “Replication Channels”** for more information.

• **Master_TLS_Version**

  The TLS version used on the source. For TLS version information, see **Section 6.3.2, “Encrypted Connection TLS Protocols and Ciphers”**.

• **Source_public_key_path**

  The path name to a file containing a replica-side copy of the public key required by the source for RSA key pair-based password exchange. The file must be in PEM format. This column applies to replicas that authenticate with the `sha256_password` or `caching_sha2_password` authentication plugin.

  If **Source_public_key_path** is given and specifies a valid public key file, it takes precedence over **Get_source_public_key**.

• **Get_source_public_key**
Whether to request from the source the public key required for RSA key pair-based password exchange. This column applies to replicas that authenticate with the `caching_sha2_password` authentication plugin. For that plugin, the source does not send the public key unless requested.

If `Source_public_key_path` is given and specifies a valid public key file, it takes precedence over `Get_source_public_key`.

- **Network_Namespace**

  The network namespace name; empty if the connection uses the default (global) namespace. For information about network namespaces, see Section 5.1.14, “Network Namespace Support”. This column was added in MySQL 8.0.22.

### 13.7.7.36 SHOW SLAVE | REPLICA STATUS Statement

```
SHOW {SLAVE | REPLICA} STATUS [FOR CHANNEL channel]
```

This statement provides status information on essential parameters of the replica threads. From MySQL 8.0.22, `SHOW SLAVE STATUS` is deprecated and the alias `SHOW REPLICA STATUS` should be used instead. The statement works in the same way as before, only the terminology used for the statement and its output has changed. Both versions of the statement update the same status variables when used. Please see the documentation for `SHOW REPLICA STATUS` for a description of the statement.

### 13.7.7.37 SHOW STATUS Statement

```
SHOW {[GLOBAL | SESSION]} STATUS [LIKE 'pattern' | WHERE expr]
```

`SHOW STATUS` provides server status information (see Section 5.1.10, “Server Status Variables”). This statement does not require any privilege. It requires only the ability to connect to the server.

Status variable information is also available from these sources:

- Performance Schema tables. See Section 27.12.15, “Performance Schema Status Variable Tables”.
- The `mysqladmin extended-status` command. See Section 4.5.2, “mysqladmin — A MySQL Server Administration Program”.

For `SHOW STATUS`, a `LIKE` clause, if present, indicates which variable names to match. A `WHERE` clause can be given to select rows using more general conditions, as discussed in Section 26.8, “Extensions to SHOW Statements”.

`SHOW STATUS` accepts an optional `GLOBAL` or `SESSION` variable scope modifier:

- With a `GLOBAL` modifier, the statement displays the global status values. A global status variable may represent status for some aspect of the server itself (for example, `Aborted_connects`), or the aggregated status over all connections to MySQL (for example, `Bytes_received` and `Bytes_sent`). If a variable has no global value, the session value is displayed.
- With a `SESSION` modifier, the statement displays the status variable values for the current connection. If a variable has no session value, the global value is displayed. `LOCAL` is a synonym for `SESSION`.
- If no modifier is present, the default is `SESSION`.

The scope for each status variable is listed at Section 5.1.10, “Server Status Variables”.

Each invocation of the `SHOW STATUS` statement uses an internal temporary table and increments the global `Created_tmp_tables` value.
Partial output is shown here. The list of names and values may differ for your server. The meaning of each variable is given in Section 5.1.10, “Server Status Variables”.

```
mysql> SHOW STATUS;
+--------------------------+------------+
| Variable_name            | Value      |
+--------------------------+------------+
| Aborted_clients          | 0          |
| Aborted_connects         | 0          |
| Bytes_received           | 155372598  |
| Bytes_sent               | 1176560426 |
| Connections              | 30023      |
| Created_tmp_disk_tables  | 0          |
| Created_tmp_tables       | 8340       |
| Created_tmp_files        | 60         |
| ...                      |            |
| Opened_tables            | 1          |
| Open_files               | 2          |
| Open_streams             | 0          |
| Opened_tables            | 44600      |
| Questions                | 2026873    |
| ...                      |            |
| Table_locks_immediate    | 1920382    |
| Table_locks_waited       | 0          |
| Threads_cached           | 0          |
| Threads_created          | 30022      |
| Threads_connected        | 1          |
| Threads_running          | 1          |
| Uptime                   | 80380      |
+--------------------------+------------+
```

With a `LIKE` clause, the statement displays only rows for those variables with names that match the pattern:

```
mysql> SHOW STATUS LIKE 'Key%';
+--------------------------+------------+
| Variable_name            | Value      |
+--------------------------+------------+
| Key_blocks_used          | 14955      |
| Key_read_requests        | 96854827   |
| Key_reads                | 162040     |
| Key_write_requests       | 7589728    |
| Key_writes               | 3813196    |
+--------------------------+------------+
```

### 13.7.7.38 SHOW TABLE STATUS Statement

```
SHOW TABLE STATUS
    [\{FROM | IN\} \{db_name\}]
    [LIKE \{pattern\} | WHERE expr]
```

`SHOW TABLE STATUS` works like `SHOW TABLES`, but provides a lot of information about each non-TEMPORARY table. You can also get this list using the `mysqlshow --status db_name` command. The `LIKE` clause, if present, indicates which table names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in Section 26.8, “Extensions to SHOW Statements”.

This statement also displays information about views.

`SHOW TABLE STATUS` output has these columns:

- **Name**

  The name of the table.
SHOW Statements

- **Engine**

  For partitioned tables, Engine shows the name of the storage engine used by all partitions.

- **Version**
  This column is unused. With the removal of .frm files in MySQL 8.0, this column now reports a hardcoded value of 10, which is the last .frm file version used in MySQL 5.7.

- **Row_format**
  The row-storage format (Fixed, Dynamic, Compressed, Redundant, Compact). For MyISAM tables, Dynamic corresponds to what myisamchk -dvv reports as Packed.

- **Rows**
  The number of rows. Some storage engines, such as MyISAM, store the exact count. For other storage engines, such as InnoDB, this value is an approximation, and may vary from the actual value by as much as 40% to 50%. In such cases, use SELECT COUNT(*) to obtain an accurate count.

  The Rows value is NULL for INFORMATION_SCHEMA tables.

  For InnoDB tables, the row count is only a rough estimate used in SQL optimization. (This is also true if the InnoDB table is partitioned.)

- **Avg_row_length**
  The average row length.

- **Data_length**
  For MyISAM, Data_length is the length of the data file, in bytes.

  For InnoDB, Data_length is the approximate amount of space allocated for the clustered index, in bytes. Specifically, it is the clustered index size, in pages, multiplied by the InnoDB page size.

  Refer to the notes at the end of this section for information regarding other storage engines.

- **Max_data_length**
  For MyISAM, Max_data_length is maximum length of the data file. This is the total number of bytes of data that can be stored in the table, given the data pointer size used.

  Unused for InnoDB.

  Refer to the notes at the end of this section for information regarding other storage engines.

- **Index_length**
  For MyISAM, Index_length is the length of the index file, in bytes.

  For InnoDB, Index_length is the approximate amount of space allocated for non-clustered indexes, in bytes. Specifically, it is the sum of non-clustered index sizes, in pages, multiplied by the InnoDB page size.

  Refer to the notes at the end of this section for information regarding other storage engines.
SHOW Statements

- **Data_free**
  
  The number of allocated but unused bytes.

  *InnoDB* tables report the free space of the tablespace to which the table belongs. For a table located in the shared tablespace, this is the free space of the shared tablespace. If you are using multiple tablespaces and the table has its own tablespace, the free space is for only that table. Free space means the number of bytes in completely free extents minus a safety margin. Even if free space displays as 0, it may be possible to insert rows as long as new extents need not be allocated.

  For NDB Cluster, **Data_free** shows the space allocated on disk for, but not used by, a Disk Data table or fragment on disk. (In-memory data resource usage is reported by the **Data_length** column.)

  For partitioned tables, this value is only an estimate and may not be absolutely correct. A more accurate method of obtaining this information in such cases is to query the **INFORMATION_SCHEMA PARTITIONS** table, as shown in this example:

  ```
  SELECT SUM(DATA_FREE)
  FROM INFORMATION_SCHEMA.PARTITIONS
  WHERE TABLE_SCHEMA = 'mydb'
  AND   TABLE_NAME   = 'mytable';
  ```

  For more information, see Section 26.3.21, “The INFORMATION_SCHEMA PARTITIONS Table”.

- **Auto_increment**
  
  The next **AUTO_INCREMENT** value.

- **Create_time**
  
  When the table was created.

- **Update_time**
  
  When the data file was last updated. For some storage engines, this value is **NULL**. For example, *InnoDB* stores multiple tables in its **system tablespace** and the data file timestamp does not apply. Even with **file-per-table** mode with each *InnoDB* table in a separate `.ibd` file, **change buffering** can delay the write to the data file, so the file modification time is different from the time of the last insert, update, or delete. For **MyISAM**, the data file timestamp is used; however, on Windows the timestamp is not updated by updates, so the value is inaccurate.

  **Update_time** displays a timestamp value for the last **UPDATE**, **INSERT**, or **DELETE** performed on *InnoDB* tables that are not partitioned. For MVCC, the timestamp value reflects the **COMMIT** time, which is considered the last update time. Timestamps are not persisted when the server is restarted or when the table is evicted from the **InnoDB** data dictionary cache.

- **Check_time**
  
  When the table was last checked. Not all storage engines update this time, in which case, the value is always **NULL**.

  For partitioned **InnoDB** tables, **Check_time** is always **NULL**.

- **Collation**
  
  The table default collation. The output does not explicitly list the table default character set, but the collation name begins with the character set name.
SHOW Statements

- **Checksum**
  
The live checksum value, if any.

- **Create_options**
  
  Extra options used with `CREATE TABLE`.

  `Create_options` shows partitioned for a partitioned table.

Prior to MySQL 8.0.16, `Create_options` shows the `ENCRYPTION` clause specified for tables created in file-per-table tablespaces. As of MySQL 8.0.16, it shows the encryption clause for file-per-table tablespaces if the table is encrypted or if the specified encryption differs from the schema encryption. The encryption clause is not shown for tables created in general tablespaces. To identify encrypted file-per-table and general tablespaces, query the `INNODB_TABLESPACES ENCRYPTION` column.

When creating a table with strict mode disabled, the storage engine's default row format is used if the specified row format is not supported. The actual row format of the table is reported in the `Row_format` column. `Create_options` shows the row format that was specified in the `CREATE TABLE` statement.

When altering the storage engine of a table, table options that are not applicable to the new storage engine are retained in the table definition to enable reverting the table with its previously defined options to the original storage engine, if necessary. `Create_options` may show retained options.

- **Comment**
  
The comment used when creating the table (or information as to why MySQL could not access the table information).

**Notes**

- For InnoDB tables, `SHOW TABLE STATUS` does not give accurate statistics except for the physical size reserved by the table. The row count is only a rough estimate used in SQL optimization.

- For NDB tables, the output of this statement shows appropriate values for the `Avg_row_length` and `Data_length` columns, with the exception that `BLOB` columns are not taken into account.

- For NDB tables, `Data_length` includes data stored in main memory only; the `Max_data_length` and `Data_free` columns apply to Disk Data.

- For NDB Cluster Disk Data tables, `Max_data_length` shows the space allocated for the disk part of a Disk Data table or fragment. (In-memory data resource usage is reported by the `Data_length` column.)

- For MEMORY tables, the `Data_length`, `Max_data_length`, and `Index_length` values approximate the actual amount of allocated memory. The allocation algorithm reserves memory in large amounts to reduce the number of allocation operations.

- For views, most columns displayed by `SHOW TABLE STATUS` are 0 or `NULL` except that `Name` indicates the view name, `Create_time` indicates the creation time, and `Comment` says `VIEW`.

  Table information is also available from the `INFORMATION_SCHEMA TABLES` table. See Section 26.3.38, “The INFORMATION_SCHEMA TABLES Table”.

### 13.7.7.39 SHOW TABLES Statement

```sql
SHOW [EXTENDED] [FULL] TABLES
   [ [FROM | IN] db_name]
```

3226
SHOW Statements

SHOW TABLES lists the non-TEMPORARY tables in a given database. You can also get this list using the mysqlshow `db_name` command. The LIKE clause, if present, indicates which table names to match. The WHERE clause can be given to select rows using more general conditions, as discussed in Section 26.8, “Extensions to SHOW Statements”.

Matching performed by the LIKE clause is dependent on the setting of the lower_case_table_names system variable.

The optional EXTENDED modifier causes SHOW TABLES to list hidden tables created by failed ALTER TABLE statements. These temporary tables have names beginning with `#sql` and can be dropped using DROP TABLE.

This statement also lists any views in the database. The optional FULL modifier causes SHOW TABLES to display a second output column with values of BASE TABLE for a table, VIEW for a view, or SYSTEM VIEW for an INFORMATION_SCHEMA table.

If you have no privileges for a base table or view, it does not show up in the output from SHOW TABLES or mysqlshow db_name.

Table information is also available from the INFORMATION_SCHEMA TABLES table. See Section 26.3.38, “The INFORMATION_SCHEMA TABLES Table”.

13.7.7.40 SHOW TRIGGERS Statement

SHOW TRIGGERS

SHOW TRIGGERS lists the triggers currently defined for tables in a database (the default database unless a FROM clause is given). This statement returns results only for databases and tables for which you have the TRIGGER privilege. The LIKE clause, if present, indicates which table names (not trigger names) to match and causes the statement to display triggers for those tables. The WHERE clause can be given to select rows using more general conditions, as discussed in Section 26.8, “Extensions to SHOW Statements”.

For the `ins_sum` trigger defined in Section 25.3, “Using Triggers”, the output of SHOW TRIGGERS is as shown here:

```
mysql> SHOW TRIGGERS LIKE 'acc%'\G
*************************** 1. row ***************************
Trigger: ins_sum
   Event: INSERT
   Table: account
Statement: SET @sum = @sum + NEW.amount
   Timing: BEFORE
Created: 2018-08-08 10:10:12.61
sql_mode: ONLY_FULL_GROUP_BY,STRICT_TRANS_TABLES,
          NO_ZERO_IN_DATE,NO_ZERO_DATE,
          ERROR_FOR_DIVISION_BY_ZERO,
          NO_ENGINE_SUBSTITUTION
Definer: me@localhost
character_set_client: utf8mb4
collation_connection: utf8mb4_0900_ai_ci
Database Collation: utf8mb4_0900_ai_ci
```

SHOW TRIGGERS output has these columns:

- Trigger
SHOW Statements

The name of the trigger.

• **Event**
  The trigger event. This is the type of operation on the associated table for which the trigger activates. The value is **INSERT** (a row was inserted), **DELETE** (a row was deleted), or **UPDATE** (a row was modified).

• **Table**
  The table for which the trigger is defined.

• **Statement**
  The trigger body; that is, the statement executed when the trigger activates.

• **Timing**
  Whether the trigger activates before or after the triggering event. The value is **BEFORE** or **AFTER**.

• **Created**
  The date and time when the trigger was created. This is a **TIMESTAMP(2)** value (with a fractional part in hundredths of seconds) for triggers.

• **sql_mode**
  The SQL mode in effect when the trigger was created, and under which the trigger executes. For the permitted values, see Section 5.1.11, “Server SQL Modes”.

• **Definer**
  The account of the user who created the trigger, in **'user_name'@'host_name'** format.

• **character_set_client**
  The session value of the **character_set_client** system variable when the trigger was created.

• **collation_connection**
  The session value of the **collation_connection** system variable when the trigger was created.

• **Database Collation**
  The collation of the database with which the trigger is associated.

Trigger information is also available from the **INFORMATION_SCHEMA TRIGGERS** table. See Section 26.3.45, “The INFORMATION_SCHEMA TRIGGERS Table”.

13.7.7.41 SHOW VARIABLES Statement

```
SHOW [GLOBAL | SESSION] VARIABLES
    [LIKE 'pattern' | WHERE expr]
```

SHOW VARIABLES shows the values of MySQL system variables (see Section 5.1.8, “Server System Variables”). This statement does not require any privilege. It requires only the ability to connect to the server.
System variable information is also available from these sources:

- The `mysqladmin variables` command. See Section 4.5.2, “mysqladmin — A MySQL Server Administration Program”.

For `SHOW VARIABLES`, a `LIKE` clause, if present, indicates which variable names to match. A `WHERE` clause can be given to select rows using more general conditions, as discussed in Section 26.8, “Extensions to SHOW Statements”.

`SHOW VARIABLES` accepts an optional `GLOBAL` or `SESSION` variable scope modifier:

- With a `GLOBAL` modifier, the statement displays global system variable values. These are the values used to initialize the corresponding session variables for new connections to MySQL. If a variable has no global value, no value is displayed.
- With a `SESSION` modifier, the statement displays the system variable values that are in effect for the current connection. If a variable has no session value, the global value is displayed. `LOCAL` is a synonym for `SESSION`.
- If no modifier is present, the default is `SESSION`.

The scope for each system variable is listed at Section 5.1.8, “Server System Variables”.

`SHOW VARIABLES` is subject to a version-dependent display-width limit. For variables with very long values that are not completely displayed, use `SELECT` as a workaround. For example:

```
SELECT @@GLOBAL.innodb_data_file_path;
```

Most system variables can be set at server startup (read-only variables such as `version_comment` are exceptions). Many can be changed at runtime with the `SET` statement. See Section 5.1.9, “Using System Variables”, and Section 13.7.6.1, “SET Syntax for Variable Assignment”.

Partial output is shown here. The list of names and values may differ for your server. Section 5.1.8, “Server System Variables”, describes the meaning of each variable, and Section 5.1.1, “Configuring the Server”, provides information about tuning them.

```
mysql> SHOW VARIABLES;
+--------------------------------------------+------------------------------+
| Variable_name                              | Value                        |
+--------------------------------------------+------------------------------+
| activate_all_roles_on_login                | OFF                          |
| auto_generate_certs                        | ON                           |
| auto_increment_increment                   | 1                            |
| auto_increment_offset                      | 1                            |
| autocommit                                 | ON                           |
| automatic_sp_privileges                    | ON                           |
| avoid_temporal_upgrade                     | OFF                          |
| back_log                                   | 151                          |
| basedir                                    | /usr/                        |
| big_tables                                 | OFF                          |
| bind_address                               | *                            |
| binlog_cache_size                          | 32768                        |
| binlog_checksum                            | CRC32                        |
| binlog_direct_non_transactional_updates    | OFF                          |
| binlog_error_action                        | ABORT_SERVER                 |
| binlog_expire_logs_seconds                 | 2592000                      |
| binlog_format                              | ROW                          |
| binlog_group_commit_sync_delay             | 0                            |
| binlog_group_commit_sync_no_delay_count    | 0                            |
+--------------------------------------------+------------------------------+
```
SHOW Statements

With a **LIKE** clause, the statement displays only rows for those variables with names that match the pattern. To obtain the row for a specific variable, use a **LIKE** clause as shown:

```sql
SHOW VARIABLES LIKE 'max_join_size';
SHOW SESSION VARIABLES LIKE 'max_join_size';
```

To get a list of variables whose name match a pattern, use the `%` wildcard character in a **LIKE** clause:

```sql
SHOW VARIABLES LIKE '%size%';
SHOW SESSION VARIABLES LIKE '%size%';
SHOW GLOBAL VARIABLES LIKE '%size%';
```
Wildcard characters can be used in any position within the pattern to be matched. Strictly speaking, because _ is a wildcard that matches any single character, you should escape it as \_ to match it literally. In practice, this is rarely necessary.

### 13.7.7.42 SHOW WARNINGS Statement

`SHOW WARNINGS [LIMIT [offset,] row_count]`  
`SHOW COUNT(*) WARNINGS`

`SHOW WARNINGS` is a diagnostic statement that displays information about the conditions (errors, warnings, and notes) resulting from executing a statement in the current session. Warnings are generated for DML statements such as `INSERT`, `UPDATE`, and `LOAD DATA` as well as DDL statements such as `CREATE TABLE` and `ALTER TABLE`.

The `LIMIT` clause has the same syntax as for the `SELECT` statement. See Section 13.2.13, “SELECT Statement”.

`SHOW WARNINGS` is also used following `EXPLAIN`, to display the extended information generated by `EXPLAIN`. See Section 8.8.3, “Extended EXPLAIN Output Format”.

`SHOW WARNINGS` displays information about the conditions resulting from execution of the most recent nondiagnostic statement in the current session. If the most recent statement resulted in an error during parsing, `SHOW WARNINGS` shows the resulting conditions, regardless of statement type (diagnostic or nondiagnostic).

The `SHOW COUNT(*) WARNINGS` diagnostic statement displays the total number of errors, warnings, and notes. You can also retrieve this number from the `warning_count` system variable:

```
SHOW COUNT(*) WARNINGS;
SELECT @@warning_count;
```

A difference in these statements is that the first is a diagnostic statement that does not clear the message list. The second, because it is a `SELECT` statement is considered nondiagnostic and does clear the message list.

A related diagnostic statement, `SHOW ERRORS`, shows only error conditions (it excludes warnings and notes), and `SHOW COUNT(*) ERRORS` statement displays the total number of errors. See Section 13.7.7.17, “SHOW ERRORS Statement”. `GET DIAGNOSTICS` can be used to examine information for individual conditions. See Section 13.6.7.3, “GET DIAGNOSTICS Statement”.

Here is a simple example that shows data-conversion warnings for `INSERT`. The example assumes that strict SQL mode is disabled. With strict mode enabled, the warnings would become errors and terminate the `INSERT`.

```
mysql> CREATE TABLE t1 (a TINYINT NOT NULL, b CHAR(4));
Query OK, 0 rows affected (0.05 sec)

mysql> INSERT INTO t1 VALUES(10,'mysql'), (NULL,'test'), (300,'xyz');
Query OK, 3 rows affected, 3 warnings (0.00 sec)
Records: 3  Duplicates: 0  Warnings: 3

mysql> SHOW WARNINGS\G
*************************** 1. row ***************************
Level: Warning
Code: 1265
Message: Data truncated for column 'b' at row 1

*************************** 2. row ***************************
Level: Warning
Code: 1048
Message: Column 'a' cannot be null

*************************** 3. row ***************************
```

3231
The `max_error_count` system variable controls the maximum number of error, warning, and note messages for which the server stores information, and thus the number of messages that `SHOW WARNINGS` displays. To change the number of messages the server can store, change the value of `max_error_count`.

`max_error_count` controls only how many messages are stored, not how many are counted. The value of `warning_count` is not limited by `max_error_count`, even if the number of messages generated exceeds `max_error_count`. The following example demonstrates this. The `ALTER TABLE` statement produces three warning messages (strict SQL mode is disabled for the example to prevent an error from occurring after a single conversion issue). Only one message is stored and displayed because `max_error_count` has been set to 1, but all three are counted (as shown by the value of `warning_count`):

```sql
mysql> SHOW VARIABLES LIKE 'max_error_count';
+-----------------+-------+
| Variable_name   | Value |
+-----------------+-------+
| max_error_count | 1024  |
+-----------------+-------+
1 row in set (0.00 sec)
mysql> SET max_error_count=1, sql_mode = '';
Query OK, 0 rows affected (0.00 sec)
mysql> ALTER TABLE t1 MODIFY b CHAR;
Query OK, 3 rows affected, 3 warnings (0.00 sec)
Records: 3  Duplicates: 0  Warnings: 3
mysql> SHOW WARNINGS;
+---------+------+----------------------------------------+
| Level   | Code | Message                                |
+---------+------+----------------------------------------+
| Warning | 1263 | Data truncated for column 'b' at row 1 |
+---------+------+----------------------------------------+
1 row in set (0.00 sec)
mysql> SELECT @@warning_count;
+-----------------+
| @@warning_count |
+-----------------+
|               3  |
+-----------------+
```

To disable message storage, set `max_error_count` to 0. In this case, `warning_count` still indicates how many warnings occurred, but messages are not stored and cannot be displayed.

The `sql_notes` system variable controls whether note messages increment `warning_count` and whether the server stores them. By default, `sql_notes` is 1, but if set to 0, notes do not increment `warning_count` and the server does not store them:

```sql
mysql> SET sql_notes = 1;
mysql> DROP TABLE IF EXISTS test.no_such_table;
Query OK, 0 rows affected, 1 warning (0.00 sec)
mysql> SHOW WARNINGS;
+---------+------+----------------------------------------+
| Level   | Code | Message                                |
+---------+------+----------------------------------------+
| Warning | 3232 |                                      |
+---------+------+----------------------------------------+
```
The MySQL server sends to each client a count indicating the total number of errors, warnings, and notes resulting from the most recent statement executed by that client. From the C API, this value can be obtained by calling mysql_warning_count(). See mysql_warning_count().

In the mysql client, you can enable and disable automatic warnings display using the warnings and nowarning commands, respectively, or their shortcuts, \W and \w (see Section 4.5.1.2, "mysql Client Commands"). For example:

```
mysql> \W
Show warnings enabled.
mysql> SELECT 1/0;
+------+
| 1/0  |
+------+
| NULL |
+------+
1 row in set, 1 warning (0.03 sec)
Warning (Code 1365): Division by 0
mysql> \w
Show warnings disabled.
```

### 13.7.8 Other Administrative Statements

#### 13.7.8.1 BINLOG Statement

```
BINLOG 'str'
```

**BINLOG** is an internal-use statement. It is generated by the mysqlbinlog program as the printable representation of certain events in binary log files. (See Section 4.6.9, "mysqlbinlog — Utility for Processing Binary Log Files"). The 'str' value is a base 64-encoded string the that server decodes to determine the data change indicated by the corresponding event.

To execute BINLOG statements when applying mysqlbinlog output, a user account requires the BINLOG_ADMIN privilege (or the deprecated SUPER privilege), or the REPLICATION_APPLIER privilege plus the appropriate privileges to execute each log event.

This statement can execute only format description events and row events.

#### 13.7.8.2 CACHE INDEX Statement

```
CACHE INDEX {
    tbl_index_list [, tbl_index_list] ...
    | tbl_name PARTITION (partition_list)
} IN key_cache_name

tbl_index_list:
    tbl_name [[INDEX|KEY] (index_name[, index_name] ...)]

partition_list: {
    partition_name[, partition_name] ...
```
The `CACHE INDEX` statement assigns table indexes to a specific key cache. It applies only to MyISAM tables, including partitioned MyISAM tables. After the indexes have been assigned, they can be preloaded into the cache if desired with `LOAD INDEX INTO CACHE`.

The following statement assigns indexes from the tables `t1`, `t2`, and `t3` to the key cache named `hot_cache`:

```
mysql> CACHE INDEX t1, t2, t3 IN hot_cache;
```

<table>
<thead>
<tr>
<th>Table</th>
<th>Op</th>
<th>Msg_type</th>
<th>Msg_text</th>
</tr>
</thead>
<tbody>
<tr>
<td>test.t1</td>
<td>assign_to_keycache</td>
<td>status</td>
<td>OK</td>
</tr>
<tr>
<td>test.t2</td>
<td>assign_to_keycache</td>
<td>status</td>
<td>OK</td>
</tr>
<tr>
<td>test.t3</td>
<td>assign_to_keycache</td>
<td>status</td>
<td>OK</td>
</tr>
</tbody>
</table>

The syntax of `CACHE INDEX` enables you to specify that only particular indexes from a table should be assigned to the cache. However, the implementation assigns all the table's indexes to the cache, so there is no reason to specify anything other than the table name.

The key cache referred to in a `CACHE INDEX` statement can be created by setting its size with a parameter setting statement or in the server parameter settings. For example:

```
SET GLOBAL keycachel.key_buffer_size=128*1024;
```

Key cache parameters are accessed as members of a structured system variable. See Section 5.1.9.5, “Structured System Variables”.

A key cache must exist before you assign indexes to it, or an error occurs:

```
mysql> CACHE INDEX t1 IN non_existent_cache;
ERROR 1284 (HY000): Unknown key cache 'non_existent_cache'
```

By default, table indexes are assigned to the main (default) key cache created at the server startup. When a key cache is destroyed, all indexes assigned to it are reassigned to the default key cache.

Index assignment affects the server globally: If one client assigns an index to a given cache, this cache is used for all queries involving the index, no matter which client issues the queries.

`CACHE INDEX` is supported for partitioned MyISAM tables. You can assign one or more indexes for one, several, or all partitions to a given key cache. For example, you can do the following:

```
CREATE TABLE pt (c1 INT, c2 VARCHAR(50), INDEX i(c1))
    ENGINE=MyISAM
    PARTITION BY HASH(c1)
    PARTITIONS 4;

SET GLOBAL kc_fast.key_buffer_size = 128 * 1024;
SET GLOBAL kc_slow.key_buffer_size = 128 * 1024;

CACHE INDEX pt PARTITION (p0) IN kc_fast;
CACHE INDEX pt PARTITION (p1, p3) IN kc_slow;
```

The previous set of statements performs the following actions:

- Creates a partitioned table with 4 partitions; these partitions are automatically named `p0`, ..., `p3`; this table has an index named `i` on column `c1`.
- Creates 2 key caches named `kc_fast` and `kc_slow`
Other Administrative Statements

- Assigns the index for partition \( p_0 \) to the \( kc_{\text{fast}} \) key cache and the index for partitions \( p_1 \) and \( p_3 \) to the \( kc_{\text{slow}} \) key cache; the index for the remaining partition (\( p_2 \)) uses the server's default key cache.

If you wish instead to assign the indexes for all partitions in table \( pt \) to a single key cache named \( kc_{\text{all}} \), you can use either of the following two statements:

```sql
CACHE INDEX pt PARTITION (ALL) IN kc_all;
CACHE INDEX pt IN kc_all;
```

The two statements just shown are equivalent, and issuing either one has exactly the same effect. In other words, if you wish to assign indexes for all partitions of a partitioned table to the same key cache, the \( \text{PARTITION (ALL)} \) clause is optional.

When assigning indexes for multiple partitions to a key cache, the partitions need not be contiguous, and you need not list their names in any particular order. Indexes for any partitions not explicitly assigned to a key cache automatically use the server default key cache.

Index preloading is also supported for partitioned MyISAM tables. For more information, see Section 13.7.8.5, “LOAD INDEX INTO CACHE Statement”.

### 13.7.8.3 FLUSH Statement

```sql
FLUSH [NO_WRITE_TO_BINLOG | LOCAL] {  
  flush_option [, flush_option] ...  
  | tables_option  
}  

flush_option: {  
  BINARY LOGS  
  ENGINE LOGS  
  ERROR LOGS  
  GENERAL LOGS  
  HOSTS  
  LOGS  
  PRIVILEGES  
  OPTIMIZER_COSTS  
  RELAY LOGS [FOR CHANNEL channel]  
  SLOW LOGS  
  STATUS  
  USER_RESOURCES  
}  

tables_option: {  
  TABLES  
  TABLES tbl_name [, tbl_name] ...  
  TABLES WITH READ LOCK  
  TABLES tbl_name [, tbl_name] ... WITH READ LOCK  
  TABLES tbl_name [, tbl_name] ... FOR EXPORT  
}
```

The \( \text{FLUSH} \) statement has several variant forms that clear or reload various internal caches, flush tables, or acquire locks. Each \( \text{FLUSH} \) operation requires the privileges indicated in its description.

**Note**

It is not possible to issue \( \text{FLUSH} \) statements within stored functions or triggers. However, you may use \( \text{FLUSH} \) in stored procedures, so long as these are not called from stored functions or triggers. See Section 25.8, “Restrictions on Stored Programs”.

By default, the server writes \( \text{FLUSH} \) statements to the binary log so that they replicate to replicas. To suppress logging, specify the optional \( \text{NO_WRITE_TO_BINLOG} \) keyword or its alias \( \text{LOCAL} \).
Other Administrative Statements

Note

FLUSH LOGS, FLUSH BINARY LOGS, FLUSH TABLES WITH READ LOCK (with or without a table list), and FLUSH TABLES tbl_name ... FOR EXPORT are not written to the binary log in any case because they would cause problems if replicated to a replica.

The FLUSH statement causes an implicit commit. See Section 13.3.3, “Statements That Cause an Implicit Commit”.

The mysqladmin utility provides a command-line interface to some flush operations, using commands such as flush-hosts, flush-logs, flush-privileges, flush-status, and flush-tables. See Section 4.5.2, “mysqladmin — A MySQL Server Administration Program”.

Sending a SIGHUP or SIGUSR1 signal to the server causes several flush operations to occur that are similar to various forms of the FLUSH statement. Signals can be sent by the root system account or the system account that owns the server process. This enables the flush operations to be performed without having to connect to the server, which requires a MySQL account that has privileges sufficient for those operations. See Section 4.10, “Unix Signal Handling in MySQL”.

The RESET statement is similar to FLUSH. See Section 13.7.8.6, “RESET Statement”, for information about using RESET with replication.

The following list describes the permitted FLUSH statement flush_option values. For descriptions of the permitted tables_option values, see FLUSH TABLES Syntax.

- **FLUSH BINARY LOGS**
  Closes and reopens any binary log file to which the server is writing. If binary logging is enabled, the sequence number of the binary log file is incremented by one relative to the previous file.
  
  This operation requires the RELOAD privilege.

- **FLUSH ENGINE LOGS**
  Closes and reopens any flushable logs for installed storage engines. This causes InnoDB to flush its logs to disk.
  
  This operation requires the RELOAD privilege.

- **FLUSH ERROR LOGS**
  Closes and reopens any error log file to which the server is writing.
  
  This operation requires the RELOAD privilege.

- **FLUSH GENERAL LOGS**
  Closes and reopens any general query log file to which the server is writing.
  
  This operation requires the RELOAD privilege.

  This operation has no effect on tables used for the general query log (see Section 5.4.1, “Selecting General Query Log and Slow Query Log Output Destinations”).

- **FLUSH HOSTS**
  Empties the host cache and the Performance Schema host_cache table that exposes the cache contents, and unblocks any blocked hosts.
This operation requires the `RELOAD` privilege.

For information about why host cache flushing might be advisable or desirable, see Section 5.1.12.3, “DNS Lookups and the Host Cache”.

Note

`FLUSH HOSTS` is deprecated as of MySQL 8.0.23; expect it to be removed in a future MySQL release. Instead, truncate the Performance Schema `host_cache` table:

```
TRUNCATE TABLE performance_schema.host_cache;
```

The `TRUNCATE TABLE` operation requires the `DROP` privilege for the table rather than the `RELOAD` privilege. You should be aware that the `TRUNCATE TABLE` statement is not written to the binary log. To obtain the same behavior from `FLUSH HOSTS`, specify `NO_WRITE_TO_BINLOG` or `LOCAL` as part of the statement.

• **FLUSH LOGS**

Closes and reopens any log file to which the server is writing.

This operation requires the `RELOAD` privilege.

The effect of this operation is equivalent to the combined effects of these operations:

- `FLUSH BINARY LOGS`
- `FLUSH ENGINE LOGS`
- `FLUSH ERROR LOGS`
- `FLUSH GENERAL LOGS`
- `FLUSH RELAY LOGS`
- `FLUSH SLOW LOGS`

• **FLUSH OPTIMIZER_COSTS**

Re-reads the cost model tables so that the optimizer starts using the current cost estimates stored in them.

This operation requires the `FLUSH_OPTIMIZER_COSTS` or `RELOAD` privilege.

The server writes a warning to the error log for any unrecognized cost model table entries. For information about these tables, see Section 8.9.5, “The Optimizer Cost Model”. This operation affects only sessions that begin subsequent to the flush. Existing sessions continue to use the cost estimates that were current when they began.

• **FLUSH PRIVILEGES**

Re-reads the privileges from the grant tables in the `mysql` system schema. As part of this operation, the server reads the `global_grants` table containing dynamic privilege assignments and registers any unregistered privileges found there.

Reloading the grant tables is necessary to enable updates to MySQL privileges and users only if you make such changes directly to the grant tables; it is not needed for account management statements such as `GRANT` or `REVOKE`, which take effect immediately. See Section 6.2.13, “When Privilege Changes Take Effect”, for more information.

This operation requires the `RELOAD` privilege.
If the `--skip-grant-tables` option was specified at server startup to disable the MySQL privilege system, `FLUSH PRIVILEGES` provides a way to enable the privilege system at runtime.

Resets failed-login tracking (or enables it if the server was started with `--skip-grant-tables`) and unlocks any temporarily locked accounts. See Section 6.2.15, “Password Management”.

Frees memory cached by the server as a result of `GRANT`, `CREATE USER`, `CREATE SERVER`, and `INSTALL PLUGIN` statements. This memory is not released by the corresponding `REVOKE`, `DROP USER`, `DROP SERVER`, and `UNINSTALL PLUGIN` statements, so for a server that executes many instances of the statements that cause caching, there is an increase in cached memory use unless it is freed with `FLUSH PRIVILEGES`.

Clears the in-memory cache used by the `caching_sha2_password` authentication plugin. See Cache Operation for SHA-2 Pluggable Authentication.

- **FLUSH RELAY LOGS [FOR CHANNEL channel]**

  Closes and reopens any relay log file to which the server is writing. If relay logging is enabled, the sequence number of the relay log file is incremented by one relative to the previous file.

  This operation requires the `RELOAD` privilege.

  The `FOR CHANNEL channel` clause enables you to name which replication channel the operation applies to. Execute `FLUSH RELAY LOGS FOR CHANNEL channel` to flush the relay log for a specific replication channel. If no channel is named and no extra replication channels exist, the operation applies to the default channel. If no channel is named and multiple replication channels exist, the operation applies to all replication channels. For more information, see Section 17.2.2, “Replication Channels”.

- **FLUSH SLOW LOGS**

  Closes and reopens any slow query log file to which the server is writing.

  This operation requires the `RELOAD` privilege.

  This operation has no effect on tables used for the slow query log (see Section 5.4.1, “Selecting General Query Log and Slow Query Log Output Destinations”).

- **FLUSH STATUS**

  Flushes status indicators.

  This operation adds the current thread's session status variable values to the global values and resets the session values to zero. Some global variables may be reset to zero as well. It also resets the counters for key caches (default and named) to zero and sets `Max_used_connections` to the current number of open connections. This information may be of use when debugging a query. See Section 1.5, “How to Report Bugs or Problems”.

  `FLUSH STATUS` is unaffected by `read_only` or `super_read_only`, and is always written to the binary log.

  This operation requires the `FLUSH_STATUS` or `RELOAD` privilege.

- **FLUSH USER_RESOURCES**

  Resets all per-hour user resource indicators to zero.

  This operation requires the `FLUSH_USER_RESOURCES` or `RELOAD` privilege.
Resetting resource indicators enables clients that have reached their hourly connection, query, or update limits to resume activity immediately. `FLUSH USER_RESOURCES` does not apply to the limit on maximum simultaneous connections that is controlled by the `max_user_connections` system variable. See Section 6.2.21, “Setting Account Resource Limits”.

**FLUSH TABLES Syntax**

`FLUSH TABLES` flushes tables, and, depending on the variant used, acquires locks. Any `TABLES` variant used in a `FLUSH` statement must be the only option used. `FLUSH TABLE` is a synonym for `FLUSH TABLES`.

**Note**

The descriptions here that indicate tables are flushed by closing them apply differently for InnoDB, which flushes table contents to disk but leaves them open. This still permits table files to be copied while the tables are open, as long as other activity does not modify them.

- **FLUSH TABLES**

  Closes all open tables, forces all tables in use to be closed, and flushes the prepared statement cache.

  This operation requires the `FLUSH_TABLES` or `RELOAD` privilege.

  For information about prepared statement caching, see Section 8.10.3, “Caching of Prepared Statements and Stored Programs”.

  `FLUSH TABLES` is not permitted when there is an active `LOCK TABLES ... READ`. To flush and lock tables, use `FLUSH TABLES tbl_name ... WITH READ LOCK` instead.

- **FLUSH TABLES tbl_name [, tbl_name] ...**

  With a list of one or more comma-separated table names, this operation is like `FLUSH TABLES` with no names except that the server flushes only the named tables. If a named table does not exist, no error occurs.

  This operation requires the `FLUSH_TABLES` or `RELOAD` privilege.

- **FLUSH TABLES WITH READ LOCK**

  Closes all open tables and locks all tables for all databases with a global read lock.

  This operation requires the `FLUSH_TABLES` or `RELOAD` privilege.

  This operation is a very convenient way to get backups if you have a file system such as Veritas or ZFS that can take snapshots in time. Use `UNLOCK TABLES` to release the lock.

  `FLUSH TABLES WITH READ LOCK` acquires a global read lock rather than table locks, so it is not subject to the same behavior as `LOCK TABLES` and `UNLOCK TABLES` with respect to table locking and implicit commits:

  - `UNLOCK TABLES` implicitly commits any active transaction only if any tables currently have been locked with `LOCK TABLES`. The commit does not occur for `UNLOCK TABLES` following `FLUSH TABLES WITH READ LOCK` because the latter statement does not acquire table locks.
Other Administrative Statements

- Beginning a transaction causes table locks acquired with `LOCK TABLES` to be released, as though you had executed `UNLOCK TABLES`. Beginning a transaction does not release a global read lock acquired with `FLUSH TABLES WITH READ LOCK`.

`FLUSH TABLES WITH READ LOCK` does not prevent the server from inserting rows into the log tables (see Section 5.4.1, “Selecting General Query Log and Slow Query Log Output Destinations”).

- `FLUSH TABLES tbl_name [, tbl_name] ... WITH READ LOCK`

Flushes and acquires read locks for the named tables.

This operation requires the `FLUSH_TABLES` or `RELOAD` privilege. Because it acquires table locks, it also requires the `LOCK TABLES` privilege for each table.

The operation first acquires exclusive metadata locks for the tables, so it waits for transactions that have those tables open to complete. Then the operation flushes the tables from the table cache, reopens the tables, acquires table locks (like `LOCK TABLES ... READ`), and downgrades the metadata locks from exclusive to shared. After the operation acquires locks and downgrades the metadata locks, other sessions can read but not modify the tables.

This operation applies only to existing base (non-TEMPORARY) tables. If a name refers to a base table, that table is used. If it refers to a TEMPORARY table, it is ignored. If a name applies to a view, an `ER_WRONG_OBJECT` error occurs. Otherwise, an `ER_NO_SUCH_TABLE` error occurs.

Use `UNLOCK TABLES` to release the locks, `LOCK TABLES` to release the locks and acquire other locks, or `START TRANSACTION` to release the locks and begin a new transaction.

This `FLUSH TABLES` variant enables tables to be flushed and locked in a single operation. It provides a workaround for the restriction that `FLUSH TABLES` is not permitted when there is an active `LOCK TABLES ... READ`.

This operation does not perform an implicit `UNLOCK TABLES`, so an error results if you perform the operation while there is any active `LOCK TABLES` or use it a second time without first releasing the locks acquired.

If a flushed table was opened with `HANDLER`, the handler is implicitly flushed and loses its position.

- `FLUSH TABLES tbl_name [, tbl_name] ... FOR EXPORT`

This `FLUSH TABLES` variant applies to InnoDB tables. It ensures that changes to the named tables have been flushed to disk so that binary table copies can be made while the server is running.

This operation requires the `FLUSH_TABLES` or `RELOAD` privilege. Because it acquires locks on tables in preparation for exporting them, it also requires the `LOCK TABLES` and `SELECT` privileges for each table.

The operation works like this:

1. It acquires shared metadata locks for the named tables. The operation blocks as long as other sessions have active transactions that have modified those tables or hold table locks for them. When
the locks have been acquired, the operation blocks transactions that attempt to update the tables, while permitting read-only operations to continue.

2. It checks whether all storage engines for the tables support FOR EXPORT. If any do not, an ER_ILLEGAL_HA error occurs and the operation fails.

3. The operation notifies the storage engine for each table to make the table ready for export. The storage engine must ensure that any pending changes are written to disk.

4. The operation puts the session in lock-tables mode so that the metadata locks acquired earlier are not released when the FOR EXPORT operation completes.

This operation applies only to existing base (non-TEMPORARY) tables. If a name refers to a base table, that table is used. If it refers to a TEMPORARY table, it is ignored. If a name applies to a view, an ER_WRONG_OBJECT error occurs. Otherwise, an ER_NO_SUCH_TABLE error occurs.

InnoDB supports FOR EXPORT for tables that have their own .ibd file (that is, tables created with the innodb_file_per_table setting enabled). InnoDB ensures when notified by the FOR EXPORT operation that any changes have been flushed to disk. This permits a binary copy of table contents to be made while the FOR EXPORT operation is in effect because the .ibd file is transaction consistent and can be copied while the server is running. FOR EXPORT does not apply to InnoDB system tablespace files, or to InnoDB tables that have FULLTEXT indexes.

FLUSH TABLES ... FOR EXPORT is supported for partitioned InnoDB tables.

When notified by FOR EXPORT, InnoDB writes to disk certain kinds of data that is normally held in memory or in separate disk buffers outside the tablespace files. For each table, InnoDB also produces a file named table_name.cfg in the same database directory as the table. The .cfg file contains metadata needed to reimport the tablespace files later, into the same or different server.

When the FOR EXPORT operation completes, InnoDB has flushed all dirty pages to the table data files. Any change buffer entries are merged prior to flushing. At this point, the tables are locked and quiescent: The tables are in a transactionally consistent state on disk and you can copy the .ibd tablespace files along with the corresponding .cfg files to get a consistent snapshot of those tables.

For the procedure to reimport the copied table data into a MySQL instance, see Section 15.6.1.3, “Importing InnoDB Tables”.

After you are done with the tables, use UNLOCK TABLES to release the locks, LOCK TABLES to release the locks and acquire other locks, or START TRANSACTION to release the locks and begin a new transaction.

While any of these statements is in effect within the session, attempts to use FLUSH TABLES ... FOR EXPORT produce an error:

| FLUSH TABLES ... WITH READ LOCK |
| FLUSH TABLES ... FOR EXPORT    |
| LOCK TABLES ... READ           |
| LOCK TABLES ... WRITE         |

While FLUSH TABLES ... FOR EXPORT is in effect within the session, attempts to use any of these statements produce an error:

| FLUSH TABLES WITH READ LOCK |
| FLUSH TABLES ... WITH READ LOCK |
| FLUSH TABLES ... FOR EXPORT   |
13.7.8.4 KILL Statement

```
KILL [CONNECTION | QUERY] processlist_id
```

Each connection to `mysqld` runs in a separate thread. You can kill a thread with the `KILL processlist_id` statement.

Thread processlist identifiers can be determined from the `ID` column of the `INFORMATION_SCHEMA` `PROCESSLIST` table, the `Id` column of `SHOW PROCESSLIST` output, and the `PROCESSLIST_ID` column of the Performance Schema `threads` table. The value for the current thread is returned by the `CONNECTION_ID()` function.

`KILL` permits an optional `CONNECTION` or `QUERY` modifier:

- `KILL CONNECTION` is the same as `KILL` with no modifier: It terminates the connection associated with the given `processlist_id`, after terminating any statement the connection is executing.
- `KILL QUERY` terminates the statement the connection is currently executing, but leaves the connection itself intact.

The ability to see which threads are available to be killed depends on the `PROCESS` privilege:

- Without `PROCESS`, you can see only your own threads.
- With `PROCESS`, you can see all threads.

The ability to kill threads and statements depends on the `CONNECTION_ADMIN` privilege and the deprecated `SUPER` privilege:

- Without `CONNECTION_ADMIN` or `SUPER`, you can kill only your own threads and statements.
- With `CONNECTION_ADMIN` or `SUPER`, you can kill all threads and statements, except that to affect a thread or statement that is executing with the `SYSTEM_USER` privilege, your own session must additionally have the `SYSTEM_USER` privilege.

You can also use the `mysqladmin processlist` and `mysqladmin kill` commands to examine and kill threads.

When you use `KILL`, a thread-specific kill flag is set for the thread. In most cases, it might take some time for the thread to die because the kill flag is checked only at specific intervals:

- During `SELECT` operations, for `ORDER BY` and `GROUP BY` loops, the flag is checked after reading a block of rows. If the kill flag is set, the statement is aborted.
- `ALTER TABLE` operations that make a table copy check the kill flag periodically for each few copied rows read from the original table. If the kill flag was set, the statement is aborted and the temporary table is deleted.

The `KILL` statement returns without waiting for confirmation, but the kill flag check aborts the operation within a reasonably small amount of time. Aborting the operation to perform any necessary cleanup also takes some time.

- During `UPDATE` or `DELETE` operations, the kill flag is checked after each block read and after each updated or deleted row. If the kill flag is set, the statement is aborted. If you are not using transactions, the changes are not rolled back.
- `GET_LOCK()` aborts and returns `NULL`. 
• If the thread is in the table lock handler (state: Locked), the table lock is quickly aborted.

• If the thread is waiting for free disk space in a write call, the write is aborted with a “disk full” error message.

• EXPLAIN ANALYZE aborts and prints the first row of output. This works in MySQL 8.0.20 and later.

Warning
Killing a REPAIR TABLE or OPTIMIZE TABLE operation on a MyISAM table results in a table that is corrupted and unusable. Any reads or writes to such a table fail until you optimize or repair it again (without interruption).

13.7.8.5 LOAD INDEX INTO CACHE Statement

```
LOAD INDEX INTO CACHE
tbl_index_list [, tbl_index_list] ...  

tbl_index_list:
tbl_name
  [PARTITION (partition_list)]
  [{INDEX|KEY} (index_name[, index_name] ...)]
  [IGNORE LEAVES]

partition_list: {
  partition_name[, partition_name] ...
  | ALL
}
```

The LOAD INDEX INTO CACHE statement preloads a table index into the key cache to which it has been assigned by an explicit CACHE INDEX statement, or into the default key cache otherwise.

LOAD INDEX INTO CACHE applies only to MyISAM tables, including partitioned MyISAM tables. In addition, indexes on partitioned tables can be preloaded for one, several, or all partitions.

The IGNORE LEAVES modifier causes only blocks for the nonleaf nodes of the index to be preloaded.

IGNORE LEAVES is also supported for partitioned MyISAM tables.

The following statement preloads nodes (index blocks) of indexes for the tables t1 and t2:

```
mysql> LOAD INDEX INTO CACHE t1, t2 IGNORE LEAVES;
+---------+--------------+----------+----------+
| Table   | Op           | Msg_type | Msg_text |
+---------+--------------+----------+----------+
| test.t1 | preload_keys | status   | OK       |
| test.t2 | preload_keys | status   | OK       |
+---------+--------------+----------+----------+
```

This statement preloads all index blocks from t1. It preloads only blocks for the nonleaf nodes from t2.

The syntax of LOAD INDEX INTO CACHE enables you to specify that only particular indexes from a table should be preloaded. However, the implementation preloads all the table’s indexes into the cache, so there is no reason to specify anything other than the table name.

It is possible to preload indexes on specific partitions of partitioned MyISAM tables. For example, of the following 2 statements, the first preloads indexes for partition p0 of a partitioned table pt, while the second preloads the indexes for partitions p1 and p3 of the same table:

```
LOAD INDEX INTO CACHE pt PARTITION (p0);
LOAD INDEX INTO CACHE pt PARTITION (p1, p3);
```
Other Administrative Statements

To preload the indexes for all partitions in table `pt`, you can use either of the following two statements:

```sql
LOAD INDEX INTO CACHE pt PARTITION (ALL);
LOAD INDEX INTO CACHE pt;
```

The two statements just shown are equivalent, and issuing either one has exactly the same effect. In other words, if you wish to preload indexes for all partitions of a partitioned table, the `PARTITION (ALL)` clause is optional.

When preloading indexes for multiple partitions, the partitions need not be contiguous, and you need not list their names in any particular order.

`LOAD INDEX INTO CACHE ... IGNORE LEAVES` fails unless all indexes in a table have the same block size. To determine index block sizes for a table, use `myisamchk -dv` and check the `Blocksize` column.

### 13.7.8.6 RESET Statement

```sql
RESET reset_option [, reset_option] ...
```

```sql
reset_option: {
    MASTER
    | REPLICA
    | SLAVE
}
```

The `RESET` statement is used to clear the state of various server operations. You must have the `RELOAD` privilege to execute `RESET`.

For information about the `RESET PERSIST` statement that removes persisted global system variables, see Section 13.7.8.7, “RESET PERSIST Statement”.

`RESET` acts as a stronger version of the `FLUSH` statement. See Section 13.7.8.3, “FLUSH Statement”.

The `RESET` statement causes an implicit commit. See Section 13.3.3, “Statements That Cause an Implicit Commit”.

The following list describes the permitted `RESET` statement `reset_option` values:

- **RESET MASTER**
  
  Deletes all binary logs listed in the index file, resets the binary log index file to be empty, and creates a new binary log file.

- **RESET REPLICA**
  
  Makes the replica forget its replication position in the source binary logs. Also resets the relay log by deleting any existing relay log files and beginning a new one. Use `RESET REPLICA` in place of `RESET SLAVE` from MySQL 8.0.22.

### 13.7.8.7 RESET PERSIST Statement

```sql
RESET PERSIST [[IF EXISTS] system_var_name]
```

`RESET PERSIST` removes persisted global system variable settings from the `mysqlld-auto.cnf` option file in the data directory. Removing a persisted system variable causes the variable no longer to be initialized from `mysqlld-auto.cnf` at server startup. For more information about persisting system variables and the `mysqlld-auto.cnf` file, see Section 5.1.9.3, “Persisted System Variables”.

3244
Other Administrative Statements

Prior to MySQL 8.0.32, this statement did not work with variables whose name contained a dot character (.), such as MyISAM multiple key cache variables and variables registered by components. (Bug #33417357)

The privileges required for \texttt{RESET PERSIST} depend on the type of system variable to be removed:

- For dynamic system variables, this statement requires the \texttt{SYSTEM_VARIABLES_ADMIN} privilege (or the deprecated \texttt{SUPER} privilege).
- For read-only system variables, this statement requires the \texttt{SYSTEM_VARIABLES_ADMIN} and \texttt{PERSIST_RO_VARIABLES_ADMIN} privileges.

See Section 5.1.9.1, “System Variable Privileges”.

Depending on whether the variable name and \texttt{IF EXISTS} clauses are present, the \texttt{RESET PERSIST} statement has these forms:

- To remove all persisted variables from \texttt{mysqld-auto.cnf}, use \texttt{RESET PERSIST} without naming any system variable:
  
  \begin{verbatim}
  RESET PERSIST;
  \end{verbatim}

     You must have privileges for removing both dynamic and read-only system variables if \texttt{mysqld-auto.cnf} contains both kinds of variables.

- To remove a specific persisted variable from \texttt{mysqld-auto.cnf}, name it in the statement:
  
  \begin{verbatim}
  RESET PERSIST system_var_name;
  \end{verbatim}

     This includes plugin system variables, even if the plugin is not currently installed. If the variable is not present in the file, an error occurs.

- To remove a specific persisted variable from \texttt{mysqld-auto.cnf}, but produce a warning rather than an error if the variable is not present in the file, add an \texttt{IF EXISTS} clause to the previous syntax:
  
  \begin{verbatim}
  RESET PERSIST IF EXISTS system_var_name;
  \end{verbatim}

\texttt{RESET PERSIST} is not affected by the value of the \texttt{persisted_globals_load} system variable.

\texttt{RESET PERSIST} affects the contents of the Performance Schema \texttt{persisted_variables} table because the table contents correspond to the contents of the \texttt{mysqld-auto.cnf} file. On the other hand, because \texttt{RESET PERSIST} does not change variable values, it has no effect on the contents of the Performance Schema \texttt{variables_info} table until the server is restarted.

For information about \texttt{RESET} statement variants that clear the state of other server operations, see Section 13.7.8.6, “RESET Statement”.

13.7.8.8 RESTART Statement

\texttt{RESTART}

This statement stops and restarts the MySQL server. It requires the \texttt{SHUTDOWN} privilege.

One use for \texttt{RESTART} is when it is not possible or convenient to gain command-line access to the MySQL server on the server host to restart it. For example, \texttt{SET PERSIST_ONLY} can be used at runtime to make configuration changes to system variables that can be set only at server startup, but the server must still be restarted for those changes to take effect. The \texttt{RESTART} statement provides a way to do so from within client sessions, without requiring command-line access on the server host.
Other Administrative Statements

Note
After executing a **RESTART** statement, the client can expect the current connection to be lost. If auto-reconnect is enabled, the connection is reestablished after the server restarts. Otherwise, the connection must be reestablished manually.

A successful **RESTART** operation requires mysqld to be running in an environment that has a monitoring process available to detect a server shutdown performed for restart purposes:

- In the presence of a monitoring process, **RESTART** causes mysqld to terminate such that the monitoring process can determine that it should start a new mysqld instance.
- If no monitoring process is present, **RESTART** fails with an error.

These platforms provide the necessary monitoring support for the **RESTART** statement:

- Windows, when mysqld is started as a Windows service or standalone. (mysqld forks, and one process acts as a monitor to the other, which acts as the server.)
- Unix and Unix-like systems that use systemd or mysqld_safe to manage mysqld.

To configure a monitoring environment such that mysqld enables the **RESTART** statement:

1. Set the **MYSQLD_PARENT_PID** environment variable to the value of the process ID of the process that starts mysqld, before starting mysqld.
2. When mysqld performs a shutdown due to use of the **RESTART** statement, it returns exit code 16.
3. When the monitoring process detects an exit code of 16, it starts mysqld again. Otherwise, it exits.

Here is a minimal example as implemented in the bash shell:

```bash
#!/bin/bash
export MYSQLD_PARENT_PID=$$
export MYSQLD_RESTART_EXIT=16
while true ; do
  bin/mysqld mysqld options here
  if [ $? -ne $MYSQLD_RESTART_EXIT ]; then
    break
  fi
done
```

On Windows, the forking used to implement **RESTART** makes determining the server process to attach to for debugging more difficult. To alleviate this, starting the server with **--gdb** suppresses forking, in addition to its other actions done to set up a debugging environment. In non-debug settings, **--no-monitor** may be used for the sole purpose of suppressing forking the monitor process. For a server started with either **--gdb** or **--no-monitor**, executing **RESTART** causes the server to simply exit without restarting.

The **Com_restart** status variable tracks the number of **RESTART** statements. Because status variables are initialized for each server startup and do not persist across restarts, **Com_restart** normally has a value of zero, but can be nonzero if **RESTART** statements were executed but failed.

### 13.7.8.9 SHUTDOWN Statement

**SHUTDOWN**

This statement stops the MySQL server. It requires the **SHUTDOWN** privilege.
SHUTDOWN provides an SQL-level interface to the same functionality available using the mysqladmin shutdown command or the mysql_shutdown() C API function. A successful SHUTDOWN sequence consists of checking the privileges, validating the arguments, and sending an OK packet to the client. Then the server is shut down.

The Com_shutdown status variable tracks the number of SHUTDOWN statements. Because status variables are initialized for each server startup and do not persist across restarts, Com_shutdown normally has a value of zero, but can be nonzero if SHUTDOWN statements were executed but failed.

Another way to stop the server is to send it a SIGHUP signal, which can be done by root or the account that owns the server process. SIGHUP enables server shutdown to be performed without having to connect to the server. See Section 4.10, "Unix Signal Handling in MySQL".

13.8 Utility Statements

13.8.1 DESCRIBE Statement

The DESCRIBE and EXPLAIN statements are synonyms, used either to obtain information about table structure or query execution plans. For more information, see Section 13.7.7.5, "SHOW COLUMNS Statement", and Section 13.8.2, "EXPLAIN Statement".

13.8.2 EXPLAIN Statement

The DESCRIBE and EXPLAIN statements are synonyms. In practice, the DESCRIBE keyword is more often used to obtain information about table structure, whereas EXPLAIN is used to obtain a query execution plan (that is, an explanation of how MySQL would execute a query).

The following discussion uses the DESCRIBE and EXPLAIN keywords in accordance with those uses, but the MySQL parser treats them as completely synonymous.

- Obtaining Table Structure Information
EXPLAIN Statement

- Obtaining Execution Plan Information
- Obtaining Information with EXPLAIN ANALYZE

Obtaining Table Structure Information

DESCRIBE provides information about the columns in a table:

```
mysql> DESCRIBE City;
+------------+----------+------+-----+---------+----------------+
| Field      | Type     | Null | Key | Default | Extra          |
+------------+----------+------+-----+---------+----------------+
| Id         | int(11)  | NO   | PRI | NULL    | auto_increment |
| Name       | char(35) | NO   |     |         |                |
| Country    | char(3)  | NO   | UNI |         |                |
| District   | char(20) | YES  | MUL |         |                |
| Population | int(11)  | NO   |     | 0       |                |
+------------+----------+------+-----+---------+----------------+
```

DESCRIBE is a shortcut for SHOW COLUMNS. These statements also display information for views. The description for SHOW COLUMNS provides more information about the output columns. See Section 13.7.7.5, “SHOW COLUMNS Statement”.

By default, DESCRIBE displays information about all columns in the table. col_name, if given, is the name of a column in the table. In this case, the statement displays information only for the named column. wild, if given, is a pattern string. It can contain the SQL % and _ wildcard characters. In this case, the statement displays output only for the columns with names matching the string. There is no need to enclose the string within quotation marks unless it contains spaces or other special characters.

The DESCRIBE statement is provided for compatibility with Oracle.

The SHOW CREATE TABLE, SHOW TABLE STATUS, and SHOW INDEX statements also provide information about tables. See Section 13.7.7, “SHOW Statements”.

The explain_format system variable, added in MySQL 8.0.32, has no effect on the output of EXPLAIN when used to obtain information about table columns.

Obtaining Execution Plan Information

The EXPLAIN statement provides information about how MySQL executes statements:

- EXPLAIN works with SELECT, DELETE, INSERT, REPLACE, and UPDATE statements. In MySQL 8.0.19 and later, it also works with TABLE statements.

- When EXPLAIN is used with an explainable statement, MySQL displays information from the optimizer about the statement execution plan. That is, MySQL explains how it would process the statement, including information about how tables are joined and in which order. For information about using EXPLAIN to obtain execution plan information, see Section 8.8.2, “EXPLAIN Output Format”.

- When EXPLAIN is used with FOR CONNECTION connection_id rather than an explainable statement, it displays the execution plan for the statement executing in the named connection. See Section 8.8.4, “Obtaining Execution Plan Information for a Named Connection”.

- For explainable statements, EXPLAIN produces additional execution plan information that can be displayed using SHOW WARNINGS. See Section 8.8.3, “Extended EXPLAIN Output Format”.

- EXPLAIN is useful for examining queries involving partitioned tables. See Section 24.3.5, “Obtaining Information About Partitions”.

3248
EXPLAIN Statement

- The **FORMAT** option can be used to select the output format. **TRADITIONAL** presents the output in tabular format. This is the default if no **FORMAT** option is present. **JSON** format displays the information in JSON format. In MySQL 8.0.16 and later, **TREE** provides tree-like output with more precise descriptions of query handling than the **TRADITIONAL** format; it is the only format which shows hash join usage (see Section 8.2.1.4, "Hash Join Optimization") and is always used for **EXPLAIN ANALYZE**.

As of MySQL 8.0.32, the default output format used by **EXPLAIN** (that is, when it has no **FORMAT** option) is determined by the value of the **explain_format** system variable. The precise effects of this variable are described later in this section.

**EXPLAIN** requires the same privileges required to execute the explained statement. Additionally, **EXPLAIN** also requires the **SHOW VIEW** privilege for any explained view. **EXPLAIN ... FOR CONNECTION** also requires the **PROCESS** privilege if the specified connection belongs to a different user.

The **explain_format** system variable introduced in MySQL 8.0.32 determines the format of the output from **EXPLAIN** when used to display a query execution plan. This variable can take any of the values used with the **FORMAT** option, with the addition of **DEFAULT** as a synonym for **TRADITIONAL**. The following example uses the **country** table from the **world** database which can be obtained from MySQL: Other Downloads:

```sql
gsql> USE world;  # Make world the current database
Database changed

Checking the value of **explain_format**, we see that it has the default value, and that **EXPLAIN** (with no **FORMAT** option) therefore uses the traditional tabular output:

```sql
gsql> SELECT @@explain_format;
+------------------+
| @@explain_format |
+------------------+
| TRADITIONAL      |
+------------------+
1 row in set (0.00 sec)
gsql>
gsql> EXPLAIN SELECT Name FROM country WHERE Code Like 'A%';
+----+-------------+---------+------------+-------+---------------+---------+---------+------+------+----------+-------------+
| id | select_type | table   | partitions | type  | possible_keys | key     | key_len | ref  | rows | filtered | Extra       |
|----|-------------|---------|------------|-------|---------------|---------|---------|------|------|----------|-------------+
|  1 | SIMPLE      | country | NULL       | range | PRIMARY       | PRIMARY | 12      | NULL |   17 |   100.00 | Using where |
+----+-------------+---------+------------+-------+---------------+---------+---------+------+------+----------+-------------+
1 row in set, 1 warning (0.00 sec)
```

If we set the value of **explain_format** to **TREE**, then rerun the same **EXPLAIN** statement, the output uses the tree-like format:

```sql
gsql> SET @@explain_format=TREE;
Query OK, 0 rows affected (0.00 sec)

gsql> SELECT @@explain_format;
+------------------+
| @@explain_format |
+------------------+
| TREE             |
+------------------+
1 row in set (0.00 sec)

gsql> EXPLAIN SELECT Name FROM country WHERE Code Like 'A%';
+--------------------------------------------------------------------------------------------------------------+
| EXPLAIN                                                                                                      |
| -> Filter: (country.`Code` like 'A\%')  (cost=3.67 rows=17)  |
|   -> Index range scan on country using PRIMARY over ('A' <= Code <= 'A?????????')  (cost=3.67 rows=17) |
+--------------------------------------------------------------------------------------------------------------+
```

3249
As stated previously, the `FORMAT` option overrides this setting. Executing the same `EXPLAIN` statement using `FORMAT=JSON` instead of `FORMAT=TREE` shows that this is the case:

```
mysql> EXPLAIN FORMAT=JSON SELECT Name FROM country WHERE Code LIKE 'A%';
```

```
+------------------------------------------------------------------------------+
| EXPLAIN                                                                      |
+------------------------------------------------------------------------------+
| {                                                                             |
|   "query_block": {                                                         |
|     "select_id": 1,                                                       |
|     "cost_info": {                                                         |
|       "query_cost": "3.67"                                                 |
|     },                                                                     |
|     "table": {                                                             |
|       "table_name": "country",                                            |
|       "access_type": "range",                                            |
|       "possible_keys": [                                                 |
|         "PRIMARY"                                                       |
|       ],                                                                  |
|       "key": "PRIMARY",                                                   |
|       "used_key_parts": [                                                 |
|         "Code"                                                           |
|       ],                                                                  |
|       "key_length": "12",                                                  |
|       "rows_examined_per_scan": 17,                                       |
|       "rows_produced_per_join": 17,                                       |
|       "filtered": "100.00",                                               |
|       "cost_info": {                                                      |
|         "read_cost": "1.97",                                              |
|         "eval_cost": "1.70",                                              |
|         "prefix_cost": "3.67",                                            |
|         "data_read_per_join": "16K"                                       |
|     },                                                                    |
|     "used_columns": [                                                     |
|       "Code",                                                            |
|       "Name"                                                             |
|     ],                                                                    |
|     "attached_condition": "(\'world\',\'country\',\'Code\' like 'A%')" |
| }                                                                          |
+------------------------------------------------------------------------------+
1 row in set, 1 warning (0.00 sec)
```

To return the default output of `EXPLAIN` to the tabular format, set `explain_format` to `TRADITIONAL`. Alternatively, you can set it to `DEFAULT`, which has the same effect, as shown here:

```
mysql> SET @@explain_format=DEFAULT;
Query OK, 0 rows affected (0.00 sec)
```

```
mysql> SELECT @@explain_format;
+------------------+
| @@explain_format |
+------------------+
| TRADITIONAL      |
+------------------+
1 row in set (0.00 sec)
```

With the help of `EXPLAIN`, you can see where you should add indexes to tables so that the statement executes faster by using indexes to find rows. You can also use `EXPLAIN` to check whether the optimizer joins the tables in an optimal order. To give a hint to the optimizer to use a join order corresponding
EXPLAIN Statement

to the order in which the tables are named in a `SELECT` statement, begin the statement with `SELECT STRAIGHT_JOIN` rather than just `SELECT`. (See Section 13.2.13, “SELECT Statement”.)

The optimizer trace may sometimes provide information complementary to that of `EXPLAIN`. However, the optimizer trace format and content are subject to change between versions. For details, see MySQL Internals: Tracing the Optimizer.

If you have a problem with indexes not being used when you believe that they should be, run `ANALYZE TABLE` to update table statistics, such as cardinality of keys, that can affect the choices the optimizer makes. See Section 13.7.3.1, “ANALYZE TABLE Statement”.

Note
MySQL Workbench has a Visual Explain capability that provides a visual representation of `EXPLAIN` output. See Tutorial: Using Explain to Improve Query Performance.

Obtaining Information with EXPLAIN ANALYZE

MySQL 8.0.18 introduces `EXPLAIN ANALYZE`, which runs a statement and produces `EXPLAIN` output along with timing and additional, iterator-based, information about how the optimizer's expectations matched the actual execution. For each iterator, the following information is provided:

- Estimated execution cost
  (Some iterators are not accounted for by the cost model, and so are not included in the estimate.)

- Estimated number of returned rows

- Time to return first row

- Time spent executing this iterator (including child iterators, but not parent iterators), in milliseconds.
  (When there are multiple loops, this figure shows the average time per loop.)

- Number of rows returned by the iterator

- Number of loops

The query execution information is displayed using the `TREE` output format, in which nodes represent iterators. `EXPLAIN ANALYZE` always uses the `TREE` output format. In MySQL 8.0.21 and later, this can optionally be specified explicitly using `FORMAT=TREE`; formats other than `TREE` remain unsupported.

`EXPLAIN ANALYZE` can be used with `SELECT` statements, as well as with multi-table `UPDATE` and `DELETE` statements. Beginning with MySQL 8.0.19, it can also be used with `TABLE` statements.

Beginning with MySQL 8.0.20, you can terminate this statement using `KILL QUERY` or `CTRL-C`.

`EXPLAIN ANALYZE` cannot be used with `FOR CONNECTION`.

Example output:

```
mysql> EXPLAIN ANALYZE SELECT * FROM t1 JOIN t2 ON (t1.c1 = t2.c2)\G
*************************** 1. row ***************************
EXPLAIN: -> Inner hash join (t2.c2 = t1.c1) (cost=4.70 rows=6)
  (actual time=0.032..0.035 rows=6 loops=1)
     -> Table scan on t2 (cost=0.06 rows=6)
       (actual time=0.003..0.005 rows=6 loops=1)
     -> Hash
```
EXPLAIN Statement

The tables used in the example output were created by the statements shown here:

```sql
CREATE TABLE t1 {
    c1 INTEGER DEFAULT NULL,
    c2 INTEGER DEFAULT NULL
};

CREATE TABLE t2 {
    c1 INTEGER DEFAULT NULL,
    c2 INTEGER DEFAULT NULL
};

CREATE TABLE t3 {
    pk INTEGER NOT NULL PRIMARY KEY,
    i INTEGER DEFAULT NULL
};
```

Values shown for `actual time` in the output of this statement are expressed in milliseconds.

As of MySQL 8.0.32, the `explain_format` system variable has the following effects on `EXPLAIN ANALYZE`:

- If the value of this variable is `TRADITIONAL` or `TREE` (or the synonym `DEFAULT`), `EXPLAIN ANALYZE` uses the `TREE` format. This ensures that this statement continues to use the `TREE` format by default, as it did prior to the introduction of `explain_format`.

- If the value of `explain_format` is `JSON`, `EXPLAIN ANALYZE` returns an error unless `FORMAT=TREE` is specified as part of the statement. This is due to the fact that `EXPLAIN ANALYZE` supports only the `TREE` output format.

We illustrate the behavior described in the second point here, re-using the last `EXPLAIN ANALYZE` statement from the previous example:

```sql
mysql> SET @@explain_format=JSON;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @@explain_format;
+------------------+
| @@explain_format |
+------------------+
| JSON             |
+------------------+
1 row in set (0.00 sec)

mysql> EXPLAIN ANALYZE SELECT * FROM t3 WHERE pk > 17\G
ERROR 1235 (42000): This version of MySQL doesn't yet support 'EXPLAIN ANALYZE with JSON format'
```
mysql> EXPLAIN ANALYZE FORMAT=TRADITIONAL SELECT * FROM t3 WHERE pk > 17\G
ERROR 1235 (42000): This version of MySQL doesn't yet support 'EXPLAIN ANALYZE with TRADITIONAL format'

mysql> EXPLAIN ANALYZE FORMAT=TREE SELECT * FROM t3 WHERE pk > 17\G
*************************** 1. row ***************************
EXPLAIN: -> Filter: (t3.pk > 17)  (cost=1.26 rows=5)
(actual time=0.013..0.016 rows=5 loops=1)
-> Index range scan on t3 using PRIMARY  (cost=1.26 rows=5)
(actual time=0.012..0.014 rows=5 loops=1)

Using FORMAT=TRADITIONAL or FORMAT=JSON with EXPLAIN ANALYZE always raises an error, regardless of the value of explain_format.

Beginning with MySQL 8.0.33, numbers in the output of EXPLAIN ANALYZE and EXPLAIN FORMAT=TREE are formatted according to the following rules:

- Numbers in the range 0.001-999999.5 are printed as decimal numbers.
  - Decimal numbers less than 1000 have three significant digits; the remainder have four, five, or six.

- Numbers outside the range 0.001-999999.5 are printed in engineering format. Examples of such values are 1.23e+9 and 934e-6.

- No trailing zeros are printed. For example, we print 2.3 rather than 2.30, and 1.2e+6 rather than 1.20e+6.

- Numbers less than 1e-12 are printed as 0.

### 13.8.3 HELP Statement

**HELP 'search_string'**

The HELP statement returns online information from the MySQL Reference Manual. Its proper operation requires that the help tables in the mysql database be initialized with help topic information (see Section 5.1.17, "Server-Side Help Support").

The HELP statement searches the help tables for the given search string and displays the result of the search. The search string is not case-sensitive.

The search string can contain the wildcard characters % and _. These have the same meaning as for pattern-matching operations performed with the LIKE operator. For example, HELP 'rep%' returns a list of topics that begin with rep.

The HELP statement does not require a terminator such as ; or \G.

The HELP statement understands several types of search strings:

- At the most general level, use contents to retrieve a list of the top-level help categories:
  
  HELP 'contents'

- For a list of topics in a given help category, such as Data Types, use the category name:
  
  HELP 'data types'

- For help on a specific help topic, such as the ASCII() function or the CREATE TABLE statement, use the associated keyword or keywords:
  
  HELP 'ascii'
  HELP 'create table'
HELP Statement

In other words, the search string matches a category, many topics, or a single topic. The following descriptions indicate the forms that the result set can take.

• Empty result

No match could be found for the search string.

Example: HELP 'fake'

Yields:

Nothing found
Please try to run 'help contents' for a list of all accessible topics

• Result set containing a single row

This means that the search string yielded a hit for the help topic. The result includes the following items:

• name: The topic name.

• description: Descriptive help text for the topic.

• example: One or more usage examples. (May be empty.)

Example: HELP 'log'

Yields:

Name: 'LOG'
Description:
Syntax:
LOG(X), LOG(B,X)

If called with one parameter, this function returns the natural logarithm of X. If X is less than or equal to 0.0E0, the function returns NULL and a warning "Invalid argument for logarithm" is reported. Returns NULL if X or B is NULL.

The inverse of this function (when called with a single argument) is the EXP() function.

Examples:
mysql> SELECT LOG(2);
-> 0.69314718055995
mysql> SELECT LOG(-2);
-> NULL

• List of topics.

This means that the search string matched multiple help topics.

Example: HELP 'status'

Yields:

Many help items for your request exist.
To make a more specific request, please type 'help <item>',
where <item> is one of the following topics:
   FLUSH
   SHOW
   SHOW ENGINE
SHOW FUNCTION STATUS
SHOW MASTER STATUS
SHOW PROCEDURE STATUS
SHOW REPLICA STATUS
SHOW SLAVE STATUS
SHOW STATUS
SHOW TABLE STATUS

• List of topics.
A list is also displayed if the search string matches a category.

Example: HELP 'functions'

Yields:

You asked for help about help category: "Functions"
For more information, type 'help <item>', where <item> is one of the following categories:
Aggregate Functions and Modifiers
Bit Functions
Cast Functions and Operators
Comparison Operators
Date and Time Functions
Encryption Functions
Enterprise Encryption Functions
Flow Control Functions
GROUP BY Functions and Modifiers
GTID
Information Functions
Internal Functions
Locking Functions
Logical Operators
Miscellaneous Functions
Numeric Functions
Performance Schema Functions
Spatial Functions
String Functions
Window Functions
XML

13.8.4 USE Statement

USE db_name

The USE statement tells MySQL to use the named database as the default (current) database for subsequent statements. This statement requires some privilege for the database or some object within it.

The named database remains the default until the end of the session or another USE statement is issued:

USE db1;
SELECT COUNT(*) FROM mytable;   # selects from db1.mytable
USE db2;
SELECT COUNT(*) FROM mytable;   # selects from db2.mytable

The database name must be specified on a single line. Newlines in database names are not supported.

Making a particular database the default by means of the USE statement does not preclude accessing tables in other databases. The following example accesses the author table from the db1 database and the editor table from the db2 database:

USE db1;
SELECT author_name,editor_name FROM author,db2.editor
WHERE author.editor_id = db2.editor.editor_id;
MySQL Server incorporates a transactional data dictionary that stores information about database objects. In previous MySQL releases, dictionary data was stored in metadata files, nontransactional tables, and storage engine-specific data dictionaries.

This chapter describes the main features, benefits, usage differences, and limitations of the data dictionary. For other implications of the data dictionary feature, refer to the “Data Dictionary Notes” section in the MySQL 8.0 Release Notes.

Benefits of the MySQL data dictionary include:

- Simplicity of a centralized data dictionary schema that uniformly stores dictionary data. See Section 14.1, “Data Dictionary Schema”.
- A simpler and improved implementation for some INFORMATION_SCHEMA tables. See Section 14.5, “INFORMATION_SCHEMA and Data Dictionary Integration”.

Important

A data dictionary-enabled server entails some general operational differences compared to a server that does not have a data dictionary; see Section 14.7, “Data Dictionary Usage Differences”. Also, for upgrades to MySQL 8.0, the upgrade procedure differs somewhat from previous MySQL releases and requires that you verify the upgrade readiness of your installation by checking specific prerequisites. For more information, see Section 2.10, “Upgrading MySQL”, particularly Section 2.10.5, “Preparing Your Installation for Upgrade”.

14.1 Data Dictionary Schema

Data dictionary tables are protected and may only be accessed in debug builds of MySQL. However, MySQL supports access to data stored in data dictionary tables through INFORMATION_SCHEMA tables and SHOW statements. For an overview of the tables that comprise the data dictionary, see Data Dictionary Tables.
MySQL system tables still exist in MySQL 8.0 and can be viewed by issuing a `SHOW TABLES` statement on the `mysql` system database. Generally, the difference between MySQL data dictionary tables and system tables is that data dictionary tables contain metadata required to execute SQL queries, whereas system tables contain auxiliary data such as time zone and help information. MySQL system tables and data dictionary tables also differ in how they are upgraded. The MySQL server manages data dictionary upgrades. SQL server. See How the Data Dictionary is Upgraded. Upgrading MySQL system tables requires running the full MySQL upgrade procedure. See Section 2.10.3, “What the MySQL Upgrade Process Upgrades”.

### How the Data Dictionary is Upgraded

New versions of MySQL may include changes to data dictionary table definitions. Such changes are present in newly installed versions of MySQL, but when performing an in-place upgrade of MySQL binaries, changes are applied when the MySQL server is restarted using the new binaries. At startup, the data dictionary version of the server is compared to the version information stored in the data dictionary to determine if data dictionary tables should be upgraded. If an upgrade is necessary and supported, the server creates data dictionary tables with updated definitions, copies persisted metadata to the new tables, atomically replaces the old tables with the new ones, and reinitializes the data dictionary. If an upgrade is not necessary, startup continues without updating the data dictionary tables.

Upgrade of data dictionary tables is an atomic operation, which means that all of the data dictionary tables are upgraded as necessary or the operation fails. If the upgrade operation fails, server startup fails with an error. In this case, the old server binaries can be used with the old data directory to start the server. When the new server binaries are used again to start the server, the data dictionary upgrade is reattempted.

Generally, after data dictionary tables are successfully upgraded, it is not possible to restart the server using the old server binaries. As a result, downgrading MySQL server binaries to a previous MySQL version is not supported after data dictionary tables are upgraded.

The `mysqld --no-dd-upgrade` option can be used to prevent automatic upgrade of data dictionary tables at startup. When `--no-dd-upgrade` is specified, and the server finds that the data dictionary version of the server is different from the version stored in the data dictionary, startup fails with an error stating that the data dictionary upgrade is prohibited.

### Viewing Data Dictionary Tables Using a Debug Build of MySQL

Data dictionary tables are protected by default but can be accessed by compiling MySQL with debugging support (using the `-DWITH_DEBUG=1` CMake option) and specifying the `+d,skip_dd_table_access_check` debug option and modifier. For information about compiling debug builds, see Section 5.9.1.1, “Compiling MySQL for Debugging”.

**Warning**

Modifying or writing to data dictionary tables directly is not recommended and may render your MySQL instance inoperable.

After compiling MySQL with debugging support, use this `SET` statement to make data dictionary tables visible to the `mysql` client session:

```
mysql> SET SESSION debug='+d,skip_dd_table_access_check';
```

Use this query to retrieve a list of data dictionary tables:

```
mysql> SELECT name, schema_id, hidden, type FROM mysql.tables where schema_id=1 AND hidden='System';
```

Use `SHOW CREATE TABLE` to view data dictionary table definitions. For example:
14.2 Removal of File-based Metadata Storage

In previous MySQL releases, dictionary data was partially stored in metadata files. Issues with file-based metadata storage included expensive file scans, susceptibility to file system-related bugs, complex code for handling of replication and crash recovery failure states, and a lack of extensibility that made it difficult to add metadata for new features and relational objects.

The metadata files listed below are removed from MySQL. Unless otherwise noted, data previously stored in metadata files is now stored in data dictionary tables.

- `.frm` files: Table metadata files. With the removal of `.frm` files:
  - The 64KB table definition size limit imposed by the `.frm` file structure is removed.
  - The Information Schema `TABLES` table's `VERSION` column reports a hardcoded value of 10, which is the last `.frm` file version used in MySQL 5.7.

- `.par` files: Partition definition files. InnoDB stopped using partition definition files in MySQL 5.7 with the introduction of native partitioning support for InnoDB tables.

- `.TRN` files: Trigger namespace files.

- `.TRG` files: Trigger parameter files.

- `.isl` files: InnoDB Symbolic Link files containing the location of file-per-table tablespace files created outside of the data directory.

- `db.opt` files: Database configuration files. These files, one per database directory, contained database default character set attributes.

- `ddl_log.log` file: The file contained records of metadata operations generated by data definition statements such as `DROP TABLE` and `ALTER TABLE`.

14.3 Transactional Storage of Dictionary Data

The data dictionary schema stores dictionary data in transactional (InnoDB) tables. Data dictionary tables are located in the `mysql` database together with non-data dictionary system tables.

Data dictionary tables are created in a single InnoDB tablespace named `mysql.ibd`, which resides in the MySQL data directory. The `mysql.ibd` tablespace file must reside in the MySQL data directory and its name cannot be modified or used by another tablespace.

Dictionary data is protected by the same commit, rollback, and crash-recovery capabilities that protect user data that is stored in InnoDB tables.

14.4 Dictionary Object Cache

The dictionary object cache is a shared global cache that stores previously accessed data dictionary objects in memory to enable object reuse and minimize disk I/O. Similar to other cache mechanisms used by MySQL, the dictionary object cache uses an LRU-based eviction strategy to evict least recently used objects from memory.

The dictionary object cache comprises cache partitions that store different object types. Some cache partition size limits are configurable, whereas others are hardcoded.
• **tablespace definition cache partition**: Stores tablespace definition objects. The `tablespace_definition_cache` option sets a limit for the number of tablespace definition objects that can be stored in the dictionary object cache. The default value is 256.

• **schema definition cache partition**: Stores schema definition objects. The `schema_definition_cache` option sets a limit for the number of schema definition objects that can be stored in the dictionary object cache. The default value is 256.

• **table definition cache partition**: Stores table definition objects. The object limit is set to the value of `max_connections`, which has a default value of 151.

The table definition cache partition exists in parallel with the table definition cache that is configured using the `table_definition_cache` configuration option. Both caches store table definitions but serve different parts of the MySQL server. Objects in one cache have no dependence on the existence of objects in the other.

• **stored program definition cache partition**: Stores stored program definition objects. The `stored_program_definition_cache` option sets a limit for the number of stored program definition objects that can be stored in the dictionary object cache. The default value is 256.

The stored program definition cache partition exists in parallel with the stored procedure and stored function caches that are configured using the `stored_program_cache` option. The `stored_program_cache` option sets a soft upper limit for the number of cached stored procedures or functions per connection, and the limit is checked each time a connection executes a stored procedure or function. The stored program definition cache partition, on the other hand, is a shared cache that stores stored program definition objects for other purposes. The existence of objects in the stored program definition cache partition has no dependence on the existence of objects in the stored procedure cache or stored function cache, and vice versa.

• **character set definition cache partition**: Stores character set definition objects and has a hardcoded object limit of 256.

• **collation definition cache partition**: Stores collation definition objects and has a hardcoded object limit of 256.

For information about valid values for dictionary object cache configuration options, refer to Section 5.1.8, "Server System Variables".

### 14.5 INFORMATION_SCHEMA and Data Dictionary Integration

With the introduction of the data dictionary, the following INFORMATION_SCHEMA tables are implemented as views on data dictionary tables:

• CHARACTER_SETS

• CHECK_CONSTRAINTS

• COLLATIONS

• COLLATION_CHARACTER_SET_APPLICABILITY

• COLUMNS

• COLUMN_STATISTICS

• EVENTS
Queries on those tables are now more efficient because they obtain information from data dictionary tables rather than by other, slower means. In particular, for each `INFORMATION_SCHEMA` table that is a view on data dictionary tables:
• The server no longer must create a temporary table for each query of the INFORMATION_SCHEMA table.

• When the underlying data dictionary tables store values previously obtained by directory scans (for example, to enumerate database names or table names within databases) or file-opening operations (for example, to read information from .frm files), INFORMATION_SCHEMA queries for those values now use table lookups instead. (Additionally, even for a non-view INFORMATION_SCHEMA table, values such as database and table names are retrieved by lookups from the data dictionary and do not require directory or file scans.)

• Indexes on the underlying data dictionary tables permit the optimizer to construct efficient query execution plans, something not true for the previous implementation that processed the INFORMATION_SCHEMA table using a temporary table per query.

The preceding improvements also apply to SHOW statements that display information corresponding to the INFORMATION_SCHEMA tables that are views on data dictionary tables. For example, SHOW DATABASES displays the same information as the SCHEMATA table.

In addition to the introduction of views on data dictionary tables, table statistics contained in the STATISTICS and TABLES tables is now cached to improve INFORMATION_SCHEMA query performance. The information_schema_stats_expiry system variable defines the period of time before cached table statistics expire. The default is 86400 seconds (24 hours). If there are no cached statistics or statistics have expired, statistics are retrieved from storage engine when querying table statistics columns. To update cached values at any time for a given table, use ANALYZE TABLE.

information_schema_stats_expiry can be set to 0 to have INFORMATION_SCHEMA queries retrieve the latest statistics directly from the storage engine, which is not as fast as retrieving cached statistics.

For more information, see Section 8.2.3, “Optimizing INFORMATION_SCHEMA Queries”.

INFORMATION_SCHEMA tables in MySQL 8.0 are closely tied to the data dictionary, resulting in several usage differences. See Section 14.7, “Data Dictionary Usage Differences”.

### 14.6 Serialized Dictionary Information (SDI)

In addition to storing metadata about database objects in the data dictionary, MySQL stores it in serialized form. This data is referred to as serialized dictionary information (SDI). InnoDB stores SDI data within its tablespace files. NDBCLUSTER stores SDI data in the NDB dictionary. Other storage engines store SDI data in .sdi files that are created for a given table in the table’s database directory. SDI data is generated in a compact JSON format.

Serialized dictionary information (SDI) is present in all InnoDB tablespace files except for temporary tablespace and undo tablespace files. SDI records in an InnoDB tablespace file only describe table and tablespace objects contained within the tablespace.

SDI data is updated by DDL operations on a table or CHECK TABLE FOR UPGRADE. SDI data is not updated when the MySQL server is upgraded to a new release or version.

The presence of SDI data provides metadata redundancy. For example, if the data dictionary becomes unavailable, object metadata can be extracted directly from InnoDB tablespace files using the ibd2sdi tool.

For InnoDB, an SDI record requires a single index page, which is 16KB in size by default. However, SDI data is compressed to reduce the storage footprint.

For partitioned InnoDB tables comprised of multiple tablespaces, SDI data is stored in the tablespace file of the first partition.
Data Dictionary Usage Differences

The MySQL server uses an internal API that is accessed during DDL operations to create and maintain SDI records.

The `IMPORT TABLE` statement imports MyISAM tables based on information contained in `.sdi` files. For more information, see Section 13.2.6, “IMPORT TABLE Statement”.

### 14.7 Data Dictionary Usage Differences

Use of a data dictionary-enabled MySQL server entails some operational differences compared to a server that does not have a data dictionary:

- Previously, enabling the `innodb_read_only` system variable prevented creating and dropping tables only for the InnoDB storage engine. As of MySQL 8.0, enabling `innodb_read_only` prevents these operations for all storage engines. Table creation and drop operations for any storage engine modify data dictionary tables in the `mysql` system database, but those tables use the InnoDB storage engine and cannot be modified when `innodb_read_only` is enabled. The same principle applies to other table operations that require modifying data dictionary tables. Examples:
  - `ANALYZE TABLE` fails because it updates table statistics, which are stored in the data dictionary.
  - `ALTER TABLE tbl_name ENGINE=engine_name` fails because it updates the storage engine designation, which is stored in the data dictionary.

- Previously, tables in the `mysql` system database were visible to DML and DDL statements. As of MySQL 8.0, data dictionary tables are invisible and cannot be modified or queried directly. However, in most cases there are corresponding `INFORMATION_SCHEMA` tables that can be queried instead. This enables the underlying data dictionary tables to be changed as server development proceeds, while maintaining a stable `INFORMATION_SCHEMA` interface for application use.

- `INFORMATION_SCHEMA` tables in MySQL 8.0 are closely tied to the data dictionary, resulting in several usage differences:
  - Previously, `INFORMATION_SCHEMA` queries for table statistics in the `STATISTICS` and `TABLES` tables retrieved statistics directly from storage engines. As of MySQL 8.0, cached table statistics are used by default. The `information_schema_stats_expiry` system variable defines the period of time before table statistics expire. The default is 86400 seconds (24 hours). (To update the cached values at any time for a given table, use `ANALYZE TABLE`.) If there are no cached statistics or statistics have expired, statistics are retrieved from storage engines when querying table statistics columns. To always retrieve the latest statistics directly from storage engines, set `information_schema_stats_expiry` to 0. For more information, see Section 8.2.3, “Optimizing INFORMATION_SCHEMA Queries”.
  - Several `INFORMATION_SCHEMA` tables are views on data dictionary tables, which enables the optimizer to use indexes on those underlying tables. Consequently, depending on optimizer choices, the row order of results for `INFORMATION_SCHEMA` queries might differ from previous results. If a query result must have specific row ordering characteristics, include an `ORDER BY` clause.
  - Queries on `INFORMATION_SCHEMA` tables may return column names in a different lettercase than in earlier MySQL series. Applications should test result set column names in case-insensitive fashion.

- Note
  - Enabling `innodb_read_only` also has important implications for non-data dictionary tables in the `mysql` system database. For details, see the description of `innodb_read_only` in Section 15.14, “InnoDB Startup Options and System Variables”.

3263
that is not feasible, a workaround is to use column aliases in the select list that return column names in the required lettercase. For example:

```sql
SELECT TABLE_SCHEMA AS table_schema, TABLE_NAME AS table_name
FROM INFORMATION_SCHEMA.TABLES WHERE TABLE_NAME = 'users';
```

- `mysqldump` and `mysqlpump` no longer dump the `INFORMATION_SCHEMA` database, even if explicitly named on the command line.

- `CREATE TABLE dst_tbl LIKE src_tbl` requires that `src_tbl` be a base table and fails if it is an `INFORMATION_SCHEMA` table that is a view on data dictionary tables.

- Previously, result set headers of columns selected from `INFORMATION_SCHEMA` tables used the capitalization specified in the query. This query produces a result set with a header of `table_name`:

  ```sql
  SELECT table_name FROM INFORMATION_SCHEMA.TABLES;
  ```

  As of MySQL 8.0, these headers are capitalized; the preceding query produces a result set with a header of `TABLE_NAME`. If necessary, a column alias can be used to achieve a different lettercase. For example:

  ```sql
  SELECT table_name AS 'table_name' FROM INFORMATION_SCHEMA.TABLES;
  ```

- The data directory affects how `mysqldump` and `mysqlpump` dump information from the `mysql` system database:

  - Previously, it was possible to dump all tables in the `mysql` system database. As of MySQL 8.0, `mysqldump` and `mysqlpump` dump only non-data dictionary tables in that database.

  - Previously, the `--routines` and `--events` options were not required to include stored routines and events when using the `--all-databases` option: The dump included the `mysql` system database, and therefore also the `proc` and `event` tables containing stored routine and event definitions. As of MySQL 8.0, the `event` and `proc` tables are not used. Definitions for the corresponding objects are stored in data dictionary tables, but those tables are not dumped. To include stored routines and events in a dump made using `--all-databases`, use the `--routines` and `--events` options explicitly.

  - Previously, the `--routines` option required the `SELECT` privilege for the `proc` table. As of MySQL 8.0, that table is not used; `--routines` requires the global `SELECT` privilege instead.

  - Previously, it was possible to dump stored routine and event definitions together with their creation and modification timestamps, by dumping the `proc` and `event` tables. As of MySQL 8.0, those tables are not used, so it is not possible to dump timestamps.

  - Previously, creating a stored routine that contains illegal characters produced a warning. As of MySQL 8.0, this is an error.

### 14.8 Data Dictionary Limitations

This section describes temporary limitations introduced with the MySQL data dictionary.

- Manual creation of database directories under the data directory (for example, with `mkdir`) is unsupported. Manually created database directories are not recognized by the MySQL Server.

- DDL operations take longer due to writing to storage, undo logs, and redo logs instead of `.frm` files.

15.1 Introduction to InnoDB
**Key Advantages of InnoDB**

InnoDB is a general-purpose storage engine that balances high reliability and high performance. In MySQL 8.0, InnoDB is the default MySQL storage engine. Unless you have configured a different default storage engine, issuing a `CREATE TABLE` statement without an `ENGINE` clause creates an InnoDB table.

**Key Advantages of InnoDB**

- Its DML operations follow the ACID model, with transactions featuring commit, rollback, and crash-recovery capabilities to protect user data. See Section 15.2, “InnoDB and the ACID Model”.

- Row-level locking and Oracle-style consistent reads increase multi-user concurrency and performance. See Section 15.7, “InnoDB Locking and Transaction Model”.

- InnoDB tables arrange your data on disk to optimize queries based on primary keys. Each InnoDB table has a primary key index called the clustered index that organizes the data to minimize I/O for primary key lookups. See Section 15.6.2.1, “Clustered and Secondary Indexes”.

- To maintain data integrity, InnoDB supports FOREIGN KEY constraints. With foreign keys, inserts, updates, and deletes are checked to ensure they do not result in inconsistencies across related tables. See Section 13.1.20.5, “FOREIGN KEY Constraints”.

**Table 15.1 InnoDB Storage Engine Features**

<table>

To compare the features of InnoDB with other storage engines provided with MySQL, see the Storage Engine Features table in Chapter 16, Alternative Storage Engines.

InnoDB Enhancements and New Features

For information about InnoDB enhancements and new features, refer to:

- The InnoDB enhancements list in Section 1.3, “What Is New in MySQL 8.0”.
- The Release Notes.

Additional InnoDB Information and Resources

- For InnoDB-related terms and definitions, see the MySQL Glossary.
- For a forum dedicated to the InnoDB storage engine, see MySQL Forums::InnoDB.
- InnoDB is published under the same GNU GPL License Version 2 (of June 1991) as MySQL. For more information on MySQL licensing, see http://www.mysql.com/company/legal/licensing/.

15.1.1 Benefits of Using InnoDB Tables

InnoDB tables have the following benefits:

- If the server unexpectedly exits because of a hardware or software issue, regardless of what was happening in the database at the time, you don't need to do anything special after restarting the database. InnoDB crash recovery automatically finalizes changes that were committed before the time of the crash, and undoes changes that were in process but not committed, permitting you to restart and continue from where you left off. See Section 15.18.2, “InnoDB Recovery”.

- The InnoDB storage engine maintains its own buffer pool that caches table and index data in main memory as data is accessed. Frequently used data is processed directly from memory. This cache applies to many types of information and speeds up processing. On dedicated database servers, up to 80% of physical memory is often assigned to the buffer pool. See Section 15.5.1, “Buffer Pool”.

- If you split up related data into different tables, you can set up foreign keys that enforce referential integrity. See Section 13.1.20.5, “FOREIGN KEY Constraints”.

- If data becomes corrupted on disk or in memory, a checksum mechanism alerts you to the bogus data before you use it. The innodb_checksum_algorithm variable defines the checksum algorithm used by InnoDB.

- When you design a database with appropriate primary key columns for each table, operations involving those columns are automatically optimized. It is very fast to reference the primary key columns in WHERE clauses, ORDER BY clauses, GROUP BY clauses, and join operations. See Section 15.6.2.1, “Clustered and Secondary Indexes”.

- Inserts, updates, and deletes are optimized by an automatic mechanism called change buffering. InnoDB not only allows concurrent read and write access to the same table, it caches changed data to streamline disk I/O. See Section 15.5.2, “Change Buffer”.

3268
• Performance benefits are not limited to large tables with long-running queries. When the same rows are accessed over and over from a table, the Adaptive Hash Index takes over to make these lookups even faster, as if they came out of a hash table. See Section 15.5.3, “Adaptive Hash Index”.

• You can compress tables and associated indexes. See Section 15.9, “InnoDB Table and Page Compression”.

• You can encrypt your data. See Section 15.13, “InnoDB Data-at-Rest Encryption”.

• You can create and drop indexes and perform other DDL operations with much less impact on performance and availability. See Section 15.12.1, “Online DDL Operations”.

• Truncating a file-per-table tablespace is very fast and can free up disk space for the operating system to reuse rather than only InnoDB. See Section 15.6.3.2, “File-Per-Table Tablespaces”.

• The storage layout for table data is more efficient for BLOB and long text fields, with the DYNAMIC row format. See Section 15.10, “InnoDB Row Formats”.

• You can monitor the internal workings of the storage engine by querying INFORMATION_SCHEMA tables. See Section 15.15, “InnoDB INFORMATION_SCHEMA Tables”.

• You can monitor the performance details of the storage engine by querying Performance Schema tables. See Section 15.16, “InnoDB Integration with MySQL Performance Schema”.

• You can mix InnoDB tables with tables from other MySQL storage engines, even within the same statement. For example, you can use a join operation to combine data from InnoDB and MEMORY tables in a single query.

• InnoDB has been designed for CPU efficiency and maximum performance when processing large data volumes.

• InnoDB tables can handle large quantities of data, even on operating systems where file size is limited to 2GB.

For InnoDB-specific tuning techniques you can apply to your MySQL server and application code, see Section 8.5, “Optimizing for InnoDB Tables”.

15.1.2 Best Practices for InnoDB Tables

This section describes best practices when using InnoDB tables.

• Specify a primary key for every table using the most frequently queried column or columns, or an auto-increment value if there is no obvious primary key.

• Use joins wherever data is pulled from multiple tables based on identical ID values from those tables. For fast join performance, define foreign keys on the join columns, and declare those columns with the same data type in each table. Adding foreign keys ensures that referenced columns are indexed, which can improve performance. Foreign keys also propagate deletes and updates to all affected tables, and prevent insertion of data in a child table if the corresponding IDs are not present in the parent table.

• Turn off autocommit. Committing hundreds of times a second puts a cap on performance (limited by the write speed of your storage device).

• Group sets of related DML operations into transactions by bracketing them with START TRANSACTION and COMMIT statements. While you don't want to commit too often, you also don't want to issue huge batches of INSERT, UPDATE, or DELETE statements that run for hours without committing.
Verifying that InnoDB is the Default Storage Engine

- Do not use `LOCK TABLES` statements. InnoDB can handle multiple sessions all reading and writing to the same table at once without sacrificing reliability or high performance. To get exclusive write access to a set of rows, use the `SELECT ... FOR UPDATE` syntax to lock just the rows you intend to update.

- Enable the `innodb_file_per_table` variable or use general tablespaces to put the data and indexes for tables into separate files instead of the system tablespace. The `innodb_file_per_table` variable is enabled by default.

- Evaluate whether your data and access patterns benefit from the InnoDB table or page compression features. You can compress InnoDB tables without sacrificing read/write capability.

- Run the server with the `--sql_mode=NO_ENGINE_SUBSTITUTION` option to prevent tables from being created with storage engines that you do not want to use.

15.1.3 Verifying that InnoDB is the Default Storage Engine

Issue the `SHOW ENGINES` statement to view the available MySQL storage engines. Look for `DEFAULT` in the `SUPPORT` column.

```sql
mysql> SHOW ENGINES;
```

Alternatively, query the Information Schema `ENGINES` table.

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.ENGINES;
```

15.1.4 Testing and Benchmarking with InnoDB

If InnoDB is not the default storage engine, you can determine if your database server and applications work correctly with InnoDB by restarting the server with `--default-storage-engine=InnoDB` defined on the command line or with `default-storage-engine=innodb` defined in the `[mysqld]` section of the MySQL server option file.

Since changing the default storage engine only affects newly created tables, run your application installation and setup steps to confirm that everything installs properly, then exercise the application features to make sure the data loading, editing, and querying features work. If a table relies on a feature that is specific to another storage engine, you receive an error. In this case, add the `ENGINE=other_engine_name` clause to the `CREATE TABLE` statement to avoid the error.

If you did not make a deliberate decision about the storage engine, and you want to preview how certain tables work when created using InnoDB, issue the command `ALTER TABLE table_name ENGINE=InnoDB;` for each table. Alternatively, to run test queries and other statements without disturbing the original table, make a copy:

```sql
CREATE TABLE ... ENGINE=InnoDB AS SELECT * FROM other_engine_table;
```

To assess performance with a full application under a realistic workload, install the latest MySQL server and run benchmarks.

Test the full application lifecycle, from installation, through heavy usage, and server restart. Kill the server process while the database is busy to simulate a power failure, and verify that the data is recovered successfully when you restart the server.

Test any replication configurations, especially if you use different MySQL versions and options on the source server and replicas.

15.2 InnoDB and the ACID Model
Atomicity

The **ACID** model is a set of database design principles that emphasize aspects of reliability that are important for business data and mission-critical applications. MySQL includes components such as the InnoDB storage engine that adhere closely to the ACID model so that data is not corrupted and results are not distorted by exceptional conditions such as software crashes and hardware malfunctions. When you rely on ACID-compliant features, you do not need to reinvent the wheel of consistency checking and crash recovery mechanisms. In cases where you have additional software safeguards, ultra-reliable hardware, or an application that can tolerate a small amount of data loss or inconsistency, you can adjust MySQL settings to trade some of the ACID reliability for greater performance or throughput.

The following sections discuss how MySQL features, in particular the InnoDB storage engine, interact with the categories of the ACID model:

- **A**: atomicity.
- **C**: consistency.
- **I**: isolation.
- **D**: durability.

### Atomicity

The **atomicity** aspect of the ACID model mainly involves InnoDB transactions. Related MySQL features include:

- The `autocommit` setting.
- The `COMMIT` statement.
- The `ROLLBACK` statement.

### Consistency

The **consistency** aspect of the ACID model mainly involves internal InnoDB processing to protect data from crashes. Related MySQL features include:

- The InnoDB doublewrite buffer. See Section 15.6.4, “Doublewrite Buffer”.
- InnoDB crash recovery. See InnoDB Crash Recovery.

### Isolation

The **isolation** aspect of the ACID model mainly involves InnoDB transactions, in particular the isolation level that applies to each transaction. Related MySQL features include:

- The `autocommit` setting.
- Transaction isolation levels and the `SET TRANSACTION` statement. See Section 15.7.2.1, “Transaction Isolation Levels”.
- The low-level details of InnoDB locking. Details can be viewed in the INFORMATION_SCHEMA tables (see Section 15.15.2, “InnoDB INFORMATION_SCHEMA Transaction and Locking Information”) and Performance Schema `data_locks` and `data_lock_waits` tables.

### Durability

The **durability** aspect of the ACID model involves MySQL software features interacting with your particular hardware configuration. Because of the many possibilities depending on the capabilities of your CPU,
network, and storage devices, this aspect is the most complicated to provide concrete guidelines for. (And those guidelines might take the form of “buy new hardware”.) Related MySQL features include:

- The InnoDB doublewrite buffer. See Section 15.6.4, “Doublewrite Buffer”.
- The `innodb_flush_log_at_trx_commit` variable.
- The `sync_binlog` variable.
- The `innodb_file_per_table` variable.
- The write buffer in a storage device, such as a disk drive, SSD, or RAID array.
- A battery-backed cache in a storage device.
- The operating system used to run MySQL, in particular its support for the `fsync()` system call.
- An uninterruptible power supply (UPS) protecting the electrical power to all computer servers and storage devices that run MySQL servers and store MySQL data.
- Your backup strategy, such as frequency and types of backups, and backup retention periods.
- For distributed or hosted data applications, the particular characteristics of the data centers where the hardware for the MySQL servers is located, and network connections between the data centers.

### 15.3 InnoDB Multi-Versioning

**InnoDB** is a multi-version storage engine. It keeps information about old versions of changed rows to support transactional features such as concurrency and rollback. This information is stored in undo tablespaces in a data structure called a rollback segment. See Section 15.6.3.4, “Undo Tablespaces”.

**InnoDB** uses the information in the rollback segment to perform the undo operations needed in a transaction rollback. It also uses the information to build earlier versions of a row for a consistent read. See Section 15.7.2.3, “Consistent Nonlocking Reads”.

Internally, **InnoDB** adds three fields to each row stored in the database:

- A 6-byte `DB_TRX_ID` field indicates the transaction identifier for the last transaction that inserted or updated the row. Also, a deletion is treated internally as an update where a special bit in the row is set to mark it as deleted.

- A 7-byte `DB_ROLL_PTR` field called the roll pointer. The roll pointer points to an undo log record written to the rollback segment. If the row was updated, the undo log record contains the information necessary to rebuild the content of the row before it was updated.

- A 6-byte `DB_ROW_ID` field contains a row ID that increases monotonically as new rows are inserted. If **InnoDB** generates a clustered index automatically, the index contains row ID values. Otherwise, the `DB_ROW_ID` column does not appear in any index.

Undo logs in the rollback segment are divided into insert and update undo logs. Insert undo logs are needed only in transaction rollback and can be discarded as soon as the transaction commits. Update undo logs are used also in consistent reads, but they can be discarded only after there is no transaction present for which **InnoDB** has assigned a snapshot that in a consistent read could require the information in the update undo log to build an earlier version of a database row. For additional information about undo logs, see Section 15.6.6, “Undo Logs”.

It is recommended that you commit transactions regularly, including transactions that issue only consistent reads. Otherwise, **InnoDB** cannot discard data from the update undo logs, and the rollback segment may
Multi-Versioning and Secondary Indexes

grow too big, filling up the undo tablespace in which it resides. For information about managing undo
tablespaces, see Section 15.6.3.4, “Undo Tablespaces”.

The physical size of an undo log record in the rollback segment is typically smaller than the corresponding
inserted or updated row. You can use this information to calculate the space needed for your rollback
segment.

In the InnoDB multi-versioning scheme, a row is not physically removed from the database immediately
when you delete it with an SQL statement. InnoDB only physically removes the corresponding row and its
index records when it discards the update undo log record written for the deletion. This removal operation
is called a purge, and it is quite fast, usually taking the same order of time as the SQL statement that did
the deletion.

If you insert and delete rows in smallish batches at about the same rate in the table, the purge thread
can start to lag behind and the table can grow bigger and bigger because of all the “dead” rows, making
everything disk-bound and very slow. In such cases, throttle new row operations, and allocate more
resources to the purge thread by tuning the innodb_max_purge_lag system variable. For more
information, see Section 15.8.9, “Purge Configuration”.

Multi-Versioning and Secondary Indexes

InnoDB multiversion concurrency control (MVCC) treats secondary indexes differently than clustered
indexes. Records in a clustered index are updated in-place, and their hidden system columns point undo
log entries from which earlier versions of records can be reconstructed. Unlike clustered index records,
secondary index records do not contain hidden system columns nor are they updated in-place.

When a secondary index column is updated, old secondary index records are delete-marked, new records
are inserted, and delete-marked records are eventually purged. When a secondary index record is delete-
marked or the secondary index page is updated by a newer transaction, InnoDB looks up the database
record in the clustered index. In the clustered index, the record’s DB_TRX_ID is checked, and the correct
version of the record is retrieved from the undo log if the record was modified after the reading transaction
was initiated.

If a secondary index record is marked for deletion or the secondary index page is updated by a newer
transaction, the covering index technique is not used. Instead of returning values from the index structure,
InnoDB looks up the record in the clustered index.

However, if the index condition pushdown (ICP) optimization is enabled, and parts of the WHERE condition
can be evaluated using only fields from the index, the MySQL server still pushes this part of the WHERE
condition down to the storage engine where it is evaluated using the index. If no matching records are
found, the clustered index lookup is avoided. If matching records are found, even among delete-marked
records, InnoDB looks up the record in the clustered index.

15.4 InnoDB Architecture

The following diagram shows in-memory and on-disk structures that comprise the InnoDB storage engine
architecture. For information about each structure, see Section 15.5, “InnoDB In-Memory Structures”, and
Section 15.6, “InnoDB On-Disk Structures”.

3273
15.5 InnoDB In-Memory Structures

This section describes InnoDB in-memory structures and related topics.

15.5.1 Buffer Pool

The buffer pool is an area in main memory where InnoDB caches table and index data as it is accessed. The buffer pool permits frequently used data to be accessed directly from memory, which speeds up processing. On dedicated servers, up to 80% of physical memory is often assigned to the buffer pool.

For efficiency of high-volume read operations, the buffer pool is divided into pages that can potentially hold multiple rows. For efficiency of cache management, the buffer pool is implemented as a linked list of pages; data that is rarely used is aged out of the cache using a variation of the least recently used (LRU) algorithm.

Knowing how to take advantage of the buffer pool to keep frequently accessed data in memory is an important aspect of MySQL tuning.
Buffer Pool LRU Algorithm

The buffer pool is managed as a list using a variation of the LRU algorithm. When room is needed to add a new page to the buffer pool, the least recently used page is evicted and a new page is added to the middle of the list. This midpoint insertion strategy treats the list as two sublists:

- At the head, a sublist of new ("young") pages that were accessed recently
- At the tail, a sublist of old pages that were accessed less recently

Figure 15.2 Buffer Pool List

The algorithm keeps frequently used pages in the new sublist. The old sublist contains less frequently used pages; these pages are candidates for eviction.

By default, the algorithm operates as follows:

- 3/8 of the buffer pool is devoted to the old sublist.
- The midpoint of the list is the boundary where the tail of the new sublist meets the head of the old sublist.
- When InnoDB reads a page into the buffer pool, it initially inserts it at the midpoint (the head of the old sublist). A page can be read because it is required for a user-initiated operation such as an SQL query, or as part of a read-ahead operation performed automatically by InnoDB.
• Accessing a page in the old sublist makes it “young”, moving it to the head of the new sublist. If the page was read because it was required by a user-initiated operation, the first access occurs immediately and the page is made young. If the page was read due to a read-ahead operation, the first access does not occur immediately and might not occur at all before the page is evicted.

• As the database operates, pages in the buffer pool that are not accessed “age” by moving toward the tail of the list. Pages in both the new and old sublists age as other pages are made new. Pages in the old sublist also age as pages are inserted at the midpoint. Eventually, a page that remains unused reaches the tail of the old sublist and is evicted.

By default, pages read by queries are immediately moved into the new sublist, meaning they stay in the buffer pool longer. A table scan, performed for a `mysqldump` operation or a `SELECT` statement with no `WHERE` clause, for example, can bring a large amount of data into the buffer pool and evict an equivalent amount of older data, even if the new data is never used again. Similarly, pages that are loaded by the read-ahead background thread and accessed only once are moved to the head of the new list. These situations can push frequently used pages to the old sublist where they become subject to eviction. For information about optimizing this behavior, see Section 15.8.3.3, “Making the Buffer Pool Scan Resistant”, and Section 15.8.3.4, “Configuring InnoDB Buffer Pool Prefetching (Read-Ahead)”. 

InnoDB Standard Monitor output contains several fields in the BUFFER POOL AND MEMORY section regarding operation of the buffer pool LRU algorithm. For details, see Monitoring the Buffer Pool Using the InnoDB Standard Monitor.

Buffer Pool Configuration

You can configure the various aspects of the buffer pool to improve performance.

• Ideally, you set the size of the buffer pool to as large a value as practical, leaving enough memory for other processes on the server to run without excessive paging. The larger the buffer pool, the more InnoDB acts like an in-memory database, reading data from disk once and then accessing the data from memory during subsequent reads. See Section 15.8.3.1, “Configuring InnoDB Buffer Pool Size”.

• On 64-bit systems with sufficient memory, you can split the buffer pool into multiple parts to minimize contention for memory structures among concurrent operations. For details, see Section 15.8.3.2, “Configuring Multiple Buffer Pool Instances”.

• You can keep frequently accessed data in memory regardless of sudden spikes of activity from operations that would bring large amounts of infrequently accessed data into the buffer pool. For details, see Section 15.8.3.3, “Making the Buffer Pool Scan Resistant”.

• You can control how and when to perform read-ahead requests to prefetch pages into the buffer pool asynchronously in anticipation of impending need for them. For details, see Section 15.8.3.4, “Configuring InnoDB Buffer Pool Prefetching (Read-Ahead)”.

• You can control when background flushing occurs and whether or not the rate of flushing is dynamically adjusted based on workload. For details, see Section 15.8.3.5, “Configuring Buffer Pool Flushing”.

• You can configure how InnoDB preserves the current buffer pool state to avoid a lengthy warmup period after a server restart. For details, see Section 15.8.3.6, “Saving and Restoring the Buffer Pool State”.

Monitoring the Buffer Pool Using the InnoDB Standard Monitor

InnoDB Standard Monitor output, which can be accessed using `SHOW ENGINE INNODB STATUS`, provides metrics regarding operation of the buffer pool. Buffer pool metrics are located in the BUFFER POOL AND MEMORY section of InnoDB Standard Monitor output:

```
----------------------
BUFFER POOL AND MEMORY
```
The following table describes buffer pool metrics reported by the InnoDB Standard Monitor.

Per second averages provided in InnoDB Standard Monitor output are based on the elapsed time since InnoDB Standard Monitor output was last printed.

### Table 15.2 InnoDB Buffer Pool Metrics

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Total memory allocated</td>
<td>The total memory allocated for the buffer pool in bytes.</td>
</tr>
<tr>
<td>Dictionary memory allocated</td>
<td>The total memory allocated for the InnoDB data dictionary in bytes.</td>
</tr>
<tr>
<td>Buffer pool size</td>
<td>The total size in pages allocated to the buffer pool.</td>
</tr>
<tr>
<td>Free buffers</td>
<td>The total size in pages of the buffer pool free list.</td>
</tr>
<tr>
<td>Database pages</td>
<td>The total size in pages of the buffer pool LRU list.</td>
</tr>
<tr>
<td>Old database pages</td>
<td>The total size in pages of the buffer pool old LRU sublist.</td>
</tr>
<tr>
<td>Modified db pages</td>
<td>The current number of pages modified in the buffer pool.</td>
</tr>
<tr>
<td>Pending reads</td>
<td>The number of buffer pool pages waiting to be read into the buffer pool.</td>
</tr>
<tr>
<td>Pending writes LRU</td>
<td>The number of old dirty pages within the buffer pool to be written from the bottom of the LRU list.</td>
</tr>
<tr>
<td>Pending writes flush list</td>
<td>The number of buffer pool pages to be flushed during checkpointing.</td>
</tr>
<tr>
<td>Pending writes single page</td>
<td>The number of pending independent page writes within the buffer pool.</td>
</tr>
<tr>
<td>Pages made young</td>
<td>The total number of pages made young in the buffer pool LRU list (moved to the head of sublist of “new” pages).</td>
</tr>
<tr>
<td>Pages made not young</td>
<td>The total number of pages not made young in the buffer pool LRU list (pages that have remained in the “old” sublist without being made young).</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>youngs/s</td>
<td>The per second average of accesses to old pages in the buffer pool LRU list that have resulted in making pages young. See the notes that follow this table for more information.</td>
</tr>
<tr>
<td>non-youngs/s</td>
<td>The per second average of accesses to old pages in the buffer pool LRU list that have resulted in not making pages young. See the notes that follow this table for more information.</td>
</tr>
<tr>
<td>Pages read</td>
<td>The total number of pages read from the buffer pool.</td>
</tr>
<tr>
<td>Pages created</td>
<td>The total number of pages created within the buffer pool.</td>
</tr>
<tr>
<td>Pages written</td>
<td>The total number of pages written from the buffer pool.</td>
</tr>
<tr>
<td>reads/s</td>
<td>The per second average number of buffer pool page reads per second.</td>
</tr>
<tr>
<td>creates/s</td>
<td>The average number of buffer pool pages created per second.</td>
</tr>
<tr>
<td>writes/s</td>
<td>The average number of buffer pool page writes per second.</td>
</tr>
<tr>
<td>Buffer pool hit rate</td>
<td>The buffer pool page hit rate for pages read from the buffer pool vs from disk storage.</td>
</tr>
<tr>
<td>young-making rate</td>
<td>The average hit rate at which page accesses have resulted in making pages young. See the notes that follow this table for more information.</td>
</tr>
<tr>
<td>not (young-making rate)</td>
<td>The average hit rate at which page accesses have not resulted in making pages young. See the notes that follow this table for more information.</td>
</tr>
<tr>
<td>Pages read ahead</td>
<td>The per second average of read ahead operations.</td>
</tr>
<tr>
<td>Pages evicted without access</td>
<td>The per second average of the pages evicted without being accessed from the buffer pool.</td>
</tr>
<tr>
<td>Random read ahead</td>
<td>The per second average of random read ahead operations.</td>
</tr>
<tr>
<td>LRU len</td>
<td>The total size in pages of the buffer pool LRU list.</td>
</tr>
<tr>
<td>unzip_LRU len</td>
<td>The length (in pages) of the buffer pool unzip_LRU list.</td>
</tr>
<tr>
<td>I/O sum</td>
<td>The total number of buffer pool LRU list pages accessed.</td>
</tr>
<tr>
<td>I/O cur</td>
<td>The total number of buffer pool LRU list pages accessed in the current interval.</td>
</tr>
<tr>
<td>I/O unzip sum</td>
<td>The total number of buffer pool unzip_LRU list pages decompressed.</td>
</tr>
<tr>
<td>I/O unzip cur</td>
<td>The total number of buffer pool unzip_LRU list pages decompressed in the current interval.</td>
</tr>
</tbody>
</table>

**Notes:**

3278
• The `youngs/s` metric is applicable only to old pages. It is based on the number of page accesses. There can be multiple accesses for a given page, all of which are counted. If you see very low `youngs/s` values when there are no large scans occurring, consider reducing the delay time or increasing the percentage of the buffer pool used for the old sublist. Increasing the percentage makes the old sublist larger so that it takes longer for pages in that sublist to move to the tail, which increases the likelihood that those pages are accessed again and made young. See Section 15.8.3.3, “Making the Buffer Pool Scan Resistant”.

• The `non-youngs/s` metric is applicable only to old pages. It is based on the number of page accesses. There can be multiple accesses for a given page, all of which are counted. If you do not see a higher `non-youngs/s` value when performing large table scans (and a higher `youngs/s` value), increase the delay value. See Section 15.8.3.3, “Making the Buffer Pool Scan Resistant”.

• The `young-making` rate accounts for all buffer pool page accesses, not just accesses for pages in the old sublist. The `young-making` rate and `not` rate do not normally add up to the overall buffer pool hit rate. Page hits in the old sublist cause pages to move to the new sublist, but page hits in the new sublist cause pages to move to the head of the list only if they are a certain distance from the head.

• `not (young-making rate)` is the average hit rate at which page accesses have not resulted in making pages young due to the delay defined by `innodb_old_blocks_time` not being met, or due to page hits in the new sublist that did not result in pages being moved to the head. This rate accounts for all buffer pool page accesses, not just accesses for pages in the old sublist.

Buffer pool server status variables and the `INNODB_BUFFER_POOL_STATS` table provide many of the same buffer pool metrics found in InnoDB Standard Monitor output. For more information, see Example 15.10, “Querying the INNODB_BUFFER_POOL_STATS Table”.

### 15.5.2 Change Buffer

The change buffer is a special data structure that caches changes to secondary index pages when those pages are not in the buffer pool. The buffered changes, which may result from `INSERT`, `UPDATE`, or `DELETE` operations (DML), are merged later when the pages are loaded into the buffer pool by other read operations.

![Change Buffer Diagram](3279)
Unlike clustered indexes, secondary indexes are usually nonunique, and inserts into secondary indexes happen in a relatively random order. Similarly, deletes and updates may affect secondary index pages that are not adjacently located in an index tree. Merging cached changes at a later time, when affected pages are read into the buffer pool by other operations, avoids substantial random access I/O that would be required to read secondary index pages into the buffer pool from disk.

Periodically, the purge operation that runs when the system is mostly idle, or during a slow shutdown, writes the updated index pages to disk. The purge operation can write disk blocks for a series of index values more efficiently than if each value were written to disk immediately.

Change buffer merging may take several hours when there are many affected rows and numerous secondary indexes to update. During this time, disk I/O is increased, which can cause a significant slowdown for disk-bound queries. Change buffer merging may also continue to occur after a transaction is committed, and even after a server shutdown and restart (see Section 15.21.3, “Forcing InnoDB Recovery” for more information).

In memory, the change buffer occupies part of the buffer pool. On disk, the change buffer is part of the system tablespace, where index changes are buffered when the database server is shut down.

The type of data cached in the change buffer is governed by the `innodb_change_buffering` variable. For more information, see Configuring Change Buffering. You can also configure the maximum change buffer size. For more information, see Configuring the Change Buffer Maximum Size.

Change buffering is not supported for a secondary index if the index contains a descending index column or if the primary key includes a descending index column.

For answers to frequently asked questions about the change buffer, see Section A.16, “MySQL 8.0 FAQ: InnoDB Change Buffer”.

### Configuring Change Buffering

When `INSERT`, `UPDATE`, and `DELETE` operations are performed on a table, the values of indexed columns (particularly the values of secondary keys) are often in an unsorted order, requiring substantial I/O to bring secondary indexes up to date. The change buffer caches changes to secondary index entries when the relevant page is not in the buffer pool, thus avoiding expensive I/O operations by not immediately reading in the page from disk. The buffered changes are merged when the page is loaded into the buffer pool, and the updated page is later flushed to disk. The InnoDB main thread merges buffered changes when the server is nearly idle, and during a slow shutdown.

Because it can result in fewer disk reads and writes, change buffering is most valuable for workloads that are I/O-bound; for example, applications with a high volume of DML operations such as bulk inserts benefit from change buffering.

However, the change buffer occupies a part of the buffer pool, reducing the memory available to cache data pages. If the working set almost fits in the buffer pool, or if your tables have relatively few secondary indexes, it may be useful to disable change buffering. If the working data set fits entirely within the buffer pool, change buffering does not impose extra overhead, because it only applies to pages that are not in the buffer pool.

The `innodb_change_buffering` variable controls the extent to which InnoDB performs change buffering. You can enable or disable buffering for inserts, delete operations (when index records are initially marked for deletion) and purge operations (when index records are physically deleted). An update operation is a combination of an insert and a delete. The default `innodb_change_buffering` value is `all`.

3280
Permitted `innodb_change_buffering` values include:

- **all**
  The default value: buffer inserts, delete-marking operations, and purges.

- **none**
  Do not buffer any operations.

- **inserts**
  Buffer insert operations.

- **deletes**
  Buffer delete-marking operations.

- **changes**
  Buffer both inserts and delete-marking operations.

- **purges**
  Buffer the physical deletion operations that happen in the background.

You can set the `innodb_change_buffering` variable in the MySQL option file (`my.cnf` or `my.ini`) or change it dynamically with the `SET GLOBAL` statement, which requires privileges sufficient to set global system variables. See Section 5.1.9.1, “System Variable Privileges”. Changing the setting affects the buffering of new operations; the merging of existing buffered entries is not affected.

### Configuring the Change Buffer Maximum Size

The `innodb_change_buffer_max_size` variable permits configuring the maximum size of the change buffer as a percentage of the total size of the buffer pool. By default, `innodb_change_buffer_max_size` is set to 25. The maximum setting is 50.

Consider increasing `innodb_change_buffer_max_size` on a MySQL server with heavy insert, update, and delete activity, where change buffer merging does not keep pace with new change buffer entries, causing the change buffer to reach its maximum size limit.

Consider decreasing `innodb_change_buffer_max_size` on a MySQL server with static data used for reporting, or if the change buffer consumes too much of the memory space shared with the buffer pool, causing pages to age out of the buffer pool sooner than desired.

Test different settings with a representative workload to determine an optimal configuration. The `innodb_change_buffer_max_size` variable is dynamic, which permits modifying the setting without restarting the server.

### Monitoring the Change Buffer

The following options are available for change buffer monitoring:

- **InnoDB** Standard Monitor output includes change buffer status information. To view monitor data, issue the `SHOW ENGINE INNODB STATUS` statement.

  ```mysql
  mysql> SHOW ENGINE INNODB STATUS\G
  ```
Change Buffer status information is located under the `INSERT BUFFER AND ADAPTIVE HASH INDEX` heading and appears similar to the following:

```
<table>
<thead>
<tr>
<th>INSERT BUFFER AND ADAPTIVE HASH INDEX</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ibuf: size 1, free list len 0, seg size 2, 0 merges</td>
</tr>
<tr>
<td>merged operations: insert 0, delete mark 0, delete 0</td>
</tr>
<tr>
<td>discarded operations: insert 0, delete mark 0, delete 0</td>
</tr>
<tr>
<td>Hash table size 4425293, used cells 32, node heap has 1 buffer(s)</td>
</tr>
<tr>
<td>13577.57 hash searches/s, 202.47 non-hash searches/s</td>
</tr>
</tbody>
</table>
```

For more information, see Section 15.17.3, “InnoDB Standard Monitor and Lock Monitor Output”.

- The Information Schema `INNODB_METRICS` table provides most of the data points found in InnoDB Standard Monitor output plus other data points. To view change buffer metrics and a description of each, issue the following query:

  ```sql
  mysql> SELECT NAME, COMMENT FROM INFORMATION_SCHEMA.INNODB METRICS WHERE NAME LIKE '%ibuf%'
  
  See Section 15.15.6, “InnoDB INFORMATION_SCHEMA Metrics Table”.

- The Information Schema `INNODB_BUFFER_PAGE` table provides metadata about each page in the buffer pool, including change buffer index and change buffer bitmap pages. Change buffer pages are identified by `PAGE_TYPE`. `IBUF_INDEX` is the page type for change buffer index pages, and `IBUF_BITMAP` is the page type for change buffer bitmap pages.

  **Warning**
  
  Querying the `INNODB_BUFFER_PAGE` table can introduce significant performance overhead. To avoid impacting performance, reproduce the issue you want to investigate on a test instance and run your queries on the test instance.

  For example, you can query the `INNODB_BUFFER_PAGE` table to determine the approximate number of `IBUF_INDEX` and `IBUF_BITMAP` pages as a percentage of total buffer pool pages.

  ```sql
  mysql> SELECT (SELECT COUNT(*) FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE WHERE PAGE_TYPE LIKE 'IBUF%') AS change_buffer_pages,
     
<table>
<thead>
<tr>
<th>change_buffer_pages</th>
<th>total_pages</th>
<th>change_buffer_page_percentage</th>
</tr>
</thead>
<tbody>
<tr>
<td>25</td>
<td>8192</td>
<td>0.3052</td>
</tr>
</tbody>
</table>
  
  For information about other data provided by the `INNODB_BUFFER_PAGE` table, see Section 26.4.2, “The INFORMATION_SCHEMA INNODB_BUFFER_PAGE Table”. For related usage information, see Section 15.15.5, “InnoDB INFORMATION_SCHEMA Buffer Pool Tables”.

- Performance Schema provides change buffer mutex wait instrumentation for advanced performance monitoring. To view change buffer instrumentation, issue the following query:

  ```sql
  mysql> SELECT * FROM performance_schema.setup_instruments WHERE NAME LIKE '%wait/synch/mutex/innodb/ibuf%';
  
<table>
<thead>
<tr>
<th>NAME</th>
<th>ENABLED</th>
<th>TIMED</th>
</tr>
</thead>
<tbody>
<tr>
<td>3282</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
  ```
15.5.3 Adaptive Hash Index

The adaptive hash index enables InnoDB to perform more like an in-memory database on systems with appropriate combinations of workload and sufficient memory for the buffer pool without sacrificing transactional features or reliability. The adaptive hash index is enabled by the `innodb_adaptive_hash_index` variable, or turned off at server startup by `--skip-innodb-adaptive-hash-index`.

Based on the observed pattern of searches, a hash index is built using a prefix of the index key. The prefix can be any length, and it may be that only some values in the B-tree appear in the hash index. Hash indexes are built on demand for the pages of the index that are accessed often.

If a table fits almost entirely in main memory, a hash index speeds up queries by enabling direct lookup of any element, turning the index value into a sort of pointer. InnoDB has a mechanism that monitors index searches. If InnoDB notices that queries could benefit from building a hash index, it does so automatically.

With some workloads, the speedup from hash index lookups greatly outweighs the extra work to monitor index lookups and maintain the hash index structure. Access to the adaptive hash index can sometimes become a source of contention under heavy workloads, such as multiple concurrent joins. Queries with LIKE operators and % wildcards also tend not to benefit. For workloads that do not benefit from the adaptive hash index, turning it off reduces unnecessary performance overhead. Because it is difficult to predict in advance whether the adaptive hash index is appropriate for a particular system and workload, consider running benchmarks with it enabled and disabled.

The adaptive hash index feature is partitioned. Each index is bound to a specific partition, and each partition is protected by a separate latch. Partitioning is controlled by the `innodb_adaptive_hash_index_parts` variable. The `innodb_adaptive_hash_index_parts` variable is set to 8 by default. The maximum setting is 512.

You can monitor adaptive hash index use and contention in the `SEMAPHORES` section of `SHOW ENGINE INNODB STATUS` output. If there are numerous threads waiting on rw-latches created in `btr0sea.c`, consider increasing the number of adaptive hash index partitions or disabling the adaptive hash index.

For information about the performance characteristics of hash indexes, see Section 8.3.9, “Comparison of B-Tree and Hash Indexes”.

15.5.4 Log Buffer

The log buffer is the memory area that holds data to be written to the log files on disk. Log buffer size is defined by the `innodb_log_buffer_size` variable. The default size is 16MB. The contents of the log buffer are periodically flushed to disk. A large log buffer enables large transactions to run without the need to write redo log data to disk before the transactions commit. Thus, if you have transactions that update, insert, or delete many rows, increasing the size of the log buffer saves disk I/O.

The `innodb_flush_log_at_trx_commit` variable controls how the contents of the log buffer are written and flushed to disk. The `innodb_flush_log_at_timeout` variable controls log flushing frequency.

For related information, see Memory Configuration, and Section 8.5.4, “Optimizing InnoDB Redo Logging”.

---

For information about monitoring InnoDB mutex waits, see Section 15.16.2, “Monitoring InnoDB Mutex Waits Using Performance Schema”.

| wait/synch/mutex/innodb/ibuf_bitmap_mutex | YES | YES |
| wait/synch/mutex/innodb/ibuf_mutex | YES | YES |
| wait/synch/mutex/innodb/ibuf_pessimistic_insert_mutex | YES | YES |

15.6 InnoDB On-Disk Structures

This section describes InnoDB on-disk structures and related topics.

15.6.1 Tables

This section covers topics related to InnoDB tables.

15.6.1.1 Creating InnoDB Tables

InnoDB tables are created using the `CREATE TABLE` statement; for example:

```
CREATE TABLE t1 (a INT, b CHAR (20), PRIMARY KEY (a)) ENGINE=InnoDB;
```

The `ENGINE=InnoDB` clause is not required when InnoDB is defined as the default storage engine, which it is by default. However, the `ENGINE` clause is useful if the `CREATE TABLE` statement is to be replayed on a different MySQL Server instance where the default storage engine is not InnoDB or is unknown. You can determine the default storage engine on a MySQL Server instance by issuing the following statement:

```
mysql> SELECT @@default_storage_engine;
```

```
+--------------------------+
| @@default_storage_engine |
+--------------------------+
| InnoDB                   |
+--------------------------+
```

InnoDB tables are created in file-per-table tablespaces by default. To create an InnoDB table in the InnoDB system tablespace, disable the `innodb_file_per_table` variable before creating the table. To create an InnoDB table in a general tablespace, use `CREATE TABLE ... TABLESPACE` syntax. For more information, see Section 15.6.3, “Tablespaces”.

Row Formats

The row format of an InnoDB table determines how its rows are physically stored on disk. InnoDB supports four row formats, each with different storage characteristics. Supported row formats include `REDUNDANT`, `COMPACT`, `DYNAMIC`, and `COMPRESSED`. The `DYNAMIC` row format is the default. For information about row format characteristics, see Section 15.10, “InnoDB Row Formats”.

The `innodb_default_row_format` variable defines the default row format. The format of a table can also be defined explicitly using the `ROW_FORMAT` table option in a `CREATE TABLE` or `ALTER TABLE` statement. See Defining the Row Format of a Table.

Primary Keys

It is recommended that you define a primary key for each table that you create. When selecting primary key columns, choose columns with the following characteristics:

- Columns that are referenced by the most important queries.
- Columns that are never left blank.
- Columns that never have duplicate values.
- Columns that rarely if ever change value once inserted.

For example, in a table containing information about people, you would not create a primary key on `(firstname, lastname)` because more than one person can have the same name, a name column may be left blank, and sometimes people change their names. With so many constraints, often there is not
an obvious set of columns to use as a primary key, so you create a new column with a numeric ID to serve as all or part of the primary key. You can declare an auto-increment column so that ascending values are filled in automatically as rows are inserted:

```sql
# The value of ID can act like a pointer between related items in different tables.
CREATE TABLE t5 (id INT AUTO_INCREMENT, b CHAR (20), PRIMARY KEY (id));

# The primary key can consist of more than one column. Any autoinc column must come first.
CREATE TABLE t6 (id INT AUTO_INCREMENT, a INT, b CHAR (20), PRIMARY KEY (id,a));
```

For more information about auto-increment columns, see Section 15.6.1.6, “AUTO_INCREMENT Handling in InnoDB”.

Although a table works correctly without defining a primary key, the primary key is involved with many aspects of performance and is a crucial design aspect for any large or frequently used table. It is recommended that you always specify a primary key in the `CREATE TABLE` statement. If you create the table, load data, and then run `ALTER TABLE` to add a primary key later, that operation is much slower than defining the primary key when creating the table. For more information about primary keys, see Section 15.6.2.1, “Clustered and Secondary Indexes”.

### Viewing InnoDB Table Properties

To view the properties of an InnoDB table, issue a `SHOW TABLE STATUS` statement:

```sql
mysql> SHOW TABLE STATUS FROM test LIKE 't%' \G;
*************************** 1. row ***************************
Name: t1
Engine: InnoDB
Version: 10
Row_format: Dynamic
Rows: 0
Avg_row_length: 0
Data_length: 16384
Max_data_length: 0
Index_length: 0
Data_free: 0
Auto_increment: NULL
Create_time: 2021-02-18 12:18:28
Update_time: NULL
Check_time: NULL
Collation: utf8mb4_0900_ai_ci
Checksum: NULL
Create_options:
Comment:
```

For information about `SHOW TABLE STATUS` output, see Section 13.7.7.38, “SHOW TABLE STATUS Statement”.

You can also access InnoDB table properties by querying the InnoDB Information Schema system tables:

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_TABLES WHERE NAME='test/t1' \G
*************************** 1. row ***************************
TABLE_ID: 1144
NAME: test/t1
FLAG: 33
N_COLS: 5
SPACE: 30
ROW_FORMAT: Dynamic
ZIP_PAGE_SIZE: 0
SPACE_TYPE: Single
INSTANT_COLS: 0
```

For more information, see Section 15.15.3, “InnoDB INFORMATION_SCHEMA Schema Object Tables”. 
15.6.1.2 Creating Tables Externally

There are different reasons for creating InnoDB tables externally; that is, creating tables outside of the data directory. Those reasons might include space management, I/O optimization, or placing tables on a storage device with particular performance or capacity characteristics, for example.

InnoDB supports the following methods for creating tables externally:

- Using the DATA DIRECTORY Clause
- Using CREATE TABLE ... TABLESPACE Syntax
- Creating a Table in an External General Tablespace

Using the DATA DIRECTORY Clause

You can create an InnoDB table in an external directory by specifying a DATA DIRECTORY clause in the CREATE TABLE statement.

```sql
CREATE TABLE t1 (c1 INT PRIMARY KEY) DATA DIRECTORY = '/external/directory';
```

The DATA DIRECTORY clause is supported for tables created in file-per-table tablespaces. Tables are implicitly created in file-per-table tablespaces when the innodb_file_per_table variable is enabled, which it is by default.

```sql
mysql> SELECT @@innodb_file_per_table;
+-------------------------+
| @@innodb_file_per_table |
+-------------------------+
|                       1 |
+-------------------------+

For more information about file-per-table tablespaces, see Section 15.6.3.2, “File-Per-Table Tablespaces”.

When you specify a DATA DIRECTORY clause in a CREATE TABLE statement, the table's data file (table_name.ibd) is created in a schema directory under the specified directory.

As of MySQL 8.0.21, tables and table partitions created outside of the data directory using the DATA DIRECTORY clause are restricted to directories known to InnoDB. This requirement permits database administrators to control where tablespace data files are created and ensures that data files can be found during recovery (see Tablespace Discovery During Crash Recovery). Known directories are those defined by the datadir, innodb_data_home_dir, and innodb_directories variables. You can use the following statement to check those settings:

```sql
mysql> SELECT @@datadir,@@innodb_data_home_dir,@@innodb_directories;
```

If the directory you want to use is unknown, add it to the innodb_directories setting before you create the table. The innodb_directories variable is read-only. Configuring it requires restarting the server. For general information about setting system variables, see Section 5.1.9, “Using System Variables”.

The following example demonstrates creating a table in an external directory using the DATA DIRECTORY clause. It is assumed that the innodb_file_per_table variable is enabled and that the directory is known to InnoDB.

```sql
mysql> USE test;
Database changed

mysql> CREATE TABLE t1 (c1 INT PRIMARY KEY) DATA DIRECTORY = '/external/directory';

# MySQL creates the table's data file in a schema directory
# under the external directory

```bash
$> cd /external/directory/test
$> ls
t1.ibd
```

### Usage Notes:

- MySQL initially holds the tablespace data file open, preventing you from dismounting the device, but might eventually close the file if the server is busy. Be careful not to accidentally dismount an external device while MySQL is running, or start MySQL while the device is disconnected. Attempting to access a table when the associated data file is missing causes a serious error that requires a server restart.

A server restart might fail if the data file is not found at the expected path. In this case, you can restore the tablespace data file from a backup or drop the table to remove the information about it from the data dictionary.

- Before placing a table on an NFS-mounted volume, review potential issues outlined in Using NFS with MySQL.

- If using an LVM snapshot, file copy, or other file-based mechanism to back up the table's data file, always use the `FLUSH TABLES ... FOR EXPORT` statement first to ensure that all changes buffered in memory are flushed to disk before the backup occurs.

- Using the `DATA DIRECTORY` clause to create a table in an external directory is an alternative to using symbolic links, which InnoDB does not support.

- The `DATA DIRECTORY` clause is not supported in a replication environment where the source and replica reside on the same host. The `DATA DIRECTORY` clause requires a full directory path. Replicating the path in this case would cause the source and replica to create the table in the same location.

- As of MySQL 8.0.21, tables created in file-per-table tablespaces can no longer be created in the undo tablespace directory (`innodb_undo_directory`) unless that directly is known to InnoDB. Known directories are those defined by the `datadir`, `innodb_data_home_dir`, and `innodb_directories` variables.

### Using CREATE TABLE ... TABLESPACE Syntax

`CREATE TABLE ... TABLESPACE` syntax can be used in combination with the `DATA DIRECTORY` clause to create a table in an external directory. To do so, specify `innodb_file_per_table` as the tablespace name.

```sql
mysql> CREATE TABLE t2 (c1 INT PRIMARY KEY) TABLESPACE = innodb_file_per_table
DATA DIRECTORY = '/external/directory';
```

This method is supported only for tables created in file-per-table tablespaces, but does not require the `innodb_file_per_table` variable to be enabled. In all other respects, this method is equivalent to the `CREATE TABLE ... DATA DIRECTORY` method described above. The same usage notes apply.

### Creating a Table in an External General Tablespace

You can create a table in a general tablespace that resides in an external directory.

- For information about creating a general tablespace in an external directory, see Creating a General Tablespace.

- For information about creating a table in a general tablespace, see Adding Tables to a General Tablespace.
15.6.1.3 Importing InnoDB Tables

This section describes how to import tables using the *Transportable Tablespaces* feature, which permits importing tables, partitioned tables, or individual table partitions that reside in file-per-table tablespaces. There are many reasons why you might want to import tables:

- To run reports on a non-production MySQL server instance to avoid placing extra load on a production server.
- To copy data to a new replica server.
- To restore a table from a backed-up tablespace file.
- As a faster way of moving data than importing a dump file, which requires reinserting data and rebuilding indexes.
- To move a data to a server with storage media that is better suited to your storage requirements. For example, you might move busy tables to an SSD device, or move large tables to a high-capacity HDD device.

The *Transportable Tablespaces* feature is described under the following topics in this section:

- Prerequisites
- Importing Tables
- Importing Partitioned Tables
- Importing Table Partitions
- Limitations
- Usage Notes
- Internals

**Prerequisites**

- The `innodb_file_per_table` variable must be enabled, which it is by default.
- The page size of the tablespace must match the page size of the destination MySQL server instance. InnoDB page size is defined by the `innodb_page_size` variable, which is configured when initializing a MySQL server instance.
- If the table has a foreign key relationship, `foreign_key_checks` must be disabled before executing `DISCARD TABLESPACE`. Also, you should export all foreign key related tables at the same logical point in time, as `ALTER TABLE ... IMPORT TABLESPACE` does not enforce foreign key constraints on imported data. To do so, stop updating the related tables, commit all transactions, acquire shared locks on the tables, and perform the export operations.
- When importing a table from another MySQL server instance, both MySQL server instances must have General Availability (GA) status and must be the same version. Otherwise, the table must be created on the same MySQL server instance into which it is being imported.
- If the table was created in an external directory by specifying the `DATA DIRECTORY` clause in the `CREATE TABLE` statement, the table that you replace on the destination instance must be defined with the same `DATA DIRECTORY` clause. A schema mismatch error is reported if the clauses do not match.
To determine if the source table was defined with a `DATA DIRECTORY` clause, use `SHOW CREATE TABLE` to view the table definition. For information about using the `DATA DIRECTORY` clause, see Section 15.6.1.2, "Creating Tables Externally".

- If a `ROW_FORMAT` option is not defined explicitly in the table definition or `ROW_FORMAT=DEFAULT` is used, the `innodb_default_row_format` setting must be the same on the source and destination instances. Otherwise, a schema mismatch error is reported when you attempt the import operation. Use `SHOW CREATE TABLE` to check the table definition. Use `SHOW VARIABLES` to check the `innodb_default_row_format` setting. For related information, see Defining the Row Format of a Table.

### Importing Tables

This example demonstrates how to import a regular non-partitioned table that resides in a file-per-table tablespace.

1. On the destination instance, create a table with the same definition as the table you intend to import. (You can obtain the table definition using `SHOW CREATE TABLE` syntax.) If the table definition does not match, a schema mismatch error is reported when you attempt the import operation.

   ```
   mysql> USE test;
   mysql> CREATE TABLE t1 (c1 INT) ENGINE=INNODB;
   ```

2. On the destination instance, discard the tablespace of the table that you just created. (Before importing, you must discard the tablespace of the receiving table.)

   ```
   mysql> ALTER TABLE t1 DISCARD TABLESPACE;
   ```

3. On the source instance, run `FLUSH TABLES ... FOR EXPORT` to quiesce the table you intend to import. When a table is quiesced, only read-only transactions are permitted on the table.

   ```
   mysql> USE test;
   mysql> FLUSH TABLES t1 FOR EXPORT;
   ```

   `FLUSH TABLES ... FOR EXPORT` ensures that changes to the named table are flushed to disk so that a binary table copy can be made while the server is running. When `FLUSH TABLES ... FOR EXPORT` is run, InnoDB generates a `.cfg` metadata file in the schema directory of the table. The `.cfg` file contains metadata that is used for schema verification during the import operation.

   **Note**

   The connection executing `FLUSH TABLES ... FOR EXPORT` must remain open while the operation is running; otherwise, the `.cfg` file is removed as locks are released upon connection closure.

4. Copy the `.ibd` file and `.cfg` metadata file from the source instance to the destination instance. For example:

   ```
   $> scp /path/to/datadir/test/t1.{ibd,cfg} destination-server:/path/to/datadir/test
   ```

   The `.ibd` file and `.cfg` file must be copied before releasing the shared locks, as described in the next step.

   **Note**

   If you are importing a table from an encrypted tablespace, InnoDB generates a `.cfp` file in addition to a `.cfg` metadata file. The `.cfp` file must be copied to the destination instance together with the `.cfg` file. The `.cfp` file contains
Tables

InnoDB uses a transfer key and an encrypted tablespace key. On import, InnoDB uses the transfer key to decrypt the tablespace key. For related information, see Section 15.13, “InnoDB Data-at-Rest Encryption”.

5. On the source instance, use UNLOCK TABLES to release the locks acquired by the FLUSH TABLES ... FOR EXPORT statement:

```sql
mysql> USE test;
mysql> UNLOCK TABLES;
```

The UNLOCK TABLES operation also removes the .cfg file.

6. On the destination instance, import the tablespace:

```sql
mysql> USE test;
mysql> ALTER TABLE t1 IMPORT TABLESPACE;
```

Importing Partitioned Tables

This example demonstrates how to import a partitioned table, where each table partition resides in a file-per-table tablespace.

1. On the destination instance, create a partitioned table with the same definition as the partitioned table that you want to import. (You can obtain the table definition using SHOW CREATE TABLE syntax.) If the table definition does not match, a schema mismatch error is reported when you attempt the import operation.

```sql
mysql> USE test;
mysql> CREATE TABLE t1 (i int) ENGINE = InnoDB PARTITION BY KEY (i) PARTITIONS 3;
```

In the /datadir/test directory, there is a tablespace .ibd file for each of the three partitions.

```bash
!/path/to/datadir/test/
t1#p#p0.ibd t1#p#p1.ibd t1#p#p2.ibd
```

2. On the destination instance, discard the tablespace for the partitioned table. (Before the import operation, you must discard the tablespace of the receiving table.)

```sql
mysql> ALTER TABLE t1 DISCARD TABLESPACE;
```

The three tablespace .ibd files of the partitioned table are discarded from the /datadir/test directory.

3. On the source instance, run FLUSH TABLES ... FOR EXPORT to quiesce the partitioned table that you intend to import. When a table is quiesced, only read-only transactions are permitted on the table.

```sql
mysql> USE test;
mysql> FLUSH TABLES t1 FOR EXPORT;
```

FLUSH TABLES ... FOR EXPORT ensures that changes to the named table are flushed to disk so that binary table copy can be made while the server is running. When FLUSH TABLES ... FOR EXPORT is run, InnoDB generates .cfg metadata files in the schema directory of the table for each of the table’s tablespace files.

```bash
!/path/to/datadir/test/
t1#p#p0.ibd t1#p#p1.ibd t1#p#p2.ibd
t1#p#p0.cfg t1#p#p1.cfg t1#p#p2.cfg
```

The .cfg files contain metadata that is used for schema verification when importing the tablespace. FLUSH TABLES ... FOR EXPORT can only be run on the table, not on individual table partitions.
4. Copy the `.ibd` and `.cfg` files from the source instance schema directory to the destination instance schema directory. For example:

```
scp /path/to/datadir/test/t1*.{ibd,cfg} destination-server:/path/to/datadir/test
```

The `.ibd` and `.cfg` files must be copied before releasing the shared locks, as described in the next step.

**Note**

If you are importing a table from an encrypted tablespace, InnoDB generates a `.cfp` files in addition to a `.cfg` metadata files. The `.cfp` files must be copied to the destination instance together with the `.cfg` files. The `.cfp` files contain a transfer key and an encrypted tablespace key. On import, InnoDB uses the transfer key to decrypt the tablespace key. For related information, see Section 15.13, “InnoDB Data-at-Rest Encryption”.

5. On the source instance, use `UNLOCK TABLES` to release the locks acquired by `FLUSH TABLES ... FOR EXPORT`:

```
mysql> USE test;
mysql> UNLOCK TABLES;
```

6. On the destination instance, import the tablespace of the partitioned table:

```
mysql> USE test;
mysql> ALTER TABLE t1 IMPORT TABLESPACE;
```

---

### Importing Table Partitions

This example demonstrates how to import individual table partitions, where each partition resides in a file-per-table tablespace file.

In the following example, two partitions (`p2` and `p3`) of a four-partition table are imported.

1. On the destination instance, create a partitioned table with the same definition as the partitioned table that you want to import partitions from. (You can obtain the table definition using `SHOW CREATE TABLE` syntax.) If the table definition does not match, a schema mismatch error is reported when you attempt the import operation.

```
mysql> USE test;
mysql> CREATE TABLE t1 (i int) ENGINE = InnoDB PARTITION BY KEY (i) PARTITIONS 4;
```

In the `/datadir/test` directory, there is a tablespace `.ibd` file for each of the four partitions.

```
mysql> \ls /path/to/datadir/test/
t1#p#p0.ibd  t1#p#p1.ibd  t1#p#p2.ibd  t1#p#p3.ibd
```

2. On the destination instance, discard the partitions that you intend to import from the source instance. (Before importing partitions, you must discard the corresponding partitions from the receiving partitioned table.)

```
mysql> ALTER TABLE t1 DISCARD PARTITION p2, p3 TABLESPACE;
```

The tablespace `.ibd` files for the two discarded partitions are removed from the `/datadir/test` directory on the destination instance, leaving the following files:

```
mysql> \ls /path/to/datadir/test/
t1#p#p0.ibd  t1#p#p1.ibd
```
When `ALTER TABLE ... DISCARD PARTITION ... TABLESPACE` is run on subpartitioned tables, both partition and subpartition table names are permitted. When a partition name is specified, subpartitions of that partition are included in the operation.

3. On the source instance, run `FLUSH TABLES ... FOR EXPORT` to quiesce the partitioned table. When a table is quiesced, only read-only transactions are permitted on the table.

```sql
mysql> USE test;
mysql> FLUSH TABLES t1 FOR EXPORT;
```

`FLUSH TABLES ... FOR EXPORT` ensures that changes to the named table are flushed to disk so that binary table copy can be made while the instance is running. When `FLUSH TABLES ... FOR EXPORT` is run, InnoDB generates a `.cfg` metadata file for each of the table’s tablespace files in the schema directory of the table.

```bash
mysql> \! ls /path/to/datadir/test/
```

```plaintext
 t1#p#p0.ibd  t1#p#p1.ibd  t1#p#p2.ibd  t1#p#p3.ibd
 t1#p#p0.cfg  t1#p#p1.cfg  t1#p#p2.cfg  t1#p#p3.cfg
```

The `.cfg` files contain metadata that used for schema verification during the import operation. `FLUSH TABLES ... FOR EXPORT` can only be run on the table, not on individual table partitions.

4. Copy the `.ibd` and `.cfg` files for partition `p2` and partition `p3` from the source instance schema directory to the destination instance schema directory.

```bash
$> scp t1#p#p2.ibd t1#p#p2.cfg t1#p#p3.ibd t1#p#p3.cfg destination-server:/path/to/datadir/test
```

The `.ibd` and `.cfg` files must be copied before releasing the shared locks, as described in the next step.

Note

If you are importing partitions from an encrypted tablespace, InnoDB generates a `.cfp` files in addition to a `.cfg` metadata files. The `.cfp` files must be copied to the destination instance together with the `.cfg` files. The `.cfp` files contain a transfer key and an encrypted tablespace key. On import, InnoDB uses the transfer key to decrypt the tablespace key. For related information, see Section 15.13, “InnoDB Data-at-Rest Encryption”.

5. On the source instance, use `UNLOCK TABLES` to release the locks acquired by `FLUSH TABLES ... FOR EXPORT`:

```sql
mysql> USE test;
mysql> UNLOCK TABLES;
```

6. On the destination instance, import table partitions `p2` and `p3`:

```sql
mysql> USE test;
mysql> ALTER TABLE t1 IMPORT PARTITION p2, p3 TABLESPACE;
```

Note

When `ALTER TABLE ... IMPORT PARTITION ... TABLESPACE` is run on subpartitioned tables, both partition and subpartition table names are permitted.
When a partition name is specified, subpartitions of that partition are included in the operation.

Limitations

- The Transportable Tablespaces feature is only supported for tables that reside in file-per-table tablespaces. It is not supported for the tables that reside in the system tablespace or general tablespaces. Tables in shared tablespaces cannot be quiesced.

- FLUSH TABLES ... FOR EXPORT is not supported on tables with a FULLTEXT index, as full-text search auxiliary tables cannot be flushed. After importing a table with a FULLTEXT index, run OPTIMIZE TABLE to rebuild the FULLTEXT indexes. Alternatively, drop FULLTEXT indexes before the export operation and recreate the indexes after importing the table on the destination instance.

- Due to a .cfg metadata file limitation, schema mismatches are not reported for partition type or partition definition differences when importing a partitioned table. Column differences are reported.

- Prior to MySQL 8.0.19, index key part sort order information is not stored to the .cfg metadata file used during a tablespace import operation. The index key part sort order is therefore assumed to be ascending, which is the default. As a result, records could be sorted in an unintended order if one table involved in the import operation is defined with a DESC index key part sort order and the other table is not. The workaround is to drop and recreate affected indexes. For information about index key part sort order, see Section 13.1.15, “CREATE INDEX Statement”.

The .cfg file format was updated in MySQL 8.0.19 to include index key part sort order information. The issue described above does not affect import operations between MySQL 8.0.19 server instances or higher.

Usage Notes

- With the exception of tables that contain instantly added or dropped columns, ALTER TABLE ... IMPORT TABLESPACE does not require a .cfg metadata file to import a table. However, metadata checks are not performed when importing without a .cfg file, and a warning similar to the following is issued:

```
Message: InnoDB: IO Read error: (2, No such file or directory) Error opening '.\test\t.cfg', will attempt to import without schema verification
1 row in set (0.00 sec)
```

Importing a table without a .cfg metadata file should only be considered if no schema mismatches are expected and the table does not contain any instantly added or dropped columns. The ability to import without a .cfg file could be useful in crash recovery scenarios where metadata is not accessible.

Attempting to import a table with columns that were added or dropped using ALGORITHM=INSTANT without using a .cfg file can result in undefined behavior.

- On Windows, InnoDB stores database, tablespace, and table names internally in lowercase. To avoid import problems on case-sensitive operating systems such as Linux and Unix, create all databases, tablespaces, and tables using lowercase names. A convenient way to ensure that names are created in lowercase is to set lower_case_table_names to 1 before initializing the server. (It is prohibited to start the server with a lower_case_table_names setting that is different from the setting used when the server was initialized.)

```
[mysqld]
lower_case_table_names=1
```

- When running ALTER TABLE ... DISCARD PARTITION ... TABLESPACE and ALTER TABLE ... IMPORT PARTITION ... TABLESPACE on subpartitioned tables, both partition and
subpartition table names are permitted. When a partition name is specified, subpartitions of that partition are included in the operation.

**Internals**

The following information describes internals and messages written to the error log during a table import procedure.

When `ALTER TABLE ... DISCARD TABLESPACE` is run on the destination instance:
- The table is locked in X mode.
- The tablespace is detached from the table.

When `FLUSH TABLES ... FOR EXPORT` is run on the source instance:
- The table being flushed for export is locked in shared mode.
- The purge coordinator thread is stopped.
- Dirty pages are synchronized to disk.
- Table metadata is written to the binary `.cfg` file.

Expected error log messages for this operation:

```
[Note] InnoDB: Sync to disk of "test"."t1" started.
[Note] InnoDB: Stopping purge
[Note] InnoDB: Writing table metadata to './test/t1.cfg'
[Note] InnoDB: Table "test"."t1"flushed to disk
```

When `UNLOCK TABLES` is run on the source instance:
- The binary `.cfg` file is deleted.
- The shared lock on the table or tables being imported is released and the purge coordinator thread is restarted.

Expected error log messages for this operation:

```
[Note] InnoDB: Deleting the meta-data file './test/t1.cfg'
[Note] InnoDB: Resuming purge
```

When `ALTER TABLE ... IMPORT TABLESPACE` is run on the destination instance, the import algorithm performs the following operations for each tablespace being imported:
- Each tablespace page is checked for corruption.
- The space ID and log sequence numbers (LSNs) on each page are updated.
- Flags are validated and LSN updated for the header page.
- Btree pages are updated.
- The page state is set to dirty so that it is written to disk.

Expected error log messages for this operation:

```
[Note] InnoDB: Importing tablespace for table 'test/t1' that was exported from host 'host_name'
[Note] InnoDB: Phase I - Update all pages
[Note] InnoDB: Sync to disk
```
15.6.1.4 Moving or Copying InnoDB Tables

This section describes techniques for moving or copying some or all InnoDB tables to a different server or instance. For example, you might move an entire MySQL instance to a larger, faster server; you might clone an entire MySQL instance to a new replica server; you might copy individual tables to another instance to develop and test an application, or to a data warehouse server to produce reports.

On Windows, InnoDB always stores database and table names internally in lowercase. To move databases in a binary format from Unix to Windows or from Windows to Unix, create all databases and tables using lowercase names. A convenient way to accomplish this is to add the following line to the [mysqld] section of your my.cnf or my.ini file before creating any databases or tables:

```
[mysqld]
lower_case_table_names=1
```

Techniques for moving or copying InnoDB tables include:

- Importing Tables
- MySQL Enterprise Backup
- Copying Data Files (Cold Backup Method)
- Restoring from a Logical Backup

Importing Tables

A table that resides in a file-per-table tablespace can be imported from another MySQL server instance or from a backup using the Transportable Tablespace feature. See Section 15.6.1.3, “Importing InnoDB Tables”.

MySQL Enterprise Backup

The MySQL Enterprise Backup product lets you back up a running MySQL database with minimal disruption to operations while producing a consistent snapshot of the database. When MySQL Enterprise Backup is copying tables, reads and writes can continue. In addition, MySQL Enterprise Backup can create compressed backup files, and back up subsets of tables. In conjunction with the MySQL binary log, you can perform point-in-time recovery. MySQL Enterprise Backup is included as part of the MySQL Enterprise subscription.
Tables

For more details about MySQL Enterprise Backup, see Section 30.2, “MySQL Enterprise Backup Overview”.

Copying Data Files (Cold Backup Method)

You can move an InnoDB database simply by copying all the relevant files listed under ”Cold Backups” in Section 15.18.1, “InnoDB Backup”.

InnoDB data and log files are binary-compatible on all platforms having the same floating-point number format. If the floating-point formats differ but you have not used FLOAT or DOUBLE data types in your tables, then the procedure is the same: simply copy the relevant files.

When you move or copy file-per-table .ibd files, the database directory name must be the same on the source and destination systems. The table definition stored in the InnoDB shared tablespace includes the database name. The transaction IDs and log sequence numbers stored in the tablespace files also differ between databases.

To move an .ibd file and the associated table from one database to another, use a RENAME TABLE statement:

```
RENAME TABLE db1.tbl_name TO db2.tbl_name;
```

If you have a “clean” backup of an .ibd file, you can restore it to the MySQL installation from which it originated as follows:

1. The table must not have been dropped or truncated since you copied the .ibd file, because doing so changes the table ID stored inside the tablespace.

2. Issue this ALTER TABLE statement to delete the current .ibd file:

   ```
   ALTER TABLE tbl_name DISCARD TABLESPACE;
   ```

3. Copy the backup .ibd file to the proper database directory.

4. Issue this ALTER TABLE statement to tell InnoDB to use the new .ibd file for the table:

   ```
   ALTER TABLE tbl_name IMPORT TABLESPACE;
   ```

   **Note**

   The ALTER TABLE ... IMPORT TABLESPACE feature does not enforce foreign key constraints on imported data.

In this context, a “clean” .ibd file backup is one for which the following requirements are satisfied:

- There are no uncommitted modifications by transactions in the .ibd file.
- There are no unmerged insert buffer entries in the .ibd file.
- Purge has removed all delete-marked index records from the .ibd file.
- mysqld has flushed all modified pages of the .ibd file from the buffer pool to the file.

You can make a clean backup .ibd file using the following method:

1. Stop all activity from the mysqld server and commit all transactions.

2. Wait until SHOW ENGINE INNODB STATUS shows that there are no active transactions in the database, and the main thread status of InnoDB is Waiting for server activity. Then you can make a copy of the .ibd file.
Another method for making a clean copy of an .ibd file is to use the MySQL Enterprise Backup product:

1. Use MySQL Enterprise Backup to back up the InnoDB installation.
2. Start a second mysqld server on the backup and let it clean up the .ibd files in the backup.

**Restoring from a Logical Backup**

You can use a utility such as mysqldump to perform a logical backup, which produces a set of SQL statements that can be executed to reproduce the original database object definitions and table data for transfer to another SQL server. Using this method, it does not matter whether the formats differ or if your tables contain floating-point data.

To improve the performance of this method, disable autocommit when importing data. Perform a commit only after importing an entire table or segment of a table.

### 15.6.1.5 Converting Tables from MyISAM to InnoDB

If you have MyISAM tables that you want to convert to InnoDB for better reliability and scalability, review the following guidelines and tips before converting.

**Note**

Partitioned MyISAM tables created in previous versions of MySQL are not compatible with MySQL 8.0. Such tables must be prepared prior to upgrade, either by removing the partitioning, or by converting them to InnoDB. See Section 24.6.2, “Partitioning Limitations Relating to Storage Engines”, for more information.

- Adjusting Memory Usage for MyISAM and InnoDB
- Handling Too-Long Or Too-Short Transactions
- Handling Deadlocks
- Storage Layout
- Converting an Existing Table
- Cloning the Structure of a Table
- Transferring Data
- Storage Requirements
- Defining Primary Keys
- Application Performance Considerations
- Understanding Files Associated with InnoDB Tables

**Adjusting Memory Usage for MyISAM and InnoDB**

As you transition away from MyISAM tables, lower the value of the key_buffer_size configuration option to free memory no longer needed for caching results. Increase the value of the innodb_buffer_pool_size configuration option, which performs a similar role of allocating cache memory for InnoDB tables. The InnoDB buffer pool caches both table data and index data, speeding up lookups for queries and keeping query results in memory for reuse. For guidance regarding buffer pool size configuration, see Section 8.12.3.1, “How MySQL Uses Memory”.

**Handling Too-Long Or Too-Short Transactions**
Because MyISAM tables do not support transactions, you might not have paid much attention to the autocommit configuration option and the COMMIT and ROLLBACK statements. These keywords are important to allow multiple sessions to read and write InnoDB tables concurrently, providing substantial scalability benefits in write-heavy workloads.

While a transaction is open, the system keeps a snapshot of the data as seen at the beginning of the transaction, which can cause substantial overhead if the system inserts, updates, and deletes millions of rows while a stray transaction keeps running. Thus, take care to avoid transactions that run for too long:

- If you are using a mysql session for interactive experiments, always COMMIT (to finalize the changes) or ROLLBACK (to undo the changes) when finished. Close down interactive sessions rather than leave them open for long periods, to avoid keeping transactions open for long periods by accident.

- Make sure that any error handlers in your application also ROLLBACK incomplete changes or COMMIT completed changes.

- ROLLBACK is a relatively expensive operation, because INSERT, UPDATE, and DELETE operations are written to InnoDB tables prior to the COMMIT, with the expectation that most changes are committed successfully and rollbacks are rare. When experimenting with large volumes of data, avoid making changes to large numbers of rows and then rolling back those changes.

- When loading large volumes of data with a sequence of INSERT statements, periodically COMMIT the results to avoid having transactions that last for hours. In typical load operations for data warehousing, if something goes wrong, you truncate the table (using TRUNCATE TABLE) and start over from the beginning rather than doing a ROLLBACK.

The preceding tips save memory and disk space that can be wasted during too-long transactions. When transactions are shorter than they should be, the problem is excessive I/O. With each COMMIT, MySQL makes sure each change is safely recorded to disk, which involves some I/O.

- For most operations on InnoDB tables, you should use the setting autocommit=0. From an efficiency perspective, this avoids unnecessary I/O when you issue large numbers of consecutive INSERT, UPDATE, or DELETE statements. From a safety perspective, this allows you to issue a ROLLBACK statement to recover lost or garbled data if you make a mistake on the mysql command line, or in an exception handler in your application.

- autocommit=1 is suitable for InnoDB tables when running a sequence of queries for generating reports or analyzing statistics. In this situation, there is no I/O penalty related to COMMIT or ROLLBACK, and InnoDB can automatically optimize the read-only workload.

- If you make a series of related changes, finalize all the changes at once with a single COMMIT at the end. For example, if you insert related pieces of information into several tables, do a single COMMIT after making all the changes. Or if you run many consecutive INSERT statements, do a single COMMIT after all the data is loaded; if you are doing millions of INSERT statements, perhaps split up the huge transaction by issuing a COMMIT every ten thousand or hundred thousand records, so the transaction does not grow too large.

- Remember that even a SELECT statement opens a transaction, so after running some report or debugging queries in an interactive mysql session, either issue a COMMIT or close the mysql session.

For related information, see Section 15.7.2.2, “autocommit, Commit, and Rollback”.

Handling Deadlocks

You might see warning messages referring to “deadlocks” in the MySQL error log, or the output of SHOW ENGINE INNODB STATUS. A deadlock is not a serious issue for InnoDB tables, and often does not require any corrective action. When two transactions start modifying multiple tables, accessing the
tables in a different order, they can reach a state where each transaction is waiting for the other and neither can proceed. When deadlock detection is enabled (the default), MySQL immediately detects this condition and cancels (rolls back) the “smaller” transaction, allowing the other to proceed. If deadlock detection is disabled using the innodb_deadlock_detect configuration option, InnoDB relies on the innodb_lock_wait_timeout setting to roll back transactions in case of a deadlock.

Either way, your applications need error-handling logic to restart a transaction that is forcibly cancelled due to a deadlock. When you re-issue the same SQL statements as before, the original timing issue no longer applies. Either the other transaction has already finished and yours can proceed, or the other transaction is still in progress and your transaction waits until it finishes.

If deadlock warnings occur constantly, you might review the application code to reorder the SQL operations in a consistent way, or to shorten the transactions. You can test with the innodb_print_all_deadlocks option enabled to see all deadlock warnings in the MySQL error log, rather than only the last warning in the SHOW ENGINE INNODB STATUS output.

For more information, see Section 15.7.5, “Deadlocks in InnoDB”.

Storage Layout

To get the best performance from InnoDB tables, you can adjust a number of parameters related to storage layout.

When you convert MyISAM tables that are large, frequently accessed, and hold vital data, investigate and consider the innodb_file_per_table and innodb_page_size variables, and the ROW_FORMAT and KEY_BLOCK_SIZE clauses of the CREATE TABLE statement.

During your initial experiments, the most important setting is innodb_file_per_table. When this setting is enabled, which is the default, new InnoDB tables are implicitly created in file-per-table tablespaces. In contrast with the InnoDB system tablespace, file-per-table tablespaces allow disk space to be reclaimed by the operating system when a table is truncated or dropped. File-per-table tablespaces also support DYNAMIC and COMPRESSED row formats and associated features such as table compression, efficient off-page storage for long variable-length columns, and large index prefixes. For more information, see Section 15.6.3.2, “File-Per-Table Tablespaces”.

You can also store InnoDB tables in a shared general tablespace, which support multiple tables and all row formats. For more information, see Section 15.6.3.3, “General Tablespaces”.

Converting an Existing Table

To convert a non-InnoDB table to use InnoDB use ALTER TABLE:

```
ALTER TABLE table_name ENGINE=InnoDB;
```

Cloning the Structure of a Table

You might make an InnoDB table that is a clone of a MyISAM table, rather than using ALTER TABLE to perform conversion, to test the old and new table side-by-side before switching.

Create an empty InnoDB table with identical column and index definitions. Use SHOW CREATE TABLE table_name\G to see the full CREATE TABLE statement to use. Change the ENGINE clause to ENGINE=INNODB.

Transferring Data

To transfer a large volume of data into an empty InnoDB table created as shown in the previous section, insert the rows with INSERT INTO innodb_table SELECT * FROM myisam_table ORDER BY primary_key_columns.
You can also create the indexes for the InnoDB table after inserting the data. Historically, creating new secondary indexes was a slow operation for InnoDB, but now you can create the indexes after the data is loaded with relatively little overhead from the index creation step.

If you have UNIQUE constraints on secondary keys, you can speed up a table import by turning off the uniqueness checks temporarily during the import operation:

```
SET unique_checks=0;
... import operation ...
SET unique_checks=1;
```

For big tables, this saves disk I/O because InnoDB can use its change buffer to write secondary index records as a batch. Be certain that the data contains no duplicate keys. unique_checks permits but does not require storage engines to ignore duplicate keys.

For better control over the insertion process, you can insert big tables in pieces:

```
INSERT INTO newtable SELECT * FROM oldtable
  WHERE yourkey > something AND yourkey <= somethingelse;
```

After all records are inserted, you can rename the tables.

During the conversion of big tables, increase the size of the InnoDB buffer pool to reduce disk I/O. Typically, the recommended buffer pool size is 50 to 75 percent of system memory. You can also increase the size of InnoDB log files.

### Storage Requirements

If you intend to make several temporary copies of your data in InnoDB tables during the conversion process, it is recommended that you create the tables in file-per-table tablespaces so that you can reclaim the disk space when you drop the tables. When the innodb_file_per_table configuration option is enabled (the default), newly created InnoDB tables are implicitly created in file-per-table tablespaces.

Whether you convert the MyISAM table directly or create a cloned InnoDB table, make sure that you have sufficient disk space to hold both the old and new tables during the process. InnoDB tables require more disk space than MyISAM tables. If an ALTER_TABLE operation runs out of space, it starts a rollback, and that can take hours if it is disk-bound. For inserts, InnoDB uses the insert buffer to merge secondary index records to indexes in batches. That saves a lot of disk I/O. For rollback, no such mechanism is used, and the rollback can take 30 times longer than the insertion.

In the case of a runaway rollback, if you do not have valuable data in your database, it may be advisable to kill the database process rather than wait for millions of disk I/O operations to complete. For the complete procedure, see Section 15.21.3, “Forcing InnoDB Recovery”.

### Defining Primary Keys

The PRIMARY KEY clause is a critical factor affecting the performance of MySQL queries and the space usage for tables and indexes. The primary key uniquely identifies a row in a table. Every row in the table should have a primary key value, and no two rows can have the same primary key value.

These are guidelines for the primary key, followed by more detailed explanations.

- Declare a PRIMARY KEY for each table. Typically, it is the most important column that you refer to in WHERE clauses when looking up a single row.
- Declare the PRIMARY KEY clause in the original CREATE TABLE statement, rather than adding it later through an ALTER TABLE statement.
• Choose the column and its data type carefully. Prefer numeric columns over character or string ones.

• Consider using an auto-increment column if there is not another stable, unique, non-null, numeric column to use.

• An auto-increment column is also a good choice if there is any doubt whether the value of the primary key column could ever change. Changing the value of a primary key column is an expensive operation, possibly involving rearranging data within the table and within each secondary index.

Consider adding a primary key to any table that does not already have one. Use the smallest practical numeric type based on the maximum projected size of the table. This can make each row slightly more compact, which can yield substantial space savings for large tables. The space savings are multiplied if the table has any secondary indexes, because the primary key value is repeated in each secondary index entry. In addition to reducing data size on disk, a small primary key also lets more data fit into the buffer pool, speeding up all kinds of operations and improving concurrency.

If the table already has a primary key on some longer column, such as a VARCHAR, consider adding a new unsigned AUTO_INCREMENT column and switching the primary key to that, even if that column is not referenced in queries. This design change can produce substantial space savings in the secondary indexes. You can designate the former primary key columns as UNIQUE NOT NULL to enforce the same constraints as the PRIMARY KEY clause, that is, to prevent duplicate or null values across all those columns.

If you spread related information across multiple tables, typically each table uses the same column for its primary key. For example, a personnel database might have several tables, each with a primary key of employee number. A sales database might have some tables with a primary key of customer number, and other tables with a primary key of order number. Because lookups using the primary key are very fast, you can construct efficient join queries for such tables.

If you leave the PRIMARY KEY clause out entirely, MySQL creates an invisible one for you. It is a 6-byte value that might be longer than you need, thus wasting space. Because it is hidden, you cannot refer to it in queries.

**Application Performance Considerations**

The reliability and scalability features of InnoDB require more disk storage than equivalent MyISAM tables. You might change the column and index definitions slightly, for better space utilization, reduced I/O and memory consumption when processing result sets, and better query optimization plans making efficient use of index lookups.

If you set up a numeric ID column for the primary key, use that value to cross-reference with related values in any other tables, particularly for join queries. For example, rather than accepting a country name as input and doing queries searching for the same name, do one lookup to determine the country ID, then do other queries (or a single join query) to look up relevant information across several tables. Rather than storing a customer or catalog item number as a string of digits, potentially using up several bytes, convert it to a numeric ID for storing and querying. A 4-byte unsigned INT column can index over 4 billion items (with the US meaning of billion: 1000 million). For the ranges of the different integer types, see Section 11.1.2, “Integer Types (Exact Value) - INTEGER, INT, SMALLINT, TINYINT, MEDIUMINT, BIGINT”.

**Understanding Files Associated with InnoDB Tables**

InnoDB files require more care and planning than MyISAM files do.

• You must not delete the ibdata files that represent the InnoDB system tablespace.

• Methods of moving or copying InnoDB tables to a different server are described in Section 15.6.1.4, “Moving or Copying InnoDB Tables”.
15.6.1.6 AUTO_INCREMENT Handling in InnoDB

InnoDB provides a configurable locking mechanism that can significantly improve scalability and performance of SQL statements that add rows to tables with AUTO_INCREMENT columns. To use the AUTO_INCREMENT mechanism with an InnoDB table, an AUTO_INCREMENT column must be defined as the first or only column of some index such that it is possible to perform the equivalent of an indexed SELECT MAX(ai_col) lookup on the table to obtain the maximum column value. The index is not required to be a PRIMARY_KEY or UNIQUE, but to avoid duplicate values in the AUTO_INCREMENT column, those index types are recommended.

This section describes the AUTO_INCREMENT lock modes, usage implications of different AUTO_INCREMENT lock mode settings, and how InnoDB initializes the AUTO_INCREMENT counter.

- InnoDB AUTO_INCREMENT Lock Modes
- InnoDB AUTO_INCREMENT Lock Mode Usage Implications
- InnoDB AUTO_INCREMENT Counter Initialization
- Notes

InnoDB AUTO_INCREMENT Lock Modes

This section describes the AUTO_INCREMENT lock modes used to generate auto-increment values, and how each lock mode affects replication. The auto-increment lock mode is configured at startup using the innodb_autoinc_lock_mode variable.

The following terms are used in describing innodb_autoinc_lock_mode settings:

- “INSERT-like” statements
  
  All statements that generate new rows in a table, including INSERT, INSERT ... SELECT, REPLACE, REPLACE ... SELECT, and LOAD DATA. Includes “simple-inserts”, “bulk-inserts”, and “mixed-mode” inserts.

- “Simple inserts”
  
  Statements for which the number of rows to be inserted can be determined in advance (when the statement is initially processed). This includes single-row and multiple-row INSERT and REPLACE statements that do not have a nested subquery, but not INSERT ... ON DUPLICATE KEY UPDATE.

- “Bulk inserts”
  
  Statements for which the number of rows to be inserted (and the number of required auto-increment values) is not known in advance. This includes INSERT ... SELECT, REPLACE ... SELECT, and LOAD DATA statements, but not plain INSERT. InnoDB assigns new values for the AUTO_INCREMENT column one at a time as each row is processed.

- “Mixed-mode inserts”
  
  These are “simple insert” statements that specify the auto-increment value for some (but not all) of the new rows. An example follows, where c1 is an AUTO_INCREMENT column of table t1:

  ```
  INSERT INTO t1 (c1,c2) VALUES (1,'a'), (NULL,'b'), (5,'c'), (NULL,'d');
  ```

  Another type of “mixed-mode insert” is INSERT ... ON DUPLICATE KEY UPDATE, which in the worst case is in effect an INSERT followed by a UPDATE, where the allocated value for the AUTO_INCREMENT column may or may not be used during the update phase.
There are three possible settings for the `innodb_autoinc_lock_mode` variable. The settings are 0, 1, or 2, for “traditional”, “consecutive”, or “interleaved” lock mode, respectively. As of MySQL 8.0, interleaved lock mode (`innodb_autoinc_lock_mode=2`) is the default setting. Prior to MySQL 8.0, consecutive lock mode is the default (`innodb_autoinc_lock_mode=1`).

The default setting of interleaved lock mode in MySQL 8.0 reflects the change from statement-based replication to row based replication as the default replication type. Statement-based replication requires the consecutive auto-increment lock mode to ensure that auto-increment values are assigned in a predictable and repeatable order for a given sequence of SQL statements, whereas row-based replication is not sensitive to the execution order of SQL statements.

- `innodb_autoinc_lock_mode = 0` (“traditional” lock mode)

  The traditional lock mode provides the same behavior that existed before the `innodb_autoinc_lock_mode` variable was introduced. The traditional lock mode option is provided for backward compatibility, performance testing, and working around issues with “mixed-mode inserts”, due to possible differences in semantics.

  In this lock mode, all “INSERT-like” statements obtain a special table-level AUTO-INC lock for inserts into tables with AUTO_INCREMENT columns. This lock is normally held to the end of the statement (not to the end of the transaction) to ensure that auto-increment values are assigned in a predictable and repeatable order for a given sequence of INSERT statements, and to ensure that auto-increment values assigned by any given statement are consecutive.

  In the case of statement-based replication, this means that when an SQL statement is replicated on a replica server, the same values are used for the auto-increment column as on the source server. The result of execution of multiple INSERT statements is deterministic, and the replica reproduces the same data as on the source. If auto-increment values generated by multiple INSERT statements were interleaved, the result of two concurrent INSERT statements would be nondeterministic, and could not reliably be propagated to a replica server using statement-based replication.

  To make this clear, consider an example that uses this table:

  ```
  CREATE TABLE t1 (
    c1 INT(11) NOT NULL AUTO_INCREMENT,
    c2 VARCHAR(10) DEFAULT NULL,
    PRIMARY KEY (c1)
  ) ENGINE=InnoDB;
  ```

  Suppose that there are two transactions running, each inserting rows into a table with an AUTO_INCREMENT column. One transaction is using an INSERT ... SELECT statement that inserts 1000 rows, and another is using a simple INSERT statement that inserts one row:

  ```
  Tx1: INSERT INTO t1 (c2) SELECT 1000 rows from another table ...
  Tx2: INSERT INTO t1 (c2) VALUES ('xxx');
  ```

  InnoDB cannot tell in advance how many rows are retrieved from the SELECT in the INSERT statement in Tx1, and it assigns the auto-increment values one at a time as the statement proceeds. With a table-level lock, held to the end of the statement, only one INSERT statement referring to table `t1` can execute at a time, and the generation of auto-increment numbers by different statements is not interleaved. The auto-increment values generated by the Tx1 INSERT ... SELECT statement are consecutive, and the (single) auto-increment value used by the INSERT statement in Tx2 is either smaller or larger than all those used for Tx1, depending on which statement executes first.

  As long as the SQL statements execute in the same order when replayed from the binary log (when using statement-based replication, or in recovery scenarios), the results are the same as they were when Tx1 and Tx2 first ran. Thus, table-level locks held until the end of a statement make INSERT statements
using auto-increment safe for use with statement-based replication. However, those table-level locks
limit concurrency and scalability when multiple transactions are executing insert statements at the same
time.

In the preceding example, if there were no table-level lock, the value of the auto-increment column
used for the INSERT in Tx2 depends on precisely when the statement executes. If the INSERT of Tx2
executes while the INSERT of Tx1 is running (rather than before it starts or after it completes), the
specific auto-increment values assigned by the two INSERT statements are nondeterministic, and may
vary from run to run.

Under the consecutive lock mode, InnoDB can avoid using table-level AUTO-INC locks for “simple
insert” statements where the number of rows is known in advance, and still preserve deterministic
execution and safety for statement-based replication.

If you are not using the binary log to replay SQL statements as part of recovery or replication, the
interleaved lock mode can be used to eliminate all use of table-level AUTO-INC locks for even greater
concurrency and performance, at the cost of permitting gaps in auto-increment numbers assigned
by a statement and potentially having the numbers assigned by concurrently executing statements
interleaved.

• \texttt{innodb\_autoinc\_lock\_mode} = 1 ("consecutive" lock mode)

In this mode, “bulk inserts” use the special AUTO-INC table-level lock and hold it until the end of the
statement. This applies to all \texttt{INSERT ... SELECT}, \texttt{REPLACE ... SELECT}, and \texttt{LOAD DATA}
statements. Only one statement holding the AUTO-INC lock can execute at a time. If the source table of
the bulk insert operation is different from the target table, the AUTO-INC lock on the target table is taken
after a shared lock is taken on the first row selected from the source table. If the source and target of the
bulk insert operation are the same table, the AUTO-INC lock is taken after shared locks are taken on all
selected rows.

“Simple inserts” (for which the number of rows to be inserted is known in advance) avoid table-level
AUTO-INC locks by obtaining the required number of auto-increment values under the control of a
mutex (a light-weight lock) that is only held for the duration of the allocation process, \textit{not} until the
statement completes. No table-level AUTO-INC lock is used unless an AUTO-INC lock is held by another
transaction. If another transaction holds an AUTO-INC lock, a “simple insert” waits for the AUTO-INC
lock, as if it were a “bulk insert”.

This lock mode ensures that, in the presence of INSERT statements where the number of rows is not
known in advance (and where auto-increment numbers are assigned as the statement progresses), all
auto-increment values assigned by any “INSERT-like” statement are consecutive, and operations are
safe for statement-based replication.

Simply put, this lock mode significantly improves scalability while being safe for use with statement-
based replication. Further, as with “traditional” lock mode, auto-increment numbers assigned by any
given statement are consecutive. There is no change in semantics compared to “traditional” mode for
any statement that uses auto-increment, with one important exception.

The exception is for “mixed-mode inserts”, where the user provides explicit values for an
AUTO_INCREMENT column for some, but not all, rows in a multiple-row “simple insert”. For such inserts,
InnoDB allocates more auto-increment values than the number of rows to be inserted. However, all
values automatically assigned are consecutively generated (and thus higher than) the auto-increment
value generated by the most recently executed previous statement. “Excess” numbers are lost.
• `innodb_autoinc_lock_mode = 2` ("interleaved" lock mode)

In this lock mode, no "INSERT-like" statements use the table-level AUTO-INC lock, and multiple statements can execute at the same time. This is the fastest and most scalable lock mode, but it is not safe when using statement-based replication or recovery scenarios when SQL statements are replayed from the binary log.

In this lock mode, auto-increment values are guaranteed to be unique and monotonically increasing across all concurrently executing "INSERT-like" statements. However, because multiple statements can be generating numbers at the same time (that is, allocation of numbers is interleaved across statements), the values generated for the rows inserted by any given statement may not be consecutive.

If the only statements executing are "simple inserts" where the number of rows to be inserted is known ahead of time, there are no gaps in the numbers generated for a single statement, except for "mixed-mode inserts". However, when "bulk inserts" are executed, there may be gaps in the auto-increment values assigned by any given statement.

**InnoDB AUTO_INCREMENT Lock Mode Usage Implications**

• Using auto-increment with replication

If you are using statement-based replication, set `innodb_autoinc_lock_mode` to 0 or 1 and use the same value on the source and its replicas. Auto-increment values are not ensured to be the same on the replicas as on the source if you use `innodb_autoinc_lock_mode = 2` ("interleaved") or configurations where the source and replicas do not use the same lock mode.

If you are using row-based or mixed-format replication, all of the auto-increment lock modes are safe, since row-based replication is not sensitive to the order of execution of the SQL statements (and the mixed format uses row-based replication for any statements that are unsafe for statement-based replication).

• “Lost” auto-increment values and sequence gaps

In all lock modes (0, 1, and 2), if a transaction that generated auto-increment values rolls back, those auto-increment values are "lost". Once a value is generated for an auto-increment column, it cannot be rolled back, whether or not the "INSERT-like" statement is completed, and whether or not the containing transaction is rolled back. Such lost values are not reused. Thus, there may be gaps in the values stored in an AUTO_INCREMENT column of a table.

• Specifying NULL or 0 for the AUTO_INCREMENT column

In all lock modes (0, 1, and 2), if a user specifies NULL or 0 for the AUTO_INCREMENT column in an INSERT, InnoDB treats the row as if the value was not specified and generates a new value for it.

• Assigning a negative value to the AUTO_INCREMENT column

In all lock modes (0, 1, and 2), the behavior of the auto-increment mechanism is undefined if you assign a negative value to the AUTO_INCREMENT column.

• If the AUTO_INCREMENT value becomes larger than the maximum integer for the specified integer type

In all lock modes (0, 1, and 2), the behavior of the auto-increment mechanism is undefined if the value becomes larger than the maximum integer that can be stored in the specified integer type.

• Gaps in auto-increment values for “bulk inserts”
With `innodb_autoinc_lock_mode` set to 0 ("traditional") or 1 ("consecutive"), the auto-increment values generated by any given statement are consecutive, without gaps, because the table-level AUTO_INCREMENT lock is held until the end of the statement, and only one such statement can execute at a time.

With `innodb_autoinc_lock_mode` set to 2 ("interleaved"), there may be gaps in the auto-increment values generated by "bulk inserts," but only if there are concurrently executing "INSERT-like" statements.

For lock modes 1 or 2, gaps may occur between successive statements because for bulk inserts the exact number of auto-increment values required by each statement may not be known and overestimation is possible.

- **Auto-increment values assigned by “mixed-mode inserts”**

Consider a “mixed-mode insert,” where a “simple insert” specifies the auto-increment value for some (but not all) resulting rows. Such a statement behaves differently in lock modes 0, 1, and 2. For example, assume `c1` is an AUTO_INCREMENT column of table `t1`, and that the most recent automatically generated sequence number is 100.

```
mysql> CREATE TABLE t1 (  
--> c1 INT UNSIGNED NOT NULL AUTO_INCREMENT PRIMARY KEY,  
--> c2 CHAR(1)  
--> ) ENGINE = INNODB;
```

Now, consider the following “mixed-mode insert” statement:

```
mysql> INSERT INTO t1 (c1,c2) VALUES (1,'a'), (NULL,'b'), (5,'c'), (NULL,'d');
```

With `innodb_autoinc_lock_mode` set to 0 ("traditional"), the four new rows are:

```
mysql> SELECT c1, c2 FROM t1 ORDER BY c2;
```

```
+-----+------+
<table>
<thead>
<tr>
<th>c1</th>
<th>c2</th>
</tr>
</thead>
<tbody>
<tr>
<td>103</td>
<td>a</td>
</tr>
<tr>
<td>101</td>
<td>b</td>
</tr>
<tr>
<td>102</td>
<td>c</td>
</tr>
<tr>
<td>101</td>
<td>d</td>
</tr>
</tbody>
</table>
```

The next available auto-increment value is 103 because the auto-increment values are allocated one at a time, not all at once at the beginning of statement execution. This result is true whether or not there are concurrently executing "INSERT-like" statements (of any type).

With `innodb_autoinc_lock_mode` set to 1 ("consecutive"), the four new rows are also:

```
mysql> SELECT c1, c2 FROM t1 ORDER BY c2;
```

```
+-----+------+
<table>
<thead>
<tr>
<th>c1</th>
<th>c2</th>
</tr>
</thead>
<tbody>
<tr>
<td>101</td>
<td>a</td>
</tr>
<tr>
<td>101</td>
<td>b</td>
</tr>
<tr>
<td>102</td>
<td>c</td>
</tr>
<tr>
<td>102</td>
<td>d</td>
</tr>
</tbody>
</table>
```
However, in this case, the next available auto-increment value is 105, not 103 because four auto-increment values are allocated at the time the statement is processed, but only two are used. This result is true whether or not there are concurrently executing "INSERT-like" statements (of any type).

With `innodb_autoinc_lock_mode` set to 2 ("interleaved"), the four new rows are:

```
mysql> SELECT c1, c2 FROM t1 ORDER BY c2;
+-----+------+
| c1  | c2   |
+-----+------+
|   1 | a    |
| x   | b    |
| 5   | c    |
| y   | d    |
```

The values of \textit{x} and \textit{y} are unique and larger than any previously generated rows. However, the specific values of \textit{x} and \textit{y} depend on the number of auto-increment values generated by concurrently executing statements.

Finally, consider the following statement, issued when the most-recently generated sequence number is 100:

```
mysql> INSERT INTO t1 (c1,c2) VALUES (1,'a'), (NULL,'b'), (101,'c'), (NULL,'d');
```

With any `innodb_autoinc_lock_mode` setting, this statement generates a duplicate-key error 23000 (Can't write; duplicate key in table) because 101 is allocated for the row (NULL, 'b') and insertion of the row (101, 'c') fails.

• Modifying \textit{AUTO_INCREMENT} column values in the middle of a sequence of \textit{INSERT} statements

In MySQL 5.7 and earlier, modifying an \textit{AUTO_INCREMENT} column value in the middle of a sequence of \textit{INSERT} statements could lead to "Duplicate entry" errors. For example, if you performed an \textit{UPDATE} operation that changed an \textit{AUTO_INCREMENT} column value to a value larger than the current maximum auto-increment value, subsequent \textit{INSERT} operations that did not specify an unused auto-increment value could encounter "Duplicate entry" errors. In MySQL 8.0 and later, if you modify an \textit{AUTO_INCREMENT} column value to a value larger than the current maximum auto-increment value, the new value is persisted, and subsequent \textit{INSERT} operations allocate auto-increment values starting from the new, larger value. This behavior is demonstrated in the following example.

```
mysql> CREATE TABLE t1 (  -> c1 INT NOT NULL AUTO_INCREMENT,  -> PRIMARY KEY (c1)  -> ) ENGINE = InnoDB;

mysql> INSERT INTO t1 VALUES(0), (0), (3);

mysql> SELECT c1 FROM t1;
+----+
| c1 |
+----+
|  1 |
|  2 |
|  3 |

mysql> UPDATE t1 SET c1 = 4 WHERE c1 = 1;

mysql> SELECT c1 FROM t1;
+----+
| c1 |
+----+
|  1 |
|  2 |
|  3 |
```

3307
InnoDB AUTO_INCREMENT Counter Initialization

This section describes how InnoDB initializes AUTO_INCREMENT counters.

If you specify an AUTO_INCREMENT column for an InnoDB table, the in-memory table object contains a special counter called the auto-increment counter that is used when assigning new values for the column.

In MySQL 5.7 and earlier, the auto-increment counter is stored in main memory, not on disk. To initialize an auto-increment counter after a server restart, InnoDB would execute the equivalent of the following statement on the first insert into a table containing an AUTO_INCREMENT column.

```
SELECT MAX(ai_col) FROM table_name FOR UPDATE;
```

In MySQL 8.0, this behavior is changed. The current maximum auto-increment counter value is written to the redo log each time it changes and saved to the data dictionary on each checkpoint. These changes make the current maximum auto-increment counter value persistent across server restarts.

On a server restart following a normal shutdown, InnoDB initializes the in-memory auto-increment counter using the current maximum auto-increment value stored in the data dictionary.

On a server restart during crash recovery, InnoDB initializes the in-memory auto-increment counter using the current maximum auto-increment value stored in the data dictionary and scans the redo log for auto-increment counter values written since the last checkpoint. If a redo-logged value is greater than the in-memory counter value, the redo-logged value is applied. However, in the case of an unexpected server exit, reuse of a previously allocated auto-increment value cannot be guaranteed. Each time the current maximum auto-increment value is changed due to an INSERT or UPDATE operation, the new value is written to the redo log, but if the unexpected exit occurs before the redo log is flushed to disk, the previously allocated value could be reused when the auto-increment counter is initialized after the server is restarted.

The only circumstance in which InnoDB uses the equivalent of a SELECT MAX(ai_col) FROM table_name FOR UPDATE statement to initialize an auto-increment counter is when importing a table without a .cfg metadata file. Otherwise, the current maximum auto-increment counter value is read from the .cfg metadata file if present. Aside from counter value initialization, the equivalent of a SELECT MAX(ai_col) FROM table_name statement is used to determine the current maximum auto-increment counter value of the table when attempting to set the counter value to one that is smaller than or equal to the persisted counter value using an ALTER TABLE ... AUTO_INCREMENT = N statement. For example, you might try to set the counter value to a lesser value after deleting some records. In this case, the table must be searched to ensure that the new counter value is not less than or equal to the actual current maximum counter value.
In MySQL 5.7 and earlier, a server restart cancels the effect of the `AUTO_INCREMENT = N` table option, which may be used in a `CREATE TABLE` or `ALTER TABLE` statement to set an initial counter value or alter the existing counter value, respectively. In MySQL 8.0, a server restart does not cancel the effect of the `AUTO_INCREMENT = N` table option. If you initialize the auto-increment counter to a specific value, or if you alter the auto-increment counter value to a larger value, the new value is persisted across server restarts.

**Note**

`ALTER TABLE ... AUTO_INCREMENT = N` can only change the auto-increment counter value to a value larger than the current maximum.

In MySQL 5.7 and earlier, a server restart immediately following a `ROLLBACK` operation could result in the reuse of auto-increment values that were previously allocated to the rolled-back transaction, effectively rolling back the current maximum auto-increment value. In MySQL 8.0, the current maximum auto-increment value is persisted, preventing the reuse of previously allocated values.

If a `SHOW TABLE STATUS` statement examines a table before the auto-increment counter is initialized, `InnoDB` opens the table and initializes the counter value using the current maximum auto-increment value that is stored in the data dictionary. The value is then stored in memory for use by later inserts or updates. Initialization of the counter value uses a normal exclusive-locking read on the table which lasts to the end of the transaction. `InnoDB` follows the same procedure when initializing the auto-increment counter for a newly created table that has a user-specified auto-increment value greater than 0.

After the auto-increment counter is initialized, if you do not explicitly specify an auto-increment value when inserting a row, `InnoDB` implicitly increments the counter and assigns the new value to the column. If you insert a row that explicitly specifies an auto-increment column value, and the value is greater than the current maximum counter value, the counter is set to the specified value.

`InnoDB` uses the in-memory auto-increment counter as long as the server runs. When the server is stopped and restarted, `InnoDB` reinitializes the auto-increment counter, as described earlier.

The `auto_increment_offset` variable determines the starting point for the `AUTO_INCREMENT` column value. The default setting is 1.

The `auto_increment_increment` variable controls the interval between successive column values. The default setting is 1.

**Notes**

When an `AUTO_INCREMENT` integer column runs out of values, a subsequent `INSERT` operation returns a duplicate-key error. This is general MySQL behavior.

### 15.6.2 Indexes

This section covers topics related to `InnoDB` indexes.

#### 15.6.2.1 Clustered and Secondary Indexes

Each `InnoDB` table has a special index called the clustered index that stores row data. Typically, the clustered index is synonymous with the primary key. To get the best performance from queries, inserts, and other database operations, it is important to understand how `InnoDB` uses the clustered index to optimize the common lookup and DML operations.

- When you define a `PRIMARY KEY` on a table, `InnoDB` uses it as the clustered index. A primary key should be defined for each table. If there is no logical unique and non-null column or set of columns to
Indexes

use a primary key, add an auto-increment column. Auto-increment column values are unique and are added automatically as new rows are inserted.

- If you do not define a PRIMARY KEY for a table, InnoDB uses the first UNIQUE index with all key columns defined as NOT NULL as the clustered index.

- If a table has no PRIMARY KEY or suitable UNIQUE index, InnoDB generates a hidden clustered index named GEN_CLUST_INDEX on a synthetic column that contains row ID values. The rows are ordered by the row ID that InnoDB assigns. The row ID is a 6-byte field that increases monotonically as new rows are inserted. Thus, the rows ordered by the row ID are physically in order of insertion.

How the Clustered Index Speeds Up Queries

Accessing a row through the clustered index is fast because the index search leads directly to the page that contains the row data. If a table is large, the clustered index architecture often saves a disk I/O operation when compared to storage organizations that store row data using a different page from the index record.

How Secondary Indexes Relate to the Clustered Index

Indexes other than the clustered index are known as secondary indexes. In InnoDB, each record in a secondary index contains the primary key columns for the row, as well as the columns specified for the secondary index. InnoDB uses this primary key value to search for the row in the clustered index.

If the primary key is long, the secondary indexes use more space, so it is advantageous to have a short primary key.

For guidelines to take advantage of InnoDB clustered and secondary indexes, see Section 8.3, “Optimization and Indexes”.

15.6.2.2 The Physical Structure of an InnoDB Index

With the exception of spatial indexes, InnoDB indexes are B-tree data structures. Spatial indexes use R-trees, which are specialized data structures for indexing multi-dimensional data. Index records are stored in the leaf pages of their B-tree or R-tree data structure. The default size of an index page is 16KB. The page size is determined by the innodb_page_size setting when the MySQL instance is initialized. See Section 15.8.1, “InnoDB Startup Configuration”.

When new records are inserted into an InnoDB clustered index, InnoDB tries to leave 1/16 of the page free for future insertions and updates of the index records. If index records are inserted in a sequential order (ascending or descending), the resulting index pages are about 15/16 full. If records are inserted in a random order, the pages are from 1/2 to 15/16 full.

InnoDB performs a bulk load when creating or rebuilding B-tree indexes. This method of index creation is known as a sorted index build. The innodb_fill_factor variable defines the percentage of space on each B-tree page that is filled during a sorted index build, with the remaining space reserved for future index growth. Sorted index builds are not supported for spatial indexes. For more information, see Section 15.6.2.3, “Sorted Index Builds”. An innodb_fill_factor setting of 100 leaves 1/16 of the space in clustered index pages free for future index growth.

If the fill factor of an InnoDB index page drops below the MERGE_THRESHOLD, which is 50% by default if not specified, InnoDB tries to contract the index tree to free the page. The MERGE_THRESHOLD setting applies to both B-tree and R-tree indexes. For more information, see Section 15.8.11, “Configuring the Merge Threshold for Index Pages”.

15.6.2.3 Sorted Index Builds
InnoDB performs a bulk load instead of inserting one index record at a time when creating or rebuilding indexes. This method of index creation is also known as a sorted index build. Sorted index builds are not supported for spatial indexes.

There are three phases to an index build. In the first phase, the clustered index is scanned, and index entries are generated and added to the sort buffer. When the sort buffer becomes full, entries are sorted and written out to a temporary intermediate file. This process is also known as a “run”. In the second phase, with one or more runs written to the temporary intermediate file, a merge sort is performed on all entries in the file. In the third and final phase, the sorted entries are inserted into the B-tree.

Prior to the introduction of sorted index builds, index entries were inserted into the B-tree one record at a time using insert APIs. This method involved opening a B-tree cursor to find the insert position and then inserting entries into a B-tree page using an optimistic insert. If an insert failed due to a page being full, a pessimistic insert would be performed, which involves opening a B-tree cursor and splitting and merging B-tree nodes as necessary to find space for the entry. The drawbacks of this “top-down” method of building an index are the cost of searching for an insert position and the constant splitting and merging of B-tree nodes.

Sorted index builds use a “bottom-up” approach to building an index. With this approach, a reference to the right-most leaf page is held at all levels of the B-tree. The right-most leaf page at the necessary B-tree depth is allocated and entries are inserted according to their sorted order. Once a leaf page is full, a node pointer is appended to the parent page and a sibling leaf page is allocated for the next insert. This process continues until all entries are inserted, which may result in inserts up to the root level. When a sibling page is allocated, the reference to the previously pinned leaf page is released, and the newly allocated leaf page becomes the right-most leaf page and new default insert location.

Reserving B-tree Page Space for Future Index Growth

To set aside space for future index growth, you can use the innodb_fill_factor variable to reserve a percentage of B-tree page space. For example, setting innodb_fill_factor to 80 reserves 20 percent of the space in B-tree pages during a sorted index build. This setting applies to both B-tree leaf and non-leaf pages. It does not apply to external pages used for TEXT or BLOB entries. The amount of space that is reserved may not be exactly as configured, as the innodb_fill_factor value is interpreted as a hint rather than a hard limit.

Sorted Index Builds and Full-Text Index Support

Sorted index builds are supported for fulltext indexes. Previously, SQL was used to insert entries into a fulltext index.

Sorted Index Builds and Compressed Tables

For compressed tables, the previous index creation method appended entries to both compressed and uncompressed pages. When the modification log (representing free space on the compressed page) became full, the compressed page would be recompressed. If compression failed due to a lack of space, the page would be split. With sorted index builds, entries are only appended to uncompressed pages. When an uncompressed page becomes full, it is compressed. Adaptive padding is used to ensure that compression succeeds in most cases, but if compression fails, the page is split and compression is attempted again. This process continues until compression is successful. For more information about compression of B-Tree pages, see Section 15.9.1.5, “How Compression Works for InnoDB Tables”.

Sorted Index Builds and Redo Logging

Redo logging is disabled during a sorted index build. Instead, there is a checkpoint to ensure that the index build can withstand an unexpected exit or failure. The checkpoint forces a write of all dirty pages to disk. During a sorted index build, the page cleaner thread is signaled periodically to flush dirty pages to ensure
that the checkpoint operation can be processed quickly. Normally, the page cleaner thread flushes dirty
pages when the number of clean pages falls below a set threshold. For sorted index builds, dirty pages are
flushed promptly to reduce checkpoint overhead and to parallelize I/O and CPU activity.

**Sorted Index Builds and Optimizer Statistics**

Sorted index builds may result in optimizer statistics that differ from those generated by the previous
method of index creation. The difference in statistics, which is not expected to affect workload
performance, is due to the different algorithm used to populate the index.

**15.6.2.4 InnoDB Full-Text Indexes**

Full-text indexes are created on text-based columns (CHAR, VARCHAR, or TEXT columns) to speed up
queries and DML operations on data contained within those columns.

A full-text index is defined as part of a CREATE TABLE statement or added to an existing table using
ALTER TABLE or CREATE INDEX.

Full-text search is performed using MATCH() ... AGAINST syntax. For usage information, see
Section 12.9, “Full-Text Search Functions”.

InnoDB full-text indexes are described under the following topics in this section:

- InnoDB Full-Text Index Design
- InnoDB Full-Text Index Tables
- InnoDB Full-Text Index Cache
- InnoDB Full-Text Index DOC_ID and FTS_DOC_ID Column
- InnoDB Full-Text Index Deletion Handling
- InnoDB Full-Text Index Transaction Handling
- Monitoring InnoDB Full-Text Indexes

**InnoDB Full-Text Index Design**

**InnoDB** full-text indexes have an inverted index design. Inverted indexes store a list of words, and for each
word, a list of documents that the word appears in. To support proximity search, position information for
each word is also stored, as a byte offset.

**InnoDB Full-Text Index Tables**

When an InnoDB full-text index is created, a set of index tables is created, as shown in the following
example:

```sql
mysql> CREATE TABLE opening_lines (
    -> id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
    -> opening_line TEXT(500),
    -> author VARCHAR(200),
    -> title VARCHAR(200),
    -> FULLTEXT idx (opening_line)
) ENGINE=InnoDB;

mysql> SELECT table_id, name, space FROM INFORMATION_SCHEMA.INNODB_TABLES
    -> WHERE name LIKE 'test/%';
```

---

3312
The first six index tables comprise the inverted index and are referred to as auxiliary index tables. When incoming documents are tokenized, the individual words (also referred to as “tokens”) are inserted into the index tables along with position information and an associated DOC_ID. The words are fully sorted and partitioned among the six index tables based on the character set sort weight of the word’s first character.

The inverted index is partitioned into six auxiliary index tables to support parallel index creation. By default, two threads tokenize, sort, and insert words and associated data into the index tables. The number of threads that perform this work is configurable using the innodb_ft_sort_pll_degree variable. Consider increasing the number of threads when creating full-text indexes on large tables.

Auxiliary index table names are prefixed with fts_ and postfixed with index_. Each auxiliary index table is associated with the indexed table by a hex value in the auxiliary index table name that matches the table_id of the indexed table. For example, the table_id of the test/opening_lines table is 327, for which the hex value is 0x147. As shown in the preceding example, the “147” hex value appears in the names of auxiliary index tables that are associated with the test/opening_lines table.

A hex value representing the index_id of the full-text index also appears in auxiliary index table names. For example, in the auxiliary table name test/fts_0000000000000147_00000000000001c9_index_1, the hex value 1c9 has a decimal value of 457. The index defined on the opening_lines table (idx) can be identified by querying the Information Schema INNODB_INDEXES table for this value (457).

Index tables are stored in their own tablespace if the primary table is created in a file-per-table tablespace. Otherwise, index tables are stored in the tablespace where the indexed table resides.

The other index tables shown in the preceding example are referred to as common index tables and are used for deletion handling and storing the internal state of full-text indexes. Unlike the inverted index tables, which are created for each full-text index, this set of tables is common to all full-text indexes created on a particular table.

Common index tables are retained even if full-text indexes are dropped. When a full-text index is dropped, the FTS_DOC_ID column that was created for the index is retained, as removing the FTS_DOC_ID column would require rebuilding the previously indexed table. Common index tables are required to manage the FTS_DOC_ID column.

- fts_*_deleted and fts_*_deleted_cache
Indexes

Contain the document IDs (DOC_ID) for documents that are deleted but whose data is not yet removed from the full-text index. The `fts_*_deleted_cache` is the in-memory version of the `fts_*_deleted` table.

- `fts_*_being_deleted` and `fts_*_being_deleted_cache`

Contain the document IDs (DOC_ID) for documents that are deleted and whose data is currently in the process of being removed from the full-text index. The `fts_*_being_deleted_cache` table is the in-memory version of the `fts_*_being_deleted` table.

- `fts_*_config`

Stores information about the internal state of the full-text index. Most importantly, it stores the `FTS_SYNCED_DOC_ID`, which identifies documents that have been parsed and flushed to disk. In case of crash recovery, `FTS_SYNCED_DOC_ID` values are used to identify documents that have not been flushed to disk so that the documents can be re-parsed and added back to the full-text index cache. To view the data in this table, query the Information Schema `INNODB_FT_CONFIG` table.

InnoDB Full-Text Index Cache

When a document is inserted, it is tokenized, and the individual words and associated data are inserted into the full-text index. This process, even for small documents, can result in numerous small insertions into the auxiliary index tables, making concurrent access to these tables a point of contention. To avoid this problem, InnoDB uses a full-text index cache to temporarily cache index table insertions for recently inserted rows. This in-memory cache structure holds insertions until the cache is full and then batch flushes them to disk (to the auxiliary index tables). You can query the Information Schema `INNODB_FT_INDEX_CACHE` table to view tokenized data for recently inserted rows.

The caching and batch flushing behavior avoids frequent updates to auxiliary index tables, which could result in concurrent access issues during busy insert and update times. The batching technique also avoids multiple insertions for the same word, and minimizes duplicate entries. Instead of flushing each word individually, insertions for the same word are merged and flushed to disk as a single entry, improving insertion efficiency while keeping auxiliary index tables as small as possible.

The `innodb_ft_cache_size` variable is used to configure the full-text index cache size (on a per-table basis), which affects how often the full-text index cache is flushed. You can also define a global full-text index cache size limit for all tables in a given instance using the `innodb_ft_total_cache_size` variable.

The full-text index cache stores the same information as auxiliary index tables. However, the full-text index cache only caches tokenized data for recently inserted rows. The data that is already flushed to disk (to the auxiliary index tables) is not brought back into the full-text index cache when queried. The data in auxiliary index tables is queried directly, and results from the auxiliary index tables are merged with results from the full-text index cache before being returned.

InnoDB Full-Text Index DOC_ID and FTS_DOC_ID Column

InnoDB uses a unique document identifier referred to as the DOC_ID to map words in the full-text index to document records where the word appears. The mapping requires an `FTS_DOC_ID` column on the indexed table. If an `FTS_DOC_ID` column is not defined, InnoDB automatically adds a hidden `FTS_DOC_ID` column when the full-text index is created. The following example demonstrates this behavior.

The following table definition does not include an `FTS_DOC_ID` column:

```sql
mysql> CREATE TABLE opening_lines (  
  id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,  
  opening_line TEXT(500),
);```
When you create a full-text index on the table using `CREATE FULLTEXT INDEX` syntax, a warning is returned which reports that `InnoDB` is rebuilding the table to add the `FTS_DOC_ID` column.

mysql> CREATE FULLTEXT INDEX idx ON opening_lines(opening_line);  
Query OK, 0 rows affected, 1 warning (0.19 sec)  
Records: 0  Duplicates: 0  Warnings: 1

mysql> SHOW WARNINGS;
+---------+------+--------------------------------------------------+
| Level   | Code | Message                                          |
|---------+------|--------------------------------------------------|
| Warning | 124  | InnoDB rebuilding table to add column FTS_DOC_ID |
+---------+------|--------------------------------------------------+

The same warning is returned when using `ALTER TABLE` to add a full-text index to a table that does not have an `FTS_DOC_ID` column. If you create a full-text index at `CREATE TABLE` time and do not specify an `FTS_DOC_ID` column, `InnoDB` adds a hidden `FTS_DOC_ID` column, without warning.

Defining an `FTS_DOC_ID` column at `CREATE TABLE` time is less expensive than creating a full-text index on a table that is already loaded with data. If an `FTS_DOC_ID` column is defined on a table prior to loading data, the table and its indexes do not have to be rebuilt to add the new column. If you are not concerned with `CREATE FULLTEXT INDEX` performance, leave out the `FTS_DOC_ID` column to have `InnoDB` create it for you. `InnoDB` creates a hidden `FTS_DOC_ID` column along with a unique index (`FTS_DOC_ID_INDEX`) on the `FTS_DOC_ID` column. If you want to create your own `FTS_DOC_ID` column, the column must be defined as `BIGINT UNSIGNED NOT NULL` and named `FTS_DOC_ID` (all uppercase), as in the following example:

```
Note
The `FTS_DOC_ID` column does not need to be defined as an `AUTO_INCREMENT` column, but doing so could make loading data easier.
```

```
mysql> CREATE TABLE opening_lines (  
    | FTS_DOC_ID BIGINT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,  
    | opening_line TEXT(500),  
    | author VARCHAR(200),  
    | title VARCHAR(200)  
) ENGINE=InnoDB;
```

If you choose to define the `FTS_DOC_ID` column yourself, you are responsible for managing the column to avoid empty or duplicate values. `FTS_DOC_ID` values cannot be reused, which means `FTS_DOC_ID` values must be ever increasing.

Optionally, you can create the required unique `FTS_DOC_ID_INDEX` (all uppercase) on the `FTS_DOC_ID` column.

```
mysql> CREATE UNIQUE INDEX FTS_DOC_ID_INDEX on opening_lines(FTS_DOC_ID);
```

If you do not create the `FTS_DOC_ID_INDEX`, `InnoDB` creates it automatically.

```
Note
`FTS_DOC_ID_INDEX` cannot be defined as a descending index because the `InnoDB` SQL parser does not use descending indexes.
```

The permitted gap between the largest used `FTS_DOC_ID` value and new `FTS_DOC_ID` value is 65535. To avoid rebuilding the table, the `FTS_DOC_ID` column is retained when dropping a full-text index.
InnoDB Full-Text Index Deletion Handling

Deleting a record that has a full-text index column could result in numerous small deletions in the auxiliary index tables, making concurrent access to these tables a point of contention. To avoid this problem, the DOC_ID of a deleted document is logged in a special FTS_*_DELETED table whenever a record is deleted from an indexed table, and the indexed record remains in the full-text index. Before returning query results, information in the FTS_*_DELETED table is used to filter out deleted DOC_IDs. The benefit of this design is that deletions are fast and inexpensive. The drawback is that the size of the index is not immediately reduced after deleting records. To remove full-text index entries for deleted records, run OPTIMIZE TABLE on the indexed table with innodb_optimize_fulltext_only=ON to rebuild the full-text index. For more information, see Optimizing InnoDB Full-Text Indexes.

InnoDB Full-Text Index Transaction Handling

InnoDB full-text indexes have special transaction handling characteristics due its caching and batch processing behavior. Specifically, updates and insertions on a full-text index are processed at transaction commit time, which means that a full-text search can only see committed data. The following example demonstrates this behavior. The full-text search only returns a result after the inserted lines are committed.

```
mysql> CREATE TABLE opening_lines (          
id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,  
opening_line TEXT(500),  
author VARCHAR(200),  
title VARCHAR(200),  
FULLTEXT idx (opening_line)  
) ENGINE=InnoDB;

mysql> BEGIN;

mysql> INSERT INTO opening_lines(opening_line,author,title) VALUES  
('Call me Ishmael.','Herman Melville','Moby-Dick'),  
('A screaming comes across the sky.','Thomas Pynchon','Gravity\'s Rainbow'),  
('I am an invisible man.','Ralph Ellison','Invisible Man'),  
('Where now? Who now? When now?','Samuel Beckett','The Unnamable'),  
('It was love at first sight.','Joseph Heller','Catch-22'),  
('All this happened, more or less.','Kurt Vonnegut','Slaughterhouse-Five'),  
('Mrs. Dalloway said she would buy the flowers herself.','Virginia Woolf','Mrs. Dalloway'),  
('It was a pleasure to burn.','Ray Bradbury','Fahrenheit 451');

mysql> SELECT COUNT(*) FROM opening_lines WHERE MATCH(opening_line) AGAINST('Ishmael');
+----------+
| COUNT(*) |
+----------+
|        0 |
+----------+

mysql> COMMIT;

mysql> SELECT COUNT(*) FROM opening_lines WHERE MATCH(opening_line) AGAINST('Ishmael');
+----------+
| COUNT(*) |
+----------+
|        1 |
+----------+
```

Monitoring InnoDB Full-Text Indexes

You can monitor and examine the special text-processing aspects of InnoDB full-text indexes by querying the following INFORMATION_SCHEMA tables:

- INNODB_FT_CONFIG
- INNODB_FT_INDEX_TABLE
You can also view basic information for full-text indexes and tables by querying `INNODB_INDEXES` and `INNODB_TABLES`.

For more information, see Section 15.15.4, “InnoDB INFORMATION_SCHEMA FULLTEXT Index Tables”.

### 15.6.3 Tablespaces

This section covers topics related to InnoDB tablespaces.

#### 15.6.3.1 The System Tablespace

The system tablespace is the storage area for the change buffer. It may also contain table and index data if tables are created in the system tablespace rather than file-per-table or general tablespaces. In previous MySQL versions, the system tablespace contained the InnoDB data dictionary. In MySQL 8.0, InnoDB stores metadata in the MySQL data dictionary. See Chapter 14, MySQL Data Dictionary. In previous MySQL releases, the system tablespace also contained the doublewrite buffer storage area. This storage area resides in separate doublewrite files as of MySQL 8.0.20. See Section 15.6.4, “Doublewrite Buffer”.

The system tablespace can have one or more data files. By default, a single system tablespace data file, named `ibdata1`, is created in the data directory. The size and number of system tablespace data files is defined by the `innodb_data_file_path` startup option. For configuration information, see System Tablespace Data File Configuration.

Additional information about the system tablespace is provided under the following topics in the section:

- Resizing the System Tablespace
- Using Raw Disk Partitions for the System Tablespace

#### Resizing the System Tablespace

This section describes how to increase or decrease the size of the system tablespace.

#### Increasing the Size of the System Tablespace

The easiest way to increase the size of the system tablespace is to configure it to be auto-extending. To do so, specify the `autoextend` attribute for the last data file in the `innodb_data_file_path` setting, and restart the server. For example:

```
innodb_data_file_path=ibdata1:10M:autoextend
```

When the `autoextend` attribute is specified, the data file automatically increases in size by 8MB increments as space is required. The `innodb_autoextend_increment` variable controls the increment size.

You can also increase system tablespace size by adding another data file. To do so:

1. Stop the MySQL server.
2. If the last data file in the `innodb_data_file_path` setting is defined with the `autoextend` attribute, remove it, and modify the size attribute to reflect the current data file size. To determine the appropriate...
data file size to specify, check your file system for the file size, and round that value down to the closest MB value, where a MB is equal to 1024 x 1024 bytes.

3. Append a new data file to the `innodb_data_file_path` setting, optionally specifying the `autoextend` attribute. The `autoextend` attribute can be specified only for the last data file in the `innodb_data_file_path` setting.

4. Start the MySQL server.

For example, this tablespace has one auto-extending data file:

```plaintext
innodb_data_home_dir =
innodb_data_file_path = /ibdata/ibdata1:10M:autoextend
```

Suppose that the data file has grown to 988MB over time. This is the `innodb_data_file_path` setting after modifying the size attribute to reflect the current data file size, and after specifying a new 50MB auto-extending data file:

```plaintext
innodb_data_home_dir =
innodb_data_file_path = /ibdata/ibdata1:988M;/disk2/ibdata2:50M:autoextend
```

When adding a new data file, do not specify an existing file name. InnoDB creates and initializes the new data file when you start the server.

Note

You cannot increase the size of an existing system tablespace data file by changing its size attribute. For example, changing the `innodb_data_file_path` setting from `ibdata1:10M:autoextend` to `ibdata1:12M:autoextend` produces the following error when starting the server:

```
[ERROR] [MY-012263] [InnoDB] The Auto-extending innodb_system data file './ibdata1' is of a different size 640 pages (rounded down to MB) than specified in the .cnf file: initial 768 pages, max 0 (relevant if non-zero) pages!
```

The error indicates that the existing data file size (expressed in InnoDB pages) is different from the data file size specified in the configuration file. If you encounter this error, restore the previous `innodb_data_file_path` setting, and refer to the system tablespace resizing instructions.

Decreasing the Size of the InnoDB System Tablespace

Decreasing the size of an existing system tablespace is not supported. The only option to achieve a smaller system tablespace is to restore your data from a backup to a new MySQL instance created with the desired system tablespace size configuration.

For information about creating backups, see Section 15.18.1, “InnoDB Backup”.

For information about configuring data files for a new system tablespace. See System Tablespace Data File Configuration.

To avoid a large system tablespace, consider using file-per-table tablespaces or general tablespaces for your data. File-per-table tablespaces are the default tablespace type and are used implicitly when creating an InnoDB table. Unlike the system tablespace, file-per-table tablespaces return disk space to the operating system when they are truncated or dropped. For more information, see Section 15.6.3.2, “File-Per-Table Tablespaces”. General tablespaces are multi-table tablespaces that can also be used as an alternative to the system tablespace. See Section 15.6.3.3, “General Tablespaces”.

Using Raw Disk Partitions for the System Tablespace
Raw disk partitions can be used as system tablespace data files. This technique enables nonbuffered I/O on Windows and some Linux and Unix systems without file system overhead. Perform tests with and without raw partitions to verify whether they improve performance on your system.

When using a raw disk partition, ensure that the user ID that runs the MySQL server has read and write privileges for that partition. For example, if running the server as the `mysql` user, the partition must be readable and writeable by `mysql`. If running the server with the `--memlock` option, the server must be run as `root`, so the partition must be readable and writeable by `root`.

The procedures described below involve option file modification. For additional information, see Section 4.2.2.2, "Using Option Files".

### Allocating a Raw Disk Partition on Linux and Unix Systems

1. When creating a new data file, specify the keyword `newraw` immediately after the data file size for the `innodb_data_file_path` option. The partition must be at least as large as the size that you specify. Note that 1MB in InnoDB is 1024 x 1024 bytes, whereas 1MB in disk specifications usually means 1,000,000 bytes.

   ```
   [mysqld]
   innodb_data_home_dir=
   innodb_data_file_path=/dev/hdd1:3Gnewraw;/dev/hdd2:2Gnewraw
   ```

2. Restart the server. InnoDB notices the `newraw` keyword and initializes the new partition. However, do not create or change any InnoDB tables yet. Otherwise, when you next restart the server, InnoDB reinitializes the partition and your changes are lost. (As a safety measure InnoDB prevents users from modifying data when any partition with `newraw` is specified.)

3. After InnoDB has initialized the new partition, stop the server, change `newraw` in the data file specification to `raw`:

   ```
   [mysqld]
   innodb_data_home_dir=
   innodb_data_file_path=/dev/hdd1:3Graw;/dev/hdd2:2Graw
   ```

4. Restart the server. InnoDB now permits changes to be made.

### Allocating a Raw Disk Partition on Windows

On Windows systems, the same steps and accompanying guidelines described for Linux and Unix systems apply except that the `innodb_data_file_path` setting differs slightly on Windows.

1. When creating a new data file, specify the keyword `newraw` immediately after the data file size for the `innodb_data_file_path` option:

   ```
   [mysqld]
   innodb_data_home_dir=
   innodb_data_file_path=//./D::10Gnewraw
   ```

   The `//./` corresponds to the Windows syntax of `\\.` for accessing physical drives. In the example above, `D:` is the drive letter of the partition.

2. Restart the server. InnoDB notices the `newraw` keyword and initializes the new partition.

3. After InnoDB has initialized the new partition, stop the server, change `newraw` in the data file specification to `raw`:

   ```
   [mysqld]
   innodb_data_home_dir=
   innodb_data_file_path=//./D::10Graw
   ```
4. Restart the server. InnoDB now permits changes to be made.

15.6.3.2 File-Per-Table Tablespaces

A file-per-table tablespace contains data and indexes for a single InnoDB table, and is stored on the file system in a single data file.

File-per-table tablespace characteristics are described under the following topics in this section:

- File-Per-Table Tablespace Configuration
- File-Per-Table Tablespace Data Files
- File-Per-Table Tablespace Advantages
- File-Per-Table Tablespace Disadvantages

File-Per-Table Tablespace Configuration

InnoDB creates tables in file-per-table tablespaces by default. This behavior is controlled by the innodb_file_per_table variable. Disabling innodb_file_per_table causes InnoDB to create tables in the system tablespace.

An innodb_file_per_table setting can be specified in an option file or configured at runtime using a SET GLOBAL statement. Changing the setting at runtime requires privileges sufficient to set global system variables. See Section 5.1.9.1, “System Variable Privileges”.

Option file:

```ini
[mysqld]
ininnodb_file_per_table=ON
```

Using SET GLOBAL at runtime:

```sql
mysql> SET GLOBAL innodb_file_per_table=ON;
```

File-Per-Table Tablespace Data Files

A file-per-table tablespace is created in an .ibd data file in a schema directory under the MySQL data directory. The .ibd file is named for the table (table_name.ibd). For example, the data file for table `test.t1` is created in the `test` directory under the MySQL data directory:

```sql
mysql> USE test;

mysql> CREATE TABLE t1 (id INT PRIMARY KEY AUTO_INCREMENT,
 name VARCHAR(100)
) ENGINE = InnoDB;

$> cd /path/to/mysql/data/test
$> ls
    t1.ibd
```

You can use the DATA DIRECTORY clause of the CREATE TABLE statement to implicitly create a file-per-table tablespace data file outside of the data directory. For more information, see Section 15.6.1.2, “Creating Tables Externally”.

File-Per-Table Tablespace Advantages

File-per-table tablespaces have the following advantages over shared tablespaces such as the system tablespace or general tablespaces.
• Disk space is returned to the operating system after truncating or dropping a table created in a file-per-table tablespace. Truncating or dropping a table stored in a shared tablespace creates free space within the shared tablespace data file, which can only be used for InnoDB data. In other words, a shared tablespace data file does not shrink in size after a table is truncated or dropped.

• A table-copying `ALTER TABLE` operation on a table that resides in a shared tablespace can increase the amount of disk space occupied by the tablespace. Such operations may require as much additional space as the data in the table plus indexes. This space is not released back to the operating system as it is for file-per-table tablespaces.

• `TRUNCATE TABLE` performance is better when executed on tables that reside in file-per-table tablespaces.

• File-per-table tablespace data files can be created on separate storage devices for I/O optimization, space management, or backup purposes. See Section 15.6.1.2, “Creating Tables Externally”.

• You can import a table that resides in file-per-table tablespace from another MySQL instance. See Section 15.6.1.3, “Importing InnoDB Tables”.

• Tables created in file-per-table tablespaces support features associated with DYNAMIC and COMPRESSED row formats, which are not supported by the system tablespace. See Section 15.10, “InnoDB Row Formats”.

• Tables stored in individual tablespace data files can save time and improve chances for a successful recovery when data corruption occurs, when backups or binary logs are unavailable, or when the MySQL server instance cannot be restarted.

• Tables created in file-per-table tablespaces can be backed up or restored quickly using MySQL Enterprise Backup, without interrupting the use of other InnoDB tables. This is beneficial for tables on varying backup schedules or that require backup less frequently. See Making a Partial Backup for details.

• File-per-table tablespaces permit monitoring table size on the file system by monitoring the size of the tablespace data file.

• Common Linux file systems do not permit concurrent writes to a single file such as a shared tablespace data file when `innodb_flush_method` is set to O_DIRECT. As a result, there are possible performance improvements when using file-per-table tablespaces in conjunction with this setting.

• Tables in a shared tablespace are limited in size by the 64TB tablespace size limit. By comparison, each file-per-table tablespace has a 64TB size limit, which provides plenty of room for individual tables to grow in size.

**File-Per-Table Tablespace Disadvantages**

File-per-table tablespaces have the following disadvantages compared to shared tablespaces such as the system tablespace or general tablespaces.

• With file-per-table tablespaces, each table may have unused space that can only be utilized by rows of the same table, which can lead to wasted space if not properly managed.

• `fsync` operations are performed on multiple file-per-table data files instead of a single shared tablespace data file. Because `fsync` operations are per file, write operations for multiple tables cannot be combined, which can result in a higher total number of `fsync` operations.

• `mysqlld` must keep an open file handle for each file-per-table tablespace, which may impact performance if you have numerous tables in file-per-table tablespaces.
• More file descriptors are required when each table has its own data file.

• There is potential for more fragmentation, which can impede DROP TABLE and table scan performance. However, if fragmentation is managed, file-per-table tablespaces can improve performance for these operations.

• The buffer pool is scanned when dropping a table that resides in a file-per-table tablespace, which can take several seconds for large buffer pools. The scan is performed with a broad internal lock, which may delay other operations.

• The `innodb_autoextend_increment` variable, which defines the increment size for extending the size of an auto-extending shared tablespace file when it becomes full, does not apply to file-per-table tablespace files, which are auto-extending regardless of the `innodb_autoextend_increment` setting. Initial file-per-table tablespace extensions are by small amounts, after which extensions occur in increments of 4MB.

15.6.3.3 General Tablespaces

A general tablespace is a shared InnoDB tablespace that is created using `CREATE TABLESPACE` syntax. General tablespace capabilities and features are described under the following topics in this section:

• General Tablespace Capabilities
• Creating a General Tablespace
• Adding Tables to a General Tablespace
• General Tablespace Row Format Support
• Moving Tables Between Tablespaces Using ALTER TABLE
• Renaming a General Tablespace
• Dropping a General Tablespace
• General Tablespace Limitations

General Tablespace Capabilities

General tablespaces provide the following capabilities:

• Similar to the system tablespace, general tablespaces are shared tablespaces capable of storing data for multiple tables.

• General tablespaces have a potential memory advantage over file-per-table tablespaces. The server keeps tablespace metadata in memory for the lifetime of a tablespace. Multiple tables in fewer general tablespaces consume less memory for tablespace metadata than the same number of tables in separate file-per-table tablespaces.

• General tablespace data files can be placed in a directory relative to or independent of the MySQL data directory, which provides you with many of the data file and storage management capabilities of file-per-table tablespaces. As with file-per-table tablespaces, the ability to place data files outside of the MySQL data directory allows you to manage performance of critical tables separately, setup RAID or DRBD for specific tables, or bind tables to particular disks, for example.

• General tablespaces support all table row formats and associated features.

• The `TABLESPACE` option can be used with `CREATE TABLE` to create tables in a general tablespace, file-per-table tablespace, or in the system tablespace.
Tables

• The TABLESPACE option can be used with ALTER TABLE to move tables between general tablespaces, file-per-table tablespaces, and the system tablespace.

Creating a General Tablespace

General tablespaces are created using CREATE TABLESPACE syntax.

CREATE TABLESPACE `tablespace_name`
[ADD DATAFILE 'file_name']
[FILE_BLOCK_SIZE = value]
[ENGINE [ = ] engine_name]

A general tablespace can be created in the data directory or outside of it. To avoid conflicts with implicitly created file-per-table tablespaces, creating a general tablespace in a subdirectory under the data directory is not supported. When creating a general tablespace outside of the data directory, the directory must exist and must be known to InnoDB prior to creating the tablespace. To make an unknown directory known to InnoDB, add the directory to the innodb_directories argument value. innodb_directories is a read-only startup option. Configuring it requires restarting the server.

Examples:

Creating a general tablespace in the data directory:

mysql> CREATE TABLESPACE `ts1` ADD DATAFILE 'ts1.ibd' Engine=InnoDB;

or

mysql> CREATE TABLESPACE `ts1` Engine=InnoDB;

The ADD DATAFILE clause is optional as of MySQL 8.0.14 and required before that. If the ADD DATAFILE clause is not specified when creating a tablespace, a tablespace data file with a unique file name is created implicitly. The unique file name is a 128 bit UUID formatted into five groups of hexadecimal numbers separated by dashes (aaaaaaaa-bbbb-cccc-dddd-eeeeeeeeee). General tablespace data files include an .ibd file extension. In a replication environment, the data file name created on the source is not the same as the data file name created on the replica.

Creating a general tablespace in a directory outside of the data directory:

mysql> CREATE TABLESPACE `ts1` ADD DATAFILE '/my/tablespace/directory/ts1.ibd' Engine=InnoDB;

You can specify a path that is relative to the data directory as long as the tablespace directory is not under the data directory. In this example, the my_tablespace directory is at the same level as the data directory:

mysql> CREATE TABLESPACE `ts1` ADD DATAFILE '../my_tablespace/ts1.ibd' Engine=InnoDB;

Note

The ENGINE = InnoDB clause must be defined as part of the CREATE TABLESPACE statement, or InnoDB must be defined as the default storage engine (default_storage_engine=InnoDB).

Adding Tables to a General Tablespace

After creating a general tablespace, CREATE TABLE tbl_name ... TABLESPACE [=] tablespace_name or ALTER TABLE tbl_name TABLESPACE [=] tablespace_name statements can be used to add tables to the tablespace, as shown in the following examples:
### Tablespace Row Format Support

General tablespaces support all table row formats (REDUNDANT, COMPACT, DYNAMIC, COMPRESSED) with the caveat that compressed and uncompressed tables cannot coexist in the same general tablespace due to different physical page sizes.

For a general tablespace to contain compressed tables (ROW_FORMAT=COMPRESSED), the FILE_BLOCK_SIZE option must be specified, and the FILE_BLOCK_SIZE value must be a valid compressed page size in relation to the innodb_page_size value. Also, the physical page size of the compressed table (KEY_BLOCK_SIZE) must be equal to FILE_BLOCK_SIZE/1024. For example, if innodb_page_size=16KB and FILE_BLOCK_SIZE=8K, the KEY_BLOCK_SIZE of the table must be 8.

The following table shows permitted innodb_page_size, FILE_BLOCK_SIZE, and KEY_BLOCK_SIZE combinations. FILE_BLOCK_SIZE values may also be specified in bytes. To determine a valid KEY_BLOCK_SIZE value for a given FILE_BLOCK_SIZE, divide the FILE_BLOCK_SIZE value by 1024. Table compression is not support for 32K and 64K InnoDB page sizes. For more information about KEY_BLOCK_SIZE, see CREATE TABLE, and Section 15.9.1.2, “Creating Compressed Tables”.

**Table 15.3 Permitted Page Size, FILE_BLOCK_SIZE, and KEY_BLOCK_SIZE Combinations for Compressed Tables**

<table>
<thead>
<tr>
<th>InnoDB Page Size (innodb_page_size)</th>
<th>Permitted FILE_BLOCK_SIZE Value</th>
<th>Permitted KEY_BLOCK_SIZE Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>64KB</td>
<td>64K (65536)</td>
<td>Compression is not supported</td>
</tr>
<tr>
<td>32KB</td>
<td>32K (32768)</td>
<td>Compression is not supported</td>
</tr>
<tr>
<td>16KB</td>
<td>16K (16384)</td>
<td>None. If innodb_page_size is equal to FILE_BLOCK_SIZE, the tablespace cannot contain a compressed table.</td>
</tr>
<tr>
<td>16KB</td>
<td>8K (8192)</td>
<td>8</td>
</tr>
<tr>
<td>16KB</td>
<td>4K (4096)</td>
<td>4</td>
</tr>
<tr>
<td>16KB</td>
<td>2K (2048)</td>
<td>2</td>
</tr>
<tr>
<td>16KB</td>
<td>1K (1024)</td>
<td>1</td>
</tr>
<tr>
<td>8KB</td>
<td>8K (8192)</td>
<td>None. If innodb_page_size is equal to FILE_BLOCK_SIZE, the tablespace cannot contain a compressed table.</td>
</tr>
</tbody>
</table>
### Tablespaces

<table>
<thead>
<tr>
<th>InnoDB Page Size (innodb_page_size)</th>
<th>Permitted FILE_BLOCK_SIZE Value</th>
<th>Permitted KEY_BLOCK_SIZE Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>8KB</td>
<td>4K (4096)</td>
<td>4</td>
</tr>
<tr>
<td>8KB</td>
<td>2K (2048)</td>
<td>2</td>
</tr>
<tr>
<td>8KB</td>
<td>1K (1024)</td>
<td>1</td>
</tr>
<tr>
<td>4KB</td>
<td>4K (4096)</td>
<td>None. If innodb_page_size is equal to FILE_BLOCK_SIZE, the tablespace cannot contain a compressed table.</td>
</tr>
<tr>
<td>4KB</td>
<td>2K (2048)</td>
<td>2</td>
</tr>
<tr>
<td>4KB</td>
<td>1K (1024)</td>
<td>1</td>
</tr>
</tbody>
</table>

This example demonstrates creating a general tablespace and adding a compressed table. The example assumes a default innodb_page_size of 16KB. The FILE_BLOCK_SIZE of 8192 requires that the compressed table have a KEY_BLOCK_SIZE of 8.

```sql
mysql> CREATE TABLESPACE `ts2` ADD DATAFILE 'ts2.ibd' FILE_BLOCK_SIZE = 8192 Engine=InnoDB;
```

```sql
mysql> CREATE TABLE t4 (c1 INT PRIMARY KEY) TABLESPACE ts2 ROW_FORMAT=COMPRESSED KEY_BLOCK_SIZE=8;
```

If you do not specify FILE_BLOCK_SIZE when creating a general tablespace, FILE_BLOCK_SIZE defaults to innodb_page_size. When FILE_BLOCK_SIZE is equal to innodb_page_size, the tablespace may only contain tables with an uncompressed row format (COMPACT, REDUNDANT, and DYNAMIC row formats).

#### Moving Tables Between Tablespaces Using ALTER TABLE

**ALTER TABLE** with the TABLESPACE option can be used to move a table to an existing general tablespace, to a new file-per-table tablespace, or to the system tablespace.

**Note**

Support for placing table partitions in shared tablespaces was deprecated in MySQL 5.7.24 and removed MySQL 8.0.13. Shared tablespaces include the InnoDB system tablespace and general tablespaces.

To move a table from a file-per-table tablespace or from the system tablespace to a general tablespace, specify the name of the general tablespace. The general tablespace must exist. See **ALTER TABLESPACE** for more information.

```sql
ALTER TABLE tbl_name TABLESPACE [=] tablespace_name;
```

To move a table from a general tablespace or file-per-table tablespace to the system tablespace, specify innodb_system as the tablespace name.

```sql
ALTER TABLE tbl_name TABLESPACE [=] innodb_system;
```

To move a table from the system tablespace or a general tablespace to a file-per-table tablespace, specify innodb_file_per_table as the tablespace name.

```sql
ALTER TABLE tbl_name TABLESPACE [=] innodb_file_per_table;
```

**ALTER TABLE ... TABLESPACE** operations cause a full table rebuild, even if the TABLESPACE attribute has not changed from its previous value.
### Tablespace

**ALTER TABLE ... TABLESPACE** syntax does not support moving a table from a temporary tablespace to a persistent tablespace.

The **DATA DIRECTORY** clause is permitted with **CREATE TABLE ... TABLESPACE=innodb_file_per_table** but is otherwise not supported for use in combination with the **TABLESPACE** option. As of MySQL 8.0.21, the directory specified in a **DATA DIRECTORY** clause must be known to InnoDB. For more information, see Using the **DATA DIRECTORY** Clause.

Restrictions apply when moving tables from encrypted tablespaces. See Encryption Limitations.

### Renaming a General Tablespace

Renaming a general tablespace is supported using **ALTER TABLESPACE ... RENAME TO** syntax.

```
ALTER TABLESPACE s1 RENAME TO s2;
```

The **CREATE TABLESPACE** privilege is required to rename a general tablespace.

**RENAME TO** operations are implicitly performed in autocommit mode regardless of the autocommit setting.

A **RENAME TO** operation cannot be performed while **LOCK TABLES** or **FLUSH TABLES WITH READ LOCK** is in effect for tables that reside in the tablespace.

Exclusive *metadata locks* are taken on tables within a general tablespace while the tablespace is renamed, which prevents concurrent DDL. Concurrent DML is supported.

### Dropping a General Tablespace

The **DROP TABLESPACE** statement is used to drop an InnoDB general tablespace.

All tables must be dropped from the tablespace prior to a **DROP TABLESPACE** operation. If the tablespace is not empty, **DROP TABLESPACE** returns an error.

Use a query similar to the following to identify tables in a general tablespace.

```
mysql> SELECT a.NAME AS space_name, b.NAME AS table_name FROM INFORMATION_SCHEMA.INNODB_TABLESPACES a, INFORMATION_SCHEMA.INNODB_TABLES b WHERE a.SPACE=b.SPACE AND a.NAME LIKE 'ts1';
```

<table>
<thead>
<tr>
<th>space_name</th>
<th>table_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>ts1</td>
<td>test/t1</td>
</tr>
<tr>
<td>ts1</td>
<td>test/t2</td>
</tr>
<tr>
<td>ts1</td>
<td>test/t3</td>
</tr>
</tbody>
</table>

A general InnoDB tablespace is not deleted automatically when the last table in the tablespace is dropped. The tablespace must be dropped explicitly using **DROP TABLESPACE** tablespace_name.

A general tablespace does not belong to any particular database. A **DROP DATABASE** operation can drop tables that belong to a general tablespace but it cannot drop the tablespace, even if the **DROP DATABASE** operation drops all tables that belong to the tablespace.

Similar to the system tablespace, truncating or dropping tables stored in a general tablespace creates free space internally in the general tablespace .ibd data file which can only be used for new InnoDB data. Space is not released back to the operating system as it is when a file-per-table tablespace is deleted during a **DROP TABLE** operation.
This example demonstrates how to drop an InnoDB general tablespace. The general tablespace `ts1` is created with a single table. The table must be dropped before dropping the tablespace.

```sql
mysql> CREATE TABLESPACE `ts1` ADD DATAFILE 'ts1.ibd' Engine=InnoDB;
mysql> CREATE TABLE t1 (c1 INT PRIMARY KEY) TABLESPACE ts1 Engine=InnoDB;
mysql> DROP TABLE t1;
mysql> DROP TABLESPACE ts1;
```

**Note**

`tablespace_name` is a case-sensitive identifier in MySQL.

**General Tablespace Limitations**

- A generated or existing tablespace cannot be changed to a general tablespace.
- Creation of temporary general tablespaces is not supported.
- General tablespaces do not support temporary tables.
- Similar to the system tablespace, truncating or dropping tables stored in a general tablespace creates free space internally in the general tablespace `.ibd` file which can only be used for new InnoDB data. Space is not released back to the operating system as it is for file-per-table tablespaces.

Additionally, a table-copying `ALTER TABLE` operation on table that resides in a shared tablespace (a general tablespace or the system tablespace) can increase the amount of space used by the tablespace. Such operations require as much additional space as the data in the table plus indexes. The additional space required for the table-copying `ALTER TABLE` operation is not released back to the operating system as it is for file-per-table tablespaces.

- `ALTER TABLE ... DISCARD TABLESPACE` and `ALTER TABLE ...IMPORT TABLESPACE` are not supported for tables that belong to a general tablespace.
- Support for placing table partitions in general tablespaces was deprecated in MySQL 5.7.24 and removed in MySQL 8.0.13.
- The `ADD DATAFILE` clause is not supported in a replication environment where the source and replica reside on the same host, as it would cause the source and replica to create a tablespace of the same name in the same location, which is not supported. However, if the `ADD DATAFILE` clause is omitted, the tablespace is created in the data directory with a generated file name that is unique, which is permitted.
- As of MySQL 8.0.21, general tablespaces cannot be created in the undo tablespace directory (`innodb_undo_directory`) unless that directly is known to InnoDB. Known directories are those defined by the `datadir`, `innodb_data_home_dir`, and `innodb_directories` variables.

### 15.6.3.4 Undo Tablespaces

Undo tablespaces contain undo logs, which are collections of records containing information about how to undo the latest change by a transaction to a clustered index record.

Undo tablespaces are described under the following topics in this section:

- **Default Undo Tablespaces**
Tables

- **Undo Tablespace Size**
- **Adding Undo Tablespaces**
- **Dropping Undo Tablespaces**
- **Moving Undo Tablespaces**
- **Configuring the Number of Rollback Segments**
- **Truncating Undo Tablespaces**
- **Undo Tablespace Status Variables**

**Default Undo Tablespaces**

Two default undo tablespaces are created when the MySQL instance is initialized. Default undo tablespaces are created at initialization time to provide a location for rollback segments that must exist before SQL statements can be accepted. A minimum of two undo tablespaces is required to support automated truncation of undo tablespaces. See **Truncating Undo Tablespaces**.

Default undo tablespaces are created in the location defined by the `innodb_undo_directory` variable. If the `innodb_undo_directory` variable is undefined, default undo tablespaces are created in the data directory. Default undo tablespace data files are named `undo_001` and `undo_002`. The corresponding undo tablespace names defined in the data dictionary are `innodb_undo_001` and `innodb_undo_002`.

As of MySQL 8.0.14, additional undo tablespaces can be created at runtime using SQL. See **Adding Undo Tablespaces**.

**Undo Tablespace Size**

Prior to MySQL 8.0.23, the initial size of an undo tablespace depends on the `innodb_page_size` value. For the default 16KB page size, the initial undo tablespace file size is 10MiB. For 4KB, 8KB, 32KB, and 64KB page sizes, the initial undo tablespace files sizes are 7MiB, 8MiB, 20MiB, and 40MiB, respectively. As of MySQL 8.0.23, the initial undo tablespace size is normally 16MiB. The initial size may differ when a new undo tablespace is created by a truncate operation. In this case, if the file extension size is larger than 16MB, and the previous file extension occurred within the last second, the new undo tablespace is created at a quarter of the size defined by the `innodb_max_undo_log_size` variable.

Prior to MySQL 8.0.23, an undo tablespace is extended four extents at a time. From MySQL 8.0.23, an undo tablespace is extended by a minimum of 16MB. To handle aggressive growth, the file extension size is doubled if the previous file extension happened less than 0.1 seconds earlier. Doubling of the extension size can occur multiple times to a maximum of 256MB. If the previous file extension occurred more than 0.1 seconds earlier, the extension size is reduced by half, which can also occur multiple times, to a minimum of 16MB. If the `AUTOEXTEND_SIZE` option is defined for an undo tablespace, it is extended by the greater of the `AUTOEXTEND_SIZE` setting and the extension size determined by the logic described above. For information about the `AUTOEXTEND_SIZE` option, see Section 15.6.3.9, "Tablespace AUTOEXTEND_SIZE Configuration".

**Adding Undo Tablespaces**

Because undo logs can become large during long-running transactions, creating additional undo tablespaces can help prevent individual undo tablespaces from becoming too large. As of MySQL 8.0.14, additional undo tablespaces can be created at runtime using `CREATE UNDO TABLESPACE` syntax.

```
CREATE UNDO TABLESPACE `tablespace_name` ADD DATAFILE 'file_name.ibu';
```
The undo tablespace file name must have an `.ibu` extension. It is not permitted to specify a relative path when defining the undo tablespace file name. A fully qualified path is permitted, but the path must be known to InnoDB. Known paths are those defined by the `innodb_directories` variable. Unique undo tablespace file names are recommended to avoid potential file name conflicts when moving or cloning data.

Note

In a replication environment, the source and each replica must have its own undo tablespace file directory. Replicating the creation of an undo tablespace file to a common directory would cause a file name conflict.

At startup, directories defined by the `innodb_directories` variable are scanned for undo tablespace files. (The scan also traverses subdirectories.) Directories defined by the `innodb_data_home_dir`, `innodb_undo_directory`, and `datadir` variables are automatically appended to the `innodb_directories` value regardless of whether the `innodb_directories` variable is defined explicitly. An undo tablespace can therefore reside in paths defined by any of those variables.

If the undo tablespace file name does not include a path, the undo tablespace is created in the directory defined by the `innodb_undo_directory` variable. If that variable is undefined, the undo tablespace is created in the data directory.

Note

The InnoDB recovery process requires that undo tablespace files reside in known directories. Undo tablespace files must be discovered and opened before redo recovery and before other data files are opened to permit uncommitted transactions and data dictionary changes to be rolled back. An undo tablespace not found before recovery cannot be used, which can lead to database inconsistencies. An error message is reported at startup if an undo tablespace known to the data dictionary is not found. The known directory requirement also supports undo tablespace portability. See Moving Undo Tablespaces.

To create undo tablespaces in a path relative to the data directory, set the `innodb_undo_directory` variable to the relative path, and specify the file name only when creating an undo tablespace.

To view undo tablespace names and paths, query `INFORMATION_SCHEMA.FILES`:

```
SELECT TABLESPACE_NAME, FILE_NAME FROM INFORMATION_SCHEMA.FILES
WHERE FILE_TYPE LIKE 'UNDO LOG';
```

A MySQL instance supports up to 127 undo tablespaces including the two default undo tablespaces created when the MySQL instance is initialized.

Note

Prior to MySQL 8.0.14, additional undo tablespaces are created by configuring the `innodb_undo_tablespaces` startup variable. This variable is deprecated and no longer configurable as of MySQL 8.0.14.

Prior to MySQL 8.0.14, increasing the `innodb_undo_tablespaces` setting creates the specified number of undo tablespaces and adds them to the list of active undo tablespaces. Decreasing the `innodb_undo_tablespaces` setting removes undo tablespaces from the list of active undo tablespaces. Undo tablespaces that are removed from the active list remain active until they are no longer used by existing transactions. The `innodb_undo_tablespaces` variable
can be configured at runtime using a `SET` statement or defined in a configuration file.

Prior to MySQL 8.0.14, deactivated undo tablespaces cannot be removed. Manual removal of undo tablespace files is possible after a slow shutdown but is not recommended, as deactivated undo tablespaces may contain active undo logs for some time after the server is restarted if open transactions were present when shutting down the server. As of MySQL 8.0.14, undo tablespaces can be dropped using `DROP UNDO TABLESPACE` syntax. See Dropping Undo Tablespaces.

## Dropping Undo Tablespaces

As of MySQL 8.0.14, undo tablespaces created using `CREATE UNDO TABLESPACE` syntax can be dropped at runtime using `DROP UNDO TABLESPACE` syntax.

An undo tablespace must be empty before it can be dropped. To empty an undo tablespace, the undo tablespace must first be marked as inactive using `ALTER UNDO TABLESPACE` syntax so that the tablespace is no longer used for assigning rollback segments to new transactions.

```
ALTER UNDO TABLESPACE tablespace_name SET INACTIVE;
```

After an undo tablespace is marked as inactive, transactions currently using rollback segments in the undo tablespace are permitted to finish, as are any transactions started before those transactions are completed. After transactions are completed, the purge system frees the rollback segments in the undo tablespace, and the undo tablespace is truncated to its initial size. (The same process is used when truncating undo tablespaces. See Truncating Undo Tablespaces.) Once the undo tablespace is empty, it can be dropped.

```
DROP UNDO TABLESPACE tablespace_name;
```

### Note

Alternatively, the undo tablespace can be left in an empty state and reactivated later, if needed, by issuing an `ALTER UNDO TABLESPACE tablespace_name SET ACTIVE` statement.

The state of an undo tablespace can be monitored by querying the Information Schema `INNODB_TABLESPACES` table.

```
SELECT NAME, STATE FROM INFORMATION_SCHEMA.INNODB_TABLESPACES WHERE NAME LIKE 'tablespace_name';
```

An inactive state indicates that rollback segments in an undo tablespace are no longer used by new transactions. An empty state indicates that an undo tablespace is empty and ready to be dropped, or ready to be made active again using an `ALTER UNDO TABLESPACE tablespace_name SET ACTIVE` statement. Attempting to drop an undo tablespace that is not empty returns an error.

The default undo tablespaces (`innodb.undo_001` and `innodb.undo_002`) created when the MySQL instance is initialized cannot be dropped. They can, however, be made inactive using an `ALTER UNDO TABLESPACE tablespace_name SET INACTIVE` statement. Before a default undo tablespace can be made inactive, there must be an undo tablespace to take its place. A minimum of two active undo tablespaces are required at all times to support automated truncation of undo tablespaces.

## Moving Undo Tablespaces

Undo tablespaces created with `CREATE UNDO TABLESPACE` syntax can be moved while the server is offline to any known directory. Known directories are those defined by the `innodb_directories`
variable. Directories defined by `innodb_data_home_dir`, `innodb_undo_directory`, and `datadir` are automatically appended to the `innodb_directories` value regardless of whether the `innodb_directories` variable is defined explicitly. Those directories and their subdirectories are scanned at startup for undo tablespaces files. An undo tablespace file moved to any of those directories is discovered at startup and assumed to be the undo tablespace that was moved.

The default undo tablespaces (`innodb_undo_001` and `innodb_undo_002`) created when the MySQL instance is initialized must reside in the directory defined by the `innodb_undo_directory` variable. If the `innodb_undo_directory` variable is undefined, default undo tablespaces reside in the data directory. If default undo tablespaces are moved while the server is offline, the server must be started with the `innodb_undo_directory` variable configured to the new directory.

The I/O patterns for undo logs make undo tablespaces good candidates for SSD storage.

### Configuring the Number of Rollback Segments

The `innodb_rollback_segments` variable defines the number of rollback segments allocated to each undo tablespace and to the global temporary tablespace. The `innodb_rollback_segments` variable can be configured at startup or while the server is running.

The default setting for `innodb_rollback_segments` is 128, which is also the maximum value. For information about the number of transactions that a rollback segment supports, see Section 15.6.6, “Undo Logs”.

### Truncating Undo Tablespaces

There are two methods of truncating undo tablespaces, which can be used individually or in combination to manage undo tablespace size. One method is automated, enabled using configuration variables. The other method is manual, performed using SQL statements.

The automated method does not require monitoring undo tablespace size and, once enabled, it performs deactivation, truncation, and reactivation of undo tablespaces without manual intervention. The manual truncation method may be preferable if you want to control when undo tablespaces are taken offline for truncation. For example, you may want to avoid truncating undo tablespaces during peak workload times.

#### Automated Truncation

Automated truncation of undo tablespaces requires a minimum of two active undo tablespaces, which ensures that one undo tablespace remains active while the other is taken offline to be truncated. By default, two undo tablespaces are created when the MySQL instance is initialized.

To have undo tablespaces automatically truncated, enable the `innodb_undo_log_truncate` variable. For example:

```sql
mysql> SET GLOBAL innodb_undo_log_truncate=ON;
```

When the `innodb_undo_log_truncate` variable is enabled, undo tablespaces that exceed the size limit defined by the `innodb_max_undo_log_size` variable are subject to truncation. The `innodb_max_undo_log_size` variable is dynamic and has a default value of 1073741824 bytes (1024 MiB).

```sql
mysql> SELECT @@innodb_max_undo_log_size;
+-----------------------------+
<table>
<thead>
<tr>
<th>@@innodb_max_undo_log_size</th>
</tr>
</thead>
<tbody>
<tr>
<td>1073741824</td>
</tr>
</tbody>
</table>
+-----------------------------+
```
When the `innodb_undo_log_truncate` variable is enabled:

1. Default and user-defined undo tablespaces that exceed the `innodb_max_undo_log_size` setting are marked for truncation. Selection of an undo tablespace for truncation is performed in a circular fashion to avoid truncating the same undo tablespace each time.

2. Rollback segments residing in the selected undo tablespace are made inactive so that they are not assigned to new transactions. Existing transactions that are currently using rollback segments are permitted to finish.

3. The `purge` system empties rollback segments by freeing undo logs that are no longer in use.

4. After all rollback segments in the undo tablespace are freed, the truncate operation runs and truncates the undo tablespace to its initial size.

   The size of an undo tablespace after a truncate operation may be larger than the initial size due to immediate use following the completion of the operation.

   The `innodb_undo_directory` variable defines the location of default undo tablespace files. If the `innodb_undo_directory` variable is undefined, default undo tablespaces reside in the data directory. The location of all undo tablespace files including user-defined undo tablespaces created using `CREATE UNDO TABLESPACE` syntax can be determined by querying the Information Schema `FILES` table:

   ```sql
   SELECT TABLESPACE_NAME, FILE_NAME FROM INFORMATION_SCHEMA.FILES WHERE FILE_TYPE LIKE 'UNDO LOG';
   ```

5. Rollback segments are reactivated so that they can be assigned to new transactions.

### Manual Truncation

Manual truncation of undo tablespaces requires a minimum of three active undo tablespaces. Two active undo tablespaces are required at all times to support the possibility that automated truncation is enabled. A minimum of three undo tablespaces satisfies this requirement while permitting an undo tablespace to be taken offline manually.

To manually initiate truncation of an undo tablespace, deactivate the undo tablespace by issuing the following statement:

```sql
ALTER UNDO TABLESPACE tablespace_name SET INACTIVE;
```

After the undo tablespace is marked as inactive, transactions currently using rollback segments in the undo tablespace are permitted to finish, as are any transactions started before those transactions are completed. After transactions are completed, the purge system frees the rollback segments in the undo tablespace, the undo tablespace is truncated to its initial size, and the undo tablespace state changes from `inactive` to `empty`.

**Note**

When an `ALTER UNDO TABLESPACE tablespace_name SET INACTIVE` statement deactivates an undo tablespace, the purge thread looks for that undo tablespace at the next opportunity. Once the undo tablespace is found and marked for truncation, the purge thread returns with increased frequency to quickly empty and truncate the undo tablespace.

To check the state of an undo tablespace, query the Information Schema `INNODB_TABLESPACES` table:

```sql
SELECT NAME, STATE FROM INFORMATION_SCHEMA.INNODB_TABLESPACES;
```
Tables

WHERE NAME LIKE 'tablespace_name';

Once the undo tablespace is in an empty state, it can be reactivated by issuing the following statement:

ALTER UNDO TABLESPACE tablespace_name SET ACTIVE;

An undo tablespace in an empty state can also be dropped. See Dropping Undo Tablespaces.

Expediting Automated Truncation of Undo Tablespaces

The purge thread is responsible for emptying and truncating undo tablespaces. By default, the purge thread looks for undo tablespaces to truncate once every 128 times that purge is invoked. The frequency with which the purge thread looks for undo tablespaces to truncate is controlled by the innodb_purge_rseg_truncate_frequency variable, which has a default setting of 128.

mysql> SELECT @@innodb_purge_rseg_truncate_frequency;
+----------------------------------------+
<table>
<thead>
<tr>
<th>@@innodb_purge_rseg_truncate_frequency</th>
</tr>
</thead>
<tbody>
<tr>
<td>128</td>
</tr>
</tbody>
</table>
+----------------------------------------+

To increase the frequency, decrease the innodb_purge_rseg_truncate_frequency setting. For example, to have the purge thread look for undo tablespaces once every 32 times that purge is invoked, set innodb_purge_rseg_truncate_frequency to 32.

mysql> SET GLOBAL innodb_purge_rseg_truncate_frequency=32;

Performance Impact of Truncating Undo Tablespace Files

When an undo tablespace is truncated, the rollback segments in the undo tablespace are deactivated. The active rollback segments in other undo tablespaces assume responsibility for the entire system load, which may result in a slight performance degradation. The extent to which performance is affected depends on a number of factors:

- Number of undo tablespaces
- Number of undo logs
- Undo tablespace size
- Speed of the I/O subsystem
- Existing long running transactions
- System load

The easiest way to avoid the potential performance impact is to increase the number of undo tablespaces.

Monitoring Undo Tablespace Truncation

As of MySQL 8.0.16, undo and purge subsystem counters are provided for monitoring background activities associated with undo log truncation. For counter names and descriptions, query the Information Schema INNODB_METRICS table.

SELECT NAME, SUBSYSTEM, COMMENT FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME LIKE '%truncate%';

For information about enabling counters and querying counter data, see Section 15.15.6, “InnoDB INFORMATION_SCHEMA Metrics Table”.

3333
Undo Tablespace Truncation Limit

As of MySQL 8.0.21, the number of truncate operations on the same undo tablespace between checkpoints is limited to 64. The limit prevents potential issues caused by an excessive number of undo tablespace truncate operations, which can occur if `innodb_max_undo_log_size` is set too low on a busy system, for example. If the limit is exceeded, an undo tablespace can still be made inactive, but it is not truncated until after the next checkpoint. The limit was raised from 64 to 50,000 in MySQL 8.0.22.

Undo Tablespace Truncation Recovery

An undo tablespace truncate operation creates a temporary `undo_space_number_trunc.log` file in the server log directory. That log directory is defined by `innodb_log_group_home_dir`. If a system failure occurs during the truncate operation, the temporary log file permits the startup process to identify undo tablespaces that were being truncated and to continue the operation.

Undo Tablespace Status Variables

The following status variables permit tracking the total number of undo tablespaces, implicit (InnoDB-created) undo tablespaces, explicit (user-created) undo tablespaces, and the number of active undo tablespaces:

```sql
mysql> SHOW STATUS LIKE 'Innodb_undo_tablespaces%';
+--------------------------------------------------+-------+
| Variable_name                                    | Value |
+--------------------------------------------------+-------+
| Innodb_undo_tablespaces_total                    | 2     |
| Innodb_undo_tablespaces_implicit                 | 2     |
| Innodb_undo_tablespaces_explicit                 | 0     |
| Innodb_undo_tablespaces_active                   | 2     |
+--------------------------------------------------+-------+
```

For status variable descriptions, see Section 5.1.10, “Server Status Variables”.

15.6.3.5 Temporary Tablespaces

InnoDB uses session temporary tablespaces and a global temporary tablespace.

Session Temporary Tablespaces

Session temporary tablespaces store user-created temporary tables and internal temporary tables created by the optimizer when InnoDB is configured as the storage engine for on-disk internal temporary tables. Beginning with MySQL 8.0.16, the storage engine used for on-disk internal temporary tables is InnoDB. (Previously, the storage engine was determined by the value of `internal_tmp_disk_storage_engine`.)

Session temporary tablespaces are allocated to a session from a pool of temporary tablespaces on the first request to create an on-disk temporary table. A maximum of two tablespaces is allocated to a session, one for user-created temporary tables and the other for internal temporary tables created by the optimizer. The temporary tablespaces allocated to a session are used for all on-disk temporary tables created by the session. When a session disconnects, its temporary tablespaces are truncated and released back to the pool. A pool of 10 temporary tablespaces is created when the server is started. The size of the pool never shrinks and tablespaces are added to the pool automatically as necessary. The pool of temporary tablespaces is removed on normal shutdown or on an aborted initialization. Session temporary tablespace files are five pages in size when created and have an `.ibt` file name extension.

A range of 400 thousand space IDs is reserved for session temporary tablespaces. Because the pool of session temporary tablespaces is recreated each time the server is started, space IDs for session temporary tablespaces are not persisted when the server is shut down, and may be reused.
The `innodb_temp_tablespaces_dir` variable defines the location where session temporary tablespaces are created. The default location is the `$innodb_temp` directory in the data directory. Startup is refused if the pool of temporary tablespaces cannot be created.

```bash
$> cd BASEDIR/data/#innodb_temp
$> ls
    temp_10.ibt  temp_2.ibt  temp_4.ibt  temp_6.ibt  temp_8.ibt
    temp_1.ibt   temp_3.ibt  temp_5.ibt  temp_7.ibt  temp_9.ibt
```

In statement based replication (SBR) mode, temporary tables created on a replica reside in a single session temporary tablespace that is truncated only when the MySQL server is shut down.

The `INNODB_SESSION_TEMP_TABLESPACES` table provides metadata about session temporary tablespaces.

The Information Schema `INNODB_TEMP_TABLE_INFO` table provides metadata about user-created temporary tables that are active in an InnoDB instance.

### Global Temporary Tablespace

The global temporary tablespace (ibtmp1) stores rollback segments for changes made to user-created temporary tables.

The `innodb_temp_data_file_path` variable defines the relative path, name, size, and attributes for global temporary tablespace data files. If no value is specified for `innodb_temp_data_file_path`, the default behavior is to create a single auto-extending data file named `ibtmp1` in the `innodb_data_home_dir` directory. The initial file size is slightly larger than 12MB.

The global temporary tablespace is removed on normal shutdown or on an aborted initialization, and recreated each time the server is started. The global temporary tablespace receives a dynamically generated space ID when it is created. Startup is refused if the global temporary tablespace cannot be created. The global temporary tablespace is not removed if the server halts unexpectedly. In this case, a database administrator can remove the global temporary tablespace manually or restart the MySQL server. Restarting the MySQL server removes and recreates the global temporary tablespace automatically.

The global temporary tablespace cannot reside on a raw device.

The Information Schema `FILES` table provides metadata about the global temporary tablespace. Issue a query similar to this one to view global temporary tablespace metadata:

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.FILES WHERE TABLESPACE_NAME='innodb_temporary'
```

By default, the global temporary tablespace data file is autoextending and increases in size as necessary.

To determine if a global temporary tablespace data file is autoextending, check the `innodb_temp_data_file_path` setting:

```sql
mysql> SELECT @@innodb_temp_data_file_path;
```

To check the size of global temporary tablespace data files, examine the Information Schema `FILES` table using a query similar to this one:

```sql
mysql> SELECT FILE_NAME, TABLESPACE_NAME, ENGINE, INITIAL_SIZE, TOTAL_EXTENTS*EXTENT_SIZE
```
TotalSizeBytes shows the current size of the global temporary tablespace data file. For information about other field values, see Section 26.3.15, “The INFORMATION_SCHEMA FILES Table”.

Alternatively, check the global temporary tablespace data file size on your operating system. The global temporary tablespace data file is located in the directory defined by the `innodb_temp_data_file_path` variable.

To reclaim disk space occupied by a global temporary tablespace data file, restart the MySQL server. Restarting the server removes and recreates the global temporary tablespace data file according to the attributes defined by `innodb_temp_data_file_path`.

To limit the size of the global temporary tablespace data file, configure `innodb_temp_data_file_path` to specify a maximum file size. For example:

```
[mysqld]
innodb_temp_data_file_path=ibtmp1:12M:autoextend:max:500M
```

Configuring `innodb_temp_data_file_path` requires restarting the server.

### 15.6.3.6 Moving Tablespace Files While the Server is Offline

The `innodb_directories` variable, which defines directories to scan at startup for tablespace files, supports moving or restoring tablespace files to a new location while the server is offline. During startup, discovered tablespace files are used instead those referenced in the data dictionary, and the data dictionary is updated to reference the relocated files. If duplicate tablespace files are discovered by the scan, startup fails with an error indicating that multiple files were found for the same tablespace ID.

The directories defined by the `innodb_data_home_dir`, `innodb_undo_directory`, and `datadir` variables are automatically appended to the `innodb_directories` argument value. These directories are scanned at startup regardless of whether an `innodb_directories` setting is specified explicitly. The implicit addition of these directories permits moving system tablespace files, the data directory, or undo tablespace files without configuring the `innodb_directories` setting. However, settings must be updated when directories change. For example, after relocating the data directory, you must update the `--datadir` setting before restarting the server.

The `innodb_directories` variable can be specified in a startup command or MySQL option file. Quotes are used around the argument value because a semicolon (;) is interpreted as a special character by some command interpreters. (Unix shells treat it as a command terminator, for example.)

**Startup command:**
```
mysqld --innodb-directories="directory_path_1;directory_path_2"
```

**MySQL option file:**
```
[mysqld]
```
Tablespaces

The following procedure is applicable to moving individual file-per-table and general tablespace files, system tablespace files, undo tablespace files, or the data directory. Before moving files or directories, review the usage notes that follow.

1. Stop the server.
2. Move the tablespace files or directories to the desired location.
3. Make the new directory known to InnoDB.
   - If moving individual file-per-table or general tablespace files, add unknown directories to the innodb_directories value.
   - The directories defined by the innodb_data_home_dir, innodb_undo_directory, and datadir variables are automatically appended to the innodb_directories argument value, so you need not specify these.
   - A file-per-table tablespace file can only be moved to a directory with same name as the schema. For example, if the actor table belongs to the sakila schema, then the actor.ibd data file can only be moved to a directory named sakila.
   - General tablespace files cannot be moved to the data directory or a subdirectory of the data directory.
   - If moving system tablespace files, undo tablespaces, or the data directory, update the innodb_data_home_dir, innodb_undo_directory, and datadir settings, as necessary.
4. Restart the server.

Usage Notes

- Wildcard expressions cannot be used in the innodb_directories argument value.
- The innodb_directories scan also traverses subdirectories of specified directories. Duplicate directories and subdirectories are discarded from the list of directories to be scanned.
- innodb_directories supports moving InnoDB tablespace files. Moving files that belong to a storage engine other than InnoDB is not supported. This restriction also applies when moving the entire data directory.
- innodb_directories supports renaming of tablespace files when moving files to a scanned directory. It also supports moving tablespace files to other supported operating systems.
- When moving tablespace files to a different operating system, ensure that tablespace file names do not include prohibited characters or characters with a special meaning on the destination system.
- When moving a data directory from a Windows operating system to a Linux operating system, modify the binary log file paths in the binary log index file to use backward slashes instead of forward slashes. By default, the binary log index file has the same base name as the binary log file, with the extension '.index'. The location of the binary log index file is defined by --log-bin. The default location is the data directory.
- If moving tablespace files to a different operating system introduces cross-platform replication, it is the database administrator's responsibility to ensure proper replication of DDL statements that contain platform-specific directories. Statements that permit specifying directories include CREATE TABLE ... DATA DIRECTORY and CREATE TABLESPACE ... ADD DATAFILE.
Tablespaces

- Add the directories of file-per-table and general tablespaces created with an absolute path or in a location outside of the data directory to the `innodb_directories` setting. Otherwise, InnoDB is not able to locate the files during recovery. For related information, see Tablespace Discovery During Crash Recovery.

To view tablespace file locations, query the Information Schema `FILES` table:

```sql
mysql> SELECT TABLESPACE_NAME, FILE_NAME FROM INFORMATION_SCHEMA.FILES \G
```

### 15.6.3.7 Disabling Tablespace Path Validation

At startup, InnoDB scans directories defined by the `innodb_directories` variable for tablespace files. The paths of discovered tablespace files are validated against the paths recorded in the data dictionary. If the paths do not match, the paths in the data dictionary are updated.

The `innodb_validate_tablespace_paths` variable, introduced in MySQL 8.0.21, permits disabling tablespace path validation. This feature is intended for environments where tablespaces files are not moved. Disabling path validation improves startup time on systems with a large number of tablespace files.

If `log_error_verbosity` is set to 3, the following message is printed at startup when tablespace path validation is disabled:

```
[InnoDB] Skipping InnoDB tablespace path validation.
Manually moved tablespace files will not be detected!
```

**Warning**

Starting the server with tablespace path validation disabled after moving tablespace files can lead to undefined behavior.

### 15.6.3.8 Optimizing Tablespace Space Allocation on Linux

As of MySQL 8.0.22, you can optimize how InnoDB allocates space to file-per-table and general tablespaces on Linux. By default, when additional space is required, InnoDB allocates pages to the tablespace and physically writes NULLs to those pages. This behavior can affect performance if new pages are allocated frequently. As of MySQL 8.0.22, you can disable `innodb_extend_and_initialize` on Linux systems to avoid physically writing NULLs to newly allocated tablespace pages. When `innodb_extend_and_initialize` is disabled, space is allocated to tablespace files using `posix_fallocate()` calls, which reserve space without physically writing NULLs.

When pages are allocated using `posix_fallocate()` calls, the extension size is small by default and pages are often allocated only a few at a time, which can cause fragmentation and increase random I/O. To avoid this issue, increase the tablespace extension size when enabling `posix_fallocate()` calls. Tablespace extension size can be increased up to 4GB using the `AUTOEXTEND_SIZE` option. For more information, see Section 15.6.3.9, “Tablespace AUTOEXTEND_SIZE Configuration”.

InnoDB writes a redo log record before allocating a new tablespace page. If a page allocation operation is interrupted, the operation is replayed from the redo log record during recovery. (A page allocation operation replayed from a redo log record physically writes NULLs to the newly allocated page.) A redo log record is written before allocating a page regardless of the `innodb_extend_and_initialize` setting.

On non-Linux systems and Windows, InnoDB allocates new pages to the tablespace and physically writes NULLs to those pages, which is the default behavior. Attempting to disable `innodb_extend_and_initialize` on those systems returns the following error:

```
Changing innodb_extend_and_initialize not supported on this platform. Falling back to the default.
```
15.6.3.9 Tablespace AUTOEXTEND_SIZE Configuration

By default, when a file-per-table or general tablespace requires additional space, the tablespace is extended incrementally according to the following rules:

- If the tablespace is less than an extent in size, it is extended one page at a time.
- If the tablespace is greater than 1 extent but smaller than 32 extents in size, it is extended one extent at a time.
- If the tablespace is more than 32 extents in size, it is extended four extents at a time.

For information about extent size, see Section 15.11.2, “File Space Management”.

From MySQL 8.0.23, the amount by which a file-per-table or general tablespace is extended is configurable by specifying the `AUTOEXTEND_SIZE` option. Configuring a larger extension size can help avoid fragmentation and facilitate ingestion of large amounts of data.

To configure the extension size for a file-per-table tablespace, specify the `AUTOEXTEND_SIZE` size in a `CREATE TABLE` or `ALTER TABLE` statement:

```sql
CREATE TABLE t1 (c1 INT) AUTOEXTEND_SIZE = 4M;
ALTER TABLE t1 AUTOEXTEND_SIZE = 8M;
```

To configure the extension size for a general tablespace, specify the `AUTOEXTEND_SIZE` size in a `CREATE TABLESPACE` or `ALTER TABLESPACE` statement:

```sql
CREATE TABLESPACE ts1 AUTOEXTEND_SIZE = 4M;
ALTER TABLESPACE ts1 AUTOEXTEND_SIZE = 8M;
```

**Note**

The `AUTOEXTEND_SIZE` option can also be used when creating an undo tablespace, but the extension behavior for undo tablespaces differs. For more information, see Section 15.6.3.4, “Undo Tablespaces”.

The `AUTOEXTEND_SIZE` setting must be a multiple of 4M. Specifying an `AUTOEXTEND_SIZE` setting that is not a multiple of 4M returns an error.

The `AUTOEXTEND_SIZE` default setting is 0, which causes the tablespace to be extended according to the default behavior described above.

The maximum `AUTOEXTEND_SIZE` setting is 64M in MySQL 8.0.23. From MySQL 8.0.24, the maximum setting is 4GB.

The minimum `AUTOEXTEND_SIZE` setting depends on the InnoDB page size, as shown in the following table:

<table>
<thead>
<tr>
<th>InnoDB Page Size</th>
<th>Minimum AUTOEXTEND_SIZE</th>
</tr>
</thead>
<tbody>
<tr>
<td>4K</td>
<td>4M</td>
</tr>
<tr>
<td>8K</td>
<td>4M</td>
</tr>
<tr>
<td>16K</td>
<td>4M</td>
</tr>
<tr>
<td>32K</td>
<td>8M</td>
</tr>
<tr>
<td>64K</td>
<td>16M</td>
</tr>
</tbody>
</table>
The default InnoDB page size is 16K (16384 bytes). To determine the InnoDB page size for your MySQL instance, query the `innodb_page_size` setting:

```
mysql> SELECT @@GLOBAL.innodb_page_size;
+---------------------------+
<table>
<thead>
<tr>
<th>@@GLOBAL.innodb_page_size</th>
</tr>
</thead>
<tbody>
<tr>
<td>16384</td>
</tr>
</tbody>
</table>
+---------------------------+
```

When the `AUTOEXTEND_SIZE` setting for a tablespace is altered, the first extension that occurs afterward increases the tablespace size to a multiple of the `AUTOEXTEND_SIZE` setting. Subsequent extensions are of the configured size.

When a file-per-table or general tablespace is created with a non-zero `AUTOEXTEND_SIZE` setting, the tablespace is initialized at the specified `AUTOEXTEND_SIZE` size.

ALTER TABLESPACE cannot be used to configure the `AUTOEXTEND_SIZE` of a file-per-table tablespace. ALTER TABLE must be used.

For tables created in file-per-table tablespaces, SHOW CREATE TABLE shows the `AUTOEXTEND_SIZE` option only when it is configured to a non-zero value.

To determine the `AUTOEXTEND_SIZE` for any InnoDB tablespace, query the Information Schema `INNODB_TABLESPACES` table. For example:

```
mysql> SELECT NAME, AUTOEXTEND_SIZE FROM INFORMATION_SCHEMA.INNODB_TABLESPACES
WHERE NAME LIKE 'test/t1';
+---------+-----------------+
| NAME    | AUTOEXTEND_SIZE |
+---------+-----------------+
| test/t1 |         4194304 |
+---------+-----------------+
```

```
mysql> SELECT NAME, AUTOEXTEND_SIZE FROM INFORMATION_SCHEMA.INNODB_TABLESPACES
WHERE NAME LIKE 'ts1';
+------+-----------------+
| NAME | AUTOEXTEND_SIZE |
+------+-----------------+
| ts1  |         4194304 |
+------+-----------------+
```

Note
---
An `AUTOEXTEND_SIZE` of 0, which is the default setting, means that the tablespace is extended according to the default tablespace extension behavior described above.

### 15.6.4 Doublewrite Buffer

The doublewrite buffer is a storage area where InnoDB writes pages flushed from the buffer pool before writing the pages to their proper positions in the InnoDB data files. If there is an operating system, storage subsystem, or unexpected mysqld process exit in the middle of a page write, InnoDB can find a good copy of the page from the doublewrite buffer during crash recovery.

Although data is written twice, the doublewrite buffer does not require twice as much I/O overhead or twice as many I/O operations. Data is written to the doublewrite buffer in a large sequential chunk, with a single fsync() call to the operating system (except in the case that `innodb_flush_method` is set to O_DIRECT_NO_FSYNC).
Doublewrite Buffer

Prior to MySQL 8.0.20, the doublewrite buffer storage area is located in the InnoDB system tablespace. As of MySQL 8.0.20, the doublewrite buffer storage area is located in doublewrite files.

The following variables are provided for doublewrite buffer configuration:

- **innodb_doublewrite**

  The `innodb_doublewrite` variable controls whether the doublewrite buffer is enabled. It is enabled by default in most cases. To disable the doublewrite buffer, set `innodb_doublewrite` to OFF. Consider disabling the doublewrite buffer if you are more concerned with performance than data integrity, as may be the case when performing benchmarks, for example.

  From MySQL 8.0.30, `innodb_doublewrite` supports DETECT_AND_RECOVER and DETECT_ONLY settings.

  The DETECT_AND_RECOVER setting is the same as the ON setting. With this setting, the doublewrite buffer is fully enabled, with database page content written to the doublewrite buffer where it is accessed during recovery to fix incomplete page writes.

  With the DETECT_ONLY setting, only metadata is written to the doublewrite buffer. Database page content is not written to the doublewrite buffer, and recovery does not use the doublewrite buffer to fix incomplete page writes. This lightweight setting is intended for detecting incomplete page writes only.

  MySQL 8.0.30 onwards supports dynamic changes to the `innodb_doublewrite` setting that enables the doublewrite buffer, between ON, DETECT_AND_RECOVER, and DETECT_ONLY. MySQL does not support dynamic changes between a setting that enables the doublewrite buffer and OFF or vice versa.

  If the doublewrite buffer is located on a Fusion-io device that supports atomic writes, the doublewrite buffer is automatically disabled and data file writes are performed using Fusion-io atomic writes instead. However, be aware that the `innodb_doublewrite` setting is global. When the doublewrite buffer is disabled, it is disabled for all data files including those that do not reside on Fusion-io hardware. This feature is only supported on Fusion-io hardware and is only enabled for Fusion-io NVMFS on Linux. To take full advantage of this feature, an `innodb_flush_method` setting of O_DIRECT is recommended.

- **innodb_doublewrite_dir**

  The `innodb_doublewrite_dir` variable (introduced in MySQL 8.0.20) defines the directory where InnoDB creates doublewrite files. If no directory is specified, doublewrite files are created in the `innodb_data_home_dir` directory, which defaults to the data directory if unspecified.

  A hash symbol '#' is automatically prefixed to the specified directory name to avoid conflicts with schema names. However, if a '.', '#'. or '/' prefix is specified explicitly in the directory name, the hash symbol '#' is not prefixed to the directory name.

  Ideally, the doublewrite directory should be placed on the fastest storage media available.

- **innodb_doublewrite_files**

  The `innodb_doublewrite_files` variable defines the number of doublewrite files. By default, two doublewrite files are created for each buffer pool instance: A flush list doublewrite file and an LRU list doublewrite file.

  The flush list doublewrite file is for pages flushed from the buffer pool flush list. The default size of a flush list doublewrite file is the InnoDB page size * doublewrite page bytes.

  The LRU list doublewrite file is for pages flushed from the buffer pool LRU list. It also contains slots for single page flushes. The default size of an LRU list doublewrite file is the InnoDB page size *
Redo Log

(doublewrite pages + (512 / the number of buffer pool instances)) where 512 is the total number of slots reserved for single page flushes.

At a minimum, there are two doublewrite files. The maximum number of doublewrite files is two times the number of buffer pool instances. (The number of buffer pool instances is controlled by the `innodb_buffer_pool_instances` variable.)

Doublewrite file names have the following format: `#ib_page_size_file_number.dblwr` (or `.bdblwr` with the `DETECT_ONLY` setting). For example, the following doublewrite files are created for a MySQL instance with an InnoDB pages size of 16KB and a single buffer pool:

```plaintext
#ib_16384_0.dblwr
#ib_16384_1.dblwr
```

The `innodb_doublewrite_files` variable is intended for advanced performance tuning. The default setting should be suitable for most users.

- `innodb_doublewrite_pages`

  The `innodb_doublewrite_pages` variable (introduced in MySQL 8.0.20) controls the maximum number of doublewrite pages per thread. If no value is specified, `innodb_doublewrite_pages` is set to the `innodb_write_io_threads` value. This variable is intended for advanced performance tuning. The default value should be suitable for most users.

- `innodb_doublewrite_batch_size`

  The `innodb_doublewrite_batch_size` variable (introduced in MySQL 8.0.20) controls the number of doublewrite pages to write in a batch. This variable is intended for advanced performance tuning. The default value should be suitable for most users.

As of MySQL 8.0.23, InnoDB automatically encrypts doublewrite file pages that belong to encrypted tablespaces (see Section 15.13, “InnoDB Data-at-Rest Encryption”). Likewise, doublewrite file pages belonging to page-compressed tablespaces are compressed. As a result, doublewrite files can contain different page types including unencrypted and uncompressed pages, encrypted pages, compressed pages, and pages that are both encrypted and compressed.

15.6.5 Redo Log

The redo log is a disk-based data structure used during crash recovery to correct data written by incomplete transactions. During normal operations, the redo log encodes requests to change table data that result from SQL statements or low-level API calls. Modifications that did not finish updating data files before an unexpected shutdown are replayed automatically during initialization and before connections are accepted. For information about the role of the redo log in crash recovery, see Section 15.18.2, “InnoDB Recovery”.

The redo log is physically represented on disk by redo log files. Data that is written to redo log files is encoded in terms of records affected, and this data is collectively referred to as redo. The passage of data through redo log files is represented by an ever-increasing LSN value. Redo log data is appended as data modifications occur, and the oldest data is truncated as the checkpoint progresses.

Information and procedures related to redo logs are described under the following topics in the section:

- Configuring Redo Log Capacity (MySQL 8.0.30 or Higher)
- Configuring Redo Log Capacity (Before MySQL 8.0.30)
- Automatic Redo Log Capacity Configuration
Redo Log

- Redo Log Archiving
- Disabling Redo Logging
- Related Topics

Configuring Redo Log Capacity (MySQL 8.0.30 or Higher)

From MySQL 8.0.30, the `innodb_redo_log_capacity` system variable controls the amount of disk space occupied by redo log files. You can set this variable in an option file at startup or at runtime using a `SET GLOBAL` statement; for example, the following statement sets the redo log capacity to 8GB:

```
SET GLOBAL innodb_redo_log_capacity = 8589934592;
```

When set at runtime, the configuration change occurs immediately but it may take some time for the new limit to be fully implemented. If the redo log files occupy less space than the specified value, dirty pages are flushed from the buffer pool to tablespace data files less aggressively, eventually increasing the disk space occupied by the redo log files. If the redo log files occupy more space than the specified value, dirty pages are flushed more aggressively, eventually decreasing the disk space occupied by redo log files.

The `innodb_redo_log_capacity` variable supersedes the `innodb_log_files_in_group` and `innodb_log_file_size` variables, which are deprecated. When the `innodb_redo_log_capacity` setting is defined, the `innodb_log_files_in_group` and `innodb_log_file_size` settings are ignored; otherwise, these settings are used to compute the `innodb_redo_log_capacity` setting (`innodb_log_files_in_group * innodb_log_file_size = innodb_redo_log_capacity`). If none of those variables are set, redo log capacity is set to the `innodb_redo_log_capacity` default value, which is 104857600 bytes (100MB). The maximum redo log capacity is 128GB.

Redo log files reside in the `#innodb_redo` directory in the data directory unless a different directory was specified by the `innodb_log_group_home_dir` variable. If `innodb_log_group_home_dir` was defined, the redo log files reside in the `#innodb_redo` directory in that directory. There are two types of redo log files, ordinary and spare. Ordinary redo log files are those being used. Spare redo log files are those waiting to be used. InnoDB tries to maintain 32 redo log files in total, with each file equal in size to `1/32 * innodb_redo_log_capacity`; however, file sizes may differ for a time after modifying the `innodb_redo_log_capacity` setting.

Redo log files use an `#ib_redoN` naming convention, where `N` is the redo log file number. Spare redo log files are denoted by a `_tmp` suffix. The following example shows the redo log files in an `#innodb_redo` directory, where there are 21 active redo log files and 11 spare redo log files, numbered sequentially.

```
"#ib_redo582" "#ib_redo590" "#ib_redo598" "#ib_redo606_tmp"
"#ib_redo583" "#ib_redo591" "#ib_redo599" "#ib_redo607_tmp"
"#ib_redo584" "#ib_redo592" "#ib_redo600" "#ib_redo608_tmp"
"#ib_redo585" "#ib_redo593" "#ib_redo601" "#ib_redo609_tmp"
"#ib_redo586" "#ib_redo594" "#ib_redo602" "#ib_redo610_tmp"
"#ib_redo587" "#ib_redo595" "#ib_redo603_tmp" "#ib_redo611_tmp"
"#ib_redo588" "#ib_redo596" "#ib_redo604_tmp" "#ib_redo612_tmp"
"#ib_redo589" "#ib_redo597" "#ib_redo605_tmp" "#ib_redo613_tmp"
```

Each ordinary redo log file is associated with a particular range of LSN values; for example, the following query shows the `START_LSN` and `END_LSN` values for the active redo log files listed in the previous example:

```
mysql> SELECT FILE_NAME, START_LSN, END_LSN FROM performance_schema.innodb_redo_log_files;
+----------------------------+--------------+--------------+
| FILE_NAME                  | START_LSN    | END_LSN      |
|----------------------------+--------------+--------------|
| ./#innodb_redo/#ib_redo582 | 117654982144 | 117658256896 |
| ./#innodb_redo/#ib_redo583 | 117658256896 | 117661531648 |
| ./#innodb_redo/#ib_redo584 | 117661531648 | 117664806400 |
```
When doing a checkpoint, InnoDB stores the checkpoint LSN in the header of the file which contains this LSN. During recovery, all redo log files are checked and recovery starts at the latest checkpoint LSN.

Several status variables are provided for monitoring the redo log and redo log capacity resize operations; for example, you can query `Innodb_redo_log_resize_status` to view the status of a resize operation:

```
mysql> SHOW STATUS LIKE 'Innodb_redo_log_resize_status';
+-------------------------------+-------+
| Variable_name                 | Value |
+-------------------------------+-------+
| Innodb_redo_log_resize_status | OK    |
+-------------------------------+-------+
```

The `Innodb_redo_log_capacity_resized` status variable shows the current redo log capacity limit:

```
mysql> SHOW STATUS LIKE 'Innodb_redo_log_capacity_resized';
+--------------------------+-----------+
| Variable_name            | Value     |
+--------------------------+-----------+
| Innodb_redo_log_capacity_resized | 104857600 |
+--------------------------+-----------+
```

Other applicable status variables include:

- `Innodb_redo_log_checkpoint_lsn`
- `Innodb_redo_log_current_lsn`
- `Innodb_redo_log_flushed_to_disk_lsn`
- `Innodb_redo_log_logical_size`
- `Innodb_redo_log_physical_size`
- `Innodb_redo_log_read_only`
- `Innodb_redo_log_uuid`

Refer to the status variable descriptions for more information.

You can view information about active redo log files by querying the `innodb_redo_log_files` Performance Schema table. The following query retrieves data from all of the table's columns:

```
SELECT FILE_ID, START_LSN, END_LSN, SIZE_IN_BYTES, IS_FULL, CONSUMER_LEVEL
```

Configuring Redo Log Capacity (Before MySQL 8.0.30)

Prior to MySQL 8.0.30, InnoDB creates two redo log files in the data directory by default, named `ib_logfile0` and `ib_logfile1`, and writes to these files in a circular fashion.

Modifying redo log capacity requires changing the number or the size of redo log files, or both.

1. Stop the MySQL server and make sure that it shuts down without errors.
2. Edit `my.cnf` to change the redo log file configuration. To change the redo log file size, configure `innodb_log_file_size`. To increase the number of redo log files, configure `innodb_log_files_in_group`.
3. Start the MySQL server again.

If InnoDB detects that the `innodb_log_file_size` differs from the redo log file size, it writes a log checkpoint, closes and removes the old log files, creates new log files at the requested size, and opens the new log files.

Automatic Redo Log Capacity Configuration

When `innodb_dedicated_server` is enabled, InnoDB automatically configures certain InnoDB parameters, including redo log capacity. Automated configuration is intended for MySQL instances that reside on a server dedicated to MySQL, where the MySQL server can use all available system resources. For more information, see Section 15.8.12, “Enabling Automatic Configuration for a Dedicated MySQL Server”.

Redo Log Archiving

Backup utilities that copy redo log records may sometimes fail to keep pace with redo log generation while a backup operation is in progress, resulting in lost redo log records due to those records being overwritten. This issue most often occurs when there is significant MySQL server activity during the backup operation, and the redo log file storage media operates at a faster speed than the backup storage media. The redo log archiving feature, introduced in MySQL 8.0.17, addresses this issue by sequentially writing redo log records to an archive file in addition to the redo log files. Backup utilities can copy redo log records from the archive file as necessary, thereby avoiding the potential loss of data.

If redo log archiving is configured on the server, MySQL Enterprise Backup, available with the MySQL Enterprise Edition, uses the redo log archiving feature when backing up a MySQL server.

Enabling redo log archiving on the server requires setting a value for the `innodb_redo_log_archive_dirs` system variable. The value is specified as a semicolon-separated list of labeled redo log archive directories. The `label:directory` pair is separated by a colon (:). For example:

```sql
mysql> SET GLOBAL innodb_redo_log_archive_dirs='label1:directory_path1[;label2:directory_path2;...];'
```

The `label` is an arbitrary identifier for the archive directory. It can be any string of characters, with the exception of colons (:), which are not permitted. An empty label is also permitted, but the colon (:) is still required in this case. A `directory_path` must be specified. The directory selected for the redo log archive file must exist when redo log archiving is activated, or an error is returned. The path can contain colons (':'), but semicolons (;) are not permitted.

The `innodb_redo_log_archive_dirs` variable must be configured before redo log archiving can be activated. The default value is `NULL`, which does not permit activating redo log archiving.
Redo Log

Notes

The archive directories that you specify must satisfy the following requirements. (The requirements are enforced when redo log archiving is activated.):

- Directories must exist. Directories are not created by the redo log archive process. Otherwise, the following error is returned:

  ERROR 3844 (HY000): Redo log archive directory 'directory_path1' does not exist or is not a directory

- Directories must not be world-accessible. This is to prevent the redo log data from being exposed to unauthorized users on the system. Otherwise, the following error is returned:

  ERROR 3846 (HY000): Redo log archive directory 'directory_path1' is accessible to all OS users

- Directories cannot be those defined by `datadir`, `innodb_data_home_dir`, `innodb_directories`, `innodb_log_group_home_dir`, `innodb_temp_tablespaces_dir`, `innodb_tmpdir`, `innodb_undo_directory`, or `secure_file_priv`, nor can they be parent directories or subdirectories of those directories. Otherwise, an error similar to the following is returned:

  ERROR 3845 (HY000): Redo log archive directory 'directory_path1' is in, under, or over server directory 'datadir' - '/path/to/data_directory'

When a backup utility that supports redo log archiving initiates a backup, the backup utility activates redo log archiving by invoking the `innodb_redo_log_archive_start()` function.

If you are not using a backup utility that supports redo log archiving, redo log archiving can also be activated manually, as shown:

```sql
mysql> SELECT innodb_redo_log_archive_start('label', 'subdir');
+------------------------------------------+
| innodb_redo_log_archive_start('label') |
| 0                                       |
+------------------------------------------+

Or:

```sql
mysql> DO innodb_redo_log_archive_start('label', 'subdir');
Query OK, 0 rows affected (0.09 sec)
```

Note

The MySQL session that activates redo log archiving (using `innodb_redo_logArchiveStart()`) must remain open for the duration of the archiving. The same session must deactivate redo log archiving (using `innodb_redo_logArchiveStop()`). If the session is terminated before the redo log archiving is explicitly deactivated, the server deactivates redo log archiving implicitly and removes the redo log archive file.

where `label` is a label defined by `innodb_redo_log_archive_dirs`; `subdir` is an optional argument for specifying a subdirectory of the directory identified by `label` for saving the archive file; it must be a
simple directory name (no slash (/), backslash (\), or colon (:) is permitted). `subdir` can be empty, null, or it can be left out.

Only users with the INNODB_REDO_LOG_ARCHIVE privilege can activate redo log archiving by invoking `innodb_redo_log_archive_start()`, or deactivate it using `innodb_redo_log_archive_stop()`. The MySQL user running the backup utility or the MySQL user activating and deactivating redo log archiving manually must have this privilege.

The redo log archive file path is `directory_identified_by_label/ [subdir/]archive. serverUUID.000001.log`, where `directory_identified_by_label` is the archive directory identified by the `label` argument for `innodb_redo_log_archive_start()`. `subdir` is the optional argument used for `innodb_redo_log_archive_start()`.

For example, the full path and name for a redo log archive file appears similar to the following:

```
/directory_path/subdirectory/archive.e71a47dc-61f8-11e9-a3cb-080027154b4d.000001.log
```

After the backup utility finishes copying InnoDB data files, it deactivates redo log archiving by calling the `innodb_redo_log_archive_stop()` function.

If you are not using a backup utility that supports redo log archiving, redo log archiving can also be deactivated manually, as shown:

```
mysql> SELECT innodb_redo_log_archive_stop();
+--------------------------------+
| innodb_redo_log_archive_stop() |
| 0                              |
+--------------------------------+
```

Or:

```
mysql> DO innodb_redo_log_archive_stop();
Query OK, 0 rows affected (0.01 sec)
```

After the stop function completes successfully, the backup utility looks for the relevant section of redo log data from the archive file and copies it into the backup.

After the backup utility finishes copying the redo log data and no longer needs the redo log archive file, it deletes the archive file.

Removal of the archive file is the responsibility of the backup utility in normal situations. However, if the redo log archiving operation quits unexpectedly before `innodb_redo_log_archive_stop()` is called, the MySQL server removes the file.

**Performance Considerations**

Activating redo log archiving typically has a minor performance cost due to the additional write activity.

On Unix and Unix-like operating systems, the performance impact is typically minor, assuming there is not a sustained high rate of updates. On Windows, the performance impact is typically a bit higher, assuming the same.

If there is a sustained high rate of updates and the redo log archive file is on the same storage media as the redo log files, the performance impact may be more significant due to compounded write activity.

If there is a sustained high rate of updates and the redo log archive file is on slower storage media than the redo log files, performance is impacted arbitrarily.

Writing to the redo log archive file does not impede normal transactional logging except in the case that the redo log archive file storage media operates at a much slower rate than the redo log file storage media,
and there is a large backlog of persisted redo log blocks waiting to be written to the redo log archive file. In this case, the transactional logging rate is reduced to a level that can be managed by the slower storage media where the redo log archive file resides.

Disabling Redo Logging

As of MySQL 8.0.21, you can disable redo logging using the `ALTER INSTANCE DISABLE INNODB REDO_LOG` statement. This functionality is intended for loading data into a new MySQL instance. Disabling redo logging speeds up data loading by avoiding redo log writes and doublewrite buffering.

Warning

This feature is intended only for loading data into a new MySQL instance. Do not disable redo logging on a production system. It is permitted to shutdown and restart the server while redo logging is disabled, but an unexpected server stoppage while redo logging is disabled can cause data loss and instance corruption.

Attempting to restart the server after an unexpected server stoppage while redo logging is disabled is refused with the following error:

```
[ERROR] [MY-013598] [InnoDB] Server was killed when Innodb Redo logging was disabled. Data files could be corrupt. You can try to restart the database with innodb_force_recovery=6
```

In this case, initialize a new MySQL instance and start the data loading procedure again.

The `INNODB_REDO_LOG_ENABLE` privilege is required to enable and disable redo logging.

The `Innodb_redo_log_enabled` status variable permits monitoring redo logging status.

Cloning operations and redo log archiving are not permitted while redo logging is disabled and vice versa.

An `ALTER INSTANCE [ENABLE|DISABLE] INNODB REDO_LOG` operation requires an exclusive backup metadata lock, which prevents other `ALTER INSTANCE` operations from executing concurrently. Other `ALTER INSTANCE` operations must wait for the lock to be released before executing.

The following procedure demonstrates how to disable redo logging when loading data into a new MySQL instance.

1. On the new MySQL instance, grant the `INNODB_REDO_LOG_ENABLE` privilege to the user account responsible for disabling redo logging.

   ```sql
   mysql> GRANT INNODB_REDO_LOG_ENABLE ON *.* to 'data_load_admin';
   ```

2. As the `data_load_admin` user, disable redo logging:

   ```sql
   mysql> ALTER INSTANCE DISABLE INNODB REDO_LOG;
   ```

3. Check the `Innodb_redo_log_enabled` status variable to ensure that redo logging is disabled.

   ```sql
   mysql> SHOW GLOBAL STATUS LIKE 'Innodb_redo_log_enabled';
   +-------------------------+-------+
   | Variable_name           | Value |
   +-------------------------+-------+
   | Innodb_redo_log_enabled | OFF   |
   +-------------------------+-------+
   ```

4. Run the data load operation.

5. As the `data_load_admin` user, enable redo logging after the data load operation finishes:
Undo Logs

mysql> ALTER INSTANCE ENABLE INNODB REDO_LOG;

6. Check the **Innodb_redo_log_enabled** status variable to ensure that redo logging is enabled.

mysql> SHOW GLOBAL STATUS LIKE 'Innodb_redo_log_enabled';

<table>
<thead>
<tr>
<th>Variable_name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Innodb_redo_log_enabled</td>
<td>ON</td>
</tr>
</tbody>
</table>

### 15.6.6 Undo Logs

An undo log is a collection of undo log records associated with a single read-write transaction. An undo log record contains information about how to undo the latest change by a transaction to a clustered index record. If another transaction needs to see the original data as part of a consistent read operation, the unmodified data is retrieved from undo log records. Undo logs exist within **undo log segments**, which are contained within **rollback segments**. Rollback segments reside in **undo tablespaces** and in the **global temporary tablespace**.

Undo logs that reside in the global temporary tablespace are used for transactions that modify data in user-defined temporary tables. These undo logs are not redo-logged, as they are not required for crash recovery. They are used only for rollback while the server is running. This type of undo log benefits performance by avoiding redo logging I/O.

For information about data-at-rest encryption for undo logs, see **Undo Log Encryption**.

Each undo tablespace and the global temporary tablespace individually support a maximum of 128 rollback segments. The **innodb_rollback_segments** variable defines the number of rollback segments.

The number of transactions that a rollback segment supports depends on the number of undo slots in the rollback segment and the number of undo logs required by each transaction. The number of undo slots in a rollback segment differs according to **InnoDB page size**.

<table>
<thead>
<tr>
<th>InnoDB Page Size</th>
<th>Number of Undo Slots in a Rollback Segment (InnoDB Page Size / 16)</th>
</tr>
</thead>
<tbody>
<tr>
<td>4096 (4KB)</td>
<td>256</td>
</tr>
<tr>
<td>8192 (8KB)</td>
<td>512</td>
</tr>
<tr>
<td>16384 (16KB)</td>
<td>1024</td>
</tr>
<tr>
<td>32768 (32KB)</td>
<td>2048</td>
</tr>
<tr>
<td>65536 (64KB)</td>
<td>4096</td>
</tr>
</tbody>
</table>

A transaction is assigned up to four undo logs, one for each of the following operation types:

1. **INSERT** operations on user-defined tables
2. **UPDATE** and **DELETE** operations on user-defined tables
3. **INSERT** operations on user-defined temporary tables
4. **UPDATE** and **DELETE** operations on user-defined temporary tables

Undo logs are assigned as needed. For example, a transaction that performs **INSERT**, **UPDATE**, and **DELETE** operations on regular and temporary tables requires a full assignment of four undo logs. A transaction that performs only **INSERT** operations on regular tables requires a single undo log.

A transaction that performs operations on regular tables is assigned undo logs from an assigned undo tablespace rollback segment. A transaction that performs operations on temporary tables is assigned undo logs from an assigned global temporary tablespace rollback segment.

An undo log assigned to a transaction remains attached to the transaction for its duration. For example, an undo log assigned to a transaction for an **INSERT** operation on a regular table is used for all **INSERT** operations on regular tables performed by that transaction.

Given the factors described above, the following formulas can be used to estimate the number of concurrent read-write transactions that InnoDB is capable of supporting.

**Note**

It is possible to encounter a concurrent transaction limit error before reaching the number of concurrent read-write transactions that InnoDB is capable of supporting. This occurs when a rollback segment assigned to a transaction runs out of undo slots. In such cases, try rerunning the transaction.

When transactions perform operations on temporary tables, the number of concurrent read-write transactions that InnoDB is capable of supporting is constrained by the number of rollback segments allocated to the global temporary tablespace, which is 128 by default.

- If each transaction performs either an **INSERT** or an **UPDATE** or **DELETE** operation, the number of concurrent read-write transactions that InnoDB is capable of supporting is:

  \[
  \text{number of concurrent read-write transactions} = \frac{\text{innodb_page_size}}{16} \times \text{innodb_rollback_segments} \times \text{number of undo tablespaces}
  \]

- If each transaction performs an **INSERT** and an **UPDATE** or **DELETE** operation, the number of concurrent read-write transactions that InnoDB is capable of supporting is:

  \[
  \text{number of concurrent read-write transactions} = \frac{\text{innodb_page_size}}{16 \times 2} \times \text{innodb_rollback_segments} \times \text{number of undo tablespaces}
  \]

- If each transaction performs an **INSERT** operation on a temporary table, the number of concurrent read-write transactions that InnoDB is capable of supporting is:

  \[
  \text{number of concurrent read-write transactions} = \frac{\text{innodb_page_size}}{16} \times \text{innodb_rollback_segments}
  \]

- If each transaction performs an **INSERT** and an **UPDATE** or **DELETE** operation on a temporary table, the number of concurrent read-write transactions that InnoDB is capable of supporting is:

  \[
  \text{number of concurrent read-write transactions} = \frac{\text{innodb_page_size}}{16 \times 2} \times \text{innodb_rollback_segments}
  \]

### 15.7 InnoDB Locking and Transaction Model

To implement a large-scale, busy, or highly reliable database application, to port substantial code from a different database system, or to tune MySQL performance, it is important to understand InnoDB locking and the InnoDB transaction model.

This section discusses several topics related to InnoDB locking and the InnoDB transaction model with which you should be familiar.

- **Section 15.7.1, “InnoDB Locking”** describes lock types used by InnoDB.
• Section 15.7.2, “InnoDB Transaction Model” describes transaction isolation levels and the locking strategies used by each. It also discusses the use of autocommit, consistent non-locking reads, and locking reads.

• Section 15.7.3, “Locks Set by Different SQL Statements in InnoDB” discusses specific types of locks set in InnoDB for various statements.

• Section 15.7.4, “Phantom Rows” describes how InnoDB uses next-key locking to avoid phantom rows.

• Section 15.7.5, “Deadlocks in InnoDB” provides a deadlock example, discusses deadlock detection, and provides tips for minimizing and handling deadlocks in InnoDB.

15.7.1 InnoDB Locking

This section describes lock types used by InnoDB.

• Shared and Exclusive Locks

• Intention Locks

• Record Locks

• Gap Locks

• Next-Key Locks

• Insert Intention Locks

• AUTO-INC Locks

• Predicate Locks for Spatial Indexes

Shared and Exclusive Locks

InnoDB implements standard row-level locking where there are two types of locks, shared (s) locks and exclusive (x) locks.

• A shared (s) lock permits the transaction that holds the lock to read a row.

• An exclusive (x) lock permits the transaction that holds the lock to update or delete a row.

If transaction T1 holds a shared (s) lock on row r, then requests from some distinct transaction T2 for a lock on row r are handled as follows:

• A request by T2 for an s lock can be granted immediately. As a result, both T1 and T2 hold an s lock on r.

• A request by T2 for an x lock cannot be granted immediately.

If a transaction T1 holds an exclusive (x) lock on row r, a request from some distinct transaction T2 for a lock of either type on r cannot be granted immediately. Instead, transaction T2 has to wait for transaction T1 to release its lock on row r.

Intention Locks

InnoDB supports multiple granularity locking which permits coexistence of row locks and table locks. For example, a statement such as LOCK TABLES ... WRITE takes an exclusive lock (an x lock) on the specified table. To make locking at multiple granularity levels practical, InnoDB uses intention locks. Intention locks are table-level locks that indicate which type of lock (shared or exclusive) a transaction requires later for a row in a table. There are two types of intention locks:
InnoDB Locking

- An intention shared lock (IS) indicates that a transaction intends to set a shared lock on individual rows in a table.

- An intention exclusive lock (IX) indicates that a transaction intends to set an exclusive lock on individual rows in a table.

For example, `SELECT ... FOR SHARE` sets an IS lock, and `SELECT ... FOR UPDATE` sets an IX lock.

The intention locking protocol is as follows:

- Before a transaction can acquire a shared lock on a row in a table, it must first acquire an IS lock or stronger on the table.

- Before a transaction can acquire an exclusive lock on a row in a table, it must first acquire an IX lock on the table.

Table-level lock type compatibility is summarized in the following matrix.

<table>
<thead>
<tr>
<th></th>
<th>X</th>
<th>IX</th>
<th>S</th>
<th>IS</th>
</tr>
</thead>
<tbody>
<tr>
<td>X</td>
<td>Conflict</td>
<td>Conflict</td>
<td>Conflict</td>
<td>Conflict</td>
</tr>
<tr>
<td>IX</td>
<td>Conflict</td>
<td>Compatible</td>
<td>Conflict</td>
<td>Compatible</td>
</tr>
<tr>
<td>S</td>
<td>Conflict</td>
<td>Compatible</td>
<td>Compatible</td>
<td>Compatible</td>
</tr>
<tr>
<td>IS</td>
<td>Conflict</td>
<td>Compatible</td>
<td>Compatible</td>
<td>Compatible</td>
</tr>
</tbody>
</table>

A lock is granted to a requesting transaction if it is compatible with existing locks, but not if it conflicts with existing locks. A transaction waits until the conflicting existing lock is released. If a lock request conflicts with an existing lock and cannot be granted because it would cause deadlock, an error occurs.

Intention locks do not block anything except full table requests (for example, `LOCK TABLES ... WRITE`). The main purpose of intention locks is to show that someone is locking a row, or going to lock a row in the table.

Transaction data for an intention lock appears similar to the following in `SHOW ENGINE INNODB STATUS` and InnoDB monitor output:

<table>
<thead>
<tr>
<th>TABLE LOCK</th>
<th>table <code>test</code>.<code>t</code></th>
<th>trx id 10080</th>
<th>lock mode</th>
<th>IX</th>
</tr>
</thead>
</table>

Record Locks

A record lock is a lock on an index record. For example, `SELECT c1 FROM t WHERE c1 = 10 FOR UPDATE;` prevents any other transaction from inserting, updating, or deleting rows where the value of `t.c1` is 10.

Record locks always lock index records, even if a table is defined with no indexes. For such cases, InnoDB creates a hidden clustered index and uses this index for record locking. See Section 15.6.2.1, “Clustered and Secondary Indexes”.

Transaction data for a record lock appears similar to the following in `SHOW ENGINE INNODB STATUS` and InnoDB monitor output:

```sql
RECORD LOCKS space id 58 page no 3 n bits 72 index `PRIMARY` of table `test`.`t`
trx id 10078 lock_mode X locks rec but not gap
Record lock, heap no 2 PHYSICAL RECORD: n_fields 3; compact format; info bits 0
  0: len 4; hex 8000000a; asc 'O';
  1: len 6; hex 000000274f; asc 'O';
  2: len 7; hex b60000019d0110; asc 'O';
```
InnoDB Locking

**Gap Locks**

A gap lock is a lock on a gap between index records, or a lock on the gap before the first or after the last index record. For example, `SELECT c1 FROM t WHERE c1 BETWEEN 10 and 20 FOR UPDATE;` prevents other transactions from inserting a value of 15 into column `t.c1`, whether or not there was already any such value in the column, because the gaps between all existing values in the range are locked.

A gap might span a single index value, multiple index values, or even be empty.

Gap locks are part of the tradeoff between performance and concurrency, and are used in some transaction isolation levels and not others.

Gap locking is not needed for statements that lock rows using a unique index to search for a unique row. (This does not include the case that the search condition includes only some columns of a multiple-column unique index; in that case, gap locking does occur.) For example, if the `id` column has a unique index, the following statement uses only an index-record lock for the row having `id` value 100 and it does not matter whether other sessions insert rows in the preceding gap:

```
SELECT * FROM child WHERE id = 100;
```

If `id` is not indexed or has a nonunique index, the statement does lock the preceding gap.

It is also worth noting here that conflicting locks can be held on a gap by different transactions. For example, transaction A can hold a shared gap lock (gap S-lock) on a gap while transaction B holds an exclusive gap lock (gap X-lock) on the same gap. The reason conflicting gap locks are allowed is that if a record is purged from an index, the gap locks held on the record by different transactions must be merged.

Gap locks in InnoDB are “purely inhibitive”, which means that their only purpose is to prevent other transactions from inserting to the gap. Gap locks can co-exist. A gap lock taken by one transaction does not prevent another transaction from taking a gap lock on the same gap. There is no difference between shared and exclusive gap locks. They do not conflict with each other, and they perform the same function.

Gap locking can be disabled explicitly. This occurs if you change the transaction isolation level to `READ COMMITTED`. In this case, gap locking is disabled for searches and index scans and is used only for foreign-key constraint checking and duplicate-key checking.

There are also other effects of using the `READ COMMITTED` isolation level. Record locks for nonmatching rows are released after MySQL has evaluated the `WHERE` condition. For `UPDATE` statements, InnoDB does a “semi-consistent” read, such that it returns the latest committed version to MySQL so that MySQL can determine whether the row matches the `WHERE` condition of the `UPDATE`.

**Next-Key Locks**

A next-key lock is a combination of a record lock on the index record and a gap lock on the gap before the index record.

InnoDB performs row-level locking in such a way that when it searches or scans a table index, it sets shared or exclusive locks on the index records it encounters. Thus, the row-level locks are actually index-record locks. A next-key lock on an index record also affects the “gap” before that index record. That is, a next-key lock is an index-record lock plus a gap lock on the gap preceding the index record. If one session has a shared or exclusive lock on record `R` in an index, another session cannot insert a new index record in the gap immediately before `R` in the index order.

Suppose that an index contains the values 10, 11, 13, and 20. The possible next-key locks for this index cover the following intervals, where a round bracket denotes exclusion of the interval endpoint and a square bracket denotes inclusion of the endpoint:
InnoDB Locking

For the last interval, the next-key lock locks the gap above the largest value in the index and the "supremum" pseudo-record having a value higher than any value actually in the index. The supremum is not a real index record, so, in effect, this next-key lock locks only the gap following the largest index value.

By default, InnoDB operates in REPEATABLE_READ transaction isolation level. In this case, InnoDB uses next-key locks for searches and index scans, which prevents phantom rows (see Section 15.7.4, "Phantom Rows").

Transaction data for a next-key lock appears similar to the following in SHOW ENGINE INNODB STATUS and InnoDB monitor output:

```
RECORD LOCKS space id 58 page no 3 n bits 72 index `PRIMARY` of table `test`.`t`
trx id 10080 lock_mode X
Record lock, heap no 1 PHYSICAL RECORD: n_fields 1; compact format; info bits 0
  0: len 8; hex 73757072656d756d; asc supremum;;
Record lock, heap no 2 PHYSICAL RECORD: n_fields 3; compact format; info bits 0
  0: len 4; hex 8000000a; asc ;;
  1: len 6; hex 00000000274f; asc 'O';
  2: len 7; hex b60000019d0110; asc ;;
```

Insert Intention Locks

An insert intention lock is a type of gap lock set by INSERT operations prior to row insertion. This lock signals the intent to insert in such a way that multiple transactions inserting into the same index gap need not wait for each other if they are not inserting at the same position within the gap. Suppose that there are index records with values of 4 and 7. Separate transactions that attempt to insert values of 5 and 6, respectively, each lock the gap between 4 and 7 with insert intention locks prior to obtaining the exclusive lock on the inserted row, but do not block each other because the rows are nonconflicting.

The following example demonstrates a transaction taking an insert intention lock prior to obtaining an exclusive lock on the inserted record. The example involves two clients, A and B.

Client A creates a table containing two index records (90 and 102) and then starts a transaction that places an exclusive lock on index records with an ID greater than 100. The exclusive lock includes a gap lock before record 102:

```
mysql> CREATE TABLE child (id int(11) NOT NULL, PRIMARY KEY(id)) ENGINE=InnoDB;
mysql> INSERT INTO child (id) values (90),(102);
mysql> START TRANSACTION;
mysql> SELECT * FROM child WHERE id > 100 FOR UPDATE;
+-----+
<table>
<thead>
<tr>
<th>id</th>
</tr>
</thead>
<tbody>
<tr>
<td>102</td>
</tr>
</tbody>
</table>
+-----+
```

Client B begins a transaction to insert a record into the gap. The transaction takes an insert intention lock while it waits to obtain an exclusive lock.

```
mysql> START TRANSACTION;
mysql> INSERT INTO child (id) VALUES (101);
```

Transaction data for an insert intention lock appears similar to the following in SHOW ENGINE INNODB STATUS and InnoDB monitor output:
AUTO-INC Locks

An AUTO-INC lock is a special table-level lock taken by transactions inserting into tables with AUTO_INCREMENT columns. In the simplest case, if one transaction is inserting values into the table, any other transactions must wait to do their own inserts into that table, so that rows inserted by the first transaction receive consecutive primary key values.

The `innodb_autoinc_lock_mode` variable controls the algorithm used for auto-increment locking. It allows you to choose how to trade off between predictable sequences of auto-increment values and maximum concurrency for insert operations.

For more information, see Section 15.6.1.6, “AUTO_INCREMENT Handling in InnoDB”.

Predicate Locks for Spatial Indexes

InnoDB supports SPATIAL indexing of columns containing spatial data (see Section 11.4.9, “Optimizing Spatial Analysis”).

To handle locking for operations involving SPATIAL indexes, next-key locking does not work well to support REPEATABLE READ or SERIALIZABLE transaction isolation levels. There is no absolute ordering concept in multidimensional data, so it is not clear which is the “next” key.

To enable support of isolation levels for tables with SPATIAL indexes, InnoDB uses predicate locks. A SPATIAL index contains minimum bounding rectangle (MBR) values, so InnoDB enforces consistent read on the index by setting a predicate lock on the MBR value used for a query. Other transactions cannot insert or modify a row that would match the query condition.

15.7.2 InnoDB Transaction Model

The InnoDB transaction model aims to combine the best properties of a multi-versioning database with traditional two-phase locking. InnoDB performs locking at the row level and runs queries as nonlocking consistent reads by default, in the style of Oracle. The lock information in InnoDB is stored space-efficiently so that lock escalation is not needed. Typically, several users are permitted to lock every row in InnoDB tables, or any random subset of the rows, without causing InnoDB memory exhaustion.

15.7.2.1 Transaction Isolation Levels

Transaction isolation is one of the foundations of database processing. Isolation is the I in the acronym ACID; the isolation level is the setting that fine-tunes the balance between performance and reliability, consistency, and reproducibility of results when multiple transactions are making changes and performing queries at the same time.

InnoDB offers all four transaction isolation levels described by the SQL:1992 standard: READ UNCOMMITTED, READ COMMITTED, REPEATABLE READ, and SERIALIZABLE. The default isolation level for InnoDB is REPEATABLE READ.

A user can change the isolation level for a single session or for all subsequent connections with the SET TRANSACTION statement. To set the server’s default isolation level for all connections, use the --transaction-isolation option on the command line or in an option file. For detailed information about isolation levels and level-setting syntax, see Section 13.3.7, “SET TRANSACTION Statement”.

3355
InnoDB supports each of the transaction isolation levels described here using different locking strategies. You can enforce a high degree of consistency with the default REPEATABLE READ level, for operations on crucial data where ACID compliance is important. Or you can relax the consistency rules with READ COMMITTED or even READ UNCOMMITTED, in situations such as bulk reporting where precise consistency and repeatable results are less important than minimizing the amount of overhead for locking. SERIALizable enforces even stricter rules than REPEATABLE READ, and is used mainly in specialized situations, such as with XA transactions and for troubleshooting issues with concurrency and deadlocks.

The following list describes how MySQL supports the different transaction levels. The list goes from the most commonly used level to the least used.

- **REPEATABLE READ**

  This is the default isolation level for InnoDB. Consistent reads within the same transaction read the snapshot established by the first read. This means that if you issue several plain (nonlocking) SELECT statements within the same transaction, these SELECT statements are consistent also with respect to each other. See Section 15.7.2.3, “Consistent Nonlocking Reads”.

  For locking reads (SELECT with FOR UPDATE or FOR SHARE), UPDATE, and DELETE statements, locking depends on whether the statement uses a unique index with a unique search condition, or a range-type search condition.

  - For a unique index with a unique search condition, InnoDB locks only the index record found, not the gap before it.
  
  - For other search conditions, InnoDB locks the index range scanned, using gap locks or next-key locks to block insertions by other sessions into the gaps covered by the range. For information about gap locks and next-key locks, see Section 15.7.1, “InnoDB Locking”.

- **READ COMMITTED**

  Each consistent read, even within the same transaction, sets and reads its own fresh snapshot. For information about consistent reads, see Section 15.7.2.3, “Consistent Nonlocking Reads”.

  For locking reads (SELECT with FOR UPDATE or FOR SHARE), UPDATE statements, and DELETE statements, InnoDB locks only index records, not the gaps before them, and thus permits the free insertion of new records next to locked records. Gap locking is only used for foreign-key constraint checking and duplicate-key checking.

  Because gap locking is disabled, phantom row problems may occur, as other sessions can insert new rows into the gaps. For information about phantom rows, see Section 15.7.4, “Phantom Rows”.

  Only row-based binary logging is supported with the READ COMMITTED isolation level. If you use READ COMMITTED with binlog_format=MIXED, the server automatically uses row-based logging.

  Using READ COMMITTED has additional effects:

  - For UPDATE or DELETE statements, InnoDB holds locks only for rows that it updates or deletes. Record locks for nonmatching rows are released after MySQL has evaluated the WHERE condition. This greatly reduces the probability of deadlocks, but they can still happen.
  
  - For UPDATE statements, if a row is already locked, InnoDB performs a “semi-consistent” read, returning the latest committed version to MySQL so that MySQL can determine whether the row matches the WHERE condition of the UPDATE. If the row matches (must be updated), MySQL reads the row again and this time InnoDB either locks it or waits for a lock on it.

  Consider the following example, beginning with this table:
CREATE TABLE t (a INT NOT NULL, b INT) ENGINE = InnoDB;
INSERT INTO t VALUES (1,2),(2,3),(3,2),(4,3),(5,2);
COMMIT;

In this case, the table has no indexes, so searches and index scans use the hidden clustered index for record locking (see Section 15.6.2.1, “Clustered and Secondary Indexes”) rather than indexed columns.

Suppose that one session performs an UPDATE using these statements:

```sql
# Session A
START TRANSACTION;
UPDATE t SET b = 5 WHERE b = 3;
```

Suppose also that a second session performs an UPDATE by executing these statements following those of the first session:

```sql
# Session B
UPDATE t SET b = 4 WHERE b = 2;
```

As InnoDB executes each UPDATE, it first acquires an exclusive lock for each row, and then determines whether to modify it. If InnoDB does not modify the row, it releases the lock. Otherwise, InnoDB retains the lock until the end of the transaction. This affects transaction processing as follows.

When using the default REPEATABLE READ isolation level, the first UPDATE acquires an x-lock on each row that it reads and does not release any of them:

```sql
x-lock(1,2); retain x-lock
x-lock(2,3); update(2,3) to (2,5); retain x-lock
x-lock(3,2); retain x-lock
x-lock(4,3); update(4,3) to (4,5); retain x-lock
x-lock(5,2); retain x-lock
```

The second UPDATE blocks as soon as it tries to acquire any locks (because first update has retained locks on all rows), and does not proceed until the first UPDATE commits or rolls back:

```sql
x-lock(1,2); block and wait for first UPDATE to commit or roll back
```

If READ COMMITTED is used instead, the first UPDATE acquires an x-lock on each row that it reads and releases those for rows that it does not modify:

```sql
x-lock(1,2); unlock(1,2)
x-lock(2,3); update(2,3) to (2,5); retain x-lock
x-lock(3,2); unlock(3,2)
x-lock(4,3); update(4,3) to (4,5); retain x-lock
x-lock(5,2); unlock(5,2)
```

For the second UPDATE, InnoDB does a “semi-consistent” read, returning the latest committed version of each row that it reads to MySQL so that MySQL can determine whether the row matches the WHERE condition of the UPDATE:

```sql
x-lock(1,2); update(1,2) to (1,4); retain x-lock
x-lock(2,3); unlock(2,3)
x-lock(3,2); update(3,2) to (3,4); retain x-lock
x-lock(4,3); unlock(4,3)
x-lock(5,2); update(5,2) to (5,4); retain x-lock
```

However, if the WHERE condition includes an indexed column, and InnoDB uses the index, only the indexed column is considered when taking and retaining record locks. In the following example, the first
**UPDATE** takes and retains an x-lock on each row where \( b = 2 \). The second **UPDATE** blocks when it tries to acquire x-locks on the same records, as it also uses the index defined on column b.

```sql
CREATE TABLE t (a INT NOT NULL, b INT, c INT, INDEX (b)) ENGINE = InnoDB;
INSERT INTO t VALUES (1,2,3),(2,2,4);
COMMIT;

### Session A
START TRANSACTION;
UPDATE t SET b = 3 WHERE b = 2 AND c = 3;
### Session B
UPDATE t SET b = 4 WHERE b = 2 AND c = 4;
```

The **READ COMMITTED** isolation level can be set at startup or changed at runtime. At runtime, it can be set globally for all sessions, or individually per session.

- **READ UNCOMMITTED**

  **SELECT** statements are performed in a nonlocking fashion, but a possible earlier version of a row might be used. Thus, using this isolation level, such reads are not consistent. This is also called a *dirty read*. Otherwise, this isolation level works like **READ COMMITTED**.

- **SERIALIZABLE**

  This level is like **REPEATABLE READ**, but **InnoDB** implicitly converts all plain **SELECT** statements to **SELECT ... FOR SHARE** if **autocommit** is disabled. If **autocommit** is enabled, the **SELECT** is its own transaction. It therefore is known to be read only and can be serialized if performed as a consistent (nonlocking) read and need not block for other transactions. (To force a plain **SELECT** to block if other transactions have modified the selected rows, disable **autocommit**.)

**Note**

As of MySQL 8.0.22, DML operations that read data from MySQL grant tables (through a join list or subquery) but do not modify them do not acquire read locks on the MySQL grant tables, regardless of the isolation level. For more information, see Grant Table Concurrency.

### 15.7.2.2 autocommit, Commit, and Rollback

In **InnoDB**, all user activity occurs inside a transaction. If **autocommit** mode is enabled, each SQL statement forms a single transaction on its own. By default, MySQL starts the session for each new connection with **autocommit** enabled, so MySQL does a commit after each SQL statement if that statement did not return an error. If a statement returns an error, the commit or rollback behavior depends on the error. See Section 15.21.5, “**InnoDB** Error Handling”.

A session that has **autocommit** enabled can perform a multiple-statement transaction by starting it with an explicit **START TRANSACTION** or **BEGIN** statement and ending it with a **COMMIT** or **ROLLBACK** statement. See Section 13.3.1, “**START TRANSACTION**, **COMMIT**, and **ROLLBACK** Statements”.

If **autocommit** mode is disabled within a session with **SET autocommit = 0**, the session always has a transaction open. A **COMMIT** or **ROLLBACK** statement ends the current transaction and a new one starts.

If a session that has **autocommit** disabled ends without explicitly committing the final transaction, **MySQL** rolls back that transaction.

Some statements implicitly end a transaction, as if you had done a **COMMIT** before executing the statement. For details, see Section 13.3.3, “Statements That Cause an Implicit Commit”.
A **COMMIT** means that the changes made in the current transaction are made permanent and become visible to other sessions. A **ROLLBACK** statement, on the other hand, cancels all modifications made by the current transaction. Both **COMMIT** and **ROLLBACK** release all **InnoDB** locks that were set during the current transaction.

### Grouping DML Operations with Transactions

By default, connection to the MySQL server begins with **autocommit** mode enabled, which automatically commits every SQL statement as you execute it. This mode of operation might be unfamiliar if you have experience with other database systems, where it is standard practice to issue a sequence of **DML** statements and commit them or roll them back all together.

To use multiple-statement transactions, switch autocommit off with the SQL statement **SET autocommit = 0** and end each transaction with **COMMIT** or **ROLLBACK** as appropriate. To leave autocommit on, begin each transaction with **START TRANSACTION** and end it with **COMMIT** or **ROLLBACK**. The following example shows two transactions. The first is committed; the second is rolled back.

```
$> mysql test

mysql> CREATE TABLE customer (a INT, b CHAR (20), INDEX (a));
Query OK, 0 rows affected (0.00 sec)
mysql> -- Do a transaction with autocommit turned on.
mysql> START TRANSACTION;
Query OK, 0 rows affected (0.00 sec)
mysql> INSERT INTO customer VALUES (10, 'Heikki');
Query OK, 1 row affected (0.00 sec)
mysql> COMMIT;
Query OK, 0 rows affected (0.00 sec)
mysql> -- Do another transaction with autocommit turned off.
mysql> SET autocommit=0;
Query OK, 0 rows affected (0.00 sec)
mysql> INSERT INTO customer VALUES (15, 'John');
Query OK, 1 row affected (0.00 sec)
mysql> INSERT INTO customer VALUES (20, 'Paul');
Query OK, 1 row affected (0.00 sec)
mysql> DELETE FROM customer WHERE b = 'Heikki';
Query OK, 1 row affected (0.00 sec)
mysql> -- Now we undo those last 2 inserts and the delete.
mysql> ROLLBACK;
Query OK, 0 rows affected (0.00 sec)
mysql> SELECT * FROM customer;
+------+--------+
| a    | b      |
+------+--------+
|   10 | Heikki |
+------+--------+
1 row in set (0.00 sec)
```

### Transactions in Client-Side Languages

In APIs such as PHP, Perl DBI, JDBC, ODBC, or the standard C call interface of MySQL, you can send transaction control statements such as **COMMIT** to the MySQL server as strings just like any other SQL statements such as **SELECT** or **INSERT**. Some APIs also offer separate special transaction commit and rollback functions or methods.

### 15.7.2.3 Consistent Nonlocking Reads

A **consistent read** means that **InnoDB** uses multi-versioning to present to a query a snapshot of the database at a point in time. The query sees the changes made by transactions that committed before that point in time, and no changes made by later or uncommitted transactions. The exception to this rule is that the query sees the changes made by earlier statements within the same transaction. This exception
causes the following anomaly: If you update some rows in a table, a `SELECT` sees the latest version of the updated rows, but it might also see older versions of any rows. If other sessions simultaneously update the same table, the anomaly means that you might see the table in a state that never existed in the database.

If the transaction isolation level is `REPEATABLE READ` (the default level), all consistent reads within the same transaction read the snapshot established by the first such read in that transaction. You can get a fresher snapshot for your queries by committing the current transaction and after that issuing new queries.

With `READ COMMITTED` isolation level, each consistent read within a transaction sets and reads its own fresh snapshot.

Consistent read is the default mode in which InnoDB processes `SELECT` statements in `READ COMMITTED` and `REPEATABLE READ` isolation levels. A consistent read does not set any locks on the tables it accesses, and therefore other sessions are free to modify those tables at the same time a consistent read is being performed on the table.

Suppose that you are running in the default `REPEATABLE READ` isolation level. When you issue a consistent read (that is, an ordinary `SELECT` statement), InnoDB gives your transaction a timepoint according to which your query sees the database. If another transaction deletes a row and commits after your timepoint was assigned, you do not see the row as having been deleted. Inserts and updates are treated similarly.

### Note

The snapshot of the database state applies to `SELECT` statements within a transaction, not necessarily to `DML` statements. If you insert or modify some rows and then commit that transaction, a `DELETE` or `UPDATE` statement issued from another concurrent `REPEATABLE READ` transaction could affect those just-committed rows, even though the session could not query them. If a transaction does update or delete rows committed by a different transaction, those changes do become visible to the current transaction. For example, you might encounter a situation like the following:

```sql
SELECT COUNT(c1) FROM t1 WHERE c1 = 'xyz';
-- Returns 0: no rows match.
DELETE FROM t1 WHERE c1 = 'xyz';
-- Deletes several rows recently committed by other transaction.

SELECT COUNT(c2) FROM t1 WHERE c2 = 'abc';
-- Returns 0: no rows match.
UPDATE t1 SET c2 = 'cba' WHERE c2 = 'abc';
-- Affects 10 rows: another txn just committed 10 rows with 'abc' values.
SELECT COUNT(c2) FROM t1 WHERE c2 = 'cba';
-- Returns 10: this txn can now see the rows it just updated.
```

You can advance your timepoint by committing your transaction and then doing another `SELECT` or `START TRANSACTION WITH CONSISTENT SNAPSHOT`.

This is called *multi-versioned concurrency control*.

In the following example, session A sees the row inserted by B only when B has committed the insert and A has committed as well, so that the timepoint is advanced past the commit of B.
InnoDB Transaction Model

If you want to see the “freshest” state of the database, use either the `READ COMMITTED` isolation level or a locking read:

```
SELECT * FROM t FOR SHARE;
```

With `READ COMMITTED` isolation level, each consistent read within a transaction sets and reads its own fresh snapshot. With `FOR SHARE`, a locking read occurs instead: A `SELECT` blocks until the transaction containing the freshest rows ends (see Section 15.7.2.4, “Locking Reads”).

Consistent read does not work over certain DDL statements:

- Consistent read does not work over `DROP TABLE`, because MySQL cannot use a table that has been dropped and InnoDB destroys the table.
- Consistent read does not work over `ALTER TABLE` operations that make a temporary copy of the original table and delete the original table when the temporary copy is built. When you reissue a consistent read within a transaction, rows in the new table are not visible because those rows did not exist when the transaction’s snapshot was taken. In this case, the transaction returns an error: `ER_TABLE_DEF_CHANGED`, “Table definition has changed, please retry transaction”.

The type of read varies for selects in clauses like `INSERT INTO ... SELECT`, `UPDATE ... (SELECT)`, and `CREATE TABLE ... SELECT` that do not specify `FOR UPDATE` or `FOR SHARE`:

- By default, InnoDB uses stronger locks for those statements and the `SELECT` part acts like `READ COMMITTED`, where each consistent read, even within the same transaction, sets and reads its own fresh snapshot.
- To perform a nonlocking read in such cases, set the isolation level of the transaction to `READ UNCOMMITTED` or `READ COMMITTED` to avoid setting locks on rows read from the selected table.

15.7.2.4 Locking Reads

If you query data and then insert or update related data within the same transaction, the regular `SELECT` statement does not give enough protection. Other transactions can update or delete the same rows you just queried. InnoDB supports two types of locking reads that offer extra safety:

- `SELECT ... FOR SHARE`

Sets a shared mode lock on any rows that are read. Other sessions can read the rows, but cannot modify them until your transaction commits. If any of these rows were changed by another transaction that has not yet committed, your query waits until that transaction ends and then uses the latest values.

Note

`SELECT ... FOR SHARE` is a replacement for `SELECT ... LOCK IN SHARE MODE`, but `LOCK IN SHARE MODE` remains available for backward
InnoDB Transaction Model

compatibility. The statements are equivalent. However, \texttt{FOR SHARE} supports \texttt{OF table_name}, \texttt{NOWAIT}, and \texttt{SKIP LOCKED} options. See \texttt{Locking Read Concurrency with NOWAIT} and \texttt{SKIP LOCKED}.

Prior to MySQL 8.0.22, \texttt{SELECT ... FOR SHARE} requires the \texttt{SELECT} privilege and at least one of the \texttt{DELETE, LOCK TABLES}, or \texttt{UPDATE} privileges. From MySQL 8.0.22, only the \texttt{SELECT} privilege is required.

From MySQL 8.0.22, \texttt{SELECT ... FOR SHARE} statements do not acquire read locks on MySQL grant tables. For more information, see \texttt{Grant Table Concurrency}.

\textbf{SELECT ... FOR UPDATE}

For index records the search encounters, locks the rows and any associated index entries, the same as if you issued an \texttt{UPDATE} statement for those rows. Other transactions are blocked from updating those rows, from doing \texttt{SELECT ... FOR SHARE}, or from reading the data in certain transaction isolation levels. Consistent reads ignore any locks set on the records that exist in the read view. (Old versions of a record cannot be locked; they are reconstructed by applying \texttt{undo logs} on an in-memory copy of the record.)

\texttt{SELECT ... FOR UPDATE} requires the \texttt{SELECT} privilege and at least one of the \texttt{DELETE, LOCK TABLES}, or \texttt{UPDATE} privileges.

These clauses are primarily useful when dealing with tree-structured or graph-structured data, either in a single table or split across multiple tables. You traverse edges or tree branches from one place to another, while reserving the right to come back and change any of these "pointer" values.

All locks set by \texttt{FOR SHARE} and \texttt{FOR UPDATE} queries are released when the transaction is committed or rolled back.

\textbf{Note}

Locking reads are only possible when autocommit is disabled (either by beginning transaction with \texttt{START TRANSACTION} or by setting \texttt{autocommit} to 0.

A locking read clause in an outer statement does not lock the rows of a table in a nested subquery unless a locking read clause is also specified in the subquery. For example, the following statement does not lock rows in table \texttt{t2}.

\begin{verbatim}
SELECT * FROM t1 WHERE c1 = (SELECT c1 FROM t2) FOR UPDATE;
\end{verbatim}

To lock rows in table \texttt{t2}, add a locking read clause to the subquery:

\begin{verbatim}
SELECT * FROM t1 WHERE c1 = (SELECT c1 FROM t2 FOR UPDATE) FOR UPDATE;
\end{verbatim}

\textbf{Locking Read Examples}

Suppose that you want to insert a new row into a table \texttt{child}, and make sure that the child row has a parent row in table \texttt{parent}. Your application code can ensure referential integrity throughout this sequence of operations.

First, use a consistent read to query the table \texttt{PARENT} and verify that the parent row exists. Can you safely insert the child row to table \texttt{CHILD}? No, because some other session could delete the parent row in the moment between your \texttt{SELECT} and your \texttt{INSERT}, without you being aware of it.

To avoid this potential issue, perform the \texttt{SELECT} using \texttt{FOR SHARE}:
InnoDB Transaction Model

```sql
SELECT * FROM parent WHERE NAME = 'Jones' FOR SHARE;
```

After the `FOR SHARE` query returns the parent 'Jones', you can safely add the child record to the `CHILD` table and commit the transaction. Any transaction that tries to acquire an exclusive lock in the applicable row in the `PARENT` table waits until you are finished, that is, until the data in all tables is in a consistent state.

For another example, consider an integer counter field in a table `CHILD_CODES`, used to assign a unique identifier to each child added to table `CHILD`. Do not use either consistent read or a shared mode read to read the present value of the counter, because two users of the database could see the same value for the counter, and a duplicate-key error occurs if two transactions attempt to add rows with the same identifier to the `CHILD` table.

Here, `FOR SHARE` is not a good solution because if two users read the counter at the same time, at least one of them ends up in deadlock when it attempts to update the counter.

To implement reading and incrementing the counter, first perform a locking read of the counter using `FOR UPDATE`, and then increment the counter. For example:

```sql
SELECT counter_field FROM child_codes FOR UPDATE;
UPDATE child_codes SET counter_field = counter_field + 1;
```

A `SELECT ... FOR UPDATE` reads the latest available data, setting exclusive locks on each row it reads. Thus, it sets the same locks a searched SQL `UPDATE` would set on the rows.

The preceding description is merely an example of how `SELECT ... FOR UPDATE` works. In MySQL, the specific task of generating a unique identifier actually can be accomplished using only a single access to the table:

```sql
UPDATE child_codes SET counter_field = LAST_INSERT_ID(counter_field + 1);
SELECT LAST_INSERT_ID();
```

The `SELECT` statement merely retrieves the identifier information (specific to the current connection). It does not access any table.

**Locking Read Concurrency with NOWAIT and SKIP LOCKED**

If a row is locked by a transaction, a `SELECT ... FOR UPDATE` or `SELECT ... FOR SHARE` transaction that requests the same locked row must wait until the blocking transaction releases the row lock. This behavior prevents transactions from updating or deleting rows that are queried for updates by other transactions. However, waiting for a row lock to be released is not necessary if you want the query to return immediately when a requested row is locked, or if excluding locked rows from the result set is acceptable.

To avoid waiting for other transactions to release row locks, `NOWAIT` and `SKIP LOCKED` options may be used with `SELECT ... FOR UPDATE` or `SELECT ... FOR SHARE` locking read statements.

- **NOWAIT**
  
  A locking read that uses `NOWAIT` never waits to acquire a row lock. The query executes immediately, failing with an error if a requested row is locked.

- **SKIP LOCKED**
  
  A locking read that uses `SKIP LOCKED` never waits to acquire a row lock. The query executes immediately, removing locked rows from the result set.
Queries that skip locked rows return an inconsistent view of the data. `SKIP LOCKED` is therefore not suitable for general transactional work. However, it may be used to avoid lock contention when multiple sessions access the same queue-like table.

`NOWAIT` and `SKIP LOCKED` only apply to row-level locks.

Statements that use `NOWAIT` or `SKIP LOCKED` are unsafe for statement based replication.

The following example demonstrates `NOWAIT` and `SKIP LOCKED`. Session 1 starts a transaction that takes a row lock on a single record. Session 2 attempts a locking read on the same record using the `NOWAIT` option. Because the requested row is locked by Session 1, the locking read returns immediately with an error. In Session 3, the locking read with `SKIP LOCKED` returns the requested rows except for the row that is locked by Session 1.

```sql
# Session 1:
mysql> CREATE TABLE t (i INT, PRIMARY KEY (i)) ENGINE = InnoDB;
mysql> INSERT INTO t (i) VALUES(1),(2),(3);
mysql> START TRANSACTION;

mysql> SELECT * FROM t WHERE i = 2 FOR UPDATE;
+---+
| i |
+---+
| 2 |
+---+

# Session 2:
mysql> START TRANSACTION;

mysql> SELECT * FROM t WHERE i = 2 FOR UPDATE NOWAIT;
ERROR 3572 (HY000): Do not wait for lock.

# Session 3:
mysql> START TRANSACTION;

mysql> SELECT * FROM t FOR UPDATE SKIP LOCKED;
+---+
| i |
+---+
| 1 |
| 3 |
+---+
```

15.7.3 Locks Set by Different SQL Statements in InnoDB

A locking read, an `UPDATE`, or a `DELETE` generally set record locks on every index record that is scanned in the processing of an SQL statement. It does not matter whether there are `WHERE` conditions in the statement that would exclude the row. InnoDB does not remember the exact `WHERE` condition, but only knows which index ranges were scanned. The locks are normally `next-key locks` that also block inserts into the “gap” immediately before the record. However, `gap locking` can be disabled explicitly, which causes `next-key locking` not to be used. For more information, see Section 15.7.1, “InnoDB Locking”. The transaction isolation level can also affect which locks are set; see Section 15.7.2.1, “Transaction Isolation Levels”.

3364
If a secondary index is used in a search and the index record locks to be set are exclusive, InnoDB also retrieves the corresponding clustered index records and sets locks on them.

If you have no indexes suitable for your statement and MySQL must scan the entire table to process the statement, every row of the table becomes locked, which in turn blocks all inserts by other users to the table. It is important to create good indexes so that your queries do not scan more rows than necessary.

InnoDB sets specific types of locks as follows.

• **SELECT ... FROM** is a consistent read, reading a snapshot of the database and setting no locks unless the transaction isolation level is set to **SERIALIZABLE**. For **SERIALIZABLE** level, the search sets shared next-key locks on the index records it encounters. However, only an index record lock is required for statements that lock rows using a unique index to search for a unique row.

• **SELECT ... FOR UPDATE** and **SELECT ... FOR SHARE** statements that use a unique index acquire locks for scanned rows, and release the locks for rows that do not qualify for inclusion in the result set (for example, if they do not meet the criteria given in the **WHERE** clause). However, in some cases, rows might not be unlocked immediately because the relationship between a result row and its original source is lost during query execution. For example, in a **UNION**, scanned (and locked) rows from a table might be inserted into a temporary table before evaluating whether they qualify for the result set. In this circumstance, the relationship of the rows in the temporary table to the rows in the original table is lost and the latter rows are not unlocked until the end of query execution.

• For locking reads (**SELECT** with **FOR UPDATE** or **FOR SHARE**), **UPDATE**, and **DELETE** statements, the locks that are taken depend on whether the statement uses a unique index with a unique search condition or a range-type search condition.

  • For a unique index with a unique search condition, InnoDB locks only the index record found, not the gap before it.

  • For other search conditions, and for non-unique indexes, InnoDB locks the index range scanned, using gap locks or next-key locks to block insertions by other sessions into the gaps covered by the range. For information about gap locks and next-key locks, see Section 15.7.1, "InnoDB Locking".

• For index records the search encounters, **SELECT ... FOR UPDATE** blocks other sessions from doing **SELECT ... FOR SHARE** or from reading in certain transaction isolation levels. Consistent reads ignore any locks set on the records that exist in the read view.

• **UPDATE ... WHERE ...** sets an exclusive next-key lock on every record the search encounters. However, only an index record lock is required for statements that lock rows using a unique index to search for a unique row.

• When **UPDATE** modifies a clustered index record, implicit locks are taken on affected secondary index records. The **UPDATE** operation also takes shared locks on affected secondary index records when performing duplicate check scans prior to inserting new secondary index records, and when inserting new secondary index records.

• **DELETE FROM ... WHERE ...** sets an exclusive next-key lock on every record the search encounters. However, only an index record lock is required for statements that lock rows using a unique index to search for a unique row.

• **INSERT** sets an exclusive lock on the inserted row. This lock is an index-record lock, not a next-key lock (that is, there is no gap lock) and does not prevent other sessions from inserting into the gap before the inserted row.

Prior to inserting the row, a type of gap lock called an insert intention gap lock is set. This lock signals the intent to insert in such a way that multiple transactions inserting into the same index gap need not
wait for each other if they are not inserting at the same position within the gap. Suppose that there are
index records with values of 4 and 7. Separate transactions that attempt to insert values of 5 and 6
each lock the gap between 4 and 7 with insert intention locks prior to obtaining the exclusive lock on the
inserted row, but do not block each other because the rows are nonconflicting.

If a duplicate-key error occurs, a shared lock on the duplicate index record is set. This use of a shared
lock can result in deadlock should there be multiple sessions trying to insert the same row if another
session already has an exclusive lock. This can occur if another session deletes the row. Suppose that
an InnoDB table \( t_1 \) has the following structure:

```sql
CREATE TABLE t1 (i INT, PRIMARY KEY (i)) ENGINE = InnoDB;
```

Now suppose that three sessions perform the following operations in order:

**Session 1:**

```sql
START TRANSACTION;
INSERT INTO t1 VALUES(1);
```

**Session 2:**

```sql
START TRANSACTION;
INSERT INTO t1 VALUES(1);
```

**Session 3:**

```sql
START TRANSACTION;
INSERT INTO t1 VALUES(1);
```

**Session 1:**

```sql
ROLLBACK;
```

The first operation by session 1 acquires an exclusive lock for the row. The operations by sessions 2 and
3 both result in a duplicate-key error and they both request a shared lock for the row. When session 1
rolls back, it releases its exclusive lock on the row and the queued shared lock requests for sessions 2
and 3 are granted. At this point, sessions 2 and 3 deadlock: Neither can acquire an exclusive lock for the
row because of the shared lock held by the other.

A similar situation occurs if the table already contains a row with key value 1 and three sessions perform
the following operations in order:

**Session 1:**

```sql
START TRANSACTION;
DELETE FROM t1 WHERE i = 1;
```

**Session 2:**

```sql
START TRANSACTION;
INSERT INTO t1 VALUES(1);
```

**Session 3:**

```sql
START TRANSACTION;
```
**Locks Set by Different SQL Statements in InnoDB**

**INSERT INTO t1 VALUES(1);**

**Session 1:**

**COMMIT;**

The first operation by session 1 acquires an exclusive lock for the row. The operations by sessions 2 and 3 both result in a duplicate-key error and they both request a shared lock for the row. When session 1 commits, it releases its exclusive lock on the row and the queued shared lock requests for sessions 2 and 3 are granted. At this point, sessions 2 and 3 deadlock: Neither can acquire an exclusive lock for the row because of the shared lock held by the other.

- **INSERT ... ON DUPLICATE KEY UPDATE** differs from a simple **INSERT** in that an exclusive lock rather than a shared lock is placed on the row to be updated when a duplicate-key error occurs. An exclusive index-record lock is taken for a duplicate primary key value. An exclusive next-key lock is taken for a duplicate unique key value.

- **REPLACE** is done like an **INSERT** if there is no collision on a unique key. Otherwise, an exclusive next-key lock is placed on the row to be replaced.

- **INSERT INTO T SELECT ... FROM S WHERE ...** sets an exclusive index record lock (without a gap lock) on each row inserted into **T**. If the transaction isolation level is **READ COMMITTED**, **InnoDB** does the search on **S** as a consistent read (no locks). Otherwise, **InnoDB** sets shared next-key locks on rows from **S**. **InnoDB** has to set locks in the latter case: During roll-forward recovery using a statement-based binary log, every SQL statement must be executed in exactly the same way it was done originally.

  **CREATE TABLE ... SELECT ...** performs the **SELECT** with shared next-key locks or as a consistent read, as for **INSERT ... SELECT**.

  When a **SELECT** is used in the constructs **REPLACE INTO t SELECT ... FROM s WHERE ...** or **UPDATE t ... WHERE col IN (SELECT ... FROM s ...)**, **InnoDB** sets shared next-key locks on rows from table **s**.

- **InnoDB** sets an exclusive lock on the end of the index associated with the **AUTO_INCREMENT** column while initializing a previously specified **AUTO_INCREMENT** column on a table.

  With **innodb_autoinc_lock_mode=0**, **InnoDB** uses a special **AUTO-INC** table lock mode where the lock is obtained and held to the end of the current SQL statement (not to the end of the entire transaction) while accessing the auto-increment counter. Other clients cannot insert into the table while the **AUTO-INC** table lock is held. The same behavior occurs for “bulk inserts” with **innodb_autoinc_lock_mode=1**. Table-level **AUTO-INC** locks are not used with **innodb_autoinc_lock_mode=2**. For more information, see Section 15.6.1.6, "AUTO_INCREMENT Handling in InnoDB".

  **InnoDB** fetches the value of a previously initialized **AUTO_INCREMENT** column without setting any locks.

- If a **FOREIGN KEY** constraint is defined on a table, any insert, update, or delete that requires the constraint condition to be checked sets shared record-level locks on the records that it looks at to check the constraint. **InnoDB** also sets these locks in the case where the constraint fails.

- **LOCK TABLES** sets table locks, but it is the higher MySQL layer above the **InnoDB** layer that sets these locks. **InnoDB** is aware of table locks if **innodb_table_locks = 1** (the default) and **autocommit = 0**, and the MySQL layer above **InnoDB** knows about row-level locks.

  Otherwise, **InnoDB**’s automatic deadlock detection cannot detect deadlocks where such table locks are involved. Also, because in this case the higher MySQL layer does not know about row-level locks, it is
possible to get a table lock on a table where another session currently has row-level locks. However, this does not endanger transaction integrity, as discussed in Section 15.7.5.2, “Deadlock Detection”.

- **LOCK TABLES** acquires two locks on each table if `innodb_table_locks=1` (the default). In addition to a table lock on the MySQL layer, it also acquires an InnoDB table lock. To avoid acquiring InnoDB table locks, set `innodb_table_locks=0`. If no InnoDB table lock is acquired, **LOCK TABLES** completes even if some records of the tables are being locked by other transactions.

  In MySQL 8.0, `innodb_table_locks=0` has no effect for tables locked explicitly with **LOCK TABLES** ... **WRITE**. It does have an effect for tables locked for read or write by **LOCK TABLES** ... **WRITE** implicitly (for example, through triggers) or by **LOCK TABLES** ... **READ**.

- All InnoDB locks held by a transaction are released when the transaction is committed or aborted. Thus, it does not make much sense to invoke **LOCK TABLES** on InnoDB tables in **autocommit=1** mode because the acquired InnoDB table locks would be released immediately.

- You cannot lock additional tables in the middle of a transaction because **LOCK TABLES** performs an implicit **COMMIT** and **UNLOCK TABLES**.

### 15.7.4 Phantom Rows

The so-called *phantom* problem occurs within a transaction when the same query produces different sets of rows at different times. For example, if a **SELECT** is executed twice, but returns a row the second time that was not returned the first time, the row is a “phantom” row.

Suppose that there is an index on the `id` column of the `child` table and that you want to read and lock all rows from the table having an identifier value larger than 100, with the intention of updating some column in the selected rows later:

```sql
SELECT * FROM child WHERE id > 100 FOR UPDATE;
```

The query scans the index starting from the first record where `id` is bigger than 100. Let the table contain rows having `id` values of 90 and 102. If the locks set on the index records in the scanned range do not lock out inserts made in the gaps (in this case, the gap between 90 and 102), another session can insert a new row into the table with an `id` of 101. If you were to execute the same **SELECT** within the same transaction, you would see a new row with an `id` of 101 (a “phantom”) in the result set returned by the query. If we regard a set of rows as a data item, the new phantom child would violate the isolation principle of transactions that a transaction should be able to run so that the data it has read does not change during the transaction.

To prevent phantoms, InnoDB uses an algorithm called *next-key locking* that combines index-row locking with gap locking. InnoDB performs row-level locking in such a way that when it searches or scans a table index, it sets shared or exclusive locks on the index records it encounters. Thus, the row-level locks are actually index-record locks. In addition, a next-key lock on an index record also affects the “gap” before the index record. That is, a next-key lock is an index-record lock plus a gap lock on the gap preceding the index record. If one session has a shared or exclusive lock on record `R` in an index, another session cannot insert a new index record in the gap immediately before `R` in the index order.

When InnoDB scans an index, it can also lock the gap after the last record in the index. Just that happens in the preceding example: To prevent any insert into the table where `id` would be bigger than 100, the locks set by InnoDB include a lock on the gap following `id` value 102.

You can use next-key locking to implement a uniqueness check in your application: If you read your data in share mode and do not see a duplicate for a row you are going to insert, then you can safely insert your row and know that the next-key lock set on the successor of your row during the read prevents anyone meanwhile inserting a duplicate for your row. Thus, the next-key locking enables you to “lock” the nonexistence of something in your table.
Gap locking can be disabled as discussed in Section 15.7.1, “InnoDB Locking”. This may cause phantom problems because other sessions can insert new rows into the gaps when gap locking is disabled.

### 15.7.5 Deadlocks in InnoDB

A deadlock is a situation where different transactions are unable to proceed because each holds a lock that the other needs. Because both transactions are waiting for a resource to become available, neither ever release the locks it holds.

A deadlock can occur when transactions lock rows in multiple tables (through statements such as `UPDATE` or `SELECT ... FOR UPDATE`), but in the opposite order. A deadlock can also occur when such statements lock ranges of index records and gaps, with each transaction acquiring some locks but not others due to a timing issue. For a deadlock example, see Section 15.7.5.1, “An InnoDB Deadlock Example”.

To reduce the possibility of deadlocks, use transactions rather than `LOCK TABLES` statements; keep transactions that insert or update data small enough that they do not stay open for long periods of time; when different transactions update multiple tables or large ranges of rows, use the same order of operations (such as `SELECT ... FOR UPDATE`) in each transaction; create indexes on the columns used in `SELECT ... FOR UPDATE` and `UPDATE ... WHERE` statements. The possibility of deadlocks is not affected by the isolation level, because the isolation level changes the behavior of read operations, while deadlocks occur because of write operations. For more information about avoiding and recovering from deadlock conditions, see Section 15.7.5.3, “How to Minimize and Handle Deadlocks”.

When deadlock detection is enabled (the default) and a deadlock does occur, InnoDB detects the condition and rolls back one of the transactions (the victim). If deadlock detection is disabled using the `innodb_deadlock_detect` variable, InnoDB relies on the `innodb_lock_wait_timeout` setting to roll back transactions in case of a deadlock. Thus, even if your application logic is correct, you must still handle the case where a transaction must be retried. To view the last deadlock in an InnoDB user transaction, use `SHOW ENGINE INNODB STATUS`. If frequent deadlocks highlight a problem with transaction structure or application error handling, enable `innodb_print_all_deadlocks` to print information about all deadlocks to the `mysqld` error log. For more information about how deadlocks are automatically detected and handled, see Section 15.7.5.2, “Deadlock Detection”.

### 15.7.5.1 An InnoDB Deadlock Example

The following example illustrates how an error can occur when a lock request causes a deadlock. The example involves two clients, A and B.

InnoDB status contains details of the last deadlock. For frequent deadlocks, enable global variable `innodb_print_all_deadlocks`. This adds deadlock information to the error log.

Client A enables `innodb_print_all_deadlocks`, creates two tables, 'Animals' and 'Birds', and inserts data into each. Client A begins a transaction, and selects a row in Animals in share mode:

```sql
mysql> SET GLOBAL innodb_print_all_deadlocks = ON;
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE Animals (name VARCHAR(10) PRIMARY KEY, value INT) ENGINE = InnoDB;
Query OK, 0 rows affected (0.01 sec)

mysql> CREATE TABLE Birds (name VARCHAR(10) PRIMARY KEY, value INT) ENGINE = InnoDB;
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO Animals (name, value) VALUES ('Aardvark', 10);
Query OK, 1 row affected (0.00 sec)
```
mysql> INSERT INTO Birds (name,value) VALUES ('Buzzard',20);
Query OK, 1 row affected (0.00 sec)

mysql> START TRANSACTION;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT value FROM Animals WHERE name='Aardvark' FOR SHARE;
+-------+
<table>
<thead>
<tr>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
</tr>
</tbody>
</table>
+-------+
1 row in set (0.00 sec)

Next, client B begins a transaction, and selects a row in Birds in share mode:

mysql> START TRANSACTION;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT value FROM Birds WHERE name='Buzzard' FOR SHARE;
+-------+
<table>
<thead>
<tr>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>20</td>
</tr>
</tbody>
</table>
+-------+
1 row in set (0.00 sec)

The Performance Schema shows the locks after the two select statements:

mysql> SELECT ENGINE_TRANSACTION_ID as Trx_Id, OBJECT_NAME as `Table`, INDEX_NAME as `Index`, LOCK_DATA as Data, LOCK_MODE as Mode, LOCK_STATUS as Status, LOCK_TYPE as Type
      FROM performance_schema.data_locks;
+-----------------+---------+---------+------------+---------------+---------+--------+
<table>
<thead>
<tr>
<th>Trx_Id</th>
<th>Table</th>
<th>Index</th>
<th>Data</th>
<th>Mode</th>
<th>Status</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>421291106147544</td>
<td>Animals</td>
<td>NULL</td>
<td>NULL</td>
<td>IS</td>
<td>GRANTED</td>
<td>TABLE</td>
</tr>
<tr>
<td>421291106147544</td>
<td>Animals</td>
<td>PRIMARY</td>
<td>'Aardvark'</td>
<td>S,REC_NOT_GAP</td>
<td>GRANTED</td>
<td>RECORD</td>
</tr>
<tr>
<td>421291106148352</td>
<td>Birds</td>
<td>NULL</td>
<td>NULL</td>
<td>IS</td>
<td>GRANTED</td>
<td>TABLE</td>
</tr>
<tr>
<td>421291106148352</td>
<td>Birds</td>
<td>PRIMARY</td>
<td>'Buzzard'</td>
<td>S,REC_NOT_GAP</td>
<td>GRANTED</td>
<td>RECORD</td>
</tr>
</tbody>
</table>
+-----------------+---------+---------+------------+---------------+---------+--------+
4 rows in set (0.00 sec)

Client B then updates a row in Animals:

mysql> UPDATE Animals SET value=30 WHERE name='Aardvark';

Client B has to wait. The Performance Schema shows the wait for a lock:

mysql> SELECT REQUESTING_ENGINE_LOCK_ID as Req_Lock_Id, REQUESTING_ENGINE_TRANSACTION_ID as Req_Trx_Id, BLOCKING_ENGINE_LOCK_ID as Blk_Lock_Id, BLOCKING_ENGINE_TRANSACTION_ID as Blk_Trx_Id
      FROM performance_schema.data_lock_waits;
+----------------------------------------+------------+----------------------------------------+-----------------+
<table>
<thead>
<tr>
<th>Req_Lock_Id</th>
<th>Req_Trx_Id</th>
<th>Blk_Lock_Id</th>
<th>Blk_Trx_Id</th>
</tr>
</thead>
</table>
+----------------------------------------+------------+----------------------------------------+-----------------+
1 row in set (0.00 sec)

mysql> SELECT ENGINE_LOCK_ID as Lock_Id,
InnoDB only uses sequential transaction ids when a transaction attempts to modify the database. Therefore, the previous read-only transaction id changes from 421291106148352 to 43260.

If client A attempts to update a row in Birds at the same time, this will lead to a deadlock:

```sql
UPDATE Birds SET value=40 WHERE name='Buzzard';
```

ERROR 1213 (40001): Deadlock found when trying to get lock; try restarting transaction

InnoDB rolls back the transaction that caused the deadlock. The first update, from Client B, can now proceed.

The Information Schema contains the number of deadlocks:

```sql
SELECT `count` FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME="lock_deadlocks";
```

<table>
<thead>
<tr>
<th>count</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
</tr>
</tbody>
</table>

1 row in set (0.00 sec)

The InnoDB status contains the following information about the deadlock and transactions. It also shows that the read-only transaction id 421291106147544 changes to sequential transaction id 43261.

```sql
SHOW ENGINE INNODB STATUS;
```

### 15.7.5.2 Deadlock Detection

When deadlock detection is enabled (the default), InnoDB automatically detects transaction deadlocks and rolls back a transaction or transactions to break the deadlock. InnoDB tries to pick small transactions to roll back, where the size of a transaction is determined by the number of rows inserted, updated, or deleted.

InnoDB is aware of table locks if `innodb_table_locks = 1` (the default) and `autocommit = 0`, and the MySQL layer above it knows about row-level locks. Otherwise, InnoDB cannot detect deadlocks where a table lock set by a MySQL `LOCK TABLES` statement or a lock set by a storage engine other than InnoDB is involved. Resolve these situations by setting the value of the `innodb_lock_wait_timeout` system variable.

If the LATEST DETECTED DEADLOCK section of InnoDB Monitor output includes a message stating TOO DEEP OR LONG SEARCH IN THE LOCK TABLE WAITS-FOR GRAPH, WE WILL ROLL BACK FOLLOWING TRANSACTION, this indicates that the number of transactions on the wait-for list has reached a limit of 200. A wait-for list that exceeds 200 transactions is treated as a deadlock and the transaction attempting to check the wait-for list is rolled back. The same error may also occur if the locking thread must look at more than 1,000,000 locks owned by transactions on the wait-for list.

For techniques to organize database operations to avoid deadlocks, see Section 15.7.5, “Deadlocks in InnoDB”.

### Disabling Deadlock Detection

On high concurrency systems, deadlock detection can cause a slowdown when numerous threads wait for the same lock. At times, it may be more efficient to disable deadlock detection and rely on the `innodb_lock_wait_timeout` setting for transaction rollback when a deadlock occurs. Deadlock detection can be disabled using the `innodb_deadlock_detect` variable.
Deadlocks in InnoDB

### 15.7.5.3 How to Minimize and Handle Deadlocks

This section builds on the conceptual information about deadlocks in Section 15.7.5.2, "Deadlock Detection". It explains how to organize database operations to minimize deadlocks and the subsequent error handling required in applications.

**Deadlocks** are a classic problem in transactional databases, but they are not dangerous unless they are so frequent that you cannot run certain transactions at all. Normally, you must write your applications so that they are always prepared to re-issue a transaction if it gets rolled back because of a deadlock.

InnoDB uses automatic row-level locking. You can get deadlocks even in the case of transactions that just insert or delete a single row. That is because these operations are not really "atomic"; they automatically set locks on the (possibly several) index records of the row inserted or deleted.

You can cope with deadlocks and reduce the likelihood of their occurrence with the following techniques:

- At any time, issue `SHOW ENGINE INNODB STATUS` to determine the cause of the most recent deadlock. That can help you to tune your application to avoid deadlocks.

- If frequent deadlock warnings cause concern, collect more extensive debugging information by enabling the `innodb_print_all_deadlocks` variable. Information about each deadlock, not just the latest one, is recorded in the MySQL error log. Disable this option when you are finished debugging.

- Always be prepared to re-issue a transaction if it fails due to deadlock. Deadlocks are not dangerous. Just try again.

- Keep transactions small and short in duration to make them less prone to collision.

- Commit transactions immediately after making a set of related changes to make them less prone to collision. In particular, do not leave an interactive `mysql` session open for a long time with an uncommitted transaction.

- If you use locking reads (`SELECT ... FOR UPDATE` or `SELECT ... FOR SHARE`), try using a lower isolation level such as `READ COMMITTED`.

- When modifying multiple tables within a transaction, or different sets of rows in the same table, do those operations in a consistent order each time. Then transactions form well-defined queues and do not deadlock. For example, organize database operations into functions within your application, or call stored routines, rather than coding multiple similar sequences of `INSERT`, `UPDATE`, and `DELETE` statements in different places.

- Add well-chosen indexes to your tables so that your queries scan fewer index records and set fewer locks. Use `EXPLAIN SELECT` to determine which indexes the MySQL server regards as the most appropriate for your queries.

- Use less locking. If you can afford to permit a `SELECT` to return data from an old snapshot, do not add a `FOR UPDATE` or `FOR SHARE` clause to it. Using the `READ COMMITTED` isolation level is good here, because each consistent read within the same transaction reads from its own fresh snapshot.

- If nothing else helps, serialize your transactions with table-level locks. The correct way to use `LOCK TABLES` with transactional tables, such as InnoDB tables, is to begin a transaction with `SET autocommit = 0` (not `START TRANSACTION`) followed by `LOCK TABLES`, and to not call `UNLOCK TABLES` until you commit the transaction explicitly. For example, if you need to write to table `t1` and read from table `t2`, you can do this:

```sql
SET autocommit=0;
LOCK TABLES t1 WRITE, t2 READ, ...;
```
... do something with tables t1 and t2 here ...
COMMIT;
UNLOCK TABLES;

Table-level locks prevent concurrent updates to the table, avoiding deadlocks at the expense of less responsiveness for a busy system.

- Another way to serialize transactions is to create an auxiliary “semaphore” table that contains just a single row. Have each transaction update that row before accessing other tables. In that way, all transactions happen in a serial fashion. Note that the InnoDB instant deadlock detection algorithm also works in this case, because the serializing lock is a row-level lock. With MySQL table-level locks, the timeout method must be used to resolve deadlocks.

### 15.7.6 Transaction Scheduling

InnoDB uses the Contention-Aware Transaction Scheduling (CATS) algorithm to prioritize transactions that are waiting for locks. When multiple transactions are waiting for a lock on the same object, the CATS algorithm determines which transaction receives the lock first.

The CATS algorithm prioritizes waiting transactions by assigning a scheduling weight, which is computed based on the number of transactions that a transaction blocks. For example, if two transactions are waiting for a lock on the same object, the transaction that blocks the most transactions is assigned a greater scheduling weight. If weights are equal, priority is given to the longest waiting transaction.

#### Note

Prior to MySQL 8.0.20, InnoDB also uses a First In First Out (FIFO) algorithm to schedule transactions, and the CATS algorithm is used under heavy lock contention only. CATS algorithm enhancements in MySQL 8.0.20 rendered the FIFO algorithm redundant, permitting its removal. Transaction scheduling previously performed by the FIFO algorithm is performed by the CATS algorithm as of MySQL 8.0.20. In some cases, this change may affect the order in which transactions are granted locks.

You can view transaction scheduling weights by querying the TRX_SCHEDULE_WEIGHT column in the Information Schema INNODB_TRX table. Weights are computed for waiting transactions only. Waiting transactions are those in a LOCK WAIT transaction execution state, as reported by the TRX_STATE column. A transaction that is not waiting for a lock reports a NULL TRX_SCHEDULE_WEIGHT value.

INNODB_METRICS counters are provided for monitoring of code-level transaction scheduling events. For information about using INNODB_METRICS counters, see Section 15.15.6, “InnoDB INFORMATION_SCHEMA Metrics Table”.

- **lock_rec_release_attempts**

  The number of attempts to release record locks. A single attempt may lead to zero or more record locks being released, as there may be zero or more record locks in a single structure.

- **lock_rec_grant_attempts**

  The number of attempts to grant record locks. A single attempt may result in zero or more record locks being granted.

- **lock_schedule_refreshes**

  The number of times the wait-for graph was analyzed to update the scheduled transaction weights.
15.8 InnoDB Configuration

This section provides configuration information and procedures for InnoDB initialization, startup, and various components and features of the InnoDB storage engine. For information about optimizing database operations for InnoDB tables, see Section 8.5, “Optimizing for InnoDB Tables”.

15.8.1 InnoDB Startup Configuration

The first decisions to make about InnoDB configuration involve the configuration of data files, log files, page size, and memory buffers, which should be configured before initializing InnoDB. Modifying the configuration after InnoDB is initialized may involve non-trivial procedures.

This section provides information about specifying InnoDB settings in a configuration file, viewing InnoDB initialization information, and important storage considerations.

- Specifying Options in a MySQL Option File
- Viewing InnoDB Initialization Information
- Important Storage Considerations
- System Tablespace Data File Configuration
- InnoDB Doublewrite Buffer File Configuration
- Redo Log Configuration
- Undo Tablespace Configuration
- Global Temporary Tablespace Configuration
- Session Temporary Tablespace Configuration
- Page Size Configuration
- Memory Configuration

Specifying Options in a MySQL Option File

Because MySQL uses data file, log file, and page size settings to initialize InnoDB, it is recommended that you define these settings in an option file that MySQL reads at startup, prior to initializing InnoDB. Normally, InnoDB is initialized when the MySQL server is started for the first time.

You can place InnoDB options in the [mysqld] group of any option file that your server reads when it starts. The locations of MySQL option files are described in Section 4.2.2.2, “Using Option Files”.

To make sure that mysqld reads options only from a specific file (and mysqld-auto.cnf), use the --defaults-file option as the first option on the command line when starting the server:

```
mysqld --defaults-file=path_to_option_file
```

Viewing InnoDB Initialization Information

To view InnoDB initialization information during startup, start mysqld from a command prompt, which prints initialization information to the console.

For example, on Windows, if mysqld is located in C:\Program Files\MySQL\MySQL Server 8.0\bin, start the MySQL server like this:

```
C:\> "C:\Program Files\MySQL\MySQL Server 8.0\bin\mysqld" --console
```
InnoDB Startup Configuration

On Unix-like systems, `mysqld` is located in the `bin` directory of your MySQL installation:

```
$> bin/mysqld --user=mysql &
```

If you do not send server output to the console, check the error log after startup to see the initialization information InnoDB printed during the startup process.

For information about starting MySQL using other methods, see Section 2.9.5, “Starting and Stopping MySQL Automatically”.

**Note**

InnoDB does not open all user tables and associated data files at startup. However, InnoDB does check for the existence of tablespace files referenced in the data dictionary. If a tablespace file is not found, InnoDB logs an error and continues the startup sequence. Tablespace files referenced in the redo log may be opened during crash recovery for redo application.

**Important Storage Considerations**

Review the following storage-related considerations before proceeding with your startup configuration.

- In some cases, you can improve database performance by placing data and log files on separate physical disks. You can also use raw disk partitions (raw devices) for InnoDB data files, which may speed up I/O. See Using Raw Disk Partitions for the System Tablespace.

- InnoDB is a transaction-safe (ACID compliant) storage engine with commit, rollback, and crash-recovery capabilities to protect user data. **However, it cannot do so** if the underlying operating system or hardware does not work as advertised. Many operating systems or disk subsystems may delay or reorder write operations to improve performance. On some operating systems, the very `fsync()` system call that should wait until all unwritten data for a file has been flushed might actually return before the data has been flushed to stable storage. Because of this, an operating system crash or a power outage may destroy recently committed data, or in the worst case, even corrupt the database because write operations have been reordered. If data integrity is important to you, perform “pull-the-plug” tests before using anything in production. On macOS, InnoDB uses a special `fcntl()` file flush method. Under Linux, it is advisable to disable the write-back cache.

- On ATA/SATA disk drives, a command such as `hdparm -W0 /dev/hda` may work to disable the write-back cache. **Beware that some drives or disk controllers may be unable to disable the write-back cache.**

- With regard to InnoDB recovery capabilities that protect user data, InnoDB uses a file flush technique involving a structure called the doublewrite buffer, which is enabled by default (`innodb_doublewrite=ON`). The doublewrite buffer adds safety to recovery following an unexpected exit or power outage, and improves performance on most varieties of Unix by reducing the need for `fsync()` operations. It is recommended that the `innodb_doublewrite` option remains enabled if you are concerned with data integrity or possible failures. For information about the doublewrite buffer, see Section 15.11.1, “InnoDB Disk I/O”.

- Before using NFS with InnoDB, review potential issues outlined in Using NFS with MySQL.

**System Tablespace Data File Configuration**

The `innodb_data_file_path` option defines the name, size, and attributes of InnoDB system tablespace data files. If you do not configure this option prior to initializing the MySQL server, the default behavior is to create a single auto-extending data file, slightly larger than 12MB, named `ibdata1`.
mysql> SHOW VARIABLES LIKE 'innodb_data_file_path';
+-----------------------+------------------------+
| Variable_name         | Value                  |
|-----------------------+------------------------+
| innodb_data_file_path | ibdata1:12M:autoextend |
+-----------------------+------------------------+

The full data file specification syntax includes the file name, file size, `autoextend` attribute, and `max` attribute:

```
file_name:file_size[:autoextend[:max:max_file_size]]
```

File sizes are specified in kilobytes, megabytes, or gigabytes by appending `K`, `M` or `G` to the size value. If specifying the data file size in kilobytes, do so in multiples of 1024. Otherwise, kilobyte values are rounded to nearest megabyte (MB) boundary. The sum of file sizes must be, at a minimum, slightly larger than 12MB.

You can specify more than one data file using a semicolon-separated list. For example:

```
[mysqld]
innodb_data_file_path=ibdata1:50M;ibdata2:50M:autoextend
```

The `autoextend` and `max` attributes can be used only for the data file that is specified last.

When the `autoextend` attribute is specified, the data file automatically increases in size by 64MB increments as space is required. The `innodb_autoextend_increment` variable controls the increment size.

To specify a maximum size for an auto-extending data file, use the `max` attribute following the `autoextend` attribute. Use the `max` attribute only in cases where constraining disk usage is of critical importance. The following configuration permits `ibdata1` to grow to a limit of 500MB:

```
[mysqld]
innodb_data_file_path=ibdata1:12M:autoextend:max:500M
```

A minimum file size is enforced for the first system tablespace data file to ensure that there is enough space for doublewrite buffer pages. The following table shows minimum file sizes for each InnoDB page size. The default InnoDB page size is 16384 (16KB).

<table>
<thead>
<tr>
<th>Page Size (innodb_page_size)</th>
<th>Minimum File Size</th>
</tr>
</thead>
<tbody>
<tr>
<td>16384 (16KB) or less</td>
<td>3MB</td>
</tr>
<tr>
<td>32768 (32KB)</td>
<td>6MB</td>
</tr>
<tr>
<td>65536 (64KB)</td>
<td>12MB</td>
</tr>
</tbody>
</table>

If your disk becomes full, you can add a data file on another disk. For instructions, see Resizing the System Tablespace.

The size limit for individual files is determined by your operating system. You can set the file size to more than 4GB on operating systems that support large files. You can also use raw disk partitions as data files. See Using Raw Disk Partitions for the System Tablespace.

InnoDB is not aware of the file system maximum file size, so be cautious on file systems where the maximum file size is a small value such as 2GB.

System tablespace files are created in the data directory by default (`datadir`). To specify an alternate location, use the `innodb_data_home_dir` option. For example, to create a system tablespace data file in a directory named `myibdata`, use this configuration:
InnoDB Startup Configuration

```
[mysqld]
innodb_data_home_dir = /myibdata/
innodb_data_file_path=ibdata1:50M:autoextend
```

A trailing slash is required when specifying a value for `innodb_data_home_dir`. InnoDB does not create directories, so ensure that the specified directory exists before you start the server. Also, ensure sure that the MySQL server has the proper access rights to create files in the directory.

InnoDB forms the directory path for each data file by textually concatenating the value of `innodb_data_home_dir` to the data file name. If `innodb_data_home_dir` is not defined, the default value is "/" , which is the data directory. (The MySQL server changes its current working directory to the data directory when it begins executing.)

Alternatively, you can specify an absolute path for system tablespace data files. The following configuration is equivalent to the preceding one:

```
[mysqld]
innodb_data_file_path=/myibdata/ibdata1:50M:autoextend
```

When you specify an absolute path for `innodb_data_file_path`, the setting is not concatenated with the `innodb_data_home_dir` setting. System tablespace files are created in the specified absolute path. The specified directory must exist before you start the server.

InnoDB Doublewrite Buffer File Configuration

As of MySQL 8.0.20, the doublewrite buffer storage area resides in doublewrite files, which provides flexibility with respect to the storage location of doublewrite pages. In previous releases, the doublewrite buffer storage area resided in the system tablespace. The `innodb_doublewrite_dir` variable defines the directory where InnoDB creates doublewrite files at startup. If no directory is specified, doublewrite files are created in the `innodb_data_home_dir` directory, which defaults to the data directory if unspecified.

To have doublewrite files created in a location other than the `innodb_data_home_dir` directory, configure `innodb_doublewrite_dir` variable. For example:

```
innodb_doublewrite_dir=/path/to/doublewrite_directory
```

Other doublewrite buffer variables permit defining the number of doublewrite files, the number of pages per thread, and the doublewrite batch size. For more information about doublewrite buffer configuration, see Section 15.6.4, “Doublewrite Buffer”.

Redo Log Configuration

From MySQL 8.0.30, the amount of disk space occupied by redo log files is controlled by the `innodb_redo_log_capacity` variable, which can be set at startup or runtime; for example, to set the variable to 8GB in an option file, add the following entry:

```
[mysqld]
innodb_redo_log_capacity = 8589934592
```

For information about configuring redo log capacity at runtime, see Configuring Redo Log Capacity (MySQL 8.0.30 or Higher).

The `innodb_redo_log_capacity` variable supersedes the `innodb_log_file_size` and `innodb_log_files_in_group` variables, which are deprecated. When the `innodb_redo_log_capacity` setting is defined, the `innodb_log_file_size` and `innodb_log_files_in_group` settings are ignored; otherwise, these settings are used to compute the
InnoDB Startup Configuration

\texttt{innodb\_redo\_log\_capacity} setting \((\text{innodb\_log\_files\_in\_group}\ast\text{innodb\_log\_file\_size} = \text{innodb\_redo\_log\_capacity})\). If none of those variables are set, \texttt{innodb\_redo\_log\_capacity} is set to the default value, which is 104857600 bytes (100MB). The maximum setting is 128GB.

From MySQL 8.0.30, InnoDB attempts to maintain 32 redo log files, with each file equal to \(\frac{1}{32}\ast\text{innodb\_redo\_log\_capacity}\). The redo log files reside in the \#innodb\_redo directory in the data directory unless a different directory was specified by the \texttt{innodb\_log\_group\_home\_dir} variable. If \texttt{innodb\_log\_group\_home\_dir} was defined, the redo log files reside in the \#innodb\_redo directory in that directory. For more information, see Section 15.6.5, “Redo Log”.

Before MySQL 8.0.30, InnoDB creates two 5MB redo log files named \texttt{ib\_logfile0} and \texttt{ib\_logfile1} in the data directory by default. You can define a different number of redo log files and different redo log file size when initializing the MySQL Server instance by configuring the \texttt{innodb\_log\_files\_in\_group} and \texttt{innodb\_log\_file\_size} variables.

\begin{itemize}
\item \texttt{innodb\_log\_files\_in\_group} defines the number of log files in the log group. The default and recommended value is 2.
\item \texttt{innodb\_log\_file\_size} defines the size in bytes of each log file in the log group. The combined log file size \((\text{innodb\_log\_file\_size}\ast\text{innodb\_log\_files\_in\_group})\) cannot exceed the maximum value, which is slightly less than 512GB. A pair of 255 GB log files, for example, approaches the limit but does not exceed it. The default log file size is 48MB. Generally, the combined size of the log files should be large enough that the server can smooth out peaks and troughs in workload activity, which often means that there is enough redo log space to handle more than an hour of write activity. A larger log file size means less checkpoint flush activity in the buffer pool, which reduces disk I/O. For additional information, see Section 8.5.4, “Optimizing InnoDB Redo Logging”.
\end{itemize}

The \texttt{innodb\_log\_group\_home\_dir} defines directory path to the InnoDB log files. You might use this option to place InnoDB redo log files in a different physical storage location than InnoDB data files to avoid potential I/O resource conflicts; for example:

\begin{verbatim}
[mysqld]
innodb\_log\_group\_home\_dir = /dr3/iblogs
\end{verbatim}

\textbf{Note}

InnoDB does not create directories, so make sure that the log directory exists before you start the server. Use the Unix or DOS \texttt{mkdir} command to create any necessary directories.

Make sure that the MySQL server has the proper access rights to create files in the log directory. More generally, the server must have access rights in any directory where it needs to create files.

Undo Tablespace Configuration

Undo logs, by default, reside in two undo tablespaces created when the MySQL instance is initialized.

The \texttt{innodb\_undo\_directory} variable defines the path where InnoDB creates default undo tablespaces. If that variable is undefined, default undo tablespaces are created in the data directory. The \texttt{innodb\_undo\_directory} variable is not dynamic. Configuring it requires restarting the server.

The I/O patterns for undo logs make undo tablespaces good candidates for SSD storage.

For information about configuring additional undo tablespaces, see Section 15.6.3.4, “Undo Tablespaces”.
Global Temporary Tablespace Configuration

The global temporary tablespace stores rollback segments for changes made to user-created temporary tables.

A single auto-extending global temporary tablespace data file named `ibtmp1` in the `innodb_data_home_dir` directory by default. The initial file size is slightly larger than 12MB.

The `innodb_temp_data_file_path` option specifies the path, file name, and file size for global temporary tablespace data files. File size is specified in KB, MB, or GB by appending K, M, or G to the size value. The file size or combined file size must be slightly larger than 12MB.

To specify an alternate location for global temporary tablespace data files, configure the `innodb_temp_data_file_path` option at startup.

Session Temporary Tablespace Configuration

In MySQL 8.0.15 and earlier, session temporary tablespaces store user-created temporary tables and internal temporary tables created by the optimizer when InnoDB is configured as the on-disk storage engine for internal temporary tables (`internal_tmp_disk_storage_engine=InnoDB`). From MySQL 8.0.16, InnoDB is always used as the on-disk storage engine for internal temporary tables.

The `innodb_temp_tablespaces_dir` variable defines the location where InnoDB creates session temporary tablespaces. The default location is the `#innodb_temp` directory in the data directory.

To specify an alternate location for session temporary tablespaces, configure the `innodb_temp_tablespaces_dir` variable at startup. A fully qualified path or path relative to the data directory is permitted.

Page Size Configuration

The `innodb_page_size` option specifies the page size for all InnoDB tablespaces in a MySQL instance. This value is set when the instance is created and remains constant afterward. Valid values are 64KB, 32KB, 16KB (the default), 8KB, and 4KB. Alternatively, you can specify page size in bytes (65536, 32768, 16384, 8192, 4096).

The default 16KB page size is appropriate for a wide range of workloads, particularly for queries involving table scans and DML operations involving bulk updates. Smaller page sizes might be more efficient for OLTP workloads involving many small writes, where contention can be an issue when a single page contains many rows. Smaller pages can also be more efficient for SSD storage devices, which typically use small block sizes. Keeping the InnoDB page size close to the storage device block size minimizes the amount of unchanged data that is rewritten to disk.

Memory Configuration

MySQL allocates memory to various caches and buffers to improve performance of database operations. When allocating memory for InnoDB, always consider memory required by the operating system, memory allocated to other applications, and memory allocated for other MySQL buffers and caches. For example, if you use MyISAM tables, consider the amount of memory allocated for the key buffer (`key_buffer_size`). For an overview of MySQL buffers and caches, see Section 8.12.3.1, “How MySQL Uses Memory”.

Buffers specific to InnoDB are configured using the following parameters:

- `innodb_buffer_pool_size` defines size of the buffer pool, which is the memory area that holds cached data for InnoDB tables, indexes, and other auxiliary buffers. The size of the buffer pool is important for system performance, and it is typically recommended that `innodb_buffer_pool_size`
is configured to 50 to 75 percent of system memory. The default buffer pool size is 128MB. For additional guidance, see Section 8.12.3.1, “How MySQL Uses Memory”. For information about how to configure InnoDB buffer pool size, see Section 15.8.3.1, “Configuring InnoDB Buffer Pool Size”. Buffer pool size can be configured at startup or dynamically.

On systems with a large amount of memory, you can improve concurrency by dividing the buffer pool into multiple buffer pool instances. The number of buffer pool instances is controlled by the by_innodb_buffer_pool_instances option. By default, InnoDB creates one buffer pool instance. The number of buffer pool instances can be configured at startup. For more information, see Section 15.8.3.2, “Configuring Multiple Buffer Pool Instances”.

• innodb_log_buffer_size defines the size of the buffer that InnoDB uses to write to the log files on disk. The default size is 16MB. A large log buffer enables large transactions to run without writing the log to disk before the transactions commit. If you have transactions that update, insert, or delete many rows, you might consider increasing the size of the log buffer to save disk I/O. innodb_log_buffer_size can be configured at startup. For related information, see Section 8.5.4, “Optimizing InnoDB Redo Logging”.

Warning

On 32-bit GNU/Linux x86, if memory usage is set too high, glibc may permit the process heap to grow over the thread stacks, causing a server failure. It is a risk if the memory allocated to the mysqld process for global and per-thread buffers and caches is close to or exceeds 2GB.

A formula similar to the following that calculates global and per-thread memory allocation for MySQL can be used to estimate MySQL memory usage. You may need to modify the formula to account for buffers and caches in your MySQL version and configuration. For an overview of MySQL buffers and caches, see Section 8.12.3.1, “How MySQL Uses Memory”.

```
innodb_buffer_pool_size
+ key_buffer_size
+ max_connections*(sort_buffer_size+read_buffer_size+binlog_cache_size)
+ max_connections*2MB
```

Each thread uses a stack (often 2MB, but only 256KB in MySQL binaries provided by Oracle Corporation,) and in the worst case also uses sort_buffer_size + read_buffer_size additional memory.

On Linux, if the kernel is enabled for large page support, InnoDB can use large pages to allocate memory for its buffer pool. See Section 8.12.3.3, “Enabling Large Page Support”.

15.8.2 Configuring InnoDB for Read-Only Operation

You can query InnoDB tables where the MySQL data directory is on read-only media by enabling the --innodb-read-only configuration option at server startup.

How to Enable

To prepare an instance for read-only operation, make sure all the necessary information is flushed to the data files before storing it on the read-only medium. Run the server with change buffering disabled (innodb_change_buffering=0) and do a slow shutdown.

To enable read-only mode for an entire MySQL instance, specify the following configuration options at server startup:
Configuring InnoDB for Read-Only Operation

- `--innodb-read-only=1`

- If the instance is on read-only media such as a DVD or CD, or the `/var` directory is not writeable by all: `--pid-file=path_on_writeable_media` and `--event-scheduler=disabled`

- `--innodb-temp-data-file-path`. This option specifies the path, file name, and file size for InnoDB temporary tablespace data files. The default setting is `ibtmp1:12M:autoextend`, which creates the `ibtmp1` temporary tablespace data file in the data directory. To prepare an instance for read-only operation, set `innodb_temp_data_file_path` to a location outside of the data directory. The path must be relative to the data directory. For example:

  ```
  --innodb-temp-data-file-path=./../../../tmp/ibtmp1:12M:autoextend
  ```

As of MySQL 8.0, enabling `innodb_read_only` prevents table creation and drop operations for all storage engines. These operations modify data dictionary tables in the `mysql` system database, but those tables use the InnoDB storage engine and cannot be modified when `innodb_read_only` is enabled. The same restriction applies to any operation that modifies data dictionary tables, such as `ANALYZE TABLE` and `ALTER TABLE tbl_name ENGINE=engine_name`.

In addition, other tables in the `mysql` system database use the InnoDB storage engine in MySQL 8.0. Making those tables read only results in restrictions on operations that modify them. For example, `CREATE USER`, `GRANT`, `REVOKE`, and `INSTALL PLUGIN` operations are not permitted in read-only mode.

Usage Scenarios

This mode of operation is appropriate in situations such as:

- Distributing a MySQL application, or a set of MySQL data, on a read-only storage medium such as a DVD or CD.

- Multiple MySQL instances querying the same data directory simultaneously, typically in a data warehousing configuration. You might use this technique to avoid bottlenecks that can occur with a heavily loaded MySQL instance, or you might use different configuration options for the various instances to tune each one for particular kinds of queries.

- Querying data that has been put into a read-only state for security or data integrity reasons, such as archived backup data.

  **Note**

  This feature is mainly intended for flexibility in distribution and deployment, rather than raw performance based on the read-only aspect. See Section 8.5.3, “Optimizing InnoDB Read-Only Transactions” for ways to tune the performance of read-only queries, which do not require making the entire server read-only.

How It Works

When the server is run in read-only mode through the `--innodb-read-only` option, certain InnoDB features and components are reduced or turned off entirely:

- No change buffering is done, in particular no merges from the change buffer. To make sure the change buffer is empty when you prepare the instance for read-only operation, disable change buffering (`innodb_change_buffering=0`) and do a slow shutdown first.

- There is no crash recovery phase at startup. The instance must have performed a slow shutdown before being put into the read-only state.
• Because the redo log is not used in read-only operation, you can set `innodb_log_file_size` to the smallest size possible (1 MB) before making the instance read-only.

• Most background threads are turned off. I/O read threads remain, as well as I/O write threads and a page flush coordinator thread for writes to temporary files, which are permitted in read-only mode. A buffer pool resize thread also remains active to enable online resizing of the buffer pool.

• Information about deadlocks, monitor output, and so on is not written to temporary files. As a consequence, `SHOW ENGINE INNODB STATUS` does not produce any output.

• Changes to configuration option settings that would normally change the behavior of write operations, have no effect when the server is in read-only mode.

• The MVCC processing to enforce isolation levels is turned off. All queries read the latest version of a record, because update and deletes are not possible.

• The undo log is not used. Disable any settings for the `innodb_undo_tablespaces` and `innodb_undo_directory` configuration options.

15.8.3 InnoDB Buffer Pool Configuration

This section provides configuration and tuning information for the InnoDB buffer pool.

15.8.3.1 Configuring InnoDB Buffer Pool Size

You can configure InnoDB buffer pool size offline or while the server is running. Behavior described in this section applies to both methods. For additional information about configuring buffer pool size online, see Configuring InnoDB Buffer Pool Size Online.

When increasing or decreasing `innodb_buffer_pool_size`, the operation is performed in chunks. Chunk size is defined by the `innodb_buffer_pool_chunk_size` configuration option, which has a default of 128M. For more information, see Configuring InnoDB Buffer Pool Chunk Size.

Buffer pool size must always be equal to or a multiple of `innodb_buffer_pool_chunk_size * innodb_buffer_pool_instances`. If you configure `innodb_buffer_pool_size` to a value that is not equal to or a multiple of `innodb_buffer_pool_chunk_size * innodb_buffer_pool_instances`, buffer pool size is automatically adjusted to a value that is equal to or a multiple of `innodb_buffer_pool_chunk_size * innodb_buffer_pool_instances`.

In the following example, `innodb_buffer_pool_size` is set to 8G, and `innodb_buffer_pool_instances` is set to 16. `innodb_buffer_pool_chunk_size` is 128M, which is the default value.

8G is a valid `innodb_buffer_pool_size` value because 8G is a multiple of
`innodb_buffer_pool_instances=16 * innodb_buffer_pool_chunk_size=128M`, which is 2G.

```sql
$> mysqld --innodb-buffer-pool-size=8G --innodb-buffer-pool-instances=16
```

In this example, `innodb_buffer_pool_size` is set to 9G, and `innodb_buffer_pool_instances` is set to 16. `innodb_buffer_pool_chunk_size` is 128M, which is the default.
value. In this case, 9G is not a multiple of `innodb_buffer_pool_instances=16 * inodb_buffer_pool_chunk_size=128M`, so `innodb_buffer_pool_size` is adjusted to 10G, which is a multiple of `innodb_buffer_pool_chunk_size * inodb_buffer_pool_instances`.

```
$> mysqld --innodb-buffer-pool-size=9G --innodb-buffer-pool-instances=16
```

### Configuring InnoDB Buffer Pool Chunk Size

`innodb_buffer_pool_chunk_size` can be increased or decreased in 1MB (1048576 byte) units but can only be modified at startup, in a command line string or in a MySQL configuration file.

**Command line:**

```
$> mysqld --innodb-buffer-pool-chunk-size=134217728
```

**Configuration file:**

```
[mysqld]
inodb_buffer_pool_chunk_size=134217728
```

The following conditions apply when altering `innodb_buffer_pool_chunk_size`:

- If the new `innodb_buffer_pool_chunk_size` value * `innodb_buffer_pool_instances` is larger than the current buffer pool size when the buffer pool is initialized, `innodb_buffer_pool_chunk_size` is truncated to `innodb_buffer_pool_size / innodb_buffer_pool_instances`.

For example, if the buffer pool is initialized with a size of 2GB (2147483648 bytes), 4 buffer pool instances, and a chunk size of 1GB (1073741824 bytes), chunk size is truncated to a value equal to `innodb_buffer_pool_size / innodb_buffer_pool_instances`, as shown below:

```
$> mysqld --innodb-buffer-pool-size=2147483648 --innodb-buffer-pool-instances=4
--innodb-buffer-pool-chunk-size=1073741824;
```

```
mysql> SELECT @@innodb_buffer_pool_size;
+---------------------------+
| @@innodb_buffer_pool_size |
+---------------------------+
|                2147483648 |
+---------------------------+

mysql> SELECT @@innodb_buffer_pool_instances;
+--------------------------------+
| @@innodb_buffer_pool_instances |
+--------------------------------+
|                              4 |
+--------------------------------+

# Chunk size was set to 1GB (1073741824 bytes) on startup but was truncated to innodb_buffer_pool_size / innodb_buffer_pool_instances

mysql> SELECT @@innodb_buffer_pool_chunk_size;
+---------------------------------+
| @@innodb_buffer_pool_chunk_size |
+---------------------------------+
```
InnoDB Buffer Pool Configuration

- Buffer pool size must always be equal to or a multiple of `innodb_buffer_pool_chunk_size * innodb_buffer_pool_instances`. If you alter `innodb_buffer_pool_chunk_size`, `innodb_buffer_pool_size` is automatically adjusted to a value that is equal to or a multiple of `innodb_buffer_pool_chunk_size * innodb_buffer_pool_instances`. The adjustment occurs when the buffer pool is initialized. This behavior is demonstrated in the following example:

```
# The buffer pool has a default size of 128MB (134217728 bytes)
mysql> SELECT @@innodb_buffer_pool_size;
+---------------------------+
| @@innodb_buffer_pool_size |
+---------------------------+
|                 134217728 |
+---------------------------+
# The chunk size is also 128MB (134217728 bytes)
mysql> SELECT @@innodb_buffer_pool_chunk_size;
+---------------------------------+
| @@innodb_buffer_pool_chunk_size |
+---------------------------------+
|                       134217728 |
+---------------------------------+
# There is a single buffer pool instance
mysql> SELECT @@innodb_buffer_pool_instances;
+--------------------------------+
| @@innodb_buffer_pool_instances |
+--------------------------------+
|                              1 |
+--------------------------------+
# Chunk size is decreased by 1MB (1048576 bytes) at startup
# (134217728 - 1048576 = 133169152):
$> mysqld --innodb-buffer-pool-chunk-size=133169152
mysql> SELECT @@innodb_buffer_pool_chunk_size;
+---------------------------------+
| @@innodb_buffer_pool_chunk_size |
+---------------------------------+
|                       133169152 |
+---------------------------------+
# Buffer pool size increases from 134217728 to 266338304
# Buffer pool size is automatically adjusted to a value that is equal to
# or a multiple of `innodb_buffer_pool_chunk_size * innodb_buffer_pool_instances`
mysql> SELECT @@innodb_buffer_pool_size;
+---------------------------+
| @@innodb_buffer_pool_size |
+---------------------------+
|                 266338304 |
+---------------------------+
```

This example demonstrates the same behavior but with multiple buffer pool instances:

```
# The buffer pool has a default size of 2GB (2147483648 bytes)
mysql> SELECT @@innodb_buffer_pool_size;
+---------------------------+
| @@innodb_buffer_pool_size |
+---------------------------+
|                 2147483648 |
+---------------------------+
```
InnoDB Buffer Pool Configuration

The chunk size is .5 GB (536870912 bytes)

mysql> SELECT @@innodb_buffer_pool_chunk_size;
+---------------------------------+
| @@innodb_buffer_pool_chunk_size |
| 536870912                       |
+---------------------------------+

There are 4 buffer pool instances

mysql> SELECT @@innodb_buffer_pool_instances;
+--------------------------------+
| @@innodb_buffer_pool_instances |
| 4                               |
+--------------------------------+

Chunk size is decreased by 1MB (1048576 bytes) at startup

(536870912 - 1048576 = 535822336):

$> mysqld --innodb-buffer-pool-chunk-size=535822336

Buffer pool size increases from 2147483648 to 4286578688

Buffer pool size is automatically adjusted to a value that is equal to
or a multiple of innodb_buffer_pool_chunk_size * innodb_buffer_pool_instances

mysql> SELECT @@innodb_buffer_pool_size;
+---------------------------+
| @@innodb_buffer_pool_size |
| 4286578688                |
+---------------------------+

Care should be taken when changing innodb_buffer_pool_chunk_size, as changing this value can increase the size of the buffer pool, as shown in the examples above. Before you change innodb_buffer_pool_chunk_size, calculate the effect on innodb_buffer_pool_size to ensure that the resulting buffer pool size is acceptable.

Note

To avoid potential performance issues, the number of chunks (innodb_buffer_pool_size / innodb_buffer_pool_chunk_size) should not exceed 1000.

Configuring InnoDB Buffer Pool Size Online

The innodb_buffer_pool_size configuration option can be set dynamically using a SET statement, allowing you to resize the buffer pool without restarting the server. For example:

mysql> SET GLOBAL innodb_buffer_pool_size=402653184;
InnoDB Buffer Pool Configuration

Note
The buffer pool size must be equal to or a multiple of
\[ \text{innodb_buffer_pool_chunk_size} \times \text{innodb_buffer_pool_instances}. \]
Changing those variable settings requires restarting the server.

Active transactions and operations performed through InnoDB APIs should be completed before resizing the buffer pool. When initiating a resizing operation, the operation does not start until all active transactions are completed. Once the resizing operation is in progress, new transactions and operations that require access to the buffer pool must wait until the resizing operation finishes. The exception to the rule is that concurrent access to the buffer pool is permitted while the buffer pool is defragmented and pages are withdrawn when buffer pool size is decreased. A drawback of allowing concurrent access is that it could result in a temporary shortage of available pages while pages are being withdrawn.

Note
Nested transactions could fail if initiated after the buffer pool resizing operation begins.

Monitoring Online Buffer Pool Resizing Progress

The \texttt{Innodb_buffer_pool_resize_status} variable reports a string value indicating buffer pool resizing progress; for example:

```
mysql> SHOW STATUS WHERE Variable_name='InnoDB_buffer_pool_resize_status';
+---------------------------------+----------------------------------+
| Variable_name                    | Value                            |
+---------------------------------+----------------------------------+
| Innodb_buffer_pool_resize_status | Resizing also other hash tables.  |
+---------------------------------+----------------------------------+
```

From MySQL 8.0.31, you can also monitor an online buffer pool resizing operation using the \texttt{Innodb_buffer_pool_resize_status_code} and \texttt{Innodb_buffer_pool_resize_status_progress} status variables, which report numeric values, preferable for programmatic monitoring.

The \texttt{Innodb_buffer_pool_resize_status_code} status variable reports a status code indicating the stage of an online buffer pool resizing operation. Status codes include:

- 0: No Resize operation in progress
- 1: Starting Resize
- 2: Disabling AHI (Adaptive Hash Index)
- 3: Withdrawing Blocks
- 4: Acquiring Global Lock
- 5: Resizing Pool
- 6: Resizing Hash
- 7: Resizing Failed

The \texttt{Innodb_buffer_pool_resize_status_progress} status variable reports a percentage value indicating the progress of each stage. The percentage value is updated after each buffer pool instance is...
InnoDB Buffer Pool Configuration

processed. As the status (reported by `innodb_buffer_pool_resize_status_code`) changes from one status to another, the percentage value is reset to 0.

The following query returns a string value indicating the buffer pool resizing progress, a code indicating the current stage of the operation, and the current progress of that stage, expressed as a percentage value:

```
SELECT variable_name, variable_value
FROM performance_schema.global_status
WHERE LOWER(variable_name) LIKE "innodb_buffer_pool_resize%";
```

Buffer pool resizing progress is also visible in the server error log. This example shows notes that are logged when increasing the size of the buffer pool:

```
[Note] InnoDB: Resizing buffer pool from 134217728 to 4294967296. (unit=134217728)
[Note] InnoDB: disabled adaptive hash index.
[Note] InnoDB: buffer pool 0 : 31 chunks (253952 blocks) was added.
[Note] InnoDB: buffer pool 0 : hash tables were resized.
[Note] InnoDB: Resized hash tables at lock_sys, adaptive hash index, dictionary.
[Note] InnoDB: completed to resize buffer pool from 134217728 to 4294967296.
[Note] InnoDB: re-enabled adaptive hash index.
```

This example shows notes that are logged when decreasing the size of the buffer pool:

```
[Note] InnoDB: Resizing buffer pool from 4294967296 to 134217728. (unit=134217728)
[Note] InnoDB: disabled adaptive hash index.
[Note] InnoDB: buffer pool 0 : start to withdraw the last 253952 blocks.
[Note] InnoDB: buffer pool 0 : withdrew 253952 blocks from free list. tried to relocate 0 pages. (253952/253952)
[Note] InnoDB: buffer pool 0 : withdrawn target 253952 blocks.
[Note] InnoDB: buffer pool 0 : 31 chunks (253952 blocks) was freed.
[Note] InnoDB: buffer pool 0 : hash tables were resized.
[Note] InnoDB: Resized hash tables at lock_sys, adaptive hash index, dictionary.
[Note] InnoDB: completed to resize buffer pool from 4294967296 to 134217728.
[Note] InnoDB: re-enabled adaptive hash index.
```

From MySQL 8.0.31, starting the server with `--log-error-verbosity=3` logs additional information to the error log during an online buffer pool resizing operation. Additional information includes the status codes reported by `innodb_buffer_pool_resize_status_code` and the percentage progress value reported by `innodb_buffer_pool_resize_status_progress`.

```
[Note] [MY-012398] [InnoDB] Requested to resize buffer pool. (new size: 1073741824 bytes)
[Note] [MY-013954] [InnoDB] Status code 1: Resizing buffer pool from 134217728 to 1073741824 (unit=134217728).
[Note] [MY-013951] [InnoDB] Status code 1: 100% complete

```
InnoDB Buffer Pool Configuration

Online Buffer Pool Resizing Internals

The resizing operation is performed by a background thread. When increasing the size of the buffer pool, the resizing operation:

- Adds pages in chunks (chunk size is defined by `innodb_buffer_pool_chunk_size`)
- Converts hash tables, lists, and pointers to use new addresses in memory
- Adds new pages to the free list

While these operations are in progress, other threads are blocked from accessing the buffer pool.

When decreasing the size of the buffer pool, the resizing operation:

- Defragments the buffer pool and withdraws (frees) pages
- Removes pages in chunks (chunk size is defined by `innodb_buffer_pool_chunk_size`)
- Converts hash tables, lists, and pointers to use new addresses in memory

Of these operations, only defragmenting the buffer pool and withdrawing pages allow other threads to access to the buffer pool concurrently.

15.8.3.2 Configuring Multiple Buffer Pool Instances

For systems with buffer pools in the multi-gigabyte range, dividing the buffer pool into separate instances can improve concurrency, by reducing contention as different threads read and write to cached pages. This feature is typically intended for systems with a buffer pool size in the multi-gigabyte range. Multiple buffer pool instances are configured using the `innodb_buffer_pool_instances` configuration option, and you might also adjust the `innodb_buffer_pool_size` value.

When the InnoDB buffer pool is large, many data requests can be satisfied by retrieving from memory. You might encounter bottlenecks from multiple threads trying to access the buffer pool at once. You can enable multiple buffer pools to minimize this contention. Each page that is stored in or read from the buffer pool is assigned to one of the buffer pools randomly, using a hashing function. Each buffer pool manages its own free lists, flush lists, LRUs, and all other data structures connected to a buffer pool. Prior to MySQL 8.0, each buffer pool was protected by its own buffer pool mutex. In MySQL 8.0 and later, the buffer pool mutex was replaced by several list and hash protecting mutexes, to reduce contention.

To enable multiple buffer pool instances, set the `innodb_buffer_pool_instances` configuration option to a value greater than 1 (the default) up to 64 (the maximum). This option takes effect only when you set `innodb_buffer_pool_size` to a size of 1GB or more. The total size you specify is divided among all the buffer pools. For best efficiency, specify a combination of `innodb_buffer_pool_instances` and `innodb_buffer_pool_size` so that each buffer pool instance is at least 1GB.
InnoDB Buffer Pool Configuration

For information about modifying InnoDB buffer pool size, see Section 15.8.3.1, “Configuring InnoDB Buffer Pool Size”.

### 15.8.3.3 Making the Buffer Pool Scan Resistant

Rather than using a strict LRU algorithm, InnoDB uses a technique to minimize the amount of data that is brought into the buffer pool and never accessed again. The goal is to make sure that frequently accessed (“hot”) pages remain in the buffer pool, even as read-ahead and full table scans bring in new blocks that might or might not be accessed afterward.

Newly read blocks are inserted into the middle of the LRU list. All newly read pages are inserted at a location that by default is \( \frac{3}{8} \) from the tail of the LRU list. The pages are moved to the front of the list (the most-recently used end) when they are accessed in the buffer pool for the first time. Thus, pages that are never accessed never make it to the front portion of the LRU list, and “age out” sooner than with a strict LRU approach. This arrangement divides the LRU list into two segments, where the pages downstream of the insertion point are considered “old” and are desirable victims for LRU eviction.

For an explanation of the inner workings of the InnoDB buffer pool and specifics about the LRU algorithm, see Section 15.5.1, “Buffer Pool”.

You can control the insertion point in the LRU list and choose whether InnoDB applies the same optimization to blocks brought into the buffer pool by table or index scans. The configuration parameter `innodb_old_blocks_pct` controls the percentage of “old” blocks in the LRU list. The default value of `innodb_old_blocks_pct` is 37, corresponding to the original fixed ratio of 3/8. The value range is 5 (new pages in the buffer pool age out very quickly) to 95 (only 5% of the buffer pool is reserved for hot pages, making the algorithm close to the familiar LRU strategy).

The optimization that keeps the buffer pool from being churned by read-ahead can avoid similar problems due to table or index scans. In these scans, a data page is typically accessed a few times in quick succession and is never touched again. The configuration parameter `innodb_old_blocks_time` specifies the time window (in milliseconds) after the first access to a page during which it can be accessed without being moved to the front (most-recently used end) of the LRU list. The default value of `innodb_old_blocks_time` is 1000. Increasing this value makes more and more blocks likely to age out faster from the buffer pool.

Both `innodb_old_blocks_pct` and `innodb_old_blocks_time` can be specified in the MySQL option file (`my.cnf` or `my.ini`) or changed at runtime with the `SET GLOBAL` statement. Changing the value at runtime requires privileges sufficient to set global system variables. See Section 5.1.9.1, “System Variable Privileges”.

To help you gauge the effect of setting these parameters, the `SHOW ENGINE INNODB STATUS` command reports buffer pool statistics. For details, see Monitoring the Buffer Pool Using the InnoDB Standard Monitor.

Because the effects of these parameters can vary widely based on your hardware configuration, your data, and the details of your workload, always benchmark to verify the effectiveness before changing these settings in any performance-critical or production environment.

In mixed workloads where most of the activity is OLTP type with periodic batch reporting queries which result in large scans, setting the value of `innodb_old_blocks_time` during the batch runs can help keep the working set of the normal workload in the buffer pool.

When scanning large tables that cannot fit entirely in the buffer pool, setting `innodb_old_blocks_pct` to a small value keeps the data that is only read once from consuming a significant portion of the buffer pool. For example, setting `innodb_old_blocks_pct=5` restricts this data that is only read once to 5% of the buffer pool.
InnoDB Buffer Pool Configuration

When scanning small tables that do fit into memory, there is less overhead for moving pages around within
the buffer pool, so you can leave innodb_old_blocks_pct at its default value, or even higher, such as
innodb_old_blocks_pct=50.

The effect of the innodb_old_blocks_time parameter is harder to predict than the
innodb_old_blocks_pct parameter, is relatively small, and varies more with the workload. To arrive
at an optimal value, conduct your own benchmarks if the performance improvement from adjusting
innodb_old_blocks_pct is not sufficient.

15.8.3.4 Configuring InnoDB Buffer Pool Prefetching (Read-Ahead)

A read-ahead request is an I/O request to prefetch multiple pages in the buffer pool asynchronously, in
anticipation of impending need for these pages. The requests bring in all the pages in one extent. InnoDB
uses two read-ahead algorithms to improve I/O performance:

Linear read-ahead is a technique that predicts what pages might be needed soon based on pages in
the buffer pool being accessed sequentially. You control when InnoDB performs a read-ahead operation
by adjusting the number of sequential page accesses required to trigger an asynchronous read request,
using the configuration parameter innodb_read_ahead_threshold. Before this parameter was added,
InnoDB would only calculate whether to issue an asynchronous prefetch request for the entire next extent
when it read the last page of the current extent.

The configuration parameter innodb_read_ahead_threshold controls how sensitive InnoDB is in
detecting patterns of sequential page access. If the number of pages read sequentially from an extent is
greater than or equal to innodb_read_ahead_threshold, InnoDB initiates an asynchronous read-ahead operation of the entire following extent. innodb_read_ahead_threshold can be set to any value from 0-64. The default value is 56. The higher the value, the more strict the access pattern check. For example, if you set the value to 48, InnoDB triggers a linear read-ahead request only when 48 pages in the current extent have been accessed sequentially. If the value is 8, InnoDB triggers an asynchronous read-ahead even if as few as 8 pages in the extent are accessed sequentially. You can set the value of this parameter in the MySQL configuration file, or change it dynamically with the SET GLOBAL statement, which requires privileges sufficient to set global system variables. See Section 5.1.9.1, “System Variable Privileges”.

Random read-ahead is a technique that predicts when pages might be needed soon based on pages
already in the buffer pool, regardless of the order in which those pages were read. If 13 consecutive
pages from the same extent are found in the buffer pool, InnoDB asynchronously issues a request
to prefetch the remaining pages of the extent. To enable this feature, set the configuration variable
innodb_random_read_ahead to ON.

The SHOW ENGINE INNODB STATUS command displays statistics to help you evaluate the effectiveness
of the read-ahead algorithm. Statistics include counter information for the following global status variables:

- Innodb_buffer_pool_read_ahead
- Innodb_buffer_pool_read_ahead_evicted
- Innodb_buffer_pool_read_ahead_rnd

This information can be useful when fine-tuning the innodb_random_read_ahead setting.

For more information about I/O performance, see Section 8.5.8, “Optimizing InnoDB Disk I/O” and
Section 8.12.1, “Optimizing Disk I/O”.

15.8.3.5 Configuring Buffer Pool Flushing
InnoDB performs certain tasks in the background, including flushing of dirty pages from the buffer pool. Dirty pages are those that have been modified but are not yet written to the data files on disk.

In MySQL 8.0, buffer pool flushing is performed by page cleaner threads. The number of page cleaner threads is controlled by the `innodb_page_cleaners` variable, which has a default value of 4. However, if the number of page cleaner threads exceeds the number of buffer pool instances, `innodb_page_cleaners` is automatically set to the same value as `innodb_buffer_pool_instances`.

Buffer pool flushing is initiated when the percentage of dirty pages reaches the low water mark value defined by the `innodb_max_dirty_pages_pct_lwm` variable. The default low water mark is 10% of buffer pool pages. A `innodb_max_dirty_pages_pct_lwm` value of 0 disables this early flushing behaviour.

The purpose of the `innodb_max_dirty_pages_pct_lwm` threshold is to control the percentage dirty pages in the buffer pool and to prevent the amount of dirty pages from reaching the threshold defined by the `innodb_max_dirty_pages_pct` variable, which has a default value of 90. InnoDB aggressively flushes buffer pool pages if the percentage of dirty pages in the buffer pool reaches the `innodb_max_dirty_pages_pct` threshold.

When configuring `innodb_max_dirty_pages_pct_lwm`, the value should always be lower than the `innodb_max_dirty_pages_pct` value.

Additional variables permit fine-tuning of buffer pool flushing behavior:

- The `innodb_flush_neighbors` variable defines whether flushing a page from the buffer pool also flushes other dirty pages in the same extent.
  - The default setting of 0 disables `innodb_flush_neighbors`. Dirty pages in the same extent are not flushed. This setting is recommended for non-rotational storage (SSD) devices where seek time is not a significant factor.
  - A setting of 1 flushes contiguous dirty pages in the same extent.
  - A setting of 2 flushes dirty pages in the same extent.

When table data is stored on a traditional HDD storage device, flushing neighbor pages in one operation reduces I/O overhead (primarily for disk seek operations) compared to flushing individual pages at different times. For table data stored on SSD, seek time is not a significant factor and you can disable this setting to spread out write operations.

- The `innodb_lru_scan_depth` variable specifies, per buffer pool instance, how far down the buffer pool LRU list the page cleaner thread scans looking for dirty pages to flush. This is a background operation performed by a page cleaner thread once per second.
  - A setting smaller than the default is generally suitable for most workloads. A value that is significantly higher than necessary may impact performance. Only consider increasing the value if you have spare I/O capacity under a typical workload. Conversely, if a write-intensive workload saturates your I/O capacity, decrease the value, especially in the case of a large buffer pool.

When tuning `innodb_lru_scan_depth`, start with a low value and configure the setting upward with the goal of rarely seeing zero free pages. Also, consider adjusting `innodb_lru_scan_depth` when changing the number of buffer pool instances, since `innodb_lru_scan_depth * innodb_buffer_pool_instances` defines the amount of work performed by the page cleaner thread each second.
The `innodb_flush_neighbors` and `innodb_lru_scan_depth` variables are primarily intended for write-intensive workloads. With heavy DML activity, flushing can fall behind if it is not aggressive enough, or disk writes can saturate I/O capacity if flushing is too aggressive. The ideal settings depend on your workload, data access patterns, and storage configuration (for example, whether data is stored on HDD or SSD devices).

**Adaptive Flushing**

InnoDB uses an adaptive flushing algorithm to dynamically adjust the rate of flushing based on the speed of redo log generation and the current rate of flushing. The intent is to smooth overall performance by ensuring that flushing activity keeps pace with the current workload. Automatically adjusting the flushing rate helps avoid sudden dips in throughput that can occur when bursts of I/O activity due to buffer pool flushing affects the I/O capacity available for ordinary read and write activity.

Sharp checkpoints, which are typically associated with write-intensive workloads that generate a lot of redo entries, can cause a sudden change in throughput, for example. A sharp checkpoint occurs when InnoDB wants to reuse a portion of a log file. Before doing so, all dirty pages with redo entries in that portion of the log file must be flushed. If log files become full, a sharp checkpoint occurs, causing a temporary reduction in throughput. This scenario can occur even if `innodb_max_dirty_pages_pct` threshold is not reached.

The adaptive flushing algorithm helps avoid such scenarios by tracking the number of dirty pages in the buffer pool and the rate at which redo log records are being generated. Based on this information, it decides how many dirty pages to flush from the buffer pool each second, which permits it to manage sudden changes in workload.

The `innodb_adaptive_flushing_lwm` variable defines a low water mark for redo log capacity. When that threshold is crossed, adaptive flushing is enabled, even if the `innodb_adaptive_flushing` variable is disabled.

Internal benchmarking has shown that the algorithm not only maintains throughput over time, but can also improve overall throughput significantly. However, adaptive flushing can affect the I/O pattern of a workload significantly and may not be appropriate in all cases. It gives the most benefit when the redo log is in danger of filling up. If adaptive flushing is not appropriate to the characteristics of your workload, you can disable it. Adaptive flushing controlled by the `innodb_adaptive_flushing` variable, which is enabled by default.

`innodb_flushing_avg_loops` defines the number of iterations that InnoDB keeps the previously calculated snapshot of the flushing state, controlling how quickly adaptive flushing responds to foreground workload changes. A high `innodb_flushing_avg_loops` value means that InnoDB keeps the previously calculated snapshot longer, so adaptive flushing responds more slowly. When setting a high value it is important to ensure that redo log utilization does not reach 75% (the hardcoded limit at which asynchronous flushing starts), and that the `innodb_max_dirty_pages_pct` threshold keeps the number of dirty pages to a level that is appropriate for the workload.

Systems with consistent workloads, a large log file size (`innodb_log_file_size`), and small spikes that do not reach 75% log space utilization should use a high `innodb_flushing_avg_loops` value to keep flushing as smooth as possible. For systems with extreme load spikes or log files that do not provide a lot of space, a smaller value allows flushing to closely track workload changes, and helps to avoid reaching 75% log space utilization.

Be aware that if flushing falls behind, the rate of buffer pool flushing can exceed the I/O capacity available to InnoDB, as defined by `innodb_io_capacity` setting. The `innodb_io_capacity_max` value defines an upper limit on I/O capacity in such situations, so that a spike in I/O activity does not consume the entire I/O capacity of the server.
The `innodb_io_capacity` setting is applicable to all buffer pool instances. When dirty pages are flushed, I/O capacity is divided equally among buffer pool instances.

**Limiting Buffer Flushing During Idle Periods**

As of MySQL 8.0.18, you can use the `innodb_idle_flush_pct` variable to limit the rate of buffer pool flushing during idle periods, which are periods of time that database pages are not modified. The `innodb_idle_flush_pct` value is a percentage of the `innodb_io_capacity` setting, which defines the number of I/O operations per second available to InnoDB. The default `innodb_idle_flush_pct` value is 100, which is 100 percent of the `innodb_io_capacity` setting. To limit flushing during idle periods, define an `innodb_idle_flush_pct` value less than 100.

Limiting page flushing during idle periods can help extend the life of solid state storage devices. Side effects of limiting page flushing during idle periods may include a longer shutdown time following a lengthy idle period, and a longer recovery period should a server failure occur.

**15.8.3.6 Saving and Restoring the Buffer Pool State**

To reduce the warmup period after restarting the server, InnoDB saves a percentage of the most recently used pages for each buffer pool at server shutdown and restores these pages at server startup. The percentage of recently used pages that is stored is defined by the `innodb_buffer_pool_dump_pct` configuration option.

After restarting a busy server, there is typically a warmup period with steadily increasing throughput, as disk pages that were in the buffer pool are brought back into memory (as the same data is queried, updated, and so on). The ability to restore the buffer pool at startup shortens the warmup period by reloading disk pages that were in the buffer pool before the restart rather than waiting for DML operations to access corresponding rows. Also, I/O requests can be performed in large batches, making the overall I/O faster. Page loading happens in the background, and does not delay database startup.

In addition to saving the buffer pool state at shutdown and restoring it at startup, you can save and restore the buffer pool state at any time, while the server is running. For example, you can save the state of the buffer pool after reaching a stable throughput under a steady workload. You could also restore the previous buffer pool state after running reports or maintenance jobs that bring data pages into the buffer pool that are only required for those operations, or after running some other non-typical workload.

Even though a buffer pool can be many gigabytes in size, the buffer pool data that InnoDB saves to disk is tiny by comparison. Only tablespace IDs and page IDs necessary to locate the appropriate pages are saved to disk. This information is derived from the `INNODB_BUFFER_PAGE_LRU` INFORMATION_SCHEMA table. By default, tablespace ID and page ID data is saved in a file named `ib_buffer_pool`, which is saved to the InnoDB data directory. The file name and location can be modified using the `innodb_buffer_pool_filename` configuration parameter.

Because data is cached in and aged out of the buffer pool as it is with regular database operations, there is no problem if the disk pages are recently updated, or if a DML operation involves data that has not yet been loaded. The loading mechanism skips requested pages that no longer exist.

The underlying mechanism involves a background thread that is dispatched to perform the dump and load operations.

Disk pages from compressed tables are loaded into the buffer pool in their compressed form. Pages are uncompressed as usual when page contents are accessed during DML operations. Because uncompressing pages is a CPU-intensive process, it is more efficient for concurrency to perform the operation in a connection thread rather than in the single thread that performs the buffer pool restore operation.
Operations related to saving and restoring the buffer pool state are described in the following topics:

- Configuring the Dump Percentage for Buffer Pool Pages
- Saving the Buffer Pool State at Shutdown and Restoring it at Startup
- Saving and Restoring the Buffer Pool State Online
- Displaying Buffer Pool Dump Progress
- Displaying Buffer Pool Load Progress
- Aborting a Buffer Pool Load Operation
- Monitoring Buffer Pool Load Progress Using Performance Schema

### Configuring the Dump Percentage for Buffer Pool Pages

Before dumping pages from the buffer pool, you can configure the percentage of most-recently-used buffer pool pages that you want to dump by setting the `innodb_buffer_pool_dump_pct` option. If you plan to dump buffer pool pages while the server is running, you can configure the option dynamically:

```
SET GLOBAL innodb_buffer_pool_dump_pct=40;
```

If you plan to dump buffer pool pages at server shutdown, set `innodb_buffer_pool_dump_pct` in your configuration file.

```
[mysqld]
innodb_buffer_pool_dump_pct=40
```

The `innodb_buffer_pool_dump_pct` default value is 25 (dump 25% of most-recently-used pages).

### Saving the Buffer Pool State at Shutdown and Restoring it at Startup

To save the state of the buffer pool at server shutdown, issue the following statement prior to shutting down the server:

```
SET GLOBAL innodb_buffer_pool_dump_at_shutdown=ON;
```

`innodb_buffer_pool_dump_at_shutdown` is enabled by default.

To restore the buffer pool state at server startup, specify the `--innodb-buffer-pool-load-at-startup` option when starting the server:

```
mysql --innodb-buffer-pool-load-at-startup=ON;
```

`innodb_buffer_pool_load_at_startup` is enabled by default.

### Saving and Restoring the Buffer Pool State Online

To save the state of the buffer pool while MySQL server is running, issue the following statement:

```
SET GLOBAL innodb_buffer_pool_dump_now=ON;
```

To restore the buffer pool state while MySQL is running, issue the following statement:

```
SET GLOBAL innodb_buffer_pool_load_now=ON;
```
Displaying Buffer Pool Dump Progress

To display progress when saving the buffer pool state to disk, issue the following statement:

```
SHOW STATUS LIKE 'Innodb_buffer_pool_dump_status';
```

If the operation has not yet started, “not started” is returned. If the operation is complete, the completion time is printed (e.g. Finished at 110505 12:18:02). If the operation is in progress, status information is provided (e.g. Dumping buffer pool 5/7, page 237/2873).

Displaying Buffer Pool Load Progress

To display progress when loading the buffer pool, issue the following statement:

```
SHOW STATUS LIKE 'Innodb_buffer_pool_load_status';
```

If the operation has not yet started, “not started” is returned. If the operation is complete, the completion time is printed (e.g. Finished at 110505 12:23:24). If the operation is in progress, status information is provided (e.g. Loaded 123/22301 pages).

Aborting a Buffer Pool Load Operation

To abort a buffer pool load operation, issue the following statement:

```
SET GLOBAL innodb_buffer_pool_load_abort=ON;
```

Monitoring Buffer Pool Load Progress Using Performance Schema

You can monitor buffer pool load progress using Performance Schema.

The following example demonstrates how to enable the `stage/innodb/buffer pool load` stage event instrument and related consumer tables to monitor buffer pool load progress.

For information about buffer pool dump and load procedures used in this example, see Section 15.8.3.6, “Saving and Restoring the Buffer Pool State”. For information about Performance Schema stage event instruments and related consumers, see Section 27.12.5, “Performance Schema Stage Event Tables”.

1. Enable the `stage/innodb/buffer pool load` instrument:

```
mysql> UPDATE performance_schema.setup_instruments SET ENABLED = 'YES'
    -> WHERE NAME LIKE 'stage/innodb/buffer%';
```

2. Enable the stage event consumer tables, which include `events_stages_current`, `events_stages_history`, and `events_stages_history_long`.

```
mysql> UPDATE performance_schema.setup_consumers SET ENABLED = 'YES'
    -> WHERE NAME LIKE '%stages%';
```

3. Dump the current buffer pool state by enabling `innodb_buffer_pool_dump_now`.

```
mysql> SET GLOBAL innodb_buffer_pool_dump_now=ON;
```

4. Check the buffer pool dump status to ensure that the operation has completed.

```
mysql> SHOW STATUS LIKE 'Innodb_buffer_pool_dump_status';
*************************** 1. row ***************************
| Variable_name: Innodb_buffer_pool_dump_status | Value: Buffer pool(s) dump completed at 150202 16:38:58 |
```

5. Load the buffer pool by enabling `innodb_buffer_pool_load_now`:

```
mysql> SET GLOBAL innodb_buffer_pool_load_now=ON;
```

6. Check the current status of the buffer pool load operation by querying the Performance Schema `events_stages_current` table. The `WORK_COMPLETED` column shows the number of buffer pool pages loaded. The `WORK_ESTIMATED` column provides an estimate of the remaining work, in pages.

```
mysql> SELECT EVENT_NAME, WORK_COMPLETED, WORK_ESTIMATED
    -> FROM performance_schema.events_stages_current;
```

<table>
<thead>
<tr>
<th>EVENT_NAME</th>
<th>WORK_COMPLETED</th>
<th>WORK_ESTIMATED</th>
</tr>
</thead>
<tbody>
<tr>
<td>stage/innodb/buffer pool load</td>
<td>5353</td>
<td>7167</td>
</tr>
</tbody>
</table>

The `events_stages_current` table returns an empty set if the buffer pool load operation has completed. In this case, you can check the `events_stages_history` table to view data for the completed event. For example:

```
mysql> SELECT EVENT_NAME, WORK_COMPLETED, WORK_ESTIMATED
    -> FROM performance_schema.events_stages_history;
```

<table>
<thead>
<tr>
<th>EVENT_NAME</th>
<th>WORK_COMPLETED</th>
<th>WORK_ESTIMATED</th>
</tr>
</thead>
<tbody>
<tr>
<td>stage/innodb/buffer pool load</td>
<td>7167</td>
<td>7167</td>
</tr>
</tbody>
</table>

**Note**

You can also monitor buffer pool load progress using Performance Schema when loading the buffer pool at startup using `innodb_buffer_pool_load_at_startup`. In this case, the `stage/innodb/buffer_pool_load` instrument and related consumers must be enabled at startup. For more information, see Section 27.3, “Performance Schema Startup Configuration”.

### 15.8.3.7 Excluding Buffer Pool Pages from Core Files

A core file records the status and memory image of a running process. Because the buffer pool resides in main memory, and the memory image of a running process is dumped to the core file, systems with large buffer pools can produce large core files when the `mysqld` process dies.

Large core files can be problematic for a number of reasons including the time it takes to write them, the amount of disk space they consume, and the challenges associated with transferring large files.

To reduce core file size, you can disable the `innodb_buffer_pool_in_core_file` variable to omit buffer pool pages from core dumps. The `innodb_buffer_pool_in_core_file` variable was introduced in MySQL 8.0.14 and is enabled by default.

Excluding buffer pool pages may also be desirable from a security perspective if you have concerns about dumping database pages to core files that may be shared inside or outside of your organization for debugging purposes.

**Note**

Access to the data present in buffer pool pages at the time the `mysqld` process died may be beneficial in some debugging scenarios. If in doubt whether to include or exclude buffer pool pages, consult MySQL Support.
Disabling `innodb_buffer_pool_in_core_file` takes effect only if the `core_file` variable is enabled and the operating system supports the `MADV_DONTDUMP` non-POSIX extension to the `madvise()` system call, which is supported in Linux 3.4 and later. The `MADV_DONTDUMP` extension causes pages in a specified range to be excluded from core dumps.

Assuming the operating system supports the `MADV_DONTDUMP` extension, start the server with the `--core-file` and `--innodb-buffer-pool-in-core-file=OFF` options to generate core files without buffer pool pages.

```
$> mysql --core-file --innodb-buffer-pool-in-core-file=OFF
```

The `core_file` variable is read only and disabled by default. It is enabled by specifying the `--core-file` option at startup. The `innodb_buffer_pool_in_core_file` variable is dynamic. It can be specified at startup or configured at runtime using a `SET` statement.

```
mysql> SET GLOBAL innodb_buffer_pool_in_core_file=OFF;
```

If the `innodb_buffer_pool_in_core_file` variable is disabled but `MADV_DONTDUMP` is not supported by the operating system, or an `madvise()` failure occurs, a warning is written to the MySQL server error log and the `core_file` variable is disabled to prevent writing core files that unintentionally include buffer pool pages. If the read-only `core_file` variable becomes disabled, the server must be restarted to enable it again.

The following table shows configuration and `MADV_DONTDUMP` support scenarios that determine whether core files are generated and whether they include buffer pool pages.

### Table 15.4 Core File Configuration Scenarios

<table>
<thead>
<tr>
<th><code>core_file</code> variable</th>
<th><code>innodb_buffer_pool_in_core_file</code> variable</th>
<th><code>madvise()</code></th>

The reduction in core file size achieved by disabling the `innodb_buffer_pool_in_core_file` variable depends on the size of the buffer pool, but it is also affected by the InnoDB page size. A smaller page size means more pages are required for the same amount of data, and more pages means more page metadata. The following table provides size reduction examples that you might see for a 1GB buffer pool with different pages sizes.

15.8.4 Configuring Thread Concurrency for InnoDB

InnoDB uses operating system threads to process requests from user transactions. (Transactions may issue many requests to InnoDB before they commit or roll back.) On modern operating systems and servers with multi-core processors, where context switching is efficient, most workloads run well without any limit on the number of concurrent threads.

In situations where it is helpful to minimize context switching between threads, InnoDB can use a number of techniques to limit the number of concurrently executing operating system threads (and thus the number of requests that are processed at any one time). When InnoDB receives a new request from a user session, if the number of threads concurrently executing is at a pre-defined limit, the new request sleeps for a short time before it tries again. A request that cannot be rescheduled after the sleep is put in a first-in/first-out queue and eventually is processed. Threads waiting for locks are not counted in the number of concurrently executing threads.

You can limit the number of concurrent threads by setting the configuration parameter `innodb_thread_concurrency`. Once the number of executing threads reaches this limit, additional threads sleep for a number of microseconds, set by the configuration parameter `innodb_thread_sleep_delay`, before being placed into the queue.

You can set the configuration option `innodb_adaptive_max_sleep_delay` to the highest value you would allow for `innodb_thread_sleep_delay`, and InnoDB automatically adjusts `innodb_thread_sleep_delay` up or down depending on the current thread-scheduling activity. This dynamic adjustment helps the thread scheduling mechanism to work smoothly during times when the system is lightly loaded and when it is operating near full capacity.

The default value for `innodb_thread_concurrency` and the implied default limit on the number of concurrent threads has been changed in various releases of MySQL and InnoDB. The default value of `innodb_thread_concurrency` is 0, so that by default there is no limit on the number of concurrently executing threads.

InnoDB causes threads to sleep only when the number of concurrent threads is limited. When there is no limit on the number of threads, all contend equally to be scheduled. That is, if `innodb_thread_concurrency` is 0, the value of `innodb_thread_sleep_delay` is ignored.

When there is a limit on the number of threads (when `innodb_thread_concurrency` is > 0), InnoDB reduces context switching overhead by permitting multiple requests made during the execution of a single SQL statement to enter InnoDB without observing the limit set by `innodb_thread_concurrency`. Since an SQL statement (such as a join) may comprise multiple row operations within InnoDB, InnoDB assigns a specified number of “tickets” that allow a thread to be scheduled repeatedly with minimal overhead.

When a new SQL statement starts, a thread has no tickets, and it must observe `innodb_thread_concurrency`. Once the thread is entitled to enter InnoDB, it is assigned a number of tickets that it can use for subsequently entering InnoDB to perform row operations. If the tickets run out, the thread is evicted, and `innodb_thread_concurrency` is observed again which may place the thread back into the first-in/first-out queue of waiting threads. When the thread is once again entitled to enter InnoDB, tickets are assigned again. The number of tickets assigned is specified by the global option `innodb_concurrency_tickets`, which is 5000 by default. A thread that is waiting for a lock is given one ticket once the lock becomes available.

The correct values of these variables depend on your environment and workload. Try a range of different values to determine what value works for your applications. Before limiting the number of concurrently executing threads, it is important to consider the impact on your specific workload and system configuration.
executing threads, review configuration options that may improve the performance of InnoDB on multi-core and multi-processor computers, such as `innodb_adaptive_hash_index`.

For general performance information about MySQL thread handling, see Section 5.1.12.1, “Connection Interfaces”.

### 15.8.5 Configuring the Number of Background InnoDB I/O Threads

InnoDB uses background threads to service various types of I/O requests. You can configure the number of background threads that service read and write I/O on data pages using the `innodb_read_io_threads` and `innodb_write_io_threads` configuration parameters. These parameters signify the number of background threads used for read and write requests, respectively. They are effective on all supported platforms. You can set values for these parameters in the MySQL option file (my.cnf or my.ini); you cannot change values dynamically. The default value for these parameters is 4 and permissible values range from 1-64.

The purpose of these configuration options to make InnoDB more scalable on high end systems. Each background thread can handle up to 256 pending I/O requests. A major source of background I/O is read-ahead requests. InnoDB tries to balance the load of incoming requests in such way that most background threads share work equally. InnoDB also attempts to allocate read requests from the same extent to the same thread, to increase the chances of coalescing the requests. If you have a high end I/O subsystem and you see more than $64 \times \text{innodb_read_io_threads}$ pending read requests in `SHOW ENGINE INNODB STATUS` output, you might improve performance by increasing the value of `innodb_read_io_threads`.

On Linux systems, InnoDB uses the asynchronous I/O subsystem by default to perform read-ahead and write requests for data file pages, which changes the way that InnoDB background threads service these types of I/O requests. For more information, see Section 15.8.6, “Using Asynchronous I/O on Linux”.

For more information about InnoDB I/O performance, see Section 8.5.8, “Optimizing InnoDB Disk I/O”.

### 15.8.6 Using Asynchronous I/O on Linux

InnoDB uses the asynchronous I/O subsystem (native AIO) on Linux to perform read-ahead and write requests for data file pages. This behavior is controlled by the `innodb_use_native_aio` configuration option, which applies to Linux systems only and is enabled by default. On other Unix-like systems, InnoDB uses synchronous I/O only. Historically, InnoDB only used asynchronous I/O on Windows systems. Using the asynchronous I/O subsystem on Linux requires the `libaio` library.

With synchronous I/O, query threads queue I/O requests, and InnoDB background threads retrieve the queued requests one at a time, issuing a synchronous I/O call for each. When an I/O request is completed and the I/O call returns, the InnoDB background thread that is handling the request calls an I/O completion routine and returns to process the next request. The number of requests that can be processed in parallel is $n$, where $n$ is the number of InnoDB background threads. The number of InnoDB background threads is controlled by `innodb_read_io_threads` and `innodb_write_io_threads`. See Section 15.8.5, “Configuring the Number of Background InnoDB I/O Threads”.

With native AIO, query threads dispatch I/O requests directly to the operating system, thereby removing the limit imposed by the number of background threads. InnoDB background threads wait for I/O events to signal completed requests. When a request is completed, a background thread calls an I/O completion routine and resumes waiting for I/O events.

The advantage of native AIO is scalability for heavily I/O-bound systems that typically show many pending reads/writes in `SHOW ENGINE INNODB STATUS` output. The increase in parallel processing when using
native AIO means that the type of I/O scheduler or properties of the disk array controller have a greater influence on I/O performance.

A potential disadvantage of native AIO for heavily I/O-bound systems is lack of control over the number of I/O write requests dispatched to the operating system at once. Too many I/O write requests dispatched to the operating system for parallel processing could, in some cases, result in I/O read starvation, depending on the amount of I/O activity and system capabilities.

If a problem with the asynchronous I/O subsystem in the OS prevents InnoDB from starting, you can start the server with \texttt{innodb_use_native_aio=0}. This option may also be disabled automatically during startup if InnoDB detects a potential problem such as a combination of \texttt{tmpdir} location, \texttt{tmpfs} file system, and Linux kernel that does not support asynchronous I/O on \texttt{tmpfs}.

### 15.8.7 Configuring InnoDB I/O Capacity

The InnoDB master thread and other threads perform various tasks in the background, most of which are I/O related, such as flushing dirty pages from the buffer pool and writing changes from the change buffer to the appropriate secondary indexes. InnoDB attempts to perform these tasks in a way that does not adversely affect the normal working of the server. It tries to estimate the available I/O bandwidth and tune its activities to take advantage of available capacity.

The \texttt{innodb_io_capacity} variable defines the overall I/O capacity available to InnoDB. It should be set to approximately the number of I/O operations that the system can perform per second (IOPS). When \texttt{innodb_io_capacity} is set, InnoDB estimates the I/O bandwidth available for background tasks based on the set value.

You can set \texttt{innodb_io_capacity} to a value of 100 or greater. The default value is \texttt{200}. Typically, values around 100 are appropriate for consumer-level storage devices, such as hard drives up to 7200 RPMs. Faster hard drives, RAID configurations, and solid state drives (SSDs) benefit from higher values.

Ideally, keep the setting as low as practical, but not so low that background activities fall behind. If the value is too high, data is removed from the buffer pool and change buffer too quickly for caching to provide a significant benefit. For busy systems capable of higher I/O rates, you can set a higher value to help the server handle the background maintenance work associated with a high rate of row changes. Generally, you can increase the value as a function of the number of drives used for InnoDB I/O. For example, you can increase the value on systems that use multiple disks or SSDs.

The default setting of 200 is generally sufficient for a lower-end SSD. For a higher-end, bus-attached SSD, consider a higher setting such as 1000, for example. For systems with individual 5400 RPM or 7200 RPM drives, you might lower the value to 100, which represents an estimated proportion of the I/O operations per second (IOPS) available to older-generation disk drives that can perform about 100 IOPS.

Although you can specify a high value such as a million, in practice such large values have little benefit. Generally, a value higher than 20000 is not recommended unless you are certain that lower values are insufficient for your workload.

Consider write workload when tuning \texttt{innodb_io_capacity}. Systems with large write workloads are likely to benefit from a higher setting. A lower setting may be sufficient for systems with a small write workload.

The \texttt{innodb_io_capacity} setting is not a per buffer pool instance setting. Available I/O capacity is distributed equally among buffer pool instances for flushing activities.

You can set the \texttt{innodb_io_capacity} value in the MySQL option file (\texttt{my.cnf} or \texttt{my.ini}) or modify it at runtime using a \texttt{SET GLOBAL} statement, which requires privileges sufficient to set global system variables. See Section 5.1.9.1, “System Variable Privileges”.
Ignoring I/O Capacity at Checkpoints

The `innodb_flush_sync` variable, which is enabled by default, causes the `innodb_io_capacity` setting to be ignored during bursts of I/O activity that occur at checkpoints. To adhere to the I/O rate defined by the `innodb_io_capacity` setting, disable `innodb_flush_sync`.

You can set the `innodb_flush_sync` value in the MySQL option file (`my.cnf` or `my.ini`) or modify it at runtime using a `SET GLOBAL` statement, which requires privileges sufficient to set global system variables. See Section 5.1.9.1, “System Variable Privileges”.

Configuring an I/O Capacity Maximum

If flushing activity falls behind, InnoDB can flush more aggressively, at a higher rate of I/O operations per second (IOPS) than defined by the `innodb_io_capacity` variable. The `innodb_io_capacity_max` variable defines a maximum number of IOPS performed by InnoDB background tasks in such situations.

If you specify an `innodb_io_capacity` setting at startup but do not specify a value for `innODB_io_capacity_max`, `innodb_io_capacity_max` defaults to twice the value of `innodb_io_capacity` or 2000, whichever value is greater.

When configuring `innodb_io_capacity_max`, twice the `innodb_io_capacity` is often a good starting point. The default value of 2000 is intended for workloads that use an SSD or more than one regular disk drive. A setting of 2000 is likely too high for workloads that do not use SSDs or multiple disk drives, and could allow too much flushing. For a single regular disk drive, a setting between 200 and 400 is recommended. For a high-end, bus-attached SSD, consider a higher setting such as 2500. As with the `innodb_io_capacity` setting, keep the setting as low as practical, but not so low that InnoDB cannot sufficiently extend rate of IOPS beyond the `innodb_io_capacity` setting.

Consider write workload when tuning `innodb_io_capacity_max`. Systems with large write workloads may benefit from a higher setting. A lower setting may be sufficient for systems with a small write workload.

`innodb_io_capacity_max` cannot be set to a value lower than the `innodb_io_capacity` value.

Setting `innodb_io_capacity_max` to `DEFAULT` using a `SET` statement (`SET GLOBAL innodb_io_capacity_max=DEFAULT`) sets `innodb_io_capacity_max` to the maximum value.

The `innodb_io_capacity_max` limit applies to all buffer pool instances. It is not a per buffer pool instance setting.

15.8.8 Configuring Spin Lock Polling

InnoDB mutexes and rw-locks are typically reserved for short intervals. On a multi-core system, it can be more efficient for a thread to continuously check if it can acquire a mutex or rw-lock for a period of time before it sleeps. If the mutex or rw-lock becomes available during this period, the thread can continue immediately, in the same time slice. However, too-frequent polling of a shared object such as a mutex or rw-lock by multiple threads can cause "cache ping pong", which results in processors invalidating portions of each other's cache. InnoDB minimizes this issue by forcing a random delay between polls to desynchronize polling activity. The random delay is implemented as a spin-wait loop.

The duration of a spin-wait loop is determined by the number of PAUSE instructions that occur in the loop. That number is generated by randomly selecting an integer ranging from 0 up to but not including the `innodb_spin_wait_delay` value, and multiplying that value by 50. (The multiplier value, 50, is hardcoded before MySQL 8.0.16, and configurable thereafter.) For example, an integer is randomly selected from the following range for an `innodb_spin_wait_delay` setting of 6:

\[0,1,2,3,4,5]\]
The selected integer is multiplied by 50, resulting in one of six possible PAUSE instruction values:

\{0,50,100,150,200,250\}

For that set of values, 250 is the maximum number of PAUSE instructions that can occur in a spin-wait loop. An \texttt{innodb\_spin\_wait\_delay} setting of 5 results in a set of five possible values \{0,50,100,150,200\}, where 200 is the maximum number of PAUSE instructions, and so on. In this way, the \texttt{innodb\_spin\_wait\_delay} setting controls the maximum delay between spin lock polls.

On a system where all processor cores share a fast cache memory, you might reduce the maximum delay or disable the busy loop altogether by setting \texttt{innodb\_spin\_wait\_delay=0}. On a system with multiple processor chips, the effect of cache invalidation can be more significant and you might increase the maximum delay.

In the 100MHz Pentium era, an \texttt{innodb\_spin\_wait\_delay} unit was calibrated to be equivalent to one microsecond. That time equivalence did not hold, but PAUSE instruction duration remained fairly constant in terms of processor cycles relative to other CPU instructions until the introduction of the Skylake generation of processors, which have a comparatively longer PAUSE instruction. The \texttt{innodb\_spin\_wait\_pause\_multiplier} variable was introduced in MySQL 8.0.16 to provide a way to account for differences in PAUSE instruction duration.

The \texttt{innodb\_spin\_wait\_pause\_multiplier} variable controls the size of PAUSE instruction values. For example, assuming an \texttt{innodb\_spin\_wait\_delay} setting of 6, decreasing the \texttt{innodb\_spin\_wait\_pause\_multiplier} value from 50 (the default and previously hardcoded value) to 5 generates a set of smaller PAUSE instruction values:

\{0,5,10,15,20,25\}

The ability to increase or decrease PAUSE instruction values permits fine tuning \texttt{InnoDB} for different processor architectures. Smaller PAUSE instruction values would be appropriate for processor architectures with a comparatively longer PAUSE instruction, for example.

The \texttt{innodb\_spin\_wait\_delay} and \texttt{innodb\_spin\_wait\_pause\_multiplier} variables are dynamic. They can be specified in a MySQL option file or modified at runtime using a \texttt{SET GLOBAL} statement. Modifying the variables at runtime requires privileges sufficient to set global system variables. See Section 5.1.9.1, “System Variable Privileges”.

### 15.8.9 Purge Configuration

\texttt{InnoDB} does not physically remove a row from the database immediately when you delete it with an SQL statement. A row and its index records are only physically removed when \texttt{InnoDB} discards the undo log record written for the deletion. This removal operation, which only occurs after the row is no longer required for multi-version concurrency control (MVCC) or rollback, is called a purge.

Purge runs on a periodic schedule. It parses and processes undo log pages from the history list, which is a list of undo log pages for committed transactions that is maintained by the \texttt{InnoDB} transaction system. Purge frees the undo log pages from the history list after processing them.

#### Configuring Purge Threads

Purge operations are performed in the background by one or more purge threads. The number of purge threads is controlled by the \texttt{innodb\_purge\_threads} variable. The default value is 4.

If DML action is concentrated on a single table, purge operations for the table are performed by a single purge thread, which can result in slowed purge operations, increased purge lag, and increased tablespace file size if the DML operations involve large object values. From MySQL 8.0.26, if the
Purge Configuration

**innodb_max_purge_lag** setting is exceeded, purge work is automatically redistributed among available purge threads. Too many active purge threads in this scenario can cause contention with user threads, so manage the **innodb_purge_threads** setting accordingly. The **innodb_max_purge_lag** variable is set to 0 by default, which means that there is no maximum purge lag by default.

If DML action is concentrated on few tables, keep the **innodb_purge_threads** setting low so that the threads do not contend with each other for access to the busy tables. If DML operations are spread across many tables, consider a higher **innodb_purge_threads** setting. The maximum number of purge threads is 32.

The **innodb_purge_threads** setting is the maximum number of purge threads permitted. The purge system automatically adjusts the number of purge threads that are used.

**Configuring Purge Batch Size**

The **innodb_purge_batch_size** variable defines the number of undo log pages that purge parses and processes in one batch from the history list. The default value is 300. In a multithreaded purge configuration, the coordinator purge thread divides **innodb_purge_batch_size** by **innodb_purge_threads** and assigns that number of pages to each purge thread.

The purge system also frees the undo log pages that are no longer required. It does so every 128 iterations through the undo logs. In addition to defining the number of undo log pages parsed and processed in a batch, the **innodb_purge_batch_size** variable defines the number of undo log pages that purge frees every 128 iterations through the undo logs.

The **innodb_purge_batch_size** variable is intended for advanced performance tuning and experimentation. Most users need not change **innodb_purge_batch_size** from its default value.

**Configuring the Maximum Purge Lag**

The **innodb_max_purge_lag** variable defines the desired maximum purge lag. When the purge lag exceeds the **innodb_max_purge_lag** threshold, a delay is imposed on **INSERT**, **UPDATE**, and **DELETE** operations to allow time for purge operations to catch up. The default value is 0, which means there is no maximum purge lag and no delay.

The InnoDB transaction system maintains a list of transactions that have index records delete-marked by **UPDATE** or **DELETE** operations. The length of the list is the purge lag. Prior to MySQL 8.0.14, the purge lag delay is calculated by the following formula, which results in a minimum delay of 5000 microseconds:

\[(\text{purge lag/innodb_max_purge_lag} - 0.5) \times 10000\]

As of MySQL 8.0.14, the purge lag delay is calculated by the following revised formula, which reduces the minimum delay to 5 microseconds. A delay of 5 microseconds is more appropriate for modern systems.

\[(\text{purge lag/innodb_max_purge_lag} - 0.9995) \times 10000\]

The delay is calculated at the beginning of a purge batch.

A typical **innodb_max_purge_lag** setting for a problematic workload might be 1000000 (1 million), assuming that transactions are small, only 100 bytes in size, and it is permissible to have 100MB of unpurged table rows.

The purge lag is presented as the **History list length** value in the **TRANSACTIONS** section of **SHOW ENGINE INNODB STATUS** output.

```
mysql> SHOW ENGINE INNODB STATUS;
```

```
The History list length is typically a low value, usually less than a few thousand, but a write-heavy workload or long running transactions can cause it to increase, even for transactions that are read only. The reason that a long running transaction can cause the History list length to increase is that under a consistent read transaction isolation level such as REPEATABLE READ, a transaction must return the same result as when the read view for that transaction was created. Consequently, the InnoDB multi-version concurrency control (MVCC) system must keep a copy of the data in the undo log until all transactions that depend on that data have completed. The following are examples of long running transactions that could cause the History list length to increase:

- A mysqldump operation that uses the --single-transaction option while there is a significant amount of concurrent DML.
- Running a SELECT query after disabling autocommit, and forgetting to issue an explicit COMMIT or ROLLBACK.

To prevent excessive delays in extreme situations where the purge lag becomes huge, you can limit the delay by setting the innodb_max_purge_lag_delay variable. The innodb_max_purge_lag_delay variable specifies the maximum delay in microseconds for the delay imposed when the innodb_max_purge_lag threshold is exceeded. The specified innodb_max_purge_lag_delay value is an upper limit on the delay period calculated by the innodb_max_purge_lag formula.

### Purge and Undo Tablespace Truncation

The purge system is also responsible for truncating undo tablespaces. You can configure the innodb_purge_rseg_truncate_frequency variable to control the frequency with which the purge system looks for undo tablespaces to truncate. For more information, see Truncating Undo Tablespaces.

### 15.8.10 Configuring Optimizer Statistics for InnoDB

This section describes how to configure persistent and non-persistent optimizer statistics for InnoDB tables.

Persistent optimizer statistics are persisted across server restarts, allowing for greater plan stability and more consistent query performance. Persistent optimizer statistics also provide control and flexibility with these additional benefits:

- You can use the innodb_stats_auto_recalc configuration option to control whether statistics are updated automatically after substantial changes to a table.
- You can use the STATS_PERSISTENT, STATS_AUTO_RECALC, and STATS_SAMPLE_PAGES clauses with CREATE TABLE and ALTER TABLE statements to configure optimizer statistics for individual tables.
- You can query optimizer statistics data in the mysql.innodb_table_stats and mysql.innodb_index_stats tables.
- You can view the last_update column of the mysql.innodb_table_stats and mysql.innodb_index_stats tables to see when statistics were last updated.
- You can manually modify the mysql.innodb_table_stats and mysql.innodb_index_stats tables to force a specific query optimization plan or to test alternative plans without modifying the database.
Configuring Optimizer Statistics for InnoDB

The persistent optimizer statistics feature is enabled by default (`innodb_stats_persistent=ON`).

Non-persistent optimizer statistics are cleared on each server restart and after some other operations, and recomputed on the next table access. As a result, different estimates could be produced when recomputing statistics, leading to different choices in execution plans and variations in query performance.

This section also provides information about estimating `ANALYZE TABLE` complexity, which may be useful when attempting to achieve a balance between accurate statistics and `ANALYZE TABLE` execution time.

### 15.8.10.1 Configuring Persistent Optimizer Statistics Parameters

The persistent optimizer statistics feature improves plan stability by storing statistics to disk and making them persistent across server restarts so that the optimizer is more likely to make consistent choices each time for a given query.

Optimizer statistics are persisted to disk when `innodb_stats_persistent=ON` or when individual tables are defined with `STATS_PERSISTENT=1`. `innodb_stats_persistent` is enabled by default.

Formerly, optimizer statistics were cleared when restarting the server and after some other types of operations, and recomputed on the next table access. Consequently, different estimates could be produced when recalculating statistics leading to different choices in query execution plans and variation in query performance.

Persistent statistics are stored in the `mysql.innodb_table_stats` and `mysql.innodb_index_stats` tables. See InnoDB Persistent Statistics Tables.

If you prefer not to persist optimizer statistics to disk, see Section 15.8.10.2, “Configuring Non-Persistent Optimizer Statistics Parameters”

#### Configuring Automatic Statistics Calculation for Persistent Optimizer Statistics

The `innodb_stats_auto_recalc` variable, which is enabled by default, controls whether statistics are calculated automatically when a table undergoes changes to more than 10% of its rows. You can also configure automatic statistics recalculation for individual tables by specifying the `STATS_AUTO_RECALC` clause when creating or altering a table.

Because of the asynchronous nature of automatic statistics recalculation, which occurs in the background, statistics may not be recalculated instantly after running a DML operation that affects more than 10% of a table, even when `innodb_stats_auto_recalc` is enabled. Statistics recalculation can be delayed by few seconds in some cases. If up-to-date statistics are required immediately, run `ANALYZE TABLE` to initiate a synchronous (foreground) recalculation of statistics.

If `innodb_stats_auto_recalc` is disabled, you can ensure the accuracy of optimizer statistics by executing the `ANALYZE TABLE` statement after making substantial changes to indexed columns. You might also consider adding `ANALYZE TABLE` to setup scripts that you run after loading data, and running `ANALYZE TABLE` on a schedule at times of low activity.

When an index is added to an existing table, or when a column is added or dropped, index statistics are calculated and added to the `innodb_index_stats` table regardless of the value of `innodb_stats_auto_recalc`.

#### Configuring Optimizer Statistics Parameters for Individual Tables

`innodb_stats_persistent`, `innodb_stats_auto_recalc`, and `innodb_stats_persistent_sample_pages` are global variables. To override these system-wide settings and configure optimizer statistics parameters for individual tables, you can define
Configuring Optimizer Statistics for InnoDB

STATS_PERSISTENT, STATS_AUTO_RECALC, and STATS_SAMPLE_PAGES clauses in CREATE TABLE or ALTER TABLE statements.

- **STATS_PERSISTENT** specifies whether to enable persistent statistics for an InnoDB table. The value DEFAULT causes the persistent statistics setting for the table to be determined by the innodb_stats_persistent setting. A value of 1 enables persistent statistics for the table, while a value of 0 disables the feature. After enabling persistent statistics for an individual table, use ANALYZE TABLE to calculate statistics after table data is loaded.

- **STATS_AUTO_RECALC** specifies whether to automatically recalculate persistent statistics. The value DEFAULT causes the persistent statistics setting for the table to be determined by the innodb_stats_auto_recalc setting. A value of 1 causes statistics to be recalculated when 10% of table data has changed. A value 0 prevents automatic recalculation for the table. When using a value of 0, use ANALYZE TABLE to recalculate statistics after making substantial changes to the table.

- **STATS_SAMPLE_PAGES** specifies the number of index pages to sample when cardinality and other statistics are calculated for an indexed column, by an ANALYZE TABLE operation, for example.

All three clauses are specified in the following CREATE TABLE example:

```sql
CREATE TABLE `t1` (
`id` int(8) NOT NULL auto_increment,
`data` varchar(255),
`date` datetime,
PRIMARY KEY (`id`),
INDEX `DATE_IX` (`date`)
) ENGINE=InnoDB,
STATS_PERSISTENT=1,
STATS_AUTO_RECALC=1,
STATS_SAMPLE_PAGES=25;
```

Configuring the Number of Sampled Pages for InnoDB Optimizer Statistics

The optimizer uses estimated statistics about key distributions to choose the indexes for an execution plan, based on the relative selectivity of the index. Operations such as ANALYZE TABLE cause InnoDB to sample random pages from each index on a table to estimate the cardinality of the index. This sampling technique is known as a random dive.

The innodb_stats_persistent_sample_pages controls the number of sampled pages. You can adjust the setting at runtime to manage the quality of statistics estimates used by the optimizer. The default value is 20. Consider modifying the setting when encountering the following issues:

1. **Statistics are not accurate enough and the optimizer chooses suboptimal plans**, as shown in EXPLAIN output. You can check the accuracy of statistics by comparing the actual cardinality of an index (determined by running SELECT DISTINCT on the index columns) with the estimates in the mysql.innodb_index_stats table.

   If it is determined that statistics are not accurate enough, the value of innodb_stats_persistent_sample_pages should be increased until the statistics estimates are sufficiently accurate. Increasing innodb_stats_persistent_sample_pages too much, however, could cause ANALYZE TABLE to run slowly.

2. **ANALYZE TABLE is too slow.** In this case innodb_stats_persistent_sample_pages should be decreased until ANALYZE TABLE execution time is acceptable. Decreasing the value too much, however, could lead to the first problem of inaccurate statistics and suboptimal query execution plans.

   If a balance cannot be achieved between accurate statistics and ANALYZE TABLE execution time, consider decreasing the number of indexed columns in the table or limiting the number of partitions.
Configuring Optimizer Statistics for InnoDB

to reduce `ANALYZE TABLE` complexity. The number of columns in the table's primary key is also important to consider, as primary key columns are appended to each nonunique index.

For related information, see Section 15.8.10.3, "Estimating `ANALYZE TABLE` Complexity for InnoDB Tables".

Including Delete-marked Records in Persistent Statistics Calculations

By default, InnoDB reads uncommitted data when calculating statistics. In the case of an uncommitted transaction that deletes rows from a table, delete-marked records are excluded when calculating row estimates and index statistics, which can lead to non-optimal execution plans for other transactions that are operating on the table concurrently using a transaction isolation level other than READ UNCOMMITTED. To avoid this scenario, `innodb_stats_include_delete_marked` can be enabled to ensure that delete-marked records are included when calculating persistent optimizer statistics.

When `innodb_stats_include_delete_marked` is enabled, `ANALYZE TABLE` considers delete-marked records when recalculating statistics.

`innodb_stats_include_delete_marked` is a global setting that affects all InnoDB tables, and it is only applicable to persistent optimizer statistics.

InnoDB Persistent Statistics Tables

The persistent statistics feature relies on the internally managed tables in the mysql database, named `innodb_table_stats` and `innodb_index_stats`. These tables are set up automatically in all install, upgrade, and build-from-source procedures.

Table 15.6 Columns of `innodb_table_stats`

<table>
<thead>
<tr>
<th>Column name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>database_name</td>
<td>Database name</td>
</tr>
<tr>
<td>table_name</td>
<td>Table name, partition name, or subpartition name</td>
</tr>
<tr>
<td>last_update</td>
<td>A timestamp indicating the last time that InnoDB updated this row</td>
</tr>
<tr>
<td>n_rows</td>
<td>The number of rows in the table</td>
</tr>
<tr>
<td>clustered_index_size</td>
<td>The size of the primary index, in pages</td>
</tr>
<tr>
<td>sum_of_other_index_sizes</td>
<td>The total size of other (non-primary) indexes, in pages</td>
</tr>
</tbody>
</table>

Table 15.7 Columns of `innodb_index_stats`

<table>
<thead>
<tr>
<th>Column name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>database_name</td>
<td>Database name</td>
</tr>
<tr>
<td>table_name</td>
<td>Table name, partition name, or subpartition name</td>
</tr>
<tr>
<td>index_name</td>
<td>Index name</td>
</tr>
<tr>
<td>last_update</td>
<td>A timestamp indicating the last time the row was updated</td>
</tr>
<tr>
<td>stat_name</td>
<td>The name of the statistic, whose value is reported in the <code>stat_value</code> column</td>
</tr>
<tr>
<td>stat_value</td>
<td>The value of the statistic that is named in <code>stat_name</code> column</td>
</tr>
</tbody>
</table>
InnoDB Persistent Statistics Tables Example

The `innodb_table_stats` and `innodb_index_stats` tables can be updated manually, which makes it possible to force a specific query optimization plan or test alternative plans without modifying the database. If you manually update statistics, use the `FLUSH TABLE tbl_name` statement to load the updated statistics.

Persistent statistics are considered local information, because they relate to the server instance. The `innodb_table_stats` and `innodb_index_stats` tables are therefore not replicated when automatic statistics recalculation takes place. If you run `ANALYZE TABLE` to initiate a synchronous recalculation of statistics, the statement is replicated (unless you suppressed logging for it), and recalculation takes place on replicas.
### Configuring Optimizer Statistics for InnoDB

To immediately update statistics, run `ANALYZE TABLE` (if `innodb_stats_auto_recalc` is enabled, statistics are updated automatically within a few seconds assuming that the 10% threshold for changed table rows is reached):

```plaintext
mysql> ANALYZE TABLE t1;
```

Table statistics for table `t1` show the last time InnoDB updated the table statistics (2014-03-14 14:36:34), the number of rows in the table (5), the clustered index size (1 page), and the combined size of the other indexes (2 pages).

```plaintext
mysql> SELECT * FROM mysql.innodb_table_stats WHERE table_name like 't1'
```

The `innodb_index_stats` table contains multiple rows for each index. Each row in the `innodb_index_stats` table provides data related to a particular index statistic which is named in the `stat_name` column and described in the `stat_description` column. For example:

```plaintext
mysql> SELECT index_name, stat_name, stat_value, stat_description
    FROM mysql.innodb_index_stats WHERE table_name like 't1';
```

The `stat_name` column shows the following types of statistics:

- **size**: Where `stat_name=size`, the `stat_value` column displays the total number of pages in the index.
- **n_leaf_pages**: Where `stat_name=n_leaf_pages`, the `stat_value` column displays the number of leaf pages in the index.
• **n_diff_pfxNN**: Where `stat_name=n_diff_pfx01`, the `stat_value` column displays the number of distinct values in the first column of the index. Where `stat_name=n_diff_pfx02`, the `stat_value` column displays the number of distinct values in the first two columns of the index, and so on. Where `stat_name=n_diff_pfxNN`, the `stat_description` column shows a comma separated list of the index columns that are counted.

To further illustrate the `n_diff_pfxNN` statistic, which provides cardinality data, consider once again the `t1` table example that was introduced previously. As shown below, the `t1` table is created with a primary index (columns `a`, `b`), a secondary index (columns `c`, `d`), and a unique index (columns `e`, `f`):

```
CREATE TABLE t1 (
    a INT, b INT, c INT, d INT, e INT, f INT,
    PRIMARY KEY (a, b), KEY i1 (c, d), UNIQUE KEY i2uniq (e, f)
) ENGINE=INNODB;
```

After inserting five rows of sample data, table `t1` appears as follows:

```
mysql> SELECT * FROM t1;
+---+---+------+------+------+------+
| a | b | c    | d    | e    | f    |
+---+---+------+------+------+------+
| 1 | 1 | 10   | 11   | 100  | 101  |
| 1 | 2 | 10   | 11   | 200  | 102  |
| 1 | 3 | 10   | 11   | 100  | 103  |
| 1 | 4 | 10   | 12   | 200  | 104  |
| 1 | 5 | 10   | 12   | 100  | 105  |
+---+---+------+------+------+------+
```

When you query the `index_name`, `stat_name`, `stat_value`, and `stat_description`, where `stat_name LIKE 'n_diff%'`, the following result set is returned:

```
mysql> SELECT index_name, stat_name, stat_value, stat_description
FROM mysql.innodb_index_stats
WHERE table_name like 't1' AND stat_name LIKE 'n_diff%';
+------------+--------------+------------+------------------+
| index_name | stat_name    | stat_value | stat_description |
+------------+--------------+------------+------------------+
| PRIMARY    | n_diff_pfx01 | 1          | a                |
| PRIMARY    | n_diff_pfx02 | 5          | a,b              |
| i1         | n_diff_pfx01 | 1          | c                |
| i1         | n_diff_pfx02 | 2          | c,d              |
| i1         | n_diff_pfx03 | 2          | c,d,a            |
| i1         | n_diff_pfx04 | 5          | c,d,a,b          |
| i2uniq     | n_diff_pfx01 | 2          | e                |
| i2uniq     | n_diff_pfx02 | 5          | e,f              |
+------------+--------------+------------+------------------+
```

For the **PRIMARY** index, there are two `n_diff%` rows. The number of rows is equal to the number of columns in the index.

**Note**

For nonunique indexes, InnoDB appends the columns of the primary key.

- Where `index_name=PRIMARY` and `stat_name=n_diff_pfx01`, the `stat_value` is 1, which indicates that there is a single distinct value in the first column of the index (column `a`). The number of distinct values in column `a` is confirmed by viewing the data in column `a` in table `t1`, in which there is a single distinct value (1). The counted column (a) is shown in the `stat_description` column of the result set.

- Where `index_name=PRIMARY` and `stat_name=n_diff_pfx02`, the `stat_value` is 5, which indicates that there are five distinct values in the two columns of the index (`a`, `b`). The number of distinct
values in columns a and b is confirmed by viewing the data in columns a and b in table t1, in which there are five distinct values: (1, 1), (1, 2), (1, 3), (1, 4) and (1, 5). The counted columns (a,b) are shown in the stat_description column of the result set.

For the secondary index (i1), there are four n_diff% rows. Only two columns are defined for the secondary index (c,d) but there are four n_diff% rows for the secondary index because InnoDB suffixes all nonunique indexes with the primary key. As a result, there are four n_diff% rows instead of two to account for the both the secondary index columns (c,d) and the primary key columns (a,b).

• Where index_name=i1 and stat_name=n_diff_pfx01, the stat_value is 1, which indicates that there is a single distinct value in the first column of the index (column c). The number of distinct values in column c is confirmed by viewing the data in column c in table t1, in which there is a single distinct value: (10). The counted column (c) is shown in the stat_description column of the result set.

• Where index_name=i1 and stat_name=n_diff_pfx02, the stat_value is 2, which indicates that there are two distinct values in the first two columns of the index (c,d). The number of distinct values in columns c and d is confirmed by viewing the data in columns c and d in table t1, in which there are two distinct values: (10, 11) and (10, 12). The counted columns (c,d) are shown in the stat_description column of the result set.

• Where index_name=i1 and stat_name=n_diff_pfx03, the stat_value is 2, which indicates that there are two distinct values in the first three columns of the index (c,d,a). The number of distinct values in columns c, d, and a is confirmed by viewing the data in columns c, d, and a in table t1, in which there are two distinct values: (10, 11, 1) and (10, 12, 1). The counted columns (c,d,a) are shown in the stat_description column of the result set.

• Where index_name=i1 and stat_name=n_diff_pfx04, the stat_value is 5, which indicates that there are five distinct values in the four columns of the index (c,d,a,b). The number of distinct values in columns c, d, a and b is confirmed by viewing the data in columns c, d, a and b in table t1, in which there are five distinct values: (10, 11, 1, 1), (10, 11, 1, 2), (10, 11, 1, 3), (10, 12, 1, 4), and (10, 12, 1, 5). The counted columns (c,d,a,b) are shown in the stat_description column of the result set.

For the unique index (i2uniq), there are two n_diff% rows.

• Where index_name=i2uniq and stat_name=n_diff_pfx01, the stat_value is 2, which indicates that there are two distinct values in the first column of the index (column e). The number of distinct values in column e is confirmed by viewing the data in column e in table t1, in which there are two distinct values: (100) and (200). The counted column (e) is shown in the stat_description column of the result set.

• Where index_name=i2uniq and stat_name=n_diff_pfx02, the stat_value is 5, which indicates that there are five distinct values in the two columns of the index (e,f). The number of distinct values in columns e and f is confirmed by viewing the data in columns e and f in table t1, in which there are five distinct values: (100,101), (200,102), (100,103), (200,104), and (100,105). The counted columns (e,f) are shown in the stat_description column of the result set.

Retrieving Index Size Using the innodb_index_stats Table

You can retrieve the index size for tables, partitions, or subpartitions can using the innodb_index_stats table. In the following example, index sizes are retrieved for table t1. For a definition of table t1 and corresponding index statistics, see InnoDB Persistent Statistics Tables Example.
AND stat_name = 'size' GROUP BY index_name;

<table>
<thead>
<tr>
<th>pages</th>
<th>index_name</th>
<th>size</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>PRIMARY</td>
<td>16384</td>
</tr>
<tr>
<td>1</td>
<td>i1</td>
<td>16384</td>
</tr>
<tr>
<td>1</td>
<td>i2uniq</td>
<td>16384</td>
</tr>
</tbody>
</table>

For partitions or subpartitions, you can use the same query with a modified WHERE clause to retrieve index sizes. For example, the following query retrieves index sizes for partitions of table `t1`:

```
mysql> SELECT SUM(stat_value) pages, index_name,
          SUM(stat_value)*@@innodb_page_size size
FROM mysql.innodb_index_stats WHERE table_name like 't1#P%'
AND stat_name = 'size' GROUP BY index_name;
```

15.8.10.2 Configuring Non-Persistent Optimizer Statistics Parameters

This section describes how to configure non-persistent optimizer statistics. Optimizer statistics are not persisted to disk when `innodb_stats_persistent=OFF` or when individual tables are created or altered with `STATS_PERSISTENT=0`. Instead, statistics are stored in memory, and are lost when the server is shut down. Statistics are also updated periodically by certain operations and under certain conditions.

Optimizer statistics are persisted to disk by default, enabled by the `innodb_stats_persistent` configuration option. For information about persistent optimizer statistics, see Section 15.8.10.1, “Configuring Persistent Optimizer Statistics Parameters”.

Optimizer Statistics Updates

Non-persistent optimizer statistics are updated when:

- Running `ANALYZE TABLE`.
- Running `SHOW TABLE STATUS`, `SHOW INDEX`, or querying the Information Schema `TABLES` or `STATISTICS` tables with the `innodb_stats_on_metadata` option enabled.

The default setting for `innodb_stats_on_metadata` is `OFF`. Enabling `innodb_stats_on_metadata` may reduce access speed for schemas that have a large number of tables or indexes, and reduce stability of execution plans for queries that involve InnoDB tables. `innodb_stats_on_metadata` is configured globally using a `SET` statement.

```
SET GLOBAL innodb_stats_on_metadata=ON
```

**Note**

`innodb_stats_on_metadata` only applies when optimizer statistics are configured to be non-persistent (when `innodb_stats_persistent` is disabled).

- Starting a `mysql` client with the `--auto-rehash` option enabled, which is the default. The `auto-rehash` option causes all InnoDB tables to be opened, and the open table operations cause statistics to be recalculated.

To improve the start up time of the `mysql` client and to updating statistics, you can turn off `auto-rehash` using the `--disable-auto-rehash` option. The `auto-rehash` feature enables automatic name completion of database, table, and column names for interactive users.

- A table is first opened.
• **InnoDB** detects that 1 / 16 of table has been modified since the last time statistics were updated.

### Configuring the Number of Sampled Pages

The MySQL query optimizer uses estimated statistics about key distributions to choose the indexes for an execution plan, based on the relative selectivity of the index. When **InnoDB** updates optimizer statistics, it samples random pages from each index on a table to estimate the cardinality of the index. (This technique is known as random dives.)

To give you control over the quality of the statistics estimate (and thus better information for the query optimizer), you can change the number of sampled pages using the parameter `innodb_stats_transient_sample_pages`. The default number of sampled pages is 8, which could be insufficient to produce an accurate estimate, leading to poor index choices by the query optimizer. This technique is especially important for large tables and tables used in joins. Unnecessary full table scans for such tables can be a substantial performance issue. See Section 8.2.1.23, “Avoiding Full Table Scans” for tips on tuning such queries. `innodb_stats_transient_sample_pages` is a global parameter that can be set at runtime.

The value of `innodb_stats_transient_sample_pages` affects the index sampling for all **InnoDB** tables and indexes when `innodb_stats_persistent=0`. Be aware of the following potentially significant impacts when you change the index sample size:

• Small values like 1 or 2 can result in inaccurate estimates of cardinality.

• Increasing the `innodb_stats_transient_sample_pages` value might require more disk reads. Values much larger than 8 (say, 100), can cause a significant slowdown in the time it takes to open a table or execute `SHOW TABLE STATUS`.

• The optimizer might choose very different query plans based on different estimates of index selectivity.

Whatever value of `innodb_stats_transient_sample_pages` works best for a system, set the option and leave it at that value. Choose a value that results in reasonably accurate estimates for all tables in your database without requiring excessive I/O. Because the statistics are automatically recalculated at various times other than on execution of `ANALYZE TABLE`, it does not make sense to increase the index sample size, run `ANALYZE TABLE`, then decrease sample size again.

Smaller tables generally require fewer index samples than larger tables. If your database has many large tables, consider using a higher value for `innodb_stats_transient_sample_pages` than if you have mostly smaller tables.

### 15.8.10.3 Estimating **ANALYZE TABLE** Complexity for **InnoDB** Tables

**ANALYZE TABLE** complexity for **InnoDB** tables is dependent on:

• The number of pages sampled, as defined by `innodb_stats_persistent_sample_pages`.

• The number of indexed columns in a table

• The number of partitions. If a table has no partitions, the number of partitions is considered to be 1.

Using these parameters, an approximate formula for estimating **ANALYZE TABLE** complexity would be:

The value of `innodb_stats_persistent_sample_pages` * number of indexed columns in a table * the number of partitions

Typically, the greater the resulting value, the greater the execution time for **ANALYZE TABLE**.
Configuring Optimizer Statistics for InnoDB

Note

`innodb_stats_persistent_sample_pages` defines the number of pages sampled at a global level. To set the number of pages sampled for an individual table, use the `STATS_SAMPLE_PAGES` option with `CREATE TABLE` or `ALTER TABLE`. For more information, see Section 15.8.10.1, "Configuring Persistent Optimizer Statistics Parameters".

If `innodb_stats_persistent=OFF`, the number of pages sampled is defined by `innodb_stats_transient_sample_pages`. See Section 15.8.10.2, "Configuring Non-Persistent Optimizer Statistics Parameters" for additional information.

For a more in-depth approach to estimating `ANALYZE TABLE` complexity, consider the following example.

In **Big O notation**, `ANALYZE TABLE` complexity is described as:

\[
O(n_{sample} \times (n_{cols\_in\_uniq\_i} + n_{cols\_in\_non\_uniq\_i} + n_{cols\_in\_pk} \times (1 + n_{non\_uniq\_i})) \times n_{part})
\]

where:

- `n_sample` is the number of pages sampled (defined by `innodb_stats_persistent_sample_pages`)
- `n_cols_in_uniq_i` is total number of all columns in all unique indexes (not counting the primary key columns)
- `n_cols_in_non_uniq_i` is the total number of all columns in all nonunique indexes
- `n_cols_in_pk` is the number of columns in the primary key (if a primary key is not defined, InnoDB creates a single column primary key internally)
- `n_non_uniq_i` is the number of nonunique indexes in the table
- `n_part` is the number of partitions. If no partitions are defined, the table is considered to be a single partition.

Now, consider the following table (table `t`), which has a primary key (2 columns), a unique index (2 columns), and two nonunique indexes (two columns each):

```sql
CREATE TABLE t (
    a INT,
    b INT,
    c INT,
    d INT,
    e INT,
    f INT,
    g INT,
    h INT,
    PRIMARY KEY (a, b),
    UNIQUE KEY i1uniq (c, d),
    KEY i2nonuniq (e, f),
    KEY i3nonuniq (g, h)
);```

For the column and index data required by the algorithm described above, query the `mysql.innodb_index_stats` persistent index statistics table for table `t`. The `n_diff_pfx%` statistics
show the columns that are counted for each index. For example, columns \texttt{a} and \texttt{b} are counted for the primary key index. For the nonunique indexes, the primary key columns (\texttt{a,b}) are counted in addition to the user defined columns.

**Note**

For additional information about the InnoDB persistent statistics tables, see Section 15.8.10.1, “Configuring Persistent Optimizer Statistics Parameters”

Based on the index statistics data shown above and the table definition, the following values can be determined:

• \texttt{n\_cols\_in\_uniq\_i}, the total number of all columns in all unique indexes not counting the primary key columns, is 2 (\texttt{c} and \texttt{d})

• \texttt{n\_cols\_in\_non\_uniq\_i}, the total number of all columns in all nonunique indexes, is 4 (\texttt{e}, \texttt{f}, \texttt{g} and \texttt{h})

• \texttt{n\_cols\_in\_pk}, the number of columns in the primary key, is 2 (\texttt{a} and \texttt{b})

• \texttt{n\_non\_uniq\_i}, the number of nonunique indexes in the table, is 2 (\texttt{i2nonuniq} and \texttt{i3nonuniq})

• \texttt{n\_part}, the number of partitions, is 1.

You can now calculate \texttt{innodb\_stats\_persistent\_sample\_pages} * (2 + 4 + 2 * (1 + 2)) * 1 to determine the number of leaf pages that are scanned. With \texttt{innodb\_stats\_persistent\_sample\_pages} set to the default value of 20, and with a default page size of 16 KiB (\texttt{innodb\_page\_size}=16384), you can then estimate that 20 * 12 * 16384 bytes are read for table \texttt{t}, or about 4 MiB.

**Note**

All 4 MiB may not be read from disk, as some leaf pages may already be cached in the buffer pool.

### 15.8.11 Configuring the Merge Threshold for Index Pages

You can configure the \texttt{MERGE\_THRESHOLD} value for index pages. If the “page-full” percentage for an index page falls below the \texttt{MERGE\_THRESHOLD} value when a row is deleted or when a row is shortened
by an UPDATE operation, InnoDB attempts to merge the index page with a neighboring index page. The default MERGE_THRESHOLD value is 50, which is the previously hardcoded value. The minimum MERGE_THRESHOLD value is 1 and the maximum value is 50.

When the “page-full” percentage for an index page falls below 50%, which is the default MERGE_THRESHOLD setting, InnoDB attempts to merge the index page with a neighboring page. If both pages are close to 50% full, a page split can occur soon after the pages are merged. If this merge-split behavior occurs frequently, it can have an adverse affect on performance. To avoid frequent merge-splits, you can lower the MERGE_THRESHOLD value so that InnoDB attempts page merges at a lower “page-full” percentage. Merging pages at a lower page-full percentage leaves more room in index pages and helps reduce merge-split behavior.

The MERGE_THRESHOLD for index pages can be defined for a table or for individual indexes. A MERGE_THRESHOLD value defined for an individual index takes priority over a MERGE_THRESHOLD value defined for the table. If undefined, the MERGE_THRESHOLD value defaults to 50.

### Setting MERGE_THRESHOLD for a Table

You can set the MERGE_THRESHOLD value for a table using the table_option COMMENT clause of the CREATE TABLE statement. For example:

```sql
CREATE TABLE t1 (  
id INT,  
KEY id_index (id)  
) COMMENT='MERGE_THRESHOLD=45';
```

You can also set the MERGE_THRESHOLD value for an existing table using the table_option COMMENT clause with ALTER TABLE:

```sql
CREATE TABLE t1 (  
id INT,  
KEY id_index (id)  
);

ALTER TABLE t1 COMMENT='MERGE_THRESHOLD=40';
```

### Setting MERGE_THRESHOLD for Individual Indexes

To set the MERGE_THRESHOLD value for an individual index, you can use the index_option COMMENT clause with CREATE TABLE, ALTER TABLE, or CREATE INDEX, as shown in the following examples:

- Setting MERGE_THRESHOLD for an individual index using CREATE TABLE:

  ```sql
  CREATE TABLE t1 (  
id INT,  
KEY id_index (id) COMMENT 'MERGE_THRESHOLD=40'  
);
  ```

- Setting MERGE_THRESHOLD for an individual index using ALTER TABLE:

  ```sql
  CREATE TABLE t1 (  
id INT,  
KEY id_index (id)  
);

  ALTER TABLE t1 DROP KEY id_index;
  ALTER TABLE t1 ADD KEY id_index (id) COMMENT 'MERGE_THRESHOLD=40';
  ```

- Setting MERGE_THRESHOLD for an individual index using CREATE INDEX:
Configuring the Merge Threshold for Index Pages

CREATE TABLE t1 (id INT);
CREATE INDEX id_index ON t1 (id) COMMENT 'MERGE_THRESHOLD=40';

**Note**

You cannot modify the `MERGE_THRESHOLD` value at the index level for `GEN_CLUST_INDEX`, which is the clustered index created by InnoDB when an InnoDB table is created without a primary key or unique key index. You can only modify the `MERGE_THRESHOLD` value for `GEN_CLUST_INDEX` by setting `MERGE_THRESHOLD` for the table.

**Querying the `MERGE_THRESHOLD` Value for an Index**

The current `MERGE_THRESHOLD` value for an index can be obtained by querying the `INNODB_INDEXES` table. For example:

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_INDEXES WHERE NAME='id_index' \G
*************************** 1. row ***************************
INDEX_ID: 91
NAME: id_index
TABLE_ID: 68
TYPE: 0
N_FIELDS: 1
PAGE_NO: 4
SPACE: 57
MERGE_THRESHOLD: 40
```

You can use `SHOW CREATE TABLE` to view the `MERGE_THRESHOLD` value for a table, if explicitly defined using the `table_option COMMENT` clause:

```sql
mysql> SHOW CREATE TABLE t2 \G
*************************** 1. row ***************************
Table: t2
Create Table: CREATE TABLE `t2` (  `id` int(11) DEFAULT NULL,
   KEY `id_index` (`id`) COMMENT 'MERGE_THRESHOLD=40'
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4
```

**Note**

A `MERGE_THRESHOLD` value defined at the index level takes priority over a `MERGE_THRESHOLD` value defined for the table. If undefined, `MERGE_THRESHOLD` defaults to 50% (`MERGE_THRESHOLD=50`, which is the previously hardcoded value).

Likewise, you can use `SHOW INDEX` to view the `MERGE_THRESHOLD` value for an index, if explicitly defined using the `index_option COMMENT` clause:

```sql
mysql> SHOW INDEX FROM t2 \G
*************************** 1. row ***************************
Table: t2
Non_unique: 1
Key_name: id_index
Seq_in_index: 1
Column_name: id
Collation: A
Cardinality: 0
Sub_part: NULL
Packed: NULL
Null: YES
Index_type: BTREE
Comment:
Index_comment: MERGE_THRESHOLD=40
```
Measuring the Effect of MERGE_THRESHOLD Settings

The `INNODB_METRICS` table provides two counters that can be used to measure the effect of a `MERGE_THRESHOLD` setting on index page merges.

```sql
mysql> SELECT NAME, COMMENT FROM INFORMATION_SCHEMA.INNODB_METRICS
WHERE NAME like '%index_page_merge%';
+-----------------------------+----------------------------------------+
| NAME                        | COMMENT                                |
+-----------------------------+----------------------------------------+
| index_page_merge_attempts   | Number of index page merge attempts    |
| index_page_merge_successful | Number of successful index page merges |
+-----------------------------+----------------------------------------+
```

When lowering the `MERGE_THRESHOLD` value, the objectives are:

- A smaller number of page merge attempts and successful page merges
- A similar number of page merge attempts and successful page merges

A `MERGE_THRESHOLD` setting that is too small could result in large data files due to an excessive amount of empty page space.

For information about using `INNODB_METRICS` counters, see Section 15.15.6, “InnoDB INFORMATION_SCHEMA Metrics Table”.

15.8.12 Enabling Automatic Configuration for a Dedicated MySQL Server

When `innodb_dedicated_server` is enabled, InnoDB automatically configures the following variables:

- `innodb_buffer_pool_size`
- `innodb_redo_log_capacity` or, prior to MySQL 8.0.30, `innodb_log_file_size` and `innodb_log_files_in_group`.

Note

`innodb_log_file_size` and `innodb_log_files_in_group` are deprecated in MySQL 8.0.30. These variables are superseded by the `innodb_redo_log_capacity` variable.

- `innodb_flush_method`

Only consider enabling `innodb_dedicated_server` if the MySQL instance resides on a dedicated server where it can use all available system resources. For example, consider enabling `innodb_dedicated_server` if you run MySQL Server in a Docker container or dedicated VM that only runs MySQL. Enabling `innodb_dedicated_server` is not recommended if the MySQL instance shares system resources with other applications.

The information that follows describes how each variable is automatically configured.

- `innodb_buffer_pool_size`

  Buffer pool size is configured according to the amount of memory detected on the server.

### Table 15.8 Automatically Configured Buffer Pool Size

<table>
<thead>
<tr>
<th>Detected Server Memory</th>
<th>Buffer Pool Size</th>
</tr>
</thead>
<tbody>
<tr>
<td>Less than 1GB</td>
<td>128MB (the default value)</td>
</tr>
</tbody>
</table>
Enabling Automatic Configuration for a Dedicated MySQL Server

Detected Server Memory | Buffer Pool Size
---|---
1GB to 4GB | detected server memory \* 0.5
Greater than 4GB | detected server memory \* 0.75

- **innodb_redo_log_capacity**

Redo log capacity is configured according to the amount of memory detected on the server and, in some cases, whether `innodb_buffer_pool_size` is configured explicitly. If `innodb_buffer_pool_size` is not configured explicitly, the default value is assumed.

**Warning**

Automatic redo log capacity configuration behavior is undefined if `innodb_buffer_pool_size` is set to a value larger than the detected amount of server memory.

Table 15.9 Automatically Configured Log File Size

<table>
<thead>
<tr>
<th>Detected Server Memory</th>
<th>Buffer Pool Size</th>
<th>Redo Log Capacity</th>
</tr>
</thead>
<tbody>
<tr>
<td>Less than 1GB</td>
<td>Not configured</td>
<td>100MB</td>
</tr>
<tr>
<td>Less than 1GB</td>
<td>Less than 1GB</td>
<td>100MB</td>
</tr>
<tr>
<td>1GB to 2GB</td>
<td>Not applicable</td>
<td>100MB</td>
</tr>
<tr>
<td>2GB to 4GB</td>
<td>Not configured</td>
<td>1GB</td>
</tr>
<tr>
<td>2GB to 4GB</td>
<td>Any configured value</td>
<td>round(0.5 * detected server memory in GB) * 0.5 GB</td>
</tr>
<tr>
<td>4GB to 10.66GB</td>
<td>Not applicable</td>
<td>round(0.75 * detected server memory in GB) * 0.5 GB</td>
</tr>
<tr>
<td>10.66GB to 170.66GB</td>
<td>Not applicable</td>
<td>round(0.5625 * detected server memory in GB) * 0.5 GB</td>
</tr>
<tr>
<td>Greater than 170.66GB</td>
<td>Not applicable</td>
<td>128GB</td>
</tr>
</tbody>
</table>

- **innodb_log_file_size** (deprecated in MySQL 8.0.30)

Log file size is configured according to the automatically configured buffer pool size.

Table 15.10 Automatically Configured Log File Size

<table>
<thead>
<tr>
<th>Buffer Pool Size</th>
<th>Log File Size</th>
</tr>
</thead>
<tbody>
<tr>
<td>Less than 8GB</td>
<td>512MB</td>
</tr>
<tr>
<td>8GB to 128GB</td>
<td>1024MB</td>
</tr>
<tr>
<td>Greater than 128GB</td>
<td>2048MB</td>
</tr>
</tbody>
</table>

- **innodb_log_files_in_group** (deprecated in MySQL 8.0.30)

The number of log files is configured according to the automatically configured buffer pool size. Automatic configuration of the `innodb_log_files_in_group` variable was added in MySQL 8.0.14.

Table 15.11 Automatically Configured Number of Log Files

<table>
<thead>
<tr>
<th>Buffer Pool Size</th>
<th>Number of Log Files</th>
</tr>
</thead>
<tbody>
<tr>
<td>Less than 8GB</td>
<td>round(buffer pool size)</td>
</tr>
</tbody>
</table>
InnoDB Table and Page Compression

<table>
<thead>
<tr>
<th>Buffer Pool Size</th>
<th>Number of Log Files</th>
</tr>
</thead>
<tbody>
<tr>
<td>8GB to 128GB</td>
<td>( \text{round}(\text{buffer pool size} \times 0.75) )</td>
</tr>
<tr>
<td>Greater than 128GB</td>
<td>64</td>
</tr>
</tbody>
</table>

**Note**

The minimum `innodb_log_files_in_group` value of 2 is enforced if the rounded buffer pool size value is less than 2GB.

- **innodb_flush_method**

  The flush method is set to `O_DIRECT_NO_FSYNC` when `innodb_dedicated_server` is enabled. If the `O_DIRECT_NO_FSYNC` setting is not available, the default `innodb_flush_method` setting is used.

  InnoDB uses `O_DIRECT` during flushing I/O, but skips the `fsync()` system call after each write operation.

**Warning**

Prior to MySQL 8.0.14, this setting is not suitable for file systems such as XFS and EXT4, which require an `fsync()` system call to synchronize file system metadata changes.

As of MySQL 8.0.14, `fsync()` is called after creating a new file, after increasing file size, and after closing a file, to ensure that file system metadata changes are synchronized. The `fsync()` system call is still skipped after each write operation.

Data loss is possible if redo log files and data files reside on different storage devices, and an unexpected exit occurs before data file writes are flushed from a device cache that is not battery-backed. If you use or intend to use different storage devices for redo log files and data files, and your data files reside on a device with a cache that is not battery-backed, use `O_DIRECT` instead.

If an automatically configured option is configured explicitly in an option file or elsewhere, the explicitly specified setting is used, and a startup warning similar to this is printed to `stderr`:

```
[Warning] [000000] InnoDB: Option innodb_dedicated_server is ignored for
innodb_buffer_pool_size because innodb_buffer_pool_size=134217728 is specified
explicitly.
```

Explicit configuration of one option does not prevent the automatic configuration of other options.

If `innodb_dedicated_server` is enabled and `innodb_buffer_pool_size` is configured explicitly, variables configured based on buffer pool size use the buffer pool size value calculated according to the amount of memory detected on the server rather than the explicitly defined buffer pool size value.

Automatically configured settings are evaluated and reconfigured if necessary each time the MySQL server is started.

**15.9 InnoDB Table and Page Compression**

This section provides information about the InnoDB table compression and InnoDB page compression features. The page compression feature is also referred to as transparent page compression.

Using the compression features of InnoDB, you can create tables where the data is stored in compressed form. Compression can help to improve both raw performance and scalability. The compression means...
InnoDB Table Compression

less data is transferred between disk and memory, and takes up less space on disk and in memory. The benefits are amplified for tables with secondary indexes, because index data is compressed also. Compression can be especially important for SSD storage devices, because they tend to have lower capacity than HDD devices.

15.9.1 InnoDB Table Compression

This section describes InnoDB table compression, which is supported with InnoDB tables that reside in file_per_table tablespaces or general tablespaces. Table compression is enabled using the ROW_FORMAT=COMPRESSED attribute with CREATE TABLE or ALTER TABLE.

15.9.1.1 Overview of Table Compression

Because processors and cache memories have increased in speed more than disk storage devices, many workloads are disk-bound. Data compression enables smaller database size, reduced I/O, and improved throughput, at the small cost of increased CPU utilization. Compression is especially valuable for read-intensive applications, on systems with enough RAM to keep frequently used data in memory.

An InnoDB table created with ROW_FORMAT=COMPRESSED can use a smaller page size on disk than the configured innodb_page_size value. Smaller pages require less I/O to read from and write to disk, which is especially valuable for SSD devices.

The compressed page size is specified through the CREATE TABLE or ALTER TABLE KEY_BLOCK_SIZE parameter. The different page size requires that the table be placed in a file-per-table tablespace or general tablespace rather than in the system tablespace, as the system tablespace cannot store compressed tables. For more information, see Section 15.6.3.2, “File-Per-Table Tablespaces”, and Section 15.6.3.3, “General Tablespaces”.

The level of compression is the same regardless of the KEY_BLOCK_SIZE value. As you specify smaller values for KEY_BLOCK_SIZE, you get the I/O benefits of increasingly smaller pages. But if you specify a value that is too small, there is additional overhead to reorganize the pages when data values cannot be compressed enough to fit multiple rows in each page. There is a hard limit on how small KEY_BLOCK_SIZE can be for a table, based on the lengths of the key columns for each of its indexes. Specify a value that is too small, and the CREATE TABLE or ALTER TABLE statement fails.

In the buffer pool, the compressed data is held in small pages, with a page size based on the KEY_BLOCK_SIZE value. For extracting or updating the column values, MySQL also creates an uncompressed page in the buffer pool with the uncompressed data. Within the buffer pool, any updates to the uncompressed page are also re-written back to the equivalent compressed page. You might need to size your buffer pool to accommodate the additional data of both compressed and uncompressed pages, although the uncompressed pages are evicted from the buffer pool when space is needed, and then uncompressed again on the next access.

15.9.1.2 Creating Compressed Tables

Compressed tables can be created in file-per-table tablespaces or in general tablespaces. Table compression is not available for the InnoDB system tablespace. The system tablespace (space 0, the .ibdata files) can contain user-created tables, but it also contains internal system data, which is never compressed. Thus, compression applies only to tables (and indexes) stored in file-per-table or general tablespaces.

Creating a Compressed Table in File-Per-Table Tablespace

To create a compressed table in a file-per-table tablespace, innodb_file_per_table must be enabled (the default). You can set this parameter in the MySQL configuration file (my.cnf or my.ini) or dynamically, using a SET statement.
After the `innodb_file_per_table` option is configured, specify the `ROW_FORMAT=COMPRESSED` clause or `KEY_BLOCK_SIZE` clause, or both, in a `CREATE TABLE` or `ALTER TABLE` statement to create a compressed table in a file-per-table tablesapce.

For example, you might use the following statements:

```sql
SET GLOBAL innodb_file_per_table=1;
CREATE TABLE t1
(c1 INT PRIMARY KEY)
ROW_FORMAT=COMPRESSED
KEY_BLOCK_SIZE=8;
```

### Creating a Compressed Table in a General Tablespace

To create a compressed table in a general tablespace, `FILE_BLOCK_SIZE` must be defined for the general tablespace, which is specified when the tablespace is created. The `FILE_BLOCK_SIZE` value must be a valid compressed page size in relation to the `innodb_page_size` value, and the page size of the compressed table, defined by the `CREATE TABLE` or `ALTER TABLE` `KEY_BLOCK_SIZE` clause, must be equal to `FILE_BLOCK_SIZE/1024`. For example, if `innodb_page_size=16384` and `FILE_BLOCK_SIZE=8192`, the `KEY_BLOCK_SIZE` of the table must be 8. For more information, see Section 15.6.3.3, “General Tablespaces”.

The following example demonstrates creating a general tablespace and adding a compressed table. The example assumes a default `innodb_page_size` of 16K. The `FILE_BLOCK_SIZE` of 8192 requires that the compressed table have a `KEY_BLOCK_SIZE` of 8.

```sql
mysql> CREATE TABLESPACE `ts2` ADD DATAFILE `ts2.ibd` FILE_BLOCK_SIZE = 8192 Engine=InnoDB;
mysql> CREATE TABLE t4 (c1 INT PRIMARY KEY) TABLESPACE ts2 ROW_FORMAT=COMPRESSED KEY_BLOCK_SIZE=8;
```

### Notes

- As of MySQL 8.0, the tablespace file for a compressed table is created using the physical page size instead of the InnoDB page size, which makes the initial size of a tablesapce file for an empty compressed table smaller than in previous MySQL releases.

- If you specify `ROW_FORMAT=COMPRESSED`, you can omit `KEY_BLOCK_SIZE`; the `KEY_BLOCK_SIZE` setting defaults to half the `innodb_page_size` value.

- If you specify a valid `KEY_BLOCK_SIZE` value, you can omit `ROW_FORMAT=COMPRESSED`; compression is enabled automatically.

- To determine the best value for `KEY_BLOCK_SIZE`, typically you create several copies of the same table with different values for this clause, then measure the size of the resulting `.ibd` files and see how well each performs with a realistic workload. For general tablespaces, keep in mind that dropping a table does not reduce the size of the general tablesapce `.ibd` file, nor does it return disk space to the operating system. For more information, see Section 15.6.3.3, “General Tablespaces”.

- The `KEY_BLOCK_SIZE` value is treated as a hint; a different size could be used by InnoDB if necessary. For file-per-table tablesapces, the `KEY_BLOCK_SIZE` can only be less than or equal to the `innodb_page_size` value. If you specify a value greater than the `innodb_page_size` value, the specified value is ignored, a warning is issued, and `KEY_BLOCK_SIZE` is set to half of the `innodb_page_size` value. If `innodb_strict_mode=ON`, specifying an invalid `KEY_BLOCK_SIZE` value returns an error. For general tablesapces, valid `KEY_BLOCK_SIZE` values depend on the `FILE_BLOCK_SIZE` setting of the tablesapce. For more information, see Section 15.6.3.3, “General Tablespaces”.

- InnoDB supports 32KB and 64KB page sizes but these page sizes do not support compression. For more information, refer to the `innodb_page_size` documentation.
The default uncompressed size of InnoDB data pages is 16KB. Depending on the combination of option values, MySQL uses a page size of 1KB, 2KB, 4KB, 8KB, or 16KB for the tablespace data file (.ibd file). The actual compression algorithm is not affected by the `KEY_BLOCK_SIZE` value; the value determines how large each compressed chunk is, which in turn affects how many rows can be packed into each compressed page.

When creating a compressed table in a file-per-table tablespace, setting `KEY_BLOCK_SIZE` equal to the InnoDB page size does not typically result in much compression. For example, setting `KEY_BLOCK_SIZE=16` typically would not result in much compression, since the normal InnoDB page size is 16KB. This setting may still be useful for tables with many long BLOB, VARCHAR or TEXT columns, because such values often do compress well, and might therefore require fewer overflow pages as described in Section 15.9.1.5, “How Compression Works for InnoDB Tables”. For general tablespaces, a `KEY_BLOCK_SIZE` value equal to the InnoDB page size is not permitted. For more information, see Section 15.6.3.3, “General Tablespaces”.

All indexes of a table (including the clustered index) are compressed using the same page size, as specified in the `CREATE TABLE` or `ALTER TABLE` statement. Table attributes such as `ROW_FORMAT` and `KEY_BLOCK_SIZE` are not part of the `CREATE INDEX` syntax for InnoDB tables, and are ignored if they are specified (although, if specified, they appear in the output of the `SHOW CREATE TABLE` statement).

For performance-related configuration options, see Section 15.9.1.3, “Tuning Compression for InnoDB Tables”.

Restrictions on Compressed Tables

- Compressed tables cannot be stored in the InnoDB system tablespace.
- General tablespaces can contain multiple tables, but compressed and uncompressed tables cannot coexist within the same general tablespace.
- Compression applies to an entire table and all its associated indexes, not to individual rows, despite the clause name `ROW_FORMAT`.
- InnoDB does not support compressed temporary tables. When `innodb_strict_mode` is enabled (the default), `CREATE TEMPORARY TABLE` returns errors if `ROW_FORMAT=COMPressed` or `KEY_BLOCK_SIZE` is specified. If `innodb_strict_mode` is disabled, warnings are issued and the temporary table is created using a non-compressed row format. The same restrictions apply to `ALTER TABLE` operations on temporary tables.

15.9.1.3 Tuning Compression for InnoDB Tables

Most often, the internal optimizations described in InnoDB Data Storage and Compression ensure that the system runs well with compressed data. However, because the efficiency of compression depends on the nature of your data, you can make decisions that affect the performance of compressed tables:

- Which tables to compress.
- What compressed page size to use.
- Whether to adjust the size of the buffer pool based on run-time performance characteristics, such as the amount of time the system spends compressing and uncompressing data. Whether the workload is more like a data warehouse (primarily queries) or an OLTP system (mix of queries and DML).
- If the system performs DML operations on compressed tables, and the way the data is distributed leads to expensive compression failures at runtime, you might adjust additional advanced configuration options.
Use the guidelines in this section to help make those architectural and configuration choices. When you are ready to conduct long-term testing and put compressed tables into production, see Section 15.9.1.4, “Monitoring InnoDB Table Compression at Runtime” for ways to verify the effectiveness of those choices under real-world conditions.

When to Use Compression

In general, compression works best on tables that include a reasonable number of character string columns and where the data is read far more often than it is written. Because there are no guaranteed ways to predict whether or not compression benefits a particular situation, always test with a specific workload and data set running on a representative configuration. Consider the following factors when deciding which tables to compress.

Data Characteristics and Compression

A key determinant of the efficiency of compression in reducing the size of data files is the nature of the data itself. Recall that compression works by identifying repeated strings of bytes in a block of data. Completely randomized data is the worst case. Typical data often has repeated values, and so compresses effectively. Character strings often compress well, whether defined in `CHAR`, `VARCHAR`, `TEXT` or `BLOB` columns. On the other hand, tables containing mostly binary data (integers or floating point numbers) or data that is previously compressed (for example JPEG or PNG images) may not generally compress well, significantly or at all.

You choose whether to turn on compression for each InnoDB table. A table and all of its indexes use the same (compressed) page size. It might be that the primary key (clustered) index, which contains the data for all columns of a table, compresses more effectively than the secondary indexes. For those cases where there are long rows, the use of compression might result in long column values being stored “off-page”, as discussed in DYNAMIC Row Format. Those overflow pages may compress well. Given these considerations, for many applications, some tables compress more effectively than others, and you might find that your workload performs best only with a subset of tables compressed.

To determine whether or not to compress a particular table, conduct experiments. You can get a rough estimate of how efficiently your data can be compressed by using a utility that implements LZ77 compression (such as `gzip` or WinZip) on a copy of the `.ibd` file for an uncompressed table. You can expect less compression from a MySQL compressed table than from file-based compression tools, because MySQL compresses data in chunks based on the page size, 16KB by default. In addition to user data, the page format includes some internal system data that is not compressed. File-based compression utilities can examine much larger chunks of data, and so might find more repeated strings in a huge file than MySQL can find in an individual page.

Another way to test compression on a specific table is to copy some data from your uncompressed table to a similar, compressed table (having all the same indexes) in a file-per-table tablespace and look at the size of the resulting `.ibd` file. For example:

```sql
USE test;
SET GLOBAL innodb_file_per_table=1;
SET GLOBAL autocommit=0;

-- Create an uncompressed table with a million or two rows.
CREATE TABLE big_table AS SELECT * FROM information_schema.columns;
INSERT INTO big_table SELECT * FROM big_table;
INSERT INTO big_table SELECT * FROM big_table;
INSERT INTO big_table SELECT * FROM big_table;
INSERT INTO big_table SELECT * FROM big_table;
INSERT INTO big_table SELECT * FROM big_table;
INSERT INTO big_table SELECT * FROM big_table;
INSERT INTO big_table SELECT * FROM big_table;
INSERT INTO big_table SELECT * FROM big_table;
INSERT INTO big_table SELECT * FROM big_table;
```
InnoDB Table Compression

```sql
INSERT INTO big_table SELECT * FROM big_table;
COMMIT;
ALTER TABLE big_table ADD id int unsigned NOT NULL PRIMARY KEY auto_increment;
SHOW CREATE TABLE big_table;G
select count(id) from big_table;
-- Check how much space is needed for the uncompressed table.
\! ls -l data/test/big_table.ibd
CREATE TABLE key_block_size_4 LIKE big_table;
ALTER TABLE key_block_size_4 key_block_size=4 row_format=compressed;
INSERT INTO key_block_size_4 SELECT * FROM big_table;
commit;
-- Check how much space is needed for a compressed table
-- with particular compression settings.
\! ls -l data/test/key_block_size_4.ibd
```

This experiment produced the following numbers, which of course could vary considerably depending on your table structure and data:

```
-rw-rw---- 1 cirrus  staff  310378496 Jan  9 13:44 data/test/big_table.ibd
-rw-rw---- 1 cirrus  staff  83886080 Jan  9 15:10 data/test/key_block_size_4.ibd
```

To see whether compression is efficient for your particular workload:

- For simple tests, use a MySQL instance with no other compressed tables and run queries against the Information Schema `INNODB_CMP` table.

- For more elaborate tests involving workloads with multiple compressed tables, run queries against the Information Schema `INNODB_CMP_PER_INDEX` table. Because the statistics in the `INNODB_CMP_PER_INDEX` table are expensive to collect, you must enable the configuration option `innodb_cmp_per_index_enabled` before querying that table, and you might restrict such testing to a development server or a non-critical replica server.

- Run some typical SQL statements against the compressed table you are testing.

- Examine the ratio of successful compression operations to overall compression operations by querying `INFORMATION_SCHEMA.INNODB_CMP` or `INFORMATION_SCHEMA.INNODB_CMP_PER_INDEX`, and comparing `COMPRESS_OPS` to `COMPRESS_OPS_OK`.

- If a high percentage of compression operations complete successfully, the table might be a good candidate for compression.

- If you get a high proportion of compression failures, you can adjust `innodb_compression_level`, `innodb_compression_failure_threshold_pct`, and `innodb_compression_pad_pct_max` options as described in Section 15.9.1.6, “Compression for OLTP Workloads”, and try further tests.

### Database Compression versus Application Compression

Decide whether to compress data in your application or in the table; do not use both types of compression for the same data. When you compress the data in the application and store the results in a compressed table, extra space savings are extremely unlikely, and the double compression just wastes CPU cycles.

### Compressing in the Database

When enabled, MySQL table compression is automatic and applies to all columns and index values. The columns can still be tested with operators such as `LIKE`, and sort operations can still use indexes...
InnoDB Table Compression

even when the index values are compressed. Because indexes are often a significant fraction of the total size of a database, compression could result in significant savings in storage, I/O or processor time. The compression and decompression operations happen on the database server, which likely is a powerful system that is sized to handle the expected load.

Compressing in the Application

If you compress data such as text in your application, before it is inserted into the database, you might save overhead for data that does not compress well by compressing some columns and not others. This approach uses CPU cycles for compression and decompression on the client machine rather than the database server, which might be appropriate for a distributed application with many clients, or where the client machine has spare CPU cycles.

Hybrid Approach

Of course, it is possible to combine these approaches. For some applications, it may be appropriate to use some compressed tables and some uncompressed tables. It may be best to externally compress some data (and store it in uncompressed tables) and allow MySQL to compress (some of) the other tables in the application. As always, up-front design and real-life testing are valuable in reaching the right decision.

Workload Characteristics and Compression

In addition to choosing which tables to compress (and the page size), the workload is another key determinant of performance. If the application is dominated by reads, rather than updates, fewer pages need to be reorganized and recompressed after the index page runs out of room for the per-page "modification log" that MySQL maintains for compressed data. If the updates predominantly change non-indexed columns or those containing BLOBs or large strings that happen to be stored "off-page", the overhead of compression may be acceptable. If the only changes to a table are INSERTs that use a monotonically increasing primary key, and there are few secondary indexes, there is little need to reorganize and recompress index pages. Since MySQL can "delete-mark" and delete rows on compressed pages "in place" by modifying uncompressed data, DELETE operations on a table are relatively efficient.

For some environments, the time it takes to load data can be as important as run-time retrieval. Especially in data warehouse environments, many tables may be read-only or read-mostly. In those cases, it might or might not be acceptable to pay the price of compression in terms of increased load time, unless the resulting savings in fewer disk reads or in storage cost is significant.

Fundamentally, compression works best when the CPU time is available for compressing and uncompressing data. Thus, if your workload is I/O bound, rather than CPU-bound, you might find that compression can improve overall performance. When you test your application performance with different compression configurations, test on a platform similar to the planned configuration of the production system.

Configuration Characteristics and Compression

Reading and writing database pages from and to disk is the slowest aspect of system performance. Compression attempts to reduce I/O by using CPU time to compress and uncompress data, and is most effective when I/O is a relatively scarce resource compared to processor cycles.

This is often especially the case when running in a multi-user environment with fast, multi-core CPUs. When a page of a compressed table is in memory, MySQL often uses additional memory, typically 16KB, in the buffer pool for an uncompressed copy of the page. The adaptive LRU algorithm attempts to balance the use of memory between compressed and uncompressed pages to take into account whether the workload is running in an I/O-bound or CPU-bound manner. Still, a configuration with more memory dedicated to the buffer pool tends to run better when using compressed tables than a configuration where memory is highly constrained.
Choosing the Compressed Page Size

The optimal setting of the compressed page size depends on the type and distribution of data that the table and its indexes contain. The compressed page size should always be bigger than the maximum record size, or operations may fail as noted in Compression of B-Tree Pages.

Setting the compressed page size too large wastes some space, but the pages do not have to be compressed as often. If the compressed page size is set too small, inserts or updates may require time-consuming recompression, and the B-tree nodes may have to be split more frequently, leading to bigger data files and less efficient indexing.

Typically, you set the compressed page size to 8K or 4K bytes. Given that the maximum row size for an InnoDB table is around 8K, $\text{KEY\_BLOCK\_SIZE}=8$ is usually a safe choice.

15.9.1.4 Monitoring InnoDB Table Compression at Runtime

Overall application performance, CPU and I/O utilization and the size of disk files are good indicators of how effective compression is for your application. This section builds on the performance tuning advice from Section 15.9.1.3, “Tuning Compression for InnoDB Tables”, and shows how to find problems that might not turn up during initial testing.

To dig deeper into performance considerations for compressed tables, you can monitor compression performance at runtime using the Information Schema tables described in Example 15.1, “Using the Compression Information Schema Tables”. These tables reflect the internal use of memory and the rates of compression used overall.

The $\text{INNODB\_CMP}$ table reports information about compression activity for each compressed page size ($\text{KEY\_BLOCK\_SIZE}$) in use. The information in these tables is system-wide: it summarizes the compression statistics across all compressed tables in your database. You can use this data to help decide whether or not to compress a table by examining these tables when no other compressed tables are being accessed. It involves relatively low overhead on the server, so you might query it periodically on a production server to check the overall efficiency of the compression feature.

The $\text{INNODB\_CMP\_PER\_INDEX}$ table reports information about compression activity for individual tables and indexes. This information is more targeted and more useful for evaluating compression efficiency and diagnosing performance issues one table or index at a time. (Because that each InnoDB table is represented as a clustered index, MySQL does not make a big distinction between tables and indexes in this context.) The $\text{INNODB\_CMP\_PER\_INDEX}$ table does involve substantial overhead, so it is more suitable for development servers, where you can compare the effects of different workloads, data, and compression settings in isolation. To guard against imposing this monitoring overhead by accident, you must enable the $\text{innodb\_cmp\_per\_index\_enabled}$ configuration option before you can query the $\text{INNODB\_CMP\_PER\_INDEX}$ table.

The key statistics to consider are the number of, and amount of time spent performing, compression and uncompression operations. Since MySQL splits B-tree nodes when they are too full to contain the compressed data following a modification, compare the number of “successful” compression operations with the number of such operations overall. Based on the information in the $\text{INNODB\_CMP}$ and $\text{INNODB\_CMP\_PER\_INDEX}$ tables and overall application performance and hardware resource utilization, you might make changes in your hardware configuration, adjust the size of the buffer pool, choose a different page size, or select a different set of tables to compress.

If the amount of CPU time required for compressing and uncompressing is high, changing to faster or multi-core CPUs can help improve performance with the same data, application workload and set of compressed tables. Increasing the size of the buffer pool might also help performance, so that more uncompressed pages can stay in memory, reducing the need to uncompress pages that exist in memory only in compressed form.
InnoDB Table Compression

A large number of compression operations overall (compared to the number of `INSERT`, `UPDATE` and `DELETE` operations in your application and the size of the database) could indicate that some of your compressed tables are being updated too heavily for effective compression. If so, choose a larger page size, or be more selective about which tables you compress.

If the number of “successful” compression operations (`COMPRESS_OPS_OK`) is a high percentage of the total number of compression operations (`COMPRESS_OPS`), then the system is likely performing well. If the ratio is low, then MySQL is reorganizing, recompressing, and splitting B-tree nodes more often than is desirable. In this case, avoid compressing some tables, or increase `KEY_BLOCK_SIZE` for some of the compressed tables. You might turn off compression for tables that cause the number of “compression failures” in your application to be more than 1% or 2% of the total. (Such a failure ratio might be acceptable during a temporary operation such as a data load).

### 15.9.1.5 How Compression Works for InnoDB Tables

This section describes some internal implementation details about compression for InnoDB tables. The information presented here may be helpful in tuning for performance, but is not necessary to know for basic use of compression.

#### Compression Algorithms

Some operating systems implement compression at the file system level. Files are typically divided into fixed-size blocks that are compressed into variable-size blocks, which easily leads into fragmentation. Every time something inside a block is modified, the whole block is recompressed before it is written to disk. These properties make this compression technique unsuitable for use in an update-intensive database system.

MySQL implements compression with the help of the well-known zlib library, which implements the LZ77 compression algorithm. This compression algorithm is mature, robust, and efficient in both CPU utilization and in reduction of data size. The algorithm is “lossless”, so that the original uncompressed data can always be reconstructed from the compressed form. LZ77 compression works by finding sequences of data that are repeated within the data to be compressed. The patterns of values in your data determine how well it compresses, but typical user data often compresses by 50% or more.

#### Note

InnoDB supports the zlib library up to version 1.2.11, which is the version bundled with MySQL 8.0.

Unlike compression performed by an application, or compression features of some other database management systems, InnoDB compression applies both to user data and to indexes. In many cases, indexes can constitute 40-50% or more of the total database size, so this difference is significant. When compression is working well for a data set, the size of the InnoDB data files (the `file-per-table` tablespace or `general tablespace .ibd` files) is 25% to 50% of the uncompressed size or possibly smaller. Depending on the workload, this smaller database can in turn lead to a reduction in I/O, and an increase in throughput, at a modest cost in terms of increased CPU utilization. You can adjust the balance between compression level and CPU overhead by modifying the `innodb_compression_level` configuration option.

#### InnoDB Data Storage and Compression

All user data in InnoDB tables is stored in pages comprising a B-tree index (the `clustered index`). In some other database systems, this type of index is called an “index-organized table”. Each row in the index node contains the values of the (user-specified or system-generated) `primary key` and all the other columns of the table.
**Secondary indexes** in InnoDB tables are also B-trees, containing pairs of values: the index key and a pointer to a row in the clustered index. The pointer is in fact the value of the primary key of the table, which is used to access the clustered index if columns other than the index key and primary key are required. Secondary index records must always fit on a single B-tree page.

The compression of B-tree nodes (of both clustered and secondary indexes) is handled differently from compression of *overflow pages* used to store long **VARCHAR**, **BLOB**, or **TEXT** columns, as explained in the following sections.

**Compression of B-Tree Pages**

Because they are frequently updated, B-tree pages require special treatment. It is important to minimize the number of times B-tree nodes are split, as well as to minimize the need to uncompress and recompress their content.

One technique MySQL uses is to maintain some system information in the B-tree node in uncompressed form, thus facilitating certain in-place updates. For example, this allows rows to be delete-marked and deleted without any compression operation.

In addition, MySQL attempts to avoid unnecessary uncompression and recompression of index pages when they are changed. Within each B-tree page, the system keeps an uncompressed “modification log” to record changes made to the page. Updates and inserts of small records may be written to this modification log without requiring the entire page to be completely reconstructed.

When the space for the modification log runs out, InnoDB uncompresses the page, applies the changes and recompresses the page. If recompression fails (a situation known as a compression failure), the B-tree nodes are split and the process is repeated until the update or insert succeeds.

To avoid frequent compression failures in write-intensive workloads, such as for **OLTP** applications, MySQL sometimes reserves some empty space (padding) in the page, so that the modification log fills up sooner and the page is recompressed while there is still enough room to avoid splitting it.

The amount of padding space left in each page varies as the system keeps track of the frequency of page splits. On a busy server doing frequent writes to compressed tables, you can adjust the `innodb_compression_failure_threshold_pct`, and `innodb_compression_pad_pct_max` configuration options to fine-tune this mechanism.

Generally, MySQL requires that each B-tree page in an InnoDB table can accommodate at least two records. For compressed tables, this requirement has been relaxed. Leaf pages of B-tree nodes (whether of the primary key or secondary indexes) only need to accommodate one record, but that record must fit, in uncompressed form, in the per-page modification log. If `innodb_strict_mode` is **ON**, MySQL checks the maximum row size during **CREATE TABLE** or **CREATE INDEX**. If the row does not fit, the following error message is issued: **ERROR HY000: Too big row.**

If you create a table when `innodb_strict_mode` is **OFF**, and a subsequent **INSERT** or **UPDATE** statement attempts to create an index entry that does not fit in the size of the compressed page, the operation fails with **ERROR 42000: Row size too large.** (This error message does not name the index for which the record is too large, or mention the length of the index record or the maximum record size on that particular index page.) To solve this problem, rebuild the table with **ALTER TABLE** and select a larger compressed page size (**KEY_BLOCK_SIZE**), shorten any column prefix indexes, or disable compression entirely with **ROW_FORMAT=DYNAMIC** or **ROW_FORMAT=COMPACT**.

`innodb_strict_mode` is not applicable to general tablespaces, which also support compressed tables. Tablespace management rules for general tablespaces are strictly enforced independently of `innodb_strict_mode`. For more information, see Section 13.1.21, “CREATE TABLESPACE Statement”.

**Compressing BLOB, VARCHAR, and TEXT Columns**

---

3431
In an InnoDB table, BLOB, VARCHAR, and TEXT columns that are not part of the primary key may be stored on separately allocated overflow pages. We refer to these columns as off-page columns. Their values are stored on singly-linked lists of overflow pages.

For tables created in ROW_FORMAT=DYNAMIC or ROW_FORMAT=COMPRESSED, the values of BLOB, TEXT, or VARCHAR columns may be stored fully off-page, depending on their length and the length of the entire row. For columns that are stored off-page, the clustered index record only contains 20-byte pointers to the overflow pages, one per column. Whether any columns are stored off-page depends on the page size and the total size of the row. When the row is too long to fit entirely within the page of the clustered index, MySQL chooses the longest columns for off-page storage until the row fits on the clustered index page. As noted above, if a row does not fit by itself on a compressed page, an error occurs.

**Note**

For tables created in ROW_FORMAT=DYNAMIC or ROW_FORMAT=COMPRESSED, TEXT and BLOB columns that are less than or equal to 40 bytes are always stored in-line.

Tables that use ROW_FORMAT=REDUNDANT and ROW_FORMAT=COMPACT store the first 768 bytes of BLOB, VARCHAR, and TEXT columns in the clustered index record along with the primary key. The 768-byte prefix is followed by a 20-byte pointer to the overflow pages that contain the rest of the column value.

When a table is in COMPRESSED format, all data written to overflow pages is compressed “as is”; that is, MySQL applies the zlib compression algorithm to the entire data item. Other than the data, compressed overflow pages contain an uncompressed header and trailer comprising a page checksum and a link to the next overflow page, among other things. Therefore, very significant storage savings can be obtained for longer BLOB, TEXT, or VARCHAR columns if the data is highly compressible, as is often the case with text data. Image data, such as JPEG, is typically already compressed and so does not benefit much from being stored in a compressed table; the double compression can waste CPU cycles for little or no space savings.

The overflow pages are of the same size as other pages. A row containing ten columns stored off-page occupies ten overflow pages, even if the total length of the columns is only 8K bytes. In an uncompressed table, ten uncompressed overflow pages occupy 160K bytes. In a compressed table with an 8K page size, they occupy only 80K bytes. Thus, it is often more efficient to use compressed table format for tables with long column values.

For file-per-table tablespaces, using a 16K compressed page size can reduce storage and I/O costs for BLOB, VARCHAR, or TEXT columns, because such data often compress well, and might therefore require fewer overflow pages, even though the B-tree nodes themselves take as many pages as in the uncompressed form. General tablespaces do not support a 16K compressed page size (KEY_BLOCK_SIZE). For more information, see Section 15.6.3.3, “General Tablespaces”.

**Compression and the InnoDB Buffer Pool**

In a compressed InnoDB table, every compressed page (whether 1K, 2K, 4K or 8K) corresponds to an uncompressed page of 16K bytes (or a smaller size if innodb_page_size is set). To access the data in a page, MySQL reads the compressed page from disk if it is not already in the buffer pool, then uncompressed the page to its original form. This section describes how InnoDB manages the buffer pool with respect to pages of compressed tables.

To minimize I/O and to reduce the need to decompress a page, at times the buffer pool contains both the compressed and uncompressed form of a database page. To make room for other required database pages, MySQL can evict from the buffer pool an uncompressed page, while leaving the compressed page in memory. Or, if a page has not been accessed in a while, the compressed form of the page might be written to disk, to free space for other data. Thus, at any given time, the buffer pool might contain both the compressed and uncompressed forms of the page, or only the compressed form of the page, or neither.
InnoDB Table Compression

MySQL keeps track of which pages to keep in memory and which to evict using a least-recently-used (LRU) list, so that hot (frequently accessed) data tends to stay in memory. When compressed tables are accessed, MySQL uses an adaptive LRU algorithm to achieve an appropriate balance of compressed and uncompressed pages in memory. This adaptive algorithm is sensitive to whether the system is running in an I/O-bound or CPU-bound manner. The goal is to avoid spending too much processing time uncompressing pages when the CPU is busy, and to avoid doing excess I/O when the CPU has spare cycles that can be used for uncompressing compressed pages (that may already be in memory). When the system is I/O-bound, the algorithm prefers to evict the uncompressed copy of a page rather than both copies, to make more room for other disk pages to become memory resident. When the system is CPU-bound, MySQL prefers to evict both the compressed and uncompressed page, so that more memory can be used for “hot” pages and reducing the need to uncompress data in memory only in compressed form.

Compression and the InnoDB Redo Log Files

Before a compressed page is written to a data file, MySQL writes a copy of the page to the redo log (if it has been recompressed since the last time it was written to the database). This is done to ensure that redo logs are usable for crash recovery, even in the unlikely case that the zlib library is upgraded and that change introduces a compatibility problem with the compressed data. Therefore, some increase in the size of log files, or a need for more frequent checkpoints, can be expected when using compression. The amount of increase in the log file size or checkpoint frequency depends on the number of times compressed pages are modified in a way that requires reorganization and recompression.

To create a compressed table in a file-per-table tablespace, innodb_file_per_table must be enabled. There is no dependence on the innodb_file_per_table setting when creating a compressed table in a general tablespace. For more information, see Section 15.6.3.3, “General Tablespaces”.

15.9.1.6 Compression for OLTP Workloads

Traditionally, the InnoDB compression feature was recommended primarily for read-only or read-mostly workloads, such as in a data warehouse configuration. The rise of SSD storage devices, which are fast but relatively small and expensive, makes compression attractive also for OLTP workloads: high-traffic, interactive websites can reduce their storage requirements and their I/O operations per second (IOPS) by using compressed tables with applications that do frequent INSERT, UPDATE, and DELETE operations.

These configuration options let you adjust the way compression works for a particular MySQL instance, with an emphasis on performance and scalability for write-intensive operations:

• innodb_compression_level lets you turn the degree of compression up or down. A higher value lets you fit more data onto a storage device, at the expense of more CPU overhead during compression. A lower value lets you reduce CPU overhead when storage space is not critical, or you expect the data is not especially compressible.

• innodb_compression_failure_threshold_pct specifies a cutoff point for compression failures during updates to a compressed table. When this threshold is passed, MySQL begins to leave additional free space within each new compressed page, dynamically adjusting the amount of free space up to the percentage of page size specified by innodb_compression_pad_pct_max.

• innodb_compression_pad_pct_max lets you adjust the maximum amount of space reserved within each page to record changes to compressed rows, without needing to compress the entire page again. The higher the value, the more changes can be recorded without recompressing the page. MySQL uses a variable amount of free space for the pages within each compressed table, only when a designated percentage of compression operations “fail” at runtime, requiring an expensive operation to split the compressed page.

• innodb_log_compressed_pages lets you disable writing of images of re-compressed pages to the redo log. Re-compression may occur when changes are made to compressed data. This option is
enabled by default to prevent corruption that could occur if a different version of the zlib compression algorithm is used during recovery. If you are certain that the zlib version is not subject to change, disable innodb_log_compressed_pages to reduce redo log generation for workloads that modify compressed data.

Because working with compressed data sometimes involves keeping both compressed and uncompressed versions of a page in memory at the same time, when using compression with an OLTP-style workload, be prepared to increase the value of the innodb_buffer_pool_size configuration option.

15.9.1.7 SQL Compression Syntax Warnings and Errors

This section describes syntax warnings and errors that you may encounter when using the table compression feature with file-per-table tablespaces and general tablespaces.

SQL Compression Syntax Warnings and Errors for File-Per-Table Tablespaces

When innodb_strict_mode is enabled (the default), specifying ROW_FORMAT=COMPRESSED or KEY_BLOCK_SIZE in CREATE TABLE or ALTER TABLE statements produces the following error if innodb_file_per_table is disabled.

ERROR 1031 (HY000): Table storage engine for 't1' doesn't have this option

Note
The table is not created if the current configuration does not permit using compressed tables.

When innodb_strict_mode is disabled, specifying ROW_FORMAT=COMPRESSED or KEY_BLOCK_SIZE in CREATE TABLE or ALTER TABLE statements produces the following warnings if innodb_file_per_table is disabled.

mysql> SHOW WARNINGS;
+---------+------+---------------------------------------------------------------+
| Level   | Code | Message                                                       |
|---------+------|---------------------------------------------------------------|
| Warning | 1478 | InnoDB: KEY_BLOCK_SIZE requires innodb_file_per_table.        |
| Warning | 1478 | InnoDB: ignoring KEY_BLOCK_SIZE=4.                            |
| Warning | 1478 | InnoDB: ROW_FORMAT=COMPRESSED requires innodb_file_per_table. |
| Warning | 1478 | InnoDB: assuming ROW_FORMAT=DYNAMIC.                          |

Note
These messages are only warnings, not errors, and the table is created without compression, as if the options were not specified.

The “non-strict” behavior lets you import a mysqldump file into a database that does not support compressed tables, even if the source database contained compressed tables. In that case, MySQL creates the table in ROW_FORMAT=DYNAMIC instead of preventing the operation.

To import the dump file into a new database, and have the tables re-created as they exist in the original database, ensure the server has the proper setting for the innodb_file_per_table configuration parameter.

The attribute KEY_BLOCK_SIZE is permitted only when ROW_FORMAT is specified as COMPRESSED or is omitted. Specifying a KEY_BLOCK_SIZE with any other ROW_FORMAT generates a warning that you can view with SHOW WARNINGS. However, the table is non-compressed; the specified KEY_BLOCK_SIZE is ignored.)
InnoDB Table Compression

<table>
<thead>
<tr>
<th>Level</th>
<th>Code</th>
<th>Message</th>
</tr>
</thead>
<tbody>
<tr>
<td>Warning</td>
<td>1478</td>
<td>InnoDB: ignoring KEY_BLOCK_SIZE=n unless ROW_FORMAT=COMPRESSED.</td>
</tr>
</tbody>
</table>

If you are running with `innodb_strict_mode` enabled, the combination of a `KEY_BLOCK_SIZE` with any `ROW_FORMAT` other than `COMPRESSED` generates an error, not a warning, and the table is not created.

Table 15.12, “ROW_FORMAT and KEY_BLOCK_SIZE Options” provides an overview the `ROW_FORMAT` and `KEY_BLOCK_SIZE` options that are used with `CREATE TABLE` or `ALTER TABLE`.

### Table 15.12 ROW_FORMAT and KEY_BLOCK_SIZE Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Usage Notes</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>ROW_FORMAT=REDUNDANT</code></td>
<td>Storage format used prior to MySQL 5.0.3</td>
<td>Less efficient than <code>ROW_FORMAT=COMPACT</code>; for backward compatibility</td>
</tr>
<tr>
<td><code>ROW_FORMAT=COMPACT</code></td>
<td>Default storage format since MySQL 5.0.3</td>
<td>Stores a prefix of 768 bytes of long column values in the clustered index page, with the remaining bytes stored in an overflow page</td>
</tr>
<tr>
<td><code>ROW_FORMAT=DYNAMIC</code></td>
<td></td>
<td>Store values within the clustered index page if they fit; if not, stores only a 20-byte pointer to an overflow page (no prefix)</td>
</tr>
<tr>
<td><code>ROW_FORMAT=COMPRESSED</code></td>
<td></td>
<td>Compresses the table and indexes using zlib</td>
</tr>
<tr>
<td><code>KEY_BLOCK_SIZE=n</code></td>
<td></td>
<td>Specifies compressed page size of 1, 2, 4, 8 or 16 kilobytes; implies <code>ROW_FORMAT=COMPRESSED</code>. For general table spaces, a <code>KEY_BLOCK_SIZE</code> value equal to the InnoDB page size is not permitted.</td>
</tr>
</tbody>
</table>

Table 15.13, “CREATE/ALTER TABLE Warnings and Errors when InnoDB Strict Mode is OFF” summarizes error conditions that occur with certain combinations of configuration parameters and options on the `CREATE TABLE` or `ALTER TABLE` statements, and how the options appear in the output of `SHOW TABLE STATUS`.

When `innodb_strict_mode` is `OFF`, MySQL creates or alters the table, but ignores certain settings as shown below. You can see the warning messages in the MySQL error log. When `innodb_strict_mode` is `ON`, these specified combinations of options generate errors, and the table is not created or altered. To see the full description of the error condition, issue the `SHOW ERRORS` statement: example:

```sql
mysql> CREATE TABLE x (id INT PRIMARY KEY, c INT)
   -> ENGINE=INNODB KEY_BLOCK_SIZE=33333;
ERROR 1005 (HY000): Can't create table 'test.x' (errno: 1478)
```
InnoDB Table Compression

```sql
mysql> SHOW ERRORS;
+-------+------+-------------------------------------------+
| Level | Code | Message                                   |
+-------+------+-------------------------------------------+
| Error | 1478 | InnoDB: invalid KEY_BLOCK_SIZE=33333.     |
| Error | 1005 | Can't create table 'test.x' (errno: 1478) |
+-------+------+-------------------------------------------+
```

Table 15.13 CREATE/ALTER TABLE Warnings and Errors when InnoDB Strict Mode is OFF

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Warning or Error Condition</th>
<th>Resulting ROW_FORMAT, as shown in SHOW TABLE STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>ROW_FORMAT=REDUNDANT</td>
<td>None</td>
<td>REDUNDANT</td>
</tr>
<tr>
<td>ROW_FORMAT=COMPACT</td>
<td>None</td>
<td>COMPACT</td>
</tr>
<tr>
<td>ROW_FORMAT=COMPRESSED or ROW_FORMAT=DYNAMIC or KEY_BLOCK_SIZE is specified</td>
<td>Ignored for file-per-table tablespaces unless innodb_file_per_table is enabled. General tablespaces support all row formats. See Section 15.6.3.3, “General Tablespaces”.</td>
<td>the default row format for file-per-table tablespaces; the specified row format for general tablespaces</td>
</tr>
<tr>
<td>Invalid KEY_BLOCK_SIZE is specified (not 1, 2, 4, 8 or 16)</td>
<td>KEY_BLOCK_SIZE is ignored</td>
<td>the specified row format, or the default row format</td>
</tr>
<tr>
<td>ROW_FORMAT=COMPRESSED and valid KEY_BLOCK_SIZE are specified</td>
<td>None; KEY_BLOCK_SIZE specified is used</td>
<td>COMPRESSED</td>
</tr>
<tr>
<td>KEY_BLOCK_SIZE is specified with REDUNDANT, COMPACT or DYNAMIC row format</td>
<td>KEY_BLOCK_SIZE is ignored</td>
<td>REDUNDANT, COMPACT or DYNAMIC</td>
</tr>
<tr>
<td>ROW_FORMAT is not one of REDUNDANT, COMPACT, DYNAMIC or COMPRESSED</td>
<td>Ignored if recognized by the MySQL parser. Otherwise, an error is issued.</td>
<td>the default row format or N/A</td>
</tr>
</tbody>
</table>

When innodb_strict_mode is ON, MySQL rejects invalid ROW_FORMAT or KEY_BLOCK_SIZE parameters and issues errors. Strict mode is ON by default. When innodb_strict_mode is OFF, MySQL issues warnings instead of errors for ignored invalid parameters.

It is not possible to see the chosen KEY_BLOCK_SIZE using SHOW TABLE STATUS. The statement SHOW CREATE TABLE displays the KEY_BLOCK_SIZE (even if it was ignored when creating the table). The real compressed page size of the table cannot be displayed by MySQL.

**SQL Compression Syntax Warnings and Errors for General Tablespaces**

- If **FILE_BLOCK_SIZE** was not defined for the general tablespace when the tablespace was created, the tablespace cannot contain compressed tables. If you attempt to add a compressed table, an error is returned, as shown in the following example:
  ```sql
  mysql> CREATE TABLESPACE `ts1` ADD DATAFILE `ts1.ibd` Engine=InnoDB;
  mysql> CREATE TABLE t1 (c1 INT PRIMARY KEY) TABLESPACE ts1 ROW_FORMAT=COMPRESSED KEY_BLOCK_SIZE=8;
  ERROR 1478 (HY000): InnoDB: Tablespace 'ts1' cannot contain a COMPRESSED table
  ```

- Attempting to add a table with an invalid **KEY_BLOCK_SIZE** to a general tablespace returns an error, as shown in the following example:
InnoDB Page Compression

```
mysql> CREATE TABLESPACE `ts2` ADD DATAFILE 'ts2.ibd' FILE_BLOCK_SIZE = 8192 Engine=InnoDB;
```
```
mysql> CREATE TABLE t2 (c1 INT PRIMARY KEY) TABLESPACE ts2 ROW_FORMAT=COMPRESSED KEY_BLOCK_SIZE=4;
ERROR 1478 (HY000): InnoDB: Tablespace `ts2` uses block size 8192 and cannot contain a table with physical page size 4096
```

For general tablespaces, the `KEY_BLOCK_SIZE` of the table must be equal to the `FILE_BLOCK_SIZE` of the tablespace divided by 1024. For example, if the `FILE_BLOCK_SIZE` of the tablespace is 8192, the `KEY_BLOCK_SIZE` of the table must be 8.

- Attempting to add a table with an uncompressed row format to a general tablesapce configured to store compressed tables returns an error, as shown in the following example:

```
mysql> CREATE TABLESPACE `ts3` ADD DATAFILE 'ts3.ibd' FILE_BLOCK_SIZE = 8192 Engine=InnoDB;
mysql> CREATE TABLE t3 (c1 INT PRIMARY KEY) TABLESPACE ts3 ROW_FORMAT=COMPACT;
ERROR 1478 (HY000): InnoDB: Tablespace `ts3` uses block size 8192 and cannot contain a table with physical page size 16384
```

`innodb_strict_mode` is not applicable to general tablespaces. Tablespace management rules for general tablespaces are strictly enforced independently of `innodb_strict_mode`. For more information, see Section 13.1.21, “CREATE TABLESPACE Statement”.

For more information about using compressed tables with general tablespaces, see Section 15.6.3.3, “General Tablespaces”.

### 15.9.2 InnoDB Page Compression

InnoDB supports page-level compression for tables that reside in file-per-table tablespaces. This feature is referred to as Transparent Page Compression. Page compression is enabled by specifying the `COMPRESSION` attribute with `CREATE TABLE` or `ALTER TABLE`. Supported compression algorithms include `Zlib` and `LZ4`.

**Supported Platforms**

Page compression requires sparse file and hole punching support. Page compression is supported on Windows with NTFS, and on the following subset of MySQL-supported Linux platforms where the kernel level provides hole punching support:

- RHEL 7 and derived distributions that use kernel version 3.10.0-123 or higher
- OEL 5.10 (UEK2) kernel version 2.6.39 or higher
- OEL 6.5 (UEK3) kernel version 3.8.13 or higher
- OEL 7.0 kernel version 3.8.13 or higher
- SLE11 kernel version 3.0-x
- SLE12 kernel version 3.12-x
- OES11 kernel version 3.0-x
- Ubuntu 14.0.4 LTS kernel version 3.13 or higher
- Ubuntu 12.0.4 LTS kernel version 3.2 or higher
- Debian 7 kernel version 3.2 or higher
InnoDB Page Compression

How Page Compression Works

When a page is written, it is compressed using the specified compression algorithm. The compressed data is written to disk, where the hole punching mechanism releases empty blocks from the end of the page. If compression fails, data is written out as-is.

Hole Punch Size on Linux

On Linux systems, the file system block size is the unit size used for hole punching. Therefore, page compression only works if page data can be compressed to a size that is less than or equal to the InnoDB page size minus the file system block size. For example, if innodb_page_size=16K and the file system block size is 4K, page data must compress to less than or equal to 12K to make hole punching possible.

Hole Punch Size on Windows

On Windows systems, the underlying infrastructure for sparse files is based on NTFS compression. Hole punching size is the NTFS compression unit, which is 16 times the NTFS cluster size. Cluster sizes and their compression units are shown in the following table:

<table>
<thead>
<tr>
<th>Cluster Size</th>
<th>Compression Unit</th>
</tr>
</thead>
<tbody>
<tr>
<td>512 Bytes</td>
<td>8 KB</td>
</tr>
<tr>
<td>1 KB</td>
<td>16 KB</td>
</tr>
<tr>
<td>2 KB</td>
<td>32 KB</td>
</tr>
<tr>
<td>4 KB</td>
<td>64 KB</td>
</tr>
</tbody>
</table>

Page compression on Windows systems only works if page data can be compressed to a size that is less than or equal to the InnoDB page size minus the compression unit size.

The default NTFS cluster size is 4KB, for which the compression unit size is 64KB. This means that page compression has no benefit for an out-of-the-box Windows NTFS configuration, as the maximum innodb_page_size is also 64KB.

For page compression to work on Windows, the file system must be created with a cluster size smaller than 4K, and the innodb_page_size must be at least twice the size of the compression unit. For example, for page compression to work on Windows, you could build the file system with a cluster size of 512 Bytes (which has a compression unit of 8KB) and initialize InnoDB with an innodb_page_size value of 16K or greater.

Enabling Page Compression

To enable page compression, specify the COMPRESSION attribute in the CREATE TABLE statement. For example:

```
CREATE TABLE t1 (c1 INT) COMPRESSION="zlib";
```

You can also enable page compression in an ALTER TABLE statement. However, ALTER TABLE ... COMPRESSION only updates the tablespace compression attribute. Writes to the tablespace that occur after setting the new compression algorithm use the new setting, but to apply the new compression algorithm to existing pages, you must rebuild the table using OPTIMIZE TABLE.
InnoDB Page Compression

Disabling Page Compression

To disable page compression, set `COMPRESSION=None` using `ALTER TABLE`. Writes to the tablespace that occur after setting `COMPRESSION=None` no longer use page compression. To uncompress existing pages, you must rebuild the table using `OPTIMIZE TABLE` after setting `COMPRESSION=None`.

```
ALTER TABLE t1 COMPRESSION="None";
OPTIMIZE TABLE t1;
```

Page Compression Metadata

Page compression metadata is found in the Information Schema `INNODB_TABLESPACES` table, in the following columns:

- **FS_BLOCK_SIZE**: The file system block size, which is the unit size used for hole punching.
- **FILE_SIZE**: The apparent size of the file, which represents the maximum size of the file, uncompressed.
- **ALLOCATED_SIZE**: The actual size of the file, which is the amount of space allocated on disk.

Note

On Unix-like systems, `ls -l tablespace_name.ibd` shows the apparent file size (equivalent to `FILE_SIZE`) in bytes. To view the actual amount of space allocated on disk (equivalent to `ALLOCATED_SIZE`), use `du --block-size=1 tablespace_name.ibd`. The `--block-size=1` option prints the allocated space in bytes instead of blocks, so that it can be compared to `ls -l` output.

Use `SHOW CREATE TABLE` to view the current page compression setting (`Zlib`, `Lz4`, or `None`). A table may contain a mix of pages with different compression settings.

In the following example, page compression metadata for the `employees` table is retrieved from the Information Schema `INNODB_TABLESPACES` table.

```
# Create the employees table with Zlib page compression
CREATE TABLE employees (emp_no INT NOT NULL, birth_date DATE NOT NULL, first_name VARCHAR(14) NOT NULL, last_name VARCHAR(16) NOT NULL, gender ENUM ('M', 'F') NOT NULL, hire_date DATE NOT NULL, PRIMARY KEY (emp_no)) COMPRESSION="zlib";

# Query page compression metadata in INFORMATION_SCHEMA.INNODB_TABLESPACES
cql> SELECT SPACE, NAME, FS_BLOCK_SIZE, FILE_SIZE, ALLOCATED_SIZE FROM INFORMATION_SCHEMA.INNODB_TABLESPACES WHERE NAME='employees/employees'
Space: 45
NAME: employees/employees
FS_BLOCK_SIZE: 4096
```

3439
Page compression metadata for the employees table shows that the apparent file size is 23068672 bytes while the actual file size (with page compression) is 19415040 bytes. The file system block size is 4096 bytes, which is the block size used for hole punching.

Identifying Tables Using Page Compression

To identify tables for which page compression is enabled, you can check the Information Schema TABLES table's CREATE_OPTIONS column for tables defined with the COMPRESSION attribute:

```
mysql> SELECT TABLE_NAME, TABLE_SCHEMA, CREATE_OPTIONS FROM INFORMATION_SCHEMA.TABLES
    WHERE CREATE_OPTIONS LIKE '%COMPRESSION=%';
```

<table>
<thead>
<tr>
<th>TABLE_NAME</th>
<th>TABLE_SCHEMA</th>
<th>CREATE_OPTIONS</th>
</tr>
</thead>
<tbody>
<tr>
<td>employees</td>
<td>test</td>
<td>COMPRESSION=&quot;zlib&quot;</td>
</tr>
</tbody>
</table>

SHOW CREATE TABLE also shows the COMPRESSION attribute, if used.

Page Compression Limitations and Usage Notes

- Page compression is disabled if the file system block size (or compression unit size on Windows) * 2 > innodb_page_size.
- Page compression is not supported for tables that reside in shared tablespaces, which include the system tablespace, temporary tablespaces, and general tablespaces.
- Page compression is not supported for undo log tablespaces.
- Page compression is not supported for redo log pages.
- R-tree pages, which are used for spatial indexes, are not compressed.
- Pages that belong to compressed tables (ROW_FORMAT=COMPRESSED) are left as-is.
- During recovery, updated pages are written out in an uncompressed form.
- Loading a page-compressed tablespace on a server that does not support the compression algorithm that was used causes an I/O error.
- Before downgrading to an earlier version of MySQL that does not support page compression, uncompress the tables that use the page compression feature. To uncompress a table, run ALTER TABLE ... COMPRESSION=None and OPTIMIZE TABLE.
- Page-compressed tablespaces can be copied between Linux and Windows servers if the compression algorithm that was used is available on both servers.
- Preserving page compression when moving a page-compressed tablespace file from one host to another requires a utility that preserves sparse files.
- Better page compression may be achieved on Fusion-io hardware with NVMFS than on other platforms, as NVMFS is designed to take advantage of punch hole functionality.
- Using the page compression feature with a large InnoDB page size and relatively small file system block size could result in write amplification. For example, a maximum InnoDB page size of 64KB with a 4KB file system block size may improve compression but may also increase demand on the buffer pool, leading to increased I/O and potential write amplification.
InnoDB Row Formats

15.10 InnoDB Row Formats

The row format of a table determines how its rows are physically stored, which in turn can affect the performance of queries and DML operations. As more rows fit into a single disk page, queries and index lookups can work faster, less cache memory is required in the buffer pool, and less I/O is required to write out updated values.

The data in each table is divided into pages. The pages that make up each table are arranged in a tree data structure called a B-tree index. Table data and secondary indexes both use this type of structure. The B-tree index that represents an entire table is known as the clustered index, which is organized according to the primary key columns. The nodes of a clustered index data structure contain the values of all columns in the row. The nodes of a secondary index structure contain the values of index columns and primary key columns.

Variable-length columns are an exception to the rule that column values are stored in B-tree index nodes. Variable-length columns that are too long to fit on a B-tree page are stored on separately allocated disk pages called overflow pages. Such columns are referred to as off-page columns. The values of off-page columns are stored in singly-linked lists of overflow pages, with each such column having its own list of one or more overflow pages. Depending on column length, all or a prefix of variable-length column values are stored in the B-tree to avoid wasting storage and having to read a separate page.

The InnoDB storage engine supports four row formats: REDUNDANT, COMPACT, DYNAMIC, and COMPRESSED.

The topics that follow describe row format storage characteristics and how to define and determine the row format of a table.

- REDUNDANT Row Format
- COMPACT Row Format
- DYNAMIC Row Format
- COMPRESSED Row Format
- Defining the Row Format of a Table
- Determining the Row Format of a Table

**REDUNDANT Row Format**
The **REDUNDANT** format provides compatibility with older versions of MySQL.

Tables that use the **REDUNDANT** row format store the first 768 bytes of variable-length column values (VARCHAR, VARBINARY, and BLOB and TEXT types) in the index record within the B-tree node, with the remainder stored on overflow pages. Fixed-length columns greater than or equal to 768 bytes are encoded as variable-length columns, which can be stored off-page. For example, a CHAR(255) column can exceed 768 bytes if the maximum byte length of the character set is greater than 3, as it is with utf8mb4.

If the value of a column is 768 bytes or less, an overflow page is not used, and some savings in I/O may result, since the value is stored entirely in the B-tree node. This works well for relatively short BLOB column values, but may cause B-tree nodes to fill with data rather than key values, reducing their efficiency. Tables with many BLOB columns could cause B-tree nodes to become too full, and contain too few rows, making the entire index less efficient than if rows were shorter or column values were stored off-page.

**REDUNDANT Row Format Storage Characteristics**

The **REDUNDANT** row format has the following storage characteristics:

- Each index record contains a 6-byte header. The header is used to link together consecutive records, and for row-level locking.
- Records in the clustered index contain fields for all user-defined columns. In addition, there is a 6-byte transaction ID field and a 7-byte roll pointer field.
- If no primary key is defined for a table, each clustered index record also contains a 6-byte row ID field.
- Each secondary index record contains all the primary key columns defined for the clustered index key that are not in the secondary index.
- A record contains a pointer to each field of the record. If the total length of the fields in a record is less than 128 bytes, the pointer is one byte; otherwise, two bytes. The array of pointers is called the record directory. The area where the pointers point is the data part of the record.
- Internally, fixed-length character columns such as CHAR(10) in stored in fixed-length format. Trailing spaces are not truncated from VARCHAR columns.
- Fixed-length columns greater than or equal to 768 bytes are encoded as variable-length columns, which can be stored off-page. For example, a CHAR(255) column can exceed 768 bytes if the maximum byte length of the character set is greater than 3, as it is with utf8mb4.
- An SQL NULL value reserves one or two bytes in the record directory. An SQL NULL value reserves zero bytes in the data part of the record if stored in a variable-length column. For a fixed-length column, the fixed length of the column is reserved in the data part of the record. Reserving fixed space for NULL values permits columns to be updated in place from NULL to non-NULL values without causing index page fragmentation.

**COMPACT Row Format**

The **COMPACT** row format reduces row storage space by about 20% compared to the **REDUNDANT** row format, at the cost of increasing CPU use for some operations. If your workload is a typical one that is limited by cache hit rates and disk speed, **COMPACT** format is likely to be faster. If the workload is limited by CPU speed, compact format might be slower.

Tables that use the **COMPACT** row format store the first 768 bytes of variable-length column values (VARCHAR, VARBINARY, and BLOB and TEXT types) in the index record within the B-tree node, with the
COMPACT Row Format

remainder stored on overflow pages. Fixed-length columns greater than or equal to 768 bytes are encoded as variable-length columns, which can be stored off-page. For example, a \texttt{CHAR(255)} column can exceed 768 bytes if the maximum byte length of the character set is greater than 3, as it is with \texttt{utf8mb4}.

If the value of a column is 768 bytes or less, an overflow page is not used, and some savings in I/O may result, since the value is stored entirely in the B-tree node. This works well for relatively short \texttt{BLOB} column values, but may cause B-tree nodes to fill with data rather than key values, reducing their efficiency. Tables with many \texttt{BLOB} columns could cause B-tree nodes to become too full, and contain too few rows, making the entire index less efficient than if rows were shorter or column values were stored off-page.

COMPACT Row Format Storage Characteristics

The \texttt{COMPACT} row format has the following storage characteristics:

• Each index record contains a 5-byte header that may be preceded by a variable-length header. The header is used to link together consecutive records, and for row-level locking.

• The variable-length part of the record header contains a bit vector for indicating \texttt{NULL} columns. If the number of columns in the index that can be \texttt{NULL} is \( N \), the bit vector occupies \( \text{CEILING}(N/8) \) bytes. (For example, if there are anywhere from 9 to 16 columns that can be \texttt{NULL}, the bit vector uses two bytes.) Columns that are \texttt{NULL} do not occupy space other than the bit in this vector. The variable-length part of the header also contains the lengths of variable-length columns. Each length takes one or two bytes, depending on the maximum length of the column. If all columns in the index are \texttt{NOT NULL} and have a fixed length, the record header has no variable-length part.

• For each non-\texttt{NULL} variable-length field, the record header contains the length of the column in one or two bytes. Two bytes are only needed if part of the column is stored externally in overflow pages or the maximum length exceeds 255 bytes and the actual length exceeds 127 bytes. For an externally stored column, the 2-byte length indicates the length of the internally stored part plus the 20-byte pointer to the externally stored part. The internal part is 768 bytes, so the length is 768+20. The 20-byte pointer stores the true length of the column.

• The record header is followed by the data contents of non-\texttt{NULL} columns.

• Records in the clustered index contain fields for all user-defined columns. In addition, there is a 6-byte transaction ID field and a 7-byte roll pointer field.

• If no primary key is defined for a table, each clustered index record also contains a 6-byte row ID field.

• Each secondary index record contains all the primary key columns defined for the clustered index key that are not in the secondary index. If any of the primary key columns are variable length, the record header for each secondary index has a variable-length part to record their lengths, even if the secondary index is defined on fixed-length columns.

• Internally, for nonvariable-length character sets, fixed-length character columns such as \texttt{CHAR(10)} are stored in a fixed-length format.

Trailing spaces are not truncated from \texttt{VARCHAR} columns.

• Internally, for variable-length character sets such as \texttt{utf8mb3} and \texttt{utf8mb4}, InnoDB attempts to store \texttt{CHAR}(\( N \)) in \( N \) bytes by trimming trailing spaces. If the byte length of a \texttt{CHAR}(\( N \)) column value exceeds \( N \) bytes, trailing spaces are trimmed to a minimum of the column value byte length. The maximum length of a \texttt{CHAR}(\( N \)) column is the maximum character byte length × \( N \).

A minimum of \( N \) bytes is reserved for \texttt{CHAR}(\( N \)). Reserving the minimum space \( N \) in many cases enables column updates to be done in place without causing index page fragmentation. By comparison,
**DYNAMIC Row Format**

CHAR($N$) columns occupy the maximum character byte length $\times N$ when using the REDUNDANT row format.

Fixed-length columns greater than or equal to 768 bytes are encoded as variable-length fields, which can be stored off-page. For example, a CHAR(255) column can exceed 768 bytes if the maximum byte length of the character set is greater than 3, as it is with utf8mb4.

**DYNAMIC Row Format**

The DYNAMIC row format offers the same storage characteristics as the COMPACT row format but adds enhanced storage capabilities for long variable-length columns and supports large index key prefixes.

When a table is created with ROW_FORMAT=DYNAMIC, InnoDB can store long variable-length column values (for VARCHAR, VARBINARY, and BLOB and TEXT types) fully off-page, with the clustered index record containing only a 20-byte pointer to the overflow page. Fixed-length fields greater than or equal to 768 bytes are encoded as variable-length fields. For example, a CHAR(255) column can exceed 768 bytes if the maximum byte length of the character set is greater than 3, as it is with utf8mb4.

Whether columns are stored off-page depends on the page size and the total size of the row. When a row is too long, the longest columns are chosen for off-page storage until the clustered index record fits on the B-tree page. TEXT and BLOB columns that are less than or equal to 40 bytes are stored in line.

The DYNAMIC row format maintains the efficiency of storing the entire row in the index node if it fits (as do the COMPACT and REDUNDANT formats), but the DYNAMIC row format avoids the problem of filling B-tree nodes with a large number of data bytes of long columns. The DYNAMIC row format is based on the idea that if a portion of a long data value is stored off-page, it is usually most efficient to store the entire value off-page. With DYNAMIC format, shorter columns are likely to remain in the B-tree node, minimizing the number of overflow pages required for a given row.

The DYNAMIC row format supports index key prefixes up to 3072 bytes.

Tables that use the DYNAMIC row format can be stored in the system tablespace, file-per-table tablespaces, and general tablespaces. To store DYNAMIC tables in the system tablespace, either disable innodb_file_per_table and use a regular CREATE TABLE or ALTER TABLE statement, or use the TABLESPACE [=] innodb_system table option with CREATE TABLE or ALTER TABLE. The innodb_file_per_table variable is not applicable to general tablespaces, nor is it applicable when using the TABLESPACE [=] innodb_system table option to store DYNAMIC tables in the system tablespace.

**DYNAMIC Row Format Storage Characteristics**

The DYNAMIC row format is a variation of the COMPACT row format. For storage characteristics, see COMPACT Row Format Storage Characteristics.

**COMPRESSED Row Format**

The COMPRESSED row format offers the same storage characteristics and capabilities as the DYNAMIC row format but adds support for table and index data compression.

The COMPRESSED row format uses similar internal details for off-page storage as the DYNAMIC row format, with additional storage and performance considerations from the table and index data being compressed and using smaller page sizes. With the COMPRESSED row format, the KEY_BLOCK_SIZE option controls how much column data is stored in the clustered index, and how much is placed on overflow pages. For more information about the COMPRESSED row format, see Section 15.9, “InnoDB Table and Page Compression”.
Defining the Row Format of a Table

The **COMPRESSED** row format supports index key prefixes up to 3072 bytes.

Tables that use the **COMPRESSED** row format can be created in file-per-table tablespaces or general tablespaces. The system tablespace does not support the **COMPRESSED** row format. To store a **COMPRESSED** table in a file-per-table tablespace, the `innodb_file_per_table` variable must be enabled. The `innodb_file_per_table` variable is not applicable to general tablespaces. General tablespaces support all row formats with the caveat that compressed and uncompressed tables cannot coexist in the same general tablespace due to different physical page sizes. For more information, see Section 15.6.3.3, “General Tablespaces”.

**Compressed Row Format Storage Characteristics**

The **COMPRESSED** row format is a variation of the **COMPACT** row format. For storage characteristics, see **COMPACT Row Format Storage Characteristics**.

**Defining the Row Format of a Table**

The default row format for **InnoDB** tables is defined by `innodb_default_row_format` variable, which has a default value of **DYNAMIC**. The default row format is used when the `ROW_FORMAT` table option is not defined explicitly or when `ROW_FORMAT=DEFAULT` is specified.

The row format of a table can be defined explicitly using the `ROW_FORMAT` table option in a `CREATE TABLE` or `ALTER TABLE` statement. For example:

```
CREATE TABLE t1 (c1 INT) ROW_FORMAT=DYNAMIC;
```

An explicitly defined `ROW_FORMAT` setting overrides the default row format. Specifying `ROW_FORMAT=DEFAULT` is equivalent to using the implicit default.

The `innodb_default_row_format` variable can be set dynamically:

```
mysql> SET GLOBAL innodb_default_row_format=DYNAMIC;
```

Valid `innodb_default_row_format` options include **DYNAMIC**, **COMPACT**, and **REDUNDANT**. The **COMPRESSED** row format, which is not supported for use in the system tablespace, cannot be defined as the default. It can only be specified explicitly in a `CREATE TABLE` or `ALTER TABLE` statement. Attempting to set the `innodb_default_row_format` variable to **COMPRESSED** returns an error:

```
mysql> SET GLOBAL innodb_default_row_format=COMPRESSED;
ERROR 1231 (42000): Variable 'innodb_default_row_format' can't be set to the value of 'COMPRESSED'
```

Newly created tables use the row format defined by the `innodb_default_row_format` variable when a `ROW_FORMAT` option is not specified explicitly, or when `ROW_FORMAT=DEFAULT` is used. For example, the following `CREATE TABLE` statements use the row format defined by the `innodb_default_row_format` variable.

```
CREATE TABLE t1 (c1 INT);
CREATE TABLE t2 (c1 INT) ROW_FORMAT=DEFAULT;
```

When a `ROW_FORMAT` option is not specified explicitly, or when `ROW_FORMAT=DEFAULT` is used, an operation that rebuilds a table silently changes the row format of the table to the format defined by the `innodb_default_row_format` variable.

Table-rebuilding operations include **ALTER TABLE** operations that use `ALGORITHM=COPY` or `ALGORITHM=INPLACE` where table rebuilding is required. See Section 15.12.1, “Online DDL Operations” for more information. **OPTIMIZE TABLE** is also a table-rebuilding operation.
The following example demonstrates a table-rebuilding operation that silently changes the row format of a table created without an explicitly defined row format.

```
mysql> SELECT @@innodb_default_row_format;
+-----------------------------+
| @@innodb_default_row_format |
| dynamic                     |
+-----------------------------+
mysql>
CREATE TABLE t1 (c1 INT);
mysql>
SELECT * FROM INFORMATION_SCHEMA.INNODB_TABLES WHERE NAME LIKE 'test/t1' \G
*************************** 1. row ***************************
TABLE_ID: 54
NAME: test/t1
FLAG: 33
N_COLS: 4
SPACE: 35
ROW_FORMAT: Dynamic
ZIP_PAGE_SIZE: 0
SPACE_TYPE: Single
mysql>
SET GLOBAL innodb_default_row_format=COMPACT;
mysql>
ALTER TABLE t1 ADD COLUMN (c2 INT);
mysql>
SELECT * FROM INFORMATION_SCHEMA.INNODB_TABLES WHERE NAME LIKE 'test/t1' \G
*************************** 1. row ***************************
TABLE_ID: 55
NAME: test/t1
FLAG: 1
N_COLS: 5
SPACE: 36
ROW_FORMAT: Compact
ZIP_PAGE_SIZE: 0
SPACE_TYPE: Single
```

Consider the following potential issues before changing the row format of existing tables from **REduNDANT** or **COMPACT** to **DYNAMIC**.

- The **REduNDANT** and **COMPACT** row formats support a maximum index key prefix length of 767 bytes whereas **DYNAMIC** and **COMPRESSED** row formats support an index key prefix length of 3072 bytes. In a replication environment, if the `innodb_default_row_format` variable is set to **DYNAMIC** on the source, and set to **COMPACT** on the replica, the following DDL statement, which does not explicitly define a row format, succeeds on the source but fails on the replica:

```
CREATE TABLE t1 (c1 INT PRIMARY KEY, c2 VARCHAR(5000), KEY i1(c2(3070)));
```

For related information, see Section 15.22, “InnoDB Limits”.

- Importing a table that does not explicitly define a row format results in a schema mismatch error if the `innodb_default_row_format` setting on the source server differs from the setting on the destination server. For more information, see Section 15.6.1.3, “Importing InnoDB Tables”.

### Determining the Row Format of a Table

To determine the row format of a table, use `SHOW TABLE STATUS`:

```
mysql> SHOW TABLE STATUS IN test1\G
*************************** 1. row ***************************
Name: t1
Engine: InnoDB
```

3446
15.11 InnoDB Disk I/O and File Space Management

As a DBA, you must manage disk I/O to keep the I/O subsystem from becoming saturated, and manage disk space to avoid filling up storage devices. The ACID design model requires a certain amount of I/O that might seem redundant, but helps to ensure data reliability. Within these constraints, InnoDB tries to optimize the database work and the organization of disk files to minimize the amount of disk I/O. Sometimes, I/O is postponed until the database is not busy, or until everything needs to be brought to a consistent state, such as during a database restart after a fast shutdown.

This section discusses the main considerations for I/O and disk space with the default kind of MySQL tables (also known as InnoDB tables):

- Controlling the amount of background I/O used to improve query performance.
- Enabling or disabling features that provide extra durability at the expense of additional I/O.
- Organizing tables into many small files, a few larger files, or a combination of both.
- Balancing the size of redo log files against the I/O activity that occurs when the log files become full.
- How to reorganize a table for optimal query performance.

15.11.1 InnoDB Disk I/O

InnoDB uses asynchronous disk I/O where possible, by creating a number of threads to handle I/O operations, while permitting other database operations to proceed while the I/O is still in progress. On Linux and Windows platforms, InnoDB uses the available OS and library functions to perform “native” asynchronous I/O. On other platforms, InnoDB still uses I/O threads, but the threads may actually wait for I/O requests to complete; this technique is known as “simulated” asynchronous I/O.

Read-Ahead

If InnoDB can determine there is a high probability that data might be needed soon, it performs read-ahead operations to bring that data into the buffer pool so that it is available in memory. Making a few large
read requests for contiguous data can be more efficient than making several small, spread-out requests. There are two read-ahead heuristics in InnoDB:

• In sequential read-ahead, if InnoDB notices that the access pattern to a segment in the tablespace is sequential, it posts in advance a batch of reads of database pages to the I/O system.

• In random read-ahead, if InnoDB notices that some area in a tablespace seems to be in the process of being fully read into the buffer pool, it posts the remaining reads to the I/O system.

For information about configuring read-ahead heuristics, see Section 15.8.3.4, “Configuring InnoDB Buffer Pool Prefetching (Read-Ahead)”.

Doublewrite Buffer

InnoDB uses a novel file flush technique involving a structure called the doublewrite buffer, which is enabled by default in most cases (innodb_doublewrite=ON). It adds safety to recovery following an unexpected exit or power outage, and improves performance on most varieties of Unix by reducing the need for fsync() operations.

Before writing pages to a data file, InnoDB first writes them to a storage area called the doublewrite buffer. Only after the write and the flush to the doublewrite buffer has completed does InnoDB write the pages to their proper positions in the data file. If there is an operating system, storage subsystem, or unexpected mysqld process exit in the middle of a page write (causing a torn page condition), InnoDB can later find a good copy of the page from the doublewrite buffer during recovery.

For more information about the doublewrite buffer, see Section 15.6.4, “Doublewrite Buffer”.

15.11.2 File Space Management

The data files that you define in the configuration file using the innodb_data_file_path configuration option form the InnoDB system tablespace. The files are logically concatenated to form the system tablespace. There is no striping in use. You cannot define where within the system tablespace your tables are allocated. In a newly created system tablespace, InnoDB allocates space starting from the first data file.

To avoid the issues that come with storing all tables and indexes inside the system tablespace, you can enable the innodb_file_per_table configuration option (the default), which stores each newly created table in a separate tablespace file (with extension .ibd). For tables stored this way, there is less fragmentation within the disk file, and when the table is truncated, the space is returned to the operating system rather than still being reserved by InnoDB within the system tablespace. For more information, see Section 15.6.3.2, “File-Per-Table Tablespaces”.

You can also store tables in general tablespaces. General tablespaces are shared tablespace created using CREATE TABLESPACE syntax. They can be created outside of the MySQL data directory, are capable of holding multiple tables, and support tables of all row formats. For more information, see Section 15.6.3.3, “General Tablespaces”.

Pages, Extents, Segments, and Tablespaces

Each tablespace consists of database pages. Every tablespace in a MySQL instance has the same page size. By default, all tablespaces have a page size of 16KB; you can reduce the page size to 8KB or 4KB by specifying the innodb_page_size option when you create the MySQL instance. You can also increase the page size to 32KB or 64KB. For more information, refer to the innodb_page_size documentation.

The pages are grouped into extents of size 1MB for pages up to 16KB in size (64 consecutive 16KB pages, or 128 8KB pages, or 256 4KB pages). For a page size of 32KB, extent size is 2MB. For page size of
64KB, extent size is 4MB. The “files” inside a tablespace are called segments in InnoDB. (These segments are different from the rollback segment, which actually contains many tablespace segments.)

When a segment grows inside the tablespace, InnoDB allocates the first 32 pages to it one at a time. After that, InnoDB starts to allocate whole extents to the segment. InnoDB can add up to 4 extents at a time to a large segment to ensure good sequentiality of data.

Two segments are allocated for each index in InnoDB. One is for nonleaf nodes of the B-tree, the other is for the leaf nodes. Keeping the leaf nodes contiguous on disk enables better sequential I/O operations, because these leaf nodes contain the actual table data.

Some pages in the tablespace contain bitmaps of other pages, and therefore a few extents in an InnoDB tablespace cannot be allocated to segments as a whole, but only as individual pages.

When you ask for available free space in the tablespace by issuing a SHOW TABLE STATUS statement, InnoDB reports the extents that are definitely free in the tablespace. InnoDB always reserves some extents for cleanup and other internal purposes; these reserved extents are not included in the free space.

When you delete data from a table, InnoDB contracts the corresponding B-tree indexes. Whether the freed space becomes available for other users depends on whether the pattern of deletes frees individual pages or extents to the tablespace. Dropping a table or deleting all rows from it is guaranteed to release the space to other users, but remember that deleted rows are physically removed only by the purge operation, which happens automatically some time after they are no longer needed for transaction rollbacks or consistent reads. (See Section 15.3, “InnoDB Multi-Versioning”.)

Configuring the Percentage of Reserved File Segment Pages

The innodb_segment_reserve_factor variable, introduced in MySQL 8.0.26, is an advanced feature that permits defining the percentage of tablespace file segment pages reserved as empty pages. A percentage of pages are reserved for future growth so that pages in the B-tree can be allocated contiguously. The ability to modify the percentage of reserved pages permits fine-tuning InnoDB to address issues of data fragmentation or inefficient use of storage space.

The setting is applicable to file-per-table and general tablespaces. The innodb_segment_reserve_factor default setting is 12.5 percent, which is the same percentage of pages reserved in previous MySQL releases.

The innodb_segment_reserve_factor variable is dynamic and can be configured using a SET statement. For example:

```
mysql> SET GLOBAL innodb_segment_reserve_factor=10;
```

How Pages Relate to Table Rows

For for 4KB, 8KB, 16KB, and 32KB innodb_page_size settings, the maximum row length is slightly less than half a database page size. For example, the maximum row length is slightly less than 8KB for the default 16KB InnoDB page size. For a 64KB innodb_page_size setting, the maximum row length is slightly less than 16KB.

If a row does not exceed the maximum row length, all of it is stored locally within the page. If a row exceeds the maximum row length, variable-length columns are chosen for external off-page storage until the row fits within the maximum row length limit. External off-page storage for variable-length columns differs by row format:

- **COMPACT and REDUNDANT Row Formats**
When a variable-length column is chosen for external off-page storage, **InnoDB** stores the first 768 bytes locally in the row, and the rest externally into overflow pages. Each such column has its own list of overflow pages. The 768-byte prefix is accompanied by a 20-byte value that stores the true length of the column and points into the overflow list where the rest of the value is stored. See Section 15.10, "InnoDB Row Formats".

- **DYNAMIC and COMPRESSED Row Formats**

  When a variable-length column is chosen for external off-page storage, **InnoDB** stores a 20-byte pointer locally in the row, and the rest externally into overflow pages. See Section 15.10, "InnoDB Row Formats".

**LONGBLOB** and **LONGTEXT** columns must be less than 4GB, and the total row length, including **BLOB** and **TEXT** columns, must be less than 4GB.

### 15.11.3 InnoDB Checkpoints

Making your log files very large may reduce disk I/O during checkpointing. It often makes sense to set the total size of the log files as large as the buffer pool or even larger.

#### How Checkpoint Processing Works

**InnoDB** implements a checkpoint mechanism known as fuzzy checkpointing. **InnoDB** flushes modified database pages from the buffer pool in small batches. There is no need to flush the buffer pool in one single batch, which would disrupt processing of user SQL statements during the checkpointing process.

During crash recovery, **InnoDB** looks for a checkpoint label written to the log files. It knows that all modifications to the database before the label are present in the disk image of the database. Then **InnoDB** scans the log files forward from the checkpoint, applying the logged modifications to the database.

### 15.11.4 Defragmenting a Table

Random insertions into or deletions from a secondary index can cause the index to become fragmented. Fragmentation means that the physical ordering of the index pages on the disk is not close to the index ordering of the records on the pages, or that there are many unused pages in the 64-page blocks that were allocated to the index.

One symptom of fragmentation is that a table takes more space than it “should” take. How much that is exactly, is difficult to determine. All **InnoDB** data and indexes are stored in B-trees, and their fill factor may vary from 50% to 100%. Another symptom of fragmentation is that a table scan such as this takes more time than it “should” take:

```sql
SELECT COUNT(*) FROM t WHERE non_indexed_column <> 12345;
```

The preceding query requires MySQL to perform a full table scan, the slowest type of query for a large table.

To speed up index scans, you can periodically perform a “null” **ALTER TABLE** operation, which causes MySQL to rebuild the table:

```sql
ALTER TABLE tbl_name ENGINE=INNODB
```

You can also use **ALTER TABLE tbl_name FORCE** to perform a “null” alter operation that rebuilds the table.

Both **ALTER TABLE tbl_name ENGINE=INNODB** and **ALTER TABLE tbl_name FORCE** use online DDL. For more information, see Section 15.12, “InnoDB and Online DDL”.
Another way to perform a defragmentation operation is to use `mysqldump` to dump the table to a text file, drop the table, and reload it from the dump file.

If the insertions into an index are always ascending and records are deleted only from the end, the InnoDB filespace management algorithm guarantees that fragmentation in the index does not occur.

15.11.5 Reclaiming Disk Space with TRUNCATE TABLE

To reclaim operating system disk space when truncating an InnoDB table, the table must be stored in its own .ibd file. For a table to be stored in its own .ibd file, `innodb_file_per_table` must enabled when the table is created. Additionally, there cannot be a foreign key constraint between the table being truncated and other tables, otherwise the TRUNCATE TABLE operation fails. A foreign key constraint between two columns in the same table, however, is permitted.

When a table is truncated, it is dropped and re-created in a new .ibd file, and the freed space is returned to the operating system. This is in contrast to truncating InnoDB tables that are stored within the InnoDB system tablespace (tables created when `innodb_file_per_table=OFF`) and tables stored in shared general tablespaces, where only InnoDB can use the freed space after the table is truncated.

The ability to truncate tables and return disk space to the operating system also means that physical backups can be smaller. Truncating tables that are stored in the system tablespace (tables created when `innodb_file_per_table=OFF`) or in a general tablespace leaves blocks of unused space in the tables.

15.12 InnoDB and Online DDL

The online DDL feature provides support for instant and in-place table alterations and concurrent DML. Benefits of this feature include:

- Improved responsiveness and availability in busy production environments, where making a table unavailable for minutes or hours is not practical.
- For in-place operations, the ability to adjust the balance between performance and concurrency during DDL operations using the LOCK clause. See The LOCK clause.
- Less disk space usage and I/O overhead than the table-copy method.

Note

`ALGORITHM=INSTANT` support is available for `ADD COLUMN` and other operations in MySQL 8.0.12.

Typically, you do not need to do anything special to enable online DDL. By default, MySQL performs the operation instantly or in place, as permitted, with as little locking as possible.

You can control aspects of a DDL operation using the `ALGORITHM` and `LOCK` clauses of the `ALTER TABLE` statement. These clauses are placed at the end of the statement, separated from the table and column specifications by commas. For example:

```
ALTER TABLE tbl_name ADD PRIMARY KEY (column), ALGORITHM=INPLACE, LOCK=NONE;
```

The LOCK clause may be used for operations that are performed in place and is useful for fine-tuning the degree of concurrent access to the table during operations. Only `LOCK=DEFAULT` is supported for operations that are performed instantly. The `ALGORITHM` clause is primarily intended for performance comparisons and as a fallback to the older table-copying behavior in case you encounter any issues. For example:
Online DDL Operations

• To avoid accidentally making the table unavailable for reads, writes, or both, during an in-place ALTER TABLE operation, specify a clause on the ALTER TABLE statement such as LOCK=NONE (permit reads and writes) or LOCK=SHARED (permit reads). The operation halts immediately if the requested level of concurrency is not available.

• To compare performance between algorithms, run a statement with ALGORITHM=INSTANT, ALGORITHM=INPLACE and ALGORITHM=COPY. You can also run a statement with the old_alter_table configuration option enabled to force the use of ALGORITHM=COPY.

• To avoid tying up the server with an ALTER TABLE operation that copies the table, include ALGORITHM=INSTANT or ALGORITHM=INPLACE. The statement halts immediately if it cannot use the specified algorithm.

15.12.1 Online DDL Operations

Online support details, syntax examples, and usage notes for DDL operations are provided under the following topics in this section.

• Index Operations
• Primary Key Operations
• Column Operations
• Generated Column Operations
• Foreign Key Operations
• Table Operations
• Tablespace Operations
• Partitioning Operations

Index Operations

The following table provides an overview of online DDL support for index operations. An asterisk indicates additional information, an exception, or a dependency. For details, see Syntax and Usage Notes.

<tr>
<td>Changing the index type</td>
<td>Yes</td>
<td>Yes</td>
<td>No</td>
<td>Yes</td>
<td>Yes</td>
</tr>
</tbody>
</table>

Syntax and Usage Notes

- Creating or adding a secondary index

  ```
  CREATE INDEX name ON table (col_list);
  ALTER TABLE tbl_name ADD INDEX name (col_list);
  ```

  The table remains available for read and write operations while the index is being created. The `CREATE INDEX` statement only finishes after all transactions that are accessing the table are completed, so that the initial state of the index reflects the most recent contents of the table.

  Online DDL support for adding secondary indexes means that you can generally speed the overall process of creating and loading a table and associated indexes by creating the table without secondary indexes, then adding secondary indexes after the data is loaded.

  A newly created secondary index contains only the committed data in the table at the time the `CREATE INDEX` or `ALTER TABLE` statement finishes executing. It does not contain any uncommitted values, old versions of values, or values marked for deletion but not yet removed from the old index.

  Some factors affect the performance, space usage, and semantics of this operation. For details, see Section 15.12.8, “Online DDL Limitations”.

- Dropping an index

  ```
  DROP INDEX name ON table;
  ALTER TABLE tbl_name DROP INDEX name;
  ```

  The table remains available for read and write operations while the index is being dropped. The `DROP INDEX` statement only finishes after all transactions that are accessing the table are completed, so that the initial state of the index reflects the most recent contents of the table.

- Renaming an index

  ```
  ALTER TABLE tbl_name RENAME INDEX old_index_name TO new_index_name, ALGORITHM=INPLACE, LOCK=NONE;
  ```

- Adding a FULLTEXT index

  ```
  CREATE FULLTEXT INDEX name ON table(column);
  ```

  Adding the first FULLTEXT index rebuilds the table if there is no user-defined FTS_DOC_ID column. Additional FULLTEXT indexes may be added without rebuilding the table.

- Adding a SPATIAL index

  ```
  CREATE TABLE geom (g GEOMETRY NOT NULL);
  ALTER TABLE geom ADD SPATIAL INDEX(g), ALGORITHM=INPLACE, LOCK=SHARED;
  ```

- Changing the index type (USING {BTREE | HASH})
Primary Key Operations

The following table provides an overview of online DDL support for primary key operations. An asterisk indicates additional information, an exception, or a dependency. See Syntax and Usage Notes.

Table 15.17 Online DDL Support for Primary Key Operations

<table>
<thead>
<tr>

<td>No</td>
<td>No</td>
</tr>
<tr>
<td>Dropping a primary key and adding another</td>
<td>No</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
<td>No</td>
</tr>
</tbody>
</table>

Syntax and Usage Notes

- Adding a primary key

  ```sql
  ALTER TABLE `tbl_name` ADD PRIMARY KEY (`column`), ALGORITHM=INPLACE, LOCK=NONE;
  ```

  Rebuilds the table in place. Data is reorganized substantially, making it an expensive operation. `ALGORITHM=INPLACE` is not permitted under certain conditions if columns have to be converted to `NOT NULL`.

  Restructuring the clustered index always requires copying of table data. Thus, it is best to define the primary key when you create a table, rather than issuing `ALTER TABLE ... ADD PRIMARY KEY` later.

  When you create a `UNIQUE` or `PRIMARY KEY` index, MySQL must do some extra work. For `UNIQUE` indexes, MySQL checks that the table contains no duplicate values for the key. For a `PRIMARY KEY` index, MySQL also checks that none of the `PRIMARY KEY` columns contains a `NULL`.

  When you add a primary key using the `ALGORITHM=COPY` clause, MySQL converts `NULL` values in the associated columns to default values: 0 for numbers, an empty string for character-based columns and BLOBs, and `0000-00-00 00:00:00` for `DATETIME`. This is a non-standard behavior that Oracle recommends you not rely on. Adding a primary key using `ALGORITHM=INPLACE` is only permitted when the `SQL_MODE` setting includes the `strict_trans_tables` or `strict_all_tables` flags; when the `SQL_MODE` setting is strict, `ALGORITHM=INPLACE` is permitted, but the statement can still fail if the requested primary key columns contain `NULL` values. The `ALGORITHM=INPLACE` behavior is more standard-compliant.

  If you create a table without a primary key, InnoDB chooses one for you, which can be the first `UNIQUE` key defined on `NOT NULL` columns, or a system-generated key. To avoid uncertainty and the potential space requirement for an extra hidden column, specify the `PRIMARY KEY` clause as part of the `CREATE TABLE` statement.

  MySQL creates a new clustered index by copying the existing data from the original table to a temporary table that has the desired index structure. Once the data is completely copied to the temporary table, the original table is renamed with a different temporary table name. The temporary table comprising the new
clustered index is renamed with the name of the original table, and the original table is dropped from the database.

The online performance enhancements that apply to operations on secondary indexes do not apply to the primary key index. The rows of an InnoDB table are stored in a clustered index organized based on the primary key, forming what some database systems call an "index-organized table". Because the table structure is closely tied to the primary key, redefining the primary key still requires copying the data.

When an operation on the primary key uses \texttt{ALGORITHM=INPLACE}, even though the data is still copied, it is more efficient than using \texttt{ALGORITHM=COPY} because:

- No undo logging or associated redo logging is required for \texttt{ALGORITHM=INPLACE}. These operations add overhead to DDL statements that use \texttt{ALGORITHM=COPY}.
- The secondary index entries are pre-sorted, and so can be loaded in order.
- The change buffer is not used, because there are no random-access inserts into the secondary indexes.
- Dropping a primary key

\begin{verbatim}
ALTER TABLE \texttt{tbl_name} DROP PRIMARY KEY, ALGORITHM=COPY;
\end{verbatim}

Only \texttt{ALGORITHM=COPY} supports dropping a primary key without adding a new one in the same \texttt{ALTER TABLE} statement.

- Dropping a primary key and adding another

\begin{verbatim}
ALTER TABLE \texttt{tbl_name} DROP PRIMARY KEY, ADD PRIMARY KEY (\texttt{column}), ALGORITHM=INPLACE, LOCK=NONE;
\end{verbatim}

Data is reorganized substantially, making it an expensive operation.

### Column Operations

The following table provides an overview of online DDL support for column operations. An asterisk indicates additional information, an exception, or a dependency. For details, see Syntax and Usage Notes.

</table>

### Syntax and Usage Notes

- Adding a column

  ```sql
  ALTER TABLE `tbl_name` ADD COLUMN `column_name` `column_definition`, ALGORITHM=INSTANT;
  ```

  **INSTANT** is the default algorithm as of MySQL 8.0.12, and **INPLACE** before that.

  The following limitations apply when the **INSTANT** algorithm adds a column:

  - A statement cannot combine the addition of a column with other **ALTER TABLE** actions that do not support the **INSTANT** algorithm.

  - The **INSTANT** algorithm can add a column at any position in the table. Before MySQL 8.0.29, the **INSTANT** algorithm could only add a column as the last column of the table.

  - Columns cannot be added to tables that use `ROW_FORMAT=COMPRESSED`, tables with a `FULLTEXT` index, tables that reside in the data dictionary tablespace, or temporary tables. Temporary tables only support **ALGORITHM=COPY**.

  - MySQL checks the row size when the **INSTANT** algorithm adds a column, and throws the following error if the addition exceeds the limit.

    **ERROR 4092 (HY000): Column can’t be added with ALGORITHM=INSTANT as after this max possible row size crosses max permissible row size. Try ALGORITHM=INPLACE/COPY.**

    Before MySQL 8.0.29, MySQL does not check the row size when the **INSTANT** algorithm adds a column. However, MySQL does check the row size during DML operations that insert and update rows in the table.
Online DDL Operations

• The maximum number of columns in the internal representation of the table cannot exceed 1022 after column addition with the INSTANT algorithm. The error message is:

   ERROR 4158 (HY000): Column can't be added to tbl_name with ALGORITHM=INSTANT anymore. Please try ALGORITHM=INPLACE/COPY

Multiple columns may be added in the same ALTER TABLE statement. For example:

   ALTER TABLE t1 ADD COLUMN c2 INT, ADD COLUMN c3 INT, ALGORITHM=INSTANT;

A new row version is created after each ALTER TABLE ... ALGORITHM=INSTANT operation that adds one or more columns, drops one or more columns, or adds and drops one or more columns in the same operation. The INFORMATION_SCHEMA.INNODB_TABLES.TOTAL_ROW_VERSIONS column tracks the number of row versions for a table. The value is incremented each time a column is instantly added or dropped. The initial value is 0.

   mysql> SELECT NAME, TOTAL_ROW_VERSIONS FROM INFORMATION_SCHEMA.INNODB_TABLES
           WHERE NAME LIKE 'test/t1';

     +---------+--------------------+
     | NAME    | TOTAL_ROW_VERSIONS |
     +---------+--------------------+
     | test/t1 |                  0 |
     +---------+--------------------+

When a table with instantly added or dropped columns is rebuilt by table-rebuilding ALTER TABLE or OPTIMIZE TABLE operation, the TOTAL_ROW_VERSIONS value is reset to 0. The maximum number of row versions permitted is 64, as each row version requires additional space for table metadata. When the row version limit is reached, ADD COLUMN and DROP COLUMN operations using ALGORITHM=INSTANT are rejected with an error message that recommends rebuilding the table using the COPY or INPLACE algorithm.

   ERROR 4080 (HY000): Maximum row versions reached for table test/t1. No more columns can be added or dropped instantly. Please use COPY/INPLACE.

The following INFORMATION_SCHEMA columns provide additional metadata for instantly added columns. Refer to the descriptions of those columns for more information. See Section 26.4.9, “The INFORMATION_SCHEMA INNODB_COLUMNS Table”, and Section 26.4.23, “The INFORMATION_SCHEMA INNODB_TABLES Table”.

• INNODB_COLUMNS.DEFAULT_VALUE

• INNODB_COLUMNS.HAS_DEFAULT

• INNODB_TABLES.INSTANT_COLS

Concurrent DML is not permitted when adding an auto-increment column. Data is reorganized substantially, making it an expensive operation. At a minimum, ALGORITHM=INPLACE, LOCK=SHARED is required.

The table is rebuilt if ALGORITHM=INPLACE is used to add a column.
Online DDL Operations

• Dropping a column

```sql
ALTER TABLE tbl_name DROP COLUMN column_name, ALGORITHM=INSTANT;
```

**INSTANT** is the default algorithm as of MySQL 8.0.29, and **INPLACE** before that.

The following limitations apply when the **INSTANT** algorithm is used to drop a column:

• Dropping a column cannot be combined in the same statement with other **ALTER TABLE** actions that do not support **ALGORITHM=INSTANT**.

• Columns cannot be dropped from tables that use **ROW_FORMAT=COMPRESSED**, tables with a **FULLTEXT** index, tables that reside in the data dictionary tablespace, or temporary tables. Temporary tables only support **ALGORITHM=COPY**.

Multiple columns may be dropped in the same **ALTER TABLE** statement; for example:

```sql
ALTER TABLE t1 DROP COLUMN c4, DROP COLUMN c5, ALGORITHM=INSTANT;
```

Each time a column is added or dropped using **ALGORITHM=INSTANT**, a new row version is created. The **INFORMATION_SCHEMA.INNODB_TABLES.TOTAL_ROW_VERSIONS** column tracks the number of row versions for a table. The value is incremented each time a column is instantly added or dropped. The initial value is 0.

```sql
mysql> SELECT NAME, TOTAL_ROW_VERSIONS FROM INFORMATION_SCHEMA.INNODB_TABLES
WHERE NAME LIKE 'test/t1';
+---------+--------------------+
| NAME    | TOTAL_ROW_VERSIONS |
+---------+--------------------+
| test/t1 | 0                  |
+---------+--------------------+
```

When a table with instantly added or dropped columns is rebuilt by table-rebuilding **ALTER TABLE** or **OPTIMIZE TABLE** operation, the **TOTAL_ROW_VERSIONS** value is reset to 0. The maximum number of row versions permitted is 64, as each row version requires additional space for table metadata. When the row version limit is reached, **ADD COLUMN** and **DROP COLUMN** operations using **ALGORITHM=INSTANT** are rejected with an error message that recommends rebuilding the table using the **COPY** or **INPLACE** algorithm.

**ERROR 4080 (HY000): Maximum row versions reached for table test/t1. No more columns can be added or dropped instantly. Please use COPY/INPLACE.**

If an algorithm other than **ALGORITHM=INSTANT** is used, data is reorganized substantially, making it an expensive operation.
Online DDL Operations

• Renaming a column

```sql
ALTER TABLE tbl CHANGE old_col_name new_col_name data_type, ALGORITHM=INSTANT, LOCK=NONE;
```

**ALGORITHM=INSTANT** support for renaming a column was added in MySQL 8.0.28. Earlier MySQL Server releases support only **ALGORITHM=INPLACE** and **ALGORITHM=COPY** when renaming a column.

To permit concurrent DML, keep the same data type and only change the column name.

When you keep the same data type and (NOT) NULL attribute, only changing the column name, the operation can always be performed online.

Renaming a column referenced from another table is only permitted with **ALGORITHM=INPLACE**. If you use **ALGORITHM=INSTANT, ALGORITHM=COPY**, or some other condition that causes the operation to use those algorithms, the **ALTER TABLE** statement fails.

**ALGORITHM=INSTANT** supports renaming a virtual column; **ALGORITHM=INPLACE** does not.

**ALGORITHM=INSTANT** and **ALGORITHM=INPLACE** do not support renaming a column when adding or dropping a virtual column in the same statement. In this case, only **ALGORITHM=COPY** is supported.

• Reordering columns

To reorder columns, use **FIRST** or **AFTER** in CHANGE or MODIFY operations.

```sql
ALTER TABLE tbl_name MODIFY COLUMN col_name column_definition FIRST, ALGORITHM=INPLACE, LOCK=NONE;
```

Data is reorganized substantially, making it an expensive operation.

• Changing the column data type

```sql
ALTER TABLE tbl_name CHANGE c1 c1 BIGINT, ALGORITHM=COPY;
```

Changing the column data type is only supported with **ALGORITHM=COPY**.

• Extending VARCHAR column size

```sql
ALTER TABLE tbl_name CHANGE COLUMN c1 c1 VARCHAR(255), ALGORITHM=INPLACE, LOCK=NONE;
```

The number of length bytes required by a VARCHAR column must remain the same. For VARCHAR columns of 0 to 255 bytes in size, one length byte is required to encode the value. For VARCHAR columns of 256 bytes in size or more, two length bytes are required. As a result, in-place **ALTER TABLE** only supports increasing VARCHAR column size from 0 to 255 bytes, or from 256 bytes to a greater size. In-place **ALTER TABLE** does not support increasing the size of a VARCHAR column from less than 256 bytes to a size equal to or greater than 256 bytes. In this case, the number of required length bytes changes from 1 to 2, which is only supported by a table copy (**ALGORITHM=COPY**). For example, attempting to change VARCHAR column size for a single byte character set from VARCHAR(255) to VARCHAR(256) using in-place **ALTER TABLE** returns this error:

```sql
ALTER TABLE tbl_name ALGORITHM=INPLACE, CHANGE COLUMN c1 c1 VARCHAR(256);
ERROR 1A000: ALGORITHM=INPLACE is not supported. Reason: Cannot change
```
column type INPLACE. Try ALGORITHM=COPY.

Note

The byte length of a VARCHAR column is dependant on the byte length of the character set.

Decreasing VARCHAR size using in-place ALTER TABLE is not supported. Decreasing VARCHAR size requires a table copy (ALGORITHM=COPY).

- Setting a column default value

```
ALTER TABLE tbl_name ALTER COLUMN col SET DEFAULT literal, ALGORITHM=INSTANT;
```

Only modifies table metadata. Default column values are stored in the data dictionary.

- Dropping a column default value

```
ALTER TABLE tbl ALTER COLUMN col DROP DEFAULT, ALGORITHM=INSTANT;
```

- Changing the auto-increment value

```
ALTER TABLE table AUTO_INCREMENT=next_value, ALGORITHM=INPLACE, LOCK=NONE;
```

Modifies a value stored in memory, not the data file.

In a distributed system using replication or sharding, you sometimes reset the auto-increment counter for a table to a specific value. The next row inserted into the table uses the specified value for its auto-increment column. You might also use this technique in a data warehousing environment where you periodically empty all the tables and reload them, and restart the auto-increment sequence from 1.

- Making a column NULL

```
ALTER TABLE tbl_name MODIFY COLUMN column_name data_type NULL, ALGORITHM=INPLACE, LOCK=NONE;
```

Rebuilds the table in place. Data is reorganized substantially, making it an expensive operation.

- Making a column NOT NULL

```
ALTER TABLE tbl_name MODIFY COLUMN column_name data_type NOT NULL, ALGORITHM=INPLACE, LOCK=NONE;
```

Rebuilds the table in place. STRICT_ALL_TABLES or STRICT_TRANS_TABLES SQL_MODE is required for the operation to succeed. The operation fails if the column contains NULL values. The server prohibits changes to foreign key columns that have the potential to cause loss of referential integrity. See Section 13.1.9, "ALTER TABLE Statement". Data is reorganized substantially, making it an expensive operation.

- Modifying the definition of an ENUM or SET column

```
CREATE TABLE t1 (c1 ENUM('a', 'b', 'c'));
ALTER TABLE t1 MODIFY COLUMN c1 ENUM('a', 'b', 'c', 'd'), ALGORITHM=INSTANT;
```

Modifying the definition of an ENUM or SET column by adding new enumeration or set members to the end of the list of valid member values may be performed instantly or in place, as long as the storage size of the data type does not change. For example, adding a member to a SET column that has 8 members changes the required storage per value from 1 byte to 2 bytes; this requires a table copy. Adding members in the middle of the list causes renumbering of existing members, which requires a table copy.
Generated Column Operations

The following table provides an overview of online DDL support for generated column operations. For details, see Syntax and Usage Notes.

Table 15.19 Online DDL Support for Generated Column Operations

<table>
<thead>
<tr>
<th>Operation</th>
<th>Instant</th>
<th>In Place</th>
<th>Rebuilds Table</th>
<th>Permits Concurrent DML</th>
<th>Only Modifies Metadata</th>
</tr>
</thead>
<tbody>
<tr>
<td>Adding a STORED column</td>
<td>No</td>
<td>No</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>Modifying STORED column order</td>
<td>No</td>
<td>No</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>Dropping a STORED column</td>
<td>No</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>Adding a VIRTUAL column</td>
<td>Yes</td>
<td>Yes</td>

<td>No</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>Dropping a VIRTUAL column</td>
<td>Yes</td>
<td>Yes</td>
<td>No</td>
<td>Yes</td>
<td>Yes</td>
</tr>
</tbody>
</table>

Syntax and Usage Notes

- **Adding a STORED column**

  ```sql
  ALTER TABLE t1 ADD COLUMN (c2 INT GENERATED ALWAYS AS (c1 + 1) STORED), ALGORITHM=COPY;
  ```

  ADD COLUMN is not an in-place operation for stored columns (done without using a temporary table) because the expression must be evaluated by the server.

- **Modifying STORED column order**

  ```sql
  ALTER TABLE t1 MODIFY COLUMN c2 INT GENERATED ALWAYS AS (c1 + 1) STORED FIRST, ALGORITHM=COPY;
  ```

  Rebuilds the table in place.

- **Dropping a STORED column**

  ```sql
  ALTER TABLE t1 DROP COLUMN c2, ALGORITHM=INPLACE, LOCK=NONE;
  ```

  Rebuilds the table in place.

- **Adding a VIRTUAL column**

  ```sql
  ALTER TABLE t1 ADD COLUMN (c2 INT GENERATED ALWAYS AS (c1 + 1) VIRTUAL), ALGORITHM=INSTANT;
  ```

  Adding a virtual column can be performed instantly or in place for non-partitioned tables.

  Adding a VIRTUAL is not an in-place operation for partitioned tables.
Online DDL Operations

- Modifying VIRTUAL column order
  ```sql
  ALTER TABLE t1 MODIFY COLUMN c2 INT GENERATED ALWAYS AS (c1 + 1) VIRTUAL FIRST, ALGORITHM=COPY;
  ```

- Dropping a VIRTUAL column
  ```sql
  ALTER TABLE t1 DROP COLUMN c2, ALGORITHM=INSTANT;
  ```

  Dropping a VIRTUAL column can be performed instantly or in place for non-partitioned tables.

Foreign Key Operations

The following table provides an overview of online DDL support for foreign key operations. An asterisk indicates additional information, an exception, or a dependency. For details, see Syntax and Usage Notes.

<table>
<thead>
<tr>
<th>Operation</th>
<th>Instant</th>

Syntax and Usage Notes

- Adding a foreign key constraint
  
  The INPLACE algorithm is supported when foreign_key_checks is disabled. Otherwise, only the COPY algorithm is supported.

  ```sql
  ALTER TABLE tbl1 ADD CONSTRAINT fk_name FOREIGN KEY index (col1) REFERENCES tbl2(col2) referential_actions;
  ```

- Dropping a foreign key constraint
  ```sql
  ALTER TABLE tbl DROP FOREIGN KEY fk_name;
  ```

  Dropping a foreign key can be performed online with the foreign_key_checks option enabled or disabled.

  If you do not know the names of the foreign key constraints on a particular table, issue the following statement and find the constraint name in the CONSTRAINT clause for each foreign key:

  ```sql
  SHOW CREATE TABLE table\G
  ```

  Or, query the Information Schema TABLE_CONSTRAINTS table and use the CONSTRAINT_NAME and CONSTRAINT_TYPE columns to identify the foreign key names.

  You can also drop a foreign key and its associated index in a single statement:

  ```sql
  ALTER TABLE table DROP FOREIGN KEY constraint, DROP INDEX index;
  ```

  Note

  If foreign keys are already present in the table being altered (that is, it is a child table containing a FOREIGN KEY ... REFERENCE clause), additional restrictions...
apply to online DDL operations, even those not directly involving the foreign key columns:

- An `ALTER TABLE` on the child table could wait for another transaction to commit, if a change to the parent table causes associated changes in the child table through an `ON UPDATE` or `ON DELETE` clause using the `CASCADE` or `SET NULL` parameters.

- In the same way, if a table is the parent table in a foreign key relationship, even though it does not contain any `FOREIGN KEY` clauses, it could wait for the `ALTER TABLE` to complete if an `INSERT`, `UPDATE`, or `DELETE` statement causes an `ON UPDATE` or `ON DELETE` action in the child table.

**Table Operations**

The following table provides an overview of online DDL support for table operations. An asterisk indicates additional information, an exception, or a dependency. For details, see Syntax and Usage Notes.

**Table 15.21 Online DDL Support for Table Operations**

</tr>
</tbody>
</table>

**Syntax and Usage Notes**

- Changing the **ROW_FORMAT**

  ```
  ALTER TABLE tbl_name ROW_FORMAT = row_format, ALGORITHM=INPLACE, LOCK=None;
  ```

  Data is reorganized substantially, making it an expensive operation.
Online DDL Operations

For additional information about the `ROW_FORMAT` option, see Table Options.

- **Changing the `KEY_BLOCK_SIZE`**

  ```sql
  ALTER TABLE tbl_name KEY_BLOCK_SIZE = value, ALGORITHM=INPLACE, LOCK=NONE;
  ```

  Data is reorganized substantially, making it an expensive operation.

  For additional information about the `KEY_BLOCK_SIZE` option, see Table Options.

- **Setting persistent table statistics options**

  ```sql
  ALTER TABLE tbl_name STATS_PERSISTENT=0, STATS_SAMPLE_PAGES=20, STATS_AUTO_RECALC=1, ALGORITHM=INPLACE, LOCK=NONE;
  ```

  Only modifies table metadata.

  Persistent statistics include `STATS_PERSISTENT`, `STATS_AUTO_RECALC`, and `STATS_SAMPLE_PAGES`. For more information, see Section 15.8.10.1, “Configuring Persistent Optimizer Statistics Parameters”.

- **Specifying a character set**

  ```sql
  ALTER TABLE tbl_name CHARACTER_SET = charset_name, ALGORITHM=INPLACE, LOCK=NONE;
  ```

  Rebuilds the table if the new character encoding is different.

- **Converting a character set**

  ```sql
  ALTER TABLE tbl_name CONVERT TO CHARACTER SET charset_name, ALGORITHM=COPY;
  ```

  Rebuilds the table if the new character encoding is different.

- **Optimizing a table**

  ```sql
  OPTIMIZE TABLE tbl_name;
  ```

  In-place operation is not supported for tables with `FULLTEXT` indexes. The operation uses the `INPLACE` algorithm, but `ALGORITHM` and `LOCK` syntax is not permitted.

- **Rebuilding a table with the `FORCE` option**

  ```sql
  ALTER TABLE tbl_name FORCE, ALGORITHM=INPLACE, LOCK=NONE;
  ```

  Uses `ALGORITHM=INPLACE` as of MySQL 5.6.17. `ALGORITHM=INPLACE` is not supported for tables with `FULLTEXT` indexes.

- **Performing a "null" rebuild**

  ```sql
  ALTER TABLE tbl_name ENGINE=InnoDB, ALGORITHM=INPLACE, LOCK=NONE;
  ```

  Uses `ALGORITHM=INPLACE` as of MySQL 5.6.17. `ALGORITHM=INPLACE` is not supported for tables with `FULLTEXT` indexes.

- **Renaming a table**

  ```sql
  ALTER TABLE old_tbl_name RENAME TO new_tbl_name, ALGORITHM=INSTANT;
  ```

  Renaming a table can be performed instantly or in place. MySQL renames files that correspond to the table `tbl_name` without making a copy. (You can also use the `RENAME TABLE` statement to rename tables. See Section 13.1.36, “RENAME TABLE Statement”.) Privileges granted specifically for the renamed table are not migrated to the new name. They must be changed manually.
Online DDL Operations

Tablespace Operations

The following table provides an overview of online DDL support for tablespace operations. For details, see Syntax and Usage Notes.

Table 15.22 Online DDL Support for Tablespace Operations

<table>
<thead>
<tr>

<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Syntax and Usage Notes

- Renaming a general tablespace

```
ALTER TABLESPACE tablespace_name RENAME TO new_tablespace_name;
```

`ALTER TABLESPACE ... RENAME TO` uses the `INPLACE` algorithm but does not support the `ALGORITHM` clause.

- Enabling or disabling general tablespace encryption

```
ALTER TABLESPACE tablespace_name ENCRYPTION='Y';
```

`ALTER TABLESPACE ... ENCRYPTION` uses the `INPLACE` algorithm but does not support the `ALGORITHM` clause.

For related information, see Section 15.13, “InnoDB Data-at-Rest Encryption”.

- Enabling or disabling file-per-table tablespace encryption

```
ALTER TABLE tbl_name ENCRYPTION='Y', ALGORITHM=COPY;
```

For related information, see Section 15.13, “InnoDB Data-at-Rest Encryption”.

Partitioning Operations

With the exception of some `ALTER TABLE` partitioning clauses, online DDL operations for partitioned InnoDB tables follow the same rules that apply to regular InnoDB tables.

Some `ALTERTABLE` partitioning clauses do not go through the same internal online DDL API as regular non-partitioned InnoDB tables. As a result, online support for `ALTER TABLE` partitioning clauses varies.
ALTER TABLE partitioning options that use `ALGORITHM=COPY` or that only permit `"ALGORITHM=DEFAULT, LOCK=DEFAULT"`, repartition the table using the COPY algorithm. In other words, a new partitioned table is created with the new partitioning scheme. The newly created table includes any changes applied by the ALTER TABLE statement, and table data is copied into the new table structure.

</table>

Non-partitioning online ALTER TABLE operations on partitioned tables follow the same rules that apply to regular tables. However, ALTER TABLE performs online operations on each table partition, which causes increased demand on system resources due to operations being performed on multiple partitions.

For additional information about ALTER TABLE partitioning clauses, see Partitioning Options, and Section 13.1.9.1, “ALTER TABLE Partition Operations”. For information about partitioning in general, see Chapter 24, Partitioning.

15.12.2 Online DDL Performance and Concurrency

Online DDL improves several aspects of MySQL operation:

- Applications that access the table are more responsive because queries and DML operations on the table can proceed while the DDL operation is in progress. Reduced locking and waiting for MySQL server resources leads to greater scalability, even for operations that are not involved in the DDL operation.

- Instant operations only modify metadata in the data dictionary. An exclusive metadata lock on the table may be taken briefly during the execution phase of the operation. Table data is unaffected, making operations instantaneous. Concurrent DML is permitted.

- Online operations avoid the disk I/O and CPU cycles associated with the table-copy method, which minimizes overall load on the database. Minimizing load helps maintain good performance and high throughput during the DDL operation.
Online DDL Performance and Concurrency

- Online operations read less data into the buffer pool than table-copy operations, which reduces purging of frequently accessed data from memory. Purging of frequently accessed data can cause a temporary performance dip after a DDL operation.

**The LOCK clause**

By default, MySQL uses as little locking as possible during a DDL operation. The `LOCK` clause can be specified for in-place operations and some copy operations to enforce more restrictive locking, if required. If the `LOCK` clause specifies a less restrictive level of locking than is permitted for a particular DDL operation, the statement fails with an error. `LOCK` clauses are described below, in order of least to most restrictive:

- **LOCK=NONE:**
  Permits concurrent queries and DML.
  For example, use this clause for tables involving customer signups or purchases, to avoid making the tables unavailable during lengthy DDL operations.

- **LOCK=SHARED:**
  Permits concurrent queries but blocks DML.
  For example, use this clause on data warehouse tables, where you can delay data load operations until the DDL operation is finished, but queries cannot be delayed for long periods.

- **LOCK=DEFAULT:**
  Permits as much concurrency as possible (concurrent queries, DML, or both). Omitting the `LOCK` clause is the same as specifying `LOCK=DEFAULT`.
  Use this clause when you do not expect the default locking level of the DDL statement to cause any availability problems for the table.

- **LOCK=EXCLUSIVE:**
  Blocks concurrent queries and DML.
  Use this clause if the primary concern is finishing the DDL operation in the shortest amount of time possible, and concurrent query and DML access is not necessary. You might also use this clause if the server is supposed to be idle, to avoid unexpected table accesses.

**Online DDL and Metadata Locks**

Online DDL operations can be viewed as having three phases:

- **Phase 1: Initialization**
  In the initialization phase, the server determines how much concurrency is permitted during the operation, taking into account storage engine capabilities, operations specified in the statement, and user-specified `ALGORITHM` and `LOCK` options. During this phase, a shared upgradeable metadata lock is taken to protect the current table definition.

- **Phase 2: Execution**
  In this phase, the statement is prepared and executed. Whether the metadata lock is upgraded to exclusive depends on the factors assessed in the initialization phase. If an exclusive metadata lock is required, it is only taken briefly during statement preparation.
• **Phase 3: Commit Table Definition**

In the commit table definition phase, the metadata lock is upgraded to exclusive to evict the old table definition and commit the new one. Once granted, the duration of the exclusive metadata lock is brief.

Due to the exclusive metadata lock requirements outlined above, an online DDL operation may have to wait for concurrent transactions that hold metadata locks on the table to commit or rollback. Transactions started before or during the DDL operation can hold metadata locks on the table being altered. In the case of a long running or inactive transaction, an online DDL operation can time out waiting for an exclusive metadata lock. Additionally, a pending exclusive metadata lock requested by an online DDL operation blocks subsequent transactions on the table.

The following example demonstrates an online DDL operation waiting for an exclusive metadata lock, and how a pending metadata lock blocks subsequent transactions on the table.

**Session 1:**

```
mysql> CREATE TABLE t1 (c1 int) ENGINE=InnoDB;
mysql> START TRANSACTION;
mysql> SELECT * FROM t1;
```

The session 1 `SELECT` statement takes a shared metadata lock on table t1.

**Session 2:**

```
mysql> ALTER TABLE t1 ADD COLUMN x INT, ALGORITHM=INPLACE, LOCK=NONE;
```

The online DDL operation in session 2, which requires an exclusive metadata lock on table t1 to commit table definition changes, must wait for the session 1 transaction to commit or roll back.

**Session 3:**

```
mysql> SELECT * FROM t1;
```

The `SELECT` statement issued in session 3 is blocked waiting for the exclusive metadata lock requested by the `ALTER TABLE` operation in session 2 to be granted.

You can use `SHOW FULL PROCESSLIST` to determine if transactions are waiting for a metadata lock.

```
mysql> SHOW FULL PROCESSLIST\G
...
*************** 2. row ***************
  Id: 5
  User: root
  Host: localhost
db: test
Command: Query
  Time: 44
  State: Waiting for table metadata lock
  Info: ALTER TABLE t1 ADD COLUMN x INT, ALGORITHM=INPLACE, LOCK=NONE
...
*************** 4. row ***************
  Id: 7
  User: root
  Host: localhost
db: test
Command: Query
  Time: 5
  State: Waiting for table metadata lock
  Info: SELECT * FROM t1
4 rows in set (0.00 sec)
```
Metadata lock information is also exposed through the Performance Schema `metadata_locks` table, which provides information about metadata lock dependencies between sessions, the metadata lock a session is waiting for, and the session that currently holds the metadata lock. For more information, see Section 27.12.13.3, “The metadata_locks Table”.

**Online DDL Performance**

The performance of a DDL operation is largely determined by whether the operation is performed instantly, in place, and whether it rebuilds the table.

To assess the relative performance of a DDL operation, you can compare results using `ALGORITHM=INSTANT`, `ALGORITHM=INPLACE`, and `ALGORITHM=COPY`. A statement can also be run with `old_alter_table` enabled to force the use of `ALGORITHM=COPY`.

For DDL operations that modify table data, you can determine whether a DDL operation performs changes in place or performs a table copy by looking at the “rows affected” value displayed after the command finishes. For example:

- Changing the default value of a column (fast, does not affect the table data):
  
  ```sql
  Query OK, 0 rows affected (0.07 sec)
  ```

- Adding an index (takes time, but `0 rows affected` shows that the table is not copied):
  
  ```sql
  Query OK, 0 rows affected (21.42 sec)
  ```

- Changing the data type of a column (takes substantial time and requires rebuilding all the rows of the table):
  
  ```sql
  Query OK, 1671168 rows affected (1 min 35.54 sec)
  ```

Before running a DDL operation on a large table, check whether the operation is fast or slow as follows:

1. Clone the table structure.
2. Populate the cloned table with a small amount of data.
3. Run the DDL operation on the cloned table.
4. Check whether the “rows affected” value is zero or not. A nonzero value means the operation copies table data, which might require special planning. For example, you might do the DDL operation during a period of scheduled downtime, or on each replica server one at a time.

**Note**

For a greater understanding of the MySQL processing associated with a DDL operation, examine Performance Schema and INFORMATION_SCHEMA tables related to InnoDB before and after DDL operations to see the number of physical reads, writes, memory allocations, and so on.

Performance Schema stage events can be used to monitor `ALTER TABLE` progress. See Section 15.16.1, “Monitoring ALTER TABLE Progress for InnoDB Tables Using Performance Schema”.

Because there is some processing work involved with recording the changes made by concurrent DML operations, then applying those changes at the end, an online DDL operation could take longer overall than the table-copy mechanism that blocks table access from other sessions. The reduction in raw performance is balanced against better responsiveness for applications that use the table. When evaluating the
Online DDL Space Requirements

techniques for changing table structure, consider end-user perception of performance, based on factors such as load times for web pages.

15.12.3 Online DDL Space Requirements

Disk space requirements for online DDL operations are outlined below. The requirements do not apply to operations that are performed instantly.

- Temporary log files:
  A temporary log file records concurrent DML when an online DDL operation creates an index or alters a table. The temporary log file is extended as required by the value of `innodb_sort_buffer_size` up to a maximum specified by `innodb_online_alter_log_max_size`. If the operation takes a long time and concurrent DML modifies the table so much that the size of the temporary log file exceeds the value of `innodb_online_alter_log_max_size`, the online DDL operation fails with a `DB_ONLINE_LOG_TOO_BIG` error, and uncommitted concurrent DML operations are rolled back. A large `innodb_online_alter_log_max_size` setting permits more DML during an online DDL operation, but it also extends the period of time at the end of the DDL operation when the table is locked to apply logged DML.

  The `innodb_sort_buffer_size` variable also defines the size of the temporary log file read buffer and write buffer.

- Temporary sort files:
  Online DDL operations that rebuild the table write temporary sort files to the MySQL temporary directory (`$TMPDIR` on Unix, `%TEMP%` on Windows, or the directory specified by `--tmpdir`) during index creation. Temporary sort files are not created in the directory that contains the original table. Each temporary sort file is large enough to hold one column of data, and each sort file is removed when its data is merged into the final table or index. Operations involving temporary sort files may require temporary space equal to the amount of data in the table plus indexes. An error is reported if online DDL operation uses all of the available disk space on the file system where the data directory resides.

  If the MySQL temporary directory is not large enough to hold the sort files, set `tmpdir` to a different directory. Alternatively, define a separate temporary directory for online DDL operations using `innodb_tmpdir`. This option was introduced to help avoid temporary directory overflows that could occur as a result of large temporary sort files.

- Intermediate table files:
  Some online DDL operations that rebuild the table create a temporary intermediate table file in the same directory as the original table. An intermediate table file may require space equal to the size of the original table. Intermediate table file names begin with `#sql-ib` prefix and only appear briefly during the online DDL operation.

  The `innodb_tmpdir` option is not applicable to intermediate table files.

15.12.4 Online DDL Memory Management

Online DDL operations that create or rebuild secondary indexes allocate temporary buffers during different phases of index creation. The `innodb_ddl_buffer_size` variable, introduced in MySQL 8.0.27, defines the maximum buffer size for online DDL operations. The default setting is 1048576 bytes (1 MB). The setting applies to buffers created by threads executing online DDL operations. Defining an appropriate buffer size limit avoids potential out of memory errors for online DDL operations that create or rebuild secondary indexes. The maximum buffer size per DDL thread is the maximum buffer size divided by the number of DDL threads (`innodb_ddl_buffer_size/innodb_ddl_threads`).
Prior to MySQL 8.0.27, \texttt{innodb_sort_buffer_size} variable defines the buffer size for online DDL operations that create or rebuild secondary indexes.

### 15.12.5 Configuring Parallel Threads for Online DDL Operations

The workflow of an online DDL operation that creates or rebuilds a secondary index involves:

- Scanning the clustered index and writing data to temporary sort files
- Sorting the data
- Loading sorted data from the temporary sort files into the secondary index

The number of parallel threads that can be used to scan clustered index is defined by the \texttt{innodb_parallel_read_threads} variable. The default setting is 4. The maximum setting is 256, which is the maximum number for all sessions. The actual number of threads that scan the clustered index is the number defined by the \texttt{innodb_parallel_read_threads} setting or the number of index subtrees to scan, whichever is smaller. If the thread limit is reached, sessions fall back to using a single thread.

The number of parallel threads that sort and load data is controlled by the \texttt{innodb_ddl_threads} variable, introduced in MySQL 8.0.27. The default setting is 4. Prior to MySQL 8.0.27, sort and load operations are single-threaded.

The following limitations apply:

- Parallel threads are not supported for building indexes that include virtual columns.
- Parallel threads are not supported for full-text index creation.
- Parallel threads are not supported for spatial index creation.
- Parallel scan is not supported on tables defined with virtual columns.
- Parallel scan is not supported on tables defined with a full-text index.
- Parallel scan is not supported on tables defined with a spatial index.

### 15.12.6 Simplifying DDL Statements with Online DDL

Before the introduction of online DDL, it was common practice to combine many DDL operations into a single \texttt{ALTER TABLE} statement. Because each \texttt{ALTER TABLE} statement involved copying and rebuilding the table, it was more efficient to make several changes to the same table at once, since those changes could all be done with a single rebuild operation for the table. The downside was that SQL code involving DDL operations was harder to maintain and to reuse in different scripts. If the specific changes were different each time, you might have to construct a new complex \texttt{ALTER TABLE} for each slightly different scenario.

For DDL operations that can be done online, you can separate them into individual \texttt{ALTER TABLE} statements for easier scripting and maintenance, without sacrificing efficiency. For example, you might take a complicated statement such as:

```sql
ALTER TABLE t1 ADD INDEX i1(c1), ADD UNIQUE INDEX i2(c2),
   CHANGE c4_old_name c4_new_name INTEGER UNSIGNED;
```

and break it down into simpler parts that can be tested and performed independently, such as:

```sql
ALTER TABLE t1 ADD INDEX i1(c1);
ALTER TABLE t1 ADD UNIQUE INDEX i2(c2);
ALTER TABLE t1 CHANGE c4_old_name c4_new_name INTEGER UNSIGNED NOT NULL;
```
You might still use multi-part `ALTER TABLE` statements for:

- Operations that must be performed in a specific sequence, such as creating an index followed by a foreign key constraint that uses that index.
- Operations all using the same specific `LOCK` clause, that you want to either succeed or fail as a group.
- Operations that cannot be performed online, that is, that still use the table-copy method.
- Operations for which you specify `ALGORITHM=COPY` or `old_alter_table=1`, to force the table-copying behavior if needed for precise backward-compatibility in specialized scenarios.

### 15.12.7 Online DDL Failure Conditions

The failure of an online DDL operation is typically due to one of the following conditions:

- An `ALGORITHM` clause specifies an algorithm that is not compatible with the particular type of DDL operation or storage engine.
- A `LOCK` clause specifies a low degree of locking (`SHARED` or `NONE`) that is not compatible with the particular type of DDL operation.
- A timeout occurs while waiting for an exclusive lock on the table, which may be needed briefly during the initial and final phases of the DDL operation.
- The `tmpdir` or `innodb_tmpdir` file system runs out of disk space, while MySQL writes temporary sort files on disk during index creation. For more information, see Section 15.12.3, “Online DDL Space Requirements”.
- The operation takes a long time and concurrent DML modifies the table so much that the size of the temporary online log exceeds the value of the `innodb_online_alter_log_max_size` configuration option. This condition causes a `DB_ONLINE_LOG_TOO_BIG` error.
- Concurrent DML makes changes to the table that are allowed with the original table definition, but not with the new one. The operation only fails at the very end, when MySQL tries to apply all the changes from concurrent DML statements. For example, you might insert duplicate values into a column while a unique index is being created, or you might insert `NULL` values into a column while creating a primary key index on that column. The changes made by the concurrent DML take precedence, and the `ALTER TABLE` operation is effectively rolled back.

### 15.12.8 Online DDL Limitations

The following limitations apply to online DDL operations:

- The table is copied when creating an index on a `TEMPORARY TABLE`.
- The `ALTER TABLE` clause `LOCK=NONE` is not permitted if there are `ON...CASCADE` or `ON...SET NULL` constraints on the table.
- Before an in-place online DDL operation can finish, it must wait for transactions that hold metadata locks on the table to commit or roll back. An online DDL operation may briefly require an exclusive metadata lock on the table during its execution phase, and always requires one in the final phase of the operation when updating the table definition. Consequently, transactions holding metadata locks on the table can cause an online DDL operation to block. The transactions that hold metadata locks on the table may have been started before or during the online DDL operation. A long running or inactive transaction that holds a metadata lock on the table can cause an online DDL operation to timeout.
- When running an in-place online DDL operation, the thread that runs the `ALTER TABLE` statement applies an online log of DML operations that were run concurrently on the same table from other
connection threads. When the DML operations are applied, it is possible to encounter a duplicate key entry error (ERROR 1062 (23000): Duplicate entry), even if the duplicate entry is only temporary and would be reverted by a later entry in the online log. This is similar to the idea of a foreign key constraint check in InnoDB in which constraints must hold during a transaction.

• **OPTIMIZE TABLE** for an InnoDB table is mapped to an **ALTER TABLE** operation to rebuild the table and update index statistics and free unused space in the clustered index. Secondary indexes are not created as efficiently because keys are inserted in the order they appeared in the primary key. **OPTIMIZE TABLE** is supported with the addition of online DDL support for rebuilding regular and partitioned InnoDB tables.

• Tables created before MySQL 5.6 that include temporal columns (**DATE**, **DATETIME** or **TIMESTAMP**) and have not been rebuilt using **ALGORITHM=COPY** do not support **ALGORITHM=INPLACE**. In this case, an **ALTER TABLE ... ALGORITHM=INPLACE** operation returns the following error:

```
ERROR 1846 (0A000): ALGORITHM=INPLACE is not supported.
Reason: Cannot change column type INPLACE. Try ALGORITHM=COPY.
```

• The following limitations are generally applicable to online DDL operations on large tables that involve rebuilding the table:
  
  • There is no mechanism to pause an online DDL operation or to throttle I/O or CPU usage for an online DDL operation.
  
  • Rollback of an online DDL operation can be expensive should the operation fail.
  
  • Long running online DDL operations can cause replication lag. An online DDL operation must finish running on the source before it is run on the replica. Also, DML that was processed concurrently on the source is only processed on the replica after the DDL operation on the replica is completed.

For additional information related to running online DDL operations on large tables, see Section 15.12.2, “Online DDL Performance and Concurrency”.

### 15.13 InnoDB Data-at-Rest Encryption

InnoDB supports data-at-rest encryption for file-per-table tablespaces, general tablespaces, the mysql system tablespace, redo logs, and undo logs.

As of MySQL 8.0.16, setting an encryption default for schemas and general tablespaces is also supported, which permits DBAs to control whether tables created in those schemas and tablespaces are encrypted. InnoDB data-at-rest encryption features and capabilities are described under the following topics in this section.

• **About Data-at-Rest Encryption**

• **Encryption Prerequisites**

• **Defining an Encryption Default for Schemas and General Tablespaces**

• **File-Per-Table Tablespace Encryption**

• **General Tablespace Encryption**

• **Doublewrite File Encryption**

• **mysql System Tablespace Encryption**

• **Redo Log Encryption**
About Data-at-Rest Encryption

InnoDB uses a two tier encryption key architecture, consisting of a master encryption key and tablespace keys. When a tablespace is encrypted, a tablespace key is encrypted and stored in the tablespace header. When an application or authenticated user wants to access encrypted tablespace data, InnoDB uses a master encryption key to decrypt the tablespace key. The decrypted version of a tablespace key never changes, but the master encryption key can be changed as required. This action is referred to as master key rotation.

The data-at-rest encryption feature relies on a keyring component or plugin for master encryption key management.

All MySQL editions provide a component_keyring_file component and keyring_file plugin, each of which stores keyring data in a file local to the server host.

MySQL Enterprise Edition offers additional keyring components and plugins:

- component_keyring_encrypted_file: Stores keyring data in an encrypted, password-protected file local to the server host.
- keyring_encrypted_file: Stores keyring data in an encrypted, password-protected file local to the server host.
- keyring_okv: A KMIP 1.1 plugin for use with KMIP-compatible back end keyring storage products. Supported KMIP-compatible products include centralized key management solutions such as Oracle Key Vault, Gemalto KeySecure, Thales Vormetric key management server, and Fornetix Key Orchestration.
- keyring_aws: Communicates with the Amazon Web Services Key Management Service (AWS KMS) as a back end for key generation and uses a local file for key storage.
- keyring_hashicorp: Communicates with HashiCorp Vault for back end storage.

Warning

For encryption key management, the component_keyring_file and component_keyring_encrypted_file components, and the keyring_file and keyring_encrypted_file plugins are not intended as a regulatory compliance solution. Security standards such as PCI, FIPS, and others require use of key management systems to secure, manage, and protect encryption keys in key vaults or hardware security modules (HSMs).
A secure and robust encryption key management solution is critical for security and for compliance with various security standards. When the data-at-rest encryption feature uses a centralized key management solution, the feature is referred to as “MySQL Enterprise Transparent Data Encryption (TDE)”.

The data-at-rest encryption feature supports the Advanced Encryption Standard (AES) block-based encryption algorithm. It uses Electronic Codebook (ECB) block encryption mode for tablespace key encryption and Cipher Block Chaining (CBC) block encryption mode for data encryption.

For frequently asked questions about the data-at-rest encryption feature, see Section A.17, “MySQL 8.0 FAQ: InnoDB Data-at-Rest Encryption”.

**Encryption Prerequisites**

- A keyring component or plugin must be installed and configured at startup. Early loading ensures that the component or plugin is available prior to initialization of the InnoDB storage engine. For keyring installation and configuration instructions, see Section 6.4.4, “The MySQL Keyring”. The instructions show how to ensure that the chosen component or plugin is active.

  Only one keyring component or plugin should be enabled at a time. Enabling multiple keyring components or plugins is unsupported and results may not be as anticipated.

  **Important**

  Once encrypted tablespaces are created in a MySQL instance, the keyring component or plugin that was loaded when creating the encrypted tablespace must continue to be loaded at startup. Failing to do so results in errors when starting the server and during InnoDB recovery.

- When encrypting production data, ensure that you take steps to prevent loss of the master encryption key. If the master encryption key is lost, data stored in encrypted tablespace files is unrecoverable. If you use the component_keyring_file or component_keyring_encrypted_file component, or the keyring_file or keyring_encrypted_file plugin, create a backup of the keyring data file immediately after creating the first encrypted tablespace, before master key rotation, and after master key rotation. For each component, its configuration file indicates the data file location. The keyring_file_data configuration option defines the keyring data file location for the keyring_file plugin. The keyring_encrypted_file_data configuration option defines the keyring data file location for the keyring_encrypted_file plugin. If you use the keyring_okv or keyring_aws plugin, ensure that you have performed the necessary configuration. For instructions, see Section 6.4.4, “The MySQL Keyring”.

**Defining an Encryption Default for Schemas and General Tablespaces**

As of MySQL 8.0.16, the default_table_encryption system variable defines the default encryption setting for schemas and general tablespaces. CREATE TABLESPACE and CREATE SCHEMA operations apply the default_table_encryption setting when an ENCRYPTION clause is not specified explicitly.

ALTER_SCHEMA and ALTER_TABLESPACE operations do not apply the default_table_encryption setting. An ENCRYPTION clause must be specified explicitly to alter the encryption of an existing schema or general tablespace.

The default_table_encryption variable can be set for an individual client connection or globally using SET syntax. For example, the following statement enables default schema and tablespace encryption globally:

```
mysql> SET GLOBAL default_table_encryption=ON;
```
The default encryption setting for a schema can also be defined using the `DEFAULT ENCRYPTION` clause when creating or altering a schema, as in this example:

```sql
mysql> CREATE SCHEMA test DEFAULT ENCRYPTION = 'Y';
```

If the `DEFAULT ENCRYPTION` clause is not specified when creating a schema, the `default_table_encryption` setting is applied. The `DEFAULT ENCRYPTION` clause must be specified to alter the default encryption of an existing schema. Otherwise, the schema retains its current encryption setting.

By default, a table inherits the encryption setting of the schema or general tablespace it is created in. For example, a table created in an encryption-enabled schema is encrypted by default. This behavior enables a DBA to control table encryption usage by defining and enforcing schema and general tablespace encryption defaults.

Encryption defaults are enforced by enabling the `table_encryption_privilege_check` system variable. When `table_encryption_privilege_check` is enabled, a privilege check occurs when creating or altering a schema or general tablespace with an encryption setting that differs from the `default_table_encryption` setting, or when creating or altering a table with an encryption setting that differs from the default schema encryption. When `table_encryption_privilege_check` is disabled (the default), the privilege check does not occur and the previously mentioned operations are permitted to proceed with a warning.

The `TABLE_ENCRYPTION_ADMIN` privilege is required to override default encryption settings when `table_encryption_privilege_check` is enabled. A DBA can grant this privilege to enable a user to deviate from the `default_table_encryption` setting when creating or altering a schema or general tablespace, or to deviate from the default schema encryption when creating or altering a table. This privilege does not permit deviating from the encryption of a general tablespace when creating or altering a table. A table must have the same encryption setting as the general tablespace it resides in.

**File-Per-Table Tablespace Encryption**

As of MySQL 8.0.16, a file-per-table tablespace inherits the default encryption of the schema in which the table is created unless an `ENCRYPTION` clause is specified explicitly in the `CREATE TABLE` statement. Prior to MySQL 8.0.16, an `ENCRYPTION` clause must be specified to enable encryption.

```sql
mysql> CREATE TABLE t1 (c1 INT) ENCRYPTION = 'Y';
```

To alter the encryption of an existing file-per-table tablespace, an `ENCRYPTION` clause must be specified.

```sql
mysql> ALTER TABLE t1 ENCRYPTION = 'Y';
```

As of MySQL 8.0.16, if the `table_encryption_privilege_check` variable is enabled, specifying an `ENCRYPTION` clause with a setting that differs from the default schema encryption requires the `TABLE_ENCRYPTION_ADMIN` privilege. See Defining an Encryption Default for Schemas and General Tablespaces.

**General Tablespace Encryption**

As of MySQL 8.0.16, the `default_table_encryption` variable determines the encryption of a newly created general tablespace unless an `ENCRYPTION` clause is specified explicitly in the `CREATE TABLESPACE` statement. Prior to MySQL 8.0.16, an `ENCRYPTION` clause must be specified to enable encryption.

```sql
mysql> CREATE TABLESPACE `ts1` ADD DATAFILE 'ts1.ibd' ENCRYPTION = 'Y' Engine=InnoDB;
```

To alter the encryption of an existing general tablespace, an `ENCRYPTION` clause must be specified.

```sql
mysql> ALTER TABLESPACE ts1 ENCRYPTION = 'Y';
```
As of MySQL 8.0.16, if the `table_encryption_privilege_check` variable is enabled, specifying an `ENCRYPTION` clause with a setting that differs from the `default_table_encryption` setting requires the `TABLE_ENCRYPTION_ADMIN` privilege. See Defining an Encryption Default for Schemas and General Tablespaces.

**Doublewrite File Encryption**

Encryption support for doublewrite files is available as of MySQL 8.0.23. *InnoDB* automatically encrypts doublewrite file pages that belong to encrypted tablespaces. No action is required. Doublewrite file pages are encrypted using the encryption key of the associated tablespace. The same encrypted page written to a tablespace data file is also written to a doublewrite file. Doublewrite file pages that belong to an unencrypted tablespace remain unencrypted.

During recovery, encrypted doublewrite file pages are unencrypted and checked for corruption.

**mysql System Tablespace Encryption**

Encryption support for the `mysql` system tablespace is available as of MySQL 8.0.16.

The `mysql` system tablespace contains the `mysql` system database and MySQL data dictionary tables. It is unencrypted by default. To enable encryption for the `mysql` system tablespace, specify the tablespace name and the `ENCRYPTION` option in an `ALTER TABLESPACE` statement.

```sql
mysql> ALTER TABLESPACE mysql ENCRYPTION = 'Y';
```

To disable encryption for the `mysql` system tablespace, set `ENCRYPTION = 'N'` using an `ALTER TABLESPACE` statement.

```sql
mysql> ALTER TABLESPACE mysql ENCRYPTION = 'N';
```

Enabling or disabling encryption for the `mysql` system tablespace requires the `CREATE TABLESPACE` privilege on all tables in the instance (`CREATE TABLESPACE on *.*`).

**Redo Log Encryption**

Redo log data encryption is enabled using the `innodb_redo_log_encrypt` configuration option. Redo log encryption is disabled by default.

As with tablespace data, redo log data encryption occurs when redo log data is written to disk, and decryption occurs when redo log data is read from disk. Once redo log data is read into memory, it is in unencrypted form. Redo log data is encrypted and decrypted using the tablespace encryption key.

When `innodb_redo_log_encrypt` is enabled, unencrypted redo log pages that are present on disk remain unencrypted, and new redo log pages are written to disk in encrypted form. Likewise, when `innodb_redo_log_encrypt` is disabled, encrypted redo log pages that are present on disk remain encrypted, and new redo log pages are written to disk in unencrypted form.

**Warning**

A regression introduced in MySQL 8.0.30 prevents disabling redo log encryption once it is enabled. (Bug #108052, Bug #34456802).

From MySQL 8.0.30, redo log encryption metadata, including the tablespace encryption key, is stored in the header of the redo log file with the most recent checkpoint LSN. Before MySQL 8.0.30, redo log encryption metadata, including the tablespace encryption key, is stored in the header of the first redo log file (`ib_logfile0`). If the redo log file with the encryption metadata is removed, redo log encryption is disabled.
Undo Log Encryption

Once redo log encryption is enabled, a normal restart without the keyring component or plugin or without the encryption key is not possible, as InnoDB must be able to scan redo pages during startup, which is not possible if redo log pages are encrypted. Without the keyring component or plugin or the encryption key, only a forced startup without the redo logs (SRV_FORCE_NO_LOG_REDO) is possible. See Section 15.21.3, “Forcing InnoDB Recovery”.

Undo Log Encryption

Undo log data encryption is enabled using the innodb_undo_log_encrypt configuration option. Undo log encryption applies to undo logs that reside in undo tablespaces. See Section 15.6.3.4, “Undo Tablespaces”. Undo log data encryption is disabled by default.

As with tablespace data, undo log data encryption occurs when undo log data is written to disk, and decryption occurs when undo log data is read from disk. Once undo log data is read into memory, it is in unencrypted form. Undo log data is encrypted and decrypted using the tablespace encryption key.

When innodb_undo_log_encrypt is enabled, unencrypted undo log pages that are present on disk remain unencrypted, and new undo log pages are written to disk in encrypted form. Likewise, when innodb_undo_log_encrypt is disabled, encrypted undo log pages that are present on disk remain encrypted, and new undo log pages are written to disk in unencrypted form.

Undo log encryption metadata, including the tablespace encryption key, is stored in the header of the undo log file.

Note

When undo log encryption is disabled, the server continues to require the keyring component or plugin that was used to encrypt undo log data until the undo tablespaces that contained the encrypted undo log data are truncated. (An encryption header is only removed from an undo tablespace when the undo tablespace is truncated.) For information about truncating undo tablespaces, see Truncating Undo Tablespaces.

Master Key Rotation

The master encryption key should be rotated periodically and whenever you suspect that the key has been compromised.

Master key rotation is an atomic, instance-level operation. Each time the master encryption key is rotated, all tablespace keys in the MySQL instance are re-encrypted and saved back to their respective tablespace headers. As an atomic operation, re-encryption must succeed for all tablespace keys once a rotation operation is initiated. If master key rotation is interrupted by a server failure, InnoDB rolls the operation forward on server restart. For more information, see Encryption and Recovery.

Rotating the master encryption key only changes the master encryption key and re-encrypts tablespace keys. It does not decrypt or re-encrypt associated tablespace data.

Rotating the master encryption key requires the ENCRYPTION_KEY_ADMIN privilege (or the deprecated SUPER privilege).

To rotate the master encryption key, run:

```
mysql> ALTER INSTANCE ROTATE INNODB MASTER KEY;
```

ALTER INSTANCE ROTATE INNODB MASTER KEY supports concurrent DML. However, it cannot be run concurrently with tablespace encryption operations, and locks are taken to prevent conflicts that could arise.
from concurrent execution. If an `ALTER INSTANCE ROTATE INNODB MASTER KEY` operation is running, it must finish before a tablespace encryption operation can proceed, and vice versa.

Encryption and Recovery

If a server failure occurs during an encryption operation, the operation is rolled forward when the server is restarted. For general tablespaces, the encryption operation is resumed in a background thread from the last processed page.

If a server failure occurs during master key rotation, `InnoDB` continues the operation on server restart.

The keyring component or plugin must be loaded prior to storage engine initialization so that the information necessary to decrypt tablespace data pages can be retrieved from tablespace headers before `InnoDB` initialization and recovery activities access tablespace data. (See Encryption Prerequisites.)

When `InnoDB` initialization and recovery begin, the master key rotation operation resumes. Due to the server failure, some tablespace keys may already be encrypted using the new master encryption key. `InnoDB` reads the encryption data from each tablespace header, and if the data indicates that the tablespace key is encrypted using the old master encryption key, `InnoDB` retrieves the old key from the keyring and uses it to decrypt the tablespace key. `InnoDB` then re-encrypts the tablespace key using the new master encryption key and saves the re-encrypted tablespace key back to the tablespace header.

Exporting Encrypted Tablespaces

Tablespace export is only supported for file-per-table tablespaces.

When an encrypted tablespace is exported, `InnoDB` generates a transfer key that is used to encrypt the tablespace key. The encrypted tablespace key and transfer key are stored in a `tablespace_name.cfp` file. This file together with the encrypted tablespace file is required to perform an import operation. On import, `InnoDB` uses the transfer key to decrypt the tablespace key in the `tablespace_name.cfp` file. For related information, see Section 15.6.1.3, “Importing InnoDB Tables”.

Encryption and Replication

- The `ALTER INSTANCE ROTATE INNODB MASTER KEY` statement is only supported in replication environments where the source and replica run a version of MySQL that supports tablespace encryption.
- Successful `ALTER INSTANCE ROTATE INNODB MASTER KEY` statements are written to the binary log for replication on replicas.
- If an `ALTER INSTANCE ROTATE INNODB MASTER KEY` statement fails, it is not logged to the binary log and is not replicated on replicas.
- Replication of an `ALTER INSTANCE ROTATE INNODB MASTER KEY` operation fails if the keyring component or plugin is installed on the source but not on the replica.
- If the `keyring_file` or `keyring_encrypted_file` plugin is installed on both the source and a replica but the replica does not have a keyring data file, the replicated `ALTER INSTANCE ROTATE INNODB MASTER KEY` statement creates the keyring data file on the replica, assuming the keyring file data is not cached in memory. `ALTER INSTANCE ROTATE INNODB MASTER KEY` uses keyring file data that is cached in memory, if available.

Identifying Encrypted Tablespaces and Schemas

The Information Schema `INNODB_TABLESPACES` table, introduced in MySQL 8.0.13, includes an `ENCRYPTION` column that can be used to identify encrypted tablespaces.
When the `ENCRYPTION` option is specified in a `CREATE TABLE` or `ALTER TABLE` statement, it is recorded in the `CREATE_OPTIONS` column of `INFORMATION_SCHEMA.TABLES`. This column can be queried to identify tables that reside in encrypted file-per-table tablespaces.

```
mysql> SELECT TABLE_SCHEMA, TABLE_NAME, CREATE_OPTIONS FROM INFORMATION_SCHEMA.TABLES
WHERE CREATE_OPTIONS LIKE '%ENCRYPTION%';
<table>
<thead>
<tr>
<th>TABLE_SCHEMA</th>
<th>TABLE_NAME</th>
<th>CREATE_OPTIONS</th>
</tr>
</thead>
<tbody>
<tr>
<td>test</td>
<td>t1</td>
<td>ENCRYPTION=&quot;Y&quot;</td>
</tr>
</tbody>
</table>
```

Query the Information Schema `INNODB_TABLESPACES` table to retrieve information about the tablespace associated with a particular schema and table.

```
mysql> SELECT SPACE, NAME, SPACE_TYPE FROM INFORMATION_SCHEMA.INNODB_TABLESPACES WHERE NAME='test/t1';
<table>
<thead>
<tr>
<th>SPACE</th>
<th>NAME</th>
<th>SPACE_TYPE</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>test/t1</td>
<td>Single</td>
</tr>
</tbody>
</table>
```

You can identify encryption-enabled schemas by querying the Information Schema `SCHEMATA` table.

```
mysql> SELECT SCHEMA_NAME, DEFAULT_ENCRYPTION FROM INFORMATION_SCHEMA.SCHEMATA
WHERE DEFAULT_ENCRYPTION='YES';
<table>
<thead>
<tr>
<th>SCHEMA_NAME</th>
<th>DEFAULT_ENCRYPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>test</td>
<td>YES</td>
</tr>
</tbody>
</table>
```

`SHOW CREATE SCHEMA` also shows the `DEFAULT ENCRYPTION` clause.

**Monitoring Encryption Progress**

You can monitor general tablespace and `mysql` system tablespace encryption progress using `Performance Schema`.

The `stage/innodb/alter tablespace (encryption)` stage event instrument reports `WORK_ESTIMATED` and `WORK_COMPLETED` information for general tablespace encryption operations.

The following example demonstrates how to enable the `stage/innodb/alter tablespace (encryption)` stage event instrument and related consumer tables to monitor general tablespace or `mysql` system tablespace encryption progress. For information about Performance Schema stage event instruments and related consumers, see Section 27.12.5, “Performance Schema Stage Event Tables”.

---

3482
1. Enable the `stage/innodb/alter tablespace (encryption)` instrument:

   ```
   mysql> USE performance_schema;
   mysql> UPDATE setup_instruments SET ENABLED = 'YES'
       WHERE NAME LIKE 'stage/innodb/alter tablespace (encryption)';
   ```

2. Enable the stage event consumer tables, which include `events_stages_current`, `events_stages_history`, and `events_stages_history_long`.

   ```
   mysql> UPDATE setup_consumers SET ENABLED = 'YES' WHERE NAME LIKE '%stages%';
   ```

3. Run a tablespace encryption operation. In this example, a general tablespace named `ts1` is encrypted.

   ```
   mysql> ALTER TABLESPACE ts1 ENCRYPTION = 'Y';
   ```

4. Check the progress of the encryption operation by querying the Performance Schema `events_stages_current` table. `WORK_ESTIMATED` reports the total number of pages in the tablespace. `WORK_COMPLETED` reports the number of pages processed.

   ```
   mysql> SELECT EVENT_NAME, WORK_ESTIMATED, WORK_COMPLETED FROM events_stages_current;
   +--------------------------------------------+----------------+----------------+
   | EVENT_NAME                                 | WORK_COMPLETED | WORK_ESTIMATED |
   +--------------------------------------------+----------------+----------------+
   | stage/innodb/alter tablespace (encryption) |           1056 |           1407 |
   +--------------------------------------------+----------------+----------------+
   ```

   The `events_stages_current` table returns an empty set if the encryption operation has completed. In this case, you can check the `events_stages_history` table to view event data for the completed operation. For example:

   ```
   mysql> SELECT EVENT_NAME, WORK_COMPLETED, WORK_ESTIMATED FROM events_stages_history;
   +--------------------------------------------+----------------+----------------+
   | EVENT_NAME                                 | WORK_COMPLETED | WORK_ESTIMATED |
   +--------------------------------------------+----------------+----------------+
   | stage/innodb/alter tablespace (encryption) |           1407 |           1407 |
   +--------------------------------------------+----------------+----------------+
   ```

**Encryption Usage Notes**

- Plan appropriately when altering an existing file-per-table tablespace with the `ENCRYPTION` option. Tables residing in file-per-table tablespaces are rebuilt using the `COPY` algorithm. The `INPLACE` algorithm is used when altering the `ENCRYPTION` attribute of a general tablespace or the `mysql` system tablespace. The `INPLACE` algorithm permits concurrent DML on tables that reside in the general tablespace. Concurrent DDL is blocked.

- When a general tablespace or the `mysql` system tablespace is encrypted, all tables residing in the tablespace are encrypted. Likewise, a table created in an encrypted tablespace is encrypted.

- If the server exits or is stopped during normal operation, it is recommended to restart the server using the same encryption settings that were configured previously.

- The first master encryption key is generated when the first new or existing tablespace is encrypted.

- Master key rotation re-encrypts tablespaces keys but does not change the tablespace key itself. To change a tablespace key, you must disable and re-enable encryption. For file-per-table tablespaces, re-encrypting the tablespace is an `ALGORITHM=COPY` operation that rebuilds the table. For general tablespaces and the `mysql` system tablespace, it is an `ALGORITHM=INPLACE` operation, which does not require rebuilding tables that reside in the tablespace.

- If a table is created with both the `COMPRESSION` and `ENCRYPTION` options, compression is performed before tablespace data is encrypted.
Encryption Limitations

- If a keyring data file (the file named by `keyring_file_data` or `keyring_encrypted_file_data`) is empty or missing, the first execution of `ALTER INSTANCE ROTATE INNODB MASTER KEY` creates a master encryption key.

- Uninstalling the `component_keyring_file` or `component_keyring_encrypted_file` component does not remove an existing keyring data file. Uninstalling the `keyring_file` or `keyring_encrypted_file` plugin does not remove an existing keyring data file.

- It is recommended that you not place a keyring data file under the same directory as tablespace data files.

- Modifying the `keyring_file_data` or `keyring_encrypted_file_data` setting at runtime or when restarting the server can cause previously encrypted tablespaces to become inaccessible, resulting in lost data.

- Encryption is supported for the InnoDB FULLTEXT index tables that are created implicitly when adding a FULLTEXT index. For related information, see InnoDB Full-Text Index Tables.

Encryption Limitations

- Advanced Encryption Standard (AES) is the only supported encryption algorithm. InnoDB tablespace encryption uses Electronic Codebook (ECB) block encryption mode for tablespace key encryption and Cipher Block Chaining (CBC) block encryption mode for data encryption. Padding is not used with CBC block encryption mode. Instead, InnoDB ensures that the text to be encrypted is a multiple of the block size.

- Encryption is only supported for file-per-table tablespaces, general tablespaces, and the mysql system tablespace. Encryption support for general tablespaces was introduced in MySQL 8.0.13. Encryption support for the mysql system tablespace is available as of MySQL 8.0.16. Encryption is not supported for other tablespace types including the InnoDB system tablespace.

- You cannot move or copy a table from an encrypted file-per-table tablespace, general tablespace, or the mysql system tablespace to a tablespace type that does not support encryption.

- You cannot move or copy a table from an encrypted tablespace to an unencrypted tablespace. However, moving a table from an unencrypted tablespace to an encrypted one is permitted. For example, you can move or copy a table from an unencrypted file-per-table or general tablespace to an encrypted general tablespace.

- By default, tablespace encryption only applies to data in the tablespace. Redo log and undo log data can be encrypted by enabling `innodb_redo_log_encrypt` and `innodb_undo_log_encrypt`. See Redo Log Encryption, and Undo Log Encryption. For information about binary log file and relay log file encryption, see Section 17.3.2, “Encrypting Binary Log Files and Relay Log Files”.

- It is not permitted to change the storage engine of a table that resides in, or previously resided in, an encrypted tablespace.

15.14 InnoDB Startup Options and System Variables

- System variables that are true or false can be enabled at server startup by naming them, or disabled by using a `--skip-` prefix. For example, to enable or disable the InnoDB adaptive hash index, you can use `--innodb-adaptive-hash-index` or `--skip-innodb-adaptive-hash-index` on the command line, or `innodb_adaptive_hash_index` or `skip_innodb_adaptive_hash_index` in an option file.

- Some variable descriptions refer to “enabling” or “disabling” a variable. These variables can be enabled with the `SET` statement by setting them to `ON` or `1`, or disabled by setting them to `OFF` or `0`. Boolean
variables can be set at startup to the values ON, TRUE, OFF, and FALSE (not case-sensitive), as well as 1 and 0. See Section 4.2.2.4, “Program Option Modifiers”.

- System variables that take a numeric value can be specified as `--var_name=value` on the command line or as `var_name=value` in option files.
- Many system variables can be changed at runtime (see Section 5.1.9.2, “Dynamic System Variables”).
- For information about GLOBAL and SESSION variable scope modifiers, refer to the SET statement documentation.
- Certain options control the locations and layout of the InnoDB data files. Section 15.8.1, “InnoDB Startup Configuration” explains how to use these options.
- Some options, which you might not use initially, help tune InnoDB performance characteristics based on machine capacity and your database workload.
- For more information on specifying options and system variables, see Section 4.2.2, “Specifying Program Options”.

### InnoDB Command Options

- `-innodb[=value]`
InnoDB System Variables

<table>
<thead>
<tr>
<th>Default Value</th>
<th>ON</th>
</tr>
</thead>
<tbody>
<tr>
<td>Valid Values</td>
<td>OFF ON FORCE</td>
</tr>
</tbody>
</table>

Controls loading of the InnoDB storage engine, if the server was compiled with InnoDB support. This option has a tristate format, with possible values of OFF, ON, or FORCE. See Section 5.6.1, “Installing and Uninstalling Plugins”.

To disable InnoDB, use --innodb=OFF or --skip-innodb. In this case, because the default storage engine is InnoDB, the server does not start unless you also use --default-storage-engine and --default-temp-storage-engine to set the default to some other engine for both permanent and TEMPORARY tables.

The InnoDB storage engine can no longer be disabled, and the --innodb=OFF and --skip-innodb options are deprecated and have no effect. Their use results in a warning. Expect these options to be removed in a future MySQL release.

• --innodb-status-file

Command-Line Format | --innodb-status-file[={OFF|ON}]
Type | Boolean
Default Value | OFF

The --innodb-status-file startup option controls whether InnoDB creates a file named innodb_status.pid in the data directory and writes SHOW ENGINE INNODB STATUS output to it every 15 seconds, approximately.

The innodb_status.pid file is not created by default. To create it, start mysqld with the --innodb-status-file option. InnoDB removes the file when the server is shut down normally. If an abnormal shutdown occurs, the status file may have to be removed manually.

The --innodb-status-file option is intended for temporary use, as SHOW ENGINE INNODB STATUS output generation can affect performance, and the innodb_status.pid file can become quite large over time.

For related information, see Section 15.17.2, “Enabling InnoDB Monitors”.

• --skip-innodb

Disable the InnoDB storage engine. See the description of --innodb.

InnoDB System Variables

• daemon_memcached_enable_binlog

Command-Line Format | --daemon-memcached-enable-binlog[={OFF|ON}]
System Variable | daemon_memcached_enable_binlog
Scope | Global
Dynamic | No
InnoDB System Variables

<table>
<thead>
<tr>
<th>SET_VAR</th>
<th>Hint Applies</th>
<th>Type</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>No</td>
<td>Boolean</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Enable this option on the source server to use the InnoDB memcached plugin (`daemon_memcached`) with the MySQL binary log. This option can only be set at server startup. You must also enable the MySQL binary log on the source server using the `--log-bin` option.

For more information, see Section 15.20.7, “The InnoDB memcached Plugin and Replication”.

- `daemon_memcached_engine_lib_name`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--daemon-memcached-engine-lib-name=file_name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>daemon_memcached_engine_lib_name</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>innodb_engine.so</code></td>
</tr>
</tbody>
</table>

Specifies the shared library that implements the InnoDB memcached plugin.

For more information, see Section 15.20.3, “Setting Up the InnoDB memcached Plugin”.

- `daemon_memcached_engine_lib_path`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--daemon-memcached-engine-lib-path=dir_name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>daemon_memcached_engine_lib_path</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Directory name</td>
</tr>
<tr>
<td>Default Value</td>
<td>NULL</td>
</tr>
</tbody>
</table>

The path of the directory containing the shared library that implements the InnoDB memcached plugin. The default value is NULL, representing the MySQL plugin directory. You should not need to modify this parameter unless specifying a memcached plugin for a different storage engine that is located outside of the MySQL plugin directory.

For more information, see Section 15.20.3, “Setting Up the InnoDB memcached Plugin”.

- `daemon_memcached_option`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--daemon-memcached-option=options</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>daemon_memcached_option</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
</tbody>
</table>
InnoDB System Variables

<table>
<thead>
<tr>
<th>Dynamic</th>
<th>No</th>
</tr>
</thead>
<tbody>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td></td>
</tr>
</tbody>
</table>

Used to pass space-separated memcached options to the underlying memcached memory object caching daemon on startup. For example, you might change the port that memcached listens on, reduce the maximum number of simultaneous connections, change the maximum memory size for a key-value pair, or enable debugging messages for the error log.

See Section 15.20.3, “Setting Up the InnoDB memcached Plugin” for usage details. For information about memcached options, refer to the memcached man page.

• daemon_memcached_r_batch_size

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--daemon-memcached-r-batch-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>daemon_memcached_r_batch_size</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1073741824</td>
</tr>
</tbody>
</table>

Specifies how many memcached read operations (get operations) to perform before doing a COMMIT to start a new transaction. Counterpart of daemon_memcached_w_batch_size.

This value is set to 1 by default, so that any changes made to the table through SQL statements are immediately visible to memcached operations. You might increase it to reduce the overhead from frequent commits on a system where the underlying table is only being accessed through the memcached interface. If you set the value too large, the amount of undo or redo data could impose some storage overhead, as with any long-running transaction.

For more information, see Section 15.20.3, “Setting Up the InnoDB memcached Plugin”.

• daemon_memcached_w_batch_size

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--daemon-memcached-w-batch-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>daemon_memcached_w_batch_size</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
</tbody>
</table>
InnoDB System Variables

| Maximum Value | 1048576 |

Specifies how many memcached write operations, such as add, set, and incr, to perform before doing a COMMIT to start a new transaction. Counterpart of daemon_memcached_r_batch_size.

This value is set to 1 by default, on the assumption that data being stored is important to preserve in case of an outage and should immediately be committed. When storing non-critical data, you might increase this value to reduce the overhead from frequent commits; but then the last \( N-1 \) uncommitted write operations could be lost if an unexpected exit occurs.

For more information, see Section 15.20.3, “Setting Up the InnoDB memcached Plugin”.

- **innodb_adaptive_flushing**

  Command-Line Format | --innodb-adaptive-flushing={OFF|ON}
  System Variable | innodb_adaptive_flushing
  Scope | Global
  Dynamic | Yes
  SET_VAR Hint Applies | No
  Type | Boolean
  Default Value | ON

  Specifies whether to dynamically adjust the rate of flushing dirty pages in the InnoDB buffer pool based on the workload. Adjusting the flush rate dynamically is intended to avoid bursts of I/O activity. This setting is enabled by default. See Section 15.8.3.5, “Configuring Buffer Pool Flushing” for more information. For general I/O tuning advice, see Section 8.5.8, “Optimizing InnoDB Disk I/O”.

- **innodb_adaptive_flushing_lwm**

  Command-Line Format | --innodb-adaptive-flushing-lwm=#
  System Variable | innodb_adaptive_flushing_lwm
  Scope | Global
  Dynamic | Yes
  SET_VAR Hint Applies | No
  Type | Integer
  Default Value | 10
  Minimum Value | 0
  Maximum Value | 70

  Defines the low water mark representing percentage of redo log capacity at which adaptive flushing is enabled. For more information, see Section 15.8.3.5, “Configuring Buffer Pool Flushing”.

- **innodb_adaptive_hash_index**

  Command-Line Format | --innodb-adaptive-hash-index={OFF|ON}
  System Variable | innodb_adaptive_hash_index
  Scope | Global
InnoDB System Variables

<table>
<thead>
<tr>
<th>Dynamic</th>
<th>Yes</th>
</tr>
</thead>
<tbody>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>ON</td>
</tr>
</tbody>
</table>

Whether the InnoDB adaptive hash index is enabled or disabled. It may be desirable, depending on your workload, to dynamically enable or disable adaptive hash indexing to improve query performance. Because the adaptive hash index may not be useful for all workloads, conduct benchmarks with it both enabled and disabled, using realistic workloads. See Section 15.5.3, “Adaptive Hash Index” for details.

This variable is enabled by default. You can modify this parameter using the SET GLOBAL statement, without restarting the server. Changing the setting at runtime requires privileges sufficient to set global system variables. See Section 5.1.9.1, “System Variable Privileges”. You can also use `--skip-innodb-adaptive-hash-index` at server startup to disable it.

Disabling the adaptive hash index empties the hash table immediately. Normal operations can continue while the hash table is emptied, and executing queries that were using the hash table access the index B-trees directly instead. When the adaptive hash index is re-enabled, the hash table is populated again during normal operation.

- `innodb_adaptive_hash_index_parts`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb-adaptive-hash-index-parts=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_adaptive_hash_index_parts</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>8</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>512</td>
</tr>
</tbody>
</table>

Partitions the adaptive hash index search system. Each index is bound to a specific partition, with each partition protected by a separate latch.

The adaptive hash index search system is partitioned into 8 parts by default. The maximum setting is 512.

For related information, see Section 15.5.3, “Adaptive Hash Index”.

- `innodb_adaptive_max_sleep_delay`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb-adaptive-max-sleep-delay=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_adaptive_max_sleep_delay</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
</tbody>
</table>
**InnoDB System Variables**

<table>
<thead>
<tr>
<th>Default Value</th>
<th>150000</th>
</tr>
</thead>
<tbody>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1000000</td>
</tr>
<tr>
<td>Unit</td>
<td>microseconds</td>
</tr>
</tbody>
</table>

Permits InnoDB to automatically adjust the value of `innodb_thread_sleep_delay` up or down according to the current workload. Any nonzero value enables automated, dynamic adjustment of the `innodb_thread_sleep_delay` value, up to the maximum value specified in the `innodb_adaptive_max_sleep_delay` option. The value represents the number of microseconds. This option can be useful in busy systems, with greater than 16 InnoDB threads. (In practice, it is most valuable for MySQL systems with hundreds or thousands of simultaneous connections.)

For more information, see Section 15.8.4, "Configuring Thread Concurrency for InnoDB".

- **innodb_api_bk_commit_interval**

  | Command-Line Format | --innodb-api-bk-commit-interval=\$
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_api_bk_commit_interval</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>5</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1073741824</td>
</tr>
<tr>
<td>Unit</td>
<td>seconds</td>
</tr>
</tbody>
</table>

How often to auto-commit idle connections that use the InnoDB memcached interface, in seconds. For more information, see Section 15.20.6.4, "Controlling Transactional Behavior of the InnoDB memcached Plugin".

- **innodb_api_disable_rowlock**

  | Command-Line Format | --innodb-api-disable-rowlock[=(OFF|ON)]
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_api_disable_rowlock</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Use this option to disable row locks when InnoDB memcached performs DML operations. By default, `innodb_api_disable_rowlock` is disabled, which means that memcached requests row locks for...
get and set operations. When `innodb_api_disable_rowlock` is enabled, memcached requests a table lock instead of row locks.

`innodb_api_disable_rowlock` is not dynamic. It must be specified on the `mysqld` command line or entered in the MySQL configuration file. Configuration takes effect when the plugin is installed, which occurs when the MySQL server is started.

For more information, see Section 15.20.6.4, “Controlling Transactional Behavior of the InnoDB memcached Plugin”.

- **innodb_api_enable_binlog**

| Command-Line Format | --innodb-api-enable-binlog[={OFF|ON}] |
|---------------------|---------------------------------------|
| System Variable     | innodb_api_enable_binlog               |
| Scope               | Global                                |
| Dynamic             | No                                    |
| SET_VAR Hint Applies| No                                    |
| Type                | Boolean                               |
| Default Value       | OFF                                   |

Lets you use the InnoDB memcached plugin with the MySQL binary log. For more information, see Enabling the InnoDB memcached Binary Log.

- **innodb_api_enable_mdl**

| Command-Line Format | --innodb-api-enable-mdl[={OFF|ON}] |
|---------------------|-------------------------------------|
| System Variable     | innodb_api_enable_mdl               |
| Scope               | Global                              |
| Dynamic             | No                                  |
| SET_VAR Hint Applies| No                                  |
| Type                | Boolean                             |
| Default Value       | OFF                                 |

Locks the table used by the InnoDB memcached plugin, so that it cannot be dropped or altered by DDL through the SQL interface. For more information, see Section 15.20.6.4, “Controlling Transactional Behavior of the InnoDB memcached Plugin”.

- **innodb_api_trx_level**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-api-trx-level=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_api_trx_level</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
</tbody>
</table>
InnoDB System Variables

Maximum Value | 3

Controls the transaction isolation level on queries processed by the memcached interface. The constants corresponding to the familiar names are:

- 0 = READ UNCOMMITTED
- 1 = READ COMMITTED
- 2 = REPEATABLE READ
- 3 = SERIALIZABLE

For more information, see Section 15.20.6.4, “Controlling Transactional Behavior of the InnoDB memcached Plugin”.

innodb_autoextend_increment

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-autoextend-increment=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_autoextend_increment</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>64</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1000</td>
</tr>
<tr>
<td>Unit</td>
<td>megabytes</td>
</tr>
</tbody>
</table>

The increment size (in megabytes) for extending the size of an auto-extending InnoDB system tablespace file when it becomes full. The default value is 64. For related information, see System Tablespace Data File Configuration, and Resizing the System Tablespace.

The innodb_autoextend_increment setting does not affect file-per-table tablespace files or general tablespace files. These files are auto-extending regardless of the innodb_autoextend_increment setting. The initial extensions are by small amounts, after which extensions occur in increments of 4MB.

innodb_autoinc_lock_mode

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-autoinc-lock-mode=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_autoinc_lock_mode</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>2</td>
</tr>
<tr>
<td>Valid Values</td>
<td>0, 1</td>
</tr>
</tbody>
</table>

3499
The lock mode to use for generating auto-increment values. Permissible values are 0, 1, or 2, for traditional, consecutive, or interleaved, respectively.

The default setting is 2 (interleaved) as of MySQL 8.0, and 1 (consecutive) before that. The change to interleaved lock mode as the default setting reflects the change from statement-based to row-based replication as the default replication type, which occurred in MySQL 5.7. Statement-based replication requires the consecutive auto-increment lock mode to ensure that auto-increment values are assigned in a predictable and repeatable order for a given sequence of SQL statements, whereas row-based replication is not sensitive to the execution order of SQL statements.

For the characteristics of each lock mode, see InnoDB AUTO_INCREMENT Lock Modes.

- **innodb_background_drop_list_empty**

  | Command-Line Format          | --innodb-background-drop-list-empty[={OFF|ON}] |
  |------------------------------|-----------------------------------------------|
  | System Variable              | innodb_background_drop_list_empty             |
  | Scope                        | Global                                        |
  | Dynamic                      | Yes                                           |
  | SET_VAR Hint Applies         | No                                            |
  | Type                         | Boolean                                       |
  | Default Value                | OFF                                           |

Enabling the `innodb_background_drop_list_empty` debug option helps avoid test case failures by delaying table creation until the background drop list is empty. For example, if test case A places table `t1` on the background drop list, test case B waits until the background drop list is empty before creating table `t1`.

- **innodb_buffer_pool_chunk_size**

<table>
<thead>
<tr>

</tr>
</tbody>
</table>
InnoDB System Variables

<table>
<thead>
<tr>
<th>Unit</th>
<th>bytes</th>
</tr>
</thead>
</table>

`innodb_buffer_pool_chunk_size` defines the chunk size for InnoDB buffer pool resizing operations.

To avoid copying all buffer pool pages during resizing operations, the operation is performed in "chunks". By default, `innodb_buffer_pool_chunk_size` is 128MB (134217728 bytes). The number of pages contained in a chunk depends on the value of `innodb_page_size`. `innodb_buffer_pool_chunk_size` can be increased or decreased in units of 1MB (1048576 bytes).

The following conditions apply when altering the `innodb_buffer_pool_chunk_size` value:

- If `innodb_buffer_pool_chunk_size * innodb_buffer_pool_instances` is larger than the current buffer pool size when the buffer pool is initialized, `innodb_buffer_pool_chunk_size` is truncated to `innodb_buffer_pool_size / innodb_buffer_pool_instances`.

- Buffer pool size must always be equal to or a multiple of `innodb_buffer_pool_chunk_size * innodb_buffer_pool_instances`. If you alter `innodb_buffer_pool_chunk_size`, `innodb_buffer_pool_size` is automatically rounded to a value that is equal to or a multiple of `innodb_buffer_pool_chunk_size * innodb_buffer_pool_instances`. The adjustment occurs when the buffer pool is initialized.

**Important**

Care should be taken when changing `innodb_buffer_pool_chunk_size`, as changing this value can automatically increase the size of the buffer pool. Before changing `innodb_buffer_pool_chunk_size`, calculate its effect on `innodb_buffer_pool_size` to ensure that the resulting buffer pool size is acceptable.

To avoid potential performance issues, the number of chunks (`innodb_buffer_pool_size / innodb_buffer_pool_chunk_size`) should not exceed 1000.

The `innodb_buffer_pool_size` variable is dynamic, which permits resizing the buffer pool while the server is online. However, the buffer pool size must be equal to or a multiple of `innodb_buffer_pool_chunk_size * innodb_buffer_pool_instances`, and changing either of those variable settings requires restarting the server.

See Section 15.8.3.1, “Configuring InnoDB Buffer Pool Size” for more information.

**innodb_buffer_pool_debug**

---

Command-Line Format: `--innodb-buffer-pool-debug=[{OFF|ON}]`

System Variable: `innodb_buffer_pool_debug`

Scope: Global

Dynamic: No

`SET_VAR` Hint Applies: No

Type: Boolean

Default Value: OFF

Enabling this option permits multiple buffer pool instances when the buffer pool is less than 1GB in size, ignoring the 1GB minimum buffer pool size constraint imposed on `innodb_buffer_pool_instances`. 
InnoDB System Variables

The `innodb_buffer_pool_debug` option is only available if debugging support is compiled in using the `WITH_DEBUG` CMake option.

- **innodb_buffer_pool_dump_at_shutdown**

  | Command-Line Format | `--innodb-buffer-pool-dump-at-shutdown[=(OFF|ON)]` |
  |---------------------|--------------------------------------------------|
  | System Variable     | `innodb_buffer_pool_dump_at_shutdown`             |
  | Scope               | Global                                           |
  | Dynamic             | Yes                                              |
  | `SET_VAR` Hint Applies | No                                          |
  | Type                | Boolean                                         |
  | Default Value       | `ON`                                             |

Specifies whether to record the pages cached in the InnoDB buffer pool when the MySQL server is shut down, to shorten the warmup process at the next restart. Typically used in combination with `innodb_buffer_pool_load_at_startup`. The `innodb_buffer_pool_dump_pct` option defines the percentage of most recently used buffer pool pages to dump.

Both `innodb_buffer_pool_dump_at_shutdown` and `innodb_buffer_pool_load_at_startup` are enabled by default.

For more information, see Section 15.8.3.6, “Saving and Restoring the Buffer Pool State”.

- **innodb_buffer_pool_dump_now**

  | Command-Line Format | `--innodb-buffer-pool-dump-now[=(OFF|ON)]` |
  |---------------------|--------------------------------------------------|
  | System Variable     | `innodb_buffer_pool_dump_now`                     |
  | Scope               | Global                                           |
  | Dynamic             | Yes                                              |
  | `SET_VAR` Hint Applies | No                                          |
  | Type                | Boolean                                         |
  | Default Value       | `OFF`                                           |

Immediately makes a record of pages cached in the InnoDB buffer pool. Typically used in combination with `innodb_buffer_pool_load_now`.

Enabling `innodb_buffer_pool_dump_now` triggers the recording action but does not alter the variable setting, which always remains `OFF` or `0`. To view buffer pool dump status after triggering a dump, query the `Innodb_buffer_pool_dump_status` variable.

Enabling `innodb_buffer_pool_dump_now` triggers the dump action but does not alter the variable setting, which always remains `OFF` or `0`. To view buffer pool dump status after triggering a dump, query the `Innodb_buffer_pool_dump_status` variable.

For more information, see Section 15.8.3.6, “Saving and Restoring the Buffer Pool State”.

- **innodb_buffer_pool_dump_pct**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb-buffer-pool-dump-pct=#</code></th>
</tr>
</thead>
</table>

3502
### InnoDB System Variables

<table>
<thead>
<tr>
<th>System Variable</th>
<th>innodb_buffer_pool_dump_pct</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Scope</strong></td>
<td>Global</td>
</tr>
<tr>
<td><strong>Dynamic</strong></td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Integer</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>25</td>
</tr>
<tr>
<td><strong>Minimum Value</strong></td>
<td>1</td>
</tr>
<tr>
<td><strong>Maximum Value</strong></td>
<td>100</td>
</tr>
</tbody>
</table>

Specifies the percentage of the most recently used pages for each buffer pool to read out and dump. The range is 1 to 100. The default value is 25. For example, if there are 4 buffer pools with 100 pages each, and `innodb_buffer_pool_dump_pct` is set to 25, the 25 most recently used pages from each buffer pool are dumped.

- **innodb_buffer_pool_filename**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-buffer-pool-filename=file_name</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>System Variable</strong></td>
<td>innodb_buffer_pool_filename</td>
</tr>
<tr>
<td><strong>Scope</strong></td>
<td>Global</td>
</tr>
<tr>
<td><strong>Dynamic</strong></td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>File name</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>ib_buffer_pool</td>
</tr>
</tbody>
</table>

Specifies the name of the file that holds the list of tablespace IDs and page IDs produced by `innodb_buffer_pool_dump_at_shutdown` or `innodb_buffer_pool_dump_now`. Tablespace IDs and page IDs are saved in the following format: `space, page_id`. By default, the file is named `ib_buffer_pool` and is located in the InnoDB data directory. A non-default location must be specified relative to the data directory.

A file name can be specified at runtime, using a **SET** statement:

```
SET GLOBAL innodb_buffer_pool_filename='file_name';
```

You can also specify a file name at startup, in a startup string or MySQL configuration file. When specifying a file name at startup, the file must exist or InnoDB returns a startup error indicating that there is no such file or directory.

For more information, see [Section 15.8.3.6, “Saving and Restoring the Buffer Pool State”](#).  

- **innodb_buffer_pool_in_core_file**

| Command-Line Format                  | --innodb-buffer-pool-in-core-file[={OFF|ON}] |
|--------------------------------------|---------------------------------------------|
| **Introduced**                      | 8.0.14                                      |
| **System Variable**                  | innodb_buffer_pool_in_core_file             |
| **Scope**                            | Global                                      |
Disabling the `innodb_buffer_pool_in_core_file` variable reduces the size of core files by excluding InnoDB buffer pool pages. To use this variable, the `core_file` variable must be enabled and the operating system must support the `MADV_DONTDUMP` non-POSIX extension to `madvise()`, which is supported in Linux 3.4 and later. For more information, see Section 15.8.3.7, “Excluding Buffer Pool Pages from Core Files”.

- `innodb_buffer_pool_instances`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb-buffer-pool-instances=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_buffer_pool_instances</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value (Windows, 32-bit platforms)</td>
<td>(autosized)</td>
</tr>
<tr>
<td>Default Value (Other)</td>
<td>8 (or 1 if <code>innodb_buffer_pool_size</code> &lt; 1GB)</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>64</td>
</tr>
</tbody>
</table>

The number of regions that the InnoDB buffer pool is divided into. For systems with buffer pools in the multi-gigabyte range, dividing the buffer pool into separate instances can improve concurrency, by reducing contention as different threads read and write to cached pages. Each page that is stored in or read from the buffer pool is assigned to one of the buffer pool instances randomly, using a hashing function. Each buffer pool manages its own free lists, flush lists, LRUs, and all other data structures connected to a buffer pool, and is protected by its own buffer pool mutex.

This option only takes effect when setting `innodb_buffer_pool_size` to 1GB or more. The total buffer pool size is divided among all the buffer pools. For best efficiency, specify a combination of `innodb_buffer_pool_instances` and `innodb_buffer_pool_size` so that each buffer pool instance is at least 1GB.

The default value on 32-bit Windows systems depends on the value of `innodb_buffer_pool_size`, as described below:

- If `innodb_buffer_pool_size` is greater than 1.3GB, the default for `innodb_buffer_pool_instances` is `innodb_buffer_pool_size/128MB`, with individual memory allocation requests for each chunk. 1.3GB was chosen as the boundary at which there is significant risk for 32-bit Windows to be unable to allocate the contiguous address space needed for a single buffer pool.
### InnoDB System Variables

- Otherwise, the default is 1.

On all other platforms, the default value is 8 when `innodb_buffer_pool_size` is greater than or equal to 1GB. Otherwise, the default is 1.

For related information, see Section 15.8.3.1, “Configuring InnoDB Buffer Pool Size”.

- `innodb_buffer_pool_load_abort`  

| Command-Line Format | `--innodb-buffer-pool-load-abort[=(OFF|ON)]` |
|---------------------|---------------------------------------------|
| System Variable     | `innodb_buffer_pool_load_abort`             |
| Scope               | Global                                      |
| Dynamic             | Yes                                         |
| SET_VAR Hint Applies | No                                          |
| Type                | Boolean                                     |
| Default Value       | `OFF`                                       |

Interrupts the process of restoring InnoDB buffer pool contents triggered by `innodb_buffer_pool_load_at_startup` or `innodb_buffer_pool_load_now`.

Enabling `innodb_buffer_pool_load_abort` triggers the abort action but does not alter the variable setting, which always remains OFF or 0. To view buffer pool load status after triggering an abort action, query the `Innodb_buffer_pool_load_status` variable.

For more information, see Section 15.8.3.6, “Saving and Restoring the Buffer Pool State”.

- `innodb_buffer_pool_load_at_startup`  

| Command-Line Format | `--innodb-buffer-pool-load-at-startup[=(OFF|ON)]` |
|---------------------|-----------------------------------------------|
| System Variable     | `innodb_buffer_pool_load_at_startup`          |
| Scope               | Global                                        |
| Dynamic             | No                                            |
| SET_VAR Hint Applies | No                                           |
| Type                | Boolean                                       |
| Default Value       | `ON`                                          |

Specifies that, on MySQL server startup, the InnoDB buffer pool is automatically warmed up by loading the same pages it held at an earlier time. Typically used in combination with `innodb_buffer_pool_dump_at_shutdown`.

Both `innodb_buffer_pool_dump_at_shutdown` and `innodb_buffer_pool_load_at_startup` are enabled by default.

For more information, see Section 15.8.3.6, “Saving and Restoring the Buffer Pool State”.
• **innodb_buffer_pool_load_now**

| Command-Line Format | --innodb-buffer-pool-load-now=[{OFF|ON}] |
|---------------------|-----------------------------------------|
| System Variable     | innodb_buffer_pool_load_now             |
| Scope               | Global                                  |
| Dynamic             | Yes                                     |
| SET_VAR Hint Applies| No                                      |
| Type                | Boolean                                 |
| Default Value       | OFF                                     |

Immediately **warms up** the **InnoDB buffer pool** by loading data pages without waiting for a server restart. Can be useful to bring cache memory back to a known state during benchmarking or to ready the MySQL server to resume its normal workload after running queries for reports or maintenance.

Enabling **innodb_buffer_pool_load_now** triggers the load action but does not alter the variable setting, which always remains OFF or 0. To view buffer pool load progress after triggering a load, query the `Innodb_buffer_pool_load_status` variable.

For more information, see Section 15.8.3.6, “Saving and Restoring the Buffer Pool State”.

• **innodb_buffer_pool_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-buffer-pool-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_buffer_pool_size</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>134217728</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>5242880</td>
</tr>
<tr>
<td>Maximum Value (64-bit platforms)</td>
<td>$2^{64}-1$</td>
</tr>
<tr>
<td>Maximum Value (32-bit platforms)</td>
<td>$2^{32}-1$</td>
</tr>
<tr>
<td>Unit</td>
<td>bytes</td>
</tr>
</tbody>
</table>

The size in bytes of the **buffer pool**, the memory area where **InnoDB** caches table and index data. The default value is 134217728 bytes (128MB). The maximum value depends on the CPU architecture; the maximum is 4294967295 ($2^{32}-1$) on 32-bit systems and 18446744073709551615 ($2^{64}-1$) on 64-bit systems. On 32-bit systems, the CPU architecture and operating system may impose a lower practical maximum size than the stated maximum. When the size of the buffer pool is greater than 1GB, setting **innodb_buffer_pool_instances** to a value greater than 1 can improve the scalability on a busy server.

A larger buffer pool requires less disk I/O to access the same table data more than once. On a dedicated database server, you might set the buffer pool size to 80% of the machine's physical memory size. Be
InnoDB System Variables

aware of the following potential issues when configuring buffer pool size, and be prepared to scale back
the size of the buffer pool if necessary.

- Competition for physical memory can cause paging in the operating system.
- InnoDB reserves additional memory for buffers and control structures, so that the total allocated
  space is approximately 10% greater than the specified buffer pool size.
- Address space for the buffer pool must be contiguous, which can be an issue on Windows systems
  with DLLs that load at specific addresses.
- The time to initialize the buffer pool is roughly proportional to its size. On instances with large buffer
  pools, initialization time might be significant. To reduce the initialization period, you can save the
  buffer pool state at server shutdown and restore it at server startup. See Section 15.8.3.6, “Saving and
  Restoring the Buffer Pool State”.

When you increase or decrease buffer pool size, the operation is performed in chunks. Chunk size is
defined by the `innodb_buffer_pool_chunk_size` variable, which has a default of 128 MB.

Buffer pool size must always be equal to or a multiple of `innodb_buffer_pool_chunk_size`
* `innodb_buffer_pool_instances`. If you alter the buffer pool size to a value that is not equal
to or a multiple of `innodb_buffer_pool_chunk_size`* `innodb_buffer_pool_instances`,
buffer pool size is automatically adjusted to a value that is equal to or a multiple of
`innodb_buffer_pool_chunk_size`* `innodb_buffer_pool_instances`.

`innodb_buffer_pool_size` can be set dynamically, which allows you to resize the buffer pool
without restarting the server. The `innodb_buffer_pool_resize_status` status variable reports the
status of online buffer pool resizing operations. See Section 15.8.3.1, “Configuring InnoDB Buffer Pool
Size” for more information.

If `innodb_dedicated_server` is enabled, the `innodb_buffer_pool_size` value is automatically
configured if it is not explicitly defined. For more information, see Section 15.8.12, “Enabling Automatic
Configuration for a Dedicated MySQL Server”.

- `innodb_change_buffer_max_size`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-change-buffer-max-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_change_buffer_max_size</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>

<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>25</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>50</td>
</tr>
</tbody>
</table>

Maximum size for the InnoDB change buffer, as a percentage of the total size of the buffer pool. You
might increase this value for a MySQL server with heavy insert, update, and delete activity, or decrease
it for a MySQL server with unchanging data used for reporting. For more information, see Section 15.5.2,
“Change Buffer”. For general I/O tuning advice, see Section 8.5.8, “Optimizing InnoDB Disk I/O”.

<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>2</td>
</tr>
</tbody>
</table>

Sets a debug flag for InnoDB change buffering. A value of 1 forces all changes to the change buffer. A value of 2 causes an unexpected exit at merge. A default value of 0 indicates that the change buffering debug flag is not set. This option is only available when debugging support is compiled in using the **WITH_DEBUG** CMake option.

- **innodb_checkpoint_disabled**

  | Command-Line Format     | --innodb-checkpoint-disabled[=OFF|ON] |
  |-------------------------|----------------------------------------|
  | System Variable         | innodb_checkpoint_disabled             |
  | Scope                   | Global                                 |
  | Dynamic                 | Yes                                    |
  | **SET_VAR** Hint Applies | No                                      |
  | Type                    | Boolean                                |
  | Default Value           | OFF                                    |

This is a debug option that is only intended for expert debugging use. It disables checkpoints so that a deliberate server exit always initiates InnoDB recovery. It should only be enabled for a short interval, typically before running DML operations that write redo log entries that would require recovery following a server exit. This option is only available if debugging support is compiled in using the **WITH_DEBUG** CMake option.

- **innodb_checksum_algorithm**

<table>

InnoDB System Variables

<table>
<thead>
<tr>
<th>none</th>
<th>strict_none</th>
</tr>
</thead>
</table>

Specifies how to generate and verify the checksum stored in the disk blocks of InnoDB tablespaces. The default value for innodb_checksum_algorithm is crc32.

Versions of MySQL Enterprise Backup up to 3.8.0 do not support backing up tablespaces that use CRC32 checksums. MySQL Enterprise Backup adds CRC32 checksum support in 3.8.1, with some limitations. Refer to the MySQL Enterprise Backup 3.8.1 Change History for more information.

The value innodb is backward-compatible with earlier versions of MySQL. The value crc32 uses an algorithm that is faster to compute the checksum for every modified block, and to check the checksums for each disk read. It scans blocks 64 bits at a time, which is faster than the innodb checksum algorithm, which scans blocks 8 bits at a time. The value none writes a constant value in the checksum field rather than computing a value based on the block data. The blocks in a tablespace can use a mix of old, new, and no checksum values, being updated gradually as the data is modified; once blocks in a tablespace are modified to use the crc32 algorithm, the associated tables cannot be read by earlier versions of MySQL.

The strict form of a checksum algorithm reports an error if it encounters a valid but non-matching checksum value in a tablespace. It is recommended that you only use strict settings in a new instance, to set up tablespaces for the first time. Strict settings are somewhat faster, because they do not need to compute all checksum values during disk reads.

The following table shows the difference between the none, innodb, and crc32 option values, and their strict counterparts. none, innodb, and crc32 write the specified type of checksum value into each data block, but for compatibility accept other checksum values when verifying a block during a read operation. Strict settings also accept valid checksum values but print an error message when a valid non-matching checksum value is encountered. Using the strict form can make verification faster if all InnoDB data files in an instance are created under an identical innodb_checksum_algorithm value.

**Table 15.26 Permitted innodb_checksum_algorithm Values**

<table>
<thead>
<tr>
<th>Value</th>
<th>Generated checksum (when writing)</th>
<th>Permitted checksums (when reading)</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td>A constant number.</td>
<td>Any of the checksums generated by none, innodb, or crc32.</td>
</tr>
<tr>
<td>innodb</td>
<td>A checksum calculated in software, using the original algorithm from InnoDB.</td>
<td>Any of the checksums generated by none, innodb, or crc32.</td>
</tr>
<tr>
<td>crc32</td>
<td>A checksum calculated using the crc32 algorithm, possibly done with a hardware assist.</td>
<td>Any of the checksums generated by none, innodb, or crc32.</td>
</tr>
<tr>
<td>strict_none</td>
<td>A constant number</td>
<td>Any of the checksums generated by none, innodb, or crc32. InnoDB prints an error message if a valid but non-matching checksum is encountered.</td>
</tr>
<tr>
<td>strict_innodb</td>
<td>A checksum calculated in software, using the original algorithm from InnoDB.</td>
<td>Any of the checksums generated by none, innodb, or crc32. InnoDB prints an error message</td>
</tr>
</tbody>
</table>
InnoDB System Variables

<table>
<thead>
<tr>
<th>Value</th>
<th>Generated checksum (when writing)</th>
<th>Permitted checksums (when reading)</th>
</tr>
</thead>
<tbody>
<tr>
<td>strict_crc32</td>
<td>A checksum calculated using the crc32 algorithm, possibly done with a hardware assist.</td>
<td>Any of the checksums generated by none, innodb, or crc32. InnoDB prints an error message if a valid but non-matching checksum is encountered.</td>
</tr>
</tbody>
</table>

- **innodb_cmp_per_index_enabled**

Command-Line Format

```
--innodb-cmp-per-index-enabled [=OFF|ON]
```

System Variable

`innodb_cmp_per_index_enabled`

Scope

Global

Dynamic

Yes

`SET_VAR` Hint Applies

No

Type

Boolean

Default Value

OFF

Enables per-index compression-related statistics in the Information Schema `INNODB_CMP_PER_INDEX` table. Because these statistics can be expensive to gather, only enable this option on development, test, or replica instances during performance tuning related to InnoDB compressed tables.

For more information, see Section 26.4.8, "The INFORMATION_SCHEMA INNODB_CMP_PER_INDEX and INNODB_CMP_PER_INDEX_RESET Tables", and Section 15.9.1.4, "Monitoring InnoDB Table Compression at Runtime".

- **innodb_commit_concurrency**

Command-Line Format

```
--innodb-commit-concurrency=#
```

System Variable

`innodb_commit_concurrency`

Scope

Global

Dynamic

Yes

`SET_VAR` Hint Applies

No

Type

Integer

Default Value

0

Minimum Value

0

Maximum Value

1000

The number of threads that can commit at the same time. A value of 0 (the default) permits any number of transactions to commit simultaneously.

The value of `innodb_commit_concurrency` cannot be changed at runtime from zero to nonzero or vice versa. The value can be changed from one nonzero value to another.
• **innodb_compress_debug**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-compress-debug=value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_compress_debug</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>none</td>
</tr>
<tr>
<td>Valid Values</td>
<td>none, zlib, lz4, lz4hc</td>
</tr>
</tbody>
</table>

Compresses all tables using a specified compression algorithm without having to define a `COMPRESSION` attribute for each table. This option is only available if debugging support is compiled in using the `WITH_DEBUG` CMake option.

For related information, see Section 15.9.2, “InnoDB Page Compression”.

• **innodb_compression_failure_threshold_pct**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-compression-failure-threshold-pct=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_compression_failure_threshold_pct</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>5</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>100</td>
</tr>
</tbody>
</table>

Defines the compression failure rate threshold for a table, as a percentage, at which point MySQL begins adding padding within compressed pages to avoid expensive compression failures. When this threshold is passed, MySQL begins to leave additional free space within each new compressed page, dynamically adjusting the amount of free space up to the percentage of page size specified by `innodb_compression_pad_pct_max`. A value of zero disables the mechanism that monitors compression efficiency and dynamically adjusts the padding amount.

For more information, see Section 15.9.1.6, “Compression for OLTP Workloads”.

• **innodb_compression_level**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-compression-level=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_compression_level</td>
</tr>
</tbody>
</table>
### innodb_compressionัว压缩设置

<table>
<thead>
<tr>
<th>Scope</th>
<th>Global</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>6</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>9</td>
</tr>
</tbody>
</table>

Specifies the level of zlib compression to use for InnoDB compressed tables and indexes. A higher value lets you fit more data onto a storage device, at the expense of more CPU overhead during compression. A lower value lets you reduce CPU overhead when storage space is not critical, or you expect the data is not especially compressible.

For more information, see Section 15.9.1.6, “Compression for OLTP Workloads”.

- **innodb_compression_pad_pct_max**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-compression-pad-pct-max=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_compression_pad_pct_max</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>50</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>75</td>
</tr>
</tbody>
</table>

Specifies the maximum percentage that can be reserved as free space within each compressed page, allowing room to reorganize the data and modification log within the page when a compressed table or index is updated and the data might be recompressed. Only applies when innodb_compression_failure_threshold_pct is set to a nonzero value, and the rate of compression failures passes the cutoff point.

For more information, see Section 15.9.1.6, “Compression for OLTP Workloads”.

- **innodb_concurrency_tickets**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-concurrency-tickets=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_concurrency_tickets</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>5000</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>
Determines the number of threads that can enter InnoDB concurrently. A thread is placed in a queue when it tries to enter InnoDB if the number of threads has already reached the concurrency limit. When a thread is permitted to enter InnoDB, it is given a number of “tickets” equal to the value of `innodb_concurrency_tickets`, and the thread can enter and leave InnoDB freely until it has used up its tickets. After that point, the thread again becomes subject to the concurrency check (and possible queuing) the next time it tries to enter InnoDB. The default value is 5000.

With a small `innodb_concurrency_tickets` value, small transactions that only need to process a few rows compete fairly with larger transactions that process many rows. The disadvantage of a small `innodb_concurrency_tickets` value is that large transactions must loop through the queue many times before they can complete, which extends the amount of time required to complete their task.

With a large `innodb_concurrency_tickets` value, large transactions spend less time waiting for a position at the end of the queue (controlled by `innodb_thread_concurrency`) and more time retrieving rows. Large transactions also require fewer trips through the queue to complete their task. The disadvantage of a large `innodb_concurrency_tickets` value is that too many large transactions running at the same time can starve smaller transactions by making them wait a longer time before executing.

With a nonzero `innodb_thread_concurrency` value, you may need to adjust the `innodb_concurrency_tickets` value up or down to find the optimal balance between larger and smaller transactions. The `SHOW ENGINE INNODB STATUS` report shows the number of tickets remaining for an executing transaction in its current pass through the queue. This data may also be obtained from the `TRX_CONCURRENCY_TICKETS` column of the Information Schema `INNODB_TRX` table.

For more information, see Section 15.8.4, “Configuring Thread Concurrency for InnoDB”.

```
• innodb_data_file_path
```

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-data-file-path=file_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_data_file_path</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>ibdata1:12M:autoextend</code></td>
</tr>
</tbody>
</table>

Defines the name, size, and attributes of InnoDB system tablespace data files. If you do not specify a value for `innodb_data_file_path`, the default behavior is to create a single auto-extending data file, slightly larger than 12MB, named `ibdata1`.

The full syntax for a data file specification includes the file name, file size, `autoextend` attribute, and `max` attribute:

```
file_name:[size][:autoextend][:max:max_file_size]
```

File sizes are specified in kilobytes, megabytes, or gigabytes by appending `K`, `M` or `G` to the size value. If specifying the data file size in kilobytes, do so in multiples of 1024. Otherwise, KB values are rounded.
InnoDB System Variables

to nearest megabyte (MB) boundary. The sum of file sizes must be, at a minimum, slightly larger than 12MB.

For additional configuration information, see System Tablespace Data File Configuration. For resizing instructions, see Resizing the System Tablespace.

- **innodb_data_home_dir**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-data-home-dir=dir_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_data_home_dir</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Directory name</td>
</tr>
</tbody>
</table>

The common part of the directory path for InnoDB system tablespace data files. The default value is the MySQL data directory. The setting is concatenated with the innodb_data_file_path setting, unless that setting is defined with an absolute path.

A trailing slash is required when specifying a value for innodb_data_home_dir. For example:

```
[mysqld]
innodb_data_home_dir = /path/to/myibdata/
```

This setting does not affect the location of file-per-table tablespaces.

For related information, see Section 15.8.1, “InnoDB Startup Configuration”.

- **innodb_ddl_buffer_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-ddl-buffer-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.27</td>
</tr>
<tr>
<td>System Variable</td>
<td>innodb_ddl_buffer_size</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1048576</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>65536</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
<tr>
<td>Unit</td>
<td>bytes</td>
</tr>
</tbody>
</table>

Defines the maximum buffer size for DDL operations. The default setting is 1048576 bytes (approximately 1 MB). Applies to online DDL operations that create or rebuild secondary indexes. See Section 15.12.4, “Online DDL Memory Management”. The maximum buffer size per DDL thread is the maximum buffer size divided by the number of DDL threads (innodb_ddl_buffer_size/innodb_ddl_threads).
• **innodb_ddl_log_crash_reset_debug**

| Command-Line Format | --innodb-ddl-log-crash-reset-debug[={OFF|ON}] |
|---------------------|-----------------------------------------------|
| System Variable     | innodb_ddl_log_crash_reset_debug              |
| Scope               | Global                                        |
| Dynamic             | Yes                                           |
| SET_VAR Hint Applies| No                                            |
| Type                | Boolean                                       |
| Default Value       | OFF                                           |

Enable this debug option to reset DDL log crash injection counters to 1. This option is only available when debugging support is compiled in using the `WITH_DEBUG` CMake option.

• **innodb_ddl_threads**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-ddl-threads=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.27</td>
</tr>
<tr>
<td>System Variable</td>
<td>innodb_ddl_threads</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>4</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>64</td>
</tr>
</tbody>
</table>

Defines the maximum number of parallel threads for the sort and build phases of index creation. Applies to online DDL operations that create or rebuild secondary indexes. For related information, see Section 15.12.5, “Configuring Parallel Threads for Online DDL Operations”, and Section 15.12.4, “Online DDL Memory Management”.

• **innodb_deadlock_detect**

| Command-Line Format | --innodb-deadlock-detect[={OFF|ON}] |
|---------------------|-------------------------------------|
| System Variable     | innodb_deadlock_detect              |
| Scope               | Global                              |
| Dynamic             | Yes                                 |
| SET_VAR Hint Applies| No                                  |
| Type                | Boolean                             |
| Default Value       | ON                                  |

This option is used to disable deadlock detection. On high concurrency systems, deadlock detection can cause a slowdown when numerous threads wait for the same lock. At times, it may be more efficient
to disable deadlock detection and rely on the `innodb_lock_wait_timeout` setting for transaction rollback when a deadlock occurs.

For related information, see Section 15.7.5.2, “Deadlock Detection”.

- **innodb_dedicated_server**

| Command-Line Format | `--innodb-dedicated-server[={OFF|ON}]` |
|---------------------|----------------------------------------|
| System Variable     | `innodb_dedicated_server`               |
| Scope               | Global                                 |
| Dynamic             | No                                     |
| SET_VAR Hint Applies| No                                     |
| Type                | Boolean                                |
| Default Value       | OFF                                    |

When `innodb_dedicated_server` is enabled, InnoDB automatically configures the following variables:

- **innodb_buffer_pool_size**
- **innodb_redo_log_capacity** or, prior to MySQL 8.0.30, `innodb_log_file_size` and `innodb_log_files_in_group`.

**Note**

`innodb_log_file_size` and `innodb_log_files_in_group` are deprecated in MySQL 8.0.30. These variables are superseded by `innodb_redo_log_capacity`. For more information, see Section 15.6.5, “Redo Log”.

- **innodb_flush_method**

Only consider enabling `innodb_dedicated_server` if the MySQL instance resides on a dedicated server where it can use all available system resources. Enabling `innodb_dedicated_server` is not recommended if the MySQL instance shares system resources with other applications.

For more information, see Section 15.8.12, “Enabling Automatic Configuration for a Dedicated MySQL Server”.

- **innodb_default_row_format**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb-default-row-format=value</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_default_row_format</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>DYNAMIC</td>
</tr>
<tr>
<td>Valid Values</td>
<td>REDUNDANT</td>
</tr>
<tr>
<td></td>
<td>COMPACT</td>
</tr>
</tbody>
</table>
The `innodb_default_row_format` option defines the default row format for InnoDB tables and user-created temporary tables. The default setting is `DYNAMIC`. Other permitted values are `COMPACT` and `REDUNDANT`. The `COMPRESSED` row format, which is not supported for use in the system tablespace, cannot be defined as the default.

Newly created tables use the row format defined by `innodb_default_row_format` when a ROW_FORMAT option is not specified explicitly or when `ROW_FORMAT=DEFAULT` is used.

When a ROW_FORMAT option is not specified explicitly or when `ROW_FORMAT=DEFAULT` is used, any operation that rebuilds a table also silently changes the row format of the table to the format defined by `innodb_default_row_format`. For more information, see Defining the Row Format of a Table.

Internal InnoDB temporary tables created by the server to process queries use the `DYNAMIC` row format, regardless of the `innodb_default_row_format` setting.

- `innodb_directories` table

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb-directories=dir_name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_directories</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Directory name</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>NULL</code></td>
</tr>
</tbody>
</table>

Defines directories to scan at startup for tablespace files. This option is used when moving or restoring tablespace files to a new location while the server is offline. It is also used to specify directories of tablespace files created using an absolute path or that reside outside of the data directory.

Tablespace discovery during crash recovery relies on the `innodb_directories` setting to identify tablespaces referenced in the redo logs. For more information, see Tablespace Discovery During Crash Recovery.

The default value is `NULL`, but directories defined by `innodb_data_home_dir`, `innodb_undo_directory`, and `datadir` are always appended to the `innodb_directories` argument value when InnoDB builds a list of directories to scan at startup. These directories are appended regardless of whether an `innodb_directories` setting is specified explicitly.

`innodb_directories` may be specified as an option in a startup command or in a MySQL option file. Quotes surround the argument value because otherwise some command interpreters interpret semicolon (`;`) as a special character. (For example, Unix shells treat it as a command terminator.)

Startup command:

```
mysqld --innodb-directories="directory_path_1;directory_path_2"
```

MySQL option file:

```
[mysqld]
```
InnoDB System Variables

`innodb_directories="directory_path_1;directory_path_2"`

Wildcard expressions cannot be used to specify directories.

The `innodb_directories` scan also traverses the subdirectories of specified directories. Duplicate directories and subdirectories are discarded from the list of directories to be scanned.

For more information, see Section 15.6.3.6, “Moving Tablespace Files While the Server is Offline”.

• `innodb_disable_sort_file_cache`

| Command-Line Format                                      | `--innodb-disable-sort-file-cache[={OFF|ON}]` |
|----------------------------------------------------------|---------------------------------------------|
| System Variable                                         | `innodb_disable_sort_file_cache`            |
| Scope                                                    | Global                                      |
| Dynamic                                                  | Yes                                         |
| `SET_VAR` Hint Applies                                   | No                                          |
| Type                                                     | Boolean                                     |
| Default Value                                            | `OFF`                                       |

Disables the operating system file system cache for merge-sort temporary files. The effect is to open such files with the equivalent of `O_DIRECT`.

• `innodb_doublewrite`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb-doublewrite=value (≥ 8.0.30)</code></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>`--innodb-doublewrite[={OFF</td>

<tr>
<td></td>
<td><code>DETECT_AND_RECOVER</code></td>
</tr>
</tbody>
</table>
InnoDB System Variables

The `innodb_doublewrite` variable controls doublewrite buffering. Doublewrite buffering is enabled by default in most cases.

Prior to MySQL 8.0.30, you can set `innodb_doublewrite` to ON or OFF when starting the server to enable or disable doublewrite buffering, respectively. From MySQL 8.0.30, `innodb_doublewrite` also supports `DETECT_AND_RECOVER` and `DETECT_ONLY` settings.

The `DETECT_AND_RECOVER` setting is the same as the `ON` setting. With this setting, the doublewrite buffer is fully enabled, with database page content written to the doublewrite buffer where it is accessed during recovery to fix incomplete page writes.

With the `DETECT_ONLY` setting, only metadata is written to the doublewrite buffer. Database page content is not written to the doublewrite buffer, and recovery does not use the doublewrite buffer to fix incomplete page writes. This lightweight setting is intended for detecting incomplete page writes only.

MySQL 8.0.30 onwards supports dynamic changes to the `innodb_doublewrite` setting that enables the doublewrite buffer, between `ON`, `DETECT_AND_RECOVER`, and `DETECT_ONLY`. MySQL does not support dynamic changes between a setting that enables the doublewrite buffer and OFF or vice versa.

If the doublewrite buffer is located on a Fusion-io device that supports atomic writes, the doublewrite buffer is automatically disabled and data file writes are performed using Fusion-io atomic writes instead. However, be aware that the `innodb_doublewrite` setting is global. When the doublewrite buffer is disabled, it is disabled for all data files including those that do not reside on Fusion-io hardware. This feature is only supported on Fusion-io hardware and is only enabled for Fusion-io NVMFS on Linux. To take full advantage of this feature, an `innodb_flush_method` setting of `O_DIRECT` is recommended.

For related information, see Section 15.6.4, “Doublewrite Buffer”.

- `innodb_doublewrite_batch_size`

```
Command-Line Format: --innodb-doublewrite-batch-size=#
```

<table>
<thead>
<tr>
<th>Introduced</th>
<th>System Variable</th>
<th>Scope</th>
<th>Dynamic</th>
<th>SET_VAR</th>
<th>Type</th>
<th>Default Value</th>
<th>Minimum Value</th>
<th>Maximum Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>8.0.20</td>
<td><code>innodb_doublewrite_batch_size</code></td>
<td>Global</td>
<td>No</td>
<td>No</td>
<td>Integer</td>
<td>0</td>
<td>0</td>
<td>256</td>
</tr>
</tbody>
</table>

Defines the number of doublewrite pages to write in a batch.

For more information, see Section 15.6.4, “Doublewrite Buffer”.

- `innodb_doublewrite_dir`

```
Command-Line Format: --innodb-doublewrite-dir=dir_name
```
InnoDB System Variables

<table>
<thead>
<tr>
<th>Introduced</th>
<th>8.0.20</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_doublewrite_dir</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Directory name</td>
</tr>
</tbody>
</table>

Defines the directory for doublewrite files. If no directory is specified, doublewrite files are created in the `innodb_data_home_dir` directory, which defaults to the data directory if unspecified.

For more information, see Section 15.6.4, “Doublewrite Buffer”.

* `innodb_doublewrite_files`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb-doublewrite-files=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.20</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>innodb_doublewrite_files</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>innodb_buffer_pool_instances * 2</code></td>
</tr>
<tr>
<td>Minimum Value</td>
<td>2</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>256</td>
</tr>
</tbody>
</table>

Defines the number of doublewrite files. By default, two doublewrite files are created for each buffer pool instance.

At a minimum, there are two doublewrite files. The maximum number of doublewrite files is two times the number of buffer pool instances. (The number of buffer pool instances is controlled by the `innodb_buffer_pool_instances` variable.)

For more information, see Section 15.6.4, “Doublewrite Buffer”.

* `innodb_doublewrite_pages`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb-doublewrite-pages=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.20</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>innodb_doublewrite_pages</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>innodb_write_io_threads value</code></td>
</tr>
<tr>
<td>Minimum Value</td>
<td><code>innodb_write_io_threads value</code></td>
</tr>
<tr>
<td>Maximum Value</td>
<td>512</td>
</tr>
</tbody>
</table>
InnoDB System Variables

Defines the maximum number of doublewrite pages per thread for a batch write. If no value is specified, `innodb_doublewrite_pages` is set to the `innodb_write_io_threads` value.

For more information, see Section 15.6.4, “Doublewrite Buffer”.

- `innodb_extend_and_initialize`

| Command-Line Format | `--innodb=extend-and-initialize[={OFF|ON}]` |
|---------------------|-------------------------------------------|
| Introduced          | 8.0.22                                     |
| System Variable     | `innodb_extend_and_initialize`             |
| Scope               | Global                                    |
| Dynamic             | Yes                                       |
| SET_VAR Hint Applies| No                                        |
| Type                | Boolean                                   |
| Default Value       | ON                                        |

Controls how space is allocated to file-per-table and general tablespaces on Linux systems.

When enabled, InnoDB writes NULLs to newly allocated pages. When disabled, space is allocated using `posix_fallocate()` calls, which reserve space without physically writing NULLs.

For more information, see Section 15.6.3.8, “Optimizing Tablespace Space Allocation on Linux”.

- `innodb_fast_shutdown`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb-fast-shutdown=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_fast_shutdown</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Valid Values</td>
<td>0, 1, 2</td>
</tr>
</tbody>
</table>

The `innodb_fast_shutdown` mode. If the value is 0, InnoDB does a slow shutdown, a full purge and a change buffer merge before shutting down. If the value is 1 (the default), InnoDB skips these operations at shutdown, a process known as a fast shutdown. If the value is 2, InnoDB flushes its logs and shuts down cold, as if MySQL had crashed; no committed transactions are lost, but the crash recovery operation makes the next startup take longer.

The slow shutdown can take minutes, or even hours in extreme cases where substantial amounts of data are still buffered. Use the slow shutdown technique before upgrading or downgrading between
MySQL major releases, so that all data files are fully prepared in case the upgrade process updates the file format.

Use `innodb_fast_shutdown=2` in emergency or troubleshooting situations, to get the absolute fastest shutdown if data is at risk of corruption.

- `innodb_fil_make_page_dirty_debug`

```plaintext
<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-fil-make-page.dirty-debug=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_fil_make_page_dirty_debug</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>(2^{32}-1)</td>
</tr>
</tbody>
</table>
```

By default, setting `innodb_fil_make_page_dirty_debug` to the ID of a tablespace immediately dirties the first page of the tablespace. If `innodb_saved_page_number_debug` is set to a non-default value, setting `innodb_fil_make_page_dirty_debug` dirties the specified page. The `innodb_fil_make_page_dirty_debug` option is only available if debugging support is compiled in using the `WITH_DEBUG` CMake option.

- `innodb_file_per_table`

```plaintext
| Command-Line Format               | --innodb-file-per-table=[OFF|ON] |
|-----------------------------------|---------------------------------|
| System Variable                   | innodb_file_per_table            |
| Scope                             | Global                           |
| Dynamic                           | Yes                              |
| SET_VAR Hint Applies              | No                               |
| Type                              | Boolean                          |
| Default Value                     | ON                               |
```

When `innodb_file_per_table` is enabled, tables are created in file-per-table tablespaces by default. When disabled, tables are created in the system tablespace by default. For information about file-per-table tablespaces, see Section 15.6.3.2, “File-Per-Table Tablespaces”. For information about the InnoDB system tablespace, see Section 15.6.3.1, “The System Tablespace”.

The `innodb_file_per_table` variable can be configured at runtime using a `SET GLOBAL` statement, specified on the command line at startup, or specified in an option file. Configuration at runtime requires privileges sufficient to set global system variables (see Section 5.1.9.1, “System Variable Privileges”) and immediately affects the operation of all connections.

When a table that resides in a file-per-table tablespace is truncated or dropped, the freed space is returned to the operating system. Truncating or dropping a table that resides in the system tablespace
only frees space in the system tablespace. Freed space in the system tablespace can be used again for
InnoDB data but is not returned to the operating system, as system tablespace data files never shrink.

The `innodb_file_per-table` setting does not affect the creation of temporary tables. As of MySQL
8.0.14, temporary tables are created in session temporary tablespaces, and in the global temporary
tablespace before that. See Section 15.6.3.5, “Temporary Tablespaces”.

- **innodb_fill_factor**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb-fill-factor=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_fill_factor</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>100</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>10</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>100</td>
</tr>
</tbody>
</table>

**InnoDB** performs a bulk load when creating or rebuilding indexes. This method of index creation is
known as a “sorted index build”.

`innodb_fill_factor` defines the percentage of space on each B-tree page that is filled during a
sorted index build, with the remaining space reserved for future index growth. For example, setting
`innodb_fill_factor` to 80 reserves 20 percent of the space on each B-tree page for future index
growth. Actual percentages may vary. The `innodb_fill_factor` setting is interpreted as a hint rather
than a hard limit.

An `innodb_fill_factor` setting of 100 leaves 1/16 of the space in clustered index pages free for
future index growth.

`innodb_fill_factor` applies to both B-tree leaf and non-leaf pages. It does not apply to external
pages used for TEXT or BLOB entries.

For more information, see Section 15.6.2.3, “Sorted Index Builds”.

- **innodb_flush_log_at_timeout**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb-flush-log-at-timeout=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_flush_log_at_timeout</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>2700</td>
</tr>
</tbody>
</table>
Write and flush the logs every \( N \) seconds. `innodb_flush_log_at_timeout` allows the timeout period between flushes to be increased in order to reduce flushing and avoid impacting performance of binary log group commit. The default setting for `innodb_flush_log_at_timeout` is once per second.

- **innodb_flush_log_at_trx_commit**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb-flush-log-at-trx-commit=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_flush_log_at_trx_commit</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>\textbf{SET_VAR} Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Valid Values</td>
<td>0, 1, 2</td>
</tr>
</tbody>
</table>

Controls the balance between strict ACID compliance for commit operations and higher performance that is possible when commit-related I/O operations are rearranged and done in batches. You can achieve better performance by changing the default value but then you can lose transactions in a crash.

- The default setting of 1 is required for full ACID compliance. Logs are written and flushed to disk at each transaction commit.

- With a setting of 0, logs are written and flushed to disk once per second. Transactions for which logs have not been flushed can be lost in a crash.

- With a setting of 2, logs are written after each transaction commit and flushed to disk once per second. Transactions for which logs have not been flushed can be lost in a crash.

- For settings 0 and 2, once-per-second flushing is not 100% guaranteed. Flushing may occur more frequently due to DDL changes and other internal InnoDB activities that cause logs to be flushed independently of the `innodb_flush_log_at_trx_commit` setting, and sometimes less frequently due to scheduling issues. If logs are flushed once per second, up to one second of transactions can be lost in a crash. If logs are flushed more or less frequently than once per second, the amount of transactions that can be lost varies accordingly.

- Log flushing frequency is controlled by `innodb_flush_log_at_timeout`, which allows you to set log flushing frequency to \( N \) seconds (where \( N \) is 1 \ldots 2700, with a default value of 1). However, any unexpected `mysqld` process exit can erase up to \( N \) seconds of transactions.

- DDL changes and other internal InnoDB activities flush the log independently of the `innodb_flush_log_at_trx_commit` setting.
• **InnoDB crash recovery** works regardless of the `innodb_flush_log_at_trx_commit` setting. Transactions are either applied entirely or erased entirely.

For durability and consistency in a replication setup that uses InnoDB with transactions:

• If binary logging is enabled, set `sync_binlog=1`.

• Always set `innodb_flush_log_at_trx_commit=1`.

For information on the combination of settings on a replica that is most resilient to unexpected halts, see Section 17.4.2, “Handling an Unexpected Halt of a Replica”.

---

**Caution**

Many operating systems and some disk hardware fool the flush-to-disk operation. They may tell `mysqld` that the flush has taken place, even though it has not. In this case, the durability of transactions is not guaranteed even with the recommended settings, and in the worst case, a power outage can corrupt InnoDB data. Using a battery-backed disk cache in the SCSI disk controller or in the disk itself speeds up file flushes, and makes the operation safer. You can also try to disable the caching of disk writes in hardware caches.

• **`innodb_flush_method`**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb-flush-method=value</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_flush_method</code></td>
</tr>
<tr>

<td><code>fsync</code> <code>O_DSYNC</code> <code>littlesync</code> <code>nosync</code> <code>O_DIRECT</code> <code>O_DIRECT_NO_FSYNC</code></td>
</tr>
<tr>
<td>Valid Values (Windows)</td>
<td><code>unbuffered</code></td>
</tr>
</tbody>
</table>
InnoDB System Variables

| normal |

Defines the method used to flush data to InnoDB data files and log files, which can affect I/O throughput.

On Unix-like systems, the default value is `fsync`. On Windows, the default value is `unbuffered`.

**Note**

In MySQL 8.0, `innodb_flush_method` options can be specified numerically.

The `innodb_flush_method` options for Unix-like systems include:

- **fsync or 0**: InnoDB uses the `fsync()` system call to flush both the data and log files. `fsync` is the default setting.
- **O_DSYNC or 1**: InnoDB uses `O_SYNC` to open and flush the log files, and `fsync()` to flush the data files. InnoDB does not use `O_DSYNC` directly because there have been problems with it on many varieties of Unix.
- **littlesync or 2**: This option is used for internal performance testing and is currently unsupported. Use at your own risk.
- **nosync or 3**: This option is used for internal performance testing and is currently unsupported. Use at your own risk.
- **O_DIRECT or 4**: InnoDB uses `O_DIRECT` (or `directio()` on Solaris) to open the data files, and uses `fsync()` to flush both the data and log files. This option is available on some GNU/Linux versions, FreeBSD, and Solaris.
- **O_DIRECT_NO_FSYNC**: InnoDB uses `O_DIRECT` during flushing I/O, but skips the `fsync()` system call after each write operation.

Prior to MySQL 8.0.14, this setting is not suitable for file systems such as XFS and EXT4, which require an `fsync()` system call to synchronize file system metadata changes. If you are not sure whether your file system requires an `fsync()` system call to synchronize file system metadata changes, use `O_DIRECT` instead.

As of MySQL 8.0.14, `fsync()` is called after creating a new file, after increasing file size, and after closing a file, to ensure that file system metadata changes are synchronized. The `fsync()` system call is still skipped after each write operation.

Data loss is possible if redo log files and data files reside on different storage devices, and an unexpected exit occurs before data file writes are flushed from a device cache that is not battery-backed. If you use or intend to use different storage devices for redo log files and data files, and your data files reside on a device with a cache that is not battery-backed, use `O_DIRECT` instead.

On platforms that support `fdatasync()` system calls, the `innodb_use_fdatasync` variable, introduced in MySQL 8.0.26, permits `innodb_flush_method` options that use `fsync()` to use `fdatasync()` instead. An `fdatasync()` system call does not flush changes to file metadata unless required for subsequent data retrieval, providing a potential performance benefit.

The `innodb_flush_method` options for Windows systems include:

- **unbuffered or 0**: InnoDB uses simulated asynchronous I/O and non-buffered I/O.
InnoDB System Variables

- **normal** or **1**: InnoDB uses simulated asynchronous I/O and buffered I/O.

How each setting affects performance depends on hardware configuration and workload. Benchmark your particular configuration to decide which setting to use, or whether to keep the default setting. Examine the `Innodb_data_fsyncs` status variable to see the overall number of `fsync()` calls (or `fdatasync()` calls if `innodb_use_fdatasync` is enabled) for each setting. The mix of read and write operations in your workload can affect how a setting performs. For example, on a system with a hardware RAID controller and battery-backed write cache, `O_DIRECT` can help to avoid double buffering between the InnoDB buffer pool and the operating system file system cache. On some systems where InnoDB data and log files are located on a SAN, the default value or `O_DSYNC` might be faster for a read-heavy workload with mostly `SELECT` statements. Always test this parameter with hardware and workload that reflect your production environment. For general I/O tuning advice, see Section 8.5.8, “Optimizing InnoDB Disk I/O”.

If `innodb_dedicated_server` is enabled, the `innodb_flush_method` value is automatically configured if it is not explicitly defined. For more information, see Section 15.8.12, “Enabling Automatic Configuration for a Dedicated MySQL Server”.

- **innodb_flush_neighbors**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-flush-neighbors=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_flush_neighbors</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Valid Values</td>
<td>0, 1, 2</td>
</tr>
</tbody>
</table>

Specifies whether flushing a page from the InnoDB buffer pool also flushes other dirty pages in the same extent.

- A setting of 0 disables `innodb_flush_neighbors`. Dirty pages in the same extent are not flushed.
- A setting of 1 flushes contiguous dirty pages in the same extent.
- A setting of 2 flushes dirty pages in the same extent.

When the table data is stored on a traditional HDD storage device, flushing such neighbor pages in one operation reduces I/O overhead (primarily for disk seek operations) compared to flushing individual pages at different times. For table data stored on SSD, seek time is not a significant factor and you can set this option to 0 to spread out write operations. For related information, see Section 15.8.3.5, “Configuring Buffer Pool Flushing”.

- **innodb_flush_sync**

  | Command-Line Format | --innodb-flush-sync[=OFF|ON]] |

3528
InnoDB System Variables

<table>
<thead>
<tr>
<th>System Variable</th>
<th>innodb_flush_sync</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>ON</td>
</tr>
</tbody>
</table>

The `innodb_flush_sync` variable, which is enabled by default, causes the `innodb_io_capacity` setting to be ignored during bursts of I/O activity that occur at checkpoints. To adhere to the I/O rate defined by the `innodb_io_capacity` setting, disable `innodb_flush_sync`.

For information about configuring the `innodb_flush_sync` variable, see Section 15.8.7, “Configuring InnoDB I/O Capacity”.

- `innodb_flushing_avg_loops`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-flushing-avg-loops=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>

<td>30</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1000</td>
</tr>
</tbody>
</table>

Number of iterations for which InnoDB keeps the previously calculated snapshot of the flushing state, controlling how quickly adaptive flushing responds to changing workloads. Increasing the value makes the rate of flush operations change smoothly and gradually as the workload changes. Decreasing the value makes adaptive flushing adjust quickly to workload changes, which can cause spikes in flushing activity if the workload increases and decreases suddenly.

For related information, see Section 15.8.3.5, “Configuring Buffer Pool Flushing”.

- `innodb_force_load_corrupted`

| Command-Line Format              | --innodb-force-load-corrupted[={OFF|ON}] |
|---------------------------------|-----------------------------------------|
| System Variable                 | innodb_force_load_corrupted             |
| Scope                           | Global                                  |
| Dynamic                         | No                                      |
| SET_VAR Hint Applies            | No                                      |
| Type                            | Boolean                                 |
InnoDB System Variables

<table>
<thead>
<tr>
<th>Default Value</th>
<th>OFF</th>
</tr>
</thead>
</table>

Permits InnoDB to load tables at startup that are marked as corrupted. Use only during troubleshooting, to recover data that is otherwise inaccessible. When troubleshooting is complete, disable this setting and restart the server.

- **innodb_force_recovery**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-force-recovery=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_force_recovery</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>6</td>
</tr>
</tbody>
</table>

The crash recovery mode, typically only changed in serious troubleshooting situations. Possible values are from 0 to 6. For the meanings of these values and important information about innodb_force_recovery, see Section 15.21.3, “Forcing InnoDB Recovery”.

**Warning**

Only set this variable to a value greater than 0 in an emergency situation so that you can start InnoDB and dump your tables. As a safety measure, InnoDB prevents INSERT, UPDATE, or DELETE operations when innodb_force_recovery is greater than 0. An innodb_force_recovery setting of 4 or greater places InnoDB into read-only mode.

These restrictions may cause replication administration commands to fail with an error, as replication stores the replica status logs in InnoDB tables.

- **innodb_fsync_threshold**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-fsync-threshold=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.13</td>
</tr>
<tr>
<td>System Variable</td>
<td>innodb_fsync_threshold</td>
</tr>
<tr>

<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>$2^{64}$-1</td>
</tr>
</tbody>
</table>

By default, when InnoDB creates a new data file, such as a new log file or tablespace file, the file is fully written to the operating system cache before it is flushed to disk, which can cause a large amount of
InnoDB System Variables

disk write activity to occur at once. To force smaller, periodic flushes of data from the operating system cache, you can use the `innodb_fsync_threshold` variable to define a threshold value, in bytes. When the byte threshold is reached, the contents of the operating system cache are flushed to disk. The default value of 0 forces the default behavior, which is to flush data to disk only after a file is fully written to the cache.

Specifying a threshold to force smaller, periodic flushes may be beneficial in cases where multiple MySQL instances use the same storage devices. For example, creating a new MySQL instance and its associated data files could cause large surges of disk write activity, impeding the performance of other MySQL instances that use the same storage devices. Configuring a threshold helps avoid such surges in write activity.

- **innodb_ft_aux_table**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>innodb_ft_aux_table</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

  Specifies the qualified name of an InnoDB table containing a FULLTEXT index. This variable is intended for diagnostic purposes and can only be set at runtime. For example:

  ```sql
  SET GLOBAL innodb_ft_aux_table = 'test/t1';
  ```

  After you set this variable to a name in the format `db_name/table_name`, the INFORMATION_SCHEMA tables `INNODB_FT_INDEX_TABLE`, `INNODB_FT_INDEX_CACHE`, `INNODB_FT_CONFIG`, `INNODB_FT_DELETED`, and `INNODB_FT_BEING_DELETED` show information about the search index for the specified table.

  For more information, see Section 15.15.4, “InnoDB INFORMATION_SCHEMA FULLTEXT Index Tables”.

- **innodb_ft_cache_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-ft-cache-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_ft_cache_size</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>8000000</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1600000</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>80000000</td>
</tr>
<tr>
<td>Unit</td>
<td>bytes</td>
</tr>
</tbody>
</table>

  The memory allocated, in bytes, for the InnoDB FULLTEXT search index cache, which holds a parsed document in memory while creating an InnoDB FULLTEXT index. Index inserts and updates are only committed to disk when the `innodb_ft_cache_size` size limit is reached.
**innodb_ft_cache_size** defines the cache size on a per table basis. To set a global limit for all tables, see **innodb_ft_total_cache_size**.

For more information, see InnoDB Full-Text Index Cache.

- **innodb_ft_enable_diag_print**

| Command-Line Format | `--innodb-ft-enable-diag-print=[{OFF| ON}]` |
|---------------------|---------------------------------------------|
| System Variable     | `innodb_ft_enable_diag_print`               |
| Scope               | Global                                      |
| Dynamic             | Yes                                         |
| SET_VAR Hint Applies| No                                          |
| Type                | Boolean                                     |
| Default Value       | OFF                                         |

Whether to enable additional full-text search (FTS) diagnostic output. This option is primarily intended for advanced FTS debugging and is not of interest to most users. Output is printed to the error log and includes information such as:

- FTS index sync progress (when the FTS cache limit is reached). For example:

  ```plaintext
  FTS SYNC for table test, deleted count: 100 size: 10000 bytes
  SYNC words: 100
  ```

- FTS optimize progress. For example:

  ```plaintext
  FTS start optimize test
  FTS_OPTIMIZE: optimize "mysql"
  FTS_OPTIMIZE: processed "mysql"
  ```

- FTS index build progress. For example:

  ```plaintext
  Number of doc processed: 1000
  ```

- FTS queries, the query parsing tree, word weight, query processing time, and memory usage are printed. For example:

  ```plaintext
  FTS Search Processing time: 1 secs: 100 millisec: row(s) 10000
  Full Search Memory: 245666 (bytes), Row: 10000
  ```

- **innodb_ft_enable_stopword**

| Command-Line Format | `--innodb-ft-enable-stopword=[{OFF| ON}]` |
|---------------------|---------------------------------------------|
| System Variable     | `innodb_ft_enable_stopword`                 |
| Scope               | Global, Session                            |
| Dynamic             | Yes                                         |
| SET_VAR Hint Applies| No                                          |
| Type                | Boolean                                     |
### InnoDB System Variables

<table>
<thead>
<tr>
<th>Default Value</th>
<th>ON</th>
</tr>
</thead>
</table>

Specifies that a set of stopwords is associated with an InnoDB FULLTEXT index at the time the index is created. If the `innodb_ft_user_stopword_table` option is set, the stopwords are taken from that table. Else, if the `innodb_ft_server_stopword_table` option is set, the stopwords are taken from that table. Otherwise, a built-in set of default stopwords is used.

For more information, see Section 12.9.4, "Full-Text Stopwords".

- **innodb_ft_max_token_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb-ft-max-token-size=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_ft_max_token_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>84</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>10</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>84</td>
</tr>
</tbody>
</table>

Maximum character length of words that are stored in an InnoDB FULLTEXT index. Setting a limit on this value reduces the size of the index, thus speeding up queries, by omitting long keywords or arbitrary collections of letters that are not real words and are not likely to be search terms.

For more information, see Section 12.9.6, “Fine-Tuning MySQL Full-Text Search”.

- **innodb_ft_min_token_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb-ft-min-token-size=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_ft_min_token_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>3</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>16</td>
</tr>
</tbody>
</table>

Minimum length of words that are stored in an InnoDB FULLTEXT index. Increasing this value reduces the size of the index, thus speeding up queries, by omitting common words that are unlikely to be significant in a search context, such as the English words “a” and “to”. For content using a CJK (Chinese, Japanese, Korean) character set, specify a value of 1.

For more information, see Section 12.9.6, “Fine-Tuning MySQL Full-Text Search”.

- **innodb_ft_num_word_optimize**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb-ft-num-word-optimize=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>
InnoDB System Variables

<table>
<thead>
<tr>
<th>System Variable</th>
<th>innodb_ft_num_word_optimize</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>2000</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1000</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>10000</td>
</tr>
</tbody>
</table>

Number of words to process during each OPTIMIZE TABLE operation on an InnoDB FULLTEXT index. Because a bulk insert or update operation to a table containing a full-text search index could require substantial index maintenance to incorporate all changes, you might do a series of OPTIMIZE TABLE statements, each picking up where the last left off.

For more information, see Section 12.9.6, “Fine-Tuning MySQL Full-Text Search”.

- **innodb_ft_result_cache_limit**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-ft-result-cache-limit=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_ft_result_cache_limit</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>200000000000</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1000000</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>$2^{32}$</td>
</tr>
<tr>
<td>Unit</td>
<td>bytes</td>
</tr>
</tbody>
</table>

The InnoDB full-text search query result cache limit (defined in bytes) per full-text search query or per thread. Intermediate and final InnoDB full-text search query results are handled in memory. Use `innodb_ft_result_cache_limit` to place a size limit on the full-text search query result cache to avoid excessive memory consumption in case of very large InnoDB full-text search query results (millions or hundreds of millions of rows, for example). Memory is allocated as required when a full-text search query is processed. If the result cache size limit is reached, an error is returned indicating that the query exceeds the maximum allowed memory.

The maximum value of `innodb_ft_result_cache_limit` for all platform types and bit sizes is $2^{32}$.

- **innodb_ft_server_stopword_table**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-ft-server-stopword-table=db_name/table_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_ft_server_stopword_table</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
</tbody>
</table>

**innodb_ft_user_stopword_table**

This option is used to specify your own InnoDB FULLTEXT index stopword list for all InnoDB tables. To configure your own stopword list for a specific InnoDB table, use `innodb_ft_user_stopword_table`.

Set `innodb_ft_server_stopword_table` to the name of the table containing a list of stopwords, in the format `db_name/table_name`.

The stopword table must exist before you configure `innodb_ft_server_stopword_table`. `innodb_ft_enable_stopword` must be enabled and `innodb_ft_server_stopword_table` option must be configured before you create the FULLTEXT index.

The stopword table must be an InnoDB table, containing a single VARCHAR column named `value`.

For more information, see Section 12.9.4, “Full-Text Stopwords”.

- **innodb_ft_sort_pll_degree**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb-ft-sort_pll-degree=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_ft_sort_pll_degree</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>2</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>32</td>
</tr>
</tbody>
</table>

Number of threads used in parallel to index and tokenize text in an InnoDB FULLTEXT index when building a search index.

For related information, see Section 15.6.2.4, “InnoDB Full-Text Indexes”, and `innodb_sort_buffer_size`.

- **innodb_ft_total_cache_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb-ft-total-cache-size=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_ft_total_cache_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>640000000</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>32000000</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1600000000</td>
</tr>
</tbody>
</table>
The total memory allocated, in bytes, for the InnoDB full-text search index cache for all tables. Creating numerous tables, each with a `FULLTEXT` search index, could consume a significant portion of available memory. `innodb_ft_total_cache_size` defines a global memory limit for all full-text search indexes to help avoid excessive memory consumption. If the global limit is reached by an index operation, a forced sync is triggered.

For more information, see InnoDB Full-Text Index Cache.

### innodb_ft_total_cache_size

<table>
<thead>
<tr>
<th>Unit</th>
<th>bytes</th>
</tr>
</thead>
</table>

- **Command-Line Format**: `--innodb-ft-total-cache-size=#`
- **System Variable**: `innodb_ft_total_cache_size`
- **Scope**: Global
- **Dynamic**: Yes
- **SET_VAR Hint Applies**: No
- **Type**: Integer
- **Default Value**: 0

This option is used to specify your own InnoDB `FULLTEXT` index stopword list on a specific table. To configure your own stopword list for all InnoDB tables, use `innodb_ft_server_stopword_table`.

Set `innodb_ft_user_stopword_table` to the name of the table containing a list of stopwords, in the format `db_name/table_name`.

The stopword table must exist before you configure `innodb_ft_user_stopword_table`. `innodb_ft_enable_stopword` must be enabled and `innodb_ft_user_stopword_table` must be configured before you create the `FULLTEXT` index.

The stopword table must be an InnoDB table, containing a single `VARCHAR` column named `value`.

For more information, see Section 12.9.4, “Full-Text Stopwords”.

### innodb_idle_flush_pct

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb-idle-flush-pct=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Introduced</strong></td>
<td>8.0.18</td>
</tr>
<tr>
<td><strong>System Variable</strong></td>
<td><code>innodb_idle_flush_pct</code></td>
</tr>
<tr>
<td><strong>Scope</strong></td>
<td>Global</td>
</tr>
<tr>
<td><strong>Dynamic</strong></td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR Hint Applies</strong></td>
<td>No</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Integer</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>100</td>
</tr>
<tr>
<td><strong>Minimum Value</strong></td>
<td>0</td>
</tr>
</tbody>
</table>

This option is used to specify your own InnoDB `FULLTEXT` index stopword list on a specific table. To configure your own stopword list for all InnoDB tables, use `innodb_ft_server_stopword_table`.

Set `innodb_ft_user_stopword_table` to the name of the table containing a list of stopwords, in the format `db_name/table_name`.

The stopword table must exist before you configure `innodb_ft_user_stopword_table`. `innodb_ft_enable_stopword` must be enabled and `innodb_ft_user_stopword_table` must be configured before you create the `FULLTEXT` index.

The stopword table must be an InnoDB table, containing a single `VARCHAR` column named `value`.

For more information, see Section 12.9.4, “Full-Text Stopwords”.
InnoDB System Variables

<table>
<thead>
<tr>
<th>Maximum Value</th>
<th>100</th>
</tr>
</thead>
</table>

Limits page flushing when InnoDB is idle. The `innodb_idle_flush_pct` value is a percentage of the `innodb_io_capacity` setting, which defines the number of I/O operations per second available to InnoDB. For more information, see Limiting Buffer Flushing During Idle Periods.

- `innodb_io_capacity`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb-io-capacity=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_io_capacity</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>200</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>100</td>
</tr>
<tr>
<td>Maximum Value (64-bit platforms)</td>
<td>$2^{64}-1$</td>
</tr>
<tr>
<td>Maximum Value (32-bit platforms)</td>
<td>$2^{32}-1$</td>
</tr>
</tbody>
</table>

The `innodb_io_capacity` variable defines the number of I/O operations per second (IOPS) available to InnoDB background tasks, such as flushing pages from the buffer pool and merging data from the change buffer.

For information about configuring the `innodb_io_capacity` variable, see Section 15.8.7, “Configuring InnoDB I/O Capacity”.

- `innodb_io_capacity_max`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb-io-capacity-max=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_io_capacity_max</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>See description</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>100</td>
</tr>
<tr>
<td>Maximum Value (32-bit platforms)</td>
<td>$2^{32}-1$</td>
</tr>
<tr>
<td>Maximum Value (Unix, 64-bit platforms)</td>
<td>$2^{64}-1$</td>
</tr>
<tr>
<td>Maximum Value (Windows, 64-bit platforms)</td>
<td>$2^{32}-1$</td>
</tr>
</tbody>
</table>

If flushing activity falls behind, InnoDB can flush more aggressively, at a higher rate of I/O operations per second (IOPS) than defined by the `innodb_io_capacity` variable. The `innodb_io_capacity_max` variable defines a maximum number of IOPS performed by InnoDB background tasks in such situations.

For information about configuring the `innodb_io_capacity_max` variable, see Section 15.8.7, “Configuring InnoDB I/O Capacity”. 3537
• `innodb_limit_optimistic_insert_debug`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb-limit-optimistic-insert-debug=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_limit_optimistic_insert_debug</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>$2^{32}-1$</td>
</tr>
</tbody>
</table>

Limits the number of records per B-tree page. A default value of 0 means that no limit is imposed. This option is only available if debugging support is compiled in using the `WITH_DEBUG` CMake option.

• `innodb_lock_wait_timeout`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb-lock-wait-timeout=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_lock_wait_timeout</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>50</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>$1073741824$</td>
</tr>
<tr>
<td>Unit</td>
<td>seconds</td>
</tr>
</tbody>
</table>

The length of time in seconds an InnoDB transaction waits for a row lock before giving up. The default value is 50 seconds. A transaction that tries to access a row that is locked by another InnoDB transaction waits at most this many seconds for write access to the row before issuing the following error:

```
ERROR 1205 (HY000): Lock wait timeout exceeded; try restarting transaction
```

When a lock wait timeout occurs, the current statement is rolled back (not the entire transaction). To have the entire transaction roll back, start the server with the `--innodb-rollback-on-timeout` option. See also Section 15.21.5, “InnoDB Error Handling”.

You might decrease this value for highly interactive applications or OLTP systems, to display user feedback quickly or put the update into a queue for processing later. You might increase this value for
long-running back-end operations, such as a transform step in a data warehouse that waits for other
large insert or update operations to finish.

`innodb_lock_wait_timeout` applies to InnoDB row locks. A MySQL table lock does not happen
inside InnoDB and this timeout does not apply to waits for table locks.

The lock wait timeout value does not apply to deadlocks when `innodb_deadlock_detect`
is enabled (the default) because InnoDB detects deadlocks immediately and rolls back one of
the deadlocked transactions. When `innodb_deadlock_detect` is disabled, InnoDB relies on
`innodb_lock_wait_timeout` for transaction rollback when a deadlock occurs. See Section 15.7.5.2,
“Deadlock Detection”.

`innodb_lock_wait_timeout` can be set at runtime with the `SET GLOBAL` or `SET SESSION`
statement. Changing the `GLOBAL` setting requires privileges sufficient to set global system variables (see
Section 5.1.9.1, “System Variable Privileges”) and affects the operation of all clients that subsequently
connect. Any client can change the `SESSION` setting for `innodb_lock_wait_timeout`, which affects
only that client.

• `innodb_log_buffer_size`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-log-buffer-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>

</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

The size in bytes of the buffer that InnoDB uses to write to the log files on disk. The default is 16MB.
A large log buffer enables large transactions to run without the need to write the log to disk before the
transactions commit. Thus, if you have transactions that update, insert, or delete many rows, making the
log buffer larger saves disk I/O. For related information, see Memory Configuration, and Section 8.5.4,
“Optimizing InnoDB Redo Logging”. For general I/O tuning advice, see Section 8.5.8, “Optimizing
InnoDB Disk I/O”.

• `innodb_log_checkpoint_fuzzy_now`

| Command-Line Format         | --innodb-log-checkpoint-fuzzy-now[=(OFF|ON)] |
|-----------------------------|-----------------------------------------------|
| Introduced                  | 8.0.13                                        |
| System Variable             | `innodb_log_checkpoint_fuzzy_now`             |
| Scope                       | Global                                        |
| Dynamic                     | Yes                                           |
| `SET_VAR` Hint Applies      | No                                            |
| Type                        | Boolean                                       |
InnoDB System Variables

<table>
<thead>
<tr>
<th>Default Value</th>
<th>OFF</th>
</tr>
</thead>
</table>

Enable this debug option to force InnoDB to write a fuzzy checkpoint. This option is only available if debugging support is compiled in using the WITH_DEBUG CMake option.

- **innodb_log_checkpoint_now**

| Command-Line Format | --innodb-log-checkpoint-now=[{OFF|ON}] |
|----------------------|-----------------------------------------|
| System Variable      | innodb_log_checkpoint_now               |
| Scope                | Global                                  |
| Dynamic              | Yes                                     |
| SET_VAR Hint Applies | No                                      |
| Type                 | Boolean                                 |
| Default Value        | OFF                                     |

Enable this debug option to force InnoDB to write a checkpoint. This option is only available if debugging support is compiled in using the WITH_DEBUG CMake option.

- **innodb_log_checksums**

| Command-Line Format | --innodb-log-checksums=[{OFF|ON}] |
|----------------------|-----------------------------------|
| System Variable      | innodb_log_checksums              |
| Scope                | Global                            |
| Dynamic              | Yes                               |
| SET_VAR Hint Applies | No                                |
| Type                 | Boolean                           |
| Default Value        | ON                                |

Enables or disables checksums for redo log pages.

**innodb_log_checksums=ON** enables the CRC-32C checksum algorithm for redo log pages. When **innodb_log_checksums** is disabled, the contents of the redo log page checksum field are ignored.

Checksums on the redo log header page and redo log checkpoint pages are never disabled.

- **innodb_log_compressed_pages**

| Command-Line Format | --innodb-log-compressed-pages=[{OFF|ON}] |
|----------------------|-----------------------------------------|
| System Variable      | innodb_log_compressed_pages             |
| Scope                | Global                                  |
| Dynamic              | Yes                                     |
| SET_VAR Hint Applies | No                                      |
| Type                 | Boolean                                 |
| Default Value        | ON                                      |
Specifies whether images of re-compressed pages are written to the redo log. Re-compression may occur when changes are made to compressed data.

`innodb_log_compressed_pages` is enabled by default to prevent corruption that could occur if a different version of the `zlib` compression algorithm is used during recovery. If you are certain that the `zlib` version is not subject to change, you can disable `innodb_log_compressed_pages` to reduce redo log generation for workloads that modify compressed data.

To measure the effect of enabling or disabling `innodb_log_compressed_pages`, compare redo log generation for both settings under the same workload. Options for measuring redo log generation include observing the Log sequence number (LSN) in the LOG section of SHOW ENGINE INNODB STATUS output, or monitoring `Innodb_os_log_written` status for the number of bytes written to the redo log files.

For related information, see Section 15.9.1.6, "Compression for OLTP Workloads".

- `innodb_log_file_size`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-log-file-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Deprecated</td>
<td>8.0.30</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>innodb_log_file_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>50331648</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>4194304</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>512GB / <code>innodb_log_files_in_group</code></td>
</tr>
<tr>
<td>Unit</td>
<td>bytes</td>
</tr>
</tbody>
</table>

**Note**

`innodb_log_file_size` and `innodb_log_files_in_group` are deprecated in MySQL 8.0.30. These variables are superseded by `innodb_redo_log_capacity`. For more information, see Section 15.6.5, "Redo Log".

The size in bytes of each log file in a log group. The combined size of log files (`innodb_log_file_size * innodb_log_files_in_group`) cannot exceed a maximum value that is slightly less than 512GB. A pair of 255 GB log files, for example, approaches the limit but does not exceed it. The default value is 48MB.

Generally, the combined size of the log files should be large enough that the server can smooth out peaks and troughs in workload activity, which often means that there is enough redo log space to handle
more than an hour of write activity. The larger the value, the less checkpoint flush activity is required in
the buffer pool, saving disk I/O. Larger log files also make crash recovery slower.

The minimum `innodb_log_file_size` is 4MB.

For related information, see Redo Log Configuration. For general I/O tuning advice, see Section 8.5.8,
"Optimizing InnoDB Disk I/O".

If `innodb_dedicated_server` is enabled, the `innodb_log_file_size` value is automatically
configured if it is not explicitly defined. For more information, see Section 15.8.12, "Enabling Automatic
Configuration for a Dedicated MySQL Server".

- `innodb_log_files_in_group`
### InnoDB System Variables

<table>
<thead>
<tr>
<th>Type</th>
<th>Directory name</th>
</tr>
</thead>
<tbody>
<tr>
<td>The directory path to the InnoDB redo log files.</td>
<td></td>
</tr>
<tr>
<td>For related information, see Redo Log Configuration.</td>
<td></td>
</tr>
</tbody>
</table>

**• innodb_log_spin_cpu_abs_lwm**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-log-spin-cpu-abs-lwm=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_log_spin_cpu_abs_lwm</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>80</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

 Defines the minimum amount of CPU usage below which user threads no longer spin while waiting for flushed redo. The value is expressed as a sum of CPU core usage. For example, the default value of 80 is 80% of a single CPU core. On a system with a multi-core processor, a value of 150 represents 100% usage of one CPU core plus 50% usage of a second CPU core.

 For related information, see Section 8.5.4, “Optimizing InnoDB Redo Logging”.

**• innodb_log_spin_cpu_pct_hwm**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-log-spin-cpu-pct-hwm=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_log_spin_cpu_pct_hwm</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>50</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>100</td>
</tr>
</tbody>
</table>

 Defines the maximum amount of CPU usage above which user threads no longer spin while waiting for flushed redo. The value is expressed as a percentage of the combined total processing power of all CPU cores. The default value is 50%. For example, 100% usage of two CPU cores is 50% of the combined CPU processing power on a server with four CPU cores.

 The innodb_log_spin_cpu_pct_hwm variable respects processor affinity. For example, if a server has 48 cores but the mysqld process is pinned to only four CPU cores, the other 44 CPU cores are ignored.

 For related information, see Section 8.5.4, “Optimizing InnoDB Redo Logging”.

**• innodb_log_wait_for_flush_spin_hwm**
### InnoDB System Variables

#### --innodb-log-wait-for-flush-spin-hwm=#

**System Variable**

innodb_log_wait_for_flush_spin_hwm

**Scope**

Global

**Dynamic**

Yes

**SET_VAR Hint Applies**

No

**Type**

Integer

**Default Value**

400

**Minimum Value**

0

**Maximum Value (64-bit platforms)**

$2^{64}-1$

**Maximum Value (32-bit platforms)**

$2^{32}-1$

**Unit**

microseconds

Defines the maximum average log flush time beyond which user threads no longer spin while waiting for flushed redo. The default value is 400 microseconds.

For related information, see [Section 8.5.4, “Optimizing InnoDB Redo Logging”](#).

- **innodb_log_write_ahead_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-log-write-ahead-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>System Variable</strong></td>
<td>innodb_log_write_ahead_size</td>
</tr>
<tr>
<td><strong>Scope</strong></td>
<td>Global</td>
</tr>
<tr>
<td><strong>Dynamic</strong></td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR Hint Applies</strong></td>
<td>No</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Integer</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>8192</td>
</tr>
<tr>
<td><strong>Minimum Value</strong></td>
<td>$512$ (log file block size)</td>
</tr>
<tr>
<td><strong>Maximum Value</strong></td>
<td>Equal to innodb_page_size</td>
</tr>
<tr>
<td><strong>Unit</strong></td>
<td>bytes</td>
</tr>
</tbody>
</table>

Defines the write-ahead block size for the redo log, in bytes. To avoid “read-on-write”, set **innodb_log_write_ahead_size** to match the operating system or file system cache block size. The default setting is 8192 bytes. Read-on-write occurs when redo log blocks are not entirely cached to the operating system or file system due to a mismatch between write-ahead block size for the redo log and operating system or file system cache block size.

Valid values for **innodb_log_write_ahead_size** are multiples of the InnoDB log file block size ($2^n$). The minimum value is the InnoDB log file block size (512). Write-ahead does not occur when the minimum value is specified. The maximum value is equal to the **innodb_page_size** value. If you
specify a value for `innodb_log_write_ahead_size` that is larger than the `innodb_page_size` value, the `innodb_log_write_ahead_size` setting is truncated to the `innodb_page_size` value.

Setting the `innodb_log_write_ahead_size` value too low in relation to the operating system or file system cache block size results in “read-on-write”. Setting the value too high may have a slight impact on `fsync` performance for log file writes due to several blocks being written at once.

For related information, see Section 8.5.4, “Optimizing InnoDB Redo Logging”.

- `innodb_log_writer_threads`

| Command-Line Format | --innodb-log-writer-threads[={OFF|ON}] |
|---------------------|-----------------------------------------|
| Introduced          | 8.0.22                                   |
| System Variable     | `innodb_log_writer_threads`              |
| Scope               | Global                                  |
| Dynamic             | Yes                                     |
| SET_VAR Hint Applies| No                                      |
| Type                | Boolean                                 |
| Default Value       | ON                                      |

Enables dedicated log writer threads for writing redo log records from the log buffer to the system buffers and flushing the system buffers to the redo log files. Dedicated log writer threads can improve performance on high-concurrency systems, but for low-concurrency systems, disabling dedicated log writer threads provides better performance.

For more information, see Section 8.5.4, “Optimizing InnoDB Redo Logging”.

- `innodb_lru_scan_depth`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-lru-scan-depth=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_lru_scan_depth</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1024</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>100</td>
</tr>
<tr>
<td>Maximum Value (64-bit platforms)</td>
<td>2**64-1</td>
</tr>
<tr>
<td>Maximum Value (32-bit platforms)</td>
<td>2**32-1</td>
</tr>
</tbody>
</table>

A parameter that influences the algorithms and heuristics for the flush operation for the InnoDB buffer pool. Primarily of interest to performance experts tuning I/O-intensive workloads. It specifies, per buffer pool instance, how far down the buffer pool LRU page list the page cleaner thread scans looking for dirty pages to flush. This is a background operation performed once per second.

A setting smaller than the default is generally suitable for most workloads. A value that is much higher than necessary may impact performance. Only consider increasing the value if you have spare I/O.
InnoDB System Variables

capacity under a typical workload. Conversely, if a write-intensive workload saturates your I/O capacity, decrease the value, especially in the case of a large buffer pool.

When tuning `innodb_lru_scan_depth`, start with a low value and configure the setting upward with the goal of rarely seeing zero free pages. Also, consider adjusting `innodb_lru_scan_depth` when changing the number of buffer pool instances, since `innodb_lru_scan_depth`* `innodb_buffer_pool_instances` defines the amount of work performed by the page cleaner thread each second.

For related information, see Section 15.8.3.5, “Configuring Buffer Pool Flushing”. For general I/O tuning advice, see Section 8.5.8, “Optimizing InnoDB Disk I/O”.

• `innodb_max_dirty_pages_pct`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb-max-dirty-pages-pct=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_max_dirty_pages_pct</code></td>
</tr>

<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>90</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>99.99</td>
</tr>
</tbody>
</table>

*InnoDB* tries to flush data from the buffer pool so that the percentage of dirty pages does not exceed this value.

The `innodb_max_dirty_pages_pct` setting establishes a target for flushing activity. It does not affect the rate of flushing. For information about managing the rate of flushing, see Section 15.8.3.5, “Configuring Buffer Pool Flushing”.

For related information, see Section 15.8.3.5, “Configuring Buffer Pool Flushing”. For general I/O tuning advice, see Section 8.5.8, “Optimizing InnoDB Disk I/O”.

• `innodb_max_dirty_pages_pct_lwm`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb-max-dirty-pages-pct-lwm=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_max_dirty_pages_pct_lwm</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>10</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>99.99</td>
</tr>
</tbody>
</table>

Defines a low water mark representing the percentage of dirty pages at which preflushing is enabled to control the dirty page ratio. A value of 0 disables the pre-flushing behavior entirely. The configured value
InnoDB System Variables

should always be lower than the `innodb_max_dirty_pages_pct` value. For more information, see Section 15.8.3.5, "Configuring Buffer Pool Flushing".

- **innodb_max_purge_lag**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><strong>--innodb-max-purge-lag=</strong>#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_max_purge_lag</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

Defines the desired maximum purge lag. If this value is exceeded, a delay is imposed on `INSERT`, `UPDATE`, and `DELETE` operations to allow time for purge to catch up. The default value is 0, which means there is no maximum purge lag and no delay.

For more information, see Section 15.8.9, “Purge Configuration”.

- **innodb_max_purge_lag_delay**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><strong>--innodb-max-purge-lag-delay=</strong>#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_max_purge_lag_delay</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>10000000</td>
</tr>
<tr>
<td>Unit</td>
<td>microseconds</td>
</tr>
</tbody>
</table>

Specifies the maximum delay in microseconds for the delay imposed when the `innodb_max_purge_lag` threshold is exceeded. The specified `innodb_max_purge_lag_delay` value is an upper limit on the delay period calculated by the `innodb_max_purge_lag` formula.

For more information, see Section 15.8.9, “Purge Configuration”.

- **innodb_max_undo_log_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><strong>--innodb-max-undo-log-size=</strong>#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_max_undo_log_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
</tbody>
</table>

For more information, see Section 15.8.9, “Purge Configuration”.
InnoDB System Variables

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Default Value</th>
<th>Minimum Value</th>
<th>Maximum Value</th>
<th>Unit</th>
</tr>
</thead>
<tbody>
<tr>
<td>innodb_undo_truncate_threshold</td>
<td>Integer</td>
<td>1073741824</td>
<td>10485760</td>
<td>2**64-1</td>
<td>bytes</td>
</tr>
</tbody>
</table>

Defines a threshold size for undo tablespaces. If an undo tablespace exceeds the threshold, it can be marked for truncation when `innodb_undo_log_truncate` is enabled. The default value is 1073741824 bytes (1024 MiB).

For more information, see [Truncating Undo Tablespaces](#).

- `innodb_merge_threshold_set_all_debug`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-merge-threshold-set-all-debug=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_merge_threshold_set_all_debug</td>
</tr>
<tr>

</tr>
<tr>
<td>Default Value</td>
<td>50</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>50</td>
</tr>
</tbody>
</table>

Defines a page-full percentage value for index pages that overrides the current `MERGE_THRESHOLD` setting for all indexes that are currently in the dictionary cache. This option is only available if debugging support is compiled in using the `WITH_DEBUG` CMake option. For related information, see [Section 15.8.11, “Configuring the Merge Threshold for Index Pages”](#).

- `innodb_monitor_disable`

  | Command-Line Format | --innodb-monitor-disable={counter|module|pattern|all} |
  |--------------------|------------------------------------------|
  | System Variable    | innodb_monitor_disable                   |
  | Scope              | Global                                   |
  | Dynamic            | Yes                                      |
  | SET_VAR Hint Applies | No                                       |
  | Type               | String                                   |

This variable acts as a switch, disabling InnoDB metrics counters. Counter data may be queried using the Information Schema `INNODB_METRICS` table. For usage information, see [Section 15.15.6, “InnoDB INFORMATION_SCHEMA Metrics Table”](#).

`innodb_monitor_disable='latch'` disables statistics collection for `SHOW ENGINE INNODB MUTEX`. For more information, see [Section 13.7.7.15, “SHOW ENGINE Statement”](#).
InnoDB System Variables

- **innodb_monitor_enable**

  Command-Line Format: `--innodb-monitor-enable={counter|module|pattern|all}`
  
  System Variable: `innodb_monitor_enable`
  
  Scope: Global
  
  Dynamic: Yes
  
  SET_VAR Hint Applies: No
  
  Type: String

  This variable acts as a switch, enabling InnoDB metrics counters. Counter data may be queried using the Information Schema `INNODB_METRICS` table. For usage information, see Section 15.15.6, "InnoDB INFORMATION_SCHEMA Metrics Table".

  \texttt{innodb_monitor_enable='latch'} enables statistics collection for `SHOW ENGINE INNODB MUTEX`. For more information, see Section 13.7.7.15, "SHOW ENGINE Statement".

- **innodb_monitor_reset**

  Command-Line Format: `--innodb-monitor-reset={counter|module|pattern|all}`

  System Variable: `innodb_monitor_reset`
  
  Scope: Global
  
  Dynamic: Yes
  
  SET_VAR Hint Applies: No
  
  Type: Enumeration
  
  Default Value: NULL
  
  Valid Values: `counter`, `module`, `pattern`, `all`

  This variable acts as a switch, resetting the count value for InnoDB metrics counters to zero. Counter data may be queried using the Information Schema `INNODB_METRICS` table. For usage information, see Section 15.15.6, "InnoDB INFORMATION_SCHEMA Metrics Table".

  \texttt{innodb_monitor_reset='latch'} resets statistics reported by `SHOW ENGINE INNODB MUTEX`. For more information, see Section 13.7.7.15, "SHOW ENGINE Statement".

- **innodb_monitor_reset_all**

  Command-Line Format: `--innodb-monitor-reset-all={counter|module|pattern|all}`

  System Variable: `innodb_monitor_reset_all`

  Scope: Global
InnoDB System Variables

<table>
<thead>
<tr>
<th>Dynamic</th>
<th>Yes</th>
</tr>
</thead>
<tbody>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>

<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>NULL</td>
</tr>
<tr>
<td>Valid Values</td>
<td>counter, module, pattern, all</td>
</tr>
</tbody>
</table>

This variable acts as a switch, resetting all values (minimum, maximum, and so on) for InnoDB metrics counters. Counter data may be queried using the Information Schema INNODB_METRICS table. For usage information, see Section 15.15.6, “InnoDB INFORMATION_SCHEMA Metrics Table”.

- **innodb_numa_interleave**

  | Command-Line Format | --innodb-numa-interleave[={OFF|ON}] |
  |---------------------|------------------------------------|
  | System Variable     | innodb_numa_interleave             |
  | Scope               | Global                             |
  | Dynamic             | No                                 |
  | SET_VAR Hint Applies | No                                |
  | Type                | Boolean                           |
  | Default Value       | OFF                                |

Enables the NUMA interleave memory policy for allocation of the InnoDB buffer pool. When innodb_numa_interleave is enabled, the NUMA memory policy is set to MPOL_INTERLEAVE for the mysqld process. After the InnoDB buffer pool is allocated, the NUMA memory policy is set back to MPOL_DEFAULT. For the innodb_numa_interleave option to be available, MySQL must be compiled on a NUMA-enabled Linux system.

**CMake** sets the default WITH_NUMA value based on whether the current platform has NUMA support. For more information, see Section 2.8.7, “MySQL Source-Configuration Options”.

- **innodb_old_blocks_pct**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-old-blocks-pct=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_old_blocks_pct</td>
</tr>
<tr>
<td>Scope</td>

</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>37</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>5</td>
</tr>
</tbody>
</table>
InnoDB System Variables

<table>
<thead>
<tr>
<th>Maximum Value</th>
<th>95</th>
</tr>
</thead>
</table>

Specifies the approximate percentage of the InnoDB buffer pool used for the old block sublist. The range of values is 5 to 95. The default value is 37 (that is, 3/8 of the pool). Often used in combination with innodb_old_blocks_time.

For more information, see Section 15.8.3.3, “Making the Buffer Pool Scan Resistant”. For information about buffer pool management, the LRU algorithm, and eviction policies, see Section 15.5.1, “Buffer Pool”.

- **innodb_old_blocks_time**

Command-Line Format

| --innodb-old-blocks-time=|

System Variable

| innodb_old_blocks_time |

Scope

| Global |

Dynamic

| Yes |

SET_VAR Hint Applies

| No |

Type

| Integer |

Default Value

| 1000 |

Minimum Value

| 0 |

Maximum Value

| 2**32-1 |

Unit

| milliseconds |

Non-zero values protect against the buffer pool being filled by data that is referenced only for a brief period, such as during a full table scan. Increasing this value offers more protection against full table scans interfering with data cached in the buffer pool.

Specifies how long in milliseconds a block inserted into the old sublist must stay there after its first access before it can be moved to the new sublist. If the value is 0, a block inserted into the old sublist moves immediately to the new sublist the first time it is accessed, no matter how soon after insertion the access occurs. If the value is greater than 0, blocks remain in the old sublist until an access occurs at least that many milliseconds after the first access. For example, a value of 1000 causes blocks to stay in the old sublist for 1 second after the first access before they become eligible to move to the new sublist.

The default value is 1000.

This variable is often used in combination with innodb_old_blocks_pct. For more information, see Section 15.8.3.3, “Making the Buffer Pool Scan Resistant”. For information about buffer pool management, the LRU algorithm, and eviction policies, see Section 15.5.1, “Buffer Pool”.

- **innodb_online_alter_log_max_size**

Command-Line Format

| --innodb-online-alter-log-max-size=|

System Variable

| innodb_online_alter_log_max_size |

Scope

| Global |

Dynamic

| Yes |

SET_VAR Hint Applies

| No |

Type

| Integer |

Default Value

| 134217728 |

Non-zero values protect against the buffer pool being filled by data that is referenced only for a brief period, such as during a full table scan. Increasing this value offers more protection against full table scans interfering with data cached in the buffer pool.

Specifies how long in milliseconds a block inserted into the old sublist must stay there after its first access before it can be moved to the new sublist. If the value is 0, a block inserted into the old sublist moves immediately to the new sublist the first time it is accessed, no matter how soon after insertion the access occurs. If the value is greater than 0, blocks remain in the old sublist until an access occurs at least that many milliseconds after the first access. For example, a value of 1000 causes blocks to stay in the old sublist for 1 second after the first access before they become eligible to move to the new sublist.

The default value is 1000.

This variable is often used in combination with innodb_old_blocks_pct. For more information, see Section 15.8.3.3, “Making the Buffer Pool Scan Resistant”. For information about buffer pool management, the LRU algorithm, and eviction policies, see Section 15.5.1, “Buffer Pool”.
### InnoDB System Variables

<table>
<thead>
<tr>
<th>Minimum Value</th>
<th>65536</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum Value</td>
<td>$2^{64}-1$</td>
</tr>
<tr>
<td>Unit</td>
<td>bytes</td>
</tr>
</tbody>
</table>

Specifies an upper limit in bytes on the size of the temporary log files used during online DDL operations for InnoDB tables. There is one such log file for each index being created or table being altered. This log file stores data inserted, updated, or deleted in the table during the DDL operation. The temporary log file is extended when needed by the value of `innodb_sort_buffer_size`, up to the maximum specified by `innodb_online_alter_log_max_size`. If a temporary log file exceeds the upper size limit, the `ALTER TABLE` operation fails and all uncommitted concurrent DML operations are rolled back. Thus, a large value for this option allows more DML to happen during an online DDL operation, but also extends the period of time at the end of the DDL operation when the table is locked to apply the data from the log.

- **innodb_open_files**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb-open-files=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_open_files</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic (≥ 8.0.28)</td>
<td>Yes</td>
</tr>
<tr>
<td>Dynamic (≤ 8.0.27)</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>$-1$ (signifies autosizing; do not assign this literal value)</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>10</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>2147483647</td>
</tr>
</tbody>
</table>

Specifies the maximum number of files that InnoDB can have open at one time. The minimum value is 10. If `innodb_file_per_table` is disabled, the default value is 300; otherwise, the default value is 300 or the `table_open_cache` setting, whichever is higher.

As of MySQL 8.0.28, the `innodb_open_files` limit can be set at runtime using a `SELECT innodb_set_open_files_limit(N)` statement, where $N$ is the desired `innodb_open_files` limit; for example:

```sql
mysql> SELECT innodb_set_open_files_limit(1000);
```

The statement executes a stored procedure that sets the new limit. If the procedure is successful, it returns the value of the newly set limit; otherwise, a failure message is returned.

It is not permitted to set `innodb_open_files` using a `SET` statement. To set `innodb_open_files` at runtime, use the `SELECT innodb_set_open_files_limit(N)` statement described above.

Setting `innodb_open_files=default` is not supported. Only integer values are permitted.

As of MySQL 8.0.28, to prevent non-LRU managed files from consuming the entire `innodb_open_files` limit, non-LRU managed files are limited to 90 percent of the
InnoDB System Variables

**innodb_open_files** limit, which reserves 10 percent of the **innodb_open_files** limit for LRU managed files.

Temporary tablespace files were not counted toward the **innodb_open_files** limit from MySQL 8.0.24 to MySQL 8.0.27.

• **innodb_optimize_fulltext_only**

| Command-Line Format | --innodb-optimize-fulltext-only=[OFF|ON] |
|---------------------|----------------------------------------|
| System Variable     | innodb_optimize_fulltext_only          |
| Scope               | Global                                 |
| Dynamic             | Yes                                    |
| **SET_VAR** Hint Applies | No                                |
| Type                | Boolean                                |
| Default Value       | OFF                                    |

Changes the way **OPTIMIZE TABLE** operates on InnoDB tables. Intended to be enabled temporarily, during maintenance operations for InnoDB tables with FULLTEXT indexes.

By default, **OPTIMIZE TABLE** reorganizes data in the clustered index of the table. When this option is enabled, **OPTIMIZE TABLE** skips the reorganization of table data, and instead processes newly added, deleted, and updated token data for InnoDB FULLTEXT indexes. For more information, see Optimizing InnoDB Full-Text Indexes.

• **innodb_page_cleaners**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-page-cleaners=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_page_cleaners</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>4</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>64</td>
</tr>
</tbody>
</table>

The number of page cleaner threads that flush dirty pages from buffer pool instances. Page cleaner threads perform flush list and LRU flushing. When there are multiple page cleaner threads, buffer pool flushing tasks for each buffer pool instance are dispatched to idle page cleaner threads. The **innodb_page_cleaners** default value is 4. If the number of page cleaner threads exceeds the
number of buffer pool instances, `innodb_page_cleaners` is automatically set to the same value as `innodb_buffer_pool_instances`.

If your workload is write-IO bound when flushing dirty pages from buffer pool instances to data files, and if your system hardware has available capacity, increasing the number of page cleaner threads may help improve write-IO throughput.

Multithreaded page cleaner support extends to shutdown and recovery phases.

The `setpriority()` system call is used on Linux platforms where it is supported, and where the `mysqld` execution user is authorized to give `page_cleaner` threads priority over other MySQL and InnoDB threads to help page flushing keep pace with the current workload. `setpriority()` support is indicated by this InnoDB startup message:

```
[Note] InnoDB: If the mysqld execution user is authorized, page cleaner thread priority can be changed. See the man page of setpriority().
```

For systems where server startup and shutdown is not managed by systemd, `mysqld` execution user authorization can be configured in `/etc/security/limits.conf`. For example, if `mysqld` is run under the `mysql` user, you can authorize the `mysql` user by adding these lines to `/etc/security/limits.conf`:

```
mysql              hard    nice       -20
mysql              soft    nice       -20
```

For systemd managed systems, the same can be achieved by specifying `LimitNICE=-20` in a localized systemd configuration file. For example, create a file named `override.conf` in `/etc/systemd/system/mysqld.service.d/override.conf` and add this entry:

```
[Service]
LimitNICE=-20
```

After creating or changing `override.conf`, reload the systemd configuration, then tell systemd to restart the MySQL service:

```
systemctl daemon-reload
systemctl restart mysqld  # RPM platforms
systemctl restart mysql   # Debian platforms
```

For more information about using a localized systemd configuration file, see Configuring systemd for MySQL.

After authorizing the `mysqld` execution user, use the `cat` command to verify the configured Nice limits for the `mysqld` process:

```
$> cat /proc/mysqld_pid/limits | grep nice
Max nice priority 18446744073709551596 18446744073709551596
```

- `innodb_page_size`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-page-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_page_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
</tbody>
</table>
InnoDB System Variables

<table>
<thead>
<tr>
<th>Default Value</th>
<th>16384</th>
</tr>
</thead>
<tbody>
<tr>
<td>Valid Values</td>
<td>4096</td>
</tr>
<tr>
<td></td>
<td>8192</td>
</tr>
<tr>
<td></td>
<td>16384</td>
</tr>
<tr>
<td></td>
<td>32768</td>
</tr>
<tr>
<td></td>
<td>65536</td>
</tr>
</tbody>
</table>

Specifies the page size for InnoDB tablespace. Values can be specified in bytes or kilobytes. For example, a 16 kilobyte page size value can be specified as 16384, 16KB, or 16k.

`innodb_page_size` can only be configured prior to initializing the MySQL instance and cannot be changed afterward. If no value is specified, the instance is initialized using the default page size. See Section 15.8.1, “InnoDB Startup Configuration”.

For both 32KB and 64KB page sizes, the maximum row length is approximately 16000 bytes. `ROW_FORMAT=COMPRESSED` is not supported when `innodb_page_size` is set to 32KB or 64KB. For `innodb_page_size=32KB`, extent size is 2MB. For `innodb_page_size=64KB`, extent size is 4MB. `innodb_log_buffer_size` should be set to at least 16M (the default) when using 32KB or 64KB page sizes.

The default 16KB page size or larger is appropriate for a wide range of workloads, particularly for queries involving table scans and DML operations involving bulk updates. Smaller page sizes might be more efficient for OLTP workloads involving many small writes, where contention can be an issue when single pages contain many rows. Smaller pages might also be efficient with SSD storage devices, which typically use small block sizes. Keeping the InnoDB page size close to the storage device block size minimizes the amount of unchanged data that is rewritten to disk.

The minimum file size for the first system tablespace data file (`ibdata1`) differs depending on the `innodb_page_size` value. See the `innodb_data_file_path` option description for more information.

A MySQL instance using a particular InnoDB page size cannot use data files or log files from an instance that uses a different page size.

For general I/O tuning advice, see Section 8.5.8, “Optimizing InnoDB Disk I/O”.

- `innodb_parallel_read_threads`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb-parallel-read-threads=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.14</td>
</tr>

</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>4</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
</tbody>
</table>
InnoDB System Variables

<table>
<thead>
<tr>
<th>Maximum Value</th>
<th>256</th>
</tr>
</thead>
</table>

Defines the number of threads that can be used for parallel clustered index reads. Parallel scanning of partitions is supported as of MySQL 8.0.17. Parallel read threads can improve `CHECK TABLE` performance. InnoDB reads the clustered index twice during a `CHECK TABLE` operation. The second read can be performed in parallel. This feature does not apply to secondary index scans. The `innodb_parallel_read_threads` session variable must be set to a value greater than 1 for parallel clustered index reads to occur. The actual number of threads used to perform a parallel clustered index read is determined by the `innodb_parallel_read_threads` setting or the number of index subtrees to scan, whichever is smaller. The pages read into the buffer pool during the scan are kept at the tail of the buffer pool LRU list so that they can be discarded quickly when free buffer pool pages are required.

As of MySQL 8.0.17, the maximum number of parallel read threads (256) is the total number of threads for all client connections. If the thread limit is reached, connections fall back to using a single thread.

- **innodb_print_all_deadlocks**

| Command-Line Format         | `--innodb-print-all-deadlocks [= OFF | ON]` |
|----------------------------|--------------------------------------------|
| System Variable            | `innodb_print_all_deadlocks`               |
| Scope                      | Global                                     |
| Dynamic                    | Yes                                        |
| `SET_VAR` Hint Applies     | No                                         |
| Type                       | Boolean                                    |
| Default Value              | OFF                                        |

When this option is enabled, information about all deadlocks in InnoDB user transactions is recorded in the `mysqld` error log. Otherwise, you see information about only the last deadlock, using the `SHOW ENGINE INNODB STATUS` command. An occasional InnoDB deadlock is not necessarily an issue, because InnoDB detects the condition immediately and rolls back one of the transactions automatically. You might use this option to troubleshoot why deadlocks are occurring if an application does not have appropriate error-handling logic to detect the rollback and retry its operation. A large number of deadlocks might indicate the need to restructure transactions that issue DML or `SELECT ... FOR UPDATE` statements for multiple tables, so that each transaction accesses the tables in the same order, thus avoiding the deadlock condition.

For related information, see Section 15.7.5, "Deadlocks in InnoDB".

- **innodb_print_ddl_logs**

| Command-Line Format         | `--innodb-print-ddl-logs [= OFF | ON]` |
|----------------------------|----------------------------------------|
| System Variable            | `innodb_print_ddl_logs`                |
| Scope                      | Global                                 |
| Dynamic                    | Yes                                    |
| `SET_VAR` Hint Applies     | No                                     |
| Type                       | Boolean                                |

3556
InnoDB System Variables

<table>
<thead>
<tr>
<th>Default Value</th>
<th>OFF</th>
</tr>
</thead>
</table>

Enabling this option causes MySQL to write DDL logs to stderr. For more information, see Viewing DDL Logs.

- **innodb_purge_batch_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-purge-batch-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_purge_batch_size</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>300</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>5000</td>
</tr>
</tbody>
</table>

Defines the number of undo log pages that purge parses and processes in one batch from the history list. In a multithreaded purge configuration, the coordinator purge thread divides innodb_purge_batch_size by innodb_purge_threads and assigns that number of pages to each purge thread. The innodb_purge_batch_size variable also defines the number of undo log pages that purge frees after every 128 iterations through the undo logs.

The innodb_purge_batch_size option is intended for advanced performance tuning in combination with the innodb_purge_threads setting. Most users need not change innodb_purge_batch_size from its default value.

For related information, see Section 15.8.9, “Purge Configuration”.

- **innodb_purge_threads**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-purge-threads=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_purge_threads</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>4</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>32</td>
</tr>
</tbody>
</table>

The number of background threads devoted to the InnoDB purge operation. Increasing the value creates additional purge threads, which can improve efficiency on systems where DML operations are performed on multiple tables.

For related information, see Section 15.8.9, “Purge Configuration”.
### InnoDB System Variables

1. **innodb_purge_rseg_truncate_frequency**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-purge-rseg-truncate-frequency=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_purge_rseg_truncate_frequency</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>128</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>128</td>
</tr>
</tbody>
</table>

Defines the frequency with which the purge system frees rollback segments in terms of the number of times that purge is invoked. An undo tablespace cannot be truncated until its rollback segments are freed. Normally, the purge system frees rollback segments once every 128 times that purge is invoked. The default value is 128. Reducing this value increases the frequency with which the purge thread frees rollback segments.

*innodb_purge_rseg_truncate_frequency* is intended for use with *innodb_undo_log_truncate*. For more information, see [Truncating Undo Tablespaces](#).

2. **innodb_random_read_ahead**

   | Command-Line Format | --innodb-random-read-ahead[{=OFF|ON}] |
   |---------------------|--------------------------------------|
   | System Variable     | innodb_random_read_ahead              |
   | Scope               | Global                               |
   | Dynamic             | Yes                                  |
   | SET_VAR Hint Applies| No                                   |
   | Type                | Boolean                              |
   | Default Value       | OFF                                  |

Enables the random read-ahead technique for optimizing InnoDB I/O.

For details about performance considerations for different types of read-ahead requests, see [Section 15.8.3.4, “Configuring InnoDB Buffer Pool Prefetching (Read-Ahead)”](#). For general I/O tuning advice, see [Section 8.5.8, “Optimizing InnoDB Disk I/O”](#).

3. **innodb_read_ahead_threshold**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-read-ahead-threshold=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_read_ahead_threshold</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>56</td>
</tr>
</tbody>
</table>

InnoDB System Variables

Minimum Value | 0
---|---
Maximum Value | 64

Controls the sensitivity of linear **read-ahead** that InnoDB uses to prefetch pages into the **buffer pool**. If InnoDB reads at least `innodb_readAheadThreshold` pages sequentially from an extent (64 pages), it initiates an asynchronous read for the entire following extent. The permissible range of values is 0 to 64. A value of 0 disables read-ahead. For the default of 56, InnoDB must read at least 56 pages sequentially from an extent to initiate an asynchronous read for the following extent.

Knowing how many pages are read through the read-ahead mechanism, and how many of these pages are evicted from the buffer pool without ever being accessed, can be useful when fine-tuning the `innodb_readAheadThreshold` setting. **SHOW ENGINE INNODB STATUS** output displays counter information from the `Innodb_buffer_pool_read_ahead` and `Innodb_buffer_pool_read_ahead_evicted` global status variables, which report the number of pages brought into the buffer pool by read-ahead requests, and the number of such pages evicted from the buffer pool without ever being accessed, respectively. The status variables report global values since the last server restart.

**SHOW ENGINE INNODB STATUS** also shows the rate at which the read-ahead pages are read and the rate at which such pages are evicted without being accessed. The per-second averages are based on the statistics collected since the last invocation of **SHOW ENGINE INNODB STATUS** and are displayed in the **BUFFER POOL AND MEMORY** section of the **SHOW ENGINE INNODB STATUS** output.

For more information, see Section 15.8.3.4, “Configuring InnoDB Buffer Pool Prefetching (Read-Ahead)”. For general I/O tuning advice, see Section 8.5.8, “Optimizing InnoDB Disk I/O”.

- `innodb_read_io_threads`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb-read-io-threads=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_read_io_threads</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>4</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>64</td>
</tr>
</tbody>
</table>

The number of I/O threads for read operations in InnoDB. Its counterpart for write threads is `innodb_write_io_threads`. For more information, see Section 15.8.5, “Configuring the Number of Background InnoDB I/O Threads”. For general I/O tuning advice, see Section 8.5.8, “Optimizing InnoDB Disk I/O”.

**Note**

On Linux systems, running multiple MySQL servers (typically more than 12) with default settings for `innodb_read_io_threads`, `innodb_write_io_threads`, and the Linux `aio-max-nr` setting can exceed system limits. Ideally, increase the `aio-max-nr` setting; as a workaround, you might reduce the settings for one or both of the MySQL variables.
InnoDB System Variables

- **innodb_read_only**

| Command-Line Format       | --innodb-read-only[={OFF|ON}] |
|---------------------------|-------------------------------|
| System Variable           | innodb_read_only              |
| Scope                     | Global                        |
| Dynamic                   | No                             |
| SET_VAR Hint Applies      | No                             |
| Type                      | Boolean                       |
| Default Value             | OFF                            |

Starts InnoDB in read-only mode. For distributing database applications or data sets on read-only media. Can also be used in data warehouses to share the same data directory between multiple instances. For more information, see Section 15.8.2, “Configuring InnoDB for Read-Only Operation”.

Previously, enabling the `innodb_read_only` system variable prevented creating and dropping tables only for the InnoDB storage engine. As of MySQL 8.0, enabling `innodb_read_only` prevents these operations for all storage engines. Table creation and drop operations for any storage engine modify data dictionary tables in the mysql system database, but those tables use the InnoDB storage engine and cannot be modified when `innodb_read_only` is enabled. The same principle applies to other table operations that require modifying data dictionary tables. Examples:

- If the `innodb_read_only` system variable is enabled, `ANALYZE TABLE` may fail because it cannot update statistics tables in the data dictionary, which use InnoDB. For `ANALYZE TABLE` operations that update the key distribution, failure may occur even if the operation updates the table itself (for example, if it is a MyISAM table). To obtain the updated distribution statistics, set `information_schema_stats_expiry=0`.

- `ALTER TABLE tbl_name ENGINE=engine_name` fails because it updates the storage engine designation, which is stored in the data dictionary.

In addition, other tables in the mysql system database use the InnoDB storage engine in MySQL 8.0. Making those tables read only results in restrictions on operations that modify them. Examples:

- Account-management statements such as `CREATE USER` and `GRANT` fail because the grant tables use InnoDB.

- The `INSTALL PLUGIN` and `UNINSTALL PLUGIN` plugin-management statements fail because the mysql.plugin system table uses InnoDB.

- The `CREATE FUNCTION` and `DROP FUNCTION` loadable function-management statements fail because the mysql.func system table uses InnoDB.

- **innodb_redo_log_archive_dirs**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-redo-log-archive-dirs</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.17</td>
</tr>
<tr>

<td>innodb_redo_log_archive_dirs</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
</tbody>
</table>

3560
### InnoDB System Variables

<table>
<thead>
<tr>
<th>Type</th>
<th>Default Value</th>
<th>String</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>NULL</td>
</tr>
</tbody>
</table>

Defines labeled directories where redo log archive files can be created. You can define multiple labeled directories in a semicolon-separated list. For example:

```
innodb_redo_log_archive_dirs='label1:/backups1;label2:/backups2'
```

A label can be any string of characters, with the exception of colons (:), which are not permitted. An empty label is also permitted, but the colon (:) is still required in this case.

A path must be specified, and the directory must exist. The path can contain colons (':'), but semicolons (;) are not permitted.

- **innodb_redo_log_capacity**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-redo-log-capacity=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.30</td>
</tr>
<tr>
<td>System Variable</td>
<td>innodb_redo_log_capacity</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>104857600</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>8388608</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>137438953472</td>
</tr>
<tr>
<td>Unit</td>
<td>bytes</td>
</tr>
</tbody>
</table>

Defines the amount of disk space occupied by redo log files.

This variable supersedes the `innodb_log_files_in_group` and `innodb_log_file_size` variables. When a `innodb_redo_log_capacity` setting is defined, the `innodb_log_files_in_group` and `innodb_log_file_size` settings are ignored; otherwise, these settings are used to compute the `innodb_redo_log_capacity` setting (`innodb_log_files_in_group * innodb_log_file_size = innodb_redo_log_capacity`). If none of those variables are set, redo log capacity is set to the `innodb_redo_log_capacity` default value.

For more information, see Section 15.6.5, “Redo Log”.

- **innodb_redo_log_encrypt**

  | Command-Line Format | --innodb-redo-log-encrypt [=OFF|ON]] |
  |---------------------|-------------------------------------|
  | System Variable     | innodb_redo_log_encrypt             |
  | Scope               | Global                              |
  | Dynamic             | Yes                                 |
  | SET_VAR Hint Applies| No                                  |
  | Type                | Boolean                             |

InnoDB System Variables

| Default Value | OFF |

Controls encryption of redo log data for tables encrypted using the InnoDB data-at-rest encryption feature. Encryption of redo log data is disabled by default. For more information, see Redo Log Encryption.

- **innodb_replication_delay**

  | Command-Line Format | --innodb-replication-delay=# |
  | System Variable | innodb_replication_delay |
  | Scope | Global |
  | Dynamic | Yes |
  | SET_VAR Hint Applies | No |
  | Type | Integer |
  | Default Value | 0 |
  | Minimum Value | 0 |
  | Maximum Value | 4294967295 |
  | Unit | milliseconds |

The replication thread delay in milliseconds on a replica server if innodb_thread_concurrency is reached.

- **innodb_rollback_on_timeout**

  | Command-Line Format | --innodb-rollback-on-timeout[={OFF| ON}] |
  | System Variable | innodb_rollback_on_timeout |
  | Scope | Global |
  | Dynamic | No |
  | SET_VAR Hint Applies | No |
  | Type | Boolean |
  | Default Value | OFF |

InnoDB rolls back only the last statement on a transaction timeout by default. If --innodb-rollback-on-timeout is specified, a transaction timeout causes InnoDB to abort and roll back the entire transaction.

For more information, see Section 15.21.5, “InnoDB Error Handling”.

- **innodb_rollback_segments**

  | Command-Line Format | --innodb-rollback-segments=# |
  | System Variable | innodb_rollback_segments |
  | Scope | Global |
  | Dynamic | Yes |
  | SET_VAR Hint Applies | No |
  | Type | Integer |
InnoDB System Variables

<table>
<thead>
<tr>
<th>Default Value</th>
<th>128</th>
</tr>
</thead>
<tbody>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>128</td>
</tr>
</tbody>
</table>

`innodb_rollback_segments` defines the number of rollback segments allocated to each undo tablespace and the global temporary tablespace for transactions that generate undo records. The number of transactions that each rollback segment supports depends on the InnoDB page size and the number of undo logs assigned to each transaction. For more information, see Section 15.6.6, “Undo Logs”.

For related information, see Section 15.3, “InnoDB Multi-Versioning”. For information about undo tablespaces, see Section 15.6.3.4, “Undo Tablespaces”.

• `innodb_saved_page_number_debug`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb-saved-page-number-debug=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_saved_page_number_debug</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>(2^{23} - 1)</td>
</tr>
</tbody>
</table>

Saves a page number. Setting the `innodb_fil_make_page_dirty_debug` option dirties the page defined by `innodb_saved_page_number_debug`. The `innodb_saved_page_number_debug` option is only available if debugging support is compiled in using the `WITH_DEBUG` CMake option.

• `innodb_segment_reserve_factor`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb-segment-reserve-factor=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.26</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>innodb_segment_reserve_factor</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>12.5</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0.03</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>40</td>
</tr>
</tbody>
</table>

Defines the percentage of tablespace file segment pages reserved as empty pages. The setting is applicable to file-per-table and general tablespaces. The `innodb_segment Reserve_factor` default setting is 12.5 percent, which is the same percentage of pages reserved in previous MySQL releases.

For more information, see Configuring the Percentage of Reserved File Segment Pages.
InnoDB System Variables

- **innodb_sort_buffer_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-sort-buffer-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_sort_buffer_size</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1048576</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>65536</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>67108864</td>
</tr>
<tr>
<td>Unit</td>
<td>bytes</td>
</tr>
</tbody>
</table>

This variable defines:

- The sort buffer size for online DDL operations that create or rebuild secondary indexes. However, as of MySQL 8.0.27, this responsibility is subsumed by the `innodb_ddl_buffer_size` variable.
- The amount by which the temporary log file is extended when recording concurrent DML during an online DDL operation, and the size of the temporary log file read buffer and write buffer.

For related information, see Section 15.12.3, “Online DDL Space Requirements”.

- **innodb_spin_wait_delay**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-spin-wait-delay=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_spin_wait_delay</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>6</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value (64-bit platforms, ≤ 8.0.13)</td>
<td>$2^{64}$-1</td>
</tr>
<tr>
<td>Maximum Value (32-bit platforms, ≤ 8.0.13)</td>
<td>$2^{32}$-1</td>
</tr>
<tr>
<td>Maximum Value (≥ 8.0.14)</td>
<td>1000</td>
</tr>
</tbody>
</table>

The maximum delay between polls for a spin lock. The low-level implementation of this mechanism varies depending on the combination of hardware and operating system, so the delay does not correspond to a fixed time interval.

Can be used in combination with the `innodb_spin_wait_pause_multiplier` variable for greater control over the duration of spin-lock polling delays.

For more information, see Section 15.8.8, “Configuring Spin Lock Polling”.
• `innodb_spin_wait_pause_multiplier`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb-spin-wait-pause-multiplier=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.16</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>innodb_spin_wait_pause_multiplier</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>50</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>100</td>
</tr>
</tbody>
</table>

Defines a multiplier value used to determine the number of PAUSE instructions in spin-wait loops that occur when a thread waits to acquire a mutex or rw-lock.

For more information, see Section 15.8.8, “Configuring Spin Lock Polling”.

• `innodb_stats_auto_recalc`

| Command-Line Format          | `--innodb-stats-auto-recalc={OFF|ON}]` |
|-----------------------------|---------------------------------------|
| System Variable             | `innodb_stats_auto_recalc`            |
| Scope                       | Global                                |
| Dynamic                     | Yes                                   |
| `SET_VAR` Hint Applies      | No                                    |
| Type                        | Boolean                               |
| Default Value               | ON                                    |

Causes InnoDB to automatically recalculate persistent statistics after the data in a table is changed substantially. The threshold value is 10% of the rows in the table. This setting applies to tables created when the `innodb_stats_persistent` option is enabled. Automatic statistics recalculation may also be configured by specifying `STATS_PERSISTENT=1` in a `CREATE TABLE` or `ALTER TABLE` statement. The amount of data sampled to produce the statistics is controlled by the `innodb_stats_persistent_sample_pages` variable.

For more information, see Section 15.8.10.1, “Configuring Persistent Optimizer Statistics Parameters”.

• `innodb_stats_include_delete_marked`

| Command-Line Format          | `--innodb-stats-include-delete-marked={OFF|ON}]` |
|-----------------------------|-------------------------------------------------|
| System Variable             | `innodb_stats_include_delete_marked`            |
| Scope                       | Global                                          |
| Dynamic                     | Yes                                             |
| `SET_VAR` Hint Applies      | No                                              |
| Type                        | Boolean                                         |
InnoDB System Variables

| Default Value | OFF |

By default, InnoDB reads uncommitted data when calculating statistics. In the case of an uncommitted transaction that deletes rows from a table, InnoDB excludes records that are delete-marked when calculating row estimates and index statistics, which can lead to non-optimal execution plans for other transactions that are operating on the table concurrently using a transaction isolation level other than READ UNCOMMITTED. To avoid this scenario, innodb_stats_include_delete_marked can be enabled to ensure that InnoDB includes delete-marked records when calculating persistent optimizer statistics.

When innodb_stats_include_delete_marked is enabled, ANALYZE TABLE considers delete-marked records when recalculating statistics.

innodb_stats_include_delete_marked is a global setting that affects all InnoDB tables. It is only applicable to persistent optimizer statistics.

For related information, see Section 15.8.10.1, “Configuring Persistent Optimizer Statistics Parameters”.

- innodb_stats_method

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-stats-method=value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_stats_method</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>nulls_equal</td>
</tr>
<tr>
<td>Valid Values</td>
<td>nulls_equal, nulls_unequal, nulls_ignored</td>
</tr>
</tbody>
</table>

How the server treats NULL values when collecting statistics about the distribution of index values for InnoDB tables. Permitted values are nulls_equal, nulls_unequal, and nulls_ignored. For nulls_equal, all NULL index values are considered equal and form a single value group with a size equal to the number of NULL values. For nulls_unequal, NULL values are considered unequal, and each NULL forms a distinct value group of size 1. For nulls_ignored, NULL values are ignored.

The method used to generate table statistics influences how the optimizer chooses indexes for query execution, as described in Section 8.3.8, “InnoDB and MyISAM Index Statistics Collection”.

- innodb_stats_on_metadata

| Command-Line Format | --innodb-stats-on-metadata=[OFF|ON] |
|---------------------|-----------------------------------|
| System Variable     | innodb_stats_on_metadata          |
| Scope               | Global                            |
| Dynamic             | Yes                               |
| SET_VAR Hint Applies| No                                |
| Type                | Boolean                           |
InnoDB System Variables

<table>
<thead>
<tr>
<th>Default Value</th>
<th>OFF</th>
</tr>
</thead>
</table>

This option only applies when optimizer statistics are configured to be non-persistent. Optimizer statistics are not persisted to disk when `innodb_stats_persistent` is disabled or when individual tables are created or altered with `STATS_PERSISTENT=0`. For more information, see Section 15.8.10.2, “Configuring Non-Persistent Optimizer Statistics Parameters”.

When `innodb_stats_on_metadata` is enabled, InnoDB updates non-persistent statistics when metadata statements such as `SHOW TABLE STATUS` or when accessing the Information Schema TABLES or STATISTICS tables. (These updates are similar to what happens for `ANALYZE TABLE`.) When disabled, InnoDB does not update statistics during these operations. Leaving the setting disabled can improve access speed for schemas that have a large number of tables or indexes. It can also improve the stability of execution plans for queries that involve InnoDB tables.

To change the setting, issue the statement `SET GLOBAL innodb_stats_on_metadata=mode`, where `mode` is either `ON` or `OFF` (or `1` or `0`). Changing the setting requires privileges sufficient to set global system variables (see Section 5.1.9.1, “System Variable Privileges”) and immediately affects the operation of all connections.

- **innodb_stats_persistent**

| Command-Line Format | --innodb-stats-persistent=[{OFF|ON}] |
|---------------------|--------------------------------------|
| System Variable     | innodb_stats_persistent              |
| Scope               | Global                               |
| Dynamic             | Yes                                  |
| SET_VAR Hint Applies| No                                   |
| Type                | Boolean                              |
| Default Value       | ON                                   |

Specifies whether InnoDB index statistics are persisted to disk. Otherwise, statistics may be recalculated frequently which can lead to variations in query execution plans. This setting is stored with each table when the table is created. You can set `innodb_stats_persistent` at the global level before creating a table, or use the `STATS_PERSISTENT` clause of the `CREATE TABLE` and `ALTER TABLE` statements to override the system-wide setting and configure persistent statistics for individual tables.

For more information, see Section 15.8.10.1, “Configuring Persistent Optimizer Statistics Parameters”.

- **innodb_stats_persistent_sample_pages**

<table>
<thead>
<tr>

InnoDB System Variables

| Maximum Value | 18446744073709551615 |

The number of index pages to sample when estimating cardinality and other statistics for an indexed column, such as those calculated by `ANALYZE TABLE`. Increasing the value improves the accuracy of index statistics, which can improve the query execution plan, at the expense of increased I/O during the execution of `ANALYZE TABLE` for an InnoDB table. For more information, see Section 15.8.10.1, “Configuring Persistent Optimizer Statistics Parameters”.

**Note**

Setting a high value for `innodb_stats_persistent_sample_pages` could result in lengthy `ANALYZE TABLE` execution time. To estimate the number of database pages accessed by `ANALYZE TABLE`, see Section 15.8.10.3, “Estimating ANALYZE TABLE Complexity for InnoDB Tables”.

`innodb_stats_persistent_sample_pages` only applies when `innodb_stats_persistent` is enabled for a table; when `innodb_stats_persistent` is disabled, `innodb_stats_transient_sample_pages` applies instead.

- `innodb_stats_transient_sample_pages`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb-stats-transient-sample-pages=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_stats_transient_sample_pages</code></td>

</tr>
<tr>
<td>Maximum Value</td>
<td>18446744073709551615</td>
</tr>
</tbody>
</table>

The number of index pages to sample when estimating cardinality and other statistics for an indexed column, such as those calculated by `ANALYZE TABLE`. The default value is 8. Increasing the value improves the accuracy of index statistics, which can improve the query execution plan, at the expense of increased I/O when opening an InnoDB table or recalculating statistics. For more information, see Section 15.8.10.2, “Configuring Non-Persistent Optimizer Statistics Parameters”.

**Note**

Setting a high value for `innodb_stats_transient_sample_pages` could result in lengthy `ANALYZE TABLE` execution time. To estimate the number of database pages accessed by `ANALYZE TABLE`, see Section 15.8.10.3, “Estimating ANALYZE TABLE Complexity for InnoDB Tables”.

`innodb_stats_transient_sample_pages` only applies when `innodb_stats_persistent` is disabled for a table; when `innodb_stats_persistent` is enabled, `innodb_stats_persistent_sample_pages` applies instead. Takes the place of `innodb_stats_sample_pages`. For more information, see Section 15.8.10.2, “Configuring Non-Persistent Optimizer Statistics Parameters”.

3568
InnoDB System Variables

- **innodb_status_output**

| Command-Line Format | --innodb-status-output[={OFF|ON}] |
|---------------------|-----------------------------------|
| System Variable     | innodb_status_output              |
| Scope               | Global                            |
| Dynamic             | Yes                               |
| SET_VAR Hint Applies| No                                |
| Type                | Boolean                           |
| Default Value       | OFF                               |

Enables or disables periodic output for the standard InnoDB Monitor. Also used in combination with `innodb_status_output_locks` to enable or disable periodic output for the InnoDB Lock Monitor. For more information, see Section 15.17.2, “Enabling InnoDB Monitors”.

- **innodb_status_output_locks**

| Command-Line Format | --innodb-status-output-locks[={OFF|ON}] |
|---------------------|----------------------------------------|
| System Variable     | innodb_status_output_locks             |
| Scope               | Global                                 |
| Dynamic             | Yes                                    |
| SET_VAR Hint Applies| No                                     |
| Type                | Boolean                                |
| Default Value       | OFF                                    |

Enables or disables the InnoDB Lock Monitor. When enabled, the InnoDB Lock Monitor prints additional information about locks in `SHOW ENGINE INNODB STATUS` output and in periodic output printed to the MySQL error log. Periodic output for the InnoDB Lock Monitor is printed as part of the standard InnoDB Monitor output. The standard InnoDB Monitor must therefore be enabled for the InnoDB Lock Monitor to print data to the MySQL error log periodically. For more information, see Section 15.17.2, “Enabling InnoDB Monitors”.

- **innodb_strict_mode**

| Command-Line Format | --innodb-strict-mode[={OFF|ON}] |
|---------------------|----------------------------------|
| System Variable     | innodb_strict_mode               |
| Scope               | Global, Session                  |
| Dynamic             | Yes                              |
| SET_VAR Hint Applies| No                               |
| Type                | Boolean                          |
InnoDB System Variables

<table>
<thead>
<tr>
<th>Default Value</th>
<th>ON</th>
</tr>
</thead>
</table>

When `innodb_strict_mode` is enabled, InnoDB returns errors rather than warnings when checking for invalid or incompatible table options.

It checks that `KEY_BLOCK_SIZE`, `ROW_FORMAT`, `DATA DIRECTORY`, `TEMPORARY`, and `TABLESPACE` options are compatible with each other and other settings.

`innodb_strict_mode=ON` also enables a row size check when creating or altering a table, to prevent `INSERT` or `UPDATE` from failing due to the record being too large for the selected page size.

You can enable or disable `innodb_strict_mode` on the command line when starting `mysqld`, or in a MySQL configuration file. You can also enable or disable `innodb_strict_mode` at runtime with the statement `SET [GLOBAL|SESSION] innodb_strict_mode=mode`, where `mode` is either `ON` or `OFF`. Changing the `GLOBAL` setting requires privileges sufficient to set global system variables (see Section 5.1.9.1, “System Variable Privileges”) and affects the operation of all clients that subsequently connect. Any client can change the `SESSION` setting for `innodb_strict_mode`, and the setting affects only that client.

As of MySQL 8.0.26, setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See Section 5.1.9.1, “System Variable Privileges”.

- `innodb_sync_array_size`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb-sync-array-size=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_sync_array_size</code></td>
</tr>
<tr>

<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1024</td>
</tr>
</tbody>
</table>

Defines the size of the mutex/lock wait array. Increasing the value splits the internal data structure used to coordinate threads, for higher concurrency in workloads with large numbers of waiting threads. This setting must be configured when the MySQL instance is starting up, and cannot be changed afterward. Increasing the value is recommended for workloads that frequently produce a large number of waiting threads, typically greater than 768.

- `innodb_sync_spin_loops`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb-sync-spin-loops=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_sync_spin_loops</code></td>
</tr>
<tr>

</tr>
</thead>
<tbody>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

The number of times a thread waits for an InnoDB mutex to be freed before the thread is suspended.

- **innodb_sync_debug**

  | Command-Line Format | --innodb-sync-debug[={OFF|ON}] |
  |---------------------|---------------------------------|
  | System Variable     | innodb_sync_debug               |
  | Scope               | Global                          |
  | Dynamic             | No                              |
  | SET_VAR Hint Applies| No                              |
  | Type                | Boolean                         |
  | Default Value       | OFF                             |

Enables sync debug checking for the InnoDB storage engine. This option is only available if debugging support is compiled in using the `WITH_DEBUG` CMake option.

- **innodb_table_locks**

  | Command-Line Format | --innodb-table-locks[={OFF|ON}] |
  |---------------------|---------------------------------|
  | System Variable     | innodb_table_locks              |
  | Scope               | Global, Session                 |
  | Dynamic             | Yes                             |
  | SET_VAR Hint Applies| No                              |
  | Type                | Boolean                         |
  | Default Value       | ON                              |

If `autocommit = 0`, InnoDB honors `LOCK TABLES`; MySQL does not return from `LOCK TABLES ... WRITE` until all other threads have released all their locks to the table. The default value of `innodb_table_locks` is 1, which means that `LOCK TABLES` causes InnoDB to lock a table internally if `autocommit = 0`.

`innodb_table_locks = 0` has no effect for tables locked explicitly with `LOCK TABLES ... WRITE`. It does have an effect for tables locked for read or write by `LOCK TABLES ... WRITE` implicitly (for example, through triggers) or by `LOCK TABLES ... READ`.

For related information, see Section 15.7, “InnoDB Locking and Transaction Model”.

- **innodb_temp_data_file_path**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-temp-data-file-path=file_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_temp_data_file_path</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
</tbody>
</table>
InnoDB System Variables

<table>
<thead>
<tr>
<th>Type</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>ibtmp1:12M:autoextend</td>
</tr>
</tbody>
</table>

Defines the relative path, name, size, and attributes of global temporary tablespace data files. The global temporary tablespace stores rollback segments for changes made to user-created temporary tables.

If no value is specified for `innodb_temp_data_file_path`, the default behavior is to create a single auto-extending data file named `ibtmp1` in the `innodb_data_home_dir` directory. The initial file size is slightly larger than 12MB.

The syntax for a global temporary tablespace data file specification includes the file name, file size, and `autoextend` and `max` attributes:

```
file_name:file_size[:autoextend[[:max:max_file_size]]]
```

The global temporary tablespace data file cannot have the same name as another InnoDB data file. Any inability or error creating the global temporary tablespace data file is treated as fatal and server startup is refused.

File sizes are specified in KB, MB, or GB by appending `K`, `M` or `G` to the size value. The sum of file sizes must be slightly larger than 12MB.

The size limit of individual files is determined by the operating system. File size can be more than 4GB on operating systems that support large files. Use of raw disk partitions for global temporary tablespace data files is not supported.

The `autoextend` and `max` attributes can be used only for the data file specified last in the `innodb_temp_data_file_path` setting. For example:

```
[mysqld]
innodb_temp_data_file_path=ibtmp1:50M;ibtmp2:12M:autoextend:max:500M
```

The `autoextend` option causes the data file to automatically increase in size when it runs out of free space. The `autoextend` increment is 64MB by default. To modify the increment, change the `innodb_autoextend_increment` variable setting.

The directory path for global temporary tablespace data files is formed by concatenating the paths defined by `innodb_data_home_dir` and `innodb_temp_data_file_path`.

Before running InnoDB in read-only mode, set `innodb_temp_data_file_path` to a location outside of the data directory. The path must be relative to the data directory. For example:

```
--innodb-temp-data-file-path=../../../tmp/ibtmp1:12M:autoextend
```

For more information, see Global Temporary Tablespace.

- `innodb_temp_tablespaces_dir`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb-temp-tablespaces-dir=dir_name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.13</td>
</tr>
<tr>

<td>No</td>
</tr>
</tbody>
</table>
**InnoDB System Variables**

---

<table>
<thead>
<tr>
<th>SET_VAR</th>
<th>Hint Applies</th>
<th>Type</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>No</td>
<td>Directory name</td>
<td>#innodb_temp</td>
</tr>
</tbody>
</table>

Defines the location where InnoDB creates a pool of session temporary tablespaces at startup. The default location is the #innodb_temp directory in the data directory. A fully qualified path or path relative to the data directory is permitted.

As of MySQL 8.0.16, session temporary tablespaces always store user-created temporary tables and internal temporary tables created by the optimizer using InnoDB. (Previously, the on-disk storage engine for internal temporary tables was determined by the internal_tmp_disk_storage_engine system variable, which is no longer supported. See Storage Engine for On-Disk Internal Temporary Tables.)

For more information, see Session Temporary Tablespaces.

- **innodb_thread_concurrency**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-thread-concurrency=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_thread_concurrency</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1000</td>
</tr>
</tbody>
</table>

Defines the maximum number of threads permitted inside of InnoDB. A value of 0 (the default) is interpreted as infinite concurrency (no limit). This variable is intended for performance tuning on high concurrency systems.

InnoDB tries to keep the number of threads inside InnoDB less than or equal to the innodb_thread_concurrency limit. Once the limit is reached, additional threads are placed into a “First In, First Out” (FIFO) queue for waiting threads. Threads waiting for locks are not counted in the number of concurrently executing threads.

The correct setting depends on workload and computing environment. Consider setting this variable if your MySQL instance shares CPU resources with other applications or if your workload or number of concurrent users is growing. Test a range of values to determine the setting that provides the best performance. innodb_thread_concurrency is a dynamic variable, which permits experimenting with different settings on a live test system. If a particular setting performs poorly, you can quickly set innodb_thread_concurrency back to 0.

Use the following guidelines to help find and maintain an appropriate setting:

- If the number of concurrent user threads for a workload is consistently small and does not affect performance, set innodb_thread_concurrency=0 (no limit).
- If your workload is consistently heavy or occasionally spikes, set an innodb_thread_concurrency value and adjust it until you find the number of threads that provides the best performance. For example, suppose that your system typically has 40 to 50 users, but periodically the number increases
InnoDB System Variables

To 60, 70, or more. Through testing, you find that performance remains largely stable with a limit of 80 concurrent users. In this case, set `innodb_thread_concurrency` to 80.

- If you do not want InnoDB to use more than a certain number of virtual CPUs for user threads (20 virtual CPUs, for example), set `innodb_thread_concurrency` to this number (or possibly lower, depending on performance testing). If your goal is to isolate MySQL from other applications, consider binding the `mysqld` process exclusively to the virtual CPUs. Be aware, however, that exclusive binding can result in non-optimal hardware usage if the `mysqld` process is not consistently busy. In this case, you can bind the `mysqld` process to the virtual CPUs but allow other applications to use some or all of the virtual CPUs.

**Note**

From an operating system perspective, using a resource management solution to manage how CPU time is shared among applications may be preferable to binding the `mysqld` process. For example, you could assign 90% of virtual CPU time to a given application while other critical processes are not running, and scale that value back to 40% when other critical processes are running.

- In some cases, the optimal `innodb_thread_concurrency` setting can be smaller than the number of virtual CPUs.

- An `innodb_thread_concurrency` value that is too high can cause performance regression due to increased contention on system internals and resources.

- Monitor and analyze your system regularly. Changes to workload, number of users, or computing environment may require that you adjust the `innodb_thread_concurrency` setting.

A value of 0 disables the `queries inside InnoDB` and `queries in queue` counters in the `ROW OPERATIONS` section of `SHOW ENGINE InnoDB STATUS` output.

For related information, see Section 15.8.4, “Configuring Thread Concurrency for InnoDB”.

- `innodb_thread_sleep_delay`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb-thread-sleep-delay=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_thread_sleep_delay</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>10000</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1000000</td>
</tr>
<tr>
<td>Unit</td>
<td>microseconds</td>
</tr>
</tbody>
</table>

How long InnoDB threads sleep before joining the InnoDB queue, in microseconds. The default value is 10000. A value of 0 disables sleep. You can set `innodb_adaptive_max_sleep_delay` to the highest value you would allow for `innodb_thread_sleep_delay`, and InnoDB automatically adjusts `innodb_thread_sleep_delay` up or down depending on current thread-scheduling activity. This
InnoDB System Variables

dynamic adjustment helps the thread scheduling mechanism to work smoothly during times when the
system is lightly loaded or when it is operating near full capacity.

For more information, see Section 15.8.4, “Configuring Thread Concurrency for InnoDB”.

• **innodb_tmpdir**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-tmpdir=dir_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_tmpdir</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Directory name</td>
</tr>
<tr>
<td>Default Value</td>
<td>NULL</td>
</tr>
</tbody>
</table>

Used to define an alternate directory for temporary sort files created during online ALTER TABLE
operations that rebuild the table.

Online ALTER TABLE operations that rebuild the table also create an intermediate table file in the same
directory as the original table. The innodb_tmpdir option is not applicable to intermediate table files.

A valid value is any directory path other than the MySQL data directory path. If the value is NULL
(the default), temporary files are created MySQL temporary directory ($TMPDIR on Unix, %TEMP% on
Windows, or the directory specified by the --tmpdir configuration option). If a directory is specified,
existence of the directory and permissions are only checked when innodb_tmpdir is configured using
a SET statement. If a symlink is provided in a directory string, the symlink is resolved and stored as an
absolute path. The path should not exceed 512 bytes. An online ALTER TABLE operation reports an
error if innodb_tmpdir is set to an invalid directory. innodb_tmpdir overrides the MySQL tmpdir
setting but only for online ALTER TABLE operations.

The FILE privilege is required to configure innodb_tmpdir.

The innodb_tmpdir option was introduced to help avoid overflowing a temporary file directory located
on a tmpfs file system. Such overflows could occur as a result of large temporary sort files created
during online ALTER TABLE operations that rebuild the table.

In replication environments, only consider replicating the innodb_tmpdir setting if all servers have the
same operating system environment. Otherwise, replicating the innodb_tmpdir setting could result
in a replication failure when running online ALTER TABLE operations that rebuild the table. If server
operating environments differ, it is recommended that you configure innodb_tmpdir on each server
individually.

For more information, see Section 15.12.3, “Online DDL Space Requirements”. For information about
online ALTER TABLE operations, see Section 15.12, “InnoDB and Online DDL”.

• **innodb_trx_purge_view_update_only_debug**

| Command-Line Format | --innodb-trx-purge-view-update-only-debug=[OFF|ON] |
|---------------------|-----------------------------------------------|
| System Variable     | innodb_trx_purge_view_update_only_debug       |
| Scope               | Global                                        |
| Dynamic             | Yes                                           |
InnoDB System Variables

<table>
<thead>
<tr>
<th>SET_VAR Hint Applies</th>
<th>No</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Pauses purging of delete-marked records while allowing the purge view to be updated. This option artificially creates a situation in which the purge view is updated but purges have not yet been performed. This option is only available if debugging support is compiled in using the `WITH_DEBUG CMake` option.

- `innodb_trx_rseg_n_slots_debug`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb-trx-rseg-n-slots-debug=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_trx_rseg_n_slots_debug</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1024</td>
</tr>
</tbody>
</table>

Sets a debug flag that limits `TRX_RSEG_N_SLOTS` to a given value for the `trx_rsegf_undo_find_free` function that looks for free slots for undo log segments. This option is only available if debugging support is compiled in using the `WITH_DEBUG CMake` option.

- `innodb_undo_directory`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb-undo-directory=dir_name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_undo_directory</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Directory name</td>
</tr>
</tbody>
</table>

The path where InnoDB creates undo tablespaces. Typically used to place undo tablespaces on a different storage device.

There is no default value (it is NULL). If the `innodb_undo_directory` variable is undefined, undo tablespaces are created in the data directory.

The default undo tablespaces (`innodb_undo_001` and `innodb undo_002`) created when the MySQL instance is initialized always reside in the directory defined by the `innodb_undo_directory` variable.

Undo tablespaces created using `CREATE UNDO TABLESPACE` syntax are created in the directory defined by the `innodb_undo_directory` variable if a different path is not specified.

For more information, see Section 15.6.3.4, “Undo Tablespaces”.

3576
InnoDB System Variables

- **innodb_undo_log_encrypt**

```
Command-Line Format: --innodb-undo-log-encrypt=[{OFF|ON}]
System Variable: innodb_undo_log_encrypt
Scope: Global
Dynamic: Yes
SET_VAR Hint Applies: No
Type: Boolean
Default Value: OFF
```

Controls encryption of undo log data for tables encrypted using the InnoDB data-at-rest encryption feature. Only applies to undo logs that reside in separate undo tablespaces. See Section 15.6.3.4, "Undo Tablespaces". Encryption is not supported for undo log data that resides in the system tablespace. For more information, see Undo Log Encryption.

- **innodb_undo_log_truncate**

```
Command-Line Format: --innodb-undo-log-truncate=[{OFF|ON}]
System Variable: innodb_undo_log_truncate
Scope: Global
Dynamic: Yes
SET_VAR Hint Applies: No
Type: Boolean
Default Value: ON
```

When enabled, undo tablespaces that exceed the threshold value defined by `innodb_max_undo_log_size` are marked for truncation. Only undo tablespaces can be truncated. Truncating undo logs that reside in the system tablespace is not supported. For truncation to occur, there must be at least two undo tablespaces.

The `innodb_purge_rseg_truncate_frequency` variable can be used to expedite truncation of undo tablespaces.

For more information, see Truncating Undo Tablespaces.

- **innodb_undo_tablespaces**

```
Command-Line Format: --innodb-undo-tablespaces=#
Deprecated: Yes
System Variable: innodb_undo_tablespaces
Scope: Global
Dynamic: Yes
SET_VAR Hint Applies: No
Type: Integer
Default Value: 2
Minimum Value: 2
```
InnoDB System Variables

| Maximum Value | 127 |

Defines the number of undo tablespaces used by InnoDB. The default and minimum value is 2.

Note

The innodb_undo_tablespaces variable is deprecated and is no longer configurable as of MySQL 8.0.14. Expect it to be removed in a future release.

For more information, see Section 15.6.3.4, “Undo Tablespaces”.

- innodb_use_fdatasync

| Command-Line Format | --innodb-use-fdatasync={OFF|ON} |
|---------------------|---------------------------------|
| Introduced          | 8.0.26                          |
| System Variable     | innodb_use_fdatasync            |
| Scope               | Global                          |
| Dynamic             | Yes                             |
| SET_VAR Hint Applies| No                              |
| Type                | Boolean                         |
| Default Value       | OFF                             |

On platforms that support fdatasync() system calls, enabling the innodb_use_fdatasync variable permits using fdatasync() instead of fsync() system calls for operating system flushes. An fdatasync() call does not flush changes to file metadata unless required for subsequent data retrieval, providing a potential performance benefit.

A subset of innodb_flush_method settings such as fsync, O_DSYNC, and O_DIRECT use fsync() system calls. The innodb_use_fdatasync variable is applicable when using those settings.

- innodb_use_native_aio

| Command-Line Format | --innodb-use-native-aio={OFF|ON} |
|---------------------|---------------------------------|
| System Variable     | innodb_use_native_aio           |
| Scope               | Global                          |
| Dynamic             | No                              |
| SET_VAR Hint Applies| No                              |
| Type                | Boolean                         |
| Default Value       | ON                              |

Specifies whether to use the Linux asynchronous I/O subsystem. This variable applies to Linux systems only, and cannot be changed while the server is running. Normally, you do not need to configure this option, because it is enabled by default.

The asynchronous I/O capability that InnoDB has on Windows systems is available on Linux systems. (Other Unix-like systems continue to use synchronous I/O calls.) This feature improves the scalability of
heavily I/O-bound systems, which typically show many pending reads/writes in `SHOW ENGINE INNODB STATUS` output.

Running with a large number of InnoDB I/O threads, and especially running multiple such instances on the same server machine, can exceed capacity limits on Linux systems. In this case, you may receive the following error:

```
EAGAIN: The specified maxevents exceeds the user's limit of available events.
```

You can typically address this error by writing a higher limit to `/proc/sys/fs/aio-max-nr`.

However, if a problem with the asynchronous I/O subsystem in the OS prevents InnoDB from starting, you can start the server with `innodb_use_native_aio=0`. This option may also be disabled automatically during startup if InnoDB detects a potential problem such as a combination of `tmpdir` location, `tmpfs` file system, and Linux kernel that does not support AIO on `tmpfs`.

For more information, see Section 15.8.6, “Using Asynchronous I/O on Linux”.

- `innodb_validate_tablespace_paths`

| Command-Line Format | --innodb-validate-tablespace-paths=[{OFF|ON}] |
|---------------------|---------------------------------------------|
| Introduced          | 8.0.21                                      |
| System Variable     | `innodb_validate_tablespace_paths`          |
| Scope               | Global                                      |
| Dynamic             | No                                          |
| SET_VAR Hint Applies| No                                          |
| Type                | Boolean                                     |
| Default Value       | ON                                          |

Controls tablespace file path validation. At startup, InnoDB validates the paths of known tablespace files against tablespace file paths stored in the data dictionary in case tablespace files have been moved to a different location. The `innodb_validate_tablespace_paths` variable permits disabling tablespace path validation. This feature is intended for environments where tablespaces files are not moved. Disabling path validation improves startup time on systems with a large number of tablespace files.

**Warning**

Starting the server with tablespace path validation disabled after moving tablespace files can lead to undefined behavior.

For more information, see Section 15.6.3.7, “Disabling Tablespace Path Validation”.

- `innodb_version`

The InnoDB version number. In MySQL 8.0, separate version numbering for InnoDB does not apply and this value is the same the `version` number of the server.

- `innodb_write_io_threads`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-write-io-threads=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_write_io_threads</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
</tbody>
</table>
The number of I/O threads for write operations in InnoDB. The default value is 4. Its counterpart for read threads is `innodb_read_io_threads`. For more information, see Section 15.8.5, “Configuring the Number of Background InnoDB I/O Threads”. For general I/O tuning advice, see Section 8.5.8, “Optimizing InnoDB Disk I/O”.

**Note**

On Linux systems, running multiple MySQL servers (typically more than 12) with default settings for `innodb_read_io_threads`, `innodb_write_io_threads`, and the Linux `aio-max-nr` setting can exceed system limits. Ideally, increase the `aio-max-nr` setting; as a workaround, you might reduce the settings for one or both of the MySQL variables.

Also take into consideration the value of `sync_binlog`, which controls synchronization of the binary log to disk.

For general I/O tuning advice, see Section 8.5.8, “Optimizing InnoDB Disk I/O”.

### 15.15 InnoDB INFORMATION_SCHEMA Tables

This section provides information and usage examples for InnoDB INFORMATION_SCHEMA tables.

InnoDB INFORMATION_SCHEMA tables provide metadata, status information, and statistics about various aspects of the InnoDB storage engine. You can view a list of InnoDB INFORMATION_SCHEMA tables by issuing a `SHOW TABLES` statement on the INFORMATION_SCHEMA database:

```sql
mysql> SHOW TABLES FROM INFORMATION_SCHEMA LIKE 'INNODB%';
```

For table definitions, see Section 26.4, “INFORMATION_SCHEMA InnoDB Tables”. For general information regarding the MySQL INFORMATION_SCHEMA database, see Chapter 26, INFORMATION_SCHEMA Tables.

### 15.15.1 InnoDB INFORMATION_SCHEMA Tables about Compression

There are two pairs of InnoDB INFORMATION_SCHEMA tables about compression that can provide insight into how well compression is working overall:

- `INNODB_CMP` and `INNODB_CMP_RESET` provide information about the number of compression operations and the amount of time spent performing compression.
- `INNODB_CMPMEM` and `INNODB_CMPMEM_RESET` provide information about the way memory is allocated for compression.

#### 15.15.1.1 INNODB_CMP and INNODB_CMP_RESET

The `INNODB_CMP` and `INNODB_CMP_RESET` tables provide status information about operations related to compressed tables, which are described in Section 15.9, “InnoDB Table and Page Compression”. The `PAGE_SIZE` column reports the compressed page size.
These two tables have identical contents, but reading from `INNODB_CMP_RESET` resets the statistics on compression and uncompression operations. For example, if you archive the output of `INNODB_CMP_RESET` every 60 minutes, you see the statistics for each hourly period. If you monitor the output of `INNODB_CMP` (making sure never to read `INNODB_CMP_RESET`), you see the cumulative statistics since InnoDB was started.

For the table definition, see Section 26.4.6, “The INFORMATION_SCHEMA INNODB_CMP and INNODB_CMP_RESET Tables”.

### 15.15.1.2 INNODB_CMPMEM and INNODB_CMPMEM_RESET

The `INNODB_CMPMEM` and `INNODB_CMPMEM_RESET` tables provide status information about compressed pages that reside in the buffer pool. Please consult Section 15.9, “InnoDB Table and Page Compression” for further information on compressed tables and the use of the buffer pool. The `INNODB_CMP` and `INNODB_CMP_RESET` tables should provide more useful statistics on compression.

**Internal Details**

InnoDB uses a buddy allocator system to manage memory allocated to pages of various sizes, from 1KB to 16KB. Each row of the two tables described here corresponds to a single page size.

The `INNODB_CMPMEM` and `INNODB_CMPMEM_RESET` tables have identical contents, but reading from `INNODB_CMPMEM_RESET` resets the statistics on relocation operations. For example, if every 60 minutes you archived the output of `INNODB_CMPMEM_RESET`, it would show the hourly statistics. If you never read `INNODB_CMPMEM_RESET` and monitored the output of `INNODB_CMPMEM` instead, it would show the cumulative statistics since InnoDB was started.

For the table definition, see Section 26.4.7, “The INFORMATION_SCHEMA INNODB_CMPMEM and INNODB_CMPMEM_RESET Tables”.

### 15.15.1.3 Using the Compression Information Schema Tables

**Example 15.1 Using the Compression Information Schema Tables**

The following is sample output from a database that contains compressed tables (see Section 15.9, “InnoDB Table and Page Compression”, `INNODB_CMP`, `INNODB_CMP_PER_INDEX`, and `INNODB_CMPMEM`).

The following table shows the contents of `INFORMATION_SCHEMA.INNODB_CMP` under a light workload. The only compressed page size that the buffer pool contains is 8K. Compressing or uncompressing pages has consumed less than a second since the time the statistics were reset, because the columns `COMPRESS_TIME` and `UNCOMPRESS_TIME` are zero.

<table>
<thead>
<tr>
<th>page size</th>
<th>compress ops</th>
<th>compress ops ok</th>
<th>compress time</th>
<th>uncompress ops</th>
<th>uncompress time</th>
</tr>
</thead>
<tbody>
<tr>
<td>1024</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>2048</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>4096</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>8192</td>
<td>1048</td>
<td>921</td>
<td>0</td>
<td>61</td>
<td>0</td>
</tr>
<tr>
<td>16384</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

According to `INNODB_CMPMEM`, there are 6169 compressed 8KB pages in the buffer pool. The only other allocated block size is 64 bytes. The smallest `PAGE_SIZE` in `INNODB_CMPMEM` is used for block
descriptors of those compressed pages for which no uncompressed page exists in the buffer pool. We see that there are 5910 such pages. Indirectly, we see that 259 (6169-5910) compressed pages also exist in the buffer pool in uncompressed form.

The following table shows the contents of INFORMATION_SCHEMA.INNODB_CMPMEM under a light workload. Some memory is unusable due to fragmentation of the memory allocator for compressed pages: \( \text{SUM(PAGE\_SIZE*PAGES\_FREE)} = 6784 \). This is because small memory allocation requests are fulfilled by splitting bigger blocks, starting from the 16K blocks that are allocated from the main buffer pool, using the buddy allocation system. The fragmentation is this low because some allocated blocks have been relocated (copied) to form bigger adjacent free blocks. This copying of \( \text{SUM(PAGE\_SIZE*RELOCATION\_OPS)} \) bytes has consumed less than a second \( \text{(SUM(RELOCATION\_TIME) = 0)} \).

<table>
<thead>
<tr>
<th>page size</th>
<th>pages used</th>
<th>pages free</th>
<th>relocation ops</th>
<th>relocation time</th>
</tr>
</thead>
<tbody>
<tr>
<td>64</td>
<td>5910</td>

<td>0</td>
</tr>
</tbody>
</table>

### 15.15.2 InnoDB INFORMATION_SCHEMA Transaction and Locking Information

**Note**

This section describes locking information as exposed by the Performance Schema data_locks and data_lock_waits tables, which supersede the INFORMATION_SCHEMA INNODB_LOCKS and INNODB_LOCK_WAITS tables in MySQL 8.0. For similar discussion written in terms of the older INFORMATION_SCHEMA tables, see InnoDB INFORMATION_SCHEMA Transaction and Locking Information, in MySQL 5.7 Reference Manual.

One INFORMATION_SCHEMA table and two Performance Schema tables enable you to monitor InnoDB transactions and diagnose potential locking problems:

- **INNODB_TRX**: This INFORMATION_SCHEMA table provides information about every transaction currently executing inside InnoDB, including the transaction state (for example, whether it is running or waiting for a lock), when the transaction started, and the particular SQL statement the transaction is executing.

- **data_locks**: This Performance Schema table contains a row for each hold lock and each lock request that is blocked waiting for a held lock to be released:

  - There is one row for each held lock, whatever the state of the transaction that holds the lock \( \text{(INNODB\_TRX\_TRX\_STATE is RUNNING, LOCK WAIT, ROLLING BACK or COMMITTING)} \).

  - Each transaction in InnoDB that is waiting for another transaction to release a lock \( \text{(INNODB\_TRX\_TRX\_STATE is LOCK WAIT)} \) is blocked by exactly one blocking lock request. That blocking lock request is for a row or table lock held by another transaction in an incompatible mode.
A lock request always has a mode that is incompatible with the mode of the held lock that blocks the request (read vs. write, shared vs. exclusive).

The blocked transaction cannot proceed until the other transaction commits or rolls back, thereby releasing the requested lock. For every blocked transaction, `data_locks` contains one row that describes each lock the transaction has requested, and for which it is waiting.

- `data_lock_waits`: This Performance Schema table indicates which transactions are waiting for a given lock, or for which lock a given transaction is waiting. This table contains one or more rows for each blocked transaction, indicating the lock it has requested and any locks that are blocking that request. The `REQUESTING_ENGINE_LOCK_ID` value refers to the lock requested by a transaction, and the `BLOCKING_ENGINE_LOCK_ID` value refers to the lock (held by another transaction) that prevents the first transaction from proceeding. For any given blocked transaction, all rows in `data_lock_waits` have the same value for `REQUESTING_ENGINE_LOCK_ID` and different values for `BLOCKING_ENGINE_LOCK_ID`.

For more information about the preceding tables, see Section 26.4.28, “The INFORMATION_SCHEMA INNODB_TRX Table”, Section 27.12.13.1, “The data_locks Table”, and Section 27.12.13.2, “The data_lock_waits Table”.

### 15.15.2.1 Using InnoDB Transaction and Locking Information

**Note**

This section describes locking information as exposed by the Performance Schema `data_locks` and `data_lock_waits` tables, which supersede the `INFORMATION_SCHEMA INNODB_LOCKS` and `INNODB_LOCK_WAITS` tables in MySQL 8.0. For similar discussion written in terms of the older `INFORMATION_SCHEMA` tables, see Using InnoDB Transaction and Locking Information, in MySQL 5.7 Reference Manual.

### Identifying Blocking Transactions

It is sometimes helpful to identify which transaction blocks another. The tables that contain information about InnoDB transactions and data locks enable you to determine which transaction is waiting for another, and which resource is being requested. (For descriptions of these tables, see Section 15.15.2, “InnoDB INFORMATION_SCHEMA Transaction and Locking Information”.)

Suppose that three sessions are running concurrently. Each session corresponds to a MySQL thread, and executes one transaction after another. Consider the state of the system when these sessions have issued the following statements, but none has yet committed its transaction:

- **Session A:**
  ```sql
  BEGIN;
  SELECT a FROM t FOR UPDATE;
  SELECT SLEEP(100);
  ```

- **Session B:**
  ```sql
  SELECT b FROM t FOR UPDATE;
  ```

- **Session C:**
  ```sql
  SELECT c FROM t FOR UPDATE;
  ```

In this scenario, use the following query to see which transactions are waiting and which transactions are blocking them:
InnoDB INFORMATION_SCHEMA Transaction and Locking Information

```sql
SELECT r.trx_id waiting_trx_id,  
r.trx_mysql_thread_id waiting_thread,  
r.trx_query waiting_query,  
b.trx_id blocking_trx_id,  
b.trx_mysql_thread_id blocking_thread,  
b.trx_query blocking_query
FROM performance_schema.data_lock_waits w
INNER JOIN information_schema.innodb_trx b
  ON b.trx_id = w.blocking_engine_transaction_id
INNER JOIN information_schema.innodb_trx r
  ON r.trx_id = w.requesting_engine_transaction_id;
```

Or, more simply, use the `sys` schema `innodb_lock_waits` view:

```sql
SELECT waiting_trx_id,  
waiting_pid,  
waiting_query,  
blocking_trx_id,  
blocking_pid,  
blocking_query
FROM sys.innodb_lock_waits;
```

If a NULL value is reported for the blocking query, see Identifying a Blocking Query After the Issuing Session Becomes Idle.

<table>
<thead>
<tr>
<th>waiting trx id</th>
<th>waiting thread</th>
<th>waiting query</th>
<th>blocking trx id</th>
<th>blocking thread</th>
<th>blocking query</th>
</tr>
</thead>
<tbody>
<tr>
<td>A4</td>
<td>6</td>
<td><code>SELECT b FROM t FOR UPDATE</code></td>
<td>A3</td>
<td>5</td>
<td><code>SELECT SLEEP(100)</code></td>
</tr>
<tr>
<td>A5</td>
<td>7</td>
<td><code>SELECT c FROM t FOR UPDATE</code></td>
<td>A3</td>
<td>5</td>
<td><code>SELECT SLEEP(100)</code></td>
</tr>
</tbody>
</table>

In the preceding table, you can identify sessions by the “waiting query” or “blocking query” columns. As you can see:

- Session B (trx id A4, thread 6) and Session C (trx id A5, thread 7) are both waiting for Session A (trx id A3, thread 5).
- Session C is waiting for Session B as well as Session A.

You can see the underlying data in the INFORMATION_SCHEMA INNODB_TRX table and Performance Schema data_locks and data_lock_waits tables.

The following table shows some sample contents of the INNODB_TRX table.

<table>
<thead>
<tr>
<th>trx id</th>
<th>trx state</th>
<th>trx started</th>
<th>trx requested lock id</th>
<th>trx wait started</th>
<th>trx weight</th>
<th>trx mysql thread id</th>
<th>trx query</th>
</tr>
</thead>
<tbody>
<tr>
<td>A3</td>
<td>RUNNING</td>
<td>2008-01-15 16:44:54</td>
<td>NULL</td>
<td>NULL</td>
<td>2</td>
<td>5</td>
<td><code>SELECT SLEEP(100)</code></td>
</tr>
</tbody>
</table>
Identifying a Blocking Query After the Issuing Session Becomes Idle

When identifying blocking transactions, a NULL value is reported for the blocking query if the session that issued the query has become idle. In this case, use the following steps to determine the blocking query:

1. Identify the processlist ID of the blocking transaction. In the `sys.innodb_lock_waits` table, the processlist ID of the blocking transaction is the `blocking_pid` value.

2. Using the `blocking_pid`, query the MySQL Performance Schema `threads` table to determine the `THREAD_ID` of the blocking transaction. For example, if the `blocking_pid` is 6, issue this query:

   ```sql
   SELECT THREAD_ID FROM performance_schema.threads WHERE PROCESSLIST_ID = 6;
   ```

3. Using the `THREAD_ID`, query the Performance Schema `events_statements_current` table to determine the last query executed by the thread. For example, if the `THREAD_ID` is 28, issue this query:

   ```sql
   SELECT THREAD_ID, SQL_TEXT FROM performance_schema.events_statements_current
   WHERE THREAD_ID = 28\G
   ```

4. If the last query executed by the thread is not enough information to determine why a lock is held, you can query the Performance Schema `events_statements_history` table to view the last 10 statements executed by the thread.

   ```sql
   SELECT THREAD_ID, SQL_TEXT FROM performance_schema.events_statements_history
   WHERE THREAD_ID = 28 ORDER BY EVENT_ID;
   ```
Correlating InnoDB Transactions with MySQL Sessions

Sometimes it is useful to correlate internal InnoDB locking information with the session-level information maintained by MySQL. For example, you might like to know, for a given InnoDB transaction ID, the corresponding MySQL session ID and name of the session that may be holding a lock, and thus blocking other transactions.

The following output from the INFORMATION_SCHEMA INNODB_TRX table and Performance Schema data_locks and data_lock_waits tables is taken from a somewhat loaded system. As can be seen, there are several transactions running.

The following data_locks and data_lock_waits tables show that:

- Transaction 77F (executing an INSERT) is waiting for transactions 77E, 77D, and 77B to commit.
- Transaction 77E (executing an INSERT) is waiting for transactions 77D and 77B to commit.
- Transaction 77D (executing an INSERT) is waiting for transaction 77B to commit.
- Transaction 77B (executing an INSERT) is waiting for transaction 77A to commit.
- Transaction 77A is running, currently executing SELECT.
- Transaction E56 (executing an INSERT) is waiting for transaction E55 to commit.
- Transaction E55 (executing an INSERT) is waiting for transaction 19C to commit.
- Transaction 19C is running, currently executing an INSERT.

Note

There may be inconsistencies between queries shown in the INFORMATION_SCHEMA PROCESSLIST and INNODB_TRX tables. For an explanation, see Section 15.15.2.3, “Persistence and Consistency of InnoDB Transaction and Locking Information”.

The following table shows the contents of the PROCESSLIST table for a system running a heavy workload.

<table>
<thead>
<tr>
<th>ID</th>
<th>USER</th>
<th>HOST</th>
<th>DB</th>
<th>COMMAND</th>
<th>TIME</th>
<th>STATE</th>
<th>INFO</th>
</tr>
</thead>
<tbody>
<tr>
<td>384</td>

### 15.15.2.2 InnoDB Lock and Lock-Wait Information

**Note**

This section describes locking information as exposed by the Performance Schema `data_locks` and `data_lock_waits` tables, which supersede the `INFORMATION_SCHEMA` `INNODB_LOCKS` and `INNODB_LOCK_WAITS` tables in MySQL 8.0. For similar discussion written in terms of the older `INFORMATION_SCHEMA` tables, see InnoDB Lock and Lock-Wait Information, in MySQL 5.7 Reference Manual.

When a transaction updates a row in a table, or locks it with `SELECT FOR UPDATE`, InnoDB establishes a list or queue of locks on that row. Similarly, InnoDB maintains a list of locks on a table for table-level locks. If a second transaction wants to update a row or lock a table already locked by a prior transaction in an incompatible mode, InnoDB adds a lock request for the row to the corresponding queue. For a lock to be
acquired by a transaction, all incompatible lock requests previously entered into the lock queue for that row
or table must be removed (which occurs when the transactions holding or requesting those locks either
commit or roll back).

A transaction may have any number of lock requests for different rows or tables. At any given time, a
transaction may request a lock that is held by another transaction, in which case it is blocked by that other
transaction. The requesting transaction must wait for the transaction that holds the blocking lock to commit
or roll back. If a transaction is not waiting for a lock, it is in a RUNNING state. If a transaction is waiting for
a lock, it is in a LOCK WAIT state. (The INFORMATION_SCHEMA INNODB_TRX table indicates transaction
state values.)

The Performance Schema data_locks table holds one or more rows for each LOCK WAIT transaction,
indicating any lock requests that prevent its progress. This table also contains one row describing each
lock in a queue of locks pending for a given row or table. The Performance Schema data_lock_waits
table shows which locks already held by a transaction are blocking locks requested by other transactions.

15.15.2.3 Persistence and Consistency of InnoDB Transaction and Locking Information

This section describes locking information as exposed by the Performance
Schema data_locks and data_lock_waits tables, which supersede the
INFORMATION_SCHEMA INNODB_LOCKS and INNODB_LOCK_WAITS
tables in MySQL 8.0. For similar discussion written in terms of the older
INFORMATION_SCHEMA tables, see Persistence and Consistency of InnoDB
Transaction and Locking Information, in MySQL 5.7 Reference Manual.

The data exposed by the transaction and locking tables (INFORMATION_SCHEMA INNODB_TRX table,
Performance Schema data_locks and data_lock_waits tables) represents a glimpse into fast-
changing data. This is not like user tables, where the data changes only when application-initiated updates
occur. The underlying data is internal system-managed data, and can change very quickly:

- Data might not be consistent between the INNODB_TRX, data_locks, and data_lock_waits tables.

  The data_locks and data_lock_waits tables expose live data from the InnoDB storage engine, to
  provide lock information about the transactions in the INNODB_TRX table. Data retrieved from the lock
tables exists when the SELECT is executed, but might be gone or changed by the time the query result is
  consumed by the client.

  Joining data_locks with data_lock_waits can show rows in data_lock_waits that identify a
  parent row in data_locks that no longer exists or does not exist yet.

- Data in the transaction and locking tables might not be consistent with data in the
  INFORMATION_SCHEMA PROCESSLIST table or Performance Schema threads table.

  For example, you should be careful when comparing data in the InnoDB transaction and locking
  tables with data in the PROCESSLIST table. Even if you issue a single SELECT (joining INNODB_TRX
  and PROCESSLIST, for example), the content of those tables is generally not consistent. It is
  possible for INNODB_TRX to reference rows that are not present in PROCESSLIST or for the currently
  executing SQL query of a transaction shown in INNODB_TRX.TRX_QUERY to differ from the one in
  PROCESSLIST.INFO.

15.15.3 InnoDB INFORMATION_SCHEMA Schema Object Tables

You can extract metadata about schema objects managed by InnoDB using InnoDB
INFORMATION_SCHEMA tables. This information comes from the data dictionary. Traditionally, you would
get this type of information using the techniques from Section 15.17, “InnoDB Monitors”, setting up InnoDB monitors and parsing the output from the `SHOW ENGINE INNODB STATUS` statement. The InnoDB INFORMATION_SCHEMA table interface allows you to query this data using SQL.

InnoDB INFORMATION_SCHEMA schema object tables include the tables listed below.

- **INNODB_DATAFILES** provides data file path information for InnoDB file-per-table and general tablespaces.
- **INNODB_TABLESTATS** provides a view of low-level status information about InnoDB tables that is derived from in-memory data structures.
- **INNODB_FOREIGN** provides metadata about foreign keys defined on InnoDB tables.
- **INNODB_FOREIGN_COLS** provides metadata about the columns of foreign keys that are defined on InnoDB tables.
- **INNODB_INDEXES** provides metadata about InnoDB indexes.
- **INNODB_TABLES** provides metadata about InnoDB tables.
- **INNODB_COLUMNS** provides metadata about InnoDB table columns.
- **INNODB_TABLESPACES** provides metadata about InnoDB file-per-table, general, and undo tablespaces.
- **INNODB_TABLESPACES_BRIEF** provides a subset of metadata about InnoDB tablespaces.
- **INNODB_FIELDS** provides metadata about the key columns (fields) of InnoDB indexes.

The table names are indicative of the type of data provided:

- **INNODB_TABLES** provides metadata about InnoDB tables.
- **INNODB_COLUMNS** provides metadata about InnoDB table columns.
- **INNODB_INDEXES** provides metadata about InnoDB indexes.
- **INNODB_FIELDS** provides metadata about the key columns (fields) of InnoDB indexes.
- **INNODB_TABLESTATS** provides a view of low-level status information about InnoDB tables that is derived from in-memory data structures.
- **INNODB_DATAFILES** provides data file path information for InnoDB file-per-table and general tablespaces.
- **INNODB_TABLESPACES** provides metadata about InnoDB file-per-table, general, and undo tablespaces.
- **INNODB_TABLESPACES_BRIEF** provides a subset of metadata about InnoDB tablespaces.
- **INNODB_FOREIGN** provides metadata about foreign keys defined on InnoDB tables.
- **INNODB_FOREIGN_COLS** provides metadata about the columns of foreign keys that are defined on InnoDB tables.

InnoDB INFORMATION_SCHEMA schema object tables can be joined together through fields such as **TABLE_ID**, **INDEX_ID**, and **SPACE**, allowing you to easily retrieve all available data for an object you want to study or monitor.

Refer to the InnoDB INFORMATION_SCHEMA documentation for information about the columns of each table.

Example 15.2 InnoDB INFORMATION_SCHEMA Schema Object Tables

This example uses a simple table (t1) with a single index (i1) to demonstrate the type of metadata found in the InnoDB INFORMATION_SCHEMA schema object tables.

1. Create a test database and table t1:

```sql
mysql> CREATE DATABASE test;
mysql> USE test;
mysql> CREATE TABLE t1 (```
2. After creating the table `t1`, query `INNODB_TABLES` to locate the metadata for `test/t1`:

   ```sql
   mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_TABLES WHERE NAME='test/t1' 
   **************************** 1. row ***************************
   TABLE_ID: 71
   NAME: test/t1
   FLAG: 1
   N_COLS: 6
   SPACE: 57
   ROW_FORMAT: Compact
   ZIP_PAGE_SIZE: 0
   INSTANT_COLS: 0
   ```

   Table `t1` has a `TABLE_ID` of 71. The `FLAG` field provides bit level information about table format and storage characteristics. There are six columns, three of which are hidden columns created by InnoDB (DB_ROW_ID, DB_TRX_ID, and DB_ROLL_PTR). The ID of the table's `SPACE` is 57 (a value of 0 would indicate that the table resides in the system tablespace). The `ROW_FORMAT` is Compact. `ZIP_PAGE_SIZE` only applies to tables with a Compressed row format. `INSTANT_COLS` shows number of columns in the table prior to adding the first instant column using `ALTER TABLE ... ADD COLUMN with ALGORITHM=INSTANT`.

3. Using the `TABLE_ID` information from `INNODB_TABLES`, query the `INNODB_COLUMNS` table for information about the table's columns.

   ```sql
   mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_COLUMNS where TABLE_ID = 71
   **************************** 1. row ***************************
   TABLE_ID: 71
   NAME: col1
   POS: 0
   MTYPE: 6
   PRTYPE: 1027
   LEN: 4
   HAS_DEFAULT: 0
   DEFAULT_VALUE: NULL
   **************************** 2. row ***************************
   TABLE_ID: 71
   NAME: col2
   POS: 1
   MTYPE: 2
   PRTYPE: 524542
   LEN: 10
   HAS_DEFAULT: 0
   DEFAULT_VALUE: NULL
   **************************** 3. row ***************************
   TABLE_ID: 71
   NAME: col3
   POS: 2
   MTYPE: 1
   PRTYPE: 524303
   LEN: 10
   HAS_DEFAULT: 0
   DEFAULT_VALUE: NULL
   ```

   In addition to the `TABLE_ID` and column `NAME`, `INNODB_COLUMNS` provides the ordinal position (`POS`) of each column (starting from 0 and incrementing sequentially), the column `MTYPE` or "main type" (6 = INT, 2 = CHAR, 1 = VARCHAR), the `PRTYPE` or "precise type" (a binary value with bits that represent the MySQL data type, character set code, and nullability), and the column length (`LEN`).
HAS_DEFAULT and DEFAULT_VALUE columns only apply to columns added instantly using ALTER TABLE ... ADD COLUMN with ALGORITHM=INSTANT.

4. Using the TABLE_ID information from INNODB_TABLES once again, query INNODB_INDEXES for information about the indexes associated with table t1.

\[\begin{verbatim}
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_INDEXES WHERE TABLE_ID = 71 \
GLOBAL
1. row
INDEX_ID: 111
NAME: GEN_CLUST_INDEX
TABLE_ID: 71
TYPE: 1
N_FIELDS: 0
PAGE_NO: 3
SPACE: 57
MERGE_THRESHOLD: 50
2. row
INDEX_ID: 112
NAME: i1
TABLE_ID: 71
TYPE: 0
N_FIELDS: 1
PAGE_NO: 4
SPACE: 57
MERGE_THRESHOLD: 50
\end{verbatim}\]

INNODB_INDEXES returns data for two indexes. The first index is GEN_CLUST_INDEX, which is a clustered index created by InnoDB if the table does not have a user-defined clustered index. The second index (i1) is the user-defined secondary index.

The INDEX_ID is an identifier for the index that is unique across all databases in an instance. The TABLE_ID identifies the table that the index is associated with. The index TYPE value indicates the type of index (1 = Clustered Index, 0 = Secondary index). The N_FIELDS value is the number of fields that comprise the index. PAGE_NO is the root page number of the index B-tree, and SPACE is the ID of the tablespace where the index resides. A nonzero value indicates that the index does not reside in the system tablespace. MERGE_THRESHOLD defines a percentage threshold value for the amount of data in an index page. If the amount of data in an index page falls below this value (the default is 50%) when a row is deleted or when a row is shortened by an update operation, InnoDB attempts to merge the index page with a neighboring index page.

5. Using the INDEX_ID information from INNODB_INDEXES, query INNODB_FIELDS for information about the fields of index i1.

\[\begin{verbatim}
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FIELDS WHERE INDEX_ID = 112 \
GLOBAL
1. row
INDEX_ID: 112
NAME: col1
POS: 0
\end{verbatim}\]

INNODB_FIELDS provides the NAME of the indexed field and its ordinal position within the index. If the index (i1) had been defined on multiple fields, INNODB_FIELDS would provide metadata for each of the indexed fields.

6. Using the SPACE information from INNODB_TABLES, query INNODB_TABLESPACES table for information about the table's tablespace.

\[\begin{verbatim}
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_TABLESPACES WHERE SPACE = 57 \
GLOBAL
1. row
SPACE: 57
NAME: test/t1
FLAG: 16417
RO_FORMAT: Dynamic
\end{verbatim}\]
In addition to the SPACE ID of the tablespace and the NAME of the associated table, `INNODB_TABLESPACES` provides tablespace FLAG data, which is bit level information about tablespace format and storage characteristics. Also provided are tablespace ROW_FORMAT, PAGE_SIZE, and several other tablespace metadata items.

7. Using the SPACE information from `INNODB_TABLES` once again, query `INNODB_DATAFILES` for the location of the tablespace data file.

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_DATAFILES WHERE SPACE = 57 \G
*************************** 1. row ***************************
SPACE: 57
PATH: ./test/t1.ibd
```

The datafile is located in the `test` directory under MySQL’s `data` directory. If a file-per-table tablespace were created in a location outside the MySQL data directory using the DATA DIRECTORY clause of the CREATE TABLE statement, the tablespace PATH would be a fully qualified directory path.

8. As a final step, insert a row into table `t1` (TABLE_ID = 71) and view the data in the `INNODB_TABLESTATS` table. The data in this table is used by the MySQL optimizer to calculate which index to use when querying an InnoDB table. This information is derived from in-memory data structures.

```sql
mysql> INSERT INTO t1 VALUES(5, 'abc', 'def');
Query OK, 1 row affected (0.06 sec)

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_TABLESTATS where TABLE_ID = 71 \G
*************************** 1. row ***************************
TABLE_ID: 71
NAME: test/t1
STATS_INITIALIZED: Initialized
NUM_ROWS: 1
CLUST_INDEX_SIZE: 1
OTHER_INDEX_SIZE: 0
MODIFIED_COUNTER: 1
AUTOINC: 0
REF_COUNT: 1
```

The STATS_INITIALIZED field indicates whether or not statistics have been collected for the table. NUM_ROWS is the current estimated number of rows in the table. The CLUST_INDEX_SIZE and OTHER_INDEX_SIZE fields report the number of pages on disk that store clustered and secondary indexes for the table, respectively. The MODIFIED_COUNTER value shows the number of rows modified by DML operations and cascade operations from foreign keys. The AUTOINC value is the next number to be issued for any autoincrement-based operation. There are no autoincrement columns defined on table `t1`, so the value is 0. The REF_COUNT value is a counter. When the counter reaches 0, it signifies that the table metadata can be evicted from the table cache.
InnoDB INFORMATION_SCHEMA Schema Object Tables

Example 15.3 Foreign Key INFORMATION_SCHEMA Schema Object Tables
The INNODB_FOREIGN and INNODB_FOREIGN_COLS tables provide data about foreign key relationships.
This example uses a parent table and child table with a foreign key relationship to demonstrate the data
found in the INNODB_FOREIGN and INNODB_FOREIGN_COLS tables.
1. Create the test database with parent and child tables:
mysql> CREATE DATABASE test;
mysql> USE test;
mysql> CREATE TABLE parent (id INT NOT NULL,
PRIMARY KEY (id)) ENGINE=INNODB;
mysql> CREATE TABLE child (id INT, parent_id INT,
INDEX par_ind (parent_id),
CONSTRAINT fk1
FOREIGN KEY (parent_id) REFERENCES parent(id)
ON DELETE CASCADE) ENGINE=INNODB;

2. After the parent and child tables are created, query INNODB_FOREIGN and locate the foreign key data
for the test/child and test/parent foreign key relationship:
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FOREIGN \G
*************************** 1. row ***************************
ID: test/fk1
FOR_NAME: test/child
REF_NAME: test/parent
N_COLS: 1
TYPE: 1

Metadata includes the foreign key ID (fk1), which is named for the CONSTRAINT that was defined
on the child table. The FOR_NAME is the name of the child table where the foreign key is defined.
REF_NAME is the name of the parent table (the “referenced” table). N_COLS is the number of columns
in the foreign key index. TYPE is a numerical value representing bit flags that provide additional
information about the foreign key column. In this case, the TYPE value is 1, which indicates that the ON
DELETE CASCADE option was specified for the foreign key. See the INNODB_FOREIGN table definition
for more information about TYPE values.
3. Using the foreign key ID, query INNODB_FOREIGN_COLS to view data about the columns of the foreign
key.
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FOREIGN_COLS WHERE ID = 'test/fk1' \G
*************************** 1. row ***************************
ID: test/fk1
FOR_COL_NAME: parent_id
REF_COL_NAME: id
POS: 0

FOR_COL_NAME is the name of the foreign key column in the child table, and REF_COL_NAME is the
name of the referenced column in the parent table. The POS value is the ordinal position of the key field
within the foreign key index, starting at zero.
Example 15.4 Joining InnoDB INFORMATION_SCHEMA Schema Object Tables
This example demonstrates joining three InnoDB INFORMATION_SCHEMA schema object tables
(INNODB_TABLES, INNODB_TABLESPACES, and INNODB_TABLESTATS) to gather file format, row format,
page size, and index size information about tables in the employees sample database.
The following table aliases are used to shorten the query string:

3594


InnoDB INFORMATION_SCHEMA FULLTEXT Index Tables

- INFORMATION_SCHEMA.INNODB_TABLES: a
- INFORMATION_SCHEMA.INNODB_TABLESPACES: b
- INFORMATION_SCHEMA.INNODB_TABLESTATS: c

An `IF()` control flow function is used to account for compressed tables. If a table is compressed, the index size is calculated using `ZIP_PAGE_SIZE` rather than `PAGE_SIZE`. `CLUST_INDEX_SIZE` and `OTHER_INDEX_SIZE`, which are reported in bytes, are divided by `1024*1024` to provide index sizes in megabytes (MBs). MB values are rounded to zero decimal spaces using the `ROUND()` function.

```sql
mysql> SELECT a.NAME, a.ROW_FORMAT,
   @page_size :=
   IF(a.ROW_FORMAT='Compressed',
     b.ZIP_PAGE_SIZE, b.PAGE_SIZE)
   AS page_size,
   ROUND((@page_size * c.CLUST_INDEX_SIZE)
     /(1024*1024)) AS pk_mb,
   ROUND((@page_size * c.OTHER_INDEX_SIZE)
     /(1024*1024)) AS secidx_mb
FROM INFORMATION_SCHEMA.INNODB_TABLES a
INNER JOIN INFORMATION_SCHEMA.INNODB_TABLESPACES b on a.NAME = b.NAME
INNER JOIN INFORMATION_SCHEMA.INNODB_TABLESTATS c on b.NAME = c.NAME
WHERE a.NAME LIKE 'employees/%'
ORDER BY a.NAME DESC;
```

<table>
<thead>
<tr>
<th>NAME</th>
<th>ROW_FORMAT</th>
<th>page_size</th>
<th>pk_mb</th>
<th>secidx_mb</th>
</tr>
</thead>
<tbody>
<tr>
<td>employees/titles</td>
<td>Dynamic</td>
<td>16384</td>

<td>0</td>
</tr>
</tbody>
</table>

15.15.4 InnoDB INFORMATION_SCHEMA FULLTEXT Index Tables

The following tables provide metadata for FULLTEXT indexes:

```sql
mysql> SHOW TABLES FROM INFORMATION_SCHEMA LIKE 'INNODB_FT%';
```

Table Overview

- **INNODB_FT_CONFIG**: Provides metadata about the FULLTEXT index and associated processing for an InnoDB table.
- **INNODB_FT_BEING_DELETED**: Provides a snapshot of the INNODB_FT_DELETED table; it is used only during an **OPTIMIZE TABLE** maintenance operation. When **OPTIMIZE TABLE** is run, the INNODB_FT_BEING_DELETED table is emptied, and DOC_ID values are removed from the INNODB_FT_DELETED table. Because the contents of INNODB_FT_BEING_DELETED typically have a short lifetime, this table has limited utility for monitoring or debugging. For information about running...
OPTIMIZE TABLE on tables with FULLTEXT indexes, see Section 12.9.6, “Fine-Tuning MySQL Full-Text Search”.

- **INNODB_FT_DELETED**: Stores rows that are deleted from the FULLTEXT index for an InnoDB table. To avoid expensive index reorganization during DML operations for an InnoDB FULLTEXT index, the information about newly deleted words is stored separately, filtered out of search results when you do a text search, and removed from the main search index only when you issue an OPTIMIZE TABLE statement for the InnoDB table.

- **INNODB_FT_DEFAULT_STOPWORD**: Holds a list of stopwords that are used by default when creating a FULLTEXT index on InnoDB tables.

  For information about the INNODB_FT_DEFAULT_STOPWORD table, see Section 12.9.4, “Full-Text Stopwords”.

- **INNODB_FT_INDEX_TABLE**: Provides information about the inverted index used to process text searches against the FULLTEXT index of an InnoDB table.

- **INNODB_FT_INDEX_CACHE**: Provides token information about newly inserted rows in a FULLTEXT index. To avoid expensive index reorganization during DML operations, the information about newly indexed words is stored separately, and combined with the main search index only when OPTIMIZE TABLE is run, when the server is shut down, or when the cache size exceeds a limit defined by the innodb_ft_cache_size or innodb_ft_total_cache_size system variable.

**Note**

With the exception of the INNODB_FT_DEFAULT_STOPWORD table, these tables are empty initially. Before querying any of them, set the value of the innodb_ft_aux_table system variable to the name (including the database name) of the table that contains the FULLTEXT index (for example, `test/articles`).

### Example 15.5 InnoDB FULLTEXT Index INFORMATION_SCHEMA Tables

This example uses a table with a FULLTEXT index to demonstrate the data contained in the FULLTEXT index INFORMATION_SCHEMA tables.

1. Create a table with a FULLTEXT index and insert some data:

   ```
   mysql> CREATE TABLE articles (  
      id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,  
      title VARCHAR(200),  
      body TEXT,  
      FULLTEXT (title,body)  
   ) ENGINE=InnoDB;
   mysql> INSERT INTO articles (title,body) VALUES  
      ('MySQL Tutorial','DBMS stands for DataBase ...'),  
      ('How To Use MySQL Well','After you went through a ...'),  
      ('Optimizing MySQL','In this tutorial we show ...'),  
      ('1001 MySQL Tricks','1. Never run mysql as root. 2. ...'),  
      ('MySQL vs. YourSQL','In the following database comparison ...'),  
      ('MySQL Security','When configured properly, MySQL ...');
   ```

2. Set the innodb_ft_aux_table variable to the name of the table with the FULLTEXT index. If this variable is not set, the InnoDB FULLTEXT INFORMATION_SCHEMA tables are empty, with the exception of INNODB_FT_DEFAULT_STOPWORD.

   ```
   mysql> SET GLOBAL innodb_ft_aux_table = 'test/articles';
   ```
3. Query the `INNODB_FT_INDEX_CACHE` table, which shows information about newly inserted rows in a `FULLTEXT` index. To avoid expensive index reorganization during DML operations, data for newly inserted rows remains in the `FULLTEXT` index cache until `OPTIMIZE TABLE` is run (or until the server is shut down or cache limits are exceeded).

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_INDEX_CACHE LIMIT 5;
+------------+--------------+-------------+-----------+--------+----------+
| WORD       | FIRST_DOC_ID | LAST_DOC_ID | DOC_COUNT | DOC_ID | POSITION |
+------------+--------------+-------------+-----------+--------+----------+
| 1001       |   5          |     5      |     1     |    5   |    0     |
| after      |   3          |     3      |     1     |     3  |   22     |
| comparison |   6          |     6      |     1     |     6  |   44     |
| configured |   7          |     7      |     1     |     7  |   20     |
| database   |   2          |     6      |     2     |     2  |   31     |
+------------+--------------+-------------+-----------+--------+----------+
```

4. Enable the `innodb_optimize_fulltext_only` system variable and run `OPTIMIZE TABLE` on the table that contains the `FULLTEXT` index. This operation flushes the contents of the `FULLTEXT` index cache to the main `FULLTEXT` index. `innodb_optimize_fulltext_only` changes the way the `OPTIMIZE TABLE` statement operates on InnoDB tables, and is intended to be enabled temporarily, during maintenance operations on InnoDB tables with `FULLTEXT` indexes.

```
mysql> SET GLOBAL innodb_optimize_fulltext_only=ON;
mysql> OPTIMIZE TABLE articles;
+---------------+----------+----------+----------+
| Table         | Op       | Msg_type | Msg_text |
+---------------+----------+----------+----------+
| test.articles | optimize | status   | OK       |
+---------------+----------+----------+----------+
```

5. Query the `INNODB_FT_INDEX_TABLE` table to view information about data in the main `FULLTEXT` index, including information about the data that was just flushed from the `FULLTEXT` index cache.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_INDEX_TABLE LIMIT 5;
+------------+--------------+-------------+-----------+--------+----------+
| WORD       | FIRST_DOC_ID | LAST_DOC_ID | DOC_COUNT | DOC_ID | POSITION |
+------------+--------------+-------------+-----------+--------+----------+
| 1001       |   5          |     5      |     1     |    5   |    0     |
| after      |   3          |     3      |     1     |     3  |   22     |
| comparison |   6          |     6      |     1     |     6  |   44     |
| configured |   7          |     7      |     1     |     7  |   20     |
| database   |   2          |     6      |     2     |     2  |   31     |
+------------+--------------+-------------+-----------+--------+----------+
```

The `INNODB_FT_INDEX_CACHE` table is now empty since the `OPTIMIZE TABLE` operation flushed the `FULLTEXT` index cache.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_INDEX_CACHE LIMIT 5;
Empty set (0.00 sec)
```

6. Delete some records from the `test/articles` table.

```
mysql> DELETE FROM test.articles WHERE id < 4;
```

7. Query the `INNODB_FT_DELETED` table. This table records rows that are deleted from the `FULLTEXT` index. To avoid expensive index reorganization during DML operations, information about newly deleted records is stored separately, filtered out of search results when you do a text search, and removed from the main search index when you run `OPTIMIZE TABLE`.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_DELETED;
+--------+
| DOC_ID |
+--------+
```
8. Run `OPTIMIZE TABLE` to remove the deleted records.

```sql
mysql> OPTIMIZE TABLE articles;
```

<table>
<thead>
<tr>
<th>Table</th>
<th>Op</th>
<th>Msg_type</th>
<th>Msg_text</th>
</tr>
</thead>
<tbody>
<tr>
<td>test.articles</td>
<td>optimize</td>
<td>status</td>
<td>OK</td>
</tr>
</tbody>
</table>

The `INNODB_FT_DELETED` table should now be empty.

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_DELETED;
Empty set (0.00 sec)
```

9. Query the `INNODB_FT_CONFIG` table. This table contains metadata about the `FULLTEXT` index and related processing:

- **optimize_checkpoint_limit**: The number of seconds after which an `OPTIMIZE TABLE` run stops.
- **synced_doc_id**: The next DOC_ID to be issued.
- **stopword_table_name**: The database/table name for a user-defined stopword table. The `VALUE` column is empty if there is no user-defined stopword table.
- **use_stopword**: Indicates whether a stopword table is used, which is defined when the `FULLTEXT` index is created.

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_CONFIG;
```

<table>
<thead>
<tr>
<th>KEY</th>
<th>VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>optimize_checkpoint_limit</td>
<td>180</td>
</tr>
<tr>
<td>synced_doc_id</td>
<td>8</td>
</tr>
<tr>
<td>stopword_table_name</td>
<td></td>
</tr>
<tr>
<td>use_stopword</td>
<td>1</td>
</tr>
</tbody>
</table>

10. Disable `innodb_optimize_fulltext_only`, since it is intended to be enabled only temporarily:

```sql
mysql> SET GLOBAL innodb_optimize_fulltext_only=OFF;
```

15.15.5 InnoDB INFORMATION_SCHEMA Buffer Pool Tables

The InnoDB INFORMATION_SCHEMA buffer pool tables provide buffer pool status information and metadata about the pages within the InnoDB buffer pool.

The InnoDB INFORMATION_SCHEMA buffer pool tables include those listed below:

```sql
mysql> SHOW TABLES FROM INFORMATION_SCHEMA LIKE 'INNODB_BUFFER%';
```

<table>
<thead>
<tr>
<th>Tables in INFORMATION_SCHEMA (INNODB_BUFFER%)</th>
</tr>
</thead>
<tbody>
<tr>
<td>INNODB_BUFFER_PAGE_LRU</td>
</tr>
<tr>
<td>INNODB_BUFFER_PAGE</td>
</tr>
<tr>
<td>INNODB_BUFFER_POOL_STATS</td>
</tr>
</tbody>
</table>
InnoDB INFORMATION_SCHEMA Buffer Pool Tables

Table Overview

- **INNODB_BUFFER_PAGE**: Holds information about each page in the InnoDB buffer pool.
- **INNODB_BUFFER_PAGE_LRU**: Holds information about the pages in the InnoDB buffer pool, in particular how they are ordered in the LRU list that determines which pages to evict from the buffer pool when it becomes full. The **INNODB_BUFFER_PAGE_LRU** table has the same columns as the **INNODB_BUFFER_PAGE** table, except that the **INNODB_BUFFER_PAGE_LRU** table has an LRU_POSITION column instead of a BLOCK_ID column.
- **INNODB_BUFFER_POOL_STATS**: Provides buffer pool status information. Much of the same information is provided by SHOW ENGINE INNODB STATUS output, or may be obtained using InnoDB buffer pool server status variables.

**Warning**

Querying the INNODB_BUFFER_PAGE or INNODB_BUFFER_PAGE_LRU table can affect performance. Do not query these tables on a production system unless you are aware of the performance impact and have determined it to be acceptable. To avoid impacting performance on a production system, reproduce the issue you want to investigate and query buffer pool statistics on a test instance.

Example 15.6 Querying System Data in the INNODB_BUFFER_PAGE Table

This query provides an approximate count of pages that contain system data by excluding pages where the TABLE_NAME value is either NULL or includes a slash / or period . in the table name, which indicates a user-defined table.

```
mysql> SELECT COUNT(*) FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
    WHERE TABLE_NAME IS NULL OR (INSTR(TABLE_NAME, '/') = 0 AND INSTR(TABLE_NAME, '.') = 0);
```

```
+----------+
| COUNT(*) |
+----------+
|     1516 |
+----------+
```

This query returns the approximate number of pages that contain system data, the total number of buffer pool pages, and an approximate percentage of pages that contain system data.

```
mysql> SELECT
    (SELECT COUNT(*) FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
    WHERE TABLE_NAME IS NULL OR (INSTR(TABLE_NAME, '/') = 0 AND INSTR(TABLE_NAME, '.') = 0)) AS system_pages,
    (SELECT COUNT(*) FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
    ) AS total_pages,
    (SELECT ROUND((system_pages/total_pages) * 100)) AS system_page_percentage;
```

```
+--------------+-------------+------------------------+
<table>
<thead>
<tr>
<th>system_pages</th>
<th>total_pages</th>
<th>system_page_percentage</th>
</tr>
</thead>
<tbody>
<tr>
<td>295</td>
<td>8192</td>
<td>4</td>
</tr>
</tbody>
</table>
+--------------+-------------+------------------------+
```

The type of system data in the buffer pool can be determined by querying the PAGE_TYPE value. For example, the following query returns eight distinct PAGE_TYPE values among the pages that contain system data:

```
mysql> SELECT DISTINCT PAGE_TYPE FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
    WHERE TABLE_NAME IS NULL OR (INSTR(TABLE_NAME, '/') = 0 AND INSTR(TABLE_NAME, '.') = 0);
```

3599
Example 15.7 Querying User Data in the INNODB_BUFFER_PAGE Table

This query provides an approximate count of pages containing user data by counting pages where the `TABLE_NAME` value is **NOT NULL** and **NOT LIKE 'INNODB_TABLES%'**.

```sql
mysql> SELECT COUNT(*) FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
    WHERE TABLE_NAME IS NOT NULL AND TABLE_NAME NOT LIKE 'INNODB_TABLES%';
+----------+
| COUNT(*) |
+----------+
|     7897 |
+----------+
```

This query returns the approximate number of pages that contain user data, the total number of buffer pool pages, and an approximate percentage of pages that contain user data.

```sql
mysql> SELECT
    (SELECT COUNT(*) FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
        WHERE TABLE_NAME IS NOT NULL AND (INSTR(TABLE_NAME, '/') > 0 OR INSTR(TABLE_NAME, '.') > 0)) AS user_pages,
    (SELECT COUNT(*)
        FROM information_schema.INNODB_BUFFER_PAGE) AS total_pages,
    (SELECT ROUND((user_pages/total_pages) * 100)) AS user_page_percentage;
+------------+-------------+----------------------+
| user_pages | total_pages | user_page_percentage |
+------------+-------------+----------------------+
|    7897    |     8192    |                    96 |
+------------+-------------+----------------------+
```

This query identifies user-defined tables with pages in the buffer pool:

```sql
mysql> SELECT DISTINCT TABLE_NAME FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
    WHERE TABLE_NAME IS NOT NULL AND (INSTR(TABLE_NAME, '/') > 0 OR INSTR(TABLE_NAME, '.') > 0)
    AND TABLE_NAME NOT LIKE `mysql`.`innodb_%';
+-------------------------+
| TABLE_NAME              |
+-------------------------+
| `employees`.`salaries`  |
| `employees`.`employees` |
+-------------------------+
```

Example 15.8 Querying Index Data in the INNODB_BUFFER_PAGE Table

For information about index pages, query the `INDEX_NAME` column using the name of the index. For example, the following query returns the number of pages and total data size of pages for the `emp_no` index that is defined on the `employees.salaries` table:

```sql
mysql> SELECT INDEX_NAME, COUNT(*) AS Pages,
    ROUND(SUM(IF(COMPRESSED_SIZE = 0, @@GLOBAL.innodb_page_size, COMPRESSED_SIZE))/1024/1024) AS 'Total Data (MB)'
    FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
```

3600
InnoDB INFORMATION_SCHEMA Buffer Pool Tables

```
WHERE INDEX_NAME='emp_no' AND TABLE_NAME = '"employees"."salaries"';
+------------+-------+-----------------+
| INDEX_NAME | Pages | Total Data (MB) |
+------------+-------+-----------------+
| emp_no     | 1609  |              25 |
+------------+-------+-----------------+
```

This query returns the number of pages and total data size of pages for all indexes defined on the employees.salaries table:

```sql
mysql> SELECT INDEX_NAME, COUNT(*) AS Pages,
ROUND(SUM(IF(COMPRESSED_SIZE = 0, @@GLOBAL.innodb_page_size, COMPRESSED_SIZE))/1024/1024) AS 'Total Data (MB)
FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
WHERE TABLE_NAME = '"employees"."salaries"'
GROUP BY INDEX_NAME;
```

```
| INDEX_NAME | Pages | Total Data (MB) |
|------------+-------+-----------------+
| emp_no     | 1608  |              25 |
| PRIMARY    | 6086  |              95 |
+------------+-------+-----------------+
```

Example 15.9 Querying LRU_POSITION Data in the INNODB_BUFFER_PAGE_LRU Table

The INNODB_BUFFER_PAGE_LRU table holds information about the pages in the InnoDB buffer pool, in particular how they are ordered that determines which pages to evict from the buffer pool when it becomes full. The definition for this page is the same as for INNODB_BUFFER_PAGE, except this table has an LRU_POSITION column instead of a BLOCK_ID column.

This query counts the number of positions at a specific location in the LRU list occupied by pages of the employees.employees table.

```sql
mysql> SELECT COUNT(LRU_POSITION) FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE_LRU
WHERE TABLE_NAME = '"employees"."employees"' AND LRU_POSITION < 3072;
+---------------------+
| COUNT(LRU_POSITION) |
+---------------------+
|                 548 |
+---------------------+
```

Example 15.10 Querying the INNODB_BUFFER_POOL_STATS Table

The INNODB_BUFFER_POOL_STATS table provides information similar to SHOW ENGINE INNODB STATUS and InnoDB buffer pool status variables.

```sql
mysql> SELECT * FROM information_schema.INNODB_BUFFER_POOL_STATS \G
```

```
*************************** 1. row ***************************
POOL_ID: 0
POOL_SIZE: 8192
FREE_BUFFERS: 1

</tbody>
</table>

For comparison, **SHOW ENGINE INNODB STATUS** output and **InnoDB buffer pool status variable output** is shown below, based on the same data set.

For more information about **SHOW ENGINE INNODB STATUS** output, see Section 15.17.3, "InnoDB Standard Monitor and Lock Monitor Output".

```
mysql> SHOW ENGINE INNODB STATUS \G
```

```
<table>
<thead>
<tr>
<th>Variable_name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Innodb_buffer_pool_dump_status</td>
<td>not started</td>

<td>33069332</td>
</tr>
</tbody>
</table>
```
15.15.6 InnoDB INFORMATION_SCHEMA Metrics Table

The INNODB_METRICS table provides information about InnoDB performance and resource-related counters.

INNODB_METRICS table columns are shown below. For column descriptions, see Section 26.4.21, “The INFORMATION_SCHEMA INNODB_METRICS Table”.

```
| Innodb_buffer_pool_reads              | 558         |
| Innodb_buffer_pool_wait_free          | 0           |
| Innodb_buffer_pool_write_requests     | 11985961    |
```

Enabling, Disabling, and Resetting Counters

You can enable, disable, and reset counters using the following variables:

- **innodb_monitor_enable**: Enables counters.
  
  SET GLOBAL innodb_monitor_enable = [counter-name|module_name|pattern|all];

- **innodb_monitor_disable**: Disables counters.
  
  SET GLOBAL innodb_monitor_disable = [counter-name|module_name|pattern|all];

- **innodb_monitor_reset**: Resets counter values to zero.
  
  SET GLOBAL innodb_monitor_reset = [counter-name|module_name|pattern|all];

- **innodb_monitor_reset_all**: Resets all counter values. A counter must be disabled before using `innodb_monitor_reset_all`.
  
  SET GLOBAL innodb_monitor_reset_all = [counter-name|module_name|pattern|all];

Counters and counter modules can also be enabled at startup using the MySQL server configuration file. For example, to enable the log module, `metadata_table_handles_opened` and `metadata_table_handles_closed` counters, enter the following line in the [mysqld] section of the MySQL server configuration file.

```
[mysqld]
innodb_monitor_enable = log,metadata_table_handles_opened,metadata_table_handles_closed
```

When enabling multiple counters or modules in a configuration file, specify the `innodb_monitor_enable` variable followed by counter and module names separated by a comma, as shown above. Only the
The `innodb_monitor_enable` variable can be used in a configuration file. The `innodb_monitor_disable` and `innodb_monitor_reset` variables are supported on the command line only.

**Note**

Because each counter adds a degree of runtime overhead, use counters conservatively on production servers to diagnose specific issues or monitor specific functionality. A test or development server is recommended for more extensive use of counters.

### Counters

The list of available counters is subject to change. Query the Information Schema `INNODB_METRICS` table for counters available in your MySQL server version.

The counters enabled by default correspond to those shown in `SHOW ENGINE INNODB STATUS` output. Counters shown in `SHOW ENGINE INNODB STATUS` output are always enabled at a system level but can be disable for the `INNODB_METRICS` table. Counter status is not persistent. Unless configured otherwise, counters revert to their default enabled or disabled status when the server is restarted.

If you run programs that would be affected by the addition or removal of counters, it is recommended that you review the releases notes and query the `INNODB_METRICS` table to identify those changes as part of your upgrade process.

```sql
mysql> SELECT name, subsystem, status FROM INFORMATION_SCHEMA.INNODB_METRICS ORDER BY NAME;
+---------------------------------------------+---------------------+----------+
| name                                        | subsystem           | status   |
+---------------------------------------------+---------------------+----------+
| adaptive_hash_pages_added                   | adaptive_hash_index | disabled |
| adaptive_hash_pages_removed                 | adaptive_hash_index | disabled |
| adaptive_hash_rows_added                    | adaptive_hash_index | disabled |
| adaptive_hash_rows_deleted_no_hash_entry    | adaptive_hash_index | disabled |
| adaptive_hash_rows_removed                  | adaptive_hash_index | disabled |
| adaptive_hash_searches                      | adaptive_hash_index | enabled  |
| adaptive_hash_searches_btree                | adaptive_hash_index | enabled  |
| buffer_data_reads                           | buffer              | enabled  |
| buffer_data_written                         | buffer              | enabled  |
| buffer_flush_adaptive                       | buffer              | disabled |
| buffer_flush_adaptive_avg_pass              | buffer              | disabled |
| buffer_flush_adaptive_avg_time_est          | buffer              | disabled |
| buffer_flush_adaptive_avg_time_slot         | buffer              | disabled |
| buffer_flush_adaptive_avg_time_thread       | buffer              | disabled |
| buffer_flush_adaptive_avg_time_thread       | buffer              | disabled |
| buffer_flush_adaptive_pages                 | buffer              | disabled |
| buffer_flush_adaptive_total_pages           | buffer              | disabled |
| buffer_flush_avg_page_rate                  | buffer              | disabled |
| buffer_flush_avg_pass                       | buffer              | disabled |
| buffer_flush_avg_time                       | buffer              | disabled |
| buffer_flush_background                     | buffer              | disabled |
| buffer_flush_background_pages               | buffer              | disabled |
| buffer_flush_background_total_pages         | buffer              | disabled |
| buffer_flush_batches                        | buffer              | disabled |
| buffer_flush_batch_num_scan                 | buffer              | disabled |
| buffer_flush_batch_pages                    | buffer              | disabled |
| buffer_flush_batch_scanned                  | buffer              | disabled |
| buffer_flush_batch_scanned_per_call         | buffer              | disabled |
| buffer_flush_batch_total_pages              | buffer              | disabled |
| buffer_flush_lsn_avg_rate                   | buffer              | disabled |
| buffer_flush_neighbor                       | buffer              | disabled |
| buffer_flush_neighbor_pages                 | buffer              | disabled |
| buffer_flush_neighbor_total_pages           | buffer              | disabled |
| buffer_flush_n_to_flush_by_age              | buffer              | disabled |
| buffer_flush_n_to_flush_by_dirty_page       | buffer              | disabled |
| buffer_flush_n_to_flush_requested           | buffer              | disabled |
| buffer_flush_n_to_flush_requested           | buffer              | disabled |
+---------------------------------------------+---------------------+----------+
```

314 rows in set (0.00 sec)

Counter Modules

Each counter is associated with a particular module. Module names can be used to enable, disable, or reset all counters for a particular subsystem. For example, use `module_dml` to enable all counters associated with the `dml` subsystem.

```
mysql> SET GLOBAL innodb_monitor_enable = module_dml;
```

```
mysql> SELECT name, subsystem, status FROM INFORMATION_SCHEMA.INNODB_METRICS
    WHERE subsystem = 'dml';
```

<table>
<thead>
<tr>
<th>name</th>
<th>subsystem</th>
<th>status</th>
</tr>
</thead>
<tbody>
<tr>
<td>dml_reads</td>
<td>dml</td>
<td>enabled</td>
</tr>
<tr>
<td>dml_inserts</td>
<td>dml</td>
<td>enabled</td>
</tr>
<tr>
<td>dml_deletes</td>
<td>dml</td>
<td>enabled</td>
</tr>
<tr>
<td>dml_updates</td>
<td>dml</td>
<td>enabled</td>
</tr>
</tbody>
</table>

Module names can be used with `innodb_monitor_enable` and related variables.

Module names and corresponding `SUBSYSTEM` names are listed below.

- `module_adaptive_hash` (subsystem = `adaptive_hash_index`)
- `module_buffer` (subsystem = `buffer`)
- `module_buffer_page` (subsystem = `buffer_page_io`)
- `module_compress` (subsystem = `compression`)
- `module_ddl` (subsystem = `ddl`)
- `module_dml` (subsystem = `dml`)
- `module_file` (subsystem = `file_system`)
- `module_ibuf_system` (subsystem = `change_buffer`)
- `module_icp` (subsystem = `icp`)
- `module_index` (subsystem = `index`)
- `module_innodb` (subsystem = `innodb`)
- `module_lock` (subsystem = `lock`)
- `module_log` (subsystem = `log`)
- `module_metadata` (subsystem = `metadata`
Example 15.11 Working with INNODB_METRICS Table Counters

This example demonstrates enabling, disabling, and resetting a counter, and querying counter data in the INNODB_METRICS table.

1. Create a simple InnoDB table:

   ```sql
   mysql> USE test;
   Database changed
   
   mysql> CREATE TABLE t1 (c1 INT) ENGINE=INNODB;
   Query OK, 0 rows affected (0.02 sec)
   ```

2. Enable the dml_inserts counter.

   ```sql
   mysql> SET GLOBAL innodb_monitor_enable = dml_inserts;
   Query OK, 0 rows affected (0.01 sec)
   ```

   A description of the dml_inserts counter can be found in the COMMENT column of the INNODB_METRICS table:

   ```sql
   mysql> SELECT NAME, COMMENT FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME="dml_inserts";
   +-------------+-------------------------+
   | NAME        | COMMENT                 |
   +-------------+-------------------------+
   | dml_inserts | Number of rows inserted |
   +-------------+-------------------------+
   ```

3. Query the INNODB_METRICS table for the dml_inserts counter data. Because no DML operations have been performed, the counter values are zero or NULL. The TIME_ENABLED and TIME_ELAPSED values indicate when the counter was last enabled and how many seconds have elapsed since that time.

   ```sql
   mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME="dml_inserts" \G
   *************************** 1. row ***************************
   NAME: dml_inserts
   SUBSYSTEM: dml
   COUNT: 0
   MAX_COUNT: 0
   MIN_COUNT: NULL
   AVG_COUNT: 0
   COUNT_RESET: 0
   MAX_COUNT_RESET: 0
   MIN_COUNT_RESET: NULL
   AVG_COUNT_RESET: NULL
   TIME_ENABLED: 2014-12-04 14:18:28
   TIME_DISABLED: NULL
   TIME_ELAPSED: 28
   TIME_RESET: NULL
   STATUS: enabled
   TYPE: status_counter
   COMMENT: Number of rows inserted
   ```

4. Insert three rows of data into the table.

   ```sql
   mysql> INSERT INTO t1 values(1);
   ```
5. Query the INNODB_METRICS table again for the dml_inserts counter data. A number of counter values have now incremented including COUNT, MAX_COUNT, AVG_COUNT, and COUNT_RESET. Refer to the INNODB_METRICS table definition for descriptions of these values.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME="dml Inserts";
*************************** 1. row ***************************
NAME: dml inserts
SUBSYSTEM: dml
COUNT: 3
MAX_COUNT: 3
MIN_COUNT: NULL
AVG_COUNT: 0.046153846153846156
COUNT_RESET: 3
MAX_COUNT_RESET: 3
MIN_COUNT_RESET: NULL
AVG_COUNT_RESET: NULL
TIME_ENABLED: 2014-12-04 14:18:28
TIME_DISABLED: NULL
TIME_ELAPSED: 85
TIME_RESET: 2014-12-04 14:19:44
STATUS: enabled
TYPE: status_counter
COMMENT: Number of rows inserted
```

6. Reset the dml_inserts counter and query the INNODB_METRICS table again for the dml_inserts counter data. The %_RESET values that were reported previously, such as COUNT_RESET and MAX_RESET, are set back to zero. Values such as COUNT, MAX_COUNT, and AVG_COUNT, which cumulatively collect data from the time the counter is enabled, are unaffected by the reset.

```
mysql> SET GLOBAL innodb_monitor_reset = dml_inserts;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME="dml Inserts";
*************************** 1. row ***************************
NAME: dml inserts
SUBSYSTEM: dml
COUNT: 3
MAX_COUNT: 3
MIN_COUNT: NULL
AVG_COUNT: 0.03529411764705882
COUNT_RESET: 0
MAX_COUNT_RESET: 0
MIN_COUNT_RESET: NULL
AVG_COUNT_RESET: 0
TIME_ENABLED: 2014-12-04 14:18:28
TIME_DISABLED: NULL
TIME_ELAPSED: 85
TIME_RESET: 2014-12-04 14:19:44
STATUS: enabled
TYPE: status_counter
COMMENT: Number of rows inserted
```

7. To reset all counter values, you must first disable the counter. Disabling the counter sets the STATUS value to disabled.

```
mysql> SET GLOBAL innodb_monitor_disable = dml_inserts;
Query OK, 0 rows affected (0.00 sec)
```
**Note**

Wildcard match is supported for counter and module names. For example, instead of specifying the full `dml_inserts` counter name, you can specify `dml_i%`. You can also enable, disable, or reset multiple counters or modules at once using a wildcard match. For example, specify `dml_%` to enable, disable, or reset all counters that begin with `dml_`.

8. After the counter is disabled, you can reset all counter values using the `innodb_monitor_reset_all` option. All values are set to zero or NULL.

```sql
mysql> SET GLOBAL innodb_monitor_reset_all = dml Inserts;
Query OK, 0 rows affected (0.00 sec)
```

8.15.7 InnoDB INFORMATION_SCHEMA Temporary Table Info Table

`INNODB_TEMP_TABLE_INFO` provides information about user-created InnoDB temporary tables that are active in the InnoDB instance. It does not provide information about internal InnoDB temporary tables used by the optimizer.

```sql
mysql> SHOW TABLES FROM INFORMATION_SCHEMA LIKE 'INNODB_TEMP%';
+---------------------------------------------+
| Tables in INFORMATION_SCHEMA (INNODB_TEMP%) |
+---------------------------------------------+
```

3612
For the table definition, see Section 26.4.27, “The INFORMATION_SCHEMA INNODB_TEMP_TABLE_INFO Table”.

**Example 15.12 INNODB_TEMP_TABLE_INFO**

This example demonstrates characteristics of the INNODB_TEMP_TABLE_INFO table.

1. Create a simple InnoDB temporary table:

```sql
mysql> CREATE TEMPORARY TABLE t1 (c1 INT PRIMARY KEY) ENGINE=INNODB;
```

2. Query INNODB_TEMP_TABLE_INFO to view the temporary table metadata.

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_TEMP_TABLE_INFO;
```

```
  +-----------------------+-----------------------+---------+---------+
  | TABLE_ID: 194         | NAME: #sql7a79_1_0   | N_COLS: 4 | SPACE: 182 |
  +-----------------------+-----------------------+---------+---------+
```

The TABLE_ID is a unique identifier for the temporary table. The NAME column displays the system-generated name for the temporary table, which is prefixed with “#sql”. The number of columns (N_COLS) is 4 rather than 1 because InnoDB always creates three hidden table columns (DB_ROW_ID, DB_TRX_ID, and DB_ROLL_PTR).

3. Restart MySQL and query INNODB_TEMP_TABLE_INFO.

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_TEMP_TABLE_INFO;
```

An empty set is returned because INNODB_TEMP_TABLE_INFO and its data are not persisted to disk when the server is shut down.

4. Create a new temporary table.

```sql
mysql> CREATE TEMPORARY TABLE t1 (c1 INT PRIMARY KEY) ENGINE=INNODB;
```

5. Query INNODB_TEMP_TABLE_INFO to view the temporary table metadata.

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_TEMP_TABLE_INFO;
```

```
  +-----------------------+-----------------------+---------+---------+
  | TABLE_ID: 196         | NAME: #sql7b0e_1_0   | N_COLS: 4 | SPACE: 184 |
  +-----------------------+-----------------------+---------+---------+
```

The SPACE ID may be different because it is dynamically generated when the server is started.

**15.15.8 Retrieving InnoDB Tablespace Metadata from INFORMATION_SCHEMA.FILES**

The Information Schema FILES table provides metadata about all InnoDB tablespace types including file-per-table tablespaces, general tablespaces, the system tablespace, temporary table tablespaces, and undo tablespaces (if present).

This section provides InnoDB-specific usage examples. For more information about data provided by the Information Schema FILES table, see Section 26.3.15, “The INFORMATION_SCHEMA FILES Table”.
Note

The `INNODB_TABLESPACES` and `INNODB_DATAFILES` tables also provide metadata about InnoDB tablespaces, but data is limited to file-per-table, general, and undo tablespaces.

This query retrieves metadata about the InnoDB system tablespace from fields of the Information Schema `FILES` table that are pertinent to InnoDB tablespaces. `FILES` columns that are not relevant to InnoDB always return NULL, and are excluded from the query.

```sql
mysql> SELECT FILE_ID, FILE_NAME, FILE_TYPE, TABLESPACE_NAME, FREE_EXTENTS,
            TOTAL_EXTENTS, EXTENT_SIZE, INITIAL_SIZE, MAXIMUM_SIZE, AUTOEXTEND_SIZE, DATA_FREE, STATUS, ENGINE
FROM INFORMATION_SCHEMA.FILES WHERE TABLESPACE_NAME LIKE 'innodb_system';
```

<table>
<thead>
<tr>
<th>FILE_ID</th>
<th>FILE_NAME</th>
<th>FILE_TYPE</th>
<th>TABLESPACE_NAME</th>
<th>FREE_EXTENTS</th>
<th>TOTAL_EXTENTS</th>
<th>EXTENT_SIZE</th>
<th>INITIAL_SIZE</th>
<th>MAXIMUM_SIZE</th>
<th>AUTOEXTEND_SIZE</th>
<th>DATA_FREE</th>
<th>STATUS</th>
<th>ENGINE</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>./ibdata1</td>
<td>TABLESPACE</td>
<td>innodb_system</td>
<td>0</td>
<td>12</td>
<td>1048576</td>
<td>12582912</td>
<td>NULL</td>
<td>67108864</td>
<td>4194304</td>
<td>NORMAL</td>
<td></td>
</tr>
</tbody>
</table>

This query retrieves the `FILE_ID` (equivalent to the space ID) and the `FILE_NAME` (which includes path information) for InnoDB file-per-table and general tablespaces. File-per-table and general tablespaces have a `.ibd` file extension.

```sql
mysql> SELECT FILE_ID, FILE_NAME FROM INFORMATION_SCHEMA.FILES
WHERE FILE_NAME LIKE '%.ibd%'
ORDER BY FILE_ID;
```

<table>
<thead>
<tr>
<th>FILE_ID</th>
<th>FILE_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>./mysql/plugin.ibd</td>
</tr>
<tr>
<td>3</td>
<td>./mysql/servers.ibd</td>
</tr>
<tr>
<td>4</td>
<td>./mysql/help_topic.ibd</td>
</tr>
<tr>
<td>5</td>
<td>./mysql/help_category.ibd</td>
</tr>
<tr>
<td>6</td>
<td>./mysql/help_relation.ibd</td>
</tr>
<tr>
<td>7</td>
<td>./mysql/help_keyword.ibd</td>
</tr>
<tr>
<td>8</td>
<td>./mysql/time_zone_name.ibd</td>
</tr>
<tr>
<td>9</td>
<td>./mysql/time_zone.ibd</td>
</tr>
<tr>
<td>10</td>
<td>./mysql/time_zone_transition.ibd</td>
</tr>
<tr>
<td>11</td>
<td>./mysql/time_zone_transition_type.ibd</td>
</tr>
<tr>
<td>12</td>
<td>./mysql/time_zone_leap_second.ibd</td>
</tr>
<tr>
<td>13</td>
<td>./mysql/innodb_table_stats.ibd</td>
</tr>
<tr>
<td>14</td>
<td>./mysql/innodb_index_stats.ibd</td>
</tr>
<tr>
<td>15</td>
<td>./mysql/slave_relay_log_info.ibd</td>
</tr>
<tr>
<td>16</td>
<td>./mysql/slave_master_info.ibd</td>
</tr>
<tr>
<td>17</td>
<td>./mysql/slave_worker_info.ibd</td>
</tr>
<tr>
<td>18</td>
<td>./mysql/gtid_executed.ibd</td>
</tr>
<tr>
<td>19</td>
<td>./mysql/server_cost.ibd</td>
</tr>
<tr>
<td>20</td>
<td>./mysql/engine_cost.ibd</td>
</tr>
<tr>
<td>21</td>
<td>./sys/sys_config.ibd</td>
</tr>
<tr>
<td>22</td>
<td>./test/t1.ibd</td>
</tr>
<tr>
<td>23</td>
<td>./test/t2.ibd</td>
</tr>
<tr>
<td>24</td>
<td>./home/user/test/test/t2.ibd</td>
</tr>
</tbody>
</table>

This query retrieves the `FILE_ID` and `FILE_NAME` for the InnoDB global temporary tablespace. Global temporary tablespace file names are prefixed by `ibtmp`.

```sql
mysql> SELECT FILE_ID, FILE_NAME FROM INFORMATION_SCHEMA.FILES
WHERE FILE_NAME LIKE 'ibtmp%'
```

<table>
<thead>
<tr>
<th>FILE_ID</th>
<th>FILE_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>3614</td>
<td></td>
</tr>
</tbody>
</table>
WHERE FILE_NAME LIKE '%ibtmp%';

+---------+-----------+
| FILE_ID | FILE_NAME |
+---------+-----------+
| 22      | ./ibtmp1  |
+---------+-----------+

Similarly, InnoDB undo tablespace file names are prefixed by `undo`. The following query returns the FILE_ID and FILE_NAME for InnoDB undo tablespaces.

```
mysql> SELECT FILE_ID, FILE_NAME FROM INFORMATION_SCHEMA.FILES
 WHERE FILE_NAME LIKE '%undo%';
```

### 15.16 InnoDB Integration with MySQL Performance Schema

This section provides a brief introduction to InnoDB integration with Performance Schema. For comprehensive Performance Schema documentation, see Chapter 27, *MySQL Performance Schema*.

You can profile certain internal InnoDB operations using the MySQL Performance Schema feature. This type of tuning is primarily for expert users who evaluate optimization strategies to overcome performance bottlenecks. DBAs can also use this feature for capacity planning, to see whether their typical workload encounters any performance bottlenecks with a particular combination of CPU, RAM, and disk storage; and if so, to judge whether performance can be improved by increasing the capacity of some part of the system.

To use this feature to examine InnoDB performance:

- You must be generally familiar with how to use the Performance Schema feature. For example, you should know how enable instruments and consumers, and how to query `performance_schema` tables to retrieve data. For an introductory overview, see Section 27.1, “Performance Schema Quick Start”.

- You should be familiar with Performance Schema instruments that are available for InnoDB. To view InnoDB-related instruments, you can query the `setup_instruments` table for instrument names that contain 'innodb'.

```
mysql> SELECT *
 FROM performance_schema.setup_instruments
 WHERE NAME LIKE '%innodb%';

+-------------------------------------------------------------------+---------+-------+
| NAME                                                        | ENABLED | TIMED |
|-------------------------------------------------------------------+---------+-------+
| wait/synch/mutex/innodb/commit_cond_mutex                       | NO      | NO    |
| wait/synch/mutex/innodb/innobase_share_mutex                     | NO      | NO    |
| wait/synch/mutex/innodb/autoinc_mutex                            | NO      | NO    |
| wait/synch/mutex/innodb/buf_pool_mutex                           | NO      | NO    |
| wait/synch/mutex/innodb/buf_pool_zip_mutex                       | NO      | NO    |
| wait/synch/mutex/innodb/cache_last_read_mutex                    | NO      | NO    |
| wait/synch/mutex/innodb/dict_foreign_err_mutex                  | NO      | NO    |
| wait/synch/mutex/innodb/dict_sys_mutex                           | NO      | NO    |
| wait/synch/mutex/innodb/recalc_pool_mutex                        | NO      | NO    |
| ...                                                              |         |       |
| wait/io/file/innodb/innodb_data_file                             | YES     | YES   |
| wait/io/file/innodb/innodb_log_file                              | YES     | YES   |
| wait/io/file/innodb/innodb_temp_file                             | YES     | YES   |
| stage/innodb/alter table (end)                                   | YES     | YES   |
| stage/innodb/alter table (flush)                                 | YES     | YES   |
| stage/innodb/alter table (insert)                                | YES     | YES   |
| stage/innodb/alter table (log apply index)                       | YES     | YES   |
| stage/innodb/alter table (log apply table)                       | YES     | YES   |
| stage/innodb/alter table (merge sort)                            | YES     | YES   |
| stage/innodb/alter table (read PK and internal sort)             | YES     | YES   |
| stage/innodb/buffer pool load                                    | YES     | YES   |
```
For additional information about the instrumented InnoDB objects, you can query Performance Schema instances tables, which provide additional information about instrumented objects. Instance tables relevant to InnoDB include:

- The mutex_instances table
- The rwlock_instances table
- The cond_instances table
- The file_instances table

**Note**

Mutexes and RW-locks related to the InnoDB buffer pool are not included in this coverage; the same applies to the output of the SHOW ENGINE INNODB MUTEX command.

For example, to view information about instrumented InnoDB file objects seen by the Performance Schema when executing file I/O instrumentation, you might issue the following query:

```sql
mysql> SELECT *
FROM performance_schema.file_instances
WHERE EVENT_NAME LIKE '%innodb%'
G
*************************** 1. row ***************************
FILE_NAME: /home/dtprice/mysql-8.0/data/ibdata1
EVENT_NAME: wait/io/file/innodb/innodb_data_file
OPEN_COUNT: 3
*************************** 2. row ***************************
FILE_NAME: /home/dtprice/mysql-8.0/data/#ib_16384_0.dblwr
EVENT_NAME: wait/io/file/innodb/innodb_dblwr_file
OPEN_COUNT: 2
*************************** 3. row ***************************
FILE_NAME: /home/dtprice/mysql-8.0/data/#ib_16384_1.dblwr
EVENT_NAME: wait/io/file/mysql-8.0/innodb_dblwr_file
OPEN_COUNT: 2
...```

- You should be familiar with performance_schema tables that store InnoDB event data. Tables relevant to InnoDB-related events include:
  - The Wait Event tables, which store wait events.
  - The Summary tables, which provide aggregated information for terminated events over time. Summary tables include file I/O summary tables, which aggregate information about I/O operations.
  - Stage Event tables, which store event data for InnoDB ALTER TABLE and buffer pool load operations. For more information, see Section 15.16.1, "Monitoring ALTER TABLE Progress for

If you are only interested in InnoDB-related objects, use the clause WHERE EVENT_NAME LIKE '%innodb%' or WHERE NAME LIKE '%innodb%' (as required) when querying these tables.

15.16.1 Monitoring ALTER TABLE Progress for InnoDB Tables Using Performance Schema

You can monitor ALTER TABLE progress for InnoDB tables using Performance Schema.

There are seven stage events that represent different phases of ALTER TABLE. Each stage event reports a running total of WORK_COMPLETED and WORK_ESTIMATED for the overall ALTER TABLE operation as it progresses through its different phases. WORK_ESTIMATED is calculated using a formula that takes into account all of the work that ALTER TABLE performs, and may be revised during ALTER TABLE processing. WORK_COMPLETED and WORK_ESTIMATED values are an abstract representation of all of the work performed by ALTER TABLE.

In order of occurrence, ALTER TABLE stage events include:

• stage/innodb/alter table (read PK and internal sort): This stage is active when ALTER TABLE is in the reading-primary-key phase. It starts with WORK_COMPLETED=0 and WORK_ESTIMATED set to the estimated number of pages in the primary key. When the stage is completed, WORK_ESTIMATED is updated to the actual number of pages in the primary key.

• stage/innodb/alter table (merge sort): This stage is repeated for each index added by the ALTER TABLE operation.

• stage/innodb/alter table (insert): This stage is repeated for each index added by the ALTER TABLE operation.

• stage/innodb/alter table (log apply index): This stage includes the application of DML log generated while ALTER TABLE was running.

• stage/innodb/alter table (flush): Before this stage begins, WORK_ESTIMATED is updated with a more accurate estimate, based on the length of the flush list.

• stage/innodb/alter table (log apply table): This stage includes the application of concurrent DML log generated while ALTER TABLE was running. The duration of this phase depends on the extent of table changes. This phase is instant if no concurrent DML was run on the table.

• stage/innodb/alter table (end): Includes any remaining work that appeared after the flush phase, such as reapplying DML that was executed on the table while ALTER TABLE was running.

Note

InnoDB ALTER TABLE stage events do not currently account for the addition of spatial indexes.

ALTER TABLE Monitoring Example Using Performance Schema

The following example demonstrates how to enable the stage/innodb/alter table% stage event instruments and related consumer tables to monitor ALTER TABLE progress. For information about Performance Schema stage event instruments and related consumers, see Section 27.12.5, “Performance Schema Stage Event Tables”.

1. Enable the stage/innodb/alter% instruments:
2. Enable the stage event consumer tables, which include `events_stages_current`, `events_stages_history`, and `events_stages_history_long`.

3. Run an `ALTER TABLE` operation. In this example, a `middle_name` column is added to the employees table of the employees sample database.

4. Check the progress of the `ALTER TABLE` operation by querying the Performance Schema `events_stages_current` table. The stage event shown differs depending on which `ALTER TABLE` phase is currently in progress. The `WORK_COMPLETED` column shows the work completed. The `WORK_ESTIMATED` column provides an estimate of the remaining work.

5. As shown above, the `WORK_ESTIMATED` value was revised during `ALTER TABLE` processing. The estimated work after completion of the initial stage is 1213. When `ALTER TABLE` processing completed, `WORK_ESTIMATED` was set to the actual value, which is 1981.

### 15.16.2 Monitoring InnoDB Mutex Waits Using Performance Schema

A mutex is a synchronization mechanism used in the code to enforce that only one thread at a given time can have access to a common resource. When two or more threads executing in the server need to access...
the same resource, the threads compete against each other. The first thread to obtain a lock on the mutex causes the other threads to wait until the lock is released.

For InnoDB mutexes that are instrumented, mutex waits can be monitored using Performance Schema. Wait event data collected in Performance Schema tables can help identify mutexes with the most waits or the greatest total wait time, for example.

The following example demonstrates how to enable InnoDB mutex wait instruments, how to enable associated consumers, and how to query wait event data.

1. To view available InnoDB mutex wait instruments, query the Performance Schema setup_instruments table. All InnoDB mutex wait instruments are disabled by default.

```
mysql> SELECT * FROM performance_schema.setup_instruments WHERE NAME LIKE '%wait/synch/mutex/innodb%';
+---------------------------------------------------------+---------+-------+
<table>
<thead>
<tr>
<th>NAME</th>
<th>ENABLED</th>
<th>TIMED</th>
</tr>
</thead>
<tbody>
<tr>
<td>wait/synch/mutex/innodb/commit_cond_mutex</td>
<td>NO</td>
<td>NO</td>
</tr>
<tr>
<td>wait/synch/mutex/innodb/innobase_share_mutex</td>
<td>NO</td>
<td>NO</td>
</tr>
<tr>
<td>wait/synch/mutex/innodb/autoinc_mutex</td>
<td>NO</td>
<td>NO</td>
</tr>
<tr>
<td>wait/synch/mutex/innodb/autoinc_persisted_mutex</td>
<td>NO</td>
<td>NO</td>
</tr>
<tr>
<td>wait/synch/mutex/innodb/buf_pool_flush_state_mutex</td>
<td>NO</td>
<td>NO</td>
</tr>
<tr>
<td>wait/synch/mutex/innodb/buf_pool_LRU_list_mutex</td>
<td>NO</td>
<td>NO</td>
</tr>
<tr>
<td>wait/synch/mutex/innodb/buf_pool_free_list_mutex</td>
<td>NO</td>
<td>NO</td>
</tr>
<tr>
<td>wait/synch/mutex/innodb/buf_pool_zip_free_mutex</td>
<td>NO</td>
<td>NO</td>
</tr>
<tr>
<td>wait/synch/mutex/innodb/buf_pool_zip_hash_mutex</td>
<td>NO</td>
<td>NO</td>
</tr>
<tr>
<td>wait/synch/mutex/innodb/buf_pool_zip_mutex</td>
<td>NO</td>
<td>NO</td>
</tr>
<tr>
<td>wait/synch/mutex/innodb/cache_last_read_mutex</td>
<td>NO</td>
<td>NO</td>
</tr>
<tr>
<td>wait/synch/mutex/innodb/dict_foreign_err_mutex</td>
<td>NO</td>
<td>NO</td>
</tr>
<tr>
<td>wait/synch/mutex/innodb/dict_persist_dirty_tables_mutex</td>
<td>NO</td>
<td>NO</td>
</tr>
<tr>
<td>wait/synch/mutex/innodb/dict_sys_mutex</td>
<td>NO</td>
<td>NO</td>
</tr>
<tr>
<td>wait/synch/mutex/innodb/fts_bg_threads_mutex</td>
<td>NO</td>

2. Some InnoDB mutex instances are created at server startup and are only instrumented if the associated instrument is also enabled at server startup. To ensure that all InnoDB mutex instances are instrumented and enabled, add the following performance-schema-instrument rule to your MySQL configuration file:

```
performance-schema-instrument='wait/synch/mutex/innodb/%=ON'
```

If you do not require wait event data for all InnoDB mutexes, you can disable specific instruments by adding additional `performance-schema-instrument` rules to your MySQL configuration file. For example, to disable InnoDB mutex wait event instruments related to full-text search, add the following rule:

```
performance-schema-instrument='wait/synch/mutex/innodb/fts%=OFF'
```

**Note**

Rules with a longer prefix such as `wait/synch/mutex/innodb/fts%` take precedence over rules with shorter prefixes such as `wait/synch/mutex/innodb/%`.

After adding the `performance-schema-instrument` rules to your configuration file, restart the server. All the InnoDB mutexes except for those related to full text search are enabled. To verify, query the `setup_instruments` table. The `ENABLED` and `TIMED` columns should be set to `YES` for the instruments that you enabled.

```
mysql> SELECT * FROM performance_schema.setup_instruments
   WHERE NAME LIKE '%wait/synch/mutex/innodb%';
```

```
+--------------------------------------------------------------------------------+
<table>
<thead>
<tr>
<th>NAME</th>
<th>ENABLED</th>
<th>TIMED</th>
</tr>

</tr>
</tbody>
</table>
+--------------------------------------------------------------------------------+
49 rows in set (0.00 sec)
```

3. Enable wait event consumers by updating the `setup_consumers` table. Wait event consumers are disabled by default.

```
mysql> UPDATE performance_schema.setup_consumers
    SET enabled = 'YES'
    WHERE name like 'events_waits%';
Query OK, 3 rows affected (0.00 sec)
```
You can verify that wait event consumers are enabled by querying the `setup_consumers` table. The `events_waits_current`, `events_waits_history`, and `events_waits_history_long` consumers should be enabled.

```sql
mysql> SELECT * FROM performance_schema.setup_consumers;
+----------------------------------+---------+
| NAME                             | ENABLED |
+----------------------------------+---------+
| events_stages_current            | NO      |
| events_stages_history            | NO      |
| events_stages_history_long       | NO      |
| events_statements_current        | YES     |
| events_statements_history        | YES     |
| events_statements_history_long   | NO      |
| events_transactions_current      | YES     |
| events_transactions_history      | YES     |
| events_transactions_history_long | NO      |
| events_waits_current             | YES     |
| events_waits_history             | YES     |
| events_waits_history_long        | YES     |
| global_instrumentation           | YES     |
| thread_instrumentation           | YES     |
| statements_digest                | YES     |
+----------------------------------+---------+
15 rows in set (0.00 sec)
```

4. Once instruments and consumers are enabled, run the workload that you want to monitor. In this example, the `mysqlslap` load emulation client is used to simulate a workload.

```
$> ./mysqlslap --auto-generate-sql --concurrency=100 --iterations=10
    --number-of-queries=1000 --number-char-cols=6 --number-int-cols=6;
```

5. Query the wait event data. In this example, wait event data is queried from the `events_waits_summary_global_by_event_name` table which aggregates data found in the `events_waits_current`, `events_waits_history`, and `events_waits_history_long` tables. Data is summarized by event name (`EVENT_NAME`), which is the name of the instrument that produced the event. Summarized data includes:

- **COUNT_STAR**
  The number of summarized wait events.

- **SUM_TIMER_WAIT**
  The total wait time of the summarized timed wait events.

- **MIN_TIMER_WAIT**
  The minimum wait time of the summarized timed wait events.

- **AVG_TIMER_WAIT**
  The average wait time of the summarized timed wait events.
**MAX_TIMER_WAIT**

The maximum wait time of the summarized timed wait events.

The following query returns the instrument name (EVENT_NAME), the number of wait events (COUNT_STAR), and the total wait time for the events for that instrument (SUM_TIMER_WAIT). Because waits are timed in picoseconds (trillionths of a second) by default, wait times are divided by 1000000000 to show wait times in milliseconds. Data is presented in descending order by the number of summarized wait events (COUNT_STAR). You can adjust the ORDER BY clause to order the data by total wait time.

```sql
mysql> SELECT EVENT_NAME, COUNT_STAR, SUM_TIMER_WAIT/1000000000 SUM_TIMER_WAIT_MS
    FROM performance_schema.events_waits_summary_global_by_event_name
    WHERE SUM_TIMER_WAIT > 0 AND EVENT_NAME LIKE 'wait/synch/mutex/innodb/%'
    ORDER BY COUNT_STAR DESC;
```

</tbody>
</table>

**Note**

The preceding result set includes wait event data produced during the startup process. To exclude this data, you can truncate the `events_waits_summary_global_by_event_name` table immediately after startup and before running your workload. However, the truncate operation itself may produce a negligible amount wait event data.

```
mysql> TRUNCATE performance_schema.events_waits_summary_global_by_event_name;
```
InnoDB monitors provide information about the InnoDB internal state. This information is useful for performance tuning.

15.17.1 InnoDB Monitor Types

There are two types of InnoDB monitor:

- The standard InnoDB Monitor displays the following types of information:
  - Work done by the main background thread
  - Semaphore waits
  - Data about the most recent foreign key and deadlock errors
  - Lock waits for transactions
  - Table and record locks held by active transactions
  - Pending I/O operations and related statistics
  - Insert buffer and adaptive hash index statistics
  - Redo log data
  - Buffer pool statistics
  - Row operation data
- The InnoDB Lock Monitor prints additional lock information as part of the standard InnoDB Monitor output.

15.17.2 Enabling InnoDB Monitors

When InnoDB monitors are enabled for periodic output, InnoDB writes the output to mysqld server standard error output (stderr) every 15 seconds, approximately.

InnoDB sends the monitor output to stderr rather than to stdout or fixed-size memory buffers to avoid potential buffer overflows.

On Windows, stderr is directed to the default log file unless configured otherwise. If you want to direct the output to the console window rather than to the error log, start the server from a command prompt in a console window with the --console option. For more information, see Default Error Log Destination on Windows.

On Unix and Unix-like systems, stderr is typically directed to the terminal unless configured otherwise. For more information, see Default Error Log Destination on Unix and Unix-Like Systems.

InnoDB monitors should only be enabled when you actually want to see monitor information because output generation causes some performance decrement. Also, if monitor output is directed to the error log, the log may become quite large if you forget to disable the monitor later.

Note
To assist with troubleshooting, InnoDB temporarily enables standard InnoDB Monitor output under certain conditions. For more information, see Section 15.21, "InnoDB Troubleshooting".
Enabling InnoDB Monitors

InnoDB monitor output begins with a header containing a timestamp and the monitor name. For example:

```
=====================================  
2014-10-16 18:37:29 0x7fc2a95c1700 INNODB MONITOR OUTPUT  
=====================================  
```

The header for the standard InnoDB Monitor (INNODB MONITOR OUTPUT) is also used for the Lock Monitor because the latter produces the same output with the addition of extra lock information.

The innodb_status_output and innodb_status_output_locks system variables are used to enable the standard InnoDB Monitor and InnoDB Lock Monitor.

The PROCESS privilege is required to enable or disable InnoDB Monitors.

### Enabling the Standard InnoDB Monitor

Enable the standard InnoDB Monitor by setting the innodb_status_output system variable to ON.

```
SET GLOBAL innodb_status_output=ON;  
```

To disable the standard InnoDB Monitor, set innodb_status_output to OFF.

When you shut down the server, the innodb_status_output variable is set to the default OFF value.

### Enabling the InnoDB Lock Monitor

InnoDB Lock Monitor data is printed with the InnoDB Standard Monitor output. Both the InnoDB Standard Monitor and InnoDB Lock Monitor must be enabled to have InnoDB Lock Monitor data printed periodically.

To enable the InnoDB Lock Monitor, set the innodb_status_output_locks system variable to ON.

```
SET GLOBAL innodb_status_output=ON;  
SET GLOBAL innodb_status_output_locks=ON;  
```

To disable the InnoDB Lock Monitor, set innodb_status_output_locks to OFF. Set innodb_status_output to OFF to also disable the InnoDB Standard Monitor.

When you shut down the server, the innodb_status_output and innodb_status_output_locks variables are set to the default OFF value.

---

**Note**

To enable the InnoDB Lock Monitor for SHOW ENGINE INNODB STATUS output, you are only required to enable innodb_status_output_locks.

### Obtaining Standard InnoDB Monitor Output On Demand

As an alternative to enabling the standard InnoDB Monitor for periodic output, you can obtain standard InnoDB Monitor output on demand using the SHOW ENGINE INNODB STATUS SQL statement, which fetches the output to your client program. If you are using the mysql interactive client, the output is more readable if you replace the usual semicolon statement terminator with \G:

```
mysql> SHOW ENGINE INNODB STATUS\G  
```

SHOW ENGINE INNODB STATUS output also includes InnoDB Lock Monitor data if the InnoDB Lock Monitor is enabled.
Directing Standard InnoDB Monitor Output to a Status File

Standard InnoDB Monitor output can be enabled and directed to a status file by specifying the `--innodb-status-file` option at startup. When this option is used, InnoDB creates a file named `innodb_status.pid` in the data directory and writes output to it every 15 seconds, approximately.

InnoDB removes the status file when the server is shut down normally. If an abnormal shutdown occurs, the status file may have to be removed manually.

The `--innodb-status-file` option is intended for temporary use, as output generation can affect performance, and the `innodb_status.pid` file can become quite large over time.

15.17.3 InnoDB Standard Monitor and Lock Monitor Output

The Lock Monitor is the same as the Standard Monitor except that it includes additional lock information. Enabling either monitor for periodic output turns on the same output stream, but the stream includes extra information if the Lock Monitor is enabled. For example, if you enable the Standard Monitor and Lock Monitor, that turns on a single output stream. The stream includes extra lock information until you disable the Lock Monitor.

Standard Monitor output is limited to 1MB when produced using the `SHOW ENGINE INNODB STATUS` statement. This limit does not apply to output written to server standard error output (`stderr`).

Example Standard Monitor output:

```sql
mysql> SHOW ENGINE INNODB STATUS\G
*************************** 1. row ***************************
   Type: InnoDB
   Name:
   Status: 2018-04-12 15:14:08 0x7f971c063700 INNODB MONITOR OUTPUT

------------------------------

Standard Monitor Output Sections

For a description of each metric reported by the Standard Monitor, refer to the Metrics chapter in the Oracle Enterprise Manager for MySQL Database User's Guide.

• Status

This section shows the timestamp, the monitor name, and the number of seconds that per-second averages are based on. The number of seconds is the elapsed time between the current time and the last time InnoDB Monitor output was printed.

• BACKGROUND THREAD

The srv_master_thread lines shows work done by the main background thread.

• SEMAPHORES

This section reports threads waiting for a semaphore and statistics on how many times threads have needed a spin or a wait on a mutex or a rw-lock semaphore. A large number of threads waiting for semaphores may be a result of disk I/O, or contention problems inside InnoDB. Contention can be due to heavy parallelism of queries or problems in operating system thread scheduling. Setting the innodb_thread_concurrency system variable smaller than the default value might help in such situations. The Spin rounds per wait line shows the number of spinlock rounds per OS wait for a mutex.

Mutex metrics are reported by SHOW ENGINE INNODB MUTEX.

• LATEST FOREIGN KEY ERROR

This section provides information about the most recent foreign key constraint error. It is not present if no such error has occurred. The contents include the statement that failed as well as information about the constraint that failed and the referenced and referencing tables.

• LATEST DETECTED DEADLOCK

This section provides information about the most recent deadlock. It is not present if no deadlock has occurred. The contents show which transactions are involved, the statement each was attempting to
execute, the locks they have and need, and which transaction InnoDB decided to roll back to break the deadlock. The lock modes reported in this section are explained in Section 15.7.1, “InnoDB Locking”.

• **TRANSACTIONS**

If this section reports lock waits, your applications might have lock contention. The output can also help to trace the reasons for transaction deadlocks.

• **FILE I/O**

This section provides information about threads that InnoDB uses to perform various types of I/O. The first few of these are dedicated to general InnoDB processing. The contents also display information for pending I/O operations and statistics for I/O performance.

The number of these threads are controlled by the `innodb_read_io_threads` and`innodb_write_io_threads` parameters. See Section 15.14, “InnoDB Startup Options and System Variables”.

• **INSERT BUFFER AND ADAPTIVE HASH INDEX**

This section shows the status of the InnoDB insert buffer (also referred to as the change buffer) and the adaptive hash index.

For related information, see Section 15.5.2, “Change Buffer”, and Section 15.5.3, “Adaptive Hash Index”.

• **LOG**

This section displays information about the InnoDB log. The contents include the current log sequence number, how far the log has been flushed to disk, and the position at which InnoDB last took a checkpoint. (See Section 15.11.3, “InnoDB Checkpoints”.) The section also displays information about pending writes and write performance statistics.

• **BUFFER POOL AND MEMORY**

This section gives you statistics on pages read and written. You can calculate from these numbers how many data file I/O operations your queries currently are doing.

For buffer pool statistics descriptions, see Monitoring the Buffer Pool Using the InnoDB Standard Monitor. For additional information about the operation of the buffer pool, see Section 15.5.1, “Buffer Pool”.

• **ROW OPERATIONS**

This section shows what the main thread is doing, including the number and performance rate for each type of row operation.

## 15.18 InnoDB Backup and Recovery

This section covers topics related to InnoDB backup and recovery.

• For information about backup techniques applicable to InnoDB, see Section 15.18.1, “InnoDB Backup”.

• For information about point-in-time recovery, recovery from disk failure or corruption, and how InnoDB performs crash recovery, see Section 15.18.2, “InnoDB Recovery”.

### 15.18.1 InnoDB Backup
The key to safe database management is making regular backups. Depending on your data volume, number of MySQL servers, and database workload, you can use these backup techniques, alone or in combination: **hot backup** with **MySQL Enterprise Backup**; **cold backup** by copying files while the MySQL server is shut down; **logical backup** with **mysqldump** for smaller data volumes or to record the structure of schema objects. Hot and cold backups are **physical backups** that copy actual data files, which can be used directly by the **mysql** server for faster restore.

Using **MySQL Enterprise Backup** is the recommended method for backing up **InnoDB** data.

**Note**

**InnoDB** does not support databases that are restored using third-party backup tools.

**Hot Backups**

The **mysqlbackup** command, part of the MySQL Enterprise Backup component, lets you back up a running MySQL instance, including **InnoDB** tables, with minimal disruption to operations while producing a consistent snapshot of the database. When **mysqlbackup** is copying **InnoDB** tables, reads and writes to **InnoDB** tables can continue. MySQL Enterprise Backup can also create compressed backup files, and back up subsets of tables and databases. In conjunction with the MySQL binary log, users can perform point-in-time recovery. MySQL Enterprise Backup is part of the MySQL Enterprise subscription. For more details, see Section 30.2, “MySQL Enterprise Backup Overview”.

**Cold Backups**

If you can shut down the MySQL server, you can make a physical backup that consists of all files used by **InnoDB** to manage its tables. Use the following procedure:

1. Perform a slow shutdown of the MySQL server and make sure that it stops without errors.
2. Copy all **InnoDB** data files (**ibdata** files and **.ibd** files) into a safe place.
3. Copy all **InnoDB** redo log files (**#ib_redoN** files in MySQL 8.0.30 and higher or **ib_logfile** files in earlier releases) to a safe place.
4. Copy your **my.cnf** configuration file or files to a safe place.

**Logical Backups Using mysqldump**

In addition to physical backups, it is recommended that you regularly create logical backups by dumping your tables using **mysqldump**. A binary file might be corrupted without you noticing it. Dumped tables are stored into text files that are human-readable, so spotting table corruption becomes easier. Also, because the format is simpler, the chance for serious data corruption is smaller. **mysqldump** also has a **--single-transaction** option for making a consistent snapshot without locking out other clients. See Section 7.3.1, “Establishing a Backup Policy”.

Replication works with **InnoDB** tables, so you can use MySQL replication capabilities to keep a copy of your database at database sites requiring high availability. See Section 15.19, “InnoDB and MySQL Replication”.

**15.18.2 InnoDB Recovery**

This section describes **InnoDB** recovery. Topics include:
InnoDB Recovery

- Point-in-Time Recovery
- Recovery from Data Corruption or Disk Failure
- InnoDB Crash Recovery
- Tablespace Discovery During Crash Recovery

**Point-in-Time Recovery**

To recover an InnoDB database to the present from the time at which the physical backup was made, you must run MySQL server with binary logging enabled, even before taking the backup. To achieve point-in-time recovery after restoring a backup, you can apply changes from the binary log that occurred after the backup was made. See Section 7.5, “Point-in-Time (Incremental) Recovery”.

**Recovery from Data Corruption or Disk Failure**

If your database becomes corrupted or disk failure occurs, you must perform the recovery using a backup. In the case of corruption, first find a backup that is not corrupted. After restoring the base backup, do a point-in-time recovery from the binary log files using `mysqlbinlog` and `mysql` to restore the changes that occurred after the backup was made.

In some cases of database corruption, it is enough to dump, drop, and re-create one or a few corrupt tables. You can use the `CHECK TABLE` statement to check whether a table is corrupt, although `CHECK TABLE` naturally cannot detect every possible kind of corruption.

In some cases, apparent database page corruption is actually due to the operating system corrupting its own file cache, and the data on disk may be okay. It is best to try restarting the computer first. Doing so may eliminate errors that appeared to be database page corruption. If MySQL still has trouble starting because of InnoDB consistency problems, see Section 15.21.3, “Forcing InnoDB Recovery” for steps to start the instance in recovery mode, which permits you to dump the data.

**InnoDB Crash Recovery**

To recover from an unexpected MySQL server exit, the only requirement is to restart the MySQL server. InnoDB automatically checks the logs and performs a roll-forward of the database to the present. InnoDB automatically rolls back uncommitted transactions that were present at the time of the crash.

InnoDB crash recovery consists of several steps:

- **Tablespace discovery**
  
  Tablespace discovery is the process that InnoDB uses to identify tablespaces that require redo log application. See Tablespace Discovery During Crash Recovery.

- **Redo log application**

  Redo log application is performed during initialization, before accepting any connections. If all changes are flushed from the buffer pool to the tablespaces (ibdata* and *.ibd files) at the time of the shutdown or crash, redo log application is skipped. InnoDB also skips redo log application if redo log files are missing at startup.

  - The current maximum auto-increment counter value is written to the redo log each time the value changes, which makes it crash-safe. During recovery, InnoDB scans the redo log to collect counter value changes and applies the changes to the in-memory table object.
InnoDB Recovery

For more information about how InnoDB handles auto-increment values, see Section 15.6.1.6, “AUTO_INCREMENT Handling in InnoDB”, and InnoDB AUTO_INCREMENT Counter Initialization.

- When encountering index tree corruption, InnoDB writes a corruption flag to the redo log, which makes the corruption flag crash-safe. InnoDB also writes in-memory corruption flag data to an engine-private system table on each checkpoint. During recovery, InnoDB reads corruption flags from both locations and merges results before marking in-memory table and index objects as corrupt.

- Removing redo logs to speed up recovery is not recommended, even if some data loss is acceptable. Removing redo logs should only be considered after a clean shutdown, with innodb_fast_shutdown set to 0 or 1.

- Roll back of incomplete transactions

  Incomplete transactions are any transactions that were active at the time of unexpected exit or fast shutdown. The time it takes to roll back an incomplete transaction can be three or four times the amount of time a transaction is active before it is interrupted, depending on server load.

  You cannot cancel transactions that are being rolled back. In extreme cases, when rolling back transactions is expected to take an exceptionally long time, it may be faster to start InnoDB with an innodb_force_recovery setting of 3 or greater. See Section 15.21.3, “Forcing InnoDB Recovery”.

- Change buffer merge

  Applying changes from the change buffer (part of the system tablespace) to leaf pages of secondary indexes, as the index pages are read to the buffer pool.

- Purge

  Deleting delete-marked records that are no longer visible to active transactions.

The steps that follow redo log application do not depend on the redo log (other than for logging the writes) and are performed in parallel with normal processing. Of these, only rollback of incomplete transactions is special to crash recovery. The insert buffer merge and the purge are performed during normal processing.

After redo log application, InnoDB attempts to accept connections as early as possible, to reduce downtime. As part of crash recovery, InnoDB rolls back transactions that were not committed or in XA PREPARE state when the server exited. The rollback is performed by a background thread, executed in parallel with transactions from new connections. Until the rollback operation is completed, new connections may encounter locking conflicts with recovered transactions.

In most situations, even if the MySQL server was killed unexpectedly in the middle of heavy activity, the recovery process happens automatically and no action is required of the DBA. If a hardware failure or severe system error corrupted InnoDB data, MySQL might refuse to start. In this case, see Section 15.21.3, “Forcing InnoDB Recovery”.

For information about the binary log and InnoDB crash recovery, see Section 5.4.4, “The Binary Log”.

Tablespace Discovery During Crash Recovery

If, during recovery, InnoDB encounters redo logs written since the last checkpoint, the redo logs must be applied to affected tablespaces. The process that identifies affected tablespaces during recovery is referred to as tablespace discovery.

Tablespace discovery relies on the innodb_directories setting, which defines the directories to scan at startup for tablespace files. The innodb_directories default setting is NULL, but the directories
defined by `innodb_data_home_dir`, `innodb_undo_directory`, and `datadir` are always appended to the `innodb_directories` argument value when InnoDB builds a list of directories to scan at startup. These directories are appended regardless of whether an `innodb_directories` setting is specified explicitly. Tablespace files defined with an absolute path or that reside outside of the directories appended to the `innodb_directories` setting should be added to the `innodb_directories` setting. Recovery is terminated if any tablespace file referenced in a redo log has not been discovered previously.

15.19 InnoDB and MySQL Replication

It is possible to use replication in a way where the storage engine on the replica is not the same as the storage engine on the source. For example, you can replicate modifications to an InnoDB table on the source to a MyISAM table on the replica. For more information see, Section 17.4.4, “Using Replication with Different Source and Replica Storage Engines”.

For information about setting up a replica, see Section 17.1.2.6, “Setting Up Replicas”, and Section 17.1.2.5, “Choosing a Method for Data Snapshots”. To make a new replica without taking down the source or an existing replica, use the MySQL Enterprise Backup product.

Transactions that fail on the source do not affect replication. MySQL replication is based on the binary log where MySQL writes SQL statements that modify data. A transaction that fails (for example, because of a foreign key violation, or because it is rolled back) is not written to the binary log, so it is not sent to replicas. See Section 13.3.1, “START TRANSACTION, COMMIT, and ROLLBACK Statements”.

Replication and CASCADE. Cascading actions for InnoDB tables on the source are executed on the replica only if the tables sharing the foreign key relation use InnoDB on both the source and replica. This is true whether you are using statement-based or row-based replication. Suppose that you have started replication, and then create two tables on the source, where InnoDB is defined as the default storage engine, using the following `CREATE TABLE` statements:

```sql
CREATE TABLE fc1 (
    i INT PRIMARY KEY,
    j INT
);

CREATE TABLE fc2 (
    m INT PRIMARY KEY,
    n INT,
    FOREIGN KEY ni (n) REFERENCES fc1 (i)
    ON DELETE CASCADE
);
```

If the replica has MyISAM defined as the default storage engine, the same tables are created on the replica, but they use the MyISAM storage engine, and the `FOREIGN KEY` option is ignored. Now we insert some rows into the tables on the source:

```sql
source> INSERT INTO fc1 VALUES (1, 1), (2, 2);
Query OK, 2 rows affected (0.09 sec)
Records: 2  Duplicates: 0  Warnings: 0

source> INSERT INTO fc2 VALUES (1, 1), (2, 2), (3, 1);
Query OK, 3 rows affected (0.19 sec)
Records: 3  Duplicates: 0  Warnings: 0
```

At this point, on both the source and the replica, table `fc1` contains 2 rows, and table `fc2` contains 3 rows, as shown here:

```sql
source> SELECT * FROM fc1;
+---+------+
| i | j    |
+---+------+
```

3633
Now suppose that you perform the following `DELETE` statement on the source:

```sql
source> DELETE FROM fc1 WHERE i=1;
Query OK, 1 row affected (0.09 sec)
```

Due to the cascade, table `fc2` on the source now contains only 1 row:

```sql
source> SELECT * FROM fc2;
```

```
+---+---+
| m | n |
+---+---+
| 2 | 2 |
+---+---+
1 row in set (0.00 sec)
```

However, the cascade does not propagate on the replica because on the replica the `DELETE` for `fc1` deletes no rows from `fc2`. The replica’s copy of `fc2` still contains all of the rows that were originally inserted:

```sql
replica> SELECT * FROM fc2;
```

```
+---+---+
| m | n |
+---+---+
| 1 | 1 |
| 3 | 1 |
| 2 | 2 |
+---+---+
3 rows in set (0.00 sec)
```

This difference is due to the fact that the cascading deletes are handled internally by the InnoDB storage engine, which means that none of the changes are logged.
15.20 InnoDB memcached Plugin

Note

The InnoDB memcached plugin is deprecated as of MySQL 8.0.22; expect support for it to be removed in a future version of MySQL.

The InnoDB memcached plugin (daemon_memcached) provides an integrated memcached daemon that automatically stores and retrieves data from InnoDB tables, turning the MySQL server into a fast “key-value store”. Instead of formulating queries in SQL, you can use simple get, set, and incr operations that avoid the performance overhead associated with SQL parsing and constructing a query optimization plan. You can also access the same InnoDB tables through SQL for convenience, complex queries, bulk operations, and other strengths of traditional database software.

This “NoSQL-style” interface uses the memcached API to speed up database operations, letting InnoDB handle memory caching using its buffer pool mechanism. Data modified through memcached operations such as add, set, and incr are stored to disk, in InnoDB tables. The combination of memcached simplicity and InnoDB reliability and consistency provides users with the best of both worlds, as explained in Section 15.20.1, “Benefits of the InnoDB memcached Plugin”. For an architectural overview, see Section 15.20.2, “InnoDB memcached Architecture”.

15.20.1 Benefits of the InnoDB memcached Plugin

This section outlines advantages the daemon_memcached plugin. The combination of InnoDB tables and memcached offers advantages over using either by themselves.

- Direct access to the InnoDB storage engine avoids the parsing and planning overhead of SQL.
- Running memcached in the same process space as the MySQL server avoids the network overhead of passing requests back and forth.
- Data written using the memcached protocol is transparently written to an InnoDB table, without going through the MySQL SQL layer. You can control frequency of writes to achieve higher raw performance when updating non-critical data.
- Data requested through the memcached protocol is transparently queried from an InnoDB table, without going through the MySQL SQL layer.
- Subsequent requests for the same data is served from the InnoDB buffer pool. The buffer pool handles the in-memory caching. You can tune performance of data-intensive operations using InnoDB configuration options.
- Data can be unstructured or structured, depending on the type of application. You can create a new table for data, or use existing tables.
- InnoDB can handle composing and decomposing multiple column values into a single memcached item value, reducing the amount of string parsing and concatenation required in your application. For example, you can store the string value 2|4|6|8 in the memcached cache, and have InnoDB split the value based on a separator character, then store the result in four numeric columns.
- The transfer between memory and disk is handled automatically, simplifying application logic.
- Data is stored in a MySQL database to protect against crashes, outages, and corruption.
- You can access the underlying InnoDB table through SQL for reporting, analysis, ad hoc queries, bulk loading, multi-step transactional computations, set operations such as union and intersection, and other operations suited to the expressiveness and flexibility of SQL.
You can ensure high availability by using the `daemon_memcached` plugin on a source server in combination with MySQL replication.

The integration of `memcached` with MySQL provides a way to make in-memory data persistent, so you can use it for more significant kinds of data. You can use more `add`, `incr`, and similar write operations in your application without concern that data could be lost. You can stop and start the `memcached` server without losing updates made to cached data. To guard against unexpected outages, you can take advantage of `InnoDB` crash recovery, replication, and backup capabilities.

The way `InnoDB` does fast primary key lookups is a natural fit for `memcached` single-item queries. The direct, low-level database access path used by the `daemon_memcached` plugin is much more efficient for key-value lookups than equivalent SQL queries.

The serialization features of `memcached`, which can turn complex data structures, binary files, or even code blocks into storable strings, offer a simple way to get such objects into a database.

Because you can access the underlying data through SQL, you can produce reports, search or update across multiple keys, and call functions such as `AVG()` and `MAX()` on `memcached` data. All of these operations are expensive or complicated using `memcached` by itself.

You do not need to manually load data into `memcached` at startup. As particular keys are requested by an application, values are retrieved from the database automatically, and cached in memory using the `InnoDB` buffer pool.

Because `memcached` consumes relatively little CPU, and its memory footprint is easy to control, it can run comfortably alongside a MySQL instance on the same system.

Because data consistency is enforced by mechanisms used for regular `InnoDB` tables, you do not have to worry about stale `memcached` data or fallback logic to query the database in the case of a missing key.

### 15.20.2 InnoDB memcached Architecture

The `InnoDB memcached` plugin implements `memcached` as a MySQL plugin daemon that accesses the `InnoDB` storage engine directly, bypassing the MySQL SQL layer.

The following diagram illustrates how an application accesses data through the `daemon_memcached` plugin, compared with SQL.
Features of the `daemon_memcached` plugin:

- **memcached** as a daemon plugin of `mysqld`. Both `mysqld` and `memcached` run in the same process space, with very low latency access to data.

- Direct access to InnoDB tables, bypassing the SQL parser, the optimizer, and even the Handler API layer.

- Standard memcached protocols, including the text-based protocol and the binary protocol. The `daemon_memcached` plugin passes all 55 compatibility tests of the `memcapable` command.

- Multi-column support. You can map multiple columns into the “value” part of the key-value store, with column values delimited by a user-specified separator character.

- By default, the memcached protocol is used to read and write data directly to InnoDB, letting MySQL manage in-memory caching using the InnoDB buffer pool. The default settings represent a combination of high reliability and the fewest surprises for database applications. For example, default settings avoid uncommitted data on the database side, or stale data returned for memcached get requests.

- Advanced users can configure the system as a traditional memcached server, with all data cached only in the memcached engine (memory caching), or use a combination of the “memcached engine” (memory caching) and the InnoDB memcached engine (InnoDB as back-end persistent storage).

- Control over how often data is passed back and forth between InnoDB and memcached operations through the `innodb_api_bk_commit_interval`, `daemon_memcached_r_batch_size`, and `daemon_memcached_w_batch_size` configuration options. Batch size options default to a value of 1 for maximum reliability.
• The ability to specify memcached options through the daemon_memcached_option configuration parameter. For example, you can change the port that memcached listens on, reduce the maximum number of simultaneous connections, change the maximum memory size for a key-value pair, or enable debugging messages for the error log.

• The innodb_api_trx_level configuration option controls the transaction isolation level on queries processed by memcached. Although memcached has no concept of transactions, you can use this option to control how soon memcached sees changes caused by SQL statements issued on the table used by the daemon_memcached plugin. By default, innodb_api_trx_level is set to READ UNCOMMITTED.

• The innodb_api_enable_mdl option can be used to lock the table at the MySQL level, so that the mapped table cannot be dropped or altered by DDL through the SQL interface. Without the lock, the table can be dropped from the MySQL layer, but kept in InnoDB storage until memcached or some other user stops using it. “MDL” stands for “metadata locking”.

### 15.20.3 Setting Up the InnoDB memcached Plugin

This section describes how to set up the daemon_memcached plugin on a MySQL server. Because the memcached daemon is tightly integrated with the MySQL server to avoid network traffic and minimize latency, you perform this process on each MySQL instance that uses this feature.

**Note**

Before setting up the daemon_memcached plugin, consult Section 15.20.5, “Security Considerations for the InnoDB memcached Plugin” to understand the security procedures required to prevent unauthorized access.

### Prerequisites

• The daemon_memcached plugin is only supported on Linux, Solaris, and macOS platforms. Other operating systems are not supported.

• When building MySQL from source, you must build with -DWITH_INNODB_MEMCACHED=ON. This build option generates two shared libraries in the MySQL plugin directory (plugin_dir) that are required to run the daemon_memcached plugin:
  • libmemcached.so: the memcached daemon plugin to MySQL.
  • innodb_engine.so: an InnoDB API plugin to memcached.
  • libevent must be installed.

• If you did not build MySQL from source, the libevent library is not included in your installation. Use the installation method for your operating system to install libevent 1.4.12 or later. For example, depending on the operating system, you might use apt-get, yum, or port install. For example, on Ubuntu Linux, use:

```bash
sudo apt-get install libevent-dev
```

• If you installed MySQL from a source code release, libevent 1.4.12 is bundled with the package and is located at the top level of the MySQL source code directory. If you use the bundled version of libevent, no action is required. If you want to use a local system version of libevent, you must build MySQL with the -DWITH_LIBEVENT build option set to system or yes.

### Installing and Configuring the InnoDB memcached Plugin
1. Configure the daemon_memcached plugin so it can interact with InnoDB tables by running the innodb_memcached_config.sql configuration script, which is located in MySQL_HOME/share. This script installs the innodb_memcache database with three required tables (cache_policies, config_options, and containers). It also installs the demo_test sample table in the test database.

   mysql> source MYSQL_HOME/share/innodb_memcached_config.sql

Running the innodb_memcached_config.sql script is a one-time operation. The tables remain in place if you later uninstall and re-install the daemon_memcached plugin.

   mysql> USE innodb_memcache;
   mysql> USE test;

   mysql> SHOW TABLES;
   +---------------------------+  
<table>
<thead>
<tr>
<th>Tables_in_innodb_memcache</th>
</tr>
</thead>
<tbody>
<tr>
<td>cache_policies</td>
</tr>
<tr>
<td>config_options</td>
</tr>
<tr>
<td>containers</td>
</tr>
</tbody>
</table>
   +---------------------------+  
   mysql> SHOW TABLES;
   +-----------------------------+  
<table>
<thead>
<tr>
<th>Tables_in_test</th>
</tr>
</thead>
<tbody>
<tr>
<td>demo_test</td>
</tr>
</tbody>
</table>
   +-----------------------------+

Of these tables, the innodb_memcache.containers table is the most important. Entries in the containers table provide a mapping to InnoDB table columns. Each InnoDB table used with the daemon_memcached plugin requires an entry in the containers table.

The innodb_memcached_config.sql script inserts a single entry in the containers table that provides a mapping for the demo_test table. It also inserts a single row of data into the demo_test table. This data allows you to immediately verify the installation after the setup is completed.

   mysql> SELECT * FROM innodb_memcache.containers\G
   *************************** 1. row ***************************
   | name: aaa
   | db_schema: test
   | db_table: demo_test
   | key_columns: c1
   | value_columns: c2
   | flags: c3
   | cas_column: c4
   | expire_time_column: c5
   | unique_idx_name_on_key: PRIMARY

   mysql> SELECT * FROM test.demo_test;
   +----+------------------+------+------+------+
   | c1 | c2               | c3   | c4   | c5   |
   +----+------------------+------+------+------+
   | AA | HELLO, HELLO     |    8 |    0 |    0 |
   +----+------------------+------+------+------+

For more information about innodb_memcache tables and the demo_test sample table, see Section 15.20.8, “InnoDB memcached Plugin Internals”. 
2. Activate the `daemon_memcached` plugin by running the `INSTALL PLUGIN` statement:

```
mysql> INSTALL PLUGIN daemon_memcached soname "libmemcached.so";
```

Once the plugin is installed, it is automatically activated each time the MySQL server is restarted.

### Verifying the InnoDB and memcached Setup

To verify the `daemon_memcached` plugin setup, use a `telnet` session to issue `memcached` commands. By default, the `memcached` daemon listens on port 11211.

1. Retrieve data from the `test.demo_test` table. The single row of data in the `demo_test` table has a key value of `AA`.

```
telnet localhost 11211
Trying 127.0.0.1...
Connected to localhost.
Escape character is '^]'.
get AA
VALUE AA 8 12
HELLO, HELLO
END
```

2. Insert data using a `set` command.

```
set BB 10 0 16
GOODBYE, GOODBYE
STORED
```

where:

- `set` is the command to store a value
- `BB` is the key
- `10` is a flag for the operation; ignored by `memcached` but may be used by the client to indicate any type of information; specify `0` if unused
- `0` is the expiration time (TTL); specify `0` if unused
- `16` is the length of the supplied value block in bytes
- `GOODBYE, GOODBYE` is the value that is stored

3. Verify that the data inserted is stored in MySQL by connecting to the MySQL server and querying the `test.demo_test` table.

```
mysql> SELECT * FROM test.demo_test;
+----+-----------------+------+------+------+
<table>
<thead>
<tr>
<th>c1</th>
<th>c2</th>
<th>c3</th>
<th>c4</th>
<th>c5</th>
</tr>
</thead>
<tbody>
<tr>
<td>AA</td>
<td>HELLO, HELLO</td>
<td>8</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>BB</td>
<td>GOODBYE, GOODBYE</td>
<td>10</td>
<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>
```

4. Return to the `telnet` session and retrieve the data that you inserted earlier using key `BB`.

```
get BB
VALUE BB 10 16
GOODBYE, GOODBYE
END
```

`quit`
If you shut down the MySQL server, which also shuts off the integrated memcached server, further attempts to access the memcached data fail with a connection error. Normally, the memcached data also disappears at this point, and you would require application logic to load the data back into memory when memcached is restarted. However, the InnoDB memcached plugin automates this process for you.

When you restart MySQL, get operations once again return the key-value pairs you stored in the earlier memcached session. When a key is requested and the associated value is not already in the memory cache, the value is automatically queried from the MySQL test.demo_test table.

Creating a New Table and Column Mapping

This example shows how to setup your own InnoDB table with the daemon_memcached plugin.

1. Create an InnoDB table. The table must have a key column with a unique index. The key column of the city table is city_id, which is defined as the primary key. The table must also include columns for flags, cas, and expiry values. There may be one or more value columns. The city table has three value columns (name, state, country).

   Note

   There is no special requirement with respect to column names as along as a valid mapping is added to the innodb_memcache.containers table.

   ```
   mysql> CREATE TABLE city (
       city_id VARCHAR(32),
       name VARCHAR(1024),
       state VARCHAR(1024),
       country VARCHAR(1024),
       flags INT,
       cas BIGINT UNSIGNED,
       expiry INT,
       primary key(city_id)
   ) ENGINE=InnoDB;
   ```

2. Add an entry to the innodb_memcache.containers table so that the daemon_memcached plugin knows how to access the InnoDB table. The entry must satisfy the innodb_memcache.containers table definition. For a description of each field, see Section 15.20.8, “InnoDB memcached Plugin Internals”.

   ```
   mysql> DESCRIBE innodb_memcache.containers;
   +------------------------+--------------+------+-----+---------+-------+
   | Field                  | Type         | Null | Key | Default | Extra |
   +------------------------+--------------+------+-----+---------+-------+
   | name                   | varchar(50)  | NO   | PRI | NULL    |       |
   | db_schema              | varchar(250) | NO   |     | NULL    |       |
   | db_table               | varchar(250) | NO   |     | NULL    |       |
   | key_columns            | varchar(250) | NO   |     | NULL    |       |
   | value_columns          | varchar(250) | YES  |     | NULL    |       |
   | flags                  | varchar(250) | NO   |     | 0       |       |
   | cas_column             | varchar(250) | YES  |     | NULL    |       |
   | expire_time_column     | varchar(250) | YES  |     | NULL    |       |
   | unique_idx_name_on_key | varchar(250) | NO   |     | NULL    |       |
   +------------------------+--------------+------+-----+---------+-------+
   ```

   The innodb_memcache.containers table entry for the city table is defined as:

   ```
   mysql> INSERT INTO `innodb_memcache`.containers (  
   `name`, `db_schema`, `db_table`, `key_columns`, `value_columns`,  
   `flags`, `cas_column`, `expire_time_column`, `unique_idx_name_on_key`)  
   VALUES ('default', 'test', 'city', 'city_id', 'name|state|country',  
   'flags', 'cas','expiry','PRIMARY');
   ```
Setting Up the InnoDB memcached Plugin

- **default** is specified for the `containers.name` column to configure the `city` table as the default InnoDB table to be used with the `daemon_memcached` plugin.

- Multiple InnoDB table columns (`name`, `state`, `country`) are mapped to `containers.value_columns` using a `|` delimiter.

- The `flags`, `cas_column`, and `expire_time_column` fields of the `innodb_memcache.containers` table are typically not significant in applications using the `daemon_memcached` plugin. However, a designated InnoDB table column is required for each. When inserting data, specify 0 for these columns if they are unused.

3. After updating the `innodb_memcache.containers` table, restart the `daemon_memcached` plugin to apply the changes.

```sql
mysql> UNINSTALL PLUGIN daemon_memcached;
mysql> INSTALL PLUGIN daemon_memcached soname "libmemcached.so";
```

4. Using telnet, insert data into the `city` table using a `memcached set` command.

```
telnet localhost 11211
Trying 127.0.0.1...
Connected to localhost.
Escape character is '^]'.
set B 0 0 22
BANGALORE|BANGALORE|IN
STORED
```

5. Using MySQL, query the `test.city` table to verify that the data you inserted was stored.

```sql
mysql> SELECT * FROM test.city;
```

<table>
<thead>
<tr>
<th>city_id</th>
<th>name</th>
<th>state</th>
<th>country</th>
<th>flags</th>
<th>cas</th>
<th>expiry</th>
</tr>
</thead>
<tbody>
<tr>
<td>B</td>
<td>BANGALORE</td>
<td>BANGALORE</td>
<td>IN</td>
<td>0</td>
<td>3</td>
<td>0</td>
</tr>
</tbody>
</table>

6. Using MySQL, insert additional data into the `test.city` table.

```sql
mysql> INSERT INTO city VALUES ('C','CHENNAI','TAMIL NADU','IN', 0, 0, 0);
mysql> INSERT INTO city VALUES ('D','DELHI','DELHI','IN', 0, 0, 0);
mysql> INSERT INTO city VALUES ('H','HYDERABAD','TELANGANA','IN', 0, 0, 0);
mysql> INSERT INTO city VALUES ('M','MUMBAI','MAHARASHTRA','IN', 0, 0, 0);
```

### Note
It is recommended that you specify a value of 0 for the `flags`, `cas_column`, and `expire_time_column` fields if they are unused.

7. Using telnet, issue a `memcached get` command to retrieve data you inserted using MySQL.

```
get H
VALUE H 0 22
HYDERABAD|TELANGANA|IN
END
```

### Configuring the InnoDB memcached Plugin

Traditional `memcached` configuration options may be specified in a MySQL configuration file or a `mysqld` startup string, encoded in the argument of the `daemon_memcached_option` configuration parameter.
memcached configuration options take effect when the plugin is loaded, which occurs each time the MySQL server is started.

For example, to make memcached listen on port 11222 instead of the default port 11211, specify `-p11222` as an argument of the daemon_memcached_option configuration option:

```
mysqld .... --daemon_memcached_option="-p11222"
```

Other memcached options can be encoded in the daemon_memcached_option string. For example, you can specify options to reduce the maximum number of simultaneous connections, change the maximum memory size for a key-value pair, or enable debugging messages for the error log, and so on.

There are also configuration options specific to the daemon_memcached plugin. These include:

- **daemon_memcached_engine_lib_name**: Specifies the shared library that implements the InnoDB memcached plugin. The default setting is innodb_engine.so.

- **daemon_memcached_engine_lib_path**: The path of the directory containing the shared library that implements the InnoDB memcached plugin. The default is NULL, representing the plugin directory.

- **daemon_memcached_r_batch_size**: Defines the batch commit size for read operations (get). It specifies the number of memcached read operations after which a commit occurs. `daemon_memcached_r_batch_size` is set to 1 by default so that every get request accesses the most recently committed data in the InnoDB table, whether the data was updated through memcached or by SQL. When the value is greater than 1, the counter for read operations is incremented with each get call. A flush_all call resets both read and write counters.

- **daemon_memcached_w_batch_size**: Defines the batch commit size for write operations (set, replace, append, prepend, incr, decr, and so on). `daemon_memcached_w_batch_size` is set to 1 by default so that no uncommitted data is lost in case of an outage, and so that SQL queries on the underlying table access the most recent data. When the value is greater than 1, the counter for write operations is incremented for each add, set, incr, decr, and delete call. A flush_all call resets both read and write counters.

By default, you do not need to modify `daemon_memcached_engine_lib_name` or `daemon_memcached_engine_lib_path`. You might configure these options if, for example, you want to use a different storage engine for memcached (such as the NDB memcached engine).

*daemon_memcached* plugin configuration parameters may be specified in the MySQL configuration file or in a mysqld startup string. They take effect when you load the daemon_memcached plugin.

When making changes to daemon_memcached plugin configuration, reload the plugin to apply the changes. To do so, issue the following statements:

```
mysql> UNINSTALL PLUGIN daemon_memcached;

mysql> INSTALL PLUGIN daemon_memcached soname "libmemcached.so";
```

Configuration settings, required tables, and data are preserved when the plugin is restarted.

For additional information about enabling and disabling plugins, see Section 5.6.1, “Installing and Uninstalling Plugins”.

### 15.20.4 InnoDB memcached Multiple get and Range Query Support

The daemon_memcached plugin supports multiple get operations (fetching multiple key-value pairs in a single memcached query) and range queries.
Multiple get Operations

The ability to fetch multiple key-value pairs in a single `memcached` query improves read performance by reducing communication traffic between the client and server. For InnoDB, it means fewer transactions and open-table operations.

The following example demonstrates multiple-get support. The example uses the `test.city` table described in Creating a New Table and Column Mapping.

```sql
mysql> USE test;
mysql> SELECT * FROM test.city;
```

+---------+-----------+-------------+---------+-------+------+--------+
| city_id | name      | state       | country | flags | cas  | expiry |
+---------+-----------+-------------+---------+-------+------+--------+
| B       | BANGALORE | BANGALORE   | IN      |     0 |    1 |      0 |
| C       | CHENNAI   | TAMIL NADU  | IN      |     0 |    0 |      0 |
| D       | DELHI     | DELHI       | IN      |     0 |    0 |      0 |
| H       | HYDERABAD | TELANGANA   | IN      |     0 |    0 |      0 |
| M       | MUMBAI    | MAHARASHTRA | IN      |     0 |    0 |      0 |
+---------+-----------+-------------+---------+-------+------+--------+

Run a `get` command to retrieve all values from the `city` table. The results are returned in a key-value pair sequence.

```
telnet 127.0.0.1 11211
Trying 127.0.0.1...
Connected to 127.0.0.1.
Escape character is '^]'.
get B C D H M
VALUE B 0 22
VALUE C 0 21
VALUE D 0 14
VALUE H 0 22
VALUE M 0 21
END
```

When retrieving multiple values in a single `get` command, you can switch tables (using `@@containers.name` notation) to retrieve the value for the first key, but you cannot switch tables for subsequent keys. For example, the table switch in this example is valid:

```
get @@aaa.AA BB
VALUE @aaa.AA 8 12
HELLO, HELLO
VALUE BB 10 16
GOODBYE, GOODBYE
END
```

Attempting to switch tables again in the same `get` command to retrieve a key value from a different table is not supported.

There is no limit the number of keys that can be retrieved by a multiple get operation, but there is a 128MB memory limit for storing the result.

Range Queries

For range queries, the `daemon_memcached` plugin supports the following comparison operators: `<`, `>`, `<=`, `>=`. An operator must be preceded by an `@` symbol. When a range query finds multiple matching key-value pairs, results are returned in a key-value pair sequence.
The following examples demonstrate range query support. The examples use the `test.city` table described in Creating a New Table and Column Mapping.

```
mysql> SELECT * FROM test.city;
+---------+-----------+-------------+---------+-------+------+--------+
| city_id | name      | state       | country | flags | cas  | expiry |
+---------+-----------+-------------+---------+-------+------+--------+
| B       | BANGALORE | BANGALORE   | IN      |     0 |    1 |      0 |
| C       | CHENNAI   | TAMIL NADU  | IN      |     0 |    0 |      0 |
| D       | DELHI     | DELHI       | IN      |     0 |    0 |      0 |
| H       | HYDERABAD | TELANGANA   | IN      |     0 |    0 |      0 |
| M       | MUMBAI    | MAHARASHTRA | IN      |     0 |    0 |      0 |
+---------+-----------+-------------+---------+-------+------+--------+
```

Open a telnet session:

```
telnet 127.0.0.1 11211
```

```
Trying 127.0.0.1...
Connected to 127.0.0.1.
Escape character is '^]'.
```

To get all values greater than `B`, enter `get @>B`:

```
get @>B
VALUE C 0 21
CHENNAI|TAMIL NADU|IN
VALUE D 0 14
DELHI|DELHI|IN
VALUE H 0 22
HYDERABAD|TELANGANA|IN
VALUE M 0 21
MUMBAI|MAHARASHTRA|IN
END
```

To get all values less than `M`, enter `get @<M`:

```
get @<M
VALUE B 0 22
BANGALORE|BANGALORE|IN
VALUE C 0 21
CHENNAI|TAMIL NADU|IN
VALUE D 0 14
DELHI|DELHI|IN
VALUE H 0 22
HYDERABAD|TELANGANA|IN
END
```

To get all values less than and including `M`, enter `get @<=M`:

```
get @<=M
VALUE B 0 22
BANGALORE|BANGALORE|IN
VALUE C 0 21
CHENNAI|TAMIL NADU|IN
VALUE D 0 14
DELHI|DELHI|IN
VALUE H 0 22
HYDERABAD|TELANGANA|IN
VALUE M 0 21
MUMBAI|MAHARASHTRA|IN
END
```

To get values greater than `B` but less than `M`, enter `get @>B@<M`:

```
get @>B@<M
VALUE C 0 21
CHENNAI|TAMIL NADU|IN
```

A maximum of two comparison operators can be parsed, one being either a 'less than' (@<) or 'less than or equal to' (@<=) operator, and the other being either a 'greater than' (@>) or 'greater than or equal to' (@>=) operator. Any additional operators are assumed to be part of the key. For example, if you issue a get command with three operators, the third operator (@>C) is treated as part of the key, and the get command searches for values smaller than M and greater than B@>C.

get @<M@>B@>C
Security Considerations for the InnoDB memcached Plugin

To enable SASL support, download the MySQL source and rebuild the daemon_memcached plugin after downloading the SASL libraries:

1. Install the SASL development and utility libraries. For example, on Ubuntu, use `apt-get` to obtain the libraries:

   ```bash
   sudo apt-get -f install libsasl2-2 sasl2-bin libsasl2-2 libsasl2-dev libsasl2-modules
   ```

2. Build the daemon_memcached plugin shared libraries with SASL capability by adding `ENABLE_MEMCACHED_SASL=1` to your `cmake` options. memcached also provides simple cleartext password support, which facilitates testing. To enable simple cleartext password support, specify the `ENABLE_MEMCACHED_SASL_PWDB=1` `cmake` option.

   In summary, add following three `cmake` options:

   ```bash
   cmake ... -DWITH_INNODB_MEMCACHED=1 -DENABLE_MEMCACHED_SASL=1 -DENABLE_MEMCACHED_SASL_PWDB=1
   ```

3. Install the daemon_memcached plugin, as described in Section 15.20.3, "Setting Up the InnoDB memcached Plugin".

4. Configure a user name and password file. (This example uses memcached simple cleartext password support.)

   a. In a file, create a user named `testname` and define the password as `testpasswd`:

   ```bash
   echo "testname:testpasswd:::::::" >/home/jy/memcached-sasl-db
   ```

   b. Configure the `MEMCACHED_SASL_PWDB` environment variable to inform memcached of the user name and password file:

   ```bash
   export MEMCACHED_SASL_PWDB=/home/jy/memcached-sasl-db
   ```

   c. Inform memcached that a cleartext password is used:

   ```bash
   echo "mech_list: plain" > /home/jy/work2/msasl/clients/memcached.conf
   export SASL_CONF_PATH=/home/jy/work2/msasl/clients
   ```

5. Enable SASL by restarting the MySQL server with the `memcached -S` option encoded in the `daemon_memcached_option` configuration parameter:

   ```bash
   mysqld ... --daemon_memcached_option="-S"
   ```

6. To test the setup, use an SASL-enabled client such as SASL-enabled libmemcached.

   ```bash
   memcp --servers=localhost:11211 --binary --username=testname --password=password myfile.txt
   memcat --servers=localhost:11211 --binary --username=testname --password=password myfile.txt
   ```

   If you specify an incorrect user name or password, the operation is rejected with a `memcache error AUTHENTICATION FAILURE` message. In this case, examine the cleartext password set in the `memcached-sasl-db` file to verify that the credentials you supplied are correct.

   There are other methods to test SASL authentication with memcached, but the method described above is the most straightforward.
15.20.6 Writing Applications for the InnoDB memcached Plugin

Typically, writing an application for the InnoDB memcached plugin involves some degree of rewriting or adapting existing code that uses MySQL or the memcached API.

- With the daemon_memcached plugin, instead of many traditional memcached servers running on low-powered machines, you have the same number of memcached servers as MySQL servers, running on relatively high-powered machines with substantial disk storage and memory. You might reuse some existing code that works with the memcached API, but adaptation is likely required due to the different server configuration.

- The data stored through the daemon_memcached plugin goes into VARCHAR, TEXT, or BLOB columns, and must be converted to do numeric operations. You can perform the conversion on the application side, or by using the CAST() function in queries.

- Coming from a database background, you might be used to general-purpose SQL tables with many columns. The tables accessed by memcached code likely have only a few or even a single column holding data values.

- You might adapt parts of your application that perform single-row queries, inserts, updates, or deletes, to improve performance in critical sections of code. Both queries (read) and DML (write) operations can be substantially faster when performed through the InnoDB memcached interface. The performance improvement for writes is typically greater than the performance improvement for reads, so you might focus on adapting code that performs logging or records interactive choices on a website.

The following sections explore these points in more detail.

15.20.6.1 Adapting an Existing MySQL Schema for the InnoDB memcached Plugin

Consider these aspects of memcached applications when adapting an existing MySQL schema or application to use the daemon_memcached plugin:

- memcached keys cannot contain spaces or newlines, because these characters are used as separators in the ASCII protocol. If you are using lookup values that contain spaces, transform or hash them into values without spaces before using them as keys in calls to add(), set(), get(), and so on. Although theoretically these characters are allowed in keys in programs that use the binary protocol, you should restrict the characters used in keys to ensure compatibility with a broad range of clients.

- If there is a short numeric primary key column in an InnoDB table, use it as the unique lookup key for memcached by converting the integer to a string value. If the memcached server is used for multiple applications, or with more than one InnoDB table, consider modifying the name to ensure that it is unique. For example, prepend the table name, or the database name and the table name, before the numeric value.

Note

The daemon_memcached plugin supports inserts and reads on mapped InnoDB tables that have an INTEGER defined as the primary key.

- You cannot use a partitioned table for data queried or stored using memcached.

- The memcached protocol passes numeric values around as strings. To store numeric values in the underlying InnoDB table, to implement counters that can be used in SQL functions such as SUM() or AVG(), for example:

  - Use VARCHAR columns with enough characters to hold all the digits of the largest expected number (and additional characters if appropriate for the negative sign, decimal point, or both).
Writing Applications for the InnoDB memcached Plugin

- In any query that performs arithmetic using column values, use the CAST() function to convert the values from string to integer, or to some other numeric type. For example:

  ```sql
  # Alphabetic entries are returned as zero.
  SELECT CAST(c2 as unsigned integer) FROM demo_test;
  # Since there could be numeric values of 0, can't disqualify them.
  # Test the string values to find the ones that are integers, and average only those.
  SELECT AVG(cast(c2 as unsigned integer)) FROM demo_test
    WHERE c2 BETWEEN '0' and '9999999999';
  # Views let you hide the complexity of queries. The results are already converted;
  # no need to repeat conversion functions and WHERE clauses each time.
  CREATE VIEW numbers AS SELECT c1 KEY, CAST(c2 AS UNSIGNED INTEGER) val
    FROM demo_test WHERE c2 BETWEEN '0' and '9999999999';
  SELECT SUM(val) FROM numbers;
  ```

  **Note**

  Any alphabetic values in the result set are converted into 0 by the call to CAST(). When using functions such as AVG(), which depend on the number of rows in the result set, include WHERE clauses to filter out non-numeric values.

- If the InnoDB column used as a key could have values longer than 250 bytes, hash the value to less than 250 bytes.

- To use an existing table with the daemon_memcached plugin, define an entry for it in the innodb_memcache.containers table. To make that table the default for all memcached requests, specify a value of default in the name column, then restart the MySQL server to make the change take effect. If you use multiple tables for different classes of memcached data, set up multiple entries in the innodb_memcache.containers table with name values of your choice, then issue a memcached request in the form of get @@name or set @@name within the application to specify the table to be used for subsequent memcached requests.

  For an example of using a table other than the predefined test.demo_test table, see Example 15.13, “Using Your Own Table with an InnoDB memcached Application”. For the required table layout, see Section 15.20.8, “InnoDB memcached Plugin Internals”.

- To use multiple InnoDB table column values with memcached key-value pairs, specify column names separated by comma, semicolon, space, or pipe characters in the value_columns field of the innodb_memcache.containers entry for the InnoDB table. For example, specify col1,col2,col3 or col1|col2|col3 in the value_columns field.

  Concatenate the column values into a single string using the pipe character as a separator before passing the string to memcached add or set calls. The string is unpacked automatically into the correct column. Each get call returns a single string containing the column values that is also delimited by the pipe character. You can unpack the values using the appropriate application language syntax.

**Example 15.13 Using Your Own Table with an InnoDB memcached Application**

This example shows how to use your own table with a sample Python application that uses memcached for data manipulation.

The example assumes that the daemon_memcached plugin is installed as described in Section 15.20.3, “Setting Up the InnoDB memcached Plugin”. It also assumes that your system is configured to run a Python script that uses the python-memcache module.
1. Create the `multicol` table which stores country information including population, area, and driver side data ('R' for right and 'L' for left).

```sql
mysql> USE test;

mysql> CREATE TABLE `multicol` (
    `country` varchar(128) NOT NULL DEFAULT '',
    `population` varchar(10) DEFAULT NULL,
    `area_sq_km` varchar(9) DEFAULT NULL,
    `drive_side` varchar(1) DEFAULT NULL,
    `c3` int(11) DEFAULT NULL,
    `c4` bigint(20) unsigned DEFAULT NULL,
    `c5` int(11) DEFAULT NULL,
    PRIMARY KEY (`country`)
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4;
```

2. Insert a record into the `innodb_memcache.containers` table so that the `daemon_memcached` plugin can access the `multicol` table.

```sql
mysql> INSERT INTO innodb_memcache.containers
    (name,db_schema,db_table,key_columns,value_columns,flags,cas_column,
    expire_time_column,unique_idx_name_on_key)
VALUES
('bbb','test','multicol','country','population,area_sq_km,drive_side',
'c3','c4','c5','PRIMARY');

mysql> COMMIT;
```

- The `innodb_memcache.containers` record for the `multicol` table specifies a name value of 'bbb', which is the table identifier.

  **Note**
  If a single InnoDB table is used for all memcached applications, the name value can be set to default to avoid using @@ notation to switch tables.

- The `db_schema` column is set to `test`, which is the name of the database where the `multicol` table resides.

- The `db_table` column is set to `multicol`, which is the name of the InnoDB table.

- `key_columns` is set to the unique `country` column. The `country` column is defined as the primary key in the `multicol` table definition.

- Rather than a single InnoDB table column to hold a composite data value, data is divided among three table columns (`population, area_sq_km, and drive_side`). To accommodate multiple value columns, a comma-separated list of columns is specified in the `value_columns` field. The columns defined in the `value_columns` field are the columns used when storing or retrieving values.

- Values for the `flags, expire_time, and cas_column` fields are based on values used in the `demo.test` sample table. These fields are typically not significant in applications that use the `daemon_memcached` plugin because MySQL keeps data synchronized, and there is no need to worry about data expiring or becoming stale.

- The `unique_idx_name_on_key` field is set to `PRIMARY`, which refers to the primary index defined on the unique `country` column in the `multicol` table.
3. Copy the sample Python application into a file. In this example, the sample script is copied to a file named `multicol.py`.

The sample Python application inserts data into the `multicol` table and retrieves data for all keys, demonstrating how to access an InnoDB table through the daemon_memcached plugin.

```python
import sys, os
import memcache

def connect_to_memcached():
    memc = memcache.Client(['127.0.0.1:11211'], debug=0);
    print "Connected to memcached."
    return memc

def banner(message):
    print
    print "=" * len(message)
    print message
    print "=" * len(message)

country_data = [
    ("Canada", "34820000", "9984670", "R"),
    ("USA", "314242000", "9826675", "R"),
    ("Ireland", "6399152", "64421", "L"),
    ("UK", "62262000", "243610", "L"),
    ("Mexico", "113910608", "1972550", "R"),
    ("Denmark", "5543453", "43094", "R"),
    ("Norway", "5002942", "385252", "R"),
    ("UAE", "8264070", "88360", "R"),
    ("India", "1210193422", "3287263", "L"),
    ("China", "1347350000", "9640821", "R"),
]

def switch_table(memc, table):
    key = "@" + table
    print "Switching default table to '" + table + "' by issuing GET for '" + key + "]."
    result = memc.get(key)

def insert_country_data(memc):
    banner("Inserting initial data via memcached interface")
    for item in country_data:
        country = item[0]
        population = item[1]
        area = item[2]
        drive_side = item[3]

        key = country
        value = "|".join([population, area, drive_side])
        print "Key = " + key
        print "Value = " + value

        if memc.add(key, value):
            print "Added new key, value pair."
        else:
            print "Updating value for existing key."
            memc.set(key, value)

    def query_country_data(memc):
        banner("Retrieving data for all keys (country names)")
        for item in country_data:
            key = item[0]
            result = memc.get(key)

            if result:
                print "Here is the result retrieved from the database for key " + key + "]:
                result = result.split("|")
                print "Unpacked population value: " + m_population
```

3651
Sample Python application notes:

• No database authorization is required to run the application, since data manipulation is performed through the \texttt{memcached} interface. The only required information is the port number on the local system where the \texttt{memcached} daemon listens.

• To make sure the application uses the \texttt{multicol} table, the \texttt{switch_table()} function is called, which performs a dummy \texttt{get} or \texttt{set} request using \texttt{@@} notation. The name value in the request is \texttt{bbb}, which is the \texttt{multicol} table identifier defined in the \texttt{innodb_memcache.containers.name} field.

A more descriptive \texttt{name} value might be used in a real-world application. This example simply illustrates that a table identifier is specified rather than the table name in \texttt{get \textbackslash@\textbackslash@...} requests.

• The utility functions used to insert and query data demonstrate how to turn a Python data structure into pipe-separated values for sending data to MySQL with \texttt{add} or \texttt{set} requests, and how to unpack the pipe-separated values returned by \texttt{get} requests. This extra processing is only required when mapping a single \texttt{memcached} value to multiple MySQL table columns.

4. Run the sample Python application.

$> \texttt{python multicol.py}$

If successful, the sample application returns this output:

\begin{verbatim}
Connected to memcached.
Switching default table to 'bbb' by issuing GET for '@@bbb'.

5. Query the \texttt{innodb\_memcache\_containers} table to view the record you inserted earlier for the \texttt{multicol} table. The first record is the sample entry for the \texttt{demo\_test} table that is created during
the initial daemon_memcached plugin setup. The second record is the entry you inserted for the multicol table.

```sql
mysql> SELECT * FROM innodb_memcache.containers;
```

<table>
<thead>
<tr>
<th>name</th>
<th>db_schema</th>
<th>db_table</th>
<th>key_columns</th>
<th>value_columns</th>
<th>flags</th>
<th>cas_column</th>
<th>expire_time_column</th>
<th>unique_idx_name_on_key</th>
</tr>
</thead>
<tbody>
<tr>
<td>aaa</td>
<td>test</td>
<td>demo_test</td>
<td>c1</td>
<td>c2</td>
<td>c3</td>
<td>c4</td>
<td>c5</td>
<td>PRIMARY</td>
</tr>
<tr>
<td>bbb</td>
<td>test</td>
<td>multicol</td>
<td>country</td>
<td>population,area_sq_km,drive_side</td>
<td>c3</td>
<td>c4</td>
<td>c5</td>
<td>PRIMARY</td>
</tr>
</tbody>
</table>

6. Query the multicol table to view data inserted by the sample Python application. The data is available for MySQL queries, which demonstrates how the same data can be accessed using SQL or through applications (using the appropriate MySQL Connector or API).

```sql
mysql> SELECT * FROM test.multicol;
```

<table>
<thead>
<tr>
<th>country</th>
<th>population</th>
<th>area_sq_km</th>
<th>drive_side</th>
<th>c3</th>
<th>c4</th>
<th>c5</th>
</tr>
</thead>
<tbody>
<tr>
<td>Canada</td>
<td>34820000</td>
<td>9984670</td>
<td>R</td>
<td>0</td>
<td>11</td>
<td>0</td>
</tr>
<tr>
<td>China</td>
<td>1347350000</td>
<td>9640821</td>
<td>R</td>
<td>0</td>
<td>20</td>
<td>0</td>
</tr>
<tr>
<td>Denmark</td>
<td>5543453</td>
<td>43094</td>
<td>R</td>
<td>0</td>
<td>16</td>
<td>0</td>
</tr>
<tr>
<td>India</td>
<td>123013422</td>
<td>3287263</td>
<td>L</td>
<td>0</td>
<td>19</td>
<td>0</td>
</tr>
<tr>

<td>0</td>
<td>14</td>
<td>0</td>
</tr>
<tr>
<td>USA</td>
<td>314242000</td>
<td>9826675</td>
<td>R</td>
<td>0</td>
<td>12</td>
<td>0</td>
</tr>
</tbody>
</table>

**Note**

Always allow sufficient size to hold necessary digits, decimal points, sign characters, leading zeros, and so on when defining the length for columns that are treated as numbers. Too-long values in a string column such as a VARCHAR are truncated by removing some characters, which could produce nonsensical numeric values.

7. Optionally, run report-type queries on the InnoDB table that stores the memcached data.

You can produce reports through SQL queries, performing calculations and tests across any columns, not just the country key column. (Because the following examples use data from only a few countries, the numbers are for illustration purposes only.) The following queries return the average population of countries where people drive on the right, and the average size of countries whose names start with “U”:

```sql
mysql> SELECT AVG(population) FROM multicol WHERE drive_side = 'R';
```

<table>
<thead>
<tr>
<th>country</th>
<th>population</th>
<th>area_sq_km</th>
<th>drive_side</th>
<th>c3</th>
<th>c4</th>
<th>c5</th>
</tr>
</thead>
<tbody>
<tr>
<td>Canada</td>
<td>34820000</td>
<td>9984670</td>
<td>R</td>
<td>0</td>
<td>11</td>
<td>0</td>
</tr>
<tr>
<td>China</td>
<td>1347350000</td>
<td>9640821</td>
<td>R</td>
<td>0</td>
<td>20</td>
<td>0</td>
</tr>
<tr>
<td>Denmark</td>
<td>5543453</td>
<td>43094</td>
<td>R</td>
<td>0</td>
<td>16</td>
<td>0</td>
</tr>
<tr>
<td>India</td>
<td>123013422</td>
<td>3287263</td>
<td>L</td>
<td>0</td>
<td>19</td>
<td>0</td>
</tr>
<tr>
<td>Ireland</td>
<td>6399152</td>
<td>84421</td>
<td>L</td>
<td>0</td>
<td>13</td>
<td>0</td>
</tr>
<tr>
<td>Mexico</td>
<td>113910608</td>
<td>1972550</td>
<td>R</td>
<td>0</td>
<td>15</td>
<td>0</td>
</tr>
<tr>
<td>Norway</td>
<td>5002942</td>
<td>385252</td>
<td>R</td>
<td>0</td>
<td>17</td>
<td>0</td>
</tr>
<tr>
<td>UAE</td>
<td>8264070</td>
<td>83600</td>
<td>R</td>
<td>0</td>
<td>18</td>
<td>0</td>
</tr>
<tr>
<td>UK</td>
<td>62262000</td>
<td>243610</td>
<td>L</td>
<td>0</td>
<td>14</td>
<td>0</td>
</tr>
<tr>
<td>USA</td>
<td>314242000</td>
<td>9826675</td>
<td>R</td>
<td>0</td>
<td>12</td>
<td>0</td>
</tr>
</tbody>
</table>
Because the `population` and `area_sq_km` columns store character data rather than strongly typed numeric data, functions such as `AVG()` and `SUM()` work by converting each value to a number first. This approach does not work for operators such as `<` or `>`, for example, when comparing character-based values, `9 > 1000`, which is not expected from a clause such as `ORDER BY population DESC`. For the most accurate type treatment, perform queries against views that cast numeric columns to the appropriate types. This technique lets you issue simple `SELECT *` queries from database applications, while ensuring that casting, filtering, and ordering is correct. The following example shows a view that can be queried to find the top three countries in descending order of population, with the results reflecting the latest data in the `multicol` table, and with population and area figures treated as numbers:

```
mysql> CREATE VIEW populous_countries AS
    CREATE VIEW populous_countries AS
    SELECT
    country,
    cast(population as unsigned integer) population,
    cast(area_sq_km as unsigned integer) area_sq_km,
    drive_side
    FROM multicol
    ORDER BY CAST(population as unsigned integer) DESC
    LIMIT 3;
```

```
mysql> SELECT * FROM populous_countries;
```

<table>
<thead>
<tr>
<th>country</th>
<th>population</th>
<th>area_sq_km</th>
<th>drive_side</th>
</tr>
</thead>
<tbody>
<tr>
<td>China</td>
<td>1347350000</td>
<td>9640821</td>
<td>R</td>
</tr>
<tr>
<td>India</td>
<td>1210193422</td>
<td>3287263</td>
<td>L</td>
</tr>
<tr>
<td>USA</td>
<td>314242000</td>
<td>9826675</td>
<td>R</td>
</tr>
</tbody>
</table>

```
mysql> DESC populous_countries;
```

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Null</th>
<th>Key</th>

<td>YES</td>
<td></td>
<td>NULL</td>
<td></td>
</tr>
<tr>
<td>area_sq_km</td>
<td>int(9) unsigned</td>
<td>YES</td>
<td></td>
<td>NULL</td>
<td></td>
</tr>
<tr>
<td>drive_side</td>
<td>varchar(1)</td>
<td>YES</td>
<td></td>
<td>NULL</td>
<td></td>
</tr>
</tbody>
</table>

15.20.6.2 Adapting a memcached Application for the InnoDB memcached Plugin

Consider these aspects of MySQL and InnoDB tables when adapting existing memcached applications to use the `daemon_memcached` plugin:

- If there are key values longer than a few bytes, it may be more efficient to use a numeric auto-increment column as the primary key of the InnoDB table, and to create a unique secondary index on the column that contains the `memcached` key values. This is because InnoDB performs best for large-scale insertions if primary key values are added in sorted order (as they are with auto-increment values). Primary key values are included in secondary indexes, which takes up unnecessary space if the primary key is a long string value.
Writing Applications for the InnoDB memcached Plugin

- If you store several different classes of information using memcached, consider setting up a separate InnoDB table for each type of data. Define additional table identifiers in the innodb_memcache.containers table, and use the @@table_id.key notation to store and retrieve items from different tables. Physically dividing different types of information allows you to tune the characteristics of each table for optimum space utilization, performance, and reliability. For example, you might enable compression for a table that holds blog posts, but not for a table that holds thumbnail images. You might back up one table more frequently than another because it holds critical data. You might create additional secondary indexes on tables that are frequently used to generate reports using SQL.

- Preferably, configure a stable set of table definitions for use with the daemon_memcached plugin, and leave the tables in place permanently. Changes to the innodb_memcache.containers table take effect the next time the innodb_memcache.containers table is queried. Entries in the containers table are processed at startup, and are consulted whenever an unrecognized table identifier (as defined by containers.name) is requested using @@ notation. Thus, new entries are visible as soon as you use the associated table identifier, but changes to existing entries require a server restart before they take effect.

- When you use the default innodb_only caching policy, calls to add(), set(), incr(), and so on can succeed but still trigger debugging messages such as while expecting 'STORED', got unexpected response 'NOT_STORED'. Debug messages occur because new and updated values are sent directly to the InnoDB table without being saved in the memory cache, due to the innodb_only caching policy.

15.20.6.3 Tuning InnoDB memcached Plugin Performance

Because using InnoDB in combination with memcached involves writing all data to disk, whether immediately or sometime later, raw performance is expected to be somewhat slower than using memcached by itself. When using the InnoDB memcached plugin, focus tuning goals for memcached operations on achieving better performance than equivalent SQL operations.

Benchmarks suggest that queries and DML operations (inserts, updates, and deletes) that use the memcached interface are faster than traditional SQL. DML operations typically see a larger improvements. Therefore, consider adapting write-intensive applications to use the memcached interface first. Also consider prioritizing adaptation of write-intensive applications that use fast, lightweight mechanisms that lack reliability.

Adapting SQL Queries

The types of queries that are most suited to simple GET requests are those with a single clause or a set of AND conditions in the WHERE clause:

```
<table>
<thead>
<tr>
<th>SQL:</th>
<th>memcached:</th>
</tr>
</thead>
<tbody>
<tr>
<td>SELECT col FROM tbl WHERE key = 'key_value';</td>
<td>get key_value</td>
</tr>
<tr>
<td>SQL:</td>
<td>memcached:</td>
</tr>
</tbody>
</table>
| SELECT col FROM tbl WHERE col1 = val1 and col2 = val2 and col3 = val3; | # Since you must always know these 3 values to look up the key, # combine them into a unique string and use that as the key # for all ADD, SET, and GET operations.
|           | key_value = val1 + ":" + val2 + ":" + val3
|           | get key_value |
| SQL:     | memcached: |
| SELECT 'key exists!' FROM tbl |
```
WHERE EXISTS (SELECT col1 FROM tbl WHERE KEY = 'key_value') LIMIT 1;

default:
# Test for existence of key by asking for its value and checking if the call succeeds,
# ignoring the value itself. For existence checking, you typically only store a very
# short value such as "1".
get key_value

Using System Memory

For best performance, deploy the daemon_memcached plugin on machines that are configured as typical
database servers, where the majority of system RAM is devoted to the InnoDB buffer pool, through the
innodb_buffer_pool_size configuration option. For systems with multi-gigabyte buffer pools, consider
raising the value of innodb_buffer_pool_instances for maximum throughput when most operations
involve data that is already cached in memory.

Reducing Redundant I/O

InnoDB has a number of settings that let you choose the balance between high reliability, in case of a
crash, and the amount of I/O overhead during high write workloads. For example, consider setting the
innodb_doublewrite to 0 and innodb_flush_log_at_trx_commit to 2. Measure performance with
different innodb_flush_method settings.

For other ways to reduce or tune I/O for table operations, see Section 8.5.8, “Optimizing InnoDB Disk I/O”.

Reducing Transactional Overhead

A default value of 1 for daemon_memcached_r_batch_size and daemon_memcached_w_batch_size
is intended for maximum reliability of results and safety of stored or updated data.

Depending on the type of application, you might increase one or both of these settings to
reduce the overhead of frequent commit operations. On a busy system, you might increase
daemon_memcached_r_batch_size, knowing that changes to data made through SQL may not become
visible to memcached immediately (that is, until N more get operations are processed). When processing
data where every write operation must be reliably stored, leave daemon_memcached_w_batch_size set
to 1. Increase the setting when processing large numbers of updates intended only for statistical analysis,
where losing the last N updates in an unexpected exit is an acceptable risk.

For example, imagine a system that monitors traffic crossing a busy bridge, recording data for
approximately 100,000 vehicles each day. If the application counts different types of vehicles to analyze
traffic patterns, changing daemon_memcached_w_batch_size from 1 to 100 reduces I/O overhead for
commit operations by 99%. In case of an outage, a maximum of 100 records are lost, which may be an
acceptable margin of error. If instead the application performed automated toll collection for each car, you
would set daemon_memcached_w_batch_size to 1 to ensure that each toll record is immediately saved
to disk.

Because of the way InnoDB organizes memcached key values on disk, if you have a large number of keys
to create, it may be faster to sort the data items by key value in the application and add them in sorted
order, rather than create keys in arbitrary order.

The memslap command, which is part of the regular memcached distribution but not included with the
daemon_memcached plugin, can be useful for benchmarking different configurations. It can also be used
to generate sample key-value pairs to use in your own benchmarks.

15.20.6.4 Controlling Transactional Behavior of the InnoDB memcached Plugin

Unlike traditional memcached, the daemon_memcached plugin allows you to control durability of data
values produced through calls to add, set, incr, and so on. By default, data written through the
memcached interface is stored to disk, and calls to get return the most recent value from disk. Although
the default behavior does not offer the best possible raw performance, it is still fast compared to the SQL interface for InnoDB tables.

As you gain experience using the daemon_memcached plugin, you can consider relaxing durability settings for non-critical classes of data, at the risk of losing some updated values in the event of an outage, or returning data that is slightly out-of-date.

**Frequency of Commits**

One tradeoff between durability and raw performance is how frequently new and changed data is committed. If data is critical, it should be committed immediately so that it is safe in case of an unexpected exit or outage. If data is less critical, such as counters that are reset after an unexpected exit or logging data that you can afford to lose, you might prefer higher raw throughput that is available with less frequent commits.

When a memcached operation inserts, updates, or deletes data in the underlying InnoDB table, the change might be committed to the InnoDB table instantly (if daemon_memcached_w_batch_size=1) or some time later (if the daemon_memcached_w_batch_size value is greater than 1). In either case, the change cannot be rolled back. If you increase the value of daemon_memcached_w_batch_size to avoid high I/O overhead during busy times, commits could become infrequent when the workload decreases. As a safety measure, a background thread automatically commits changes made through the memcached API at regular intervals. The interval is controlled by the innodb_api_bk_commit_interval configuration option, which has a default setting of 5 seconds.

When a memcached operation inserts or updates data in the underlying InnoDB table, the changed data is immediately visible to other memcached requests because the new value remains in the memory cache, even if it is not yet committed on the MySQL side.

**Transaction Isolation**

When a memcached operation such as get or incr causes a query or DML operation on the underlying InnoDB table, you can control whether the operation sees the very latest data written to the table, only data that has been committed, or other variations of transaction isolation level. Use the innodb_api_trx_level configuration option to control this feature. The numeric values specified for this option correspond to isolation levels such as REPEATABLE READ. See the description of the innodb_api_trx_level option for information about other settings.

A strict isolation level ensures that data you retrieve is not rolled back or changed suddenly causing subsequent queries to return different values. However, strict isolation levels require greater locking overhead, which can cause waits. For a NoSQL-style application that does not use long-running transactions, you can typically use the default isolation level or switch to a less strict isolation level.

**Disabling Row Locks for memcached DML Operations**

The innodb_api_disable_rowlock option can be used to disable row locks when memcached requests through the daemon_memcached plugin cause DML operations. By default, innodb_api_disable_rowlock is set to OFF which means that memcached requests row locks for get and set operations. When innodb_api_disable_rowlock is set to ON, memcached requests a table lock instead of row locks.

The innodb_api_disable_rowlock option is not dynamic. It must be specified at startup on the mysqld command line or entered in a MySQL configuration file.

**Allowing or Disallowing DDL**

By default, you can perform DDL operations such as ALTER TABLE on tables used by the daemon_memcached plugin. To avoid potential slowdowns when these tables are used for high-throughput
Writing Applications for the InnoDB memcached Plugin

applications, disable DDL operations on these tables by enabling `innodb_api_enable_mdl` at startup. This option is less appropriate when accessing the same tables through both memcached and SQL, because it blocks `CREATE INDEX` statements on the tables, which could be important for running reporting queries.

Storing Data on Disk, in Memory, or Both

The `innodb_memcache.cache_policies` table specifies whether to store data written through the memcached interface to disk (`innodb_only`, the default); in memory only, as with traditional memcached (`cache_only`); or both (`caching`).

With the `caching` setting, if memcached cannot find a key in memory, it searches for the value in an InnoDB table. Values returned from `get` calls under the `caching` setting could be out-of-date if the values were updated on disk in the InnoDB table but are not yet expired from the memory cache.

The caching policy can be set independently for `get`, `set` (including `incr` and `decr`), `delete`, and `flush` operations.

For example, you might allow `get` and `set` operations to query or update a table and the memcached memory cache at the same time (using the `caching` setting), while making `delete`, `flush`, or both operate only on the in-memory copy (using the `cache_only` setting). That way, deleting or flushing an item only expires the item from the cache, and the latest value is returned from the InnoDB table the next time the item is requested.

```sql
mysql> SELECT * FROM innodb_memcache.cache_policies;
+--------------+-------------+-------------+---------------+--------------+
| policy_name  | get_policy  | set_policy  | delete_policy | flush_policy |
|--------------|-------------|-------------|---------------|--------------+
| cache_policy | innodb_only | innodb_only | innodb_only   | innodb_only  |
+--------------+-------------+-------------+---------------+--------------+
mysql> UPDATE innodb_memcache.cache_policies SET set_policy = 'caching'
WHERE policy_name = 'cache_policy';
```

`innodb_memcache.cache_policies` values are only read at startup. After changing values in this table, uninstall and reinstall the `daemon_memcached` plugin to ensure that changes take effect.

```sql
mysql> UNINSTALL PLUGIN daemon_memcached;
mysql> INSTALL PLUGIN daemon_memcached soname "libmemcached.so";
```

15.20.6.5 Adapting DML Statements to memcached Operations

Benchmarks suggest that the `daemon_memcached` plugin speeds up DML operations (inserts, updates, and deletes) more than it speeds up queries. Therefore, consider focusing initial development efforts on write-intensive applications that are I/O-bound, and look for opportunities to use MySQL with the `daemon_memcached` plugin for new write-intensive applications.

Single-row DML statements are the easiest types of statements to turn into memcached operations. `INSERT` becomes `add`, `UPDATE` becomes `set`, `incr` or `decr`, and `DELETE` becomes `delete`. These operations are guaranteed to only affect one row when issued through the memcached interface, because the `key` is unique within the table.

In the following SQL examples, `t1` refers to the table used for memcached operations, based on the configuration in the `innodb_memcache.containers` table. `key` refers to the column listed under `key_columns`, and `val` refers to the column listed under `value_columns`.

```sql
INSERT INTO t1 (key, val) VALUES (some_key, some_value);
SELECT val FROM t1 WHERE key = some_key;
UPDATE t1 SET val = new_value WHERE key = some_key;
```
The following `TRUNCATE TABLE` and `DELETE` statements, which remove all rows from the table, correspond to the `flush_all` operation, where `t1` is configured as the table for `memcached` operations, as in the previous example.

```
TRUNCATE TABLE t1;
DELETE FROM t1;
```

### 15.20.6.6 Performing DML and DDL Statements on the Underlying InnoDB Table

You can access the underlying InnoDB table (which is `test.demo_test` by default) through standard SQL interfaces. However, there are some restrictions:

- When querying a table that is also accessed through the `memcached` interface, remember that `memcached` operations can be configured to be committed periodically rather than after every write operation. This behavior is controlled by the `daemon_memcached_w_batch_size` option. If this option is set to a value greater than 1, use `READ UNCOMMITTED` queries to find rows that were just inserted.

```
mysql> SET SESSION TRANSACTION ISOLATION LEVEL READ UNCOMMITTED;
```

```
+------+------+------+------+-----------+------+------+------+------+------+------+
| cx   | cy   | c1   | cz   | c2        | ca   | CB   | c3   | cu   | c4   | C5   |
| NULL | NULL | a11  | NULL | 123456789 | NULL | NULL |   10 | NULL |    3 | NULL |
+------+------+------+------+-----------+------+------+------+------+------+------+
```

- When modifying a table using SQL that is also accessed through the `memcached` interface, you can configure `memcached` operations to start a new transaction periodically rather than for every read operation. This behavior is controlled by the `daemon_memcached_r_batch_size` option. If this option is set to a value greater than 1, changes made to the table using SQL are not immediately visible to `memcached` operations.

- The InnoDB table is either IS (intention shared) or IX (intention exclusive) locked for all operations in a transaction. If you increase `daemon_memcached_r_batch_size` and `daemon_memcached_w_batch_size` substantially from their default value of 1, the table is most likely locked between each operation, preventing DDL statements on the table.

### 15.20.7 The InnoDB memcached Plugin and Replication

Because the `daemon_memcached` plugin supports the MySQL `binary log`, source server through the `memcached` interface can be replicated for backup, balancing intensive read workloads, and high availability. All `memcached` commands are supported with binary logging.

You do not need to set up the `daemon_memcached` plugin on replica servers. The primary advantage of this configuration is increased write throughput on the source. The speed of the replication mechanism is not affected.

The following sections show how to use the binary log capability when using the `daemon_memcached` plugin with MySQL replication. It is assumed that you have completed the setup described in Section 15.20.3, “Setting Up the InnoDB memcached Plugin”.

### Enabling the InnoDB memcached Binary Log

1. To use the `daemon_memcached` plugin with the MySQL `binary log`, enable the `innodb_api_enable_binlog` configuration option on the source server. This option can only be set at server startup. You must also enable the MySQL binary log on the source server using the `--log-`
The InnoDB memcached Plugin and Replication

**bin** option. You can add these options to the MySQL configuration file, or on the **mysqld** command line.

```
mysqld ... --log-bin --innodb_api_enable_binlog=1
```

2. Configure the source and replica server, as described in Section 17.1.2, “Setting Up Binary Log File Position Based Replication”.

3. Use **mysqldump** to create a source data snapshot, and sync the snapshot to the replica server.

```
source $> mysqldump --all-databases --lock-all-tables > dbdump.db
replica $> mysql < dbdump.db
```

4. On the source server, issue **SHOW MASTER STATUS** to obtain the source binary log coordinates.

```
mysql> SHOW MASTER STATUS;
```

5. On the replica server, use a **CHANGE REPLICATION SOURCE TO** statement (from MySQL 8.0.23) or **CHANGE MASTER TO** statement (before MySQL 8.0.23) to set up a replica server using the source binary log coordinates.

```
mysql> CHANGE MASTER TO
MASTER_HOST='localhost',
MASTER_USER='root',
MASTER_PASSWORD='',
MASTER_PORT = 13000,
MASTER_LOG_FILE='0.000001',
MASTER_LOG_POS=114;
```

Or from MySQL 8.0.23:

```
mysql> CHANGE REPLICATION SOURCE TO
SOURCE_HOST='localhost',
SOURCE_USER='root',
SOURCE_PASSWORD='',
SOURCE_PORT = 13000,
SOURCE_LOG_FILE='0.000001',
SOURCE_LOG_POS=114;
```

6. Start the replica.

```
mysql> START SLAVE;
```

Or from MySQL 8.0.22:

```
mysql> START REPLICA;
```

If the error log prints output similar to the following, the replica is ready for replication.

```
2013-09-24T13:04:38.639684Z 49 [Note] Replication I/O thread: connected to source 'root@localhost:13000', replication started in log '0.000001' at position 114
```

**Testing the InnoDB memcached Replication Configuration**

This example demonstrates how to test the **InnoDB memcached** replication configuration using the **memcached** and telnet to insert, update, and delete data. A MySQL client is used to verify results on the source and replica servers.

The example uses the **demo_test** table, which was created by the **innodb_memcached_config.sql** configuration script during the initial setup of the **daemon_memcached** plugin. The **demo_test** table contains a single example record.

1. Use the **set** command to insert a record with a key of **test1**, a flag value of **10**, an expiration value of **0**, a cas value of **1**, and a value of **t1**.
**The InnoDB memcached Plugin and Replication**

```
telnet 127.0.0.1 11211
Trying 127.0.0.1...
Connected to 127.0.0.1.
Escape character is '^]'.
set test1 10 0 1
t1
STORED
```

2. On the source server, check that the record was inserted into the `demo_test` table. Assuming the `demo_test` table was not previously modified, there should be two records. The example record with a key of `AA`, and the record you just inserted, with a key of `test1`. The `c1` column maps to the key, the `c2` column to the value, the `c3` column to the flag value, the `c4` column to the cas value, and the `c5` column to the expiration time. The expiration time was set to 0, since it is unused.

```
mysql> SELECT * FROM test.demo_test;
+-------+--------------+------+------+------+
| c1    | c2           | c3   | c4   | c5   |
|-------|--------------|------+------+------+
| AA    | HELLO, HELLO |    8 |    0 |    0 |
| test1 | t1           |   10 |    1 |    0 |
+-------+--------------+------+------+------+
```

3. Check to verify that the same record was replicated to the replica server.

```
mysql> SELECT * FROM test.demo_test;
+-------+--------------+------+------+------+
| c1    | c2           | c3   | c4   | c5   |
|-------|--------------|------+------+------+
| AA    | HELLO, HELLO |    8 |    0 |    0 |
| test1 | new          |   10 |    2 |    0 |
+-------+--------------+------+------+------+
```

4. Use the `set` command to update the key to a value of `new`.

```
telnet 127.0.0.1 11211
Trying 127.0.0.1...
Connected to 127.0.0.1.
Escape character is '^]'.
set test1 10 0 2
new
STORED
```

```
The update is replicated to the replica server (notice that the cas value is also updated).
```

```
mysql> SELECT * FROM test.demo_test;
+-------+--------------+------+------+------+
| c1    | c2           | c3   | c4   | c5   |
|-------|--------------|------+------+------+
| AA    | HELLO, HELLO |    8 |    0 |    0 |
| test1 | new          |   10 |    2 |    0 |
+-------+--------------+------+------+------+
```

5. Delete the `test1` record using a `delete` command.

```
telnet 127.0.0.1 11211
Trying 127.0.0.1...
Connected to 127.0.0.1.
Escape character is '^]'.
delete test1
DELETED
```

When the `delete` operation is replicated to the replica, the `test1` record on the replica is also deleted.

```
mysql> SELECT * FROM test.demo_test;
```
6. Remove all rows from the table using the `flush_all` command.

```plaintext
telnet 127.0.0.1 11211
Trying 127.0.0.1...
Connected to 127.0.0.1.
Escape character is '^]'.
flush_all
OK
```

```sql
mysql> SELECT * FROM test.demo_test;
Empty set (0.00 sec)
```

7. Telnet to the source server and enter two new records.

```plaintext
telnet 127.0.0.1 11211
Trying 127.0.0.1...
Connected to 127.0.0.1.
Escape character is '^]'.
set test2 10 0 4
again
STORED
set test3 10 0 5
again1
STORED
```

8. Confirm that the two records were replicated to the replica server.

```sql
mysql> SELECT * FROM test.demo_test;
+-------+--------------+------+------+------+
| c1    | c2           | c3   | c4   | c5   |
|-------+--------------+------+------+------+
| test2 | again        |   10 |    4 |    0 |
| test3 | again1       |   10 |    5 |    0 |
+-------+--------------+------+------+------+
```

9. Remove all rows from the table using the `flush_all` command.

```plaintext
telnet 127.0.0.1 11211
Trying 127.0.0.1...
Connected to 127.0.0.1.
Escape character is '^]'.
flush_all
OK
```

10. Check to ensure that the `flush_all` operation was replicated on the replica server.

```sql
mysql> SELECT * FROM test.demo_test;
Empty set (0.00 sec)
```

**InnoDB memcached Binary Log Notes**

**Binary Log Format:**

- Most `memcached` operations are mapped to DML statements (analogous to insert, delete, update). Since there is no actual SQL statement being processed by the MySQL server, all `memcached` commands (except for `flush_all`) use Row-Based Replication (RBR) logging, which is independent of any server `binlog_format` setting.
InnoDB memcached Plugin Internals

- The `memcached flush_all` command is mapped to the `TRUNCATE TABLE` command in MySQL 5.7 and earlier. Since DDL commands can only use statement-based logging, the `flush_all` command is replicated by sending a `TRUNCATE TABLE` statement. In MySQL 8.0 and later, `flush_all` is mapped to `DELETE` but is still replicated by sending a `TRUNCATE TABLE` statement.

Transactions:

- The concept of transactions has not typically been part of memcached applications. For performance considerations, `daemon_memcached_r_batch_size` and `daemon_memcached_w_batch_size` are used to control the batch size for read and write transactions. These settings do not affect replication. Each SQL operation on the underlying InnoDB table is replicated after successful completion.

- The default value of `daemon_memcached_w_batch_size` is 1, which means that each `memcached` write operation is committed immediately. This default setting incurs a certain amount of performance overhead to avoid inconsistencies in the data that is visible on the source and replica servers. The replicated records are always available immediately on the replica server. If you set `daemon_memcached_w_batch_size` to a value greater than 1, records inserted or updated through `memcached` are not immediately visible on the source server; to view the records on the source server before they are committed, issue `SET TRANSACTION ISOLATION LEVEL READ UNcommitted`.

15.20.8 InnoDB memcached Plugin Internals

InnoDB API for the InnoDB memcached Plugin

The InnoDB memcached engine accesses InnoDB through InnoDB APIs, most of which are directly adopted from embedded InnoDB. InnoDB API functions are passed to the InnoDB memcached engine as callback functions. InnoDB API functions access the InnoDB tables directly, and are mostly DML operations with the exception of `TRUNCATE TABLE`.

Memcached commands are implemented through the InnoDB memcached API. The following table outlines how memcached commands are mapped to DML or DDL operations.

**Table 15.27 memcached Commands and Associated DML or DDL Operations**

<table>
<thead>
<tr>
<th>memcached Command</th>
<th>DML or DDL Operations</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>get</code></td>
<td>a read/fetch command</td>
</tr>
<tr>
<td><code>set</code></td>
<td>a search followed by an INSERT or UPDATE (depending on whether or not a key exists)</td>
</tr>
<tr>
<td><code>add</code></td>
<td>a search followed by an INSERT or UPDATE</td>
</tr>
<tr>
<td><code>replace</code></td>
<td>a search followed by an UPDATE</td>
</tr>
<tr>
<td><code>append</code></td>
<td>a search followed by an UPDATE (appends data to the result before UPDATE)</td>
</tr>
<tr>
<td><code>prepend</code></td>
<td>a search followed by an UPDATE (prepends data to the result before UPDATE)</td>
</tr>
<tr>
<td><code>incr</code></td>
<td>a search followed by an UPDATE</td>
</tr>
<tr>
<td><code>decr</code></td>
<td>a search followed by an UPDATE</td>
</tr>
<tr>
<td><code>delete</code></td>
<td>a search followed by a DELETE</td>
</tr>
<tr>
<td><code>flush_all</code></td>
<td>TRUNCATE TABLE (DDL)</td>
</tr>
</tbody>
</table>

InnoDB memcached Plugin Configuration Tables
This section describes configuration tables used by the daemon_memcached plugin. The cache_policies table, config_options table, and containers table are created by the innodb_memcached_config.sql configuration script in the innodb_memcache database.

```sql
mysql> USE innodb_memcache;
Database changed
mysql> SHOW TABLES;
+---------------------------+
<table>
<thead>
<tr>
<th>Tables_in_innodb_memcache</th>
</tr>
</thead>
<tbody>
<tr>
<td>cache_policies</td>
</tr>
<tr>
<td>config_options</td>
</tr>
<tr>
<td>containers</td>
</tr>
</tbody>
</table>
+---------------------------+
```

**cache_policies Table**

The cache_policies table defines a cache policy for the InnoDB memcached installation. You can specify individual policies for get, set, delete, and flush operations, within a single cache policy. The default setting for all operations is innodb_only.

- **innodb_only**: Use InnoDB as the data store.
- **cache_only**: Use the memcached engine as the data store.
- **caching**: Use both InnoDB and the memcached engine as data stores. In this case, if memcached cannot find a key in memory, it searches for the value in an InnoDB table.
- **disable**: Disable caching.

**Table 15.28 cache_policies Columns**

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>policy_name</td>
<td>Name of the cache policy. The default cache policy name is cache_policy.</td>
</tr>
<tr>
<td>get_policy</td>
<td>The cache policy for get operations. Valid values are innodb_only, cache_only, caching, or disabled. The default setting is innodb_only.</td>
</tr>
<tr>
<td>set_policy</td>
<td>The cache policy for set operations. Valid values are innodb_only, cache_only, caching, or disabled. The default setting is innodb_only.</td>
</tr>
<tr>
<td>delete_policy</td>
<td>The cache policy for delete operations. Valid values are innodb_only, cache_only, caching, or disabled. The default setting is innodb_only.</td>
</tr>
<tr>
<td>flush_policy</td>
<td>The cache policy for flush operations. Valid values are innodb_only, cache_only, caching, or disabled. The default setting is innodb_only.</td>
</tr>
</tbody>
</table>

**config_options Table**

The config_options table stores memcached-related settings that can be changed at runtime using SQL. Supported configuration options are separator and table_map_delimiter.
**Table 15.29 config_options Columns**

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Name of the memcached-related configuration option. The following configuration options are supported by the config_options table:</td>
</tr>
<tr>
<td></td>
<td>• separator: Used to separate values of a long string into separate values when there are multiple value_columns defined. By default, the separator is a</td>
</tr>
<tr>
<td></td>
<td>• table_map_delimiter: The character separating the schema name and the table name when you use the @@ notation in a key name to access a key in a specific table. For example,</td>
</tr>
<tr>
<td></td>
<td>• @t1.some_key and @t2.some_key have the same key value, but are stored in different tables.</td>
</tr>
<tr>
<td>Value</td>
<td>The value assigned to the memcached-related configuration option.</td>
</tr>
</tbody>
</table>

**containers Table**

The containers table is the most important of the three configuration tables. Each InnoDB table that is used to store memcached values must have an entry in the containers table. The entry provides a mapping between InnoDB table columns and container table columns, which is required for memcached to work with InnoDB tables.

The containers table contains a default entry for the test.demo_test table, which is created by the innodb_memcached_config.sql configuration script. To use the daemon_memcached plugin with your own InnoDB table, you must create an entry in the containers table.

**Table 15.30 containers Columns**

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>The name given to the container. If an InnoDB table is not requested by name using @@ notation, the daemon_memcached plugin uses the InnoDB table with a containers.name value of default. If there is no such entry, the first entry in the containers table, ordered alphabetically by name (ascending), determines the default InnoDB table.</td>
</tr>
<tr>
<td>db_schema</td>
<td>The name of the database where the InnoDB table resides. This is a required value.</td>
</tr>
</tbody>
</table>
### InnoDB memcached Plugin Internals

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>db_table</td>
<td>The name of the InnoDB table that stores memcached values. This is a required value.</td>
</tr>
<tr>
<td>key_columns</td>
<td>The column in the InnoDB table that contains lookup key values for memcached operations. This is a required value.</td>
</tr>
<tr>
<td>value_columns</td>
<td>The InnoDB table columns (one or more) that store memcached data. Multiple columns can be specified using the separator character specified in the innodb_memcached.config_options table. By default, the separator is a pipe character (&quot;</td>
</tr>
<tr>
<td>flags</td>
<td>The InnoDB table columns that are used as flags (a user-defined numeric value that is stored and retrieved along with the main value) for memcached. A flag value can be used as a column specifier for some operations (such as incr, prepend) if a memcached value is mapped to multiple columns, so that an operation is performed on a specified column. For example, if you have mapped a value_columns to three InnoDB table columns, and only want the increment operation performed on one columns, use the flags column to specify the column. If you do not use the flags column, set a value of 0 to indicate that it is unused.</td>
</tr>
<tr>
<td>cas_column</td>
<td>The InnoDB table column that stores compare-and-swap (cas) values. The cas_column value is related to the way memcached hashes requests to different servers and caches data in memory. Because the InnoDB memcached plugin is tightly integrated with a single memcached daemon, and the in-memory caching mechanism is handled by MySQL and the InnoDB buffer pool, this column is rarely needed. If you do not use this column, set a value of 0 to indicate that it is unused.</td>
</tr>
<tr>
<td>expire_time_column</td>
<td>The InnoDB table column that stores expiration values. The expire_time_column value is related to the way memcached hashes requests to different servers and caches data in memory. Because the InnoDB memcached plugin is tightly integrated with a single memcached daemon, and the in-memory caching mechanism is handled by MySQL and the InnoDB buffer pool, this column is rarely needed. If you do not use this column, set a value of 0 to indicate that the column is unused. The maximum expire time is defined as INT_MAX32 or 2147483647 seconds (approximately 68 years).</td>
</tr>
<tr>
<td>unique_idx_name_on_key</td>
<td>The name of the index on the key column. It must be a unique index. It can be the primary key or</td>
</tr>
</tbody>
</table>
InnoDB memcached Plugin Internals

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>a secondary index. Preferably, use the primary key of the InnoDB table. Using the primary key avoids a lookup that is performed when using a secondary index. You cannot make a covering index for memcached lookups; InnoDB returns an error if you try to define a composite secondary index over both the key and value columns.</td>
</tr>
</tbody>
</table>

containers Table Column Constraints

- You must supply a value for `db_schema, db_name, key_columns, value_columns` and `unique_idx_name_on_key`. Specify 0 for `flags, cas_column, and expire_time_column` if they are unused. Failing to do so could cause your setup to fail.
- `key_columns`: The maximum limit for a memcached key is 250 characters, which is enforced by memcached. The mapped key must be a non-Null CHAR or VARCHAR type.
- `value_columns`: Must be mapped to a CHAR, VARCHAR, or BLOB column. There is no length restriction and the value can be NULL.
- `cas_column`: The `cas` value is a 64 bit integer. It must be mapped to a BIGINT of at least 8 bytes. If you do not use this column, set a value of 0 to indicate that it is unused.
- `expiration_time_column`: Must mapped to an INTEGER of at least 4 bytes. Expiration time is defined as a 32-bit integer for Unix time (the number of seconds since January 1, 1970, as a 32-bit value), or the number of seconds starting from the current time. For the latter, the number of seconds may not exceed 60*60*24*30 (the number of seconds in 30 days). If the number sent by a client is larger, the server considers it to be a real Unix time value rather than an offset from the current time. If you do not use this column, set a value of 0 to indicate that it is unused.
- `flags`: Must be mapped to an INTEGER of at least 32-bits and can be NULL. If you do not use this column, set a value of 0 to indicate that it is unused.

A pre-check is performed at plugin load time to enforce column constraints. If mismatches are found, the plugin is not loaded.

Multiple Value Column Mapping

- During plugin initialization, when InnoDB memcached is configured with information defined in the containers table, each mapped column defined in containers.value_columns is verified against the mapped InnoDB table. If multiple InnoDB table columns are mapped, there is a check to ensure that each column exists and is the right type.
- At run-time, for memcached insert operations, if there are more delimited values than the number of mapped columns, only the number of mapped values are taken. For example, if there are six mapped columns, and seven delimited values are provided, only the first six delimited values are taken. The seventh delimited value is ignored.
- If there are fewer delimited values than mapped columns, unfilled columns are set to NULL. If an unfilled column cannot be set to NULL, insert operations fail.
- If a table has more columns than mapped values, the extra columns do not affect results.

The demo_test Example Table

The innodb_memcached_config.sql configuration script creates a demo_test table in the test database, which can be used to verify InnoDB memcached plugin installation immediately after setup.
Troubleshooting the InnoDB memcached Plugin

The `innodb_memcached_config.sql` configuration script also creates an entry for the `demo_test` table in the `innodb_memcache.containers` table.

```sql
mysql> SELECT * FROM innodb_memcache.containers;
```

```
+------------------+------------------+---------------+----------------+-------------------+-------------------+---------------------+---------------------+---------------------+---------------------+
| name: aaa         | db_schema: test   | db_table: demo_test | key_columns: c1 | value_columns: c2 | flags: c3          | cas_column: c4      | expire_time_column: c5 | unique_idx_name_on_key: PRIMARY |
+------------------+------------------+---------------+----------------+----------------+-------------------+-------------------+---------------------+---------------------+---------------------+
mysql>
```

```sql
mysql> SELECT * FROM test.demo_test;
```

```
+----+------------------+-+-----+-----+
| c1 | c2                | c3 | c4  | c5  |
+----+------------------+-+-----+-----+
| AA | HELLO, HELLO     | 8  | 0   | 0   |
+----+------------------+-+-----+-----+
```

### 15.20.9 Troubleshooting the InnoDB memcached Plugin

This section describes issues that you may encounter when using the InnoDB memcached plugin.

- If you encounter the following error in the MySQL error log, the server might fail to start:

  ```
  failed to set rlimit for open files. Try running as root or requesting smaller maxconns value.
  ```

  The error message is from the memcached daemon. One solution is to raise the OS limit for the number of open files. The commands for checking and increasing the open file limit varies by operating system. This example shows commands for Linux and macOS:

  #### Linux
  ```
  $> ulimit -n
  1024
  $> ulimit -n 4096
  $> ulimit -n
  4096
  ```

  #### macOS
  ```
  $> ulimit -n
  256
  $> ulimit -n 4096
  $> ulimit -n
  4096
  ```

  The other solution is to reduce the number of concurrent connections permitted for the memcached daemon. To do so, encode the `-c memcached` option in the `daemon_memcached_option` configuration parameter in the MySQL configuration file. The `-c` option has a default value of 1024.

  ```
  [mysqld]
  ...
  loose-daemon_memcached_option='-c 64'
  ```

- To troubleshoot problems where the memcached daemon is unable to store or retrieve InnoDB table data, encode the `-vvv memcached` option in the `daemon_memcached_option` configuration parameter in the MySQL configuration file. Examine the MySQL error log for debug output related to memcached operations.

  ```
  [mysqld]
  ```
Troubleshooting the InnoDB memcached Plugin

• If columns specified to hold memcached values are the wrong data type, such as a numeric type instead of a string type, attempts to store key-value pairs fail with no specific error code or message.

• If the daemon_memcached plugin causes MySQL server startup issues, you can temporarily disable the daemon_memcached plugin while troubleshooting by adding this line under the [mysqld] group in the MySQL configuration file:

```
daemon_memcached=OFF
```

For example, if you run the INSTALL PLUGIN statement before running the innodb_memcached_config.sql configuration script to set up the necessary database and tables, the server might unexpectedly exit and fail to start. The server could also fail to start if you incorrectly configure an entry in the innodb_memcache.containers table.

To uninstall the memcached plugin for a MySQL instance, issue the following statement:

```
mysql> UNINSTALL PLUGIN daemon_memcached;
```

• If you run more than one instance of MySQL on the same machine with the daemon_memcached plugin enabled in each instance, use the daemon_memcached_option configuration parameter to specify a unique memcached port for each daemon_memcached plugin.

• If an SQL statement cannot find the InnoDB table or finds no data in the table, but memcached API calls retrieve the expected data, you may be missing an entry for the InnoDB table in the innodb_memcache.containers table, or you may have not switched to the correct InnoDB table by issuing a get or set request using @table_id notation. This problem could also occur if you change an existing entry in the innodb_memcache.containers table without restarting the MySQL server afterward. The free-form storage mechanism is flexible enough that your requests to store or retrieve a multi-column value such as col1|col2|col3 may still work, even if the daemon is using the test.demo_test table which stores values in a single column.

• When defining your own InnoDB table for use with the daemon_memcached plugin, and columns in the table are defined as NOT NULL, ensure that values are supplied for the NOT NULL columns when inserting a record for the table into the innodb_memcache.containers table. If the INSERT statement for the innodb_memcache.containers record contains fewer delimited values than there are mapped columns, unfilled columns are set to NULL. Attempting to insert a NULL value into a NOT NULL column causes the INSERT to fail, which may only become evident after you reinitialize the daemon_memcached plugin to apply changes to the innodb_memcache.containers table.

• If cas_column and expire_time_column fields of the innodb_memcachedcontainers table are set to NULL, the following error is returned when attempting to load the memcached plugin:

```
InnoDB_Memcached: column 6 in the entry for config table 'containers' in database 'innodb_memcache' has an invalid NULL value.
```

The memcached plugin rejects usage of NULL in the cas_column and expire_time_column columns. Set the value of these columns to 0 when the columns are unused.

• As the length of the memcached key and values increase, you might encounter size and length limits.

  • When the key exceeds 250 bytes, memcached operations return an error. This is currently a fixed limit within memcached.

  • InnoDB table limits may be encountered if values exceed 768 bytes in size, 3072 bytes in size, or half of the innodb_page_size value. These limits primarily apply if you intend to create an index on a
value column to run report-generating queries on that column using SQL. See Section 15.22, “InnoDB Limits” for details.

• The maximum size for the key-value combination is 1 MB.

• If you share configuration files across MySQL servers of different versions, using the latest configuration options for the daemon_memcached plugin could cause startup errors on older MySQL versions. To avoid compatibility problems, use the loose prefix with option names. For example, use loose-daemon_memcached_option='-c 64' instead of daemon_memcached_option='-c 64'.

• There is no restriction or check in place to validate character set settings. memcached stores and retrieves keys and values in bytes and is therefore not character set sensitive. However, you must ensure that the memcached client and the MySQL table use the same character set.

• memcached connections are blocked from accessing tables that contain an indexed virtual column. Accessing an indexed virtual column requires a callback to the server, but a memcached connection does not have access to the server code.

15.21 InnoDB Troubleshooting

The following general guidelines apply to troubleshooting InnoDB problems:

• When an operation fails or you suspect a bug, look at the MySQL server error log (see Section 5.4.2, “The Error Log”). Server Error Message Reference provides troubleshooting information for some of the common InnoDB-specific errors that you may encounter.

• If the failure is related to a deadlock, run with the innodb_print_all_deadlocks option enabled so that details about each deadlock are printed to the MySQL server error log. For information about deadlocks, see Section 15.7.5, “Deadlocks in InnoDB”.

• If the issue is related to the InnoDB data dictionary, see Section 15.21.4, “Troubleshooting InnoDB Data Dictionary Operations”.

• When troubleshooting, it is usually best to run the MySQL server from the command prompt, rather than through mysqld_safe or as a Windows service. You can then see what mysql prints to the console, and so have a better grasp of what is going on. On Windows, start mysql with the --console option to direct the output to the console window.

• Enable the InnoDB Monitors to obtain information about a problem (see Section 15.17, “InnoDB Monitors”). If the problem is performance-related, or your server appears to be hung, you should enable the standard Monitor to print information about the internal state of InnoDB. If the problem is with locks, enable the Lock Monitor. If the problem is with table creation, tablespaces, or data dictionary operations, refer to the InnoDB Information Schema system tables to examine contents of the InnoDB internal data dictionary.

InnoDB temporarily enables standard InnoDB Monitor output under the following conditions:

• A long semaphore wait

• InnoDB cannot find free blocks in the buffer pool

• Over 67% of the buffer pool is occupied by lock heaps or the adaptive hash index

• If you suspect that a table is corrupt, run CHECK TABLE on that table.

15.21.1 Troubleshooting InnoDB I/O Problems
Troubleshooting Recovery Failures

The troubleshooting steps for InnoDB I/O problems depend on when the problem occurs: during startup of the MySQL server, or during normal operations when a DML or DDL statement fails due to problems at the file system level.

Initialization Problems

If something goes wrong when InnoDB attempts to initialize its tablespace or its log files, delete all files created by InnoDB: all ibdata files and all redo log files (#ib_redoN files in MySQL 8.0.30 and higher or ib_logfile files in earlier releases). If you created any InnoDB tables, also delete any .ibd files from the MySQL database directories. Then try initializing InnoDB again. For easiest troubleshooting, start the MySQL server from a command prompt so that you see what is happening.

Runtime Problems

If InnoDB prints an operating system error during a file operation, usually the problem has one of the following solutions:

• Make sure the InnoDB data file directory and the InnoDB log directory exist.

• Make sure mysqld has access rights to create files in those directories.

• Make sure mysqld can read the proper my.cnf or my.ini option file, so that it starts with the options that you specified.

• Make sure the disk is not full and you are not exceeding any disk quota.

• Make sure that the names you specify for subdirectories and data files do not clash.

• Doublecheck the syntax of the innodb_data_home_dir and innodb_data_file_path values. In particular, any MAX value in the innodb_data_file_path option is a hard limit, and exceeding that limit causes a fatal error.

15.21.2 Troubleshooting Recovery Failures

From MySQL 8.0.26, checkpoints and advancing the checkpoint LSN are not permitted until redo log recovery is complete and data dictionary dynamic metadata (srv_dict_metadata) is transferred to data dictionary table (dict_table_t) objects. Should the redo log run out of space during recovery or after recovery (but before data dictionary dynamic metadata is transferred to data dictionary table objects) as a result of this change, an innodb_force_recovery restart may be required, starting with at least the SRV_FORCE_NO_IBUF_MERGE setting or, in case that fails, the SRV_FORCE_NO_LOG_REDO setting. If an innodb_force_recovery restart fails in this scenario, recovery from backup may be necessary. (Bug #32200595)

15.21.3 Forcing InnoDB Recovery

To investigate database page corruption, you might dump your tables from the database with SELECT ... INTO OUTFILE. Usually, most of the data obtained in this way is intact. Serious corruption might cause SELECT * FROM tbl_name statements or InnoDB background operations to unexpectedly exit or assert, or even cause InnoDB roll-forward recovery to crash. In such cases, you can use the innodb_force_recovery option to force the InnoDB storage engine to start up while preventing background operations from running, so that you can dump your tables. For example, you can add the following line to the [mysqld] section of your option file before restarting the server:

[mysqld]
inodb_force_recovery = 1
For information about using option files, see Section 4.2.2.2, “Using Option Files”.

**Warning**

Only set `innodb_force_recovery` to a value greater than 0 in an emergency situation, so that you can start InnoDB and dump your tables. Before doing so, ensure that you have a backup copy of your database in case you need to recreate it. Values of 4 or greater can permanently corrupt data files. Only use an `innodb_force_recovery` setting of 4 or greater on a production server instance after you have successfully tested the setting on a separate physical copy of your database. When forcing InnoDB recovery, you should always start with `innodb_force_recovery=1` and only increase the value incrementally, as necessary.

`innodb_force_recovery` is 0 by default (normal startup without forced recovery). The permissible nonzero values for `innodb_force_recovery` are 1 to 6. A larger value includes the functionality of lesser values. For example, a value of 3 includes all of the functionality of values 1 and 2.

If you are able to dump your tables with an `innodb_force_recovery` value of 3 or less, then you are relatively safe that only some data on corrupt individual pages is lost. A value of 4 or greater is considered dangerous because data files can be permanently corrupted. A value of 6 is considered drastic because database pages are left in an obsolete state, which in turn may introduce more corruption into B-trees and other database structures.

As a safety measure, InnoDB prevents INSERT, UPDATE, or DELETE operations when `innodb_force_recovery` is greater than 0. An `innodb_force_recovery` setting of 4 or greater places InnoDB in read-only mode.

- **1 (SRV_FORCE_IGNORE_CORRUPT)**
  
  Lets the server run even if it detects a corrupt page. Tries to make `SELECT * FROM tbl_name` jump over corrupt index records and pages, which helps in dumping tables.

- **2 (SRV_FORCE_NO_BACKGROUND)**
  
  Prevents the master thread and any purge threads from running. If an unexpected exit would occur during the purge operation, this recovery value prevents it.

- **3 (SRV_FORCE_NO_TRX_UNDO)**
  
  Does not run transaction rollbacks after crash recovery.

- **4 (SRV_FORCE_NO_IBUF_MERGE)**
  
  Prevents insert buffer merge operations. If they would cause a crash, does not do them. Does not calculate table statistics. This value can permanently corrupt data files. After using this value, be prepared to drop and recreate all secondary indexes. Sets InnoDB to read-only.

- **5 (SRV_FORCE_NO_UNDO_LOG_SCAN)**
  
  Does not look at undo logs when starting the database: InnoDB treats even incomplete transactions as committed. This value can permanently corrupt data files. Sets InnoDB to read-only.

- **6 (SRV_FORCE_NO_LOG_REDO)**
  
  Does not do the redo log roll-forward in connection with recovery. This value can permanently corrupt data files. Leaves database pages in an obsolete state, which in turn may introduce more corruption into B-trees and other database structures. Sets InnoDB to read-only.
You can `SELECT` from tables to dump them. With an `innodb_force_recovery` value of 3 or less you can `DROP` or `CREATE` tables. `DROP TABLE` is also supported with an `innodb_force_recovery` value greater than 3. `DROP TABLE` is not permitted with an `innodb_force_recovery` value greater than 4.

If you know that a given table is causing an unexpected exit on rollback, you can drop it. If you encounter a runaway rollback caused by a failing mass import or `ALTER TABLE`, you can kill the `mysqld` process and set `innodb_force_recovery` to 3 to bring the database up without the rollback, and then `DROP` the table that is causing the runaway rollback.

If corruption within the table data prevents you from dumping the entire table contents, a query with an `ORDER BY primary_key DESC` clause might be able to dump the portion of the table after the corrupted part.

If a high `innodb_force_recovery` value is required to start InnoDB, there may be corrupted data structures that could cause complex queries (queries containing `WHERE`, `ORDER BY`, or other clauses) to fail. In this case, you may only be able to run basic `SELECT * FROM t` queries.

### 15.21.4 Troubleshooting InnoDB Data Dictionary Operations

Information about table definitions is stored in the InnoDB data dictionary. If you move data files around, dictionary data can become inconsistent.

If a data dictionary corruption or consistency issue prevents you from starting InnoDB, see Section 15.21.3, “Forcing InnoDB Recovery” for information about manual recovery.

### Cannot Open Datafile

With `innodb_file_per_table` enabled (the default), the following messages may appear at startup if a `file-per-table` tablespace file (`.ibd` file) is missing:

```
[ERROR] InnoDB: Operating system error number 2 in a file operation.
[ERROR] InnoDB: The error means the system cannot find the path specified.
[ERROR] InnoDB: Cannot open datafile for read-only: './test/t1.ibd' OS error: 71
[Warning] InnoDB: Ignoring tablespace `test/t1` because it could not be opened.
```

To address these messages, issue `DROP TABLE` statement to remove data about the missing table from the data dictionary.

### Restoring Orphan File-Per-Table Ibd Files

This procedure describes how to restore orphan `file-per-table` `.ibd` files to another MySQL instance. You might use this procedure if the system tablespace is lost or unrecoverable and you want to restore `.ibd` file backups on a new MySQL instance.

The procedure is not supported for `general tablespace` `.ibd` files.

The procedure assumes that you only have `.ibd` file backups, you are recovering to the same version of MySQL that initially created the orphan `.ibd` files, and that `.ibd` file backups are clean. See Section 15.6.1.4, “Moving or Copying InnoDB Tables” for information about creating clean backups.

Table import limitations outlined in Section 15.6.1.3, “Importing InnoDB Tables” are applicable to this procedure.

1. On the new MySQL instance, recreate the table in a database of the same name.

   ```sql
   mysql> CREATE DATABASE sakila;
   mysql> USE sakila;
   mysql> CREATE TABLE actor (  
    ```
InnoDB Error Handling

The following items describe how InnoDB performs error handling. InnoDB sometimes rolls back only the statement that failed, other times it rolls back the entire transaction.

• If you run out of file space in a tablespace, a MySQL Table is full error occurs and InnoDB rolls back the SQL statement.

• A transaction deadlock causes InnoDB to roll back the entire transaction. Retry the entire transaction when this happens.

A lock wait timeout causes InnoDB to roll back the current statement (the statement that was waiting for the lock and encountered the timeout). To have the entire transaction roll back, start the server with --innodb-rollback-on-timeout enabled. Retry the statement if using the default behavior, or the entire transaction if --innodb-rollback-on-timeout is enabled.

Both deadlocks and lock wait timeouts are normal on busy servers and it is necessary for applications to be aware that they may happen and handle them by retrying. You can make them less likely by doing as little work as possible between the first change to data during a transaction and the commit, so the locks are held for the shortest possible time and for the smallest possible number of rows. Sometimes splitting work between different transactions may be practical and helpful.

• A duplicate-key error rolls back the SQL statement, if you have not specified the IGNORE option in your statement.
InnoDB Limits

• A row too long error rolls back the SQL statement.

• Other errors are mostly detected by the MySQL layer of code (above the InnoDB storage engine level), and they roll back the corresponding SQL statement. Locks are not released in a rollback of a single SQL statement.

During implicit rollbacks, as well as during the execution of an explicit ROLLBACK SQL statement, SHOW PROCESSLIST displays Rolling back in the State column for the relevant connection.

15.22 InnoDB Limits

This section describes limits for InnoDB tables, indexes, tablespaces, and other aspects of the InnoDB storage engine.

• A table can contain a maximum of 1017 columns. Virtual generated columns are included in this limit.

• A table can contain a maximum of 64 secondary indexes.

• The index key prefix length limit is 3072 bytes for InnoDB tables that use DYNAMIC or COMPRESSED row format.

The index key prefix length limit is 767 bytes for InnoDB tables that use the REDUNDANT or COMPACT row format. For example, you might hit this limit with a column prefix index of more than 191 characters on a TEXT or VARCHAR column, assuming a utf8mb4 character set and the maximum of 4 bytes for each character.

Attempting to use an index key prefix length that exceeds the limit returns an error.

If you reduce the InnoDB page size to 8KB or 4KB by specifying the innodb_page_size option when creating the MySQL instance, the maximum length of the index key is lowered proportionally, based on the limit of 3072 bytes for a 16KB page size. That is, the maximum index key length is 1536 bytes when the page size is 8KB, and 768 bytes when the page size is 4KB.

The limits that apply to index key prefixes also apply to full-column index keys.

• A maximum of 16 columns is permitted for multicolumn indexes. Exceeding the limit returns an error.

• The combined maximum size for InnoDB log files is 512GB.

3676
InnoDB Restrictions and Limitations

• The minimum tablespace size is slightly larger than 10MB. The maximum tablespace size depends on the InnoDB page size.

Table 15.31 InnoDB Maximum Tablespace Size

<table>
<thead>
<tr>
<th>InnoDB Page Size</th>
<th>Maximum Tablespace Size</th>
</tr>
</thead>
<tbody>
<tr>
<td>4KB</td>
<td>16TB</td>
</tr>
<tr>
<td>8KB</td>
<td>32TB</td>
</tr>
<tr>
<td>16KB</td>
<td>64TB</td>
</tr>
<tr>
<td>32KB</td>
<td>128TB</td>
</tr>
<tr>
<td>64KB</td>
<td>256TB</td>
</tr>
</tbody>
</table>

The maximum tablespace size is also the maximum size for a table.

• An InnoDB instance supports up to $2^{32}$ (4294967296) tablespaces, with a small number of those tablespaces reserved for undo and temporary tables.

• Shared tablespaces support up to $2^{32}$ (4294967296) tables.

• The path of a tablespace file, including the file name, cannot exceed the `MAX_PATH` limit on Windows. Prior to Windows 10, the `MAX_PATH` limit is 260 characters. As of Windows 10, version 1607, `MAX_PATH` limitations are removed from common Win32 file and directory functions, but you must enable the new behavior.

• For limits associated with concurrent read-write transactions, see Section 15.6.6, "Undo Logs".

15.23 InnoDB Restrictions and Limitations

This section describes restrictions and limitations of the InnoDB storage engine.

• You cannot create a table with a column name that matches the name of an internal InnoDB column (including `DB_ROW_ID`, `DB_TRX_ID`, and `DB_ROLL_PTR`). This restriction applies to use of the names in any lettercase.

  mysql> CREATE TABLE t1 (c1 INT, db_row_id INT) ENGINE=INNODB;
  ERROR 1166 (42000): Incorrect column name 'db_row_id'

• `SHOW TABLE STATUS` does not provide accurate statistics for InnoDB tables except for the physical size reserved by the table. The row count is only a rough estimate used in SQL optimization.

• InnoDB does not keep an internal count of rows in a table because concurrent transactions might "see" different numbers of rows at the same time. Consequently, `SELECT COUNT(*)` statements only count rows visible to the current transaction.

  For information about how InnoDB processes `SELECT COUNT(*)` statements, refer to the `COUNT()` description in Section 12.19.1, "Aggregate Function Descriptions".

• `ROW_FORMAT=COMPRESSED` is unsupported for page sizes greater than 16KB.

• A MySQL instance using a particular InnoDB page size (`innodb_page_size`) cannot use data files or log files from an instance that uses a different page size.

• For limitations associated with importing tables using the Transportable Tablespaces feature, see Table Import Limitations.

• For limitations associated with online DDL, see Section 15.12.8, "Online DDL Limitations".
InnoDB Restrictions and Limitations

- For limitations associated with general tablespaces, see General Tablespace Limitations.
- For limitations associated with data-at-rest encryption, see Encryption Limitations.

  16.11.2 The Common Database Server Layer ..................................... 3715

Storage engines are MySQL components that handle the SQL operations for different table types. InnoDB is the default and most general-purpose storage engine, and Oracle recommends using it for tables except for specialized use cases. (The CREATE TABLE statement in MySQL 8.0 creates InnoDB tables by default.)

MySQL Server uses a pluggable storage engine architecture that enables storage engines to be loaded into and unloaded from a running MySQL server.

To determine which storage engines your server supports, use the SHOW ENGINES statement. The value in the Support column indicates whether an engine can be used. A value of YES, NO, or DEFAULT indicates that an engine is available, not available, or available and currently set as the default storage engine.

```
mysql> SHOW ENGINES\G
************************** 1. row **************************
Engine: PERFORMANCE_SCHEMA
Support: YES
Comment: Performance Schema
Transactions: NO
XA: NO
Savepoints: NO
************************** 2. row **************************
Engine: InnoDB
Support: DEFAULT
Comment: Supports transactions, row-level locking, and foreign keys
```
MySQL 8.0 Supported Storage Engines

This chapter covers use cases for special-purpose MySQL storage engines. It does not cover the default InnoDB storage engine or the NDB storage engine which are covered in Chapter 15, The InnoDB Storage Engine and Chapter 23, MySQL NDB Cluster 8.0. For advanced users, it also contains a description of the pluggable storage engine architecture (see Section 16.11, "Overview of MySQL Storage Engine Architecture").

For information about features offered in commercial MySQL Server binaries, see MySQL Editions, on the MySQL website. The storage engines available might depend on which edition of MySQL you are using.

For answers to commonly asked questions about MySQL storage engines, see Section A.2, “MySQL 8.0 FAQ: Storage Engines”.

MySQL 8.0 Supported Storage Engines

- **InnoDB**: The default storage engine in MySQL 8.0. InnoDB is a transaction-safe (ACID compliant) storage engine for MySQL that has commit, rollback, and crash-recovery capabilities to protect user data. InnoDB row-level locking (without escalation to coarser granularity locks) and Oracle-style consistent nonlocking reads increase multi-user concurrency and performance. InnoDB stores user data in clustered indexes to reduce I/O for common queries based on primary keys. To maintain data integrity, InnoDB also supports FOREIGN KEY referential-integrity constraints. For more information about InnoDB, see Chapter 15, The InnoDB Storage Engine.

- **MyISAM**: These tables have a small footprint. Table-level locking limits the performance in read/write workloads, so it is often used in read-only or read-mostly workloads in Web and data warehousing configurations.

- **Memory**: Stores all data in RAM, for fast access in environments that require quick lookups of non-critical data. This engine was formerly known as the HEAP engine. Its use cases are decreasing; InnoDB with its buffer pool memory area provides a general-purpose and durable way to keep most or all data in memory, and NDBCLUSTER provides fast key-value lookups for huge distributed data sets.

- **CSV**: Its tables are really text files with comma-separated values. CSV tables let you import or dump data in CSV format, to exchange data with scripts and applications that read and write that same format. Because CSV tables are not indexed, you typically keep the data in InnoDB tables during normal operation, and only use CSV tables during the import or export stage.
MySQL 8.0 Supported Storage Engines

- **Archive**: These compact, unindexed tables are intended for storing and retrieving large amounts of seldom-referenced historical, archived, or security audit information.

- **Blackhole**: The Blackhole storage engine accepts but does not store data, similar to the Unix `/dev/null` device. Queries always return an empty set. These tables can be used in replication configurations where DML statements are sent to replica servers, but the source server does not keep its own copy of the data.

- **NDB** (also known as `NDBCluster`): This clustered database engine is particularly suited for applications that require the highest possible degree of uptime and availability.

- **Merge**: Enables a MySQL DBA or developer to logically group a series of identical MyISAM tables and reference them as one object. Good for VLDB environments such as data warehousing.

- **Federated**: Offers the ability to link separate MySQL servers to create one logical database from many physical servers. Very good for distributed or data mart environments.

- **Example**: This engine serves as an example in the MySQL source code that illustrates how to begin writing new storage engines. It is primarily of interest to developers. The storage engine is a “stub” that does nothing. You can create tables with this engine, but no data can be stored in them or retrieved from them.

You are not restricted to using the same storage engine for an entire server or schema. You can specify the storage engine for any table. For example, an application might use mostly InnoDB tables, with one CSV table for exporting data to a spreadsheet and a few MEMORY tables for temporary workspaces.

### Choosing a Storage Engine

The various storage engines provided with MySQL are designed with different use cases in mind. The following table provides an overview of some storage engines provided with MySQL, with clarifying notes following the table.

#### Table 16.1 Storage Engines Feature Summary

<table>

</tbody>
</table>
### Setting the Storage Engine

When you create a new table, you can specify which storage engine to use by adding an `ENGINE` table option to the `CREATE TABLE` statement:

```sql
-- ENGINE=INNODB not needed unless you have set a different
-- default storage engine.
CREATE TABLE t1 (i INT) ENGINE = INNODB;
CREATE TABLE t2 (i INT) ENGINE = CSV;
CREATE TABLE t3 (i INT) ENGINE = MEMORY;
```

#### Notes:

1. Implemented in the server, rather than in the storage engine.

2. Compressed MyISAM tables are supported only when using the compressed row format. Tables using the compressed row format with MyISAM are read only.

3. Implemented in the server via encryption functions.

4. Implemented in the server via encryption functions; In MySQL 5.7 and later, data-at-rest encryption is supported.

5. Implemented in the server via encryption functions; encrypted NDB backups as of NDB 8.0.22; transparent NDB file system encryption supported in NDB 8.0.29 and later.

6. Support for FULLTEXT indexes is available in MySQL 5.6 and later.

7. Support for geospatial indexing is available in MySQL 5.7 and later.

8. InnoDB utilizes hash indexes internally for its Adaptive Hash Index feature.

9. See the discussion later in this section.

#### 16.1 Setting the Storage Engine

When you create a new table, you can specify which storage engine to use by adding an `ENGINE` table option to the `CREATE TABLE` statement.
The MyISAM Storage Engine

When you omit the `ENGINE` option, the default storage engine is used. The default engine is `InnoDB` in MySQL 8.0. You can specify the default engine by using the `--default-storage-engine` server startup option, or by setting the `default-storage-engine` option in the `my.cnf` configuration file.

You can set the default storage engine for the current session by setting the `default_storage_engine` variable:

```
SET default_storage_engine=NDBCLUSTER;
```

The storage engine for `TEMPORARY` tables created with `CREATE TEMPORARY TABLE` can be set separately from the engine for permanent tables by setting the `default_tmp_storage_engine`, either at startup or at runtime.

To convert a table from one storage engine to another, use an `ALTER TABLE` statement that indicates the new engine:

```
ALTER TABLE t ENGINE = InnoDB;
```

See Section 13.1.20, “CREATE TABLE Statement”, and Section 13.1.9, “ALTER TABLE Statement”.

If you try to use a storage engine that is not compiled in or that is compiled in but deactivated, MySQL instead creates a table using the default storage engine. For example, in a replication setup, perhaps your source server uses `InnoDB` tables for maximum safety, but the replica servers use other storage engines for speed at the expense of durability or concurrency.

By default, a warning is generated whenever `CREATE TABLE` or `ALTER TABLE` cannot use the default storage engine. To prevent confusing, unintended behavior if the desired engine is unavailable, enable the `NO_ENGINE_SUBSTITUTION` SQL mode. If the desired engine is unavailable, this setting produces an error instead of a warning, and the table is not created or altered. See Section 5.1.11, “Server SQL Modes”.

MySQL may store a table's index and data in one or more other files, depending on the storage engine. Table and column definitions are stored in the MySQL data dictionary. Individual storage engines create any additional files required for the tables that they manage. If a table name contains special characters, the names for the table files contain encoded versions of those characters as described in Section 9.2.4, “Mapping of Identifiers to File Names”.

16.2 The MyISAM Storage Engine

MyISAM is based on the older (and no longer available) ISAM storage engine but has many useful extensions.

Each MyISAM table is stored on disk in two files. The files have names that begin with the table name and have an extension to indicate the file type. The data file has an .MYD (MYData) extension. The index file has an .MYI (MYIndex) extension. The table definition is stored in the MySQL data dictionary.

To specify explicitly that you want a MyISAM table, indicate that with an ENGINE table option:

```sql
CREATE TABLE t (i INT) ENGINE = MYISAM;
```

In MySQL 8.0, it is normally necessary to use ENGINE to specify the MyISAM storage engine because InnoDB is the default engine.

You can check or repair MyISAM tables with the mysqlcheck client or myisamchk utility. You can also compress MyISAM tables with myisampack to take up much less space. See Section 4.5.3, “mysqlcheck — A Table Maintenance Program”, Section 4.6.4, “myisamchk — MyISAM Table-Maintenance Utility”, and Section 4.6.6, “myisampack — Generate Compressed, Read-Only MyISAM Tables”.

In MySQL 8.0, the MyISAM storage engine provides no partitioning support. Partitioned MyISAM tables created in previous versions of MySQL cannot be used in MySQL 8.0. For more information, see Section 24.6.2, “Partitioning Limitations Relating to Storage Engines”. For help with upgrading such tables so that they can be used in MySQL 8.0, see Section 2.10.4, “Changes in MySQL 8.0”.

MyISAM tables have the following characteristics:

- All data values are stored with the low byte first. This makes the data machine and operating system independent. The only requirements for binary portability are that the machine uses two's-complement signed integers and IEEE floating-point format. These requirements are widely used among mainstream machines. Binary compatibility might not be applicable to embedded systems, which sometimes have peculiar processors.

There is no significant speed penalty for storing data low byte first; the bytes in a table row normally are unaligned and it takes little more processing to read an unaligned byte in order than in reverse order. Also, the code in the server that fetches column values is not time critical compared to other code.
The MyISAM Storage Engine

- All numeric key values are stored with the high byte first to permit better index compression.

- Large files (up to 63-bit file length) are supported on file systems and operating systems that support large files.

- There is a limit of \(2^{32} \times 2\) (1.844E+19) rows in a MyISAM table.

- The maximum number of indexes per MyISAM table is 64.

- The maximum number of columns per index is 16.

- The maximum key length is 1000 bytes. This can also be changed by changing the source and recompiling. For the case of a key longer than 250 bytes, a larger key block size than the default of 1024 bytes is used.

- When rows are inserted in sorted order (as when you are using an AUTO_INCREMENT column), the index tree is split so that the high node only contains one key. This improves space utilization in the index tree.

- Internal handling of one AUTO_INCREMENT column per table is supported. MyISAM automatically updates this column for INSERT and UPDATE operations. This makes AUTO_INCREMENT columns faster (at least 10%). Values at the top of the sequence are not reused after being deleted. (When an AUTO_INCREMENT column is defined as the last column of a multiple-column index, reuse of values deleted from the top of a sequence does occur.) The AUTO_INCREMENT value can be reset with ALTER TABLE or myisamchk.

- Dynamic-sized rows are much less fragmented when mixing deletes with updates and inserts. This is done by automatically combining adjacent deleted blocks and by extending blocks if the next block is deleted.

- MyISAM supports concurrent inserts: If a table has no free blocks in the middle of the data file, you can INSERT new rows into it at the same time that other threads are reading from the table. A free block can occur as a result of deleting rows or an update of a dynamic length row with more data than its current contents. When all free blocks are used up (filled in), future inserts become concurrent again. See Section 8.11.3, “Concurrent Inserts”.

- You can put the data file and index file in different directories on different physical devices to get more speed with the DATA DIRECTORY and INDEX DIRECTORY table options to CREATE TABLE. See Section 13.1.20, “CREATE TABLE Statement”.

- BLOB and TEXT columns can be indexed.

- NULL values are permitted in indexed columns. This takes 0 to 1 bytes per key.

- Each character column can have a different character set. See Chapter 10, Character Sets, Collations, Unicode.

- There is a flag in the MyISAM index file that indicates whether the table was closed correctly. If mysqld is started with the myisam_recover_options system variable set, MyISAM tables are automatically checked when opened, and are repaired if the table wasn't closed properly.

- myisamchk marks tables as checked if you run it with the --update-state option. myisamchk --fast checks only those tables that don't have this mark.

- myisamchk --analyze stores statistics for portions of keys, as well as for entire keys.

- myisampack can pack BLOB and VARCHAR columns.
**MyISAM** also supports the following features:

- Support for a true **VARCHAR** type; a **VARCHAR** column starts with a length stored in one or two bytes.
- Tables with **VARCHAR** columns may have fixed or dynamic row length.
- The sum of the lengths of the **VARCHAR** and **CHAR** columns in a table may be up to 64KB.
- Arbitrary length **UNIQUE** constraints.

</tbody>
</table>

The following system variables affect the behavior of **MyISAM** tables. For additional information, see [Section 5.1.8, “Server System Variables”](#).

- **bulk_insert_buffer_size**

  The size of the tree cache used in bulk insert optimization.

  **Note**

  This is a limit *per thread!*
Space Needed for Keys

- **delay_key_write=ALL**

  Don't flush key buffers between writes for any MyISAM table.

  **Note**

  If you do this, you should not access MyISAM tables from another program (such as from another MySQL server or with `myisamchk`) when the tables are in use. Doing so risks index corruption. Using `--external-locking` does not eliminate this risk.

- **myisam_max_sort_file_size**

  The maximum size of the temporary file that MySQL is permitted to use while re-creating a MyISAM index (during `REPAIR TABLE`, `ALTER TABLE`, or `LOAD DATA`). If the file size would be larger than this value, the index is created using the key cache instead, which is slower. The value is given in bytes.

- **myisam_recover_options=mode**

  Set the mode for automatic recovery of crashed MyISAM tables.

- **myisam_sort_buffer_size**

  Set the size of the buffer used when recovering tables.

  Automatic recovery is activated if you start `mysqld` with the `myisam_recover_options` system variable set. In this case, when the server opens a MyISAM table, it checks whether the table is marked as crashed or whether the open count variable for the table is not 0 and you are running the server with external locking disabled. If either of these conditions is true, the following happens:

  - The server checks the table for errors.
  - If the server finds an error, it tries to do a fast table repair (with sorting and without re-creating the data file).
  - If the repair fails because of an error in the data file (for example, a duplicate-key error), the server tries again, this time re-creating the data file.
  - If the repair still fails, the server tries once more with the old repair option method (write row by row without sorting). This method should be able to repair any type of error and has low disk space requirements.

  If the recovery wouldn't be able to recover all rows from previously completed statements and you didn't specify `FORCE` in the value of the `myisam_recover_options` system variable, automatic repair aborts with an error message in the error log:

  ```
  Error: Couldn't repair table: test.g00pages
  ```

  If you specify `FORCE`, a warning like this is written instead:

  ```
  Warning: Found 344 of 354 rows when repairing ./test/g00pages
  ```

  If the automatic recovery value includes `BACKUP`, the recovery process creates files with names of the form `tbl_name-datetime.BAK`. You should have a `cron` script that automatically moves these files from the database directories to backup media.

### 16.2.2 Space Needed for Keys
**MyISAM** tables use B-tree indexes. You can roughly calculate the size for the index file as \((\text{key_length} + 4) / 0.67\), summed over all keys. This is for the worst case when all keys are inserted in sorted order and the table doesn't have any compressed keys.

String indexes are space compressed. If the first index part is a string, it is also prefix compressed. Space compression makes the index file smaller than the worst-case figure if a string column has a lot of trailing space or is a **VARCHAR** column that is not always used to the full length. Prefix compression is used on keys that start with a string. Prefix compression helps if there are many strings with an identical prefix.

In **MyISAM** tables, you can also prefix compress numbers by specifying the **PACK_KEYS=1** table option when you create the table. Numbers are stored with the high byte first, so this helps when you have many integer keys that have an identical prefix.

### 16.2.3 MyISAM Table Storage Formats

**MyISAM** supports three different storage formats. Two of them, fixed and dynamic format, are chosen automatically depending on the type of columns you are using. The third, compressed format, can be created only with the **myisampack** utility (see Section 4.6.6, "myisampack — Generate Compressed, Read-Only MyISAM Tables").

When you use **CREATE TABLE** or **ALTER TABLE** for a table that has no **BLOB** or **TEXT** columns, you can force the table format to **FIXED** or **DYNAMIC** with the **ROW_FORMAT** table option.

See Section 13.1.20, "CREATE TABLE Statement", for information about **ROW_FORMAT**.

You can decompress (unpack) compressed **MyISAM** tables using **myisamchk --unpack**; see Section 4.6.4, "myisamchk — MyISAM Table-Maintenance Utility", for more information.

### 16.2.3.1 Static (Fixed-Length) Table Characteristics

Static format is the default for **MyISAM** tables. It is used when the table contains no variable-length columns (**VARCHAR**, **VARBINARY**, **BLOB**, or **TEXT**). Each row is stored using a fixed number of bytes.

Of the three **MyISAM** storage formats, static format is the simplest and most secure (least subject to corruption). It is also the fastest of the on-disk formats due to the ease with which rows in the data file can be found on disk: To look up a row based on a row number in the index, multiply the row number by the row length to calculate the row position. Also, when scanning a table, it is very easy to read a constant number of rows with each disk read operation.

The security is evidenced if your computer crashes while the MySQL server is writing to a fixed-format **MyISAM** file. In this case, **myisamchk** can easily determine where each row starts and ends, so it can usually reclaim all rows except the partially written one. **MyISAM** table indexes can always be reconstructed based on the data rows.

**Note**

Fixed-length row format is available only for tables having no **BLOB** or **TEXT** columns. Creating a table having such columns with an explicit **ROW_FORMAT** clause does not raise an error or warning; the format specification is ignored.

Static-format tables have these characteristics:

- **CHAR** and **VARCHAR** columns are space-padded to the specified column width, although the column type is not altered. **BINARY** and **VARBINARY** columns are padded with **0x00** bytes to the column width.
MyISAM Table Storage Formats

- **NULL** columns require additional space in the row to record whether their values are **NULL**. Each **NULL** column takes one bit extra, rounded up to the nearest byte.

- Very quick.

- Easy to cache.

- Easy to reconstruct after a crash, because rows are located in fixed positions.

- Reorganization is unnecessary unless you delete a huge number of rows and want to return free disk space to the operating system. To do this, use `OPTIMIZE TABLE` or `myisamchk -r`.

- Usually require more disk space than dynamic-format tables.

- The expected row length in bytes for static-sized rows is calculated using the following expression:

  \[
  \text{row length} = 1 + \left( \text{sum of column lengths} \right) + \left( \text{number of NULL columns} + \text{delete_flag} + 7 \right)/8 + \left( \text{number of variable-length columns} \right)
  \]

  `delete_flag` is 1 for tables with static row format. Static tables use a bit in the row record for a flag that indicates whether the row has been deleted. `delete_flag` is 0 for dynamic tables because the flag is stored in the dynamic row header.

16.2.3.2 Dynamic Table Characteristics

Dynamic storage format is used if a MyISAM table contains any variable-length columns (**VARCHAR**, **VARBINARY**, **BLOB**, or **TEXT**), or if the table was created with the `ROW_FORMAT=DYNAMIC` table option.

Dynamic format is a little more complex than static format because each row has a header that indicates how long it is. A row can become fragmented (stored in noncontiguous pieces) when it is made longer as a result of an update.

You can use `OPTIMIZE TABLE` or `myisamchk -r` to defragment a table. If you have fixed-length columns that you access or change frequently in a table that also contains some variable-length columns, it might be a good idea to move the variable-length columns to other tables just to avoid fragmentation.

Dynamic-format tables have these characteristics:

- All string columns are dynamic except those with a length less than four.

- Each row is preceded by a bitmap that indicates which columns contain the empty string (for string columns) or zero (for numeric columns). This does not include columns that contain **NULL** values. If a string column has a length of zero after trailing space removal, or a numeric column has a value of zero, it is marked in the bitmap and not saved to disk. Nonempty strings are saved as a length byte plus the string contents.

- **NULL** columns require additional space in the row to record whether their values are **NULL**. Each **NULL** column takes one bit extra, rounded up to the nearest byte.

- Much less disk space usually is required than for fixed-length tables.

- Each row uses only as much space as is required. However, if a row becomes larger, it is split into as many pieces as are required, resulting in row fragmentation. For example, if you update a row with information that extends the row length, the row becomes fragmented. In this case, you may have to run `OPTIMIZE TABLE` or `myisamchk -r` from time to time to improve performance. Use `myisamchk -ei` to obtain table statistics.
• More difficult than static-format tables to reconstruct after a crash, because rows may be fragmented into many pieces and links (fragments) may be missing.

• The expected row length for dynamic-sized rows is calculated using the following expression:

\[
\begin{align*}
3 &+ \left(\text{number of columns} + 7\right)/8 \\
&+ \left(\text{number of char columns}\right) \\
&+ (\text{packed size of numeric columns}) \\
&+ (\text{length of strings}) \\
&+ (\text{number of NULL columns} + 7)/8
\end{align*}
\]

There is a penalty of 6 bytes for each link. A dynamic row is linked whenever an update causes an enlargement of the row. Each new link is at least 20 bytes, so the next enlargement probably goes in the same link. If not, another link is created. You can find the number of links using `myisamchk -ed`. All links may be removed with `OPTIMIZE TABLE` or `myisamchk -r`.

16.2.3.3 Compressed Table Characteristics

Compressed storage format is a read-only format that is generated with the `myisampack` tool. Compressed tables can be uncompressed with `myisamchk`.

Compressed tables have the following characteristics:

• Compressed tables take very little disk space. This minimizes disk usage, which is helpful when using slow disks (such as CD-ROMs).

• Each row is compressed separately, so there is very little access overhead. The header for a row takes up one to three bytes depending on the biggest row in the table. Each column is compressed differently. There is usually a different Huffman tree for each column. Some of the compression types are:

  • Suffix space compression.
  • Prefix space compression.
  • Numbers with a value of zero are stored using one bit.
  • If values in an integer column have a small range, the column is stored using the smallest possible type. For example, a `BIGINT` column (eight bytes) can be stored as a `TINYINT` column (one byte) if all its values are in the range from `-128` to `127`.
  • If a column has only a small set of possible values, the data type is converted to `ENUM`.
  • A column may use any combination of the preceding compression types.
  • Can be used for fixed-length or dynamic-length rows.

**Note**

While a compressed table is read only, and you cannot therefore update or add rows in the table, DDL (Data Definition Language) operations are still valid. For example, you may still use `DROP` to drop the table, and `TRUNCATE TABLE` to empty the table.

16.2.4 MyISAM Table Problems

The file format that MySQL uses to store data has been extensively tested, but there are always circumstances that may cause database tables to become corrupted. The following discussion describes how this can happen and how to handle it.
16.2.4.1 Corrupted MyISAM Tables

Even though the MyISAM table format is very reliable (all changes to a table made by an SQL statement are written before the statement returns), you can still get corrupted tables if any of the following events occur:

- The mysqld process is killed in the middle of a write.
- An unexpected computer shutdown occurs (for example, the computer is turned off).
- Hardware failures.
- You are using an external program (such as myisamchk) to modify a table that is being modified by the server at the same time.
- A software bug in the MySQL or MyISAM code.

Typical symptoms of a corrupt table are:

- You get the following error while selecting data from the table:

```
Incorrect key file for table: '...'. Try to repair it
```

- Queries don't find rows in the table or return incomplete results.

You can check the health of a MyISAM table using the CHECK TABLE statement, and repair a corrupted MyISAM table with REPAIR TABLE. When mysqld is not running, you can also check or repair a table with the myisamchk command. See Section 13.7.3.2, “CHECK TABLE Statement”, Section 13.7.3.5, “REPAIR TABLE Statement”, and Section 4.6.4, “myisamchk — MyISAM Table-Maintenance Utility”.

If your tables become corrupted frequently, you should try to determine why this is happening. The most important thing to know is whether the table became corrupted as a result of an unexpected server exit. You can verify this easily by looking for a recent restarted mysqld message in the error log. If there is such a message, it is likely that table corruption is a result of the server dying. Otherwise, corruption may have occurred during normal operation. This is a bug. You should try to create a reproducible test case that demonstrates the problem. See Section B.3.3.3, “What to Do If MySQL Keeps Crashing”, and Section 5.9, “Debugging MySQL”.

16.2.4.2 Problems from Tables Not Being Closed Properly

Each MyISAM index file (.MYI file) has a counter in the header that can be used to check whether a table has been closed properly. If you get the following warning from CHECK TABLE or myisamchk, it means that this counter has gone out of sync:

```
clients are using or haven't closed the table properly
```

This warning doesn't necessarily mean that the table is corrupted, but you should at least check the table. The counter works as follows:

- The first time a table is updated in MySQL, a counter in the header of the index files is incremented.
- The counter is not changed during further updates.
- When the last instance of a table is closed (because a FLUSH TABLES operation was performed or because there is no room in the table cache), the counter is decremented if the table has been updated at any point.
- When you repair the table or check the table and it is found to be okay, the counter is reset to zero.
To avoid problems with interaction with other processes that might check the table, the counter is not decremented on close if it was zero.

In other words, the counter can become incorrect only under these conditions:

- A MyISAM table is copied without first issuing LOCK TABLES and FLUSH TABLES.
- MySQL has crashed between an update and the final close. (The table may still be okay because MySQL always issues writes for everything between each statement.)
- A table was modified by myisamchk --recover or myisamchk --update-state at the same time that it was in use by mysqld.
- Multiple mysqld servers are using the table and one server performed a REPAIR TABLE or CHECK TABLE on the table while it was in use by another server. In this setup, it is safe to use CHECK TABLE, although you might get the warning from other servers. However, REPAIR TABLE should be avoided because when one server replaces the data file with a new one, this is not known to the other servers.

In general, it is a bad idea to share a data directory among multiple servers. See Section 5.8, “Running Multiple MySQL Instances on One Machine”, for additional discussion.

### 16.3 The MEMORY Storage Engine

The MEMORY storage engine (formerly known as HEAP) creates special-purpose tables with contents that are stored in memory. Because the data is vulnerable to crashes, hardware issues, or power outages, only use these tables as temporary work areas or read-only caches for data pulled from other tables.

## When to Use MEMORY or NDB Cluster

Developers looking to deploy applications that use the `MEMORY` storage engine for important, highly available, or frequently updated data should consider whether NDB Cluster is a better choice. A typical use case for the `MEMORY` engine involves these characteristics:

- Operations involving transient, non-critical data such as session management or caching. When the MySQL server halts or restarts, the data in `MEMORY` tables is lost.

- In-memory storage for fast access and low latency. Data volume can fit entirely in memory without causing the operating system to swap out virtual memory pages.

- A read-only or read-mostly data access pattern (limited updates).

NDB Cluster offers the same features as the `MEMORY` engine with higher performance levels, and provides additional features not available with `MEMORY`:

- Row-level locking and multiple-thread operation for low contention between clients.

- Scalability even with statement mixes that include writes.

- Optional disk-backed operation for data durability.

- Shared-nothing architecture and multiple-host operation with no single point of failure, enabling 99.999% availability.

- Automatic data distribution across nodes; application developers need not craft custom sharding or partitioning solutions.

- Support for variable-length data types (including `BLOB` and `TEXT`) not supported by `MEMORY`.

### When to Use MEMORY or NDB Cluster

- Partitioning
- Performance Characteristics
- Characteristics of MEMORY Tables
- DDL Operations for MEMORY Tables
- Indexes
- User-Created and Temporary Tables
- Loading Data
- MEMORY Tables and Replication
- Managing Memory Use
- Additional Resources
Partitioning

MEMORY tables cannot be partitioned.

Performance Characteristics

MEMORY performance is constrained by contention resulting from single-thread execution and table lock overhead when processing updates. This limits scalability when load increases, particularly for statement mixes that include writes.

Despite the in-memory processing for MEMORY tables, they are not necessarily faster than InnoDB tables on a busy server, for general-purpose queries, or under a read/write workload. In particular, the table locking involved with performing updates can slow down concurrent usage of MEMORY tables from multiple sessions.

Depending on the kinds of queries performed on a MEMORY table, you might create indexes as either the default hash data structure (for looking up single values based on a unique key), or a general-purpose B-tree data structure (for all kinds of queries involving equality, inequality, or range operators such as less than or greater than). The following sections illustrate the syntax for creating both kinds of indexes. A common performance issue is using the default hash indexes in workloads where B-tree indexes are more efficient.

Characteristics of MEMORY Tables

The MEMORY storage engine does not create any files on disk. The table definition is stored in the MySQL data dictionary.

MEMORY tables have the following characteristics:

• Space for MEMORY tables is allocated in small blocks. Tables use 100% dynamic hashing for inserts. No overflow area or extra key space is needed. No extra space is needed for free lists. Deleted rows are put in a linked list and are reused when you insert new data into the table. MEMORY tables also have none of the problems commonly associated with deletes plus inserts in hashed tables.

• MEMORY tables use a fixed-length row-storage format. Variable-length types such as VARCHAR are stored using a fixed length.

• MEMORY tables cannot contain BLOB or TEXT columns.

• MEMORY includes support for AUTO_INCREMENT columns.

• Non-TEMPORARY MEMORY tables are shared among all clients, just like any other non-TEMPORARY table.

DDL Operations for MEMORY Tables

To create a MEMORY table, specify the clause ENGINE=MEMORY on the CREATE TABLE statement.

```
CREATE TABLE t (i INT) ENGINE = MEMORY;
```

As indicated by the engine name, MEMORY tables are stored in memory. They use hash indexes by default, which makes them very fast for single-value lookups, and very useful for creating temporary tables. However, when the server shuts down, all rows stored in MEMORY tables are lost. The tables themselves continue to exist because their definitions are stored in the MySQL data dictionary, but they are empty when the server restarts.

This example shows how you might create, use, and remove a MEMORY table:
Indexes

The maximum size of MEMORY tables is limited by the `max_heap_table_size` system variable, which has a default value of 16MB. To enforce different size limits for MEMORY tables, change the value of this variable. The value in effect for CREATE TABLE, or a subsequent ALTER TABLE or TRUNCATE TABLE, is the value used for the life of the table. A server restart also sets the maximum size of existing MEMORY tables to the global `max_heap_table_size` value. You can set the size for individual tables as described later in this section.

Indexes

The MEMORY storage engine supports both HASH and BTREE indexes. You can specify one or the other for a given index by adding a USING clause as shown here:

```sql
CREATE TABLE lookup
  (id INT, INDEX USING HASH (id))
ENGINE = MEMORY;

CREATE TABLE lookup
  (id INT, INDEX USING BTREE (id))
ENGINE = MEMORY;
```

For general characteristics of B-tree and hash indexes, see Section 8.3.1, “How MySQL Uses Indexes”.

MEMORY tables can have up to 64 indexes per table, 16 columns per index and a maximum key length of 3072 bytes.

If a MEMORY table hash index has a high degree of key duplication (many index entries containing the same value), updates to the table that affect key values and all deletes are significantly slower. The degree of this slowdown is proportional to the degree of duplication (or, inversely proportional to the index cardinality). You can use a BTREE index to avoid this problem.

MEMORY tables can have nonunique keys. (This is an uncommon feature for implementations of hash indexes.)

Columns that are indexed can contain NULL values.

User-Created and Temporary Tables

MEMORY table contents are stored in memory, which is a property that MEMORY tables share with internal temporary tables that the server creates on the fly while processing queries. However, the two types of tables differ in that MEMORY tables are not subject to storage conversion, whereas internal temporary tables are:

- If an internal temporary table becomes too large, the server automatically converts it to on-disk storage, as described in Section 8.4.4, “Internal Temporary Table Use in MySQL”.
- User-created MEMORY tables are never converted to disk tables.

Loading Data

To populate a MEMORY table when the MySQL server starts, you can use the `init_file` system variable. For example, you can put statements such as INSERT INTO ... SELECT or LOAD DATA into a file to load the table from a persistent data source, and use `init_file` to name the file. See Section 5.1.8, “Server System Variables”, and Section 13.2.9, “LOAD DATA Statement”.

3695
MEMORY Tables and Replication

When a replication source server shuts down and restarts, its MEMORY tables become empty. To replicate this effect to replicas, the first time that the source uses a given MEMORY table after startup, it logs an event that notifies replicas that the table must be emptied by writing a DELETE or (from MySQL 8.0.22) TRUNCATE TABLE statement for that table to the binary log. When a replica server shuts down and restarts, its MEMORY tables also become empty, and it writes a DELETE or (from MySQL 8.0.22) TRUNCATE TABLE statement to its own binary log, which is passed on to any downstream replicas.

When you use MEMORY tables in a replication topology, in some situations, the table on the source and the table on the replica can differ. For information on handling each of these situations to prevent stale reads or errors, see Section 17.5.1.21, "Replication and MEMORY Tables".

Managing Memory Use

The server needs sufficient memory to maintain all MEMORY tables that are in use at the same time.

Memory is not reclaimed if you delete individual rows from a MEMORY table. Memory is reclaimed only when the entire table is deleted. Memory that was previously used for deleted rows is re-used for new rows within the same table. To free all the memory used by a MEMORY table when you no longer require its contents, execute DELETE or TRUNCATE TABLE to remove all rows, or remove the table altogether using DROP TABLE. To free up the memory used by deleted rows, use ALTER TABLE ENGINE=MEMORY to force a table rebuild.

The memory needed for one row in a MEMORY table is calculated using the following expression:

\[
\text{memory needed per row} = \text{SUM_OVER_ALL_BTREE_KEYS}(\text{max_length_of_key} + \text{sizeof(char*)} \times 4) + \text{SUM_OVER_ALL_HASH_KEYS} (\text{sizeof(char*)} \times 2) + \text{ALIGN}(\text{length_of_row} + 1, \text{sizeof(char*)})
\]

ALIGN() represents a round-up factor to cause the row length to be an exact multiple of the char pointer size. sizeof(char*) is 4 on 32-bit machines and 8 on 64-bit machines.

As mentioned earlier, the max_heap_table_size system variable sets the limit on the maximum size of MEMORY tables. To control the maximum size for individual tables, set the session value of this variable before creating each table. (Do not change the global max_heap_table_size value unless you intend the value to be used for MEMORY tables created by all clients.) The following example creates two MEMORY tables, with a maximum size of 1MB and 2MB, respectively:

```
mysql> SET max_heap_table_size = 1024*1024;
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t1 (id INT, UNIQUE(id)) ENGINE = MEMORY;
Query OK, 0 rows affected (0.01 sec)

mysql> SET max_heap_table_size = 1024*1024*2;
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t2 (id INT, UNIQUE(id)) ENGINE = MEMORY;
Query OK, 0 rows affected (0.00 sec)
```

Both tables revert to the server's global max_heap_table_size value if the server restarts.

You can also specify a MAX_ROWS table option in CREATE TABLE statements for MEMORY tables to provide a hint about the number of rows you plan to store in them. This does not enable the table to grow beyond the max_heap_table_size value, which still acts as a constraint on maximum table size. For maximum flexibility in being able to use MAX_ROWS, set max_heap_table_size at least as high as the value to which you want each MEMORY table to be able to grow.
Additional Resources

A forum dedicated to the MEMORY storage engine is available at https://forums.mysql.com/list.php?92.

16.4 The CSV Storage Engine

The CSV storage engine stores data in text files using comma-separated values format.

The CSV storage engine is always compiled into the MySQL server.

To examine the source for the CSV engine, look in the storage/csv directory of a MySQL source distribution.

When you create a CSV table, the server creates a plain text data file having a name that begins with the table name and has a .CSV extension. When you store data into the table, the storage engine saves it into the data file in comma-separated values format.

```
mysql> CREATE TABLE test (i INT NOT NULL, c CHAR(10) NOT NULL)
    ENGINE = CSV;
Query OK, 0 rows affected (0.06 sec)
```

```
mysql> INSERT INTO test VALUES(1,'record one'),(2,'record two');
Query OK, 2 rows affected (0.05 sec)
Records: 2  Duplicates: 0  Warnings: 0
```

```
mysql> SELECT * FROM test;
+---+------------+
| i | c          |
|---+------------|
| 1 | record one |
| 2 | record two |
+---+------------+
2 rows in set (0.00 sec)
```

Creating a CSV table also creates a corresponding metafile that stores the state of the table and the number of rows that exist in the table. The name of this file is the same as the name of the table with the extension CSM.

If you examine the test.CSV file in the database directory created by executing the preceding statements, its contents should look like this:

```
"1","record one"
"2","record two"
```

This format can be read, and even written, by spreadsheet applications such as Microsoft Excel.

16.4.1 Repairing and Checking CSV Tables

The CSV storage engine supports the CHECK TABLE and REPAIR TABLE statements to verify and, if possible, repair a damaged CSV table.

When running the CHECK TABLE statement, the CSV file is checked for validity by looking for the correct field separators, escaped fields (matching or missing quotation marks), the correct number of fields compared to the table definition and the existence of a corresponding CSV metafile. The first invalid row discovered causes an error. Checking a valid table produces output like that shown here:

```
mysql> CHECK TABLE csvtest;
+---------------+-------+----------+----------+
| Table         | Op    | Msg_type | Msg_text |
|---------------+-------+----------+----------|
+---------------+-------+----------+----------+
3697
```
A check on a corrupted table returns a fault such as

```
mysql> CHECK TABLE csvtest;
```

To repair a table, use `REPAIR TABLE`, which copies as many valid rows from the existing CSV data as possible, and then replaces the existing CSV file with the recovered rows. Any rows beyond the corrupted data are lost.

```
mysql> REPAIR TABLE csvtest;
```

**Warning**

During repair, only the rows from the CSV file up to the first damaged row are copied to the new table. All other rows from the first damaged row to the end of the table are removed, even valid rows.

### 16.4.2 CSV Limitations

The CSV storage engine does not support indexing.

The CSV storage engine does not support partitioning.

All tables that you create using the CSV storage engine must have the `NOT NULL` attribute on all columns.

### 16.5 The ARCHIVE Storage Engine

The ARCHIVE storage engine produces special-purpose tables that store large amounts of unindexed data in a very small footprint.

**Table 16.5 ARCHIVE Storage Engine Features**

3698
The **ARCHIVE** storage engine is included in MySQL binary distributions. To enable this storage engine if you build MySQL from source, invoke **CMake** with the `-DWITH_ARCHIVE_STORAGE_ENGINE` option.

To examine the source for the **ARCHIVE** engine, look in the `storage/archive` directory of a MySQL source distribution.

You can check whether the **ARCHIVE** storage engine is available with the **SHOW ENGINES** statement.

When you create an **ARCHIVE** table, the storage engine creates files with names that begin with the table name. The data file has an extension of `.ARZ`. An `.ARN` file may appear during optimization operations.

The **ARCHIVE** engine supports **INSERT**, **REPLACE**, and **SELECT**, but not **DELETE** or **UPDATE**. It does support **ORDER BY** operations, **BLOB** columns, and spatial data types (see Section 11.4.1, “Spatial Data Types”). Geographic spatial reference systems are not supported. The **ARCHIVE** engine uses row-level locking.

The **ARCHIVE** engine supports the **AUTO_INCREMENT** column attribute. The **AUTO_INCREMENT** column can have either a unique or nonunique index. Attempting to create an index on any other column results in an error. The **ARCHIVE** engine also supports the **AUTO_INCREMENT** table option in **CREATE TABLE** statements to specify the initial sequence value for a new table or reset the sequence value for an existing table, respectively.

**ARCHIVE** does not support inserting a value into an **AUTO_INCREMENT** column less than the current maximum column value. Attempts to do so result in an **ER_DUP_KEY** error.

The **ARCHIVE** engine ignores **BLOB** columns if they are not requested and scans past them while reading.

The **ARCHIVE** storage engine does not support partitioning.

**Storage:** Rows are compressed as they are inserted. The **ARCHIVE** engine uses **zlib** lossless data compression (see http://www.zlib.net/). You can use **OPTIMIZE TABLE** to analyze the table and pack it into a smaller format (for a reason to use **OPTIMIZE TABLE**, see later in this section). The engine also supports **CHECK TABLE**. There are several types of insertions that are used:

- An **INSERT** statement just pushes rows into a compression buffer, and that buffer flushes as necessary. The insertion into the buffer is protected by a lock. A **SELECT** forces a flush to occur.

</tbody>
</table>
Additional Resources

- A bulk insert is visible only after it completes, unless other inserts occur at the same time, in which case it can be seen partially. A `SELECT` never causes a flush of a bulk insert unless a normal insert occurs while it is loading.

**Retrieval:** On retrieval, rows are uncompressed on demand; there is no row cache. A `SELECT` operation performs a complete table scan: When a `SELECT` occurs, it finds out how many rows are currently available and reads that number of rows. `SELECT` is performed as a consistent read. Note that lots of `SELECT` statements during insertion can deteriorate the compression, unless only bulk inserts are used. To achieve better compression, you can use `OPTIMIZE TABLE` or `REPAIR TABLE`. The number of rows in `ARCHIVE` tables reported by `SHOW TABLE STATUS` is always accurate. See Section 13.7.3.4, “OPTIMIZE TABLE Statement”, Section 13.7.3.5, “REPAIR TABLE Statement”, and Section 13.7.7.38, “SHOW TABLE STATUS Statement”.

**Additional Resources**

### 16.6 The BLACKHOLE Storage Engine

The `BLACKHOLE` storage engine acts as a “black hole” that accepts data but throws it away and does not store it. Retrievals always return an empty result:

```sql
mysql> CREATE TABLE test(i INT, c CHAR(10)) ENGINE = BLACKHOLE;
Query OK, 0 rows affected (0.03 sec)

mysql> INSERT INTO test VALUES(1,'record one'),(2,'record two');
Query OK, 2 rows affected (0.00 sec)
Records: 2  Duplicates: 0  Warnings: 0

mysql> SELECT * FROM test;
Empty set (0.00 sec)
```

To enable the `BLACKHOLE` storage engine if you build MySQL from source, invoke `CMake` with the `-DWITH_BLACKHOLE_STORAGE_ENGINE` option.

To examine the source for the `BLACKHOLE` engine, look in the `sql` directory of a MySQL source distribution.

When you create a `BLACKHOLE` table, the server creates the table definition in the global data dictionary. There are no files associated with the table.

The `BLACKHOLE` storage engine supports all kinds of indexes. That is, you can include index declarations in the table definition.

The maximum key length is 3072 bytes as of MySQL 8.0.27. Prior to 8.0.27, the maximum key length is 1000 bytes.

The `BLACKHOLE` storage engine does not support partitioning.

You can check whether the `BLACKHOLE` storage engine is available with the `SHOW ENGINES` statement.

Inserts into a `BLACKHOLE` table do not store any data, but if statement based binary logging is enabled, the SQL statements are logged and replicated to replica servers. This can be useful as a repeater or filter mechanism.

Suppose that your application requires replica-side filtering rules, but transferring all binary log data to the replica first results in too much traffic. In such a case, it is possible to set up on the replication source server a “dummy” replica process whose default storage engine is `BLACKHOLE`, depicted as follows:
The source writes to its binary log. The “dummy” `mysqld` process acts as a replica, applying the desired combination of `replicate-do-*` and `replicate-ignore-*` rules, and writes a new, filtered binary log of its own. (See Section 17.1.6, “Replication and Binary Logging Options and Variables”.) This filtered log is provided to the replica.

The dummy process does not actually store any data, so there is little processing overhead incurred by running the additional `mysqld` process on the replication source server. This type of setup can be repeated with additional replicas.

**INSERT** triggers for `BLACKHOLE` tables work as expected. However, because the `BLACKHOLE` table does not actually store any data, **UPDATE** and **DELETE** triggers are not activated: The **FOR EACH ROW** clause in the trigger definition does not apply because there are no rows.

Other possible uses for the `BLACKHOLE` storage engine include:

- Verification of dump file syntax.
- Measurement of the overhead from binary logging, by comparing performance using `BLACKHOLE` with and without binary logging enabled.
- `BLACKHOLE` is essentially a “no-op” storage engine, so it could be used for finding performance bottlenecks not related to the storage engine itself.

The `BLACKHOLE` engine is transaction-aware, in the sense that committed transactions are written to the binary log and rolled-back transactions are not.

**Blackhole Engine and Auto Increment Columns**

The `BLACKHOLE` engine is a no-op engine. Any operations performed on a table using `BLACKHOLE` have no effect. This should be borne in mind when considering the behavior of primary key columns that auto increment. The engine does not automatically increment field values, and does not retain auto increment field state. This has important implications in replication.
Consider the following replication scenario where all three of the following conditions apply:

1. On a source server there is a blackhole table with an auto increment field that is a primary key.
2. On a replica the same table exists but using the MyISAM engine.
3. Inserts are performed into the source's table without explicitly setting the auto increment value in the `INSERT` statement itself or through using a `SET INSERT_ID` statement.

In this scenario replication fails with a duplicate entry error on the primary key column.

In statement based replication, the value of `INSERT_ID` in the context event is always the same. Replication therefore fails due to trying insert a row with a duplicate value for a primary key column.

In row based replication, the value that the engine returns for the row always be the same for each insert. This results in the replica attempting to replay two insert log entries using the same value for the primary key column, and so replication fails.

**Column Filtering**

When using row-based replication, `(binlog_format=ROW)`, a replica where the last columns are missing from a table is supported, as described in the section Section 17.5.1.9, “Replication with Differing Table Definitions on Source and Replica”.

This filtering works on the replica side, that is, the columns are copied to the replica before they are filtered out. There are at least two cases where it is not desirable to copy the columns to the replica:

1. If the data is confidential, so the replica server should not have access to it.
2. If the source has many replicas, filtering before sending to the replicas may reduce network traffic.

Source column filtering can be achieved using the `BLACKHOLE` engine. This is carried out in a way similar to how source table filtering is achieved - by using the `BLACKHOLE` engine and the `--replicate-do-table` or `--replicate-ignore-table` option.

The setup for the source is:

```sql
CREATE TABLE t1 (public_col_1, ..., public_col_N, secret_col_1, ..., secret_col_M) ENGINE=MyISAM;
```

The setup for the trusted replica is:

```sql
CREATE TABLE t1 (public_col_1, ..., public_col_N) ENGINE=BLACKHOLE;
```

The setup for the untrusted replica is:

```sql
CREATE TABLE t1 (public_col_1, ..., public_col_N) ENGINE=MyISAM;
```

### 16.7 The MERGE Storage Engine

The `MERGE` storage engine, also known as the `MRG_MyISAM` engine, is a collection of identical `MyISAM` tables that can be used as one. “Identical” means that all tables have identical column data types and index information. You cannot merge `MyISAM` tables in which the columns are listed in a different order, do not have exactly the same data types in corresponding columns, or have the indexes in different order. However, any or all of the `MyISAM` tables can be compressed with `myisampack`. See Section 4.6.6, “myisampack — Generate Compressed, Read-Only MyISAM Tables”. Differences between tables such as these do not matter:

- Names of corresponding columns and indexes can differ.
The MERGE Storage Engine

- Comments for tables, columns, and indexes can differ.
- Table options such as AVG_ROW_LENGTH, MAX_ROWS, or PACK_KEYS can differ.

An alternative to a MERGE table is a partitioned table, which stores partitions of a single table in separate files and enables some operations to be performed more efficiently. For more information, see Chapter 24, Partitioning.

When you create a MERGE table, MySQL creates a .MRG file on disk that contains the names of the underlying MyISAM tables that should be used as one. The table format of the MERGE table is stored in the MySQL data dictionary. The underlying tables do not have to be in the same database as the MERGE table.

You can use SELECT, DELETE, UPDATE, and INSERT on MERGE tables. You must have SELECT, DELETE, and UPDATE privileges on the MyISAM tables that you map to a MERGE table.

**Note**
The use of MERGE tables entails the following security issue: If a user has access to MyISAM table \( t \), that user can create a MERGE table \( m \) that accesses \( t \). However, if the user's privileges on \( t \) are subsequently revoked, the user can continue to access \( t \) by doing so through \( m \).

Use of DROP TABLE with a MERGE table drops only the MERGE specification. The underlying tables are not affected.

To create a MERGE table, you must specify a UNION=(list-of-tables) option that indicates which MyISAM tables to use. You can optionally specify an INSERT_METHOD option to control how inserts into the MERGE table take place. Use a value of FIRST or LAST to cause inserts to be made in the first or last underlying table, respectively. If you specify no INSERT_METHOD option or if you specify it with a value of NO, inserts into the MERGE table are not permitted and attempts to do so result in an error.

The following example shows how to create a MERGE table:

```sql
mysql> CREATE TABLE t1 (
  ->  a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  ->  message CHAR(20)) ENGINE=MyISAM;
mysql> CREATE TABLE t2 (
  ->  a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  ->  message CHAR(20)) ENGINE=MyISAM;
mysql> INSERT INTO t1 (message) VALUES ('Testing'),('table'),('t1');
mysql> INSERT INTO t2 (message) VALUES ('Testing'),('table'),('t2');
mysql> CREATE TABLE total (
  ->  a INT NOT NULL AUTO_INCREMENT,
  ->  message CHAR(20), INDEX(a)) 
  ->  ENGINE=MERGE UNION=(t1,t2) INSERT_METHOD=LAST;
```

Column \( a \) is indexed as a PRIMARY KEY in the underlying MyISAM tables, but not in the MERGE table. There it is indexed but not as a PRIMARY KEY because a MERGE table cannot enforce uniqueness over the set of underlying tables. (Similarly, a column with a UNIQUE index in the underlying tables should be indexed in the MERGE table but not as a UNIQUE index.)

After creating the MERGE table, you can use it to issue queries that operate on the group of tables as a whole:

```sql
mysql> SELECT * FROM total;
+---+---------+
| a | message |
|---+---------|
| 1 | Testing |
| 2 | table   |
| 3 | t1      |
```
To remap a `MERGE` table to a different collection of `MyISAM` tables, you can use one of the following methods:

- **DROP** the `MERGE` table and re-create it.
- **Use** `ALTER TABLE  tbl_name  UNION=(...)` to change the list of underlying tables.

It is also possible to use `ALTER TABLE ... UNION=()` (that is, with an empty `UNION` clause) to remove all of the underlying tables. However, in this case, the table is effectively empty and inserts fail because there is no underlying table to take new rows. Such a table might be useful as a template for creating new `MERGE` tables with `CREATE TABLE ... LIKE`.

The underlying table definitions and indexes must conform closely to the definition of the `MERGE` table. Conformance is checked when a table that is part of a `MERGE` table is opened, not when the `MERGE` table is created. If any table fails the conformance checks, the operation that triggered the opening of the table fails. This means that changes to the definitions of tables within a `MERGE` may cause a failure when the `MERGE` table is accessed. The conformance checks applied to each table are:

- The underlying table and the `MERGE` table must have the same number of columns.
- The column order in the underlying table and the `MERGE` table must match.
- Additionally, the specification for each corresponding column in the parent `MERGE` table and the underlying tables are compared and must satisfy these checks:
  - The column type in the underlying table and the `MERGE` table must be equal.
  - The column length in the underlying table and the `MERGE` table must be equal.
  - The column of the underlying table and the `MERGE` table can be `NULL`.
- The underlying table must have at least as many indexes as the `MERGE` table. The underlying table may have more indexes than the `MERGE` table, but cannot have fewer.

**Note**

A known issue exists where indexes on the same columns must be in identical order, in both the `MERGE` table and the underlying `MyISAM` table. See Bug #33653.

Each index must satisfy these checks:

- The index type of the underlying table and the `MERGE` table must be the same.
- The number of index parts (that is, multiple columns within a compound index) in the index definition for the underlying table and the `MERGE` table must be the same.
- For each index part:
  - Index part lengths must be equal.
  - Index part types must be equal.
  - Index part languages must be equal.
• Check whether index parts can be NULL.

If a `MERGE` table cannot be opened or used because of a problem with an underlying table, `CHECK TABLE` displays information about which table caused the problem.

### Additional Resources

### 16.7.1 MERGE Table Advantages and Disadvantages

`MERGE` tables can help you solve the following problems:

- Easily manage a set of log tables. For example, you can put data from different months into separate tables, compress some of them with `myisampack`, and then create a `MERGE` table to use them as one.

- Obtain more speed. You can split a large read-only table based on some criteria, and then put individual tables on different disks. A `MERGE` table structured this way could be much faster than using a single large table.

- Perform more efficient searches. If you know exactly what you are looking for, you can search in just one of the underlying tables for some queries and use a `MERGE` table for others. You can even have many different `MERGE` tables that use overlapping sets of tables.

- Perform more efficient repairs. It is easier to repair individual smaller tables that are mapped to a `MERGE` table than to repair a single large table.

- Instantly map many tables as one. A `MERGE` table need not maintain an index of its own because it uses the indexes of the individual tables. As a result, `MERGE` table collections are very fast to create or remap. (You must still specify the index definitions when you create a `MERGE` table, even though no indexes are created.)

- If you have a set of tables from which you create a large table on demand, you can instead create a `MERGE` table from them on demand. This is much faster and saves a lot of disk space.

- Exceed the file size limit for the operating system. Each `MyISAM` table is bound by this limit, but a collection of `MyISAM` tables is not.

- You can create an alias or synonym for a `MyISAM` table by defining a `MERGE` table that maps to that single table. There should be no really notable performance impact from doing this (only a couple of indirect calls and `memcpy()` calls for each read).

The disadvantages of `MERGE` tables are:

- You can use only identical `MyISAM` tables for a `MERGE` table.

- Some `MyISAM` features are unavailable in `MERGE` tables. For example, you cannot create `FULLTEXT` indexes on `MERGE` tables. (You can create `FULLTEXT` indexes on the underlying `MyISAM` tables, but you cannot search the `MERGE` table with a full-text search.)

- If the `MERGE` table is nontemporary, all underlying `MyISAM` tables must be nontemporary. If the `MERGE` table is temporary, the `MyISAM` tables can be any mix of temporary and nontemporary.

- `MERGE` tables use more file descriptors than `MyISAM` tables. If 10 clients are using a `MERGE` table that maps to 10 tables, the server uses `(10 × 10) + 10` file descriptors. (10 data file descriptors for each of the 10 clients, and 10 index file descriptors shared among the clients.)
• Index reads are slower. When you read an index, the MERGE storage engine needs to issue a read on all underlying tables to check which one most closely matches a given index value. To read the next index value, the MERGE storage engine needs to search the read buffers to find the next value. Only when one index buffer is used up does the storage engine need to read the next index block. This makes MERGE indexes much slower on \textit{eq\_ref} searches, but not much slower on \textit{ref} searches. For more information about \textit{eq\_ref} and \textit{ref}, see Section 13.8.2, “EXPLAIN Statement”.

16.7.2 MERGE Table Problems

The following are known problems with MERGE tables:

• In versions of MySQL Server prior to 5.1.23, it was possible to create temporary merge tables with nontemporary child MyISAM tables.

From versions 5.1.23, MERGE children were locked through the parent table. If the parent was temporary, it was not locked and so the children were not locked either. Parallel use of the MyISAM tables corrupted them.

• If you use \textsc{ALTER TABLE} to change a MERGE table to another storage engine, the mapping to the underlying tables is lost. Instead, the rows from the underlying MyISAM tables are copied into the altered table, which then uses the specified storage engine.

• The \textsc{INSERT\_METHOD} table option for a MERGE table indicates which underlying MyISAM table to use for inserts into the MERGE table. However, use of the \textsc{AUTO\_INCREMENT} table option for that MyISAM table has no effect for inserts into the MERGE table until at least one row has been inserted directly into the MyISAM table.

• A MERGE table cannot maintain uniqueness constraints over the entire table. When you perform an \textsc{INSERT}, the data goes into the first or last MyISAM table (as determined by the \textsc{INSERT\_METHOD} option). MySQL ensures that unique key values remain unique within that MyISAM table, but not over all the underlying tables in the collection.

• Because the MERGE engine cannot enforce uniqueness over the set of underlying tables, REPLACE does not work as expected. The two key facts are:

  • REPLACE can detect unique key violations only in the underlying table to which it is going to write (which is determined by the \textsc{INSERT\_METHOD} option). This differs from violations in the MERGE table itself.

  • If REPLACE detects a unique key violation, it changes only the corresponding row in the underlying table it is writing to; that is, the first or last table, as determined by the \textsc{INSERT\_METHOD} option.

Similar considerations apply for \textsc{INSERT ... ON DUPLICATE KEY UPDATE}.

• MERGE tables do not support partitioning. That is, you cannot partition a MERGE table, nor can any of a MERGE table’s underlying MyISAM tables be partitioned.

• You should not use \textsc{ANALYZE TABLE}, \textsc{REPAIR TABLE}, \textsc{OPTIMIZE TABLE}, \textsc{ALTER TABLE}, \textsc{DROP TABLE}, \textsc{DELETE} without a \textsc{WHERE} clause, or \textsc{TRUNCATE TABLE} on any of the tables that are mapped into an open MERGE table. If you do so, the MERGE table may still refer to the original table and yield unexpected results. To work around this problem, ensure that no MERGE tables remain open by issuing a \textsc{FLUSH TABLES} statement prior to performing any of the named operations.

The unexpected results include the possibility that the operation on the MERGE table reports table corruption. If this occurs after one of the named operations on the underlying MyISAM tables, the corruption message is spurious. To deal with this, issue a \textsc{FLUSH TABLES} statement after modifying the MyISAM tables.
• **DROP TABLE** on a table that is in use by a **MERGE** table does not work on Windows because the **MERGE** storage engine's table mapping is hidden from the upper layer of MySQL. Windows does not permit open files to be deleted, so you first must flush all **MERGE** tables (with **FLUSH TABLES**) or drop the **MERGE** table before dropping the table.

• The definition of the **MyISAM** tables and the **MERGE** table are checked when the tables are accessed (for example, as part of a **SELECT** or **INSERT** statement). The checks ensure that the definitions of the tables and the parent **MERGE** table definition match by comparing column order, types, sizes and associated indexes. If there is a difference between the tables, an error is returned and the statement fails. Because these checks take place when the tables are opened, any changes to the definition of a single table, including column changes, column ordering, and engine alterations cause the statement to fail.

• The order of indexes in the **MERGE** table and its underlying tables should be the same. If you use **ALTER TABLE** to add a **UNIQUE** index to a table used in a **MERGE** table, and then use **ALTER TABLE** to add a nonunique index on the **MERGE** table, the index ordering is different for the tables if there was already a nonunique index in the underlying table. (This happens because **ALTER TABLE** puts **UNIQUE** indexes before nonunique indexes to facilitate rapid detection of duplicate keys.) Consequently, queries on tables with such indexes may return unexpected results.

• If you encounter an error message similar to **ERROR 1017 (HY000): Can't find file: 'tbl_name.MRG' (errno: 2)**, it generally indicates that some of the underlying tables do not use the **MyISAM** storage engine. Confirm that all of these tables are **MyISAM**.

• The maximum number of rows in a **MERGE** table is \(2^{64}\) (~1.844E+19; the same as for a **MyISAM** table). It is not possible to merge multiple **MyISAM** tables into a single **MERGE** table that would have more than this number of rows.

• Use of underlying **MyISAM** tables of differing row formats with a parent **MERGE** table is currently known to fail. See Bug #32364.

• You cannot change the union list of a nontemporary **MERGE** table when **LOCK TABLES** is in effect. The following does not work:

```
CREATE TABLE m1 ... ENGINE=MRG_MYISAM ...;
LOCK TABLES t1 WRITE, t2 WRITE, m1 WRITE;
ALTER TABLE m1 ... UNION=(t1,t2) ...;
```

However, you can do this with a temporary **MERGE** table.

• You cannot create a **MERGE** table with **CREATE ... SELECT**, neither as a temporary **MERGE** table, nor as a nontemporary **MERGE** table. For example:

```
CREATE TABLE m1 ... ENGINE=MRG_MYISAM ... SELECT ...;
```

Attempts to do this result in an error: **tbl_name** is not **BASE TABLE**.

• In some cases, differing **PACK_KEYS** table option values among the **MERGE** and underlying tables cause unexpected results if the underlying tables contain **CHAR** or **BINARY** columns. As a workaround, use **ALTER TABLE** to ensure that all involved tables have the same **PACK_KEYS** value. (Bug #50646)

## 16.8 The FEDERATED Storage Engine

The **FEDERATED** storage engine lets you access data from a remote MySQL database without using replication or cluster technology. Querying a local **FEDERATED** table automatically pulls the data from the remote (federated) tables. No data is stored on the local tables.

To include the **FEDERATED** storage engine if you build MySQL from source, invoke **CMake** with the **-DWITH_FEDERATED_STORAGE_ENGINE** option.
FEDERATED Storage Engine Overview

The FEDERATED storage engine is not enabled by default in the running server; to enable FEDERATED, you must start the MySQL server binary using the --federated option.

To examine the source for the FEDERATED engine, look in the storage/federated directory of a MySQL source distribution.

16.8.1 FEDERATED Storage Engine Overview

When you create a table using one of the standard storage engines (such as MyISAM, CSV or InnoDB), the table consists of the table definition and the associated data. When you create a FEDERATED table, the table definition is the same, but the physical storage of the data is handled on a remote server.

A FEDERATED table consists of two elements:

- A remote server with a database table, which in turn consists of the table definition (stored in the MySQL data dictionary) and the associated table. The table type of the remote table may be any type supported by the remote mysqld server, including MyISAM or InnoDB.

- A local server with a database table, where the table definition matches that of the corresponding table on the remote server. The table definition is stored in the data dictionary. There is no data file on the local server. Instead, the table definition includes a connection string that points to the remote table.

When executing queries and statements on a FEDERATED table on the local server, the operations that would normally insert, update or delete information from a local data file are instead sent to the remote server for execution, where they update the data file on the remote server or return matching rows from the remote server.

The basic structure of a FEDERATED table setup is shown in Figure 16.2, “FEDERATED Table Structure”.

Figure 16.2 FEDERATED Table Structure

When a client issues an SQL statement that refers to a FEDERATED table, the flow of information between the local server (where the SQL statement is executed) and the remote server (where the data is physically stored) is as follows:

1. The storage engine looks through each column that the FEDERATED table has and constructs an appropriate SQL statement that refers to the remote table.
2. The statement is sent to the remote server using the MySQL client API.

3. The remote server processes the statement and the local server retrieves any result that the statement produces (an affected-rows count or a result set).

4. If the statement produces a result set, each column is converted to internal storage engine format that the FEDERATED engine expects and can use to display the result to the client that issued the original statement.

The local server communicates with the remote server using MySQL client C API functions. It invokes `mysql_real_query()` to send the statement. To read a result set, it uses `mysql_store_result()` and fetches rows one at a time using `mysql_fetch_row()`.

### 16.8.2 How to Create FEDERATED Tables

To create a FEDERATED table you should follow these steps:

1. Create the table on the remote server. Alternatively, make a note of the table definition of an existing table, perhaps using the `SHOW CREATE TABLE` statement.

2. Create the table on the local server with an identical table definition, but adding the connection information that links the local table to the remote table.

For example, you could create the following table on the remote server:

```sql
CREATE TABLE test_table (
    id      INT(20) NOT NULL AUTO_INCREMENT,
    name    VARCHAR(32) NOT NULL DEFAULT '',
    other   INT(20) NOT NULL DEFAULT '0',
    PRIMARY KEY  (id),
    INDEX name (name),
    INDEX other_key (other)
) ENGINE=MyISAM
DEFAULT CHARSET=utf8mb4;
```

To create the local table that is federated to the remote table, there are two options available. You can either create the local table and specify the connection string (containing the server name, login, password) to be used to connect to the remote table using the `CONNECTION`, or you can use an existing connection that you have previously created using the `CREATE SERVER` statement.

#### 16.8.2.1 Creating a FEDERATED Table Using CONNECTION

To use the first method, you must specify the `CONNECTION` string after the engine type in a `CREATE TABLE` statement. For example:
CREATE TABLE federated_table (  
id     INT(20) NOT NULL AUTO_INCREMENT,
name   VARCHAR(32) NOT NULL DEFAULT '',
other  INT(20) NOT NULL DEFAULT '0',
PRIMARY KEY  (id),
INDEX name (name),
INDEX other_key (other)
)  
ENGINE=FEDERATED  
DEFAULT CHARSET=utf8mb4  
CONNECTION='mysql://fed_user@remote_host:9306/federated/test_table';

### Note

**CONNECTION** replaces the **COMMENT** used in some previous versions of MySQL.

The **CONNECTION** string contains the information required to connect to the remote server containing the table in which the data physically resides. The connection string specifies the server name, login credentials, port number and database/table information. In the example, the remote table is on the server `remote_host`, using port 9306. The name and port number should match the host name (or IP address) and port number of the remote MySQL server instance you want to use as your remote table.

The format of the connection string is as follows:

```
scheme://user_name[:password]@host_name[:port_num]/db_name/tbl_name
```

Where:

- **scheme**: A recognized connection protocol. Only `mysql` is supported as the `scheme` value at this point.
- **user_name**: The user name for the connection. This user must have been created on the remote server, and must have suitable privileges to perform the required actions (`SELECT`, `INSERT`, `UPDATE`, and so forth) on the remote table.
- **password**: (Optional) The corresponding password for `user_name`.
- **host_name**: The host name or IP address of the remote server.
- **port_num**: (Optional) The port number for the remote server. The default is 3306.
- **db_name**: The name of the database holding the remote table.
- **tbl_name**: The name of the remote table. The name of the local and the remote table do not have to match.

Sample connection strings:

```  
CONNECTION='mysql://username:password@hostname:port/database/tablename'  
CONNECTION='mysql://username@hostname/database/tablename'  
CONNECTION='mysql://username:password@hostname/database/tablename'
```

### 16.8.2.2 Creating a FEDERATED Table Using CREATE SERVER

If you are creating a number of **FEDERATED** tables on the same server, or if you want to simplify the process of creating **FEDERATED** tables, you can use the **CREATE SERVER** statement to define the server connection parameters, just as you would with the **CONNECTION** string.

The format of the **CREATE SERVER** statement is:

```
CREATE SERVER
```
The `server_name` is used in the connection string when creating a new `FEDERATED` table.

For example, to create a server connection identical to the `CONNECTION` string:

```
CONNECTION='mysql://fed_user@remote_host:9306/federated/test_table';
```

You would use the following statement:

```
CREATE SERVER fedlink
FOREIGN DATA WRAPPER mysql
OPTIONS (USER 'fed_user', HOST 'remote_host', PORT 9306, DATABASE 'federated');
```

To create a `FEDERATED` table that uses this connection, you still use the `CONNECTION` keyword, but specify the name you used in the `CREATE SERVER` statement.

```
CREATE TABLE test_table (id INT(20) NOT NULL AUTO_INCREMENT,
                          name VARCHAR(32) NOT NULL DEFAULT '',
                          other INT(20) NOT NULL DEFAULT '0',
                          PRIMARY KEY (id),
                          INDEX name (name),
                          INDEX other_key (other)
) ENGINE=FEDERATED
DEFAULT CHARSET=utf8mb4
CONNECTION='fedlink/test_table';
```

The connection name in this example contains the name of the connection (`fedlink`) and the name of the table (`test_table`) to link to, separated by a slash. If you specify only the connection name without a table name, the table name of the local table is used instead.

For more information on `CREATE SERVER`, see Section 13.1.18, “CREATE SERVER Statement”.

The `CREATE SERVER` statement accepts the same arguments as the `CONNECTION` string. The `CREATE SERVER` statement updates the rows in the `mysql.servers` table. See the following table for information on the correspondence between parameters in a connection string, options in the `CREATE SERVER` statement, and the columns in the `mysql.servers` table. For reference, the format of the `CONNECTION` string is as follows:

```
scheme://user_name[:password]@host_name[:port_num]/db_name/tbl_name
```

<table>
<thead>
<tr>
<th>Description</th>
<th><code>CONNECTION</code> string</th>
<th><code>CREATE SERVER</code> option</th>
<th><code>mysql.servers</code> column</th>
</tr>
</thead>
<tbody>
<tr>
<td>Connection scheme</td>
<td><code>scheme</code></td>

</tr>
</tbody>
</table>

### 16.8.3 FEDERATED Storage Engine Notes and Tips

You should be aware of the following points when using the `FEDERATED` storage engine:
• **FEDERATED** tables may be replicated to other replicas, but you must ensure that the replica servers are able to use the user/password combination that is defined in the `CONNECTION` string (or the row in the `mysql.servers` table) to connect to the remote server.

The following items indicate features that the **FEDERATED** storage engine does and does not support:

• The remote server must be a MySQL server.

• The remote table that a **FEDERATED** table points to *must* exist before you try to access the table through the **FEDERATED** table.

• It is possible for one **FEDERATED** table to point to another, but you must be careful not to create a loop.

• A **FEDERATED** table does not support indexes in the usual sense; because access to the table data is handled remotely, it is actually the remote table that makes use of indexes. This means that, for a query that cannot use any indexes and so requires a full table scan, the server fetches all rows from the remote table and filters them locally. This occurs regardless of any `WHERE` or `LIMIT` used with this `SELECT` statement; these clauses are applied locally to the returned rows.

Queries that fail to use indexes can thus cause poor performance and network overload. In addition, since returned rows must be stored in memory, such a query can also lead to the local server swapping, or even hanging.

• Care should be taken when creating a **FEDERATED** table since the index definition from an equivalent MyISAM or other table may not be supported. For example, creating a **FEDERATED** table fails if the table uses an index prefix on any `VARCHAR`, `TEXT` or `BLOB` columns. The following definition using MyISAM is valid:

```sql
CREATE TABLE `T1`(`A` VARCHAR(100),UNIQUE KEY(`A`(30))) ENGINE=MYISAM;
```

The key prefix in this example is incompatible with the **FEDERATED** engine, and the equivalent statement fails:

```sql
CREATE TABLE `T1`(`A` VARCHAR(100),UNIQUE KEY(`A`(30))) ENGINE=FEDERATED CONNECTION='MYSQL://127.0.0.1:3306/TEST/T1';
```

If possible, you should try to separate the column and index definition when creating tables on both the remote server and the local server to avoid these index issues.

• Internally, the implementation uses `SELECT`, `INSERT`, `UPDATE`, and `DELETE`, but not `HANDLER`.

• The **FEDERATED** storage engine supports `SELECT`, `INSERT`, `UPDATE`, `DELETE`, `TRUNCATE TABLE`, and indexes. It does not support `ALTER TABLE`, or any Data Definition Language statements that directly affect the structure of the table, other than `DROP TABLE`. The current implementation does not use prepared statements.

• **FEDERATED** accepts `INSERT ... ON DUPLICATE KEY UPDATE` statements, but if a duplicate-key violation occurs, the statement fails with an error.

• Transactions are not supported.

• **FEDERATED** performs bulk-insert handling such that multiple rows are sent to the remote table in a batch, which improves performance. Also, if the remote table is transactional, it enables the remote storage engine to perform statement rollback properly should an error occur. This capability has the following limitations:

  • The size of the insert cannot exceed the maximum packet size between servers. If the insert exceeds this size, it is broken into multiple packets and the rollback problem can occur.
FEDERATED Storage Engine Resources

- Bulk-insert handling does not occur for `INSERT ... ON DUPLICATE KEY UPDATE`.
- There is no way for the FEDERATED engine to know if the remote table has changed. The reason for this is that this table must work like a data file that would never be written to by anything other than the database system. The integrity of the data in the local table could be breached if there was any change to the remote database.
- When using a `CONNECTION` string, you cannot use an '@' character in the password. You can get round this limitation by using the `CREATE SERVER` statement to create a server connection.
- The `insert_id` and `timestamp` options are not propagated to the data provider.
- Any `DROP TABLE` statement issued against a FEDERATED table drops only the local table, not the remote table.
- User-defined partitioning is not supported for FEDERATED tables.

16.8.4 FEDERATED Storage Engine Resources

The following additional resources are available for the FEDERATED storage engine:

16.9 The EXAMPLE Storage Engine

The EXAMPLE storage engine is a stub engine that does nothing. Its purpose is to serve as an example in the MySQL source code that illustrates how to begin writing new storage engines. As such, it is primarily of interest to developers.

To enable the EXAMPLE storage engine if you build MySQL from source, invoke `CMake` with the `-DWITH_EXAMPLE_STORAGE_ENGINE` option.

To examine the source for the EXAMPLE engine, look in the `storage/example` directory of a MySQL source distribution.

When you create an EXAMPLE table, no files are created. No data can be stored into the table. Retrievals return an empty result.

```
mysql> CREATE TABLE test (i INT) ENGINE = EXAMPLE;
Query OK, 0 rows affected (0.78 sec)
mysql> INSERT INTO test VALUES(1),(2),(3);
ERROR 1031 (HY000): Table storage engine for 'test' doesn't have this option
mysql> SELECT * FROM test;
Empty set (0.31 sec)
```

The EXAMPLE storage engine does not support indexing.

The EXAMPLE storage engine does not support partitioning.

16.10 Other Storage Engines

Other storage engines may be available from third parties and community members that have used the Custom Storage Engine interface.
Third party engines are not supported by MySQL. For further information, documentation, installation guides, bug reporting or for any help or assistance with these engines, please contact the developer of the engine directly.

For more information on developing a customer storage engine that can be used with the Pluggable Storage Engine Architecture, see MySQL Internals: Writing a Custom Storage Engine.

16.11 Overview of MySQL Storage Engine Architecture

The MySQL pluggable storage engine architecture enables a database professional to select a specialized storage engine for a particular application need while being completely shielded from the need to manage any specific application coding requirements. The MySQL server architecture isolates the application programmer and DBA from all of the low-level implementation details at the storage level, providing a consistent and easy application model and API. Thus, although there are different capabilities across different storage engines, the application is shielded from these differences.

The MySQL pluggable storage engine architecture is shown in Figure 16.3, “MySQL Architecture with Pluggable Storage Engines”.

Figure 16.3 MySQL Architecture with Pluggable Storage Engines

The pluggable storage engine architecture provides a standard set of management and support services that are common among all underlying storage engines. The storage engines themselves are the components of the database server that actually perform actions on the underlying data that is maintained at the physical server level.

This efficient and modular architecture provides huge benefits for those wishing to specifically target a particular application need—such as data warehousing, transaction processing, or high availability.
situations—while enjoying the advantage of utilizing a set of interfaces and services that are independent of any one storage engine.

The application programmer and DBA interact with the MySQL database through Connector APIs and service layers that are above the storage engines. If application changes bring about requirements that demand the underlying storage engine change, or that one or more storage engines be added to support new needs, no significant coding or process changes are required to make things work. The MySQL server architecture shields the application from the underlying complexity of the storage engine by presenting a consistent and easy-to-use API that applies across storage engines.

16.11.1 Pluggable Storage Engine Architecture

MySQL Server uses a pluggable storage engine architecture that enables storage engines to be loaded into and unloaded from a running MySQL server.

**Plugging in a Storage Engine**

Before a storage engine can be used, the storage engine plugin shared library must be loaded into MySQL using the `INSTALL PLUGIN` statement. For example, if the `EXAMPLE` engine plugin is named `example` and the shared library is named `ha_example.so`, you load it with the following statement:

```
INSTALL PLUGIN example SONAME 'ha_example.so';
```

To install a pluggable storage engine, the plugin file must be located in the MySQL plugin directory, and the user issuing the `INSTALL PLUGIN` statement must have `INSERT` privilege for the `mysql.plugin` table.

The shared library must be located in the MySQL server plugin directory, the location of which is given by the `plugin_dir` system variable.

**Unplugging a Storage Engine**

To unplug a storage engine, use the `UNINSTALL PLUGIN` statement:

```
UNINSTALL PLUGIN example;
```

If you unplug a storage engine that is needed by existing tables, those tables become inaccessible, but are still present on disk (where applicable). Ensure that there are no tables using a storage engine before you unplug the storage engine.

16.11.2 The Common Database Server Layer

A MySQL pluggable storage engine is the component in the MySQL database server that is responsible for performing the actual data I/O operations for a database as well as enabling and enforcing certain feature sets that target a specific application need. A major benefit of using specific storage engines is that you are only delivered the features needed for a particular application, and therefore you have less system overhead in the database, with the end result being more efficient and higher database performance. This is one of the reasons that MySQL has always been known to have such high performance, matching or beating proprietary monolithic databases in industry standard benchmarks.

From a technical perspective, what are some of the unique supporting infrastructure components that are in a storage engine? Some of the key feature differentiations include:

- **Concurrency**: Some applications have more granular lock requirements (such as row-level locks) than others. Choosing the right locking strategy can reduce overhead and therefore improve overall performance. This area also includes support for capabilities such as multi-version concurrency control or “snapshot” read.
• **Transaction Support**: Not every application needs transactions, but for those that do, there are very well defined requirements such as ACID compliance and more.

• **Referential Integrity**: The need to have the server enforce relational database referential integrity through DDL defined foreign keys.

• **Physical Storage**: This involves everything from the overall page size for tables and indexes as well as the format used for storing data to physical disk.

• **Index Support**: Different application scenarios tend to benefit from different index strategies. Each storage engine generally has its own indexing methods, although some (such as B-tree indexes) are common to nearly all engines.

• **Memory Caches**: Different applications respond better to some memory caching strategies than others, so although some memory caches are common to all storage engines (such as those used for user connections), others are uniquely defined only when a particular storage engine is put in play.

• **Performance Aids**: This includes multiple I/O threads for parallel operations, thread concurrency, database checkpointing, bulk insert handling, and more.

• **Miscellaneous Target Features**: This may include support for geospatial operations, security restrictions for certain data manipulation operations, and other similar features.

Each set of the pluggable storage engine infrastructure components are designed to offer a selective set of benefits for a particular application. Conversely, avoiding a set of component features helps reduce unnecessary overhead. It stands to reason that understanding a particular application's set of requirements and selecting the proper MySQL storage engine can have a dramatic impact on overall system efficiency and performance.

  17.5.5 How to Report Replication Bugs or Problems ................................... 4007

Replication enables data from one MySQL database server (known as a source) to be copied to one or more MySQL database servers (known as replicas). Replication is asynchronous by default; replicas do not need to be connected permanently to receive updates from a source. Depending on the configuration, you can replicate all databases, selected databases, or even selected tables within a database.

Advantages of replication in MySQL include:

- Scale-out solutions - spreading the load among multiple replicas to improve performance. In this environment, all writes and updates must take place on the source server. Reads, however, may take place on one or more replicas. This model can improve the performance of writes (since the source
is dedicated to updates), while dramatically increasing read speed across an increasing number of replicas.

- Data security - because the replica can pause the replication process, it is possible to run backup services on the replica without corrupting the corresponding source data.

- Analytics - live data can be created on the source, while the analysis of the information can take place on the replica without affecting the performance of the source.

- Long-distance data distribution - you can use replication to create a local copy of data for a remote site to use, without permanent access to the source.

For information on how to use replication in such scenarios, see Section 17.4, “Replication Solutions”.

MySQL 8.0 supports different methods of replication. The traditional method is based on replicating events from the source's binary log, and requires the log files and positions in them to be synchronized between source and replica. The newer method based on global transaction identifiers (GTIDs) is transactional and therefore does not require working with log files or positions within these files, which greatly simplifies many common replication tasks. Replication using GTIDs guarantees consistency between source and replica as long as all transactions committed on the source have also been applied on the replica. For more information about GTIDs and GTID-based replication in MySQL, see Section 17.1.3, “Replication with Global Transaction Identifiers”. For information on using binary log file position based replication, see Section 17.1, “Configuring Replication”.

Replication in MySQL supports different types of synchronization. The original type of synchronization is one-way, asynchronous replication, in which one server acts as the source, while one or more other servers act as replicas. This is in contrast to the synchronous replication which is a characteristic of NDB Cluster (see Chapter 23, MySQL NDB Cluster 8.0). In MySQL 8.0, semisynchronous replication is supported in addition to the built-in asynchronous replication. With semisynchronous replication, a commit performed on the source blocks before returning to the session that performed the transaction until at least one replica acknowledges that it has received and logged the events for the transaction; see Section 17.4.10, “Semisynchronous Replication”. MySQL 8.0 also supports delayed replication such that a replica deliberately lags behind the source by at least a specified amount of time; see Section 17.4.11, “Delayed Replication”. For scenarios where synchronous replication is required, use NDB Cluster (see Chapter 23, MySQL NDB Cluster 8.0).

There are a number of solutions available for setting up replication between servers, and the best method to use depends on the presence of data and the engine types you are using. For more information on the available options, see Section 17.1.2, “Setting Up Binary Log File Position Based Replication”.

There are two core types of replication format, Statement Based Replication (SBR), which replicates entire SQL statements, and Row Based Replication (RBR), which replicates only the changed rows. You can also use a third variety, Mixed Based Replication (MBR). For more information on the different replication formats, see Section 17.2.1, “Replication Formats”.

Replication is controlled through a number of different options and variables. For more information, see Section 17.1.6, “Replication and Binary Logging Options and Variables”. Additional security measures can be applied to a replication topology, as described in Section 17.3, “Replication Security”.

You can use replication to solve a number of different problems, including performance, supporting the backup of different databases, and as part of a larger solution to alleviate system failures. For information on how to address these issues, see Section 17.4, “Replication Solutions”.

For notes and tips on how different data types and statements are treated during replication, including details of replication features, version compatibility, upgrades, and potential problems and their resolution,
Configuring Replication

see Section 17.5, “Replication Notes and Tips”. For answers to some questions often asked by those who are new to MySQL Replication, see Section A.14, “MySQL 8.0 FAQ: Replication”.

For detailed information on the implementation of replication, how replication works, the process and contents of the binary log, background threads and the rules used to decide how statements are recorded and replicated, see Section 17.2, “Replication Implementation”.

17.1 Configuring Replication

This section describes how to configure the different types of replication available in MySQL and includes the setup and configuration required for a replication environment, including step-by-step instructions for creating a new replication environment. The major components of this section are:

• For a guide to setting up two or more servers for replication using binary log file positions, Section 17.1.2, “Setting Up Binary Log File Position Based Replication”, deals with the configuration of the servers and provides methods for copying data between the source and replicas.

• For a guide to setting up two or more servers for replication using GTID transactions, Section 17.1.3, “Replication with Global Transaction Identifiers”, deals with the configuration of the servers.

• Events in the binary log are recorded using a number of formats. These are referred to as statement-based replication (SBR) or row-based replication (RBR). A third type, mixed-format replication (MIXED), uses SBR or RBR replication automatically to take advantage of the benefits of both SBR and RBR formats when appropriate. The different formats are discussed in Section 17.2.1, “Replication Formats”.

• Detailed information on the different configuration options and variables that apply to replication is provided in Section 17.1.6, “Replication and Binary Logging Options and Variables”.

• Once started, the replication process should require little administration or monitoring. However, for advice on common tasks that you may want to execute, see Section 17.1.7, “Common Replication Administration Tasks”.

17.1.1 Binary Log File Position Based Replication Configuration Overview

This section describes replication between MySQL servers based on the binary log file position method, where the MySQL instance operating as the source (where the database changes take place) writes updates and changes as “events” to the binary log. The information in the binary log is stored in different logging formats according to the database changes being recorded. Replicas are configured to read the binary log from the source and to execute the events in the binary log on the replica's local database.

Each replica receives a copy of the entire contents of the binary log. It is the responsibility of the replica to decide which statements in the binary log should be executed. Unless you specify otherwise, all events in the source's binary log are executed on the replica. If required, you can configure the replica to process only events that apply to particular databases or tables.

Important

You cannot configure the source to log only certain events.

Each replica keeps a record of the binary log coordinates: the file name and position within the file that it has read and processed from the source. This means that multiple replicas can be connected to the source and executing different parts of the same binary log. Because the replicas control this process, individual replicas can be connected and disconnected from the server without affecting the source's operation. Also, because each replica records the current position within the binary log, it is possible for replicas to be disconnected, reconnect and then resume processing.
The source and each replica must be configured with a unique ID (using the `server_id` system variable). In addition, each replica must be configured with information about the source’s host name, log file name, and position within that file. These details can be controlled from within a MySQL session using a `CHANGE REPLICATION SOURCE TO` statement (from MySQL 8.0.23) or `CHANGE MASTER TO` statement (before MySQL 8.0.23) on the replica. The details are stored within the replica’s connection metadata repository (see Section 17.2.4, “Relay Log and Replication Metadata Repositories”).

### 17.1.2 Setting Up Binary Log File Position Based Replication

This section describes how to set up a MySQL server to use binary log file position based replication. There are a number of different methods for setting up replication, and the exact method to use depends on how you are setting up replication, and whether you already have data in the database on the source that you want to replicate.

**Tip**

To deploy multiple instances of MySQL, you can use InnoDB Cluster which enables you to easily administer a group of MySQL server instances in MySQL Shell. InnoDB Cluster wraps MySQL Group Replication in a programmatic environment that enables you easily deploy a cluster of MySQL instances to achieve high availability. In addition, InnoDB Cluster interfaces seamlessly with MySQL Router, which enables your applications to connect to the cluster without writing your own failover process. For similar use cases that do not require high availability, however, you can use InnoDB ReplicaSet. Installation instructions for MySQL Shell can be found [here](#).

There are some generic tasks that are common to all setups:

- On the source, you must ensure that binary logging is enabled, and configure a unique server ID. This might require a server restart. See Section 17.1.2.1, “Setting the Replication Source Configuration”.

- On each replica that you want to connect to the source, you must configure a unique server ID. This might require a server restart. See Section 17.1.2.2, “Setting the Replica Configuration”.

- Optionally, create a separate user for your replicas to use during authentication with the source when reading the binary log for replication. See Section 17.1.2.3, “Creating a User for Replication”.

- Before creating a data snapshot or starting the replication process, on the source you should record the current position in the binary log. You need this information when configuring the replica so that the replica knows where within the binary log to start executing events. See Section 17.1.2.4, “Obtaining the Replication Source Binary Log Coordinates”.

- If you already have data on the source and want to use it to synchronize the replica, you need to create a data snapshot to copy the data to the replica. The storage engine you are using has an impact on how you create the snapshot. When you are using MyISAM, you must stop processing statements on the source to obtain a read-lock, then obtain its current binary log coordinates and dump its data, before permitting the source to continue executing statements. If you do not stop the execution of statements, the data dump and the source status information become mismatched, resulting in inconsistent or corrupted databases on the replicas. For more information on replicating a MyISAM source, see Section 17.1.2.4, “Obtaining the Replication Source Binary Log Coordinates”. If you are using InnoDB, you do not need a read-lock and a transaction that is long enough to transfer the data snapshot is sufficient. For more information, see Section 15.19, “InnoDB and MySQL Replication”.

- Configure the replica with settings for connecting to the source, such as the host name, login credentials, and binary log file name and position. See Section 17.1.2.7, “Setting the Source Configuration on the Replica”.
• Implement replication-specific security measures on the sources and replicas as appropriate for your system. See Section 17.3, “Replication Security”.

Note
Certain steps within the setup process require the SUPER privilege. If you do not have this privilege, it might not be possible to enable replication.

After configuring the basic options, select your scenario:

• To set up replication for a fresh installation of a source and replicas that contain no data, see Setting Up Replication with New Source and Replicas.

• To set up replication of a new source using the data from an existing MySQL server, see Setting Up Replication with Existing Data.

• To add replicas to an existing replication environment, see Section 17.1.2.8, “Adding Replicas to a Replication Environment”.

Before administering MySQL replication servers, read this entire chapter and try all statements mentioned in Section 13.4.1, “SQL Statements for Controlling Source Servers”, and Section 13.4.2, “SQL Statements for Controlling Replica Servers”. Also familiarize yourself with the replication startup options described in Section 17.1.6, “Replication and Binary Logging Options and Variables”.

17.1.2.1 Setting the Replication Source Configuration

To configure a source to use binary log file position based replication, you must ensure that binary logging is enabled, and establish a unique server ID.

Each server within a replication topology must be configured with a unique server ID, which you can specify using the server_id system variable. This server ID is used to identify individual servers within the replication topology, and must be a positive integer between 1 and \((2^{32})-1\). The default server_id value from MySQL 8.0 is 1. You can change the server_id value dynamically by issuing a statement like this:

```
SET GLOBAL server_id = 2;
```

How you organize and select the server IDs is your choice, so long as each server ID is different from every other server ID in use by any other server in the replication topology. Note that if a value of 0 (which was the default in earlier releases) was set previously for the server ID, you must restart the server to initialize the source with your new nonzero server ID. Otherwise, a server restart is not needed when you change the server ID, unless you make other configuration changes that require it.

Binary logging is required on the source because the binary log is the basis for replicating changes from the source to its replicas. Binary logging is enabled by default (the log_bin system variable is set to ON). The --log-bin option tells the server what base name to use for binary log files. It is recommended that you specify this option to give the binary log files a non-default base name, so that if the host name changes, you can easily continue to use the same binary log file names (see Section B.3.7, “Known Issues in MySQL”). If binary logging was previously disabled on the source using the --skip-log-bin option, you must restart the server without this option to enable it.

Note
The following options also have an impact on the source:

• For the greatest possible durability and consistency in a replication setup using InnoDB with transactions, you should use
Setting Up Binary Log File Position Based Replication

- **innodb_flush_log_at_trx_commit=1** and **sync_binlog=1** in the source's **my.cnf** file.
- • Ensure that the **skip_networking** system variable is not enabled on the source. If networking has been disabled, the replica cannot communicate with the source and replication fails.

### 17.1.2.2 Setting the Replica Configuration

Each replica must have a unique server ID, as specified by the **server_id** system variable. If you are setting up multiple replicas, each one must have a unique **server_id** value that differs from that of the source and from any of the other replicas. If the replica's server ID is not already set, or the current value conflicts with the value that you have chosen for the source or another replica, you must change it.

The default **server_id** value is 1. You can change the **server_id** value dynamically by issuing a statement like this:

```
SET GLOBAL server_id = 21;
```

Note that a value of 0 for the server ID prevents a replica from connecting to a source. If that server ID value (which was the default in earlier releases) was set previously, you must restart the server to initialize the replica with your new nonzero server ID. Otherwise, a server restart is not needed when you change the server ID, unless you make other configuration changes that require it. For example, if binary logging was disabled on the server and you want it enabled for your replica, a server restart is required to enable this.

If you are shutting down the replica server, you can edit the **[mysqld]** section of the configuration file to specify a unique server ID. For example:

```
[mysqld]
server-id=21
```

Binary logging is enabled by default on all servers. A replica is not required to have binary logging enabled for replication to take place. However, binary logging on a replica means that the replica's binary log can be used for data backups and crash recovery. Replicas that have binary logging enabled can also be used as part of a more complex replication topology. For example, you might want to set up replication servers using this chained arrangement:

```
A -> B -> C
```

Here, A serves as the source for the replica B, and B serves as the source for the replica C. For this to work, B must be both a source and a replica. Updates received from A must be logged by B to its binary log, in order to be passed on to C. In addition to binary logging, this replication topology requires the system variable **log_replica_updates** (from MySQL 8.0.26) or **log_slave_updates** (before MySQL 8.0.26) to be enabled. With replica updates enabled, the replica writes updates that are received from a source and performed by the replica's SQL thread to the replica's own binary log. The **log_replica_updates** or **log_slave_updates** system variable is enabled by default.

If you need to disable binary logging or replica update logging on a replica, you can do this by specifying the **--skip-log-bin** and **--log-replica-updates=OFF** or **--log-slave-updates=OFF** options for the replica. If you decide to re-enable these features on the replica, remove the relevant options and restart the server.

### 17.1.2.3 Creating a User for Replication

Each replica connects to the source using a MySQL user name and password, so there must be a user account on the source that the replica can use to connect. The user name is specified by the
SOURCE_USER | MASTER_USER option of the CHANGE REPLICA TION SOURCE TO statement (from
MySQL 8.0.23) or CHANGE MASTER TO statement (before MySQL 8.0.23) when you set up a replica. Any
account can be used for this operation, providing it has been granted the REPLICATION SLAVE privilege.
You can choose to create a different account for each replica, or connect to the source using the same
account for each replica.

Although you do not have to create an account specifically for replication, you should be aware that the
replication user name and password are stored in plain text in the replica's connection metadata repository
mysql.slave_master_info (see Section 17.2.4.2, “Replication Metadata Repositories”). Therefore, you
may want to create a separate account that has privileges only for the replication process, to minimize the
possibility of compromise to other accounts.

To create a new account, use CREATE_USER. To grant this account the privileges required for replication,
use the GRANT statement. If you create an account solely for the purposes of replication, that account
needs only the REPLICATION SLAVE privilege. For example, to set up a new user, repl, that can
connect for replication from any host within the example.com domain, issue these statements on the
source:

```
mysql> CREATE USER 'repl'@'%.example.com' IDENTIFIED BY 'password';
mysql> GRANT REPLICATION SLAVE ON *.* TO 'repl'@'%.example.com';
```

See Section 13.7.1, “Account Management Statements”, for more information on statements for
manipulation of user accounts.

Important

To connect to the source using a user account that authenticates with the
caching_sha2_password plugin, you must either set up a secure connection
as described in Section 17.3.1, “Setting Up Replication to Use Encrypted
Connections”, or enable the unencrypted connection to support password exchange
using an RSA key pair. The caching_sha2_password authentication plugin is
the default for new users created from MySQL 8.0 (for details, see Section 6.4.1.2,
“Caching SHA-2 Pluggable Authentication”). If the user account that you create
or use for replication (as specified by the MASTER_USER option) uses this
authentication plugin, and you are not using a secure connection, you must enable
RSA key pair-based password exchange for a successful connection.

17.1.2.4 Obtaining the Replication Source Binary Log Coordinates

To configure the replica to start the replication process at the correct point, you need to note the source's
current coordinates within its binary log.

Warning

This procedure uses FLUSH TABLES WITH READ LOCK, which blocks COMMIT
operations for InnoDB tables.

If you are planning to shut down the source to create a data snapshot, you can optionally skip this
procedure and instead store a copy of the binary log index file along with the data snapshot. In that
situation, the source creates a new binary log file on restart. The source binary log coordinates where the
replica must start the replication process are therefore the start of that new file, which is the next binary log
file on the source following after the files that are listed in the copied binary log index file.

To obtain the source binary log coordinates, follow these steps:

1. Start a session on the source by connecting to it with the command-line client, and flush all tables and
   block write statements by executing the FLUSH TABLES WITH READ LOCK statement:
Setting Up Binary Log File Position Based Replication

```sql
mysql> FLUSH TABLES WITH READ LOCK;
```

**Warning**

Leave the client from which you issued the `FLUSH TABLES` statement running so that the read lock remains in effect. If you exit the client, the lock is released.

2. In a different session on the source, use the `SHOW MASTER STATUS` statement to determine the current binary log file name and position:

```sql
mysql> SHOW MASTER STATUS\G
```

```
*************************** 1. row ***************************
  File: mysql-bin.000003
  Position: 73
  Binlog_Do_DB: test
  Binlog_Ignore_DB: manual, mysql
  Executed_Gtid_Set: 3E11FA47-71CA-11E1-9E33-C80AA9429562:1-5
1 row in set (0.00 sec)
```

The **File** column shows the name of the log file and the **Position** column shows the position within the file. In this example, the binary log file is `mysql-bin.000003` and the position is 73. Record these values. You need them later when you are setting up the replica. They represent the replication coordinates at which the replica should begin processing new updates from the source.

If the source has been running previously with binary logging disabled, the log file name and position values displayed by `SHOW MASTER STATUS` or `mysqldump --master-data` are empty. In that case, the values that you need to use later when specifying the source's binary log file and position are the empty string (`''`) and 4.

You now have the information you need to enable the replica to start reading from the source's binary log in the correct place to start replication.

The next step depends on whether you have existing data on the source. Choose one of the following options:

- If you have existing data that needs be synchronized with the replica before you start replication, leave the client running so that the lock remains in place. This prevents any further changes being made, so that the data copied to the replica is in synchrony with the source. Proceed to Section 17.1.2.5, “Choosing a Method for Data Snapshots”.
- If you are setting up a new source and replica combination, you can exit the first session to release the read lock. See Setting Up Replication with New Source and Replicas for how to proceed.

**17.1.2.5 Choosing a Method for Data Snapshots**

If the source database contains existing data it is necessary to copy this data to each replica. There are different ways to dump the data from the source database. The following sections describe possible options.

To select the appropriate method of dumping the database, choose between these options:

- Use the `mysqldump` tool to create a dump of all the databases you want to replicate. This is the recommended method, especially when using InnoDB.
- If your database is stored in binary portable files, you can copy the raw data files to a replica. This can be more efficient than using `mysqldump` and importing the file on each replica, because it skips the overhead of updating indexes as the `INSERT` statements are replayed. With storage engines such as InnoDB this is not recommended.
• Use MySQL Server’s clone plugin to transfer all the data from an existing replica to a clone. For instructions to use this method, see Section 5.6.7.7, “Cloning for Replication”.

Tip
To deploy multiple instances of MySQL, you can use InnoDB Cluster which enables you to easily administer a group of MySQL server instances in MySQL Shell. InnoDB Cluster wraps MySQL Group Replication in a programmatic environment that enables you to easily deploy a cluster of MySQL instances to achieve high availability. In addition, InnoDB Cluster interfaces seamlessly with MySQL Router, which enables your applications to connect to the cluster without writing your own failover process. For similar use cases that do not require high availability, however, you can use InnoDB Replicaset. Installation instructions for MySQL Shell can be found here.

Creating a Data Snapshot Using mysqldump

To create a snapshot of the data in an existing source database, use the mysqldump tool. Once the data dump has been completed, import this data into the replica before starting the replication process.

The following example dumps all databases to a file named dbdump.db, and includes the --master-data option which automatically appends the CHANGE REPLICATION SOURCE TO | CHANGE MASTER TO statement required on the replica to start the replication process:

```
$> mysqldump --all-databases --master-data > dbdump.db
```

Note
If you do not use --master-data, then it is necessary to lock all tables in a separate session manually. See Section 17.1.2.4, “Obtaining the Replication Source Binary Log Coordinates”.

It is possible to exclude certain databases from the dump using the mysqldump tool. If you want to choose which databases to include in the dump, do not use --all-databases. Choose one of these options:

• Exclude all the tables in the database using --ignore-table option.

• Name only those databases which you want dumped using the --databases option.

Note
By default, if GTIDs are in use on the source (gtid_mode=ON), mysqldump includes the GTIDs from the gtid_executed set on the source in the dump output to add them to the gtid_purged set on the replica. If you are dumping only specific databases or tables, it is important to note that the value that is included by mysqldump includes the GTIDs of all transactions in the gtid_executed set on the source, even those that changed suppressed parts of the database, or other databases on the server that were not included in the partial dump. Check the description for mysqldump’s --set-gtid-purged option to find the outcome of the default behavior for the MySQL Server versions you are using, and how to change the behavior if this outcome is not suitable for your situation.

For more information, see Section 4.5.4, “mysqldump — A Database Backup Program”.

To import the data, either copy the dump file to the replica, or access the file from the source when connecting remotely to the replica.
Creating a Data Snapshot Using Raw Data Files

This section describes how to create a data snapshot using the raw files which make up the database. Employing this method with a table using a storage engine that has complex caching or logging algorithms requires extra steps to produce a perfect “point in time” snapshot: the initial copy command could leave out cache information and logging updates, even if you have acquired a global read lock. How the storage engine responds to this depends on its crash recovery abilities.

If you use InnoDB tables, you can use the mysqlbackup command from the MySQL Enterprise Backup component to produce a consistent snapshot. This command records the log name and offset corresponding to the snapshot to be used on the replica. MySQL Enterprise Backup is a commercial product that is included as part of a MySQL Enterprise subscription. See Section 30.2, “MySQL Enterprise Backup Overview” for detailed information.

This method also does not work reliably if the source and replica have different values for ft_stopword_file, ft_min_word_len, or ft_max_word_len and you are copying tables having full-text indexes.

Assuming the above exceptions do not apply to your database, use the cold backup technique to obtain a reliable binary snapshot of InnoDB tables: do a slow shutdown of the MySQL Server, then copy the data files manually.

To create a raw data snapshot of MyISAM tables when your MySQL data files exist on a single file system, you can use standard file copy tools such as cp or copy, a remote copy tool such as scp or rsync, an archiving tool such as zip or tar, or a file system snapshot tool such as dump. If you are replicating only certain databases, copy only those files that relate to those tables. For InnoDB, all tables in all databases are stored in the system tablespace files, unless you have the innodb_file_per_table option enabled.

The following files are not required for replication:

- Files relating to the mysql database.
- The replica's connection metadata repository file master.info, if used; the use of this file is now deprecated (see Section 17.2.4, “Relay Log and Replication Metadata Repositories”).
- The source's binary log files, with the exception of the binary log index file if you are going to use this to locate the source binary log coordinates for the replica.
- Any relay log files.

Depending on whether you are using InnoDB tables or not, choose one of the following:

If you are using InnoDB tables, and also to get the most consistent results with a raw data snapshot, shut down the source server during the process, as follows:

1. Acquire a read lock and get the source’s status. See Section 17.1.2.4, “Obtaining the Replication Source Binary Log Coordinates”.
2. In a separate session, shut down the source server:

   $> mysqladmin shutdown

3. Make a copy of the MySQL data files. The following examples show common ways to do this. You need to choose only one of them:

   $> tar cf /tmp/db.tar ./data
4. Restart the source server.

If you are not using InnoDB tables, you can get a snapshot of the system from a source without shutting down the server as described in the following steps:

1. Acquire a read lock and get the source’s status. See Section 17.1.2.4, “Obtaining the Replication Source Binary Log Coordinates”.

2. Make a copy of the MySQL data files. The following examples show common ways to do this. You need to choose only one of them:

   ```
   $> tar cf /tmp/db.tar ./data  
   $> zip -r /tmp/db.zip ./data  
   $> rsync --recursive ./data /tmp/dbdata
   ```

3. In the client where you acquired the read lock, release the lock:

   ```
   mysql> UNLOCK TABLES;
   ```

Once you have created the archive or copy of the database, copy the files to each replica before starting the replication process.

### 17.1.2.6 Setting Up Replicas

The following sections describe how to set up replicas. Before you proceed, ensure that you have:

- Configured the source with the necessary configuration properties. See Section 17.1.2.1, “Setting the Replication Source Configuration”.

- Obtained the source status information, or a copy of the source’s binary log index file made during a shutdown for the data snapshot. See Section 17.1.2.4, “Obtaining the Replication Source Binary Log Coordinates”.

- On the source, released the read lock:

   ```
   mysql> UNLOCK TABLES;
   ```

- On the replica, edited the MySQL configuration. See Section 17.1.2.2, “Setting the Replica Configuration”.

The next steps depend on whether you have existing data to import to the replica or not. See Section 17.1.2.5, “Choosing a Method for Data Snapshots” for more information. Choose one of the following:

- If you do not have a snapshot of a database to import, see Setting Up Replication with New Source and Replicas.

- If you have a snapshot of a database to import, see Setting Up Replication with Existing Data.

**Setting Up Replication with New Source and Replicas**

When there is no snapshot of a previous database to import, configure the replica to start replication from the new source.

To set up replication between a source and a new replica:
1. Start up the replica.

2. Execute a `CHANGE REPLICATION SOURCE TO | CHANGE MASTER TO` statement on the replica to set the source configuration. See Section 17.1.2.7, “Setting the Source Configuration on the Replica”.

Perform these replica setup steps on each replica.

This method can also be used if you are setting up new servers but have an existing dump of the databases from a different server that you want to load into your replication configuration. By loading the data into a new source, the data is automatically replicated to the replicas.

If you are setting up a new replication environment using the data from a different existing database server to create a new source, run the dump file generated from that server on the new source. The database updates are automatically propagated to the replicas:

```bash
$> mysql -h source < fulldb.dump
```

### Setting Up Replication with Existing Data

When setting up replication with existing data, transfer the snapshot from the source to the replica before starting replication. The process for importing data to the replica depends on how you created the snapshot of data on the source.

---

**Tip**

To deploy multiple instances of MySQL, you can use InnoDB Cluster which enables you to easily administer a group of MySQL server instances in MySQL Shell. InnoDB Cluster wraps MySQL Group Replication in a programmatic environment that enables you easily deploy a cluster of MySQL instances to achieve high availability. In addition, InnoDB Cluster interfaces seamlessly with MySQL Router, which enables your applications to connect to the cluster without writing your own failover process. For similar use cases that do not require high availability, however, you can use InnoDB ReplicaSet. Installation instructions for MySQL Shell can be found here.

---

**Note**

If the replication source server or existing replica that you are copying to create the new replica has any scheduled events, ensure that these are disabled on the new replica before you start it. If an event runs on the new replica that has already run on the source, the duplicated operation causes an error. The Event Scheduler is controlled by the `event_scheduler` system variable, which defaults to `ON` from MySQL 8.0, so events that are active on the original server run by default when the new replica starts up. To stop all events from running on the new replica, set the `event_scheduler` system variable to `OFF` or `DISABLED` on the new replica. Alternatively, you can use the `ALTER EVENT` statement to set individual events to `DISABLE` or `DISABLE ON SLAVE` to prevent them from running on the new replica. You can list the events on a server using the `SHOW` statement or the Information Schema `EVENTS` table. For more information, see Section 17.5.1.16, “Replication of Invoked Features”.

As an alternative to creating a new replica in this way, MySQL Server's clone plugin can be used to transfer all the data and replication settings from an existing replica to a clone. For instructions to use this method, see Section 5.6.7.7, “Cloning for Replication”.

Follow this procedure to set up replication with existing data:
1. If you used MySQL Server’s clone plugin to create a clone from an existing replica (see Section 5.6.7.7, “Cloning for Replication”), the data is already transferred. Otherwise, import the data to the replica using one of the following methods.

   a. If you used mysqldump, start the replica server, ensuring that replication does not start by using the --skip-slave-start option, or from MySQL 8.0.24, the skip_slave_start system variable. Then import the dump file:

      ```
      $> mysql < fulldb.dump
      ```

   b. If you created a snapshot using the raw data files, extract the data files into your replica’s data directory. For example:

      ```
      $> tar xvf dbdump.tar
      ```

      You may need to set permissions and ownership on the files so that the replica server can access and modify them. Then start the replica server, ensuring that replication does not start by using the --skip-slave-start option, or from MySQL 8.0.24, the skip_slave_start system variable.

2. Configure the replica with the replication coordinates from the source. This tells the replica the binary log file and position within the file where replication needs to start. Also, configure the replica with the login credentials and host name of the source. For more information on the CHANGE REPLICATION SOURCE TO | CHANGE MASTER TO statement required, see Section 17.1.2.7, “Setting the Source Configuration on the Replica”.

3. Start the replication threads by issuing a START REPLICA (or before MySQL 8.0.22, START SLAVE) statement.

   After you have performed this procedure, the replica connects to the source and replicates any updates that have occurred on the source since the snapshot was taken. Error messages are issued to the replica’s error log if it is not able to replicate for any reason.

   The replica uses information logged in its connection metadata repository and applier metadata repository to keep track of how much of the source’s binary log it has processed. From MySQL 8.0, by default, these repositories are tables named slave_master_info and slave_relay_log_info in the mysql database. Do not remove or edit these tables unless you know exactly what you are doing and fully understand the implications. Even in that case, it is preferred that you use the CHANGE REPLICATION SOURCE TO | CHANGE MASTER TO statement to change replication parameters. The replica uses the values specified in the statement to update the replication metadata repositories automatically. See Section 17.2.4, “Relay Log and Replication Metadata Repositories”, for more information.

   **Note**

   The contents of the replica’s connection metadata repository override some of the server options specified on the command line or in my.cnf. See Section 17.1.6, “Replication and Binary Logging Options and Variables”, for more details.

   A single snapshot of the source suffices for multiple replicas. To set up additional replicas, use the same source snapshot and follow the replica portion of the procedure just described.

### 17.1.2.7 Setting the Source Configuration on the Replica

To set up the replica to communicate with the source for replication, configure the replica with the necessary connection information. To do this, on the replica, execute the CHANGE REPLICATION SOURCE TO statement (from MySQL 8.0.23) or CHANGE MASTER TO statement (before MySQL 8.0.23), replacing the option values with the actual values relevant to your system:
### Setting Up Binary Log File Position Based Replication

**mysql> CHANGE MASTER TO**
- `-> MASTER_HOST='source_host_name',`
- `-> MASTER_USER='replication_user_name',`
- `-> MASTER_PASSWORD='replication_password',`
- `-> MASTER_LOG_FILE='recorded_log_file_name',`
- `-> MASTER_LOG_POS=recorded_log_position;`

Or from MySQL 8.0.23:

**mysql> CHANGE REPLICATION SOURCE TO**
- `-> SOURCE_HOST='source_host_name',`
- `-> SOURCE_USER='replication_user_name',`
- `-> SOURCE_PASSWORD='replication_password',`
- `-> SOURCE_LOG_FILE='recorded_log_file_name',`
- `-> SOURCE_LOG_POS=recorded_log_position;`

---

**Note**

Replication cannot use Unix socket files. You must be able to connect to the source MySQL server using TCP/IP.

The `CHANGE REPLICATION SOURCE TO` | `CHANGE MASTER TO` statement has other options as well. For example, it is possible to set up secure replication using SSL. For a full list of options, and information about the maximum permissible length for the string-valued options, see [Section 13.4.2.1, “CHANGE MASTER TO Statement”](#).

---

**Important**

As noted in [Section 17.1.2.3, “Creating a User for Replication”](#), if you are not using a secure connection and the user account named in the `SOURCE_USER` | `MASTER_USER` option authenticates with the `caching_sha2_password` plugin (the default from MySQL 8.0), you must specify the `SOURCE_PUBLIC_KEY_PATH` | `MASTER_PUBLIC_KEY_PATH` or `GET_SOURCE_PUBLIC_KEY` | `GET_MASTER_PUBLIC_KEY` option in the `CHANGE REPLICATION SOURCE TO` | `CHANGE MASTER TO` statement to enable RSA key pair-based password exchange.

---

### 17.1.2.8 Adding Replicas to a Replication Environment

You can add another replica to an existing replication configuration without stopping the source server. To do this, you can set up the new replica by copying the data directory of an existing replica, and giving the new replica a different server ID (which is user-specified) and server UUID (which is generated at startup).

---

**Note**

If the replication source server or existing replica that you are copying to create the new replica has any scheduled events, ensure that these are disabled on the new replica before you start it. If an event runs on the new replica that has already run on the source, the duplicated operation causes an error. The Event Scheduler is controlled by the `event_scheduler` system variable, which defaults to `ON` from MySQL 8.0, so events that are active on the original server run by default when the new replica starts up. To stop all events from running on the new replica, set the `event_scheduler` system variable to `OFF` or `DISABLED` on the new replica. Alternatively, you can use the `ALTER EVENT` statement to set individual events to `DISABLE` or `DISABLE ON SLAVE` to prevent them from running on the new replica. You can list the events on a server using the `SHOW` statement or the Information Schema `EVENTS` table. For more information, see [Section 17.5.1.16, “Replication of Invoked Features”](#).
As an alternative to creating a new replica in this way, MySQL Server's clone plugin can be used to transfer all the data and replication settings from an existing replica to a clone. For instructions to use this method, see Section 5.6.7.7, “Cloning for Replication”.

To duplicate an existing replica without cloning, follow these steps:

1. Stop the existing replica and record the replica status information, particularly the source binary log file and relay log file positions. You can view the replica status either in the Performance Schema replication tables (see Section 27.12.11, “Performance Schema Replication Tables”), or by issuing `SHOW REPLICA STATUS` as follows:

   ```
   mysql> STOP SLAVE;
   mysql> SHOW SLAVE STATUS\G
   ```
   Or from MySQL 8.0.22:

   ```
   mysql> STOP REPLICA;
   mysql> SHOW REPLICA STATUS\G
   ```

2. Shut down the existing replica:

   ```
   $> mysqladmin shutdown
   ```

3. Copy the data directory from the existing replica to the new replica, including the log files and relay log files. You can do this by creating an archive using `tar` or `WinZip`, or by performing a direct copy using a tool such as `cp` or `rsync`.

   **Important**
   - Before copying, verify that all the files relating to the existing replica actually are stored in the data directory. For example, the InnoDB system tablespace, undo tablespace, and redo log might be stored in an alternative location. InnoDB tablespace files and file-per-table tablespaces might have been created in other directories. The binary logs and relay logs for the replica might be in their own directories outside the data directory. Check through the system variables that are set for the existing replica and look for any alternative paths that have been specified. If you find any, copy these directories over as well.

   - During copying, if files have been used for the replication metadata repositories (see Section 17.2.4, “Relay Log and Replication Metadata Repositories”), ensure that you also copy these files from the existing replica to the new replica. If tables have been used for the repositories, which is the default from MySQL 8.0, the tables are in the data directory.

   - After copying, delete the `auto.cnf` file from the copy of the data directory on the new replica, so that the new replica is started with a different generated server UUID. The server UUID must be unique.

A common problem that is encountered when adding new replicas is that the new replica fails with a series of warning and error messages like these:

```
071118 16:44:10 [Warning] Neither --relay-log nor --relay-log-index were used; so replication may break when this MySQL server acts as a replica and has his hostname changed!! Please use '--relay-log=new_replica_hostname-relay-bin' to avoid this problem.
071118 16:44:10 [ERROR] Failed to open the relay log './old_replica_hostname-relay-bin.003525' (relay_log_pos 22940879)
071118 16:44:10 [ERROR] Failed to initialize the master info structure
071118 16:44:10 [ERROR] Could not find target log during relay log initialization
```
This situation can occur if the `relay_log` system variable is not specified, as the relay log files contain the host name as part of their file names. This is also true of the relay log index file if the `relay_log_index` system variable is not used. For more information about these variables, see Section 17.1.6, “Replication and Binary Logging Options and Variables”.

To avoid this problem, use the same value for `relay_log` on the new replica that was used on the existing replica. If this option was not set explicitly on the existing replica, use `existing_replica_hostname-relay-bin`. If this is not possible, copy the existing replica's relay log index file to the new replica and set the `relay_log_index` system variable on the new replica to match what was used on the existing replica. If this option was not set explicitly on the existing replica, use `existing_replica_hostname-relay-bin.index`. Alternatively, if you have already tried to start the new replica after following the remaining steps in this section and have encountered errors like those described previously, then perform the following steps:

a. If you have not already done so, issue `STOP REPLICA` on the new replica.

   If you have already started the existing replica again, issue `STOP REPLICA` on the existing replica as well.

b. Copy the contents of the existing replica's relay log index file into the new replica's relay log index file, making sure to overwrite any content already in the file.

c. Proceed with the remaining steps in this section.

4. When copying is complete, restart the existing replica.

5. On the new replica, edit the configuration and give the new replica a unique server ID (using the `server_id` system variable) that is not used by the source or any of the existing replicas.

6. Start the new replica server, ensuring that replication does not start yet by specifying the `--skip-slave-start` option, or from MySQL 8.0.24, the `skip_slave_start` system variable. Use the Performance Schema replication tables or issue `SHOW REPLICA STATUS` to confirm that the new replica has the correct settings when compared with the existing replica. Also display the server ID and server UUID and verify that these are correct and unique for the new replica.

7. Start the replica threads by issuing a `START REPLICA` statement. The new replica now uses the information in its connection metadata repository to start the replication process.

17.1.3 Replication with Global Transaction Identifiers

This section explains transaction-based replication using `global transaction identifiers` (GTIDs). When using GTIDs, each transaction can be identified and tracked as it is committed on the originating server and applied by any replicas; this means that it is not necessary when using GTIDs to refer to log files or positions within those files when starting a new replica or failing over to a new source, which greatly simplifies these tasks. Because GTID-based replication is completely transaction-based, it is simple to determine whether sources and replicas are consistent; as long as all transactions committed on a source are also committed on a replica, consistency between the two is guaranteed. You can use either statement-based or row-based replication with GTIDs (see Section 17.2.1, “Replication Formats”); however, for best results, we recommend that you use the row-based format.

GTIDs are always preserved between source and replica. This means that you can always determine the source for any transaction applied on any replica by examining its binary log. In addition, once a transaction with a given GTID is committed on a given server, any subsequent transaction having the same GTID is ignored by that server. Thus, a transaction committed on the source can be applied no more than once on the replica, which helps to guarantee consistency.
This section discusses the following topics:

- How GTIDs are defined and created, and how they are represented in a MySQL server (see Section 17.1.3.1, “GTID Format and Storage”).
- The life cycle of a GTID (see Section 17.1.3.2, “GTID Life Cycle”).
- The auto-positioning function for synchronizing a replica and source that use GTIDs (see Section 17.1.3.3, “GTID Auto-Positioning”).
- A general procedure for setting up and starting GTID-based replication (see Section 17.1.3.4, “Setting Up Replication Using GTIDs”).
- Suggested methods for provisioning new replication servers when using GTIDs (see Section 17.1.3.5, “Using GTIDs for Failover and Scaleout”).
- Restrictions and limitations that you should be aware of when using GTID-based replication (see Section 17.1.3.7, “Restrictions on Replication with GTIDs”).
- Stored functions that you can use to work with GTIDs (see Section 17.1.3.8, “Stored Function Examples to Manipulate GTIDs”).

For information about MySQL Server options and variables relating to GTID-based replication, see Section 17.1.6.5, “Global Transaction ID System Variables”. See also Section 12.18.2, “Functions Used with Global Transaction Identifiers (GTIDs)”, which describes SQL functions supported by MySQL 8.0 for use with GTIDs.

17.1.3.1 GTID Format and Storage

A global transaction identifier (GTID) is a unique identifier created and associated with each transaction committed on the server of origin (the source). This identifier is unique not only to the server on which it originated, but is unique across all servers in a given replication topology.

GTID assignment distinguishes between client transactions, which are committed on the source, and replicated transactions, which are reproduced on a replica. When a client transaction is committed on the source, it is assigned a new GTID, provided that the transaction was written to the binary log. Client transactions are guaranteed to have monotonically increasing GTIDs without gaps between the generated numbers. If a client transaction is not written to the binary log (for example, because the transaction was filtered out, or the transaction was read-only), it is not assigned a GTID on the server of origin.

Replicated transactions retain the same GTID that was assigned to the transaction on the server of origin. The GTID is present before the replicated transaction begins to execute, and is persisted even if the replicated transaction is not written to the binary log on the replica, or is filtered out on the replica. The MySQL system table `mysql.gtid_executed` is used to preserve the assigned GTIDs of all the transactions applied on a MySQL server, except those that are stored in a currently active binary log file.

The auto-skip function for GTIDs means that a transaction committed on the source can be applied no more than once on the replica, which helps to guarantee consistency. Once a transaction with a given GTID has been committed on a given server, any attempt to execute a subsequent transaction with the same GTID is ignored by that server. No error is raised, and no statement in the transaction is executed.
